Processing	Internal `FIELDBUS_BYTE_TO_SIGNAL` processes the byte; `OUT` and `VALID` are updated.
Valid stable	After the flip-flop has been clocked, `VALID.D1` remains stable until the next event.

The state is cycled through in each cycle.

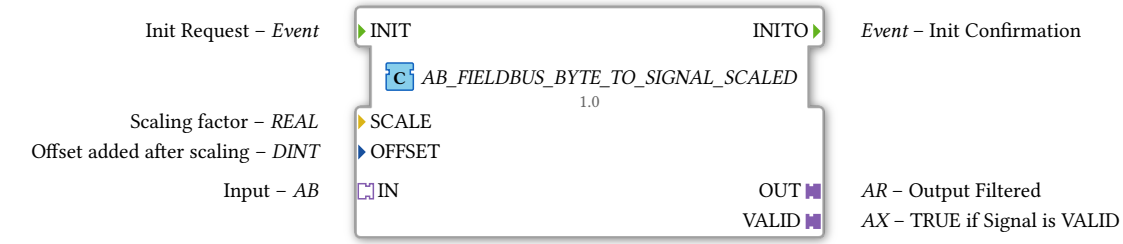
Application Scenarios

- **Fieldbus Integration**: Receiving a byte value from a fieldbus (e.g., CAN, Profibus) and forwarding it to a control logic, whereby only valid telegrams are passed through.
- **Signal Conditioning**: Converting a raw byte stream into a clocked, validation-checked signal for downstream function blocks.
- **Error Detection**: The function block can be combined with an external validation checker connected to the `IN` adapter.

Comparison with Similar Function Blocks

Simpler **Mirror** function blocks forward a signal without validation. This function block adds explicit validation and outputs the validity signal separately. Unlike a purely flip-flop-based hold function block, it processes a byte and not just Boolean values. The internal `FIELDBUS_BYTE_TO_SIGNAL` handles the specific fieldbus interpretation.

Conclusion



The `AB_FIELDBUS_BYTE_TO_SIGNAL` is a specialized function block for the safe transmission of fieldbus byte signals. The combination of mirroring and validation makes it ideal for real-time applications where only valid data may be processed. The adapter-based interface allows for easy integration into existing 4diac projects.

AB_FIELDBUS_BYTE_TO_SIGNAL_SCALED

• – ○ • – ○ • – ○ •

Introduction

The function block `AB_FIELDBUS_BYTE_TO_SIGNAL_SCALED` is used to receive an incoming byte-shaped signal via an adapter, process it with a configurable scaling factor and offset, and provide the result via an output adapter. Simultaneously, the validity of the signal is indicated via a separate adapter. This function block is specifically designed for use in fieldbus environments where raw data needs to be converted into physical or standardized values.

Interface Structure

Event Inputs

Event	Type	Description
`INIT`	EInit	Initialization request (e.g., for setting parameters)

Event Outputs

Event	Type	Description
`INITO`	EInit	Confirmation of successful initialization

Data Inputs

Name	Type	Initial Value	Description
`SCALE`	REAL	1.0	Scaling factor applied to the raw value
`OFFSET`	DINT	0	Integer offset added after scaling

Data Outputs

The module has no independent data inputs or outputs – input/output is handled exclusively via adapters.

Adapters

Adapter	Type	Direction	Description
`IN`	AB (Adapter Type A⟶B)	Socket	Receives the raw BYTE signal
`OUT`	AR (Adapter Type A⟶R)	Plug	Outputs the scaled signal

VALID	AX (Adapter Type A⟶X)	Plug	Signals whether the current output value is valid (TRUE = valid)

Functionality

1. After successful initialization (INIT ⟶ INITO), the function block becomes operational.
2. As soon as a new BYTE arrives via the IN adapter (event E1), the event is forwarded to the internal function block FIELDBUS_BYTE_TO_SIGNAL_SCALED.
3. This internal block calculates the output value: OUT = IN * SCALE + OFFSET. Simultaneously, a validity signal (VALID) is generated.
4. After the calculation is complete, the result is output via the OUT adapter (OUT.E1). Simultaneously, the validity signal is temporarily stored in a D flip-flop (module E_D_FF) and output via the VALID adapter.
5. The valid status is maintained until a new signal is processed. An invalid state (e.g., due to a missing input) can be set externally using appropriate logic.

The process is purely event-driven: Each incoming event triggers exactly one processing step.

Technical Features

- **Scaling and Offset**: The configuration of SCALE (REAL) and OFFSET (DINT) allows for flexible adaptation to different measurement ranges.
- **Adapter Interface**: The use of IEC 61499 adapters allows for loose coupling and easy reusability in different fieldbus contexts.
- **Valid Storage**: The D flip-flop (E_D_FF) ensures that the validity status remains stable until the next signal arrives.
- **Initialization**: The function block has its own INIT path to reliably set internal parameters (SCALE, OFFSET).

State Overview

The function block does not define an explicit state machine (ECC). Processing is exclusively event-driven:

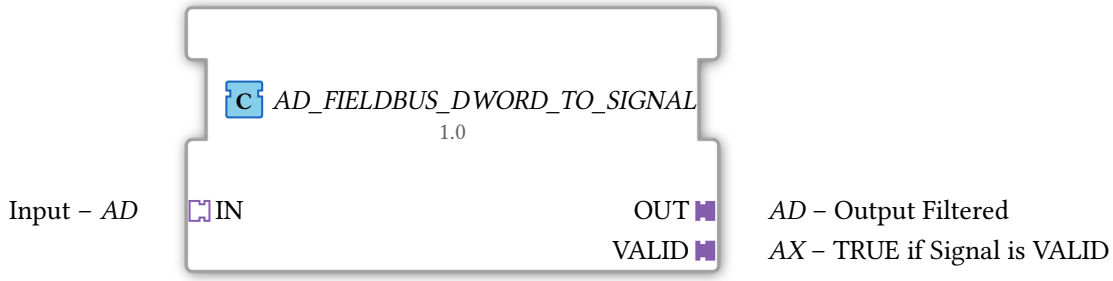
- **In idle state**, it waits for an event.
- **On INIT**, the internal function block is initialized.
- **On IN.E1**, the translation is triggered, and the results are output asynchronously.

Thus, the function block behaves like a combinational, but clocked, function.

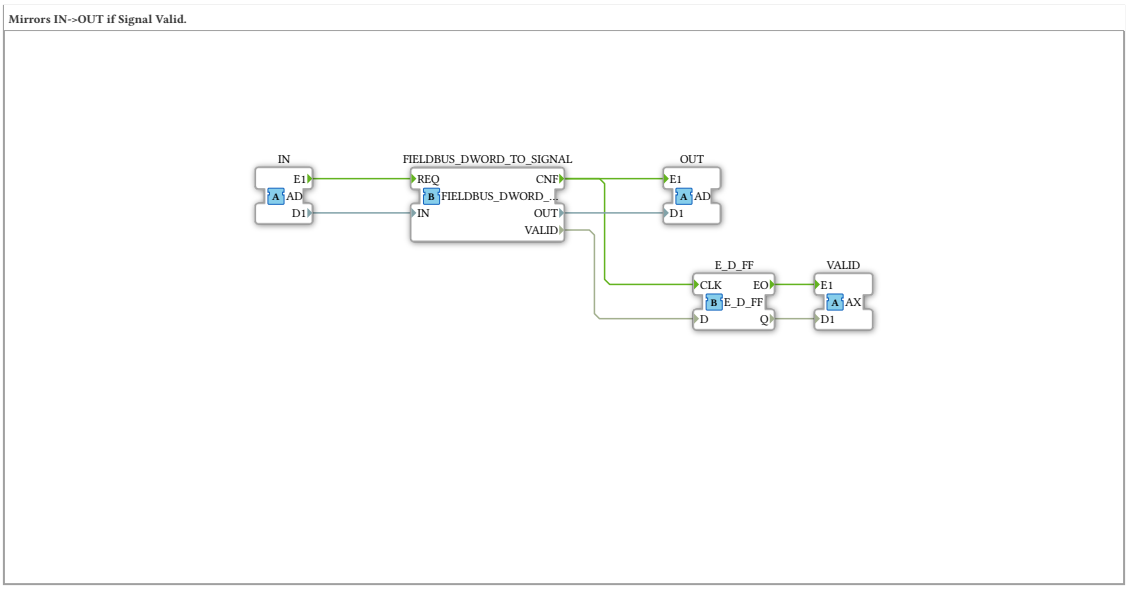
Application Scenarios

- **Fieldbus Signal Conditioning**: Receiving raw data (e.g., pressure sensor values as BYTE) and converting it into physical units (e.g., bar) using scaling and offset.
- **Normalization of Measured Values**: Adapting to a standardized value range, e.g., 0…100% or −50… +50°C.
- **Validity Check**: If the sensor only sends a signal when the measurement is valid, the Validation Adapter can be used to control downstream blocks.

Comparison with Similar Function Blocks



- **AB_FIELDBUS_BYTE_TO_SIGNAL** (without “SCALED”): Does not offer scaling/offset but transmits the raw value directly.
- **AB_FIELDBUS_SIGNAL_SCALED** (based on REAL): May work directly with REAL values but requires a different adapter configuration.



This module combines BYTE-to-REAL conversion with compact, configurable scaling and an output validity signal.

Conclusion

AB_FIELDBUS_BYTE_TO_SIGNAL_SCALED` is a specialized function block for the flexible conversion of raw BYTE data into scaled values with integrated validity signaling. Its adapter-based interface allows for easy integration into IEC 61499 systems and makes it particularly suitable for fieldbus applications where raw values need to be transformed into physical quantities.

AD_FIELDBUS_DWORD_TO_SIGNAL

• – ○ • – ○ • – ○ •

Introduction

The function block `AD_FIELDBUS_DWORD_TO_SIGNAL` is used to forward an incoming data word (DWORD) to the output – but only if the signal is classified as valid. It combines a specialized fieldbus function block with an edge-triggered D flip-flop to implement reliable, data-driven validation and forwarding.

Interface Structure

The function block has only adapter interfaces; there are no separate event or data ports at the top level. The following adapters define the inputs and outputs:

Adapter	Type	Direction	Description
`IN`	`adapter::types::unidirectional::AD`	Socket (Input)	Input data word and associated event
`OUT`	`adapter::types::unidirectional::AD`	Plug (Output)	Filtered output data word (DWORD)
`VALID`	`adapter::types::unidirectional::AX`	Plug (Output)	Validation signal (BOOL) of the current data word

Event Inputs (via adapter `IN`)

Port	Description
`E1`	Event to start processing a new data word

Event Outputs (via adapters `OUT` and `VALID`)

Adapter	Port	Description
`OUT`	`E1`	Signals that the filtered data word is present at the output
`VALID`	`E1`	Signals that the validity status (TRUE/FALSE) has been updated

Data Inputs (via adapter `IN`)

Port	Type (assumed)	Description
`D1`	`DWORD`	The data word to be processed

Data Outputs (via adapters `OUT` and `VALID`)

Adapter	Port	Type (assumed)	Description
`OUT`	`D1`	`DWORD`	The filtered – possibly identical – data word
`VALID`	`D1`	`BOOL`	`TRUE` if the attached data word is considered valid, otherwise `FALSE`

Adapters

The adapters are of type `unidirectional`, meaning they each transmit one event and one piece of data in one direction. The function block (FB) uses two different adapter types:

- **AD**: Transmits an event and a data word (DWORD)
- **AX**: Transmits an event and a Boolean signal

Functionality

The interaction of the internal function blocks can be described in the following steps:

1. An event at `IN.E1` triggers the internal FB `FIELDBUS_DWORD_TO_SIGNAL` via its `REQ` input.
2. The internal FB processes the incoming data word (`IN.D1`) and outputs two results:

- The (possibly identical) data word at `OUT`
- A Boolean signal `VALID` indicating whether the data word is valid.

1. After processing is complete, the internal function block (FB) signals with `CNF`:

- The event is forwarded to `OUT.E1` ⟶ the output adapter releases the new data word.
- Simultaneously, the event clocks the edge-triggered D flip-flop `E_D_FF` via its `CLK`.

1. The flip-flop receives the current validity status (`VALID` signal) from `FIELDBUS_DWORD_TO_SIGNAL` at its `D` input and outputs it at its `Q` output.

The flip-flop receives the current validity status (`VALID` signal) from `FIELDBUS_DWORD_TO_SIGNAL` at its `D` input and outputs it at its `Q` output. 5. The `EO` output of the flip-flop generates an event that is sent to `VALID.E1` – thus updating the validity status in sync with the data word.

In other words: The function block *mirrors* the input DWORD to the output, provided the fieldbus function block's internal validation mechanism classifies it as valid. Validity is stabilized by a flip-flop and output as a separate signal.

Technical Features

- **Composite Function Block**: The function block is implemented as a network of two subordinate function blocks (`FIELDBUS_DWORD_TO_SIGNAL` and `E_D_FF`).
- **License**: The function block is subject to the Eclipse Public License 2.0 (EPL-2.0).
- **Packet Structure**: Integrated into the namespace `logiBUS::signalprocessing::fieldbus`.
- **Edge-Triggered Validation Memory**: The use of a D flip-flop ensures that the `VALID` signal is only updated with the next clock edge (the `CNF` event) – this prevents asynchronous state transitions.
- **No Dedicated Event/Data Ports**: All communication takes place exclusively via standardized adapters.

State Overview

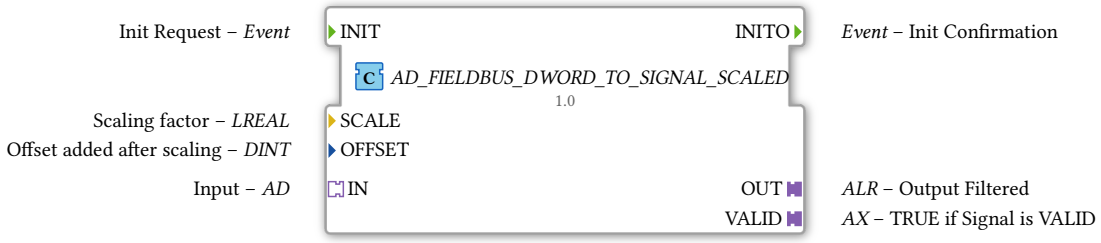
The function block (FB) does not have an explicit state machine, but operates purely on data flow. The internal flip-flop `E_D_FF` has two internal states:

State	Description
`Q = FALSE`	The currently transmitted `VALID` signal is `FALSE` (data word is considered invalid)
`Q = TRUE`	The currently transmitted `VALID` signal is `TRUE` (data word is considered valid)

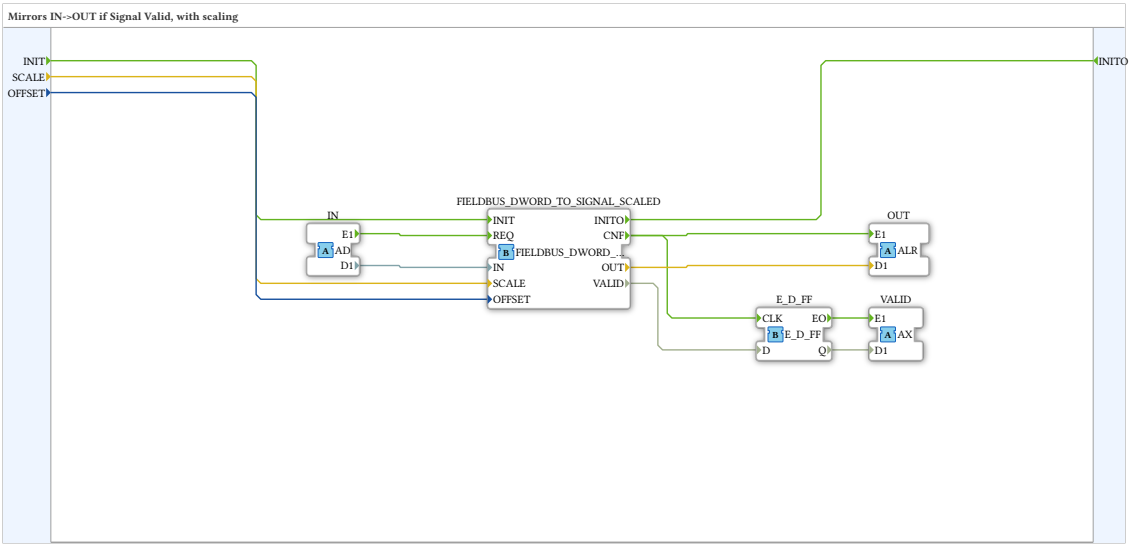
The state changes only on a rising edge at `CLK` (corresponds to the `CNF` event of the internal fieldbus module).

Application Scenarios

- **Fieldbus Data Filtering**: Used in PLC controllers where only valid telegrams from a bus system (e.g., CANopen, PROFIBUS) should be passed on to the application logic.
- **Quality Marking**: A sensor provides a measured value and a validation bit – the function block cleanly separates both pieces of information and keeps them synchronized.
- **Secure Data Transmission**: In safety-critical environments, the function block can be used to only allow verified data words into subsequent calculations.



Comparison with Similar Function Blocks



- **Simple Buffer Blocks (e.g., `MOVE`)**: These pass data without evaluation. `AD_FIELDBUS_DWORD_TO_SIGNAL` adds validation logic and separates the validity signal.
- **Typical quality function blocks (e.g., `QHandler`)**: These often process multiple quality bits; this function block focuses on a single Boolean signal, `VALID`, and works with DWORD data.
- **Adapter-based function blocks**: The pure adapter interfaces promote loose coupling and reusability in various runtime environments.

Conclusion

AD_FIELDBUS_DWORD_TO_SIGNAL` offers a compact and standardized solution for forwarding fieldbus data words to the application only when validity has been established. The combination of a specific fieldbus function block and a flip-flop ensures a timely and stable output of the validation status. Due to its adapter-based interface, the function block can be flexibly integrated into existing IEC 61499 systems.

AD_FIELDBUS_DWORD_TO_SIGNAL_SCALED

• – ○ • – ○ • – ○ •

Introduction

The function block `AD_FIELDBUS_DWORD_TO_SIGNAL_SCALED` processes a digital fieldbus signal (DWORD) into a scaled analog output value. It mirrors the input value to the output, provided the signal is valid, and applies linear scaling with an offset. The valid signal state information is synchronized via an edge-triggered flip-flop and provided as a separate output signal.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initialization request for the entire function block (forwarded to internal core function block)

Event Outputs

Event	Type	Description
INITO	EInit	Initialization confirmation after successful initialization

Data Inputs

Name	Data Type	Initial Value	Description
SCALE	LREAL	1.0	Scaling factor by which the input value is multiplied
OFFSET	DINT	0	Integer offset that is added after scaling

Data Outputs

This module has no direct data outputs. All output data is provided via the adapter interfaces.

Adapters

Name	Type	Direction	Description
IN	AD (unidirectional)	Socket	Input adapter for the DWORD value (fieldbus signal)
OUT	ALR (unidirectional)	Plug	Output adapter for the scaled analog value
VALID	AX (unidirectional)	Plug	Output adapter for signal validity (TRUE = valid)

Functionality

The module implements the following signal chain:

1. **Initialization**: The event `INIT` is forwarded directly to the internal core module `FIELDBUS_DWORD_TO_SIGNAL_SCALED`. Upon completion, `INITO` is output.
2. **Data Processing**: The DWORD value present at socket `IN` is inherited with each data event (E1). The core module multiplies the value by `SCALE` (LREAL) and adds `OFFSET` (DINT). The result is output as LREAL to plug `OUT`.
3. **Validity Signal**: The core module outputs an internal Boolean validity signal indicating whether the current data value is valid. This signal is synchronized via an edge-triggered D flip-flop (`E_D_FF`) and output to the plug `VALID`. The flip-flop clocks with the same event (`CNF` of the core module), so the validity is updated simultaneously with the output value.

The internal circuitry ensures that the validity status always corresponds to the last processed data value.

Technical Features

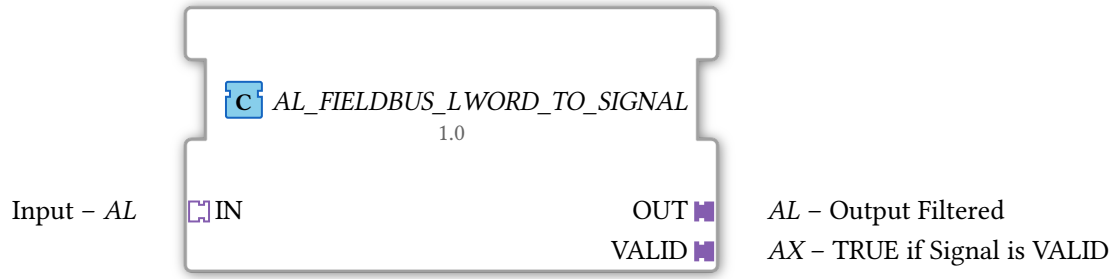
- **Scaling Order**: First, multiplication by `SCALE` (LREAL), then addition by `OFFSET` (DINT). This allows the offset to be specified in units of the scaled range.
- **Edge Synchronization**: The validity signal is output via a D flip-flop using edge triggering, so there are no metastable states on the output side.
- **Initial Value Default**: `SCALE` is predefined to 1.0, `OFFSET` to 0. In the unscaled case, the output thus directly corresponds to the input.
- **Adapter Structure**: The inputs and outputs are implemented as adapters, enabling type-safe connections with other devices from the same adapter family (AD, ALR, AX).

State Overview

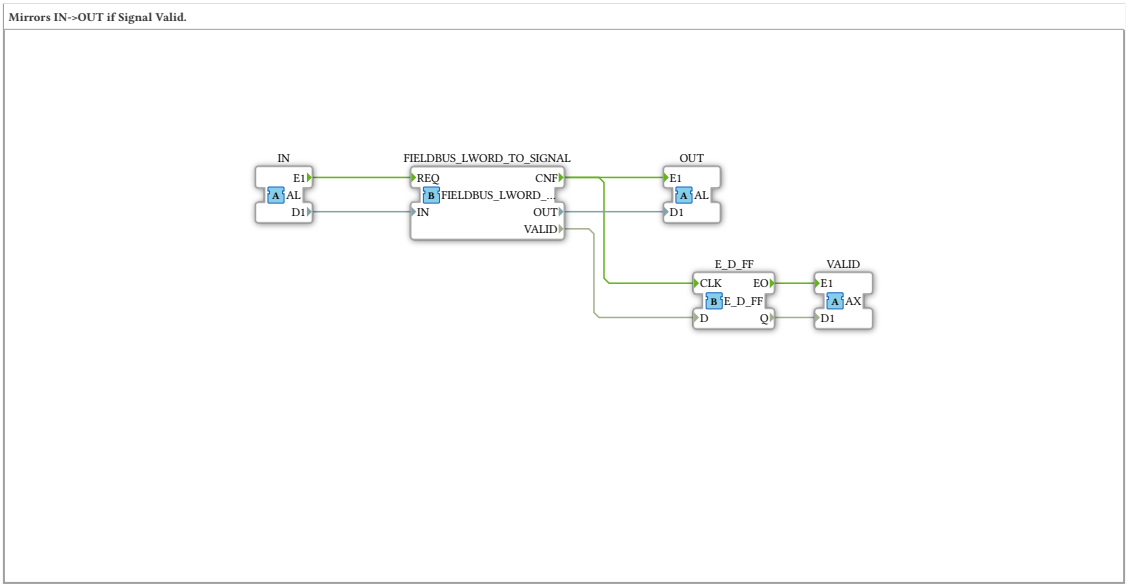
The device does not have its own explicit state diagram (ECC). All state logic resides in the internal core device `FIELDBUS_DWORD_TO_SIGNAL_SCALED` and the edge-triggered D flip-flop. This stores the last valid validity state. With each processing event, the flip-flop is clocked and outputs the current validity value.

Application Scenarios

- **Fieldbus Data Acquisition**: A raw DWORD value (e.g., from an analog-to-digital converter or encoder) is converted using physical factors (scaling) and offset and transmitted as an analog value to a controller.
- **Signal Validation with Storage**: When the fieldbus provides a validity flag (e.g., "Data Updated"), this can be evaluated via the validity adapter level. The flip-flop ensures that the validity signal remains stable until the next update.
- **Configurable Scaling**: By externally specifying `SCALE` and `OFFSET`, the same function block can be used for different sensor ranges without modifying the function block itself.
-



Comparison with Similar Function Blocks



Compared to a simple `MOVE` or `SCALE` function block, this FB offers integrated validation handling and a clean separation between data and event adapters. Similar function blocks (e.g., `FIELD_DWORD_TO_ANALOG`) often lack separate signal validity output or edge-synchronous storage. The combination of core function block and D flip-flop used here is a proven solution for safety-critical applications where the validity of a data value must be reliably maintained.

Conclusion

The `AD_FIELDBUS_DWORD_TO_SIGNAL_SCALED` function block is a robust and configurable function block for converting digital fieldbus signals into scaled analog values with synchronous validity output. Thanks to its modular adapter connections and integrated edge synchronization, it is particularly suitable for industrial automation systems where data consistency and signal quality are equally important.

AL_FIELDBUS_LWORD_TO_SIGNAL

• – ○ • – ○ • – ○ •

Introduction

The function block `AL_FIELDBUS_LWORD_TO_SIGNAL` filters and passes a fieldbus signal of type `LWORD`. It only passes the input value to the output if the corresponding valid signal is set. The valid status is provided via a separate output and stabilized by an internal flip-flop. The block is implemented as a composite function block and encapsulates the signal processing logic and the valid signal state.

Interface Structure

Event Inputs

- **`IN.E1`** (via socket `IN`): Event to request signal processing. An incoming event triggers the mirroring of the input value to the output and updates the validity status.

Event Outputs

- **`OUT.E1`** (via plug `OUT`): Event output after successful processing. Signals that the current output value (`OUT.D1`) is valid.
- **`VALID.E1`** (via plug `VALID`): Event output simultaneously with `OUT.E1`. Confirms the update of the validity signal (`VALID.D1`).

Data Inputs

- **`IN.D1`** (via socket `IN`, type: `LWORD`): The fieldbus signal to be processed. The value is passed unchanged to the output, provided the internal validity signal is active.

Data Outputs

- **`OUT.D1`** (via plug `OUT`, type: `LWORD`): The filtered output signal. Contains the value of `IN.D1` if the signal is valid; otherwise, the last valid value is retained (due to the internal behavior of the function block used, `FIELDBUS_LWORD_TO_SIGNAL`).

- **VALID.D1** (via plug VALID, type: BOOL): Indicates whether the currently output signal is valid. The value is buffered by an internal flip-flop (E_D_FF) and updated with each processing cycle.

Adapter

Adapter	Direction	Type	Description
IN	Socket	adapter::types::unidirectional::AL	Receives the event and data signal from an upstream component.
OUT	Plug	adapter::types::unidirectional::AL	Sends the filtered signal and associated event to subsequent function blocks.
VALID	Plug	adapter::types::unidirectional::AX	Sends the validity status as a Boolean value and an acknowledgment event.

Functionality

This function block operates as a composite function block with the following internal logic:

1. An incoming event at IN.E1 triggers the internal function block FIELDBUS_LWORD_TO_SIGNAL via its REQ input.
2. This internal function block (FB) reflects the value of IN.D1 to its output OUT and simultaneously generates a Boolean signal VALID indicating whether the value is valid.
3. The internal FB's CNF event is distributed to three destinations:

- It triggers the output plug OUT.E1, so the filtered value (OUT.D1) is passed to the next processing stage.
- It triggers the CLK input of the flip-flop E_D_FF.

1. The VALID signal of the internal function block is applied to the D input of the flip-flop. On each rising edge of the clock (triggered by CNF), the flip-flop takes this value and outputs it to Q.
2. The output Q of the flip-flop is set to VALID.D1, and the simultaneous event VALID.E1 is triggered by the flip-flop event EO.

This ensures that the validity status is only passed to the Valid output once the signal processing is complete. The output value OUT.D1 corresponds to the input value IN.D1, provided it was recognized as valid; otherwise, the last valid value is retained (depending on the implementation of the internal function block FIELDBUS_LWORD_TO_SIGNAL).

Technical Features

- **Composite Architecture:** The functionality is implemented through an internal network consisting of a specialized function block (FIELDBUS_LWORD_TO_SIGNAL) and an edge-triggered flip-flop (E_D_FF). This enables a modular and testable implementation.
- **State Maintenance:** The validity status is stored via a flip-flop. This ensures that the valid output remains stable between processing cycles and is only updated upon new events.
- **Unidirectional Adapters:** All interfaces are implemented as unidirectional adapters (AL or AX), which allows for a clear separation of event and data flow.
- **Licensing:** This function block is available under the Eclipse Public License 2.0 (Copyright HR Agrartechnik GmbH).

State Overview

This function block does not have an explicit ECC, as it is a composite function block. The internal state logic is limited to the flip-flop E_D_FF, which has two states:

State	Q (VALID.D1)	Meaning
RESET (Initial)	FALSE	Signal is invalid (initial).
SET	TRUE	Signal is valid after a valid value has been detected.

The state change occurs with each incoming event at CLK (from CNF) depending on the D input (from the internal VALID signal). The state is maintained until the next event arrives.

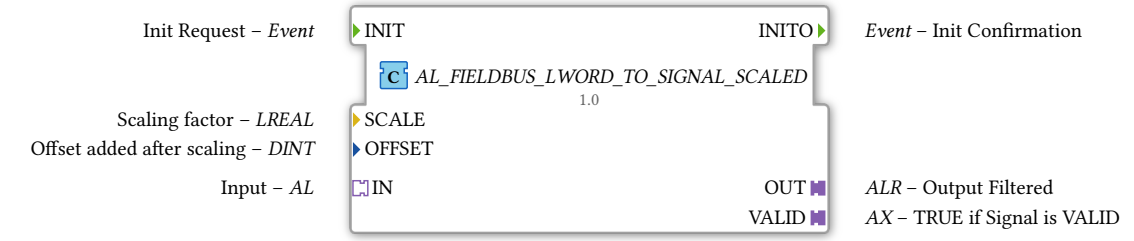
Application Scenarios

- **Fieldbus Signal Processing:** Acquisition of LWORD signals (e.g., from a CANopen or Profibus network) and their transmission only if the status is valid.
- **Filtering of Invalid Values:** If a sensor temporarily delivers invalid measured values, the function block transmits the last valid value and signals the invalidity via `VALID.D1`.
- **Synchronization of Multiple Paths:** Due to the separate outputs for signal and valid, downstream function blocks can process both pieces of information simultaneously.

Comparison with Similar Function Blocks

Simpler function blocks like `MOVE` or `REPEAT` pass incoming values unfiltered, without validation. `AL_FIELDBUS_LWORD_TO_SIGNAL` extends this functionality with validation logic and a separate validation output. Other function blocks from the `logiBUS` library might offer similar tasks for other data types (e.g., `WORD` or `BOOL`), but they are not specifically designed for `LWORD`.

Conclusion



The `AL_FIELDBUS_LWORD_TO_SIGNAL` Function Blockis a specialized composite component for the reliable transmission of fieldbus signals while adhering to a validity criterion. Its combination of signal processing and state management makes it ideal for safety-critical or quality-conscious applications in automation technology. The clearly defined adapter interfaces facilitate integration into existing 4diac IDE projects.

]

AL_FIELDBUS_LWORD_TO_SIGNAL_SCALED

• – ○ • – ○ • – ○ •

Introduction

The function block `AL_FIELDBUS_LWORD_TO_SIGNAL_SCALED` converts a fieldbus signal (LWORD) into a scaled value with an offset. A valid output signal is only generated if the input signal is marked as valid. Validity is maintained via an internal D flip-flop and output as a Boolean signal.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirmation

Data Inputs

Name	Type	Initial Value	Comment
SCALE	LREAL	1.0	Scaling Factor
OFFSET	DINT	0	Offset Added After Scaling

Adapters

Type	Direction	Name	Comment
AL	Socket	IN	Input Signal (LWORD)
ALR	Plug	OUT	Output signal (scaled)
AX	Plug	VALID	Signal valid (TRUE/FALSE)

Functionality

The function block contains two internal components:

- **FIELDBUS_LWORD_TO_SIGNAL_SCALED**: Performs the actual conversion of the LWORD input using the SCALE and OFFSET parameters. Upon an event at `IN.E1` (connected to `REQ`), the processed value is set to `OUT` and the validity signal to `VALID`.
- **E_D_FF**: An edge-triggered D flip-flop that takes the validity signal from the previous function block. The clock signal (`CLK`) is triggered by the acknowledgment event (`CNF`) of the first block. The output `Q` is written to the adapter `VALID.D1`.

This results in the following sequence:

1. An incoming event at `IN.E1` starts the processing.
2. The internal block calculates the scaled value and outputs the validation signal.
3. The flip-flop stabilizes this signal and passes it to the `VALID` adapter.
4. Simultaneously, the scaled value is output via the `OUT` adapter.

The INIT interface is used for initialization and is passed through directly.

Technical Features

- The INIT and INITO connections are marked as invisible in the network, but they exist for a clean initialization cascade.
- Scaling and offset are passed internally to the subordinate function block (FB) and are directly configurable.
- The D flip-flop prevents unwanted edges or momentary invalidity changes at the output.

State Overview

The FB does not have an explicit state machine (ECC). Its behavior is controlled by event processing:

- **After INIT**: The FB is ready to receive events at `IN.E1`.
- **After each REQ/CNF cycle**: A new scaled value and an updated validity signal are available at the adapters.

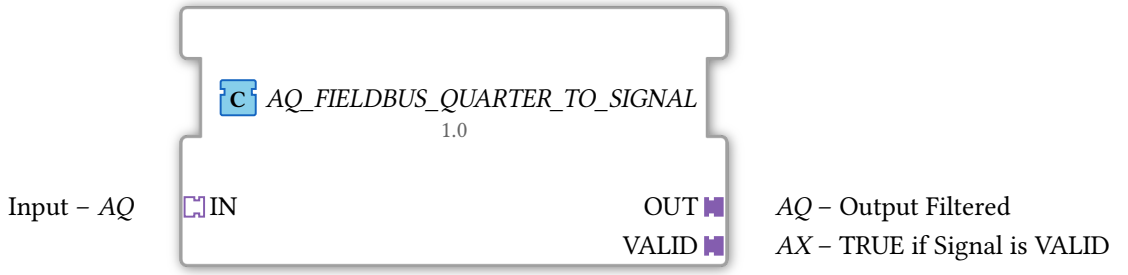
Application Scenarios

Typical application areas include:

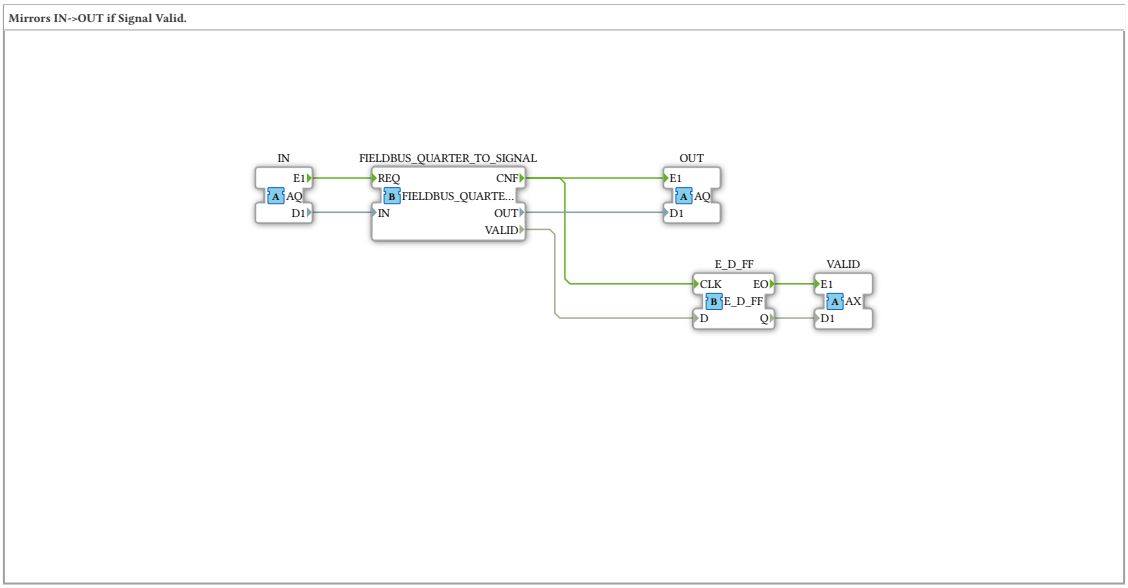
- Conversion of raw fieldbus data (e.g., LWORD from PROFIBUS, CAN, etc.) into physical quantities (temperature, pressure, speed) with user-defined scaling.
- Forwarding of sensor data where only values marked as valid should be passed to the subsequent logic.
- Integration into plant control systems that require a clean initialization sequence (via INIT).

Comparison with Similar Function Blocks

Simpler LWORD conversion function blocks often lack integrated validity checking and output the signal directly. `AL_FIELDBUS_LWORD_TO_SIGNAL_SCALED` adds this functionality with:



- A separate validity signal, edge-triggered via a D flip-flop.
- An explicit initialization interface.



The combination of scaling, offset, and validity latch distinguishes it from simple conversion function blocks.

Conclusion

This functional block represents a robust solution for conditioning fieldbus signals. It combines scaling, offset shifting, and reliable validity indication in a compact, initializable component. The use of a D flip-flop stabilizes the signal quality, which is particularly advantageous in safety-critical or noisy environments.

AQ_FIELDBUS_QUARTER_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AQ_FIELDBUS_QUARTER_TO_SIGNAL** is used to mirror a signal (of type AQ) received via a fieldbus adapter to an output adapter – but only if the signal is marked as valid. It combines a fieldbus-specific processing block with an edge-triggered D flip-flop to buffer the validity status and provide it as a separate output signal.

Interface Structure

Event Inputs

The function block does not have direct event inputs at the top level. Instead, events are provided via the **socket adapter IN** (type AQ). The event output IN.E1 initiates the processing of the incoming signal.

Event Outputs

Event outputs are also exclusively handled via the **plug adapters OUT** and VALID:

- **OUT.E1**: Triggered after successful signal mirroring. (The result is available at the data output OUT.D1.)
- **VALID.E1**: Triggered as soon as the signal's validity status is updated (rising edge of the internal D flip-flop).

Data Inputs

Data is also received via the **socket adapter IN**:

- **IN.D1**: Receives the analog or digital input signal (adapter type AQ).

Data Outputs

- **OUT.D1**: Outputs the mirrored input signal – but only if it has been recognized as valid. (If the signal is invalid, a defined value or the last valid value can be output; this depends on the internal implementation of FIELDBUS_QUARTER_TO_SIGNAL.)
- **VALID.D1**: Outputs the current validity status (TRUE = valid, FALSE = invalid). This value is the output signal Q of the D flip-flop.

Adapter

Name	Type	Direction	Description
IN	adapter::types::unidirectional::AQ	**Socket** (Input)	Fieldbus signal (event and data)
OUT	adapter::types::unidirectional::AQ	**Plug** (output)	Filtered/mirrored output signal
VALID	adapter::types::unidirectional::AX	**Plug** (output)	Signal validity status

Note: Adapter types AQ and AX are unidirectional protocols that typically combine an event and a data field.

Functionality

The function block operates as follows:

1. An incoming event on IN.E1 triggers the internal function block **FIELDBUS_QUARTER_TO_SIGNAL** (called via REQ).
2. This internal function block processes the data value (IN.D1) and generates two outputs:

- **OUT** – the processed signal (e.g., mirrored, normalized, filtered).
- **VALID** – a Boolean value (TRUE if the signal is valid).

1. The processed signal is forwarded directly to the output adapter OUT (via OUT.D1) and simultaneously triggers the event OUT.E1.
2. The validity state (VALID) is fed to the D input of an edge-triggered D flip-flop (E_D_FF). The clock edge is generated by the same event (CNF) that also triggers OUT.E1. Thus, the validity state is updated in the flip-flop with each cycle.
3. The flip-flop output Q is output via the adapter VALID.D1. The corresponding event VALID.E1 is triggered by the flip-flop output EO.

The function block ensures that the output signal is always synchronized with the currently processed validity status.

Technical Features

- The function block is implemented as a **composition** of two internal function blocks: `FIELDBUS_QUARTER_TO_SIGNAL` and `E_D_FF`. This offers high reusability and a clear separation of processing logic and state storage.
- The use of a **D flip-flop** buffers the validity status between event cycles. This ensures that the status is retained even if the input signal fails temporarily.
- The adapter interfaces follow the **unidirectional** pattern typical of fieldbus protocols. An event carries both a data value and an execution edge.
- The internal processing (`FIELDBUS_QUARTER_TO_SIGNAL`) can be adapted depending on the application (e.g., scaling, formatting, or plausibility checks) without changing the external interface.

State Overview

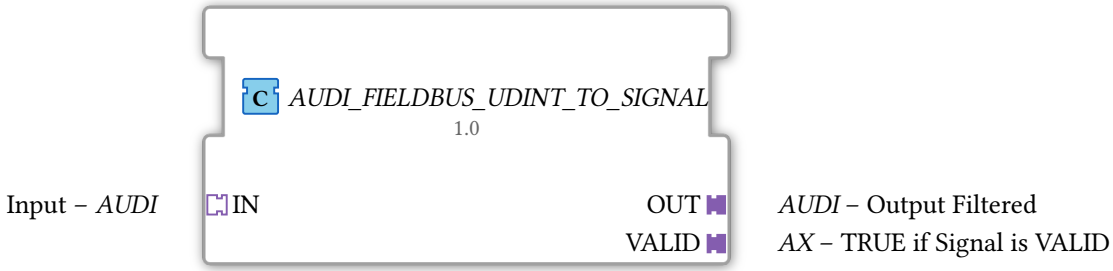
The component does not have its own visible state machine. The internal state is primarily determined by the **D flip-flop**:

- **State 0**: Flip-flop output `Q = FALSE` ⟶ Signal is considered **invalid**.
- **State 1**: Flip-flop output `Q = TRUE` ⟶ Signal is considered **valid**.

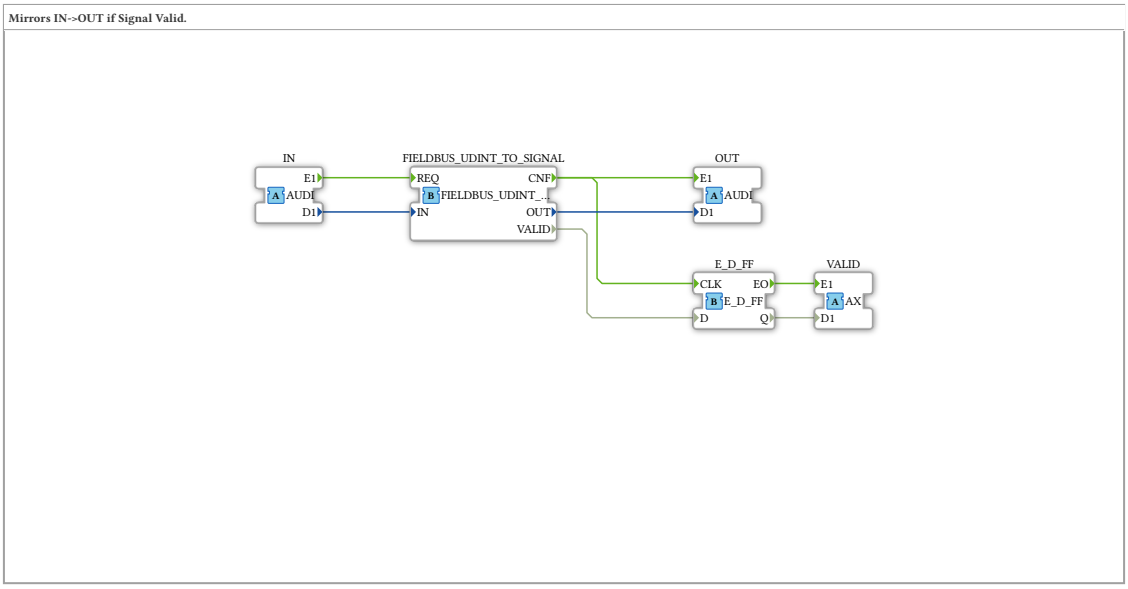
The state change occurs on the clock edge during each processing cycle (event on `IN.E1`). The current state can be read via the adapter `VALID.D1`.

Application Scenarios

- **Fieldbus Connection in Agricultural Engineering**: Receiving an analog sensor signal (e.g., torque, pressure) from a fieldbus, which is only passed on if communication is valid.
- **Signal Quality Filtering**: Integration into a chain of processing modules where only values marked as valid are used in the control or visualization.
- **Redundancy Check**: Combination with a second signal path, where the validity status serves as the switching criterion.



Comparison with Similar Modules



- **`AQ_FIELDBUS_SIGNAL_TO_QUARTER`** (hypothetical): Would represent the reverse process – conversion of a general signal into a fieldbus format.
- **`AQ_BUFFER`**: A simple buffer without validity checks; this module extends this functionality with validation and state storage.
- **`AQ_SELECT`**: Selects between two inputs; in this function block, the validity of a single signal is evaluated instead.

Conclusion

AQ_FIELDBUS_QUARTER_TO_SIGNAL is a compact, adapter-based function block for the reliable mirroring of fieldbus signals while taking signal validity into account. The combination of processing logic and edge-triggered state memory makes it particularly suitable for safety-critical or quality-controlled applications in industrial environments. The clear separation of the internal components facilitates maintenance and customization.

AUDI_FIELDBUS_UDINT_TO_SIGNAL

• – ○ • – ○ • – ○ •

Introduction

The function block `AUDI_FIELDBUS_UDINT_TO_SIGNAL` mirrors an incoming `UDINT` value (via the `IN` adapter) to the `OUT` adapter, provided the incoming signal is recognized as valid. Additionally, the validity signal is output via the `VALID` adapter. This function block acts as a filter, allowing only valid data packets to pass through and providing their status synchronously.

Interface Structure

This function block has no direct input/output events or data, but operates exclusively via adapters that transport both events and data.

Event Inputs

- **`IN.E1`** (via the `IN` adapter) – Starts processing of the incoming signal.

Event Outputs

- **`OUT.E1`** (via the `OUT` adapter) – Triggered after the `IN` value has been processed and passed to `OUT.D1`.
- **`VALID.E1`** (via the `VALID` adapter) – Triggered as soon as the signal's validity has been updated (see Functionality).

Data Inputs

- **`IN.D1`** (via the `IN` adapter) – The incoming `UDINT` value (e.g., from a fieldbus).

Data Outputs

- **`OUT.D1`** (via the `OUT` adapter) – The filtered `UDINT` value (identical to `IN.D1`, if valid).
- **`VALID.D1`** (via the `VALID` adapter) – Boolean value that signals `TRUE` if the incoming signal is valid.

Adapter

Adapter	Type	Direction	Description
`IN`	`adapter::types::unidirectional::AUDI`	Socket	Signal input (reads data and events)
`OUT`	`adapter::types::unidirectional::AUDI`	Plug	Filtered signal output
`VALID`	`adapter::types::unidirectional::AX`	Plug	Validation Indicator (Output for Boolean & Event)

Functionality

The function block contains two internal function blocks:

1. **FIELDBUS_UDINT_TO_SIGNAL** – Converts the incoming UDINT value into a signal and determines its validity.
2. **E_D_FF** – An edge-triggered D flip-flop that synchronizes the validity signal.

Process:

- An event on IN.E1 triggers the processing block FIELDBUS_UDINT_TO_SIGNAL (input REQ).
- This block reads IN.D1 and outputs an event to CNF upon completion.
- The event CNF is forwarded to three locations:
- To OUT.E1 ⟶ the output value (FIELDBUS_UDINT_TO_SIGNAL.OUT) is assigned to OUT.D1.
- To the clock input CLK of the flip-flop (E_D_FF).
- Simultaneously, the validity status (FIELDBUS_UDINT_TO_SIGNAL.VALID) is set to the data input D of the flip-flop.
- On the rising edge of CLK, the flip-flop inherits the value from D to Q and outputs an event on EO.
- The flip-flop output Q feeds VALID.D1, and the event EO triggers VALID.E1.

Thus, the validity signal is only updated and output after the signal processing is complete.

Technical Features

- **Validity Synchronization:** The D flip-flop ensures that the validity status is only available in the next clock cycle after data processing – this prevents inconsistent states.
- **Adapter-based interface:** All data and events are exchanged via standardized unidirectional adapters, which facilitates reuse in hierarchical projects.
- **License notice:** This function block is subject to the **Eclipse Public License 2.0** and contains a copyright notice (HR Agrartechnik GmbH).

State overview

The function block does not have its own state machine; its behavior is determined by the internal D flip-flop. This flip-flop has two states:

State	Q (Output)	Meaning
0	FALSE	Signal currently invalid
1	TRUE	Signal valid

The state changes on each rising clock edge (CLK) to the current value of D. A reset is not provided – if the signal is invalid, Q remains at the last known valid value until a new clock signal (D = FALSE) arrives.

Application Scenarios

- **Fieldbus Signal Conditioning:** A sensor delivers a UDINT value along with a validity flag via a fieldbus (e.g., CANopen, PROFIBUS). This function block filters out invalid values and provides only valid data to the controller.
- **Data Validation in Safety-Critical Environments:** If a higher-level application should only receive processed, valid measured values, this function block can be placed between the bus and the logic.
- **Synchronization of multiple parallel signals:** The separate validity signal can be used to clock downstream function blocks or trigger alarms.

Comparison with similar function blocks

Function block	Feature
FIELDBUS_UDINT_TO_SIGNAL alone	Passes the invalid signal on immediately – without validity synchronization.
AUDI_FIELDBUS_UDINT_TO_SIGNAL (this function block)	**Additional synchronization** of the validity signal via a D flip-flop, so that VALID is only updated with the next clock cycle.
Other validation function blocks	Often without dynamic synchronization; this function block is particularly suitable for cyclic

	bus systems where data and validity may arrive with a time delay.

Conclusion

AUDI_FIELDBUS_UDINT_TO_SIGNALis a specialized filter module for fieldbus signals that only forwards valid incomingUDINT` values to the output and outputs the status via a synchronized path. The use of an internal flip-flop prevents inconsistent states and makes it ideal for use in time-critical automation environments. Its adapter-based interface allows for easy integration into larger 4diac projects.

AUDI_FIELDBUS_UDINT_TO_SIGNAL_SCALED

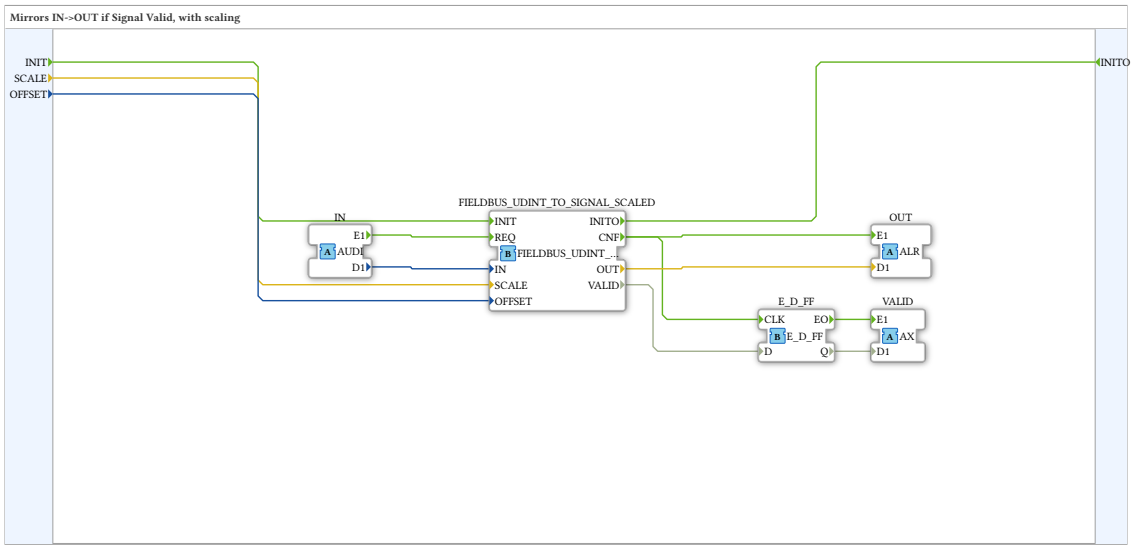

Image of the function block: not available

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_FIELDBUS_UDINT_TO_SIGNAL_SCALED** is used to convert a received UDINT value (unsigned 32-bit integer) from a fieldbus protocol into a scaled signal and only forward it to the output if the input signal is marked as valid. It represents a combined solution for scaling and signal validity checking and is primarily used in automation technology for LogiBUS applications.

Interface Structure

Event Inputs

Name	Type	Comment

INIT	EInit	Initialization Request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement

Data Inputs

Name	Type	Comment	Initial Value
SCALE	LREAL	Scaling Factor	LREAL#1.0
OFFSET	DINT	Offset Added After Scaling	DINT#0

Data Outputs

No separate data outputs – the scaled data is provided via the adapter output `OUT`.

Adapter

Name	Type	Direction	Comment
IN	unidirectional::AUDI	Input	Fieldbus UDINT input signal
OUT	unidirectional::ALR	Output	Scaled signal (if valid)
VALID	unidirectional::AX	Output	Validation flag (TRUE = valid)

Functionality

The function block operates internally as a composite block. It consists of a sub-function block `FIELDBUS_UDINT_TO_SIGNAL_SCALED` (which performs the actual scaling) and an edge-triggered D flip-flop `E_D_FF`.

- A UDINT value (via `IN.D1`) and an event (`IN.E1`) are received via the adapter `IN`.
- The incoming value is forwarded to the internal function block `FIELDBUS_UDINT_TO_SIGNAL_SCALED`, which multiplies the value by `SCALE` and then adds `OFFSET`. The result is available at the output `OUT.D1`.
- Simultaneously, the internal function block generates a validity signal (`VALID`) indicating whether the received raw value is considered valid.
- This validity signal is fed to the D flip-flop at its data input (`D`). The rising edge of the processing event (`CNF`) clocks the flip-flop (`CLK`).
- The instantaneous, synchronized validity signal is present at the flip-flop's output (`Q`) and is output via the adapter (`VALID.D1`).
- The event (`OUT.E1`) is triggered simultaneously with the update of the output data, allowing downstream function blocks to retrieve the new values.

Technical Features

- The function block (FB) is implemented as a **composite FB**, meaning its functionality is represented by an internal network of other function blocks. This allows for a clear separation of scaling and validity logic.
- Initialization occurs via the `INIT` event, which is forwarded to the internal FB. After successful initialization, `INITO` is output.
- The scaling factors `SCALE` and `OFFSET` are set during initialization and cannot be changed at runtime, as they are not updated via separate events.
- The use of a D flip-flop ensures that the validity state remains stable until the next valid data value is processed.

- This function block is designed for use in the LogiBUS environment (package `logiBUS::signalprocessing::fieldbus`).

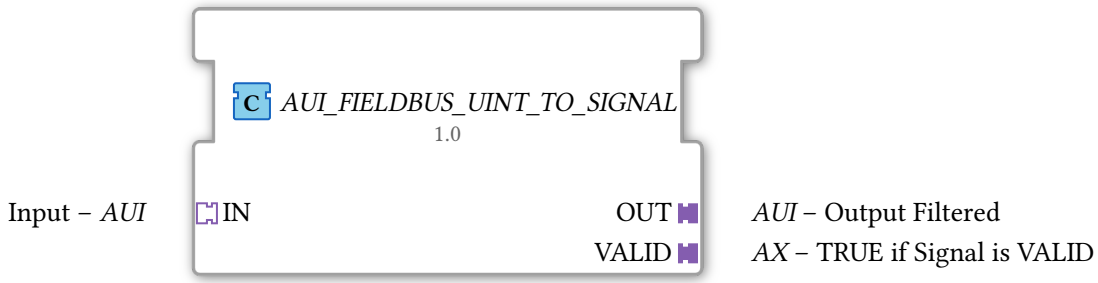
State Overview

This function block does not have explicit states in the sense of a state machine. Its internal logic is executed purely data-flow controlled via the event chain:

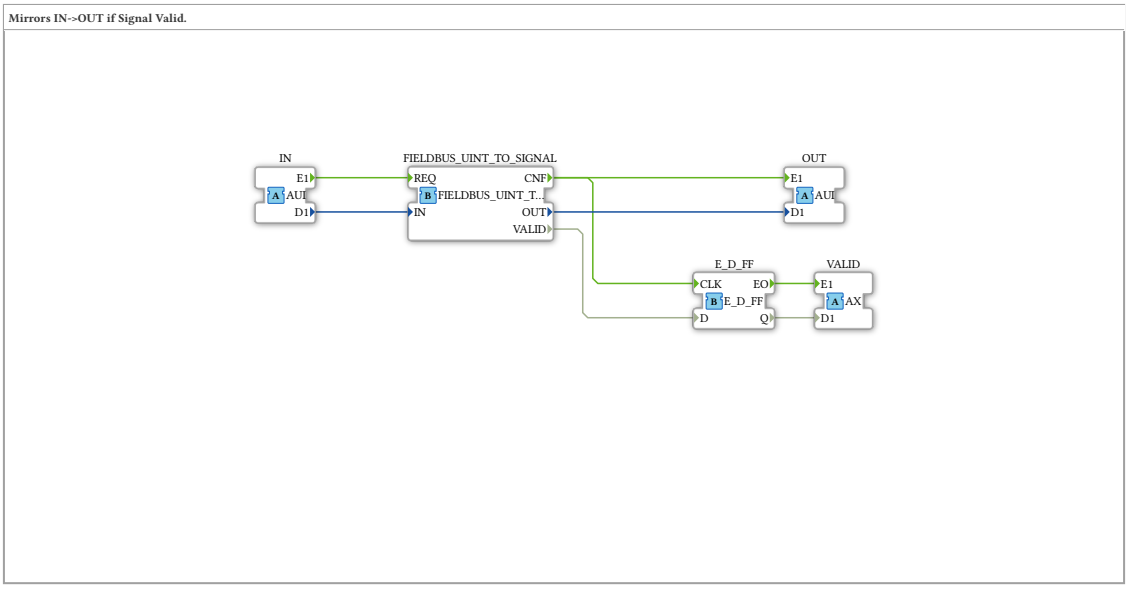
1. **Initialization Phase**: After receiving `INIT`, the internal function block is initialized and `INITO` is sent.
2. **Data Processing Phase**: An incoming `IN.E1` triggers the scaling and validity check. Upon completion, `OUT.E1` and the output data are updated.

Application Scenarios

- **Scaling of Fieldbus Signals**: When a fieldbus delivers a UDINT value (e.g., a sensor counter reading) that needs to be converted into a physical unit, e.g., scaling and offset.
- **Validity Check**: Only valid measured values should be passed on to the controller. The flag `VALID` can be evaluated by a higher-level safety block, for example.
- **Coupling of LogiBUS and IEC 61499 Systems**: The function block serves as a bridge between the LogiBUS protocol and standardized function blocks.



Comparison with Similar Function Blocks



- **FIELDBUS_UDINT_TO_SIGNAL_SCALED** (bare scaling block): This block performs only the scaling, without the validity check and without the memory logic. The present composite function block extends it to include the status management of the validity flag.
- **Standard IEC 61499 Scaling Blocks** (e.g., `SCALE`): Usually implemented as simple arithmetic blocks, they often lack integrated validity logic and connectivity to fieldbus adapters.

Conclusion

The function block `AUDI_FIELDBUS_UDINT_TO_SIGNAL_SCALED` offers a compact, reusable solution for scalable signal processing with integrated validity checking in LogiBUS environments. It combines scaling, offset, and an edge-triggered validity lock, ensuring that only valid and correctly scaled values are present at the output. Thanks to its composite structure, it is easily extensible and readily integrates into existing IEC 61499 projects.

AUI_FIELDBUS_UINT_TO_SIGNAL

• — ○ • — ○ • — ○ •

Introduction

The function block **AUI_FIELDBUS_UINT_TO_SIGNAL** forwards a fieldbus signal encoded as `UINT` to a downstream AUI adapter, provided the signal is recognized as valid. It also provides a separate validity indicator (`VALID`). The block encapsulates a data converter and an edge-triggered D flip-flop, which buffers the validity signal until the next event.

Interface Structure

Event Inputs

The function block does not have separate event inputs. All event-driven processes are handled via the **adapter socket `IN`**.

Event Outputs

The function block does not have separate event outputs. Events are output via the **adapter plugs `OUT` and `VALID`**.

Data Inputs

The function block does not have separate data inputs. The input value is provided as a data signal `D1` via the **adapter socket `IN`**.

Data Outputs

The function block does not have separate data outputs. Output data is transmitted via the **adapter plugs `OUT` and `VALID`** as data signals `D1`.

Adapter

Name	Type	Direction	Description
`IN`	AUI (unidirectional)	Socket	Receives the raw fieldbus signal as `UINT`. Provides event `E1` and data `D1`.
`OUT`	AUI (unidirectional)	Plug	Outputs the filtered signal as `UINT`. Event `E1` signals incoming data.
`VALID`	AX (unidirectional)	Plug	Provides a validity signal (`TRUE`/`FALSE`) via `D1`; event `E1` indicates an update.

Functionality

1. An external event on the **socket `IN`** (via its event input `E1`) triggers the process.
2. The incoming data value (`IN.D1`) is processed by the internal function block `FIELDBUS_UINT_TO_SIGNAL`. This generates an output value (`OUT`) and a validity flag (`VALID`).
3. The processed value is immediately passed to the **plug `OUT`** (data signal `D1`) and an event is triggered at `OUT.E1`.
4. Simultaneously, the validity flag of the internal function block is transferred to the **D flip-flop `E_D_FF`** (clocked by the same event).
5. The output of the flip-flop (`Q`) is connected to the **plug `VALID`** (data signal `D1`); simultaneously, an event is sent to `VALID.E1`.
6. The state of the validity signal is retained until the next processing cycle.

Technical Features

- The function block is implemented as a **composite FB** its functionality consists of two internal FBs:
- `FIELDBUS_UINT_TO_SIGNAL` (data converter)
- `E_D_FF` (edge-triggered D flip-flop)
- The validity indicator is **event-triggered** and is buffered via a flip-flop. This ensures stability even if the input signal is absent for several cycles.
- The signal and validity outputs are **quasi-parallel** (both via the same event of the internal FB).
- The interfaces are defined exclusively as **adapters**, which facilitates modular integration into fieldbus systems.

State Overview

The FB itself does not have an explicit state machine. However, its behavior can be described by its internal logic:

State	Description
Idle	No input event; the outputs `OUT` and `VALID` retain their last values.
Processing	An event at `IN.E1` starts processing.
Output	Upon completion, `OUT.D1` and `VALID.D1` are updated, and the events are sent to `OUT.E1` and `VALID.E1`.
Hold	The validation value is held in the flip-flop until the next event arrives.

Application Scenarios

- **Fieldbus Interface**: A `UINT` value originating from a fieldbus is to be converted into a standardized AUI signal and only passed on if data integrity is maintained.
- **Validation-Checked Forwarding**: Applications where the output signal is only considered valid after successful internal validation (e.g., CRC check).
- **Single-Channel Signal Conditioning**: This function block can be used in safety-related chains to separately signal the result of a plausibility check.

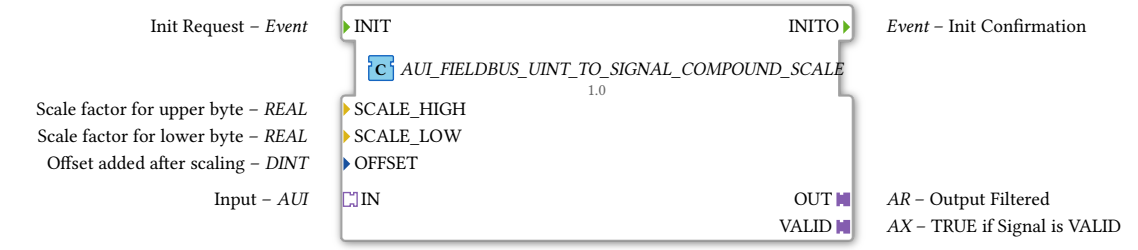
Comparison with Similar Function Blocks

Function Block	Difference / Similarity
`FIELDBUS_UINT_TO_SIGNAL`	Contains only the pure data conversion without a validity buffer.
`AUI_SIGNAL_FILTER`	Filters signals but does not offer an explicit validity indicator.
`E_D_FF`	Pure flip-flop without data conversion – used here as an auxiliary function block.

This function block combines the conversion with **event-driven validity control**, making it particularly suitable for sequential fieldbus protocols.

Conclusion

The `AUI_FIELDBUS_UINT_TO_SIGNAL` function block is a compact, adapter-based module for tested signal forwarding in fieldbus systems. Through the internal coupling of data conversion and edge-triggered



validity indication, it offers a robust and traceable interface for industrial automation. The use of adapters enables easy integration into existing 4diac networks.

AUI_FIELDBUS_UINT_TO_SIGNAL_COMPOUND_SCALE

• – ○ • – ○ • – ○ •

Introduction

The function block `AUI_FIELDBUS_UINT_TO_SIGNAL_COMPOUND_SCALE` is used to convert and scale a 16-bit value received via an AUI fieldbus adapter into a scalable signal. The block mirrors the input value to the output, provided the validity signal is active, and performs compound scaling on the upper and lower bytes of the input value. An offset can be added after scaling. The output is provided via a unidirectional AR adapter, while the validity is signaled via an AX adapter. The block is specifically designed for industrial fieldbus protocols where user data consists of two separately scalable byte ranges.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initialization request; sets the function block to a defined start state.

Event Outputs

Event	Type	Description
INITO	EInit	Initialization confirmation; sent after successful initialization.

Data Inputs

Variable	Type	Initial Value	Description
SCALE_HIGH	REAL	0.256	Scaling factor for the upper byte of the incoming value.
SCALE_LOW	REAL	0.001	Scaling factor for the lower byte of the incoming value.
OFFSET	DINT	0	Integer offset added after scaling.

Data Outputs

This function block has no separate data outputs other than `VarDeclaration`. The output data is provided via the adapters `OUT` and `VALID`.

Adapters

Adapter	Direction	Type	Description
IN	Socket	adapter::types::unidirectional::AUI	Input for the fieldbus data value to be processed.
OUT	Plug	adapter::types::unidirectional::AR	Output of the scaled value (e.g., REAL or DINT, depending on the internal function block).
VALID	Plug	adapter::types::unidirectional::AX	Output signal: TRUE if the current output value is valid.

Functionality

The function block operates as a composite function block that uses an internal function block `FIELDBUS_UINT_TO_SIGNAL_COMPOUND_SCALE` in combination with an edge-triggered D flip-flop (`E_D_FF`). The processing proceeds as follows:

1. **Input Event**: An event at the event input `IN.E1` of the AUI adapter triggers the processing of the current data value `IN.D1`.
2. **Scaling**: The incoming 16-bit value is split into an upper and a lower byte. Each byte is multiplied by its corresponding scaling factor (`SCALE_HIGH`, `SCALE_LOW`). The result of both scaling operations is summed and added to `OFFSET`. The calculated value is then passed to `OUT.D1` via the data output of the internal module.
3. **Validity Signal**: In parallel, the internal component generates a logic signal `VALID`, indicating whether the calculated value is valid. This signal is clocked by the D flip-flop with the completion event `CNF` and forwarded to the `VALID.D1` adapter. This ensures that the validity signal is only activated if the value has actually been recalculated.
4. **Output Event**: The internal block's `CNF` event is used to control both the output adapter `OUT` (event `E1`) and the `VALID` adapter (event `E1`).
5. **Initialization**: The `INIT` event is forwarded directly to the internal block; the initialization confirmation `INITO` is returned accordingly.

Technical Features

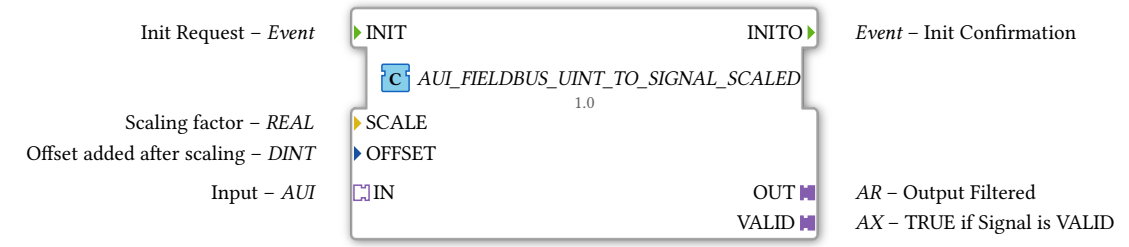
- **Compound Scaling**: Unlike simple scaling blocks, this function block allows separate weighting of the two byte halves of a 16-bit value. This is useful when a sensor value is composed of two different physical quantities (e.g., an integer and a decimal place).
- **Integrated Validation Logic**: The D flip-flop makes the `VALID` signal edge-triggered and only activates it when new calculations are actually performed. This prevents unwanted output when no update is available.
- **Initialization Pass-Through**: The INIT/INITO events are passed transparently through the composite block, ensuring that the internal scaling block is correctly initialized.

State Overview

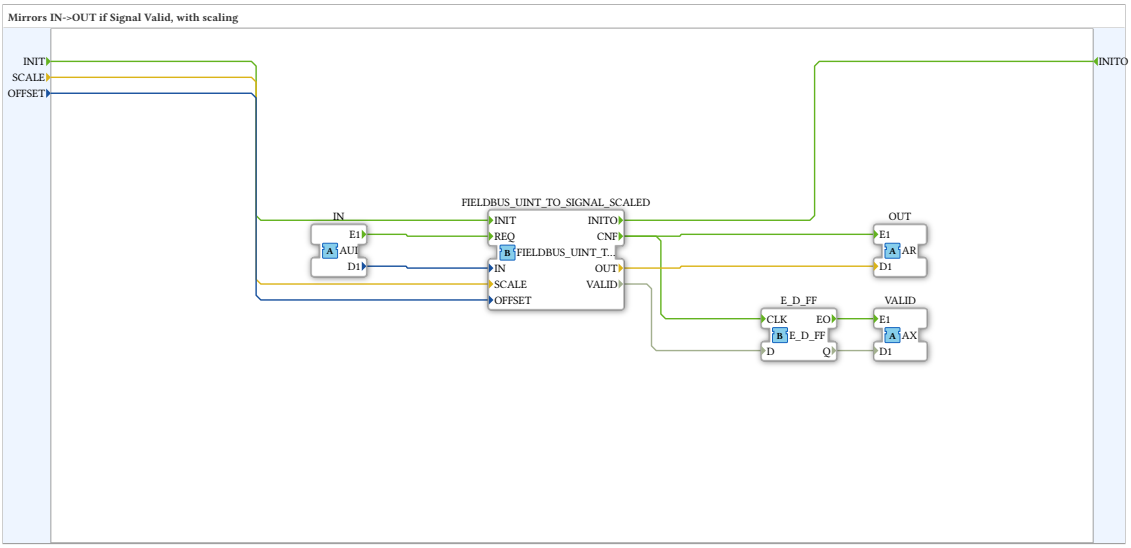
The block itself does not have an explicit state machine at the composite level. Operational readiness is established by the `INIT` event. After successful initialization, the function block waits for incoming events at the `IN` adapter and processes them cyclically. As long as no INIT event has been sent, the function block is in an undefined state (no output, `VALID` inactive).

Application Scenarios

- **Fieldbus Interfaces**: Conversion of analog sensor values transmitted as a 16-bit word with separate scaling factors for the integer and decimal parts (e.g., temperature/pressure values with decimal places).
- **Measurement Processing**: Scaling of digital input signals from fieldbus controllers that deliver raw data in two-byte ranges.
- **Signal Validation**: Used in safety-related applications where only valid and correctly calculated values may be passed on to the subsequent controller.



Comparison with Similar Function Blocks



Unlike simple scaling blocks (e.g., `SCALE` or `UINT_TO_REAL`), this function block offers differentiated processing of the two byte halves. It is specifically designed for data formats where the upper and lower bytes represent different physical units or scaling ranges. Alternative function blocks would have to implement this logic manually by splitting, scaling separately, and then adding the values, which increases the implementation effort.

Conclusion

The `AUI_FIELDBUS_UINT_TO_SIGNAL_COMPOUND_SCALE` is a specialized yet flexible function block for processing fieldbus signals. Its ability to process an incoming 16-bit word with two different scaling factors and to control the validity of the output signal makes it a valuable component in IEC-61499-based automation systems, especially when it comes to integrating devices with compounded data formats.

AUI_FIELDBUS_UINT_TO_SIGNAL_SCALED

• – ○ • – ○ • – ○ •

Introduction

The AUI_FIELDBUS_UINT_TO_SIGNAL_SCALED function block is used for the scalable transmission of an incoming UINT value (fieldbus signal) to an analog REAL output. It only operates if the incoming signal is marked as valid (VALID signal). An additional initialization interface allows the internal logic to be reset. The block is implemented as a composite and combines a scalable sub-block with a D flip-flop for validity storage.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement

Data Inputs

Name	Type	Initial Value	Comment
SCALE	REAL	REAL#1.0	Scaling Factor
OFFSET	DINT	DINT#0	Offset after Scaling

Data Outputs

(No direct data outputs – outputs are via adapters)

Adapters

Type	Name	Direction	Comment
adapter::types::unidirectional::AUI	IN	Socket	UINT input (fieldbus signal)
adapter::types::unidirectional::AR	OUT	Plug	Scaled REAL output
adapter::types::unidirectional::AX	VALID	Plug	Validation signal (TRUE = valid)

Functionality

The function block consists internally of two sub-function blocks: the scalable core function block `logiBUS::signalprocessing::fieldbus::FIELDBUS_UINT_TO_SIGNAL_SCALED` and a D flip-flop `E_D_FF`.

Initialization is performed via the INIT event input, which is forwarded directly to the internal core function block. The acknowledgment INITO is returned after successful initialization.

The actual signal processing is triggered by an incoming event (E1) from the IN adapter. This event triggers the core module, which processes the UINT value received via IN.D1 as follows:

- **Scaling**: `Wert_skaliert = (REAL)IN_D1 * SCALE`
- **Offset**: `Wert_skaliert = Wert_skaliert + OFFSET`

The result (REAL) is output as OUT.D1, and an event OUT.E1 is simultaneously generated. In parallel, the VALID signal (TRUE = valid, FALSE = invalid) calculated by the core module is applied to the D input of the D flip-flop. The same CNF event from the core module serves as the clock signal for the flip-flop. This ensures that the validity state is maintained at the Q output until the next clock cycle. The final validity value is output via the VALID adapter (D1) and its event E1.

This means the VALID signal is only updated after scaling is complete and remains stable until a new value arrives at the input.

Technical Features

- **Composite Architecture**: The function block (FB) is built entirely from sub-FBs, enabling easy adaptation and reuse.
- **Validity Storage**: A D flip-flop stores the validity signal between processing cycles. This allows the output to display a defined state even when no new data is present.
- **Scaling and Offset**: Scaling is performed using a REAL factor and a DINT offset. This allows for flexible adaptation to physical units (e.g., conversion of digital values to pressure or temperature).
- **Adapter-Based Input/Output**: All signals are exchanged via standardized 61499 adapters (AUI, AR, AX), which facilitates integration into modular fieldbus systems.

State Overview

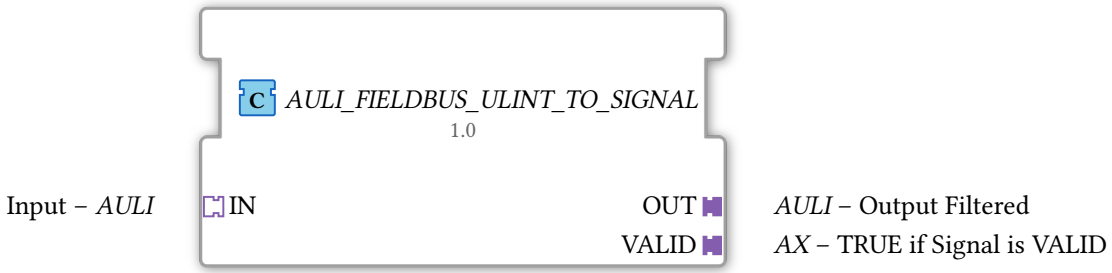
The function block itself does not have its own state machine. The internal state is represented by the D flip-flop:

- **State Q = FALSE**: The last processed value was invalid or no value has yet been received.
- **State Q = TRUE**: The last processed value was valid and is scaled and available at the OUT output.

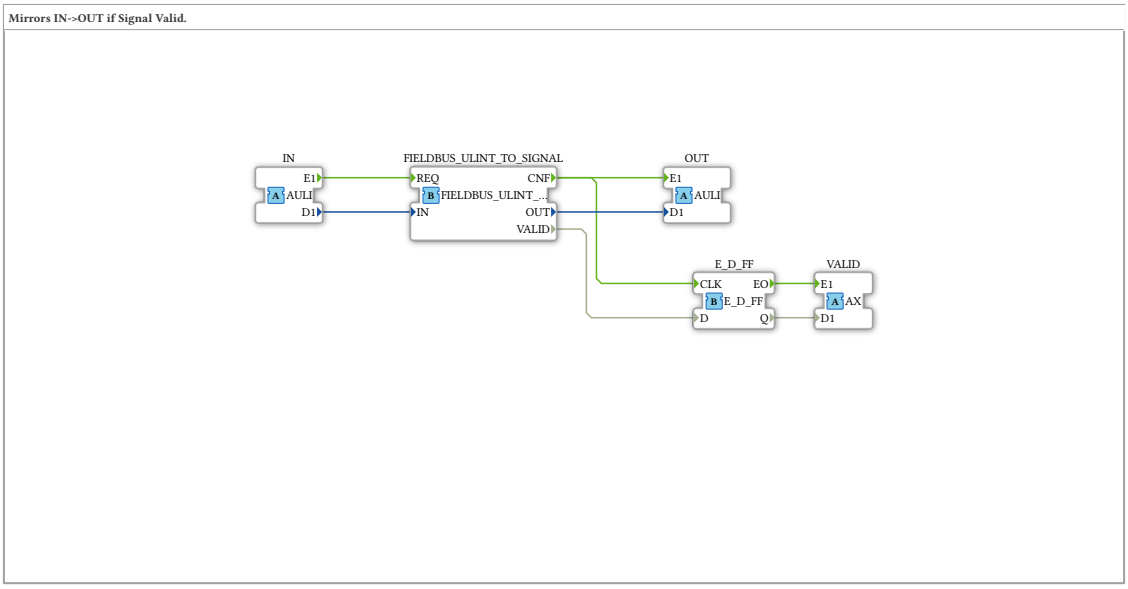
The state change occurs with each new event on the IN adapter (E1) when the core module provides a new VALID signal.

Application Scenarios

- **Agricultural Sensors**: Transmission of scaled measured values (e.g., fill level, pressure) from fieldbus sensors with a validity flag.
- **Data Preprocessing**: Conversion of raw values from digital converters (e.g., 0–10 V ⟶ REAL values) with automatic validity checks.
- **Quality Assurance**: Only values marked as valid are passed on to subsequent control logic.



Comparison with Similar Function Blocks



- **AUI_FIELDBUS_UINT_TO_SIGNAL** (without validity flag): Always outputs a scaled value, regardless of signal quality.
- **AUI_FIELDBUS_UINT_TO_SIGNAL_SCALED** (Core): Already provides a scaled output with a validity flag, but without storage. This composite adds this storage capability and allows for more stable output between events.
- **Adapter-Based Filters**: Other function blocks use similar principles, but with specific validity conditions (e.g., time filters).

Conclusion

The AUI_FIELDBUS_UINT_TO_SIGNAL_SCALED offers a reliable and flexible solution for the scaled transmission of UINT fieldbus signals with explicit validity marking. The combination of scaling, offset, and stored validity signal makes it particularly suitable for safety-critical or quality-controlled applications in automation technology.

AULI_FIELDBUS_ULINT_TO_SIGNAL

• — ○ • — ○ • — ○ •

Introduction

The function block **AULI_FIELDBUS_ULINT_TO_SIGNAL** serves as a composite module for processing a ULINT value from a fieldbus. It mirrors the incoming value to the output if the signal is recognized as valid and also outputs a synchronized validity signal. The module combines an internal fieldbus converter with a D flip-flop to ensure clocked, reliable signal transmission.

Interface Structure

The module does not have traditional top-level event or data ports, but communicates exclusively via adapters. These are implemented as sockets (inputs) and plugs (outputs).

Event Inputs

Port	Name	Description
`IN.E1`	Event Input (via Socket IN)	Triggers the processing of a new ULINT value.

Event Outputs

Port	Label	Description
`OUT.E1`	Event Output (via Plug OUT)	Signals completion of the output of the mirrored value.
`VALID.E1`	Event Output (via Plug VALID)	Indicates that the validity signal has been updated.

Data Inputs

Port	Label	Data Type	Description
`IN.D1`	Data Input (via Socket IN)	ULINT	The fieldbus value to be processed.

Data Outputs

Port	Label	Data Type	Description
`OUT.D1`	Data Output (via Plug OUT)	ULINT	The mirrored input value (if valid).
`VALID.D1`	Data Output (via Plug VALID)	BOOL	Validation signal (TRUE = value is valid).

Adapter

Adapter	Direction	Type	Description
IN	Socket (Input)	adapter::types::unidirectional::AULI	Receives the ULINT value and the associated event.
OUT	Plug (Output)	adapter::types::unidirectional::AULI	Outputs the processed ULINT value and an event.
VALID	Plug (Output)	adapter::types::unidirectional::AX	Provides the validity signal (BOOL) and an event.

Functionality

The function block operates internally with two sub-functions:

1. **FIELDBUS_ULINT_TO_SIGNAL** – A fieldbus converter that converts a ULINT value into a signal and simultaneously generates a validity signal (BOOL).
2. **E_D_FF** – An edge-triggered D flip-flop that receives the validity signal synchronously with the converter's event.

Process:

1. An event at input `IN.E1` starts the processing.
2. The input value `IN.D1` is passed to the internal converter.
3. The converter calculates the output value `OUT` and the `VALID` signal.
4. The result `OUT` is immediately mirrored to the output adapter `OUT.E1` / `OUT.D1`.
5. Simultaneously, the `VALID` signal is passed to the flip-flop and clocked by the event `CNF`.
6. The flip-flop output `Q` is output to the adapter `VALID.D1`, generating an event `VALID.E1`.

`` ``VALID`` ``Q `VALID.D1` VALID.E1` ... This ensures that the output value and the validity signal are always updated consistently and synchronously.

Technical Features

- **Adapter-Based Interface**: The function block uses standardized unidirectional adapters (`AULI`, `AX`), enabling loose coupling and reusability.
- **Synchronization via Flip-Flop**: The validity signal is edge-triggered to avoid clock and glitch issues.
- **Composite Structure**: The internal logic is implemented as a network of two standard function blocks, increasing maintainability and transparency.
- **No Direct Event/Data Ports**: All communication occurs via adapters, facilitating integration into adapter-based architectures.

State Overview

The function block itself is stateless (purely combinatorial with clocked takeover). The internal flip-flop `E_D_FF` has two states:

- **Q** = **FALSE**: No valid signal (initial or after an invalid value).
- **Q** = **TRUE**: Valid signal is present.

A state diagram for the entire function block is not required, as the behavior is fully described by the event and data flows.

Application Scenarios

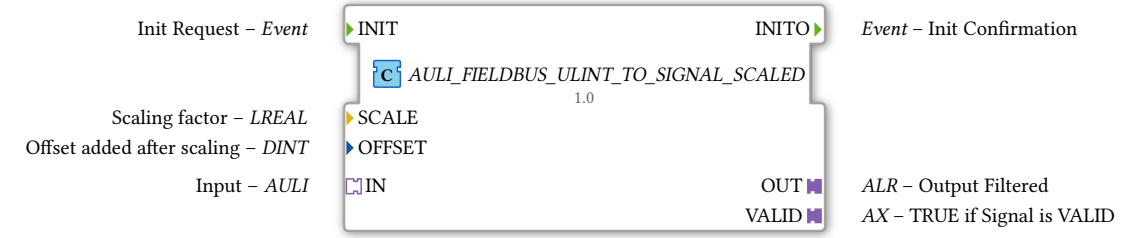
- **Fieldbus Signal Conditioning**: A ULINT value (e.g., counter reading, position value) is received from a fieldbus, checked for validity, and passed on to a controller or visualization system.
- **Quality Indication**: A Boolean signal indicating validity (e.g., "Data valid" / "Data faulty") is provided along with the data value.
- **Safety-Oriented Transmission**: By synchronously receiving the validity signal, errors in the data line can be detected and signaled.

Comparison with Similar Function Blocks

- **Simple Pass-Through Function Block**: A simple `MOVE` or `REPEAT` function block forwards the value without validation. `AULI_FIELDBUS_ULINT_TO_SIGNAL` adds explicit validity checking and signaling.

- **FIELDBUS_ULINT_TO_SIGNAL (Single)**: This core function block already provides the validity signal, but without edge-triggered synchronization. This composite function block enhances signal quality with a flip-flop.
- **Adapter-Based Function Blocks**: Specifically designed for use in 4diac environments that rely on adapter communication; other function blocks with direct ports are less flexible.

Conclusion



AULI_FIELDBUS_ULINT_TO_SIGNAL` is a robust, adapter-based function block for the reliable transmission of a ULINT fieldbus signal with validity indication. The combination of converter and flip-flop ensures synchronized and reliable signal output. Its clear interface structure makes it particularly suitable for modular automation solutions that rely on loosely coupled adapters.

AULI_FIELDBUS_ULINT_TO_SIGNAL_SCALED

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_FIELDBUS_ULINT_TO_SIGNAL_SCALED** is used for the scalable mirroring of an unsigned integer value (ULINT) into a scaled signal value (LREAL), taking validity information into account. It is implemented as a composite block and combines the actual scaling logic with a synchronized valid output. The block is designed for use in fieldbus environments where raw data (e.g., sensor values) must be converted using a linear factor and offset, and the signal's validity must be reliably transmitted.

Interface Structure

Event Inputs

| Name | Type | Comment | |—–|—–|———–| | INIT | EInit | Init Request |

Event Outputs

Name	Type	Comment
INITO	EInit	Init Confirmation

Data Inputs

Name	Type	Initial Value	Comment
SCALE	LREAL	1.0	Scaling Factor
OFFSET	DINT	0	Offset added after scaling

Data Outputs

No explicit data outputs are available on the FB interface – output is provided via the adapters.

Adapter

Socket (Input)

Name	Type	Comment
IN	adapter::types::unidirectional::AULI	Input

Plug (Output)

Name	Type	Comment
OUT	adapter::types::unidirectional::ALR	Filtered Output
VALID	adapter::types::unidirectional::AX	TRUE if Signal is VALID

Functionality

The function block operates in an event-driven manner. After an INIT event (at input `INIT`), the internal scaling block is initialized and acknowledged with `INITO`. The actual processing occurs with each event that arrives via the adapter `IN.E1`:

1. **Data Transfer:** The ULINT value provided by `IN.D1` is forwarded to the internal function block `FIELDBUS_ULINT_TO_SIGNAL_SCALED`.
2. **Scaling:** The internal block applies the scaling factor `SCALE` (LREAL) and the offset `OFFSET` (DINT) to the raw value, generating a scaled LREAL value and a validity signal (`VALID`).
3. **Synchronization:** The validity signal is synchronized via an edge-triggered D flip-flop (`E_D_FF`). The clock edge is provided by the internal block's `CNF` event.
4. **Output:** The scaled value is sent to adapter `OUT` via `OUT.D1` and the associated event `OUT.E1`. The synchronized validity signal is output to adapter `VALID` via `VALID.D1` and the event `VALID.E1`.

The internal scaling block is of the same type as the outer one, meaning that the scaling logic could be recursive. However, in this design, the inner instance contains the actual computational logic. The outer shell adds the synchronization of the validity information and provides the adapter interfaces.

The internal scaling block is of the same type as the outer one, meaning that the scaling logic could be recursive.

Technical Features

- **Adapted Inputs/Outputs:** The module uses adapters exclusively for data transmission. This enables loose coupling in fieldbus and component networks.
- **Validity Synchronization:** The validation information is clocked via a D flip-flop so that it coincides with the output signal value.
- **Scaling Parameters:** `SCALE` and `OFFSET` are directly accessible as input variables and can be changed at runtime. Initial values allow immediate operation without configuration.

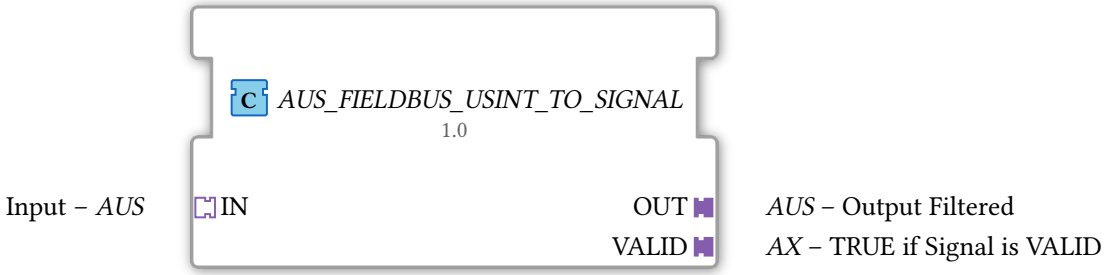
State Overview

The module does not have an explicit state machine. Its behavior is determined by event control:

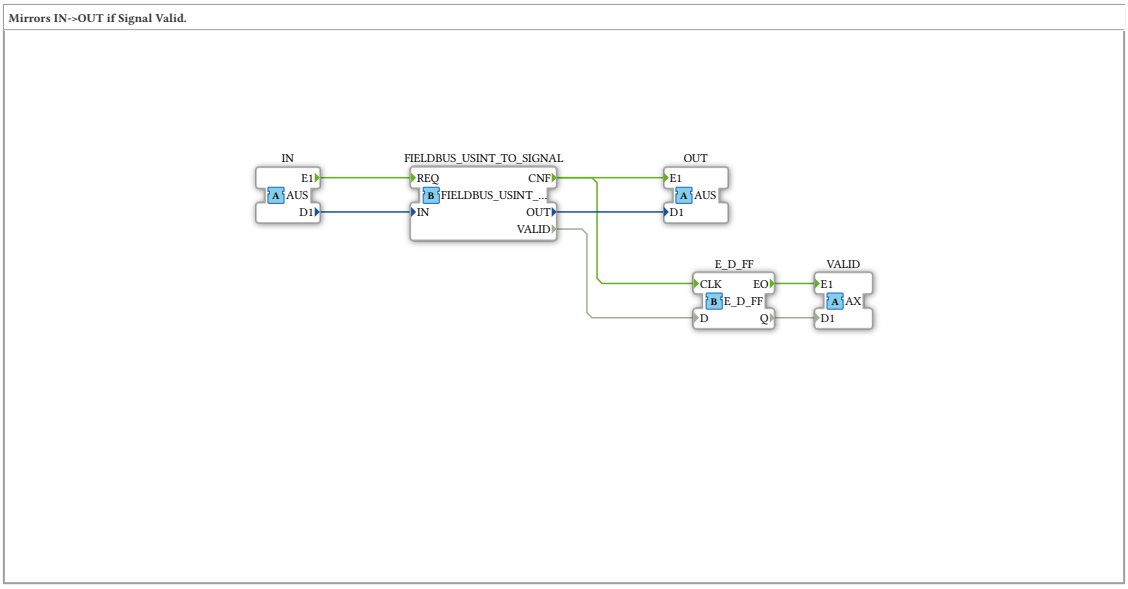
- **Initialized:** After successful `INIT`, the internal scaling block is ready.
- **Ready:** Data processing is triggered upon an event on `IN.E1`. Upon completion, `OUT.E1` and `VALID.E1` are triggered.
- **Error Case:** An erroneous scaling operation (e.g., overflow) is handled by the internal block; the validation signal would then be `FALSE`.

Application Scenarios

- **Fieldbus Sensor Evaluation:** A sensor delivers a raw ULINT value via a bus (e.g., CANopen, PROFIBUS). The block scales the value into a physical unit (e.g., temperature, pressure) and passes it to the controller as LREAL, along with a validation flag.
- **Signal conditioning in agricultural machinery** (as indicated in the copyright notice): Conversion of speed, fill level, or velocity data into standardized signals for a higher-level control system.
- **Quality-assured data transmission:** When the validity of a signal (e.g., sensor error, communication failure) must be explicitly tracked, the synchronized valid output ensures consistent signals.



Comparison with similar function blocks



- **FIELDBUS_ULINT_TO_SIGNAL** (without scaled): A direct pass without scaling – scaling is integrated here.
- **Standard scaling function blocks** (e.g., from IEC 61131-3): These often operate with simple inputs/outputs and without adapters or validity synchronization.
- **Function blocks with integrated validation:** Many fieldbus function blocks output only a single data value. This function block stands out due to its separate, clocked validity output.

Conclusion

The **AULI_FIELDBUS_ULINT_TO_SIGNAL_SCALED** is a specialized composite function block for the scaled conversion of ULINT fieldbus data into LREAL signals with synchronized validity information. Thanks to the use of adapters and the clear separation of scaling and synchronization, it is particularly suitable for modular, safety-critical applications in automation and agricultural technology. Parameterization via `SCALE` and `OFFSET` makes it highly versatile.

AUS_FIELDBUS_USINT_TO_SIGNAL

• — ○ • — ○ • — ○ •

Introduction

The function block `AUS_FIELDBUS_USINT_TO_SIGNAL` is used to pass a USINT signal from a fieldbus adapter, taking a validity check into account. It mirrors the input value to the output if the signal is recognized as valid. An additional adapter outputs the validity status. The internal logic uses a dedicated fieldbus conversion block and an edge-triggered D flip-flop for synchronization.

Interface Structure

Event Inputs

Name	Description
`IN.E1`	Event received via adapter `IN` (socket) that triggers processing.

Event Outputs

Name	Description
`OUT.E1`	Event output via adapter `OUT` (plug) after successful mirroring of the valid signal.
`VALID.E1`	Event output via adapter `VALID` (plug) after updating the validity status.

Data Inputs

Name	Type	Description
`IN.D1`	USINT (implicit)	Input data value that is checked for validity and mirrored.

Data Outputs

Name	Type	Description
`OUT.D1`	(analogous to IN)	Output data value that mirrors the input value if the signal is valid.
`VALID.D1`	BOOL	Validation flag: `TRUE` if the input signal is recognized as valid, otherwise `FALSE`.

Adapter

Name	Type	Direction	Description
IN	adapter::types::unidirectional::AUS	Socket	Receives the raw signal (event + data) from the fieldbus.
OUT	adapter::types::unidirectional::AUS	Plug	Passes the validated signal to downstream components.
VALID	adapter::types::unidirectional::AX	Plug	Provides the validity status (event + BOOL).

Functionality

The function block (FB) reacts to an incoming event IN.E1. This triggers the internal function block FIELDBUS_USINT_TO_SIGNAL, which processes the data value IN.D1 and delivers two results:

- An output value (OUT)
- A validation signal (VALID)

The output value is passed directly to OUT.D1 and acknowledged via OUT.E1. Simultaneously, the validation signal is fed to the data input D of the D flip-flop E_D_FF. The flip-flop is clocked by the same event (via CFN), so the validity status is held stably at Q and output at VALID.D1. Only after the clock pulse is VALID.E1 triggered.

In summary: The output OUT mirrors the input IN, provided the signal is recognized as valid in the fieldbus module. The validity status is stored using edge triggering.

Technical Features

- **Adapter-based communication:** All inputs and outputs are implemented via standardized unidirectional adapters (AUS, AX), which enable a clear separation between event and data paths.
- **Edge-Triggered Validation:** A D flip-flop ensures that the validity state is only updated upon an event (rising edge) – this prevents glitches and asynchronous state transitions.
- **Reused Internal Function Block:** The function block FIELDBUS_USINT_TO_SIGNAL handles the actual fieldbus-specific conversion and validity check; the outer function block serves purely as wrapper and synchronization logic.

State Overview

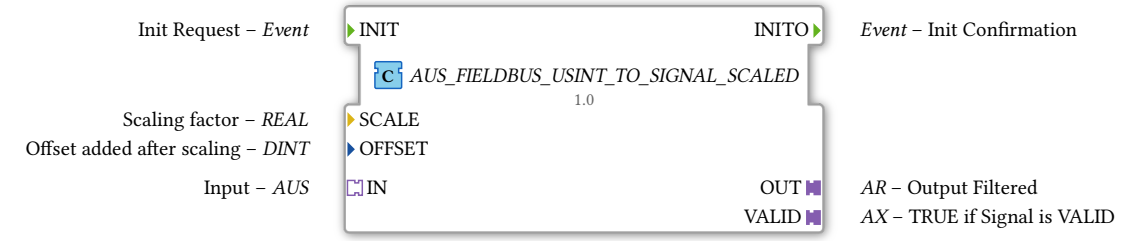
The internal state is defined by the D flip-flop E_D_FF. It has two states:

State	Description
Q = FALSE (Initial)	Output VALID.D1 indicates "invalid". After each event, the current value of VALID (D) is used.
Q = TRUE	Output VALID.D1 indicates "valid". The state remains stable until the next event.

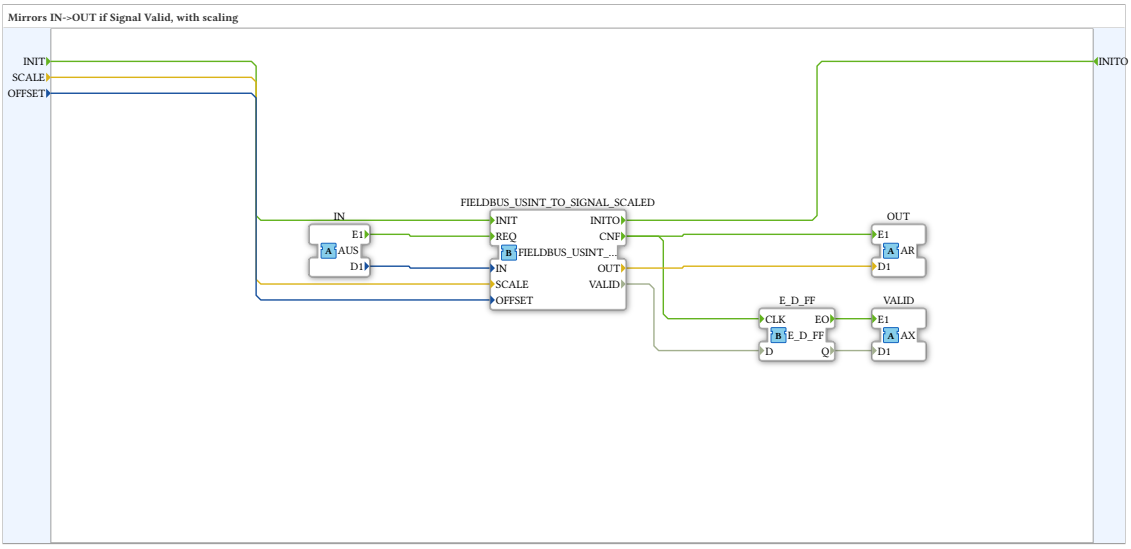
State transitions occur exclusively on each rising edge of the clock signal (event CNF of the fieldbus function block).

Application Scenarios

- **Fieldbus Signal Conditioning:** A sensor sends USINT values via a fieldbus; the function block filters out invalid values and only forwards valid data and a clear validity status.
- **Safety-Oriented Data Transmission:** In control systems that rely on valid signals (e.g., in agricultural technology), this function block (FB) can be used as a simple validation stage.
- **Interface Adaptation:** The function block connects a fieldbus-specific adapter (e.g., CANopen, PROFIBUS) to a standardized logic adapter that only triggers events when the data is valid.



Comparison with Similar Function Blocks



- **Simple Mirror Function Blocks** (e.g., MOVE or AUS_MIRROR): These pass the signal without validation. This FB additionally offers validation logic and a separate validity output.
- **Fieldbus Converters Without Memory:** Some function blocks output the validity signal directly and without a clock signal. Using a flip-flop here avoids metastable states and ensures deterministic output.

Conclusion

The `AUS_FIELDBUS_USINT_TO_SIGNAL` is a useful function block for the clean, validated forwarding of USINT signals from fieldbus systems. The combination of a specialized fieldbus module and an edge-triggered flip-flop ensures reliable separation of valid and invalid data. The adapter-based interface facilitates integration into modular control architectures.

AUS_FIELDBUS_USINT_TO_SIGNAL_SCALED

• – ○ • – ○ • – ○ •

The function block AUS_FIELDBUS_USINT_TO_SIGNAL_SCALED mirrors an incoming fieldbus signal value (USINT) to the output, provided the signal is recognized as valid. The input value is multiplied by a configurable scaling factor, and an offset is added. The function block is implemented as a composite block and consists of a sub-function block for scaling and an edge-triggered D flip-flop for synchronizing the validity signal. It is typically used in fieldbus signal processing to convert raw USINT values into physical quantities and pass on the data validity information.

- **INIT** (EInit): Initialization request. Passed through to the internal sub-function block.
- **INITO** (EInit): Initialization confirmation. This is handled by the internal sub-FB.
- **SCALE** (REAL): Scaling factor that is multiplied by the input value. Default value: 1.0.
- **OFFSET** (DINT): Offset value that is added to the scaled value after multiplication. Default value: 0.

No direct data outputs – output is exclusively via the adapters.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- **IN** (Socket, type `adapter::types::unidirectional::AUS`): Input adapter for the raw signal. Provides USINT data via `D1` and an event via `E1`.
- **VALID** (Plug, type `adapter::types::unidirectional::AX`): Output adapter for the validity signal. Outputs a Boolean value (TRUE = valid) via `D1` and an event via `E1`.

Functionality

1. **Initialization**: The event `INIT` is forwarded directly to the internal sub-FB `FIELDBUS_USINT_TO_SIGNAL_SCALED`. Its `INITO` is passed through to the external `INITO` output.
2. **Data Processing**: As soon as an event arrives at `IN.E1`, it triggers the execution of the internal sub-FB via its `REQ` input. The sub-FB processes the current value of `IN.D1` (USINT) using `SCALE` and `OFFSET` and calculates a scaled output value (REAL) and a validity flag (BOOL).
3. **Result Output**: After the calculation, the sub-FB generates a `CNF` event. This triggers:

- The output of the scaled value via `OUT.D1` and the event `OUT.E1`.
- The clock input (`CLK`) of the D flip-flop `E_D_FF`.

1. **Validation Signal**: The validation flag of the sub-FB is set to the data input (`D`) of the flip-flop. With each clock event, the flip-flop updates the current `D` value to its output `Q`. The event `E_D_FF.EO` then triggers the output of the validity signal via `VALID.D1` and `VALID.E1`.
2. **Interaction**: This ensures that the validity signal is updated only after scaling is complete and in a strictly timed manner with the output scaled value.

- **Composite Structure**: The function block consists of a specialized sub-function block (`FIELDBUS_USINT_TO_SIGNAL_SCALED`) for scaling and a standardized D flip-flop (`E_D_FF`) from the IEC 61499 event library.
- **Hidden Connections**: Some internal connections (e.g., for `INIT`, `SCALE`, `OFFSET`) are marked as invisible (`Visible="false"`) to improve clarity in the graphical representation.
- **Data Types**: The input value is assumed to be USINT (0…255), and the output is scaled to REAL. The offset is declared as DINT.
- **Edge-Triggered Synchronization**: The D flip-flop ensures debounced propagation of the validity signal, so it is only updated during a new processing cycle.

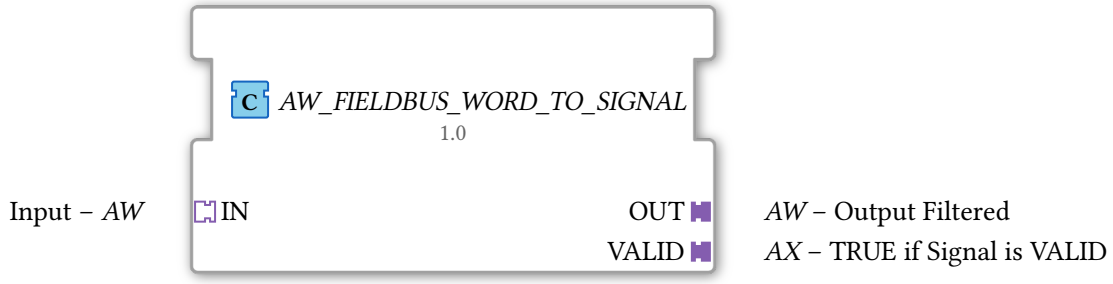
The function block (FB) does not have its own explicit states. The state logic is derived from the following sub-components:

- **Sub-FB `FIELDBUS_USINT_TO_SIGNAL_SCALED`**: Performs a flow-oriented calculation without state memory; it responds to each `REQ` event with a `CNF`.
- **D-Flipflop `E_D_FF`**: Has two states (Q = 0 or 1). On each positive clock cycle (CLK), Q = D is set. The state is retained until the next clock cycle.
- **Fieldbus Sensor Evaluation**: A sensor delivers a USINT value via fieldbus (e.g., 0–100% fill level or 0–255 pressure values). The function block scales this value to a physical unit (e.g., meters, bar) and outputs it along with a validity flag.
- **Signal conditioning in agricultural technology**: Agricultural machinery often requires scaled signals where the validity of the data (e.g., after a communication failure) must be explicitly indicated.
- **Initialization cascades**: The passed-through `INIT` output enables the initialization of downstream function blocks that also rely on this signal.
- **`AUS_FIELDBUS_USINT_TO_SIGNAL`** (without scaling): Provides only direct transmission of the USINT value without scaling or offset.

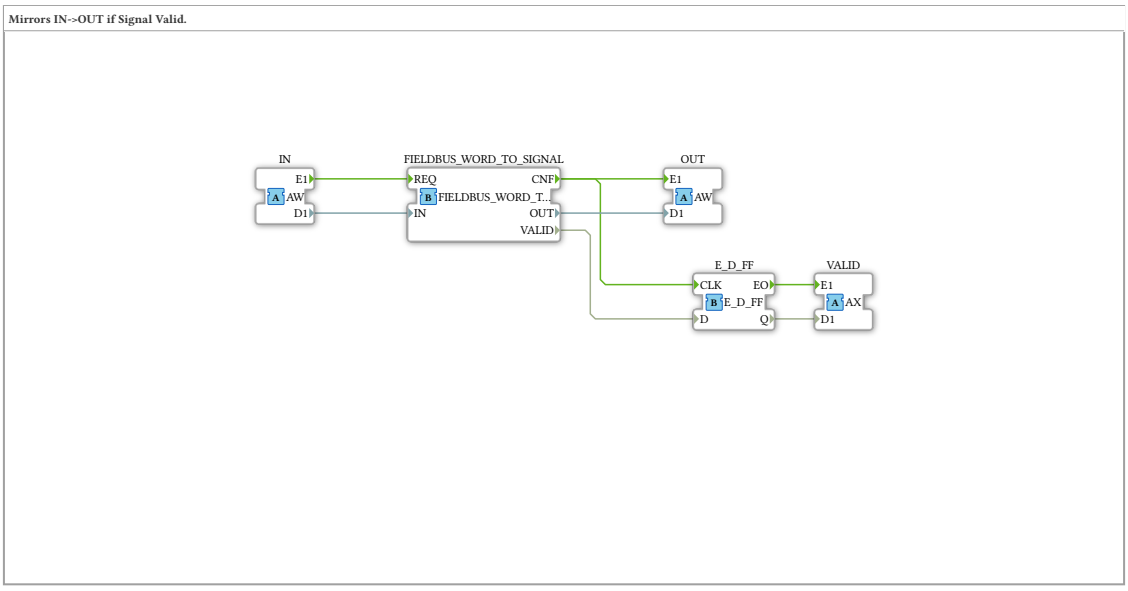
- **`AUS_FIELDBUS_USINT_TO_SIGNAL_SCALED` with separate validation toggle**: An alternative design could forward the validity signal asynchronously (without a flip-flop), but this could lead to potential jitter.
- **`AUS_FIELDBUS_USINT_TO_SIGNAL_SCALED` with integrated state machine**: Instead of a flip-flop, a custom state logic could manage the validity signal; however, this block uses proven standard components.

The `AUS_FIELDBUS_USINT_TO_SIGNAL_SCALED` function block offers a robust and maintainable solution for scaling USINT fieldbus signals and reliably forwarding the validity status. Its composite structure and the use of a D flip-flop ensure a clean temporal separation between data processing and output. It is particularly useful in systems with cycle-based data processing and explicit signal validity.

Technical Features



State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

AW_FIELDBUS_WORD_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AW_FIELDBUS_WORD_TO_SIGNAL** acts as a filter for fieldbus words. It mirrors the incoming signal (via the **IN** adapter) to the output (**OUT** adapter) if the signal is recognized as valid. Validity is indicated via a separate output adapter (**VALID**). This block is typically used in fieldbus environments to ensure that only valid data values are forwarded to subsequent components.

Interface Structure

Event Inputs

No separate event inputs are available. Event control is handled implicitly via the adapters used (see section **Adapters**).

Event Outputs

No separate event outputs available. Event output is implicit via the adapters.

Data Inputs

No separate data inputs available. Data is transferred via the connected adapters.

Data Outputs

No separate data outputs available. Data output is via the connected adapters.

Adapters

Name	Type	Description
IN	`adapter::types::unidirectional::AW` (Socket)	Input of the word to be filtered.
OUT	`adapter::types::unidirectional::AW` (Plug)	Output of the filtered word (only with a valid signal).
VALID	`adapter::types::unidirectional::AX` (Plug)	Outputs the validity status of the output signal (`TRUE` = valid).

Functionality

The function block consists internally of two sub-function blocks: `FIELDBUS_WORD_TO_SIGNAL` and `E_D_FF` (D flip-flop).

- An incoming event on `IN.E1` triggers the processing of the current word via `FIELDBUS_WORD_TO_SIGNAL.REQ`.
- The sub-block `FIELDBUS_WORD_TO_SIGNAL` checks the validity of the word and outputs a `CNF` event upon completion.
- This `CNF` event causes:
- The filtered word is passed to the output adapter via `OUT.D1` and output via `OUT.E1`.
- Simultaneously, the D flip-flop (`E_D_FF`) is clocked: The current validity status (`VALID` signal from `FIELDBUS_WORD_TO_SIGNAL`) is adopted.
- The output of the flip-flop (`Q`) is passed to the **VALID** adapter via `VALID.D1` and the event `VALID.E1` (triggered by `E_D_FF.EO`).

Thus, a valid word is only output if the internal check of the incoming signal is successful. The validity status is retained until the next processing cycle.

Technical Features

- The function block is based entirely on adapters and does not have a separate top-level event/data interface.
- The internal implementation uses a standardized fieldbus processing block (`FIELDBUS_WORD_TO_SIGNAL`) and a D flip-flop, which allows for a clear separation of the data path and status logic.
- The implementation is licensed under the **Eclipse Public License 2.0**.

State Overview

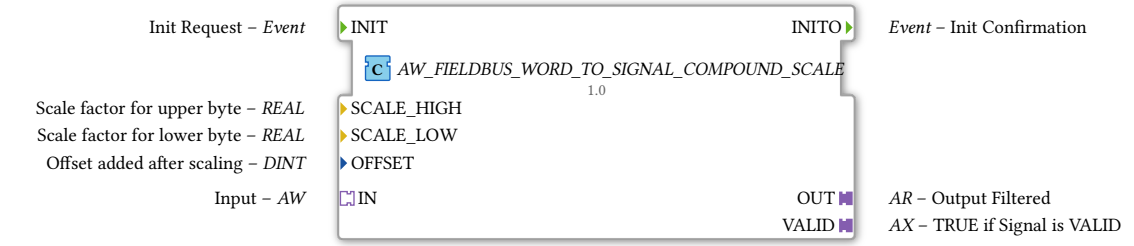
The function block itself does not have an explicit state machine. The internal state is represented by the D flip-flop:

State	Meaning
`VALID = FALSE`	The output value is invalid (old data or initial state).

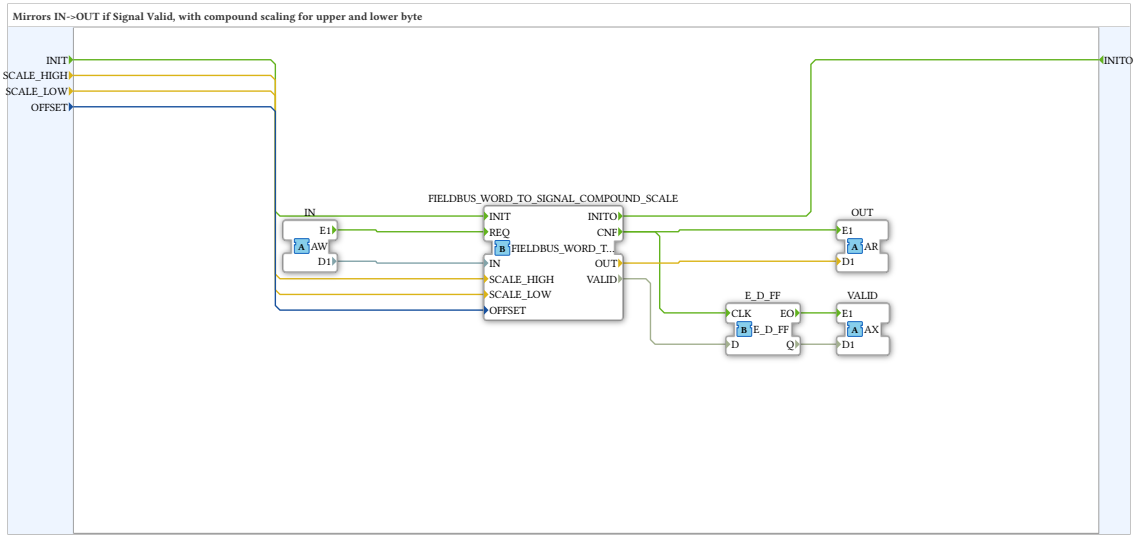
VALID = TRUE`	The output value is valid and was recognized as valid during the last processing cycle.

Application Scenarios

- **Fieldbus Data Filtering**: In automation systems where only valid measured values or control commands should be passed on to subsequent logic.
- **Signal Validation**: Used in safety-critical paths where invalid data (e.g., due to transmission errors) must not be passed on without verification.
- **Adapter-Based Interfaces**: Suitable for modular systems that communicate via standardized adapters (e.g., logiBUS environment).



Comparison with Similar Components



- Simple **Word-to-Signal** components without validation pass the input signal directly, regardless of its validity.
- In contrast, the **AW_FIELDBUS_WORD_TO_SIGNAL** provides explicit validity feedback and suppresses invalid values.
- Other filter blocks might include additional configuration options (e.g., thresholds, time windows), while this block is reduced to a simple "valid/invalid" decision.

Conclusion

The AW_FIELDBUS_WORD_TO_SIGNAL is a specialized filter block for fieldbus word data. It combines simple passthrough with a validity check and provides the result via separate adapters. By using standard sub-blocks and flip-flop logic, it is robust, traceable, and easily integrated into adapter-based architectures.

AW_FIELDBUS_WORD_TO_SIGNAL_COMPOUND_SCALE

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_FIELDBUS_WORD_TO_SIGNAL_COMPOUND_SCALE** converts a 16-bit word received via a fieldbus into a scaled signal value. The word is multiplied byte by byte by different

scaling factors, an offset is added, and the result is output as a normalized signal. Additionally, a validity signal is provided to indicate whether the incoming value is valid.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initialization Request

Event Outputs

Event	Type	Description
INITO	EInit	Initial Confirmation

Data Inputs

Name	Type	Initial Value	Description
SCALE_HIGH	REAL	0.256	Scaling factor for the upper byte
SCALE_LOW	REAL	0.001	Scaling factor for the lower byte
OFFSET	DINT	0	Additive offset after scaling

Data Outputs

The FB does not have its own data outputs. The output data is provided via the adapters listed below.

Adapters

Adapter	Type (Direction)	Description
IN	`adapter::types::unidirectional::AW`	Incoming 16-bit word
OUT	`adapter::types::unidirectional::AR`	Output signal (scaled)
VALID	`adapter::types::unidirectional::AX`	Validation signal (TRUE = valid)

Functionality

After successful initialization (INIT event → INITO), the FB begins responding to incoming data via the **IN** adapter. As soon as the event **IN.E1** is received, the 16-bit word currently present at **IN.D1** is processed:

1. **Byte-wise scaling**

The upper byte (bits 15…8) is multiplied by `SCALE_HIGH`, the lower byte (bits 7…0) by `SCALE_LOW`.

1. **Offset addition**

The sum of both scaled byte values is incremented by the configured `OFFSET`.

1. **Output**

The result is passed to the **OUT** adapter (event **OUT.E1** with data **OUT.D1**).

1. **Validity Handling**

An internal flip-flop (`E_D_FF`) is clocked in parallel. The validity status (signal **VALID**) is taken from the internal **VALID** output of the scaling module and is retained until the next valid signal.

The internal flip-flop ensures that the validity signal is only updated upon the next input event. This guarantees a stable signal state at the output.

Technical Features

- **Compound Scaling**

Separate scaling of the upper and lower bytes allows the processing of fieldbus signals encoded in two differently scaled byte halves (e.g., temperature or pressure values with range and resolution).

- **Integrated Flip-Flop**

The validity output is implemented using an edge-triggered D flip-flop. This ensures that the validity signal is only updated upon a new input event, guaranteeing a stable output.

- **Configurable Parameters**

Scaling and offset are freely adjustable via the data inputs and can be changed at runtime.

- **Initialization**

Before first use, the function block (FB) must be initialized with the INIT event. This resets the internal states.

State Overview

The FB has an internal state represented by the flip-flop `E_D_FF`:

State	Description
UNVALID	No valid signal. The **VALID** output returns FALSE.
VALID	Valid signal detected. The **VALID** output displays TRUE.

The state changes with each new input event (i.e., with each word transmission) according to the validity information of the internal scaling module.

Application Scenarios

- **Analog Value Acquisition via Fieldbus**

A fieldbus device sends a 16-bit raw value, where the upper byte represents a coarse value (e.g., 0…255) and the lower byte a fine value (e.g., 0…1000). The physical measured value is calculated using `SCALE_HIGH` and `SCALE_LOW`.

- **Process Data Preparation**

A controller requires several scaled signals whose validity must be monitored. The function block combines scaling and validation in a single block.

- **Gateway Function**

This function block can be used as a converter between a fieldbus protocol (word-based) and an internal signal protocol (with a validity flag).

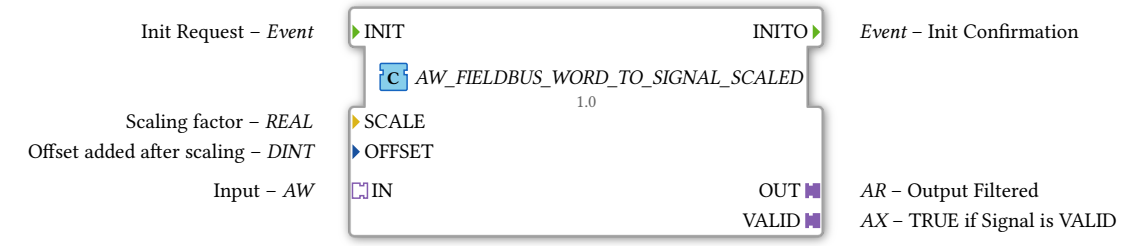
Comparison with Similar Function Blocks

- **FIELDBUS_WORD_TO_SIGNAL** (simple)

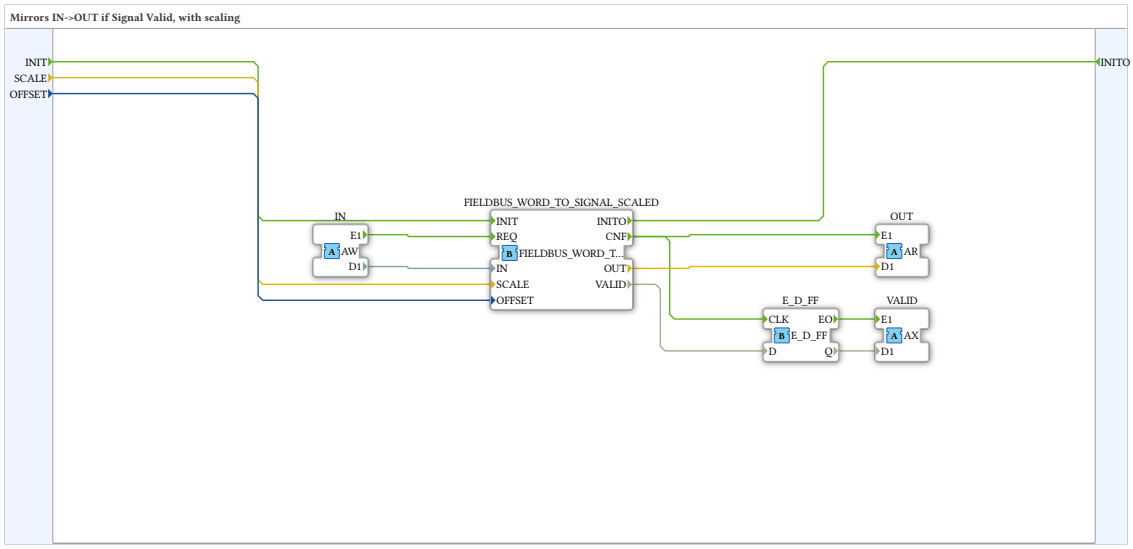
This function block scales the entire 16-bit word by a single factor. The compound function block, on the other hand, allows byte-by-byte scaling.

- **SCALE** (general)

A universal scaling function block without a fieldbus interface. This function block integrates the fieldbus adapters and validity management.



- **BADAPTER_STATUS**



Returns only a status regarding validity, without scaling. The compound function block combines both functions.

Conclusion

The **AW_FIELDBUS_WORD_TO_SIGNAL_COMPOUND_SCALE** is a specialized function block for processing fieldbus word signals with different scaling for the upper and lower bytes. Its integrated validity management via a flip-flop makes it particularly suitable for safety-critical or application-specific signal processing in automation technology. Thanks to its configurable parameters and clearly structured interface, it can be easily integrated into higher-level control logic.

AW_FIELDBUS_WORD_TO_SIGNAL_SCALED

• – ○ • – ○ • – ○ •

Introduction

The function block `AW_FIELDBUS_WORD_TO_SIGNAL_SCALED` is used to convert an incoming fieldbus word (16-bit) to a physical output value, taking into account a scaling factor and offsets. Additionally, the validity of the signal is monitored and stored via a dedicated output. The block encapsulates the typical processing chain from digital transmission to the standardized analog or signal value.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Initialization request (e.g., reset of internal logic)

Event Outputs

Event	Type	Comment
INITO	EInit	Confirmation of successful initialization

Data Inputs

Name	Type	Default	Comment
SCALE	REAL	REAL#1.0	Scaling Factor
OFFSET	DINT	DINT#0	Integer Offset (after scaling)

Data Outputs

This function block does not have separate data outputs. The output values are provided via the adapters.

Adapters

Adapter	Direction	Type (unidirectional)	Comment
IN	Socket	AW	Input signal (fieldbus word)
OUT	Plug	AR	Processed and scaled output signal
VALID	Plug	AX	Boolean value: TRUE if the signal is valid

Functionality

The function block operates with an internal sub-FB `FIELDBUS_WORD_TO_SIGNAL_SCALED` and an edge-triggered D flip-flop (`E_D_FF`).

1. **Initialization:** An INIT event is forwarded to the sub-FB. Upon its completion, INITO is output.
2. **Data Processing:** An incoming event on `IN.E1` triggers the sub-FB (`REQ`). This reads the current word from `IN.D1`, scales it by the factor `SCALE`, adds `OFFSET`, and outputs the result to the internal output `OUT`. Simultaneously, a validity flag (`VALID`) is generated.
3. **Passing and Storage:** After successful processing (`CNF`), the output event is sent to `OUT.E1`, and the validity flag is transferred to the D flip-flop (clock edge). The stored value is stably available at the validation output (`VALID.D1`).
4. **Signal Validity:** If the incoming word is recognized as invalid (e.g., due to error bits or plausibility checks in the sub-FB), the sub-FB sets the `VALID` signal to FALSE. The flip-flop freezes this state until the next valid cycle occurs.

Technical Features

- **Scaling with Offset:** Processing occurs in the sequence `(Wort * SCALE) + OFFSET`. This allows for linear conversions, e.g., raw values to physical units.
- **Validity Storage:** The D flip-flop decouples the dynamic validity from the output signal. A signal marked as invalid remains invalid until a valid cycle is completed – this prevents momentary misinterpretations.
- **Adapter-based interface:** The function block uses unidirectional adapters of a type system designed for fieldbus communication (`AW`, `AR`, `AX`). The exact data types of the adapters (e.g., Word, Real, Boolean) are provided by the adapter definitions.

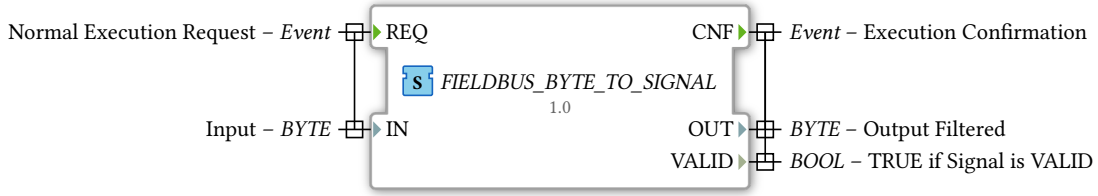
State overview

The function block itself does not have an explicit state machine in the XML. Its behavior results from the sequence of its internal elements:

- **Waiting for INIT:** No operation occurs before INIT is executed.
- **Operation:** After INIT, the function block listens for events at the `IN` socket. Each incoming event triggers a processing step.
- **Output:** The output event `OUT.E1` is sent immediately after the internal scaling is complete. The validity signal `VALID` is updated simultaneously.

Application Scenarios

- **Fieldbus Analog Value Processing:** A 16-bit signal transmitted from a fieldbus (e.g., 0…65535) is converted into a physical range such as 0…10V or 4…20mA using scaling.
- **Sensor Value with Validity Flag:** Sensors that deliver data via a fieldbus protocol can also send a validity status (e.g., “Data valid” bit). This is transmitted via the `VALID` output.
- **Safety-Oriented Transmission:** If the fieldbus word contains an error bit, the sub-FB `VALID` can set it to FALSE, causing downstream logic to recognize the signal as invalid.



Comparison with Similar Function Blocks

Unlike simple word-to-signal converters (e.g., `FIELDBUS_WORD_TO_SIGNAL`), `AW_FIELDBUS_WORD_TO_SIGNAL_SCALED` features integrated validity storage and separate adapters for output and validity. This reduces wiring in the application and simplifies the handling of temporary errors. Function blocks without offset/scaling logic would require external computation blocks.

Conclusion

AW_FIELDBUS_WORD_TO_SIGNAL_SCALED` is a compact, functional function block for conditioning fieldbus signals. It combines scaling, offset, and validity monitoring in a reusable module. The adapter-based interface and stored validity make it particularly suitable for industrial controls where signal quality and simple parameterization are paramount.

FIELDBUS_BYTE_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FIELDBUS_BYTE_TO_SIGNAL** is used for the simple validation of a BYTE signal from a fieldbus. It only passes the input value unchanged to the output if it lies within a defined valid range. The result of the validation is signaled via a separate Boolean output.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Normal execution trigger; processes the current value at the IN input.

Event Outputs

Event	Data Type	Comment
CNF	Event	Confirmation of execution; the outputs OUT and VALID have been updated.

Data Inputs

Name	Data Type	Initial Value	Comment
IN	BYTE	NOT_AVAILABLE_B	Input signal as a byte value.

Data Outputs

Name	Data Type	Initial Value	Comment
OUT	BYTE	16#00	Filtered output value; 0 if signal is invalid.
VALID	BOOL	FALSE	TRUE if the input signal is recognized as valid.

Adapter

None.

Functionality

The block checks the current BYTE input value **IN** against a predefined constant **VALID_SIGNAL_B** (from the import `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL`) on each REQ event.

The logic in the algorithm is:

```
IF (BYTE_TO_USINT(IN) <= BYTE_TO_USINT(VALID_SIGNAL_B)) THEN
OUT := IN;
VALID := TRUE;
ELSE
OUT := BYTE#0;
```

```
VALID := FALSE;
END_IF;
```

Technical Features

- The filter is based on **two external constants** from the `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL` library:
- `NOT_AVAILABLE_B` – defines the value for "Signal not available" (initial value of IN).
- `VALID_SIGNAL_B` – defines the upper limit for valid signals.
- The conversion `BYTE_TO_USINT` ensures that the values can be compared as numbers 0…255.
- The block is implemented as a **SimpleFB** with only one state (**REQ**) – not a state machine with multiple steps.
- License: Eclipse Public License 2.0.

State Overview

The function block has exactly one execution state:

State	Action	Output Event
REQ	Executes the **REQ** algorithm (filter logic)	CNF

There are no further wait or initialization states.

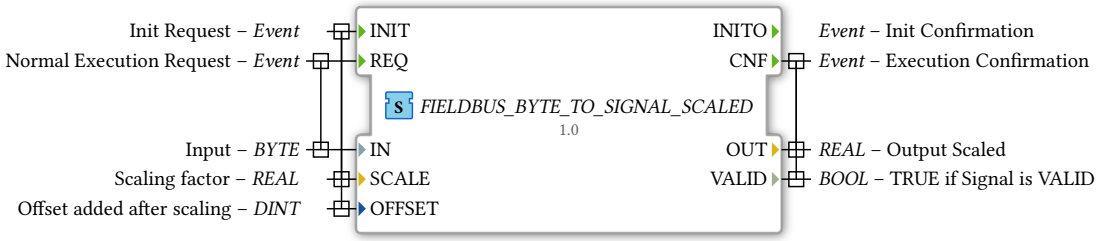
Application Scenarios

- **Fieldbus Signal Validation**: A sensor delivers a BYTE value that is only physically meaningful within a specific range (e.g., 0…100). This block prevents erroneous or implausible values from entering the control logic.
- **Safety-Related Systems**: Can be used as a simple range checker for analog or digital fieldbus signals in automation technology (e.g., agriculture, machine control).
- **Signal Switch**: Separation of valid and invalid data streams – e.g., for controlling an AND filter or for error detection.

Comparison with Similar Blocks

- Unlike simple **threshold switches** (e.g., `HYSTERESIS` or `LIMIT_ALARM`), this block operates purely at the BYTE level and outputs the original value directly as long as it is within the valid range – no hysteresis or alarm function.
- Compared to a **multiplexer** (`MUX`), it does not require a second control signal but makes the decision automatically based on the input value.
- Similar blocks in IEC 61499 often exist as `RANGE_CHECK` or `VALIDATE`, but are usually designed for generic data types. This block is specifically tailored to the BYTE format commonly used in fieldbuses.
-

Conclusion



FIELDBUS_BYTE_TO_SIGNAL is a compact, specialized filter block for validating BYTE signals. It requires no boundary configuration, as these are defined via the imported constants in the library. Due to the clear separation of the data output and the validity signal, it is ideally suited for processing fieldbus data in safety-critical or fault-tolerant automation systems.

FIELDBUS_BYTE_TO_SIGNAL_SCALED

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FIELDBUS_BYTE_TO_SIGNAL_SCALED** converts an incoming byte value into a scaled real value. It checks whether the incoming signal is valid. If so, the input value is multiplied by a scaling factor and an offset is added. Otherwise, the output is set to zero and the validity signal is reset. This block is designed for use in fieldbus systems where sensor or actuator data is transmitted as bytes and needs to be linearized or normalized.

Interface Structure

Event Inputs

Event	Type	Description	Data Carried
`INIT`	EInit	Initialization request; sets scaling and offset	`SCALE`, `OFFSET`
`REQ`	Event	Normal processing request; evaluates input `IN`	`IN`

Event Outputs

Event	Type	Description	Accompanying Data
`INITO`	EInit	Initialization Acknowledgement	–
`CNF`	Event	Confirmation of processing; provides scaled value and validity	`OUT`, `VALID`

Data Inputs

Name	Data Type	Initial Value	Description
`IN`	BYTE	`NOT_AVAILABLE_B`	Raw fieldbus value (byte)
`SCALE`	REAL	`1.0`	Scaling factor (multiplier)
`OFFSET`	DINT	`0`	Additive Offset (after scaling)

Data Outputs

Name	Data Type	Initial Value	Description
`OUT`	REAL	`0.0`	Scaled Output Value
`VALID`	BOOL	`FALSE`	`TRUE`, if the incoming byte value was deemed valid

Adapter

None.

Functionality

The function block is controlled by two events:

1. **Initialization (`INIT`)**

Upon arrival of INIT, the parameters SCALE and OFFSET are accepted. The associated algorithm (INIT) does not perform any further calculations. After successful initialization, the event INITO is sent.

1. **Processing (REQ)**

Upon arrival of REQ, the value of IN is compared to a fixed threshold value VALID_SIGNAL_B. This threshold is obtained from the imported package eclipse4diac::signalprocessing::FIELDBUS_SIGNAL.

- **Signal valid:** If IN <= VALID_SIGNAL_B is valid, the output value is calculated according to the formula

OUT := IN * SCALE + OFFSET`
and VALID is set to TRUE.

- **Signal invalid:** Otherwise, OUT is set to 0.0 and VALID is set to FALSE.

The event CNF is then sent with the current values of OUT and VALID.

The initial value of IN is NOT_AVAILABLE_B – another imported constant value that indicates an unavailable signal. Therefore, the first time REQ is called (without a previous valid input), it always produces an invalid output.

Technical Features

- The constants NOT_AVAILABLE_B and VALID_SIGNAL_B are imported from a separate library package and are not defined locally. This ensures they are consistent across the entire project.
- Scaling is linear: multiplication by SCALE and addition by OFFSET. The offset is converted from type DINT to REAL before being converted to REAL.
- The input IN is first converted from BYTE to USINT (unsigned short integer) to obtain an integer range of 0…255.
- The block has an explicit initialization mode (INIT) that allows the scaling and offset to be reset at runtime.

State Overview

The function block has two simple states, each activated by the corresponding event:

State	Triggering Event	Executable Algorithm	Outgoing Events
INIT	INIT	INIT (empty)	INITO
REQ	REQ	REQ (validation check + scaling)	CNF

There are no automatic state transitions; Each state is addressed exclusively through its corresponding event.

Application Scenarios

- **Exchange of analog sensor data via fieldbuses:**

An 8-bit sensor value (e.g., temperature 0…255) is to be converted into physical units (e.g., °C). The characteristic curve is adjusted via SCALE and OFFSET.

- **Error detection during data transmission:**

If the fieldbus defines certain byte values as invalid (e.g., 0xFF for “sensor error”), the block detects these using the threshold VALID_SIGNAL_B and reports them via VALID = FALSE.

- **Initializing Configuration Parameters:**

Before the first processing, the desired scaling factor and offset can be set using INIT.

Comparison with Similar Blocks

- **FIELDBUS_BYTE_TO_SIGNAL** (without scaling):

This block outputs the byte value directly as REAL, without multiplication or addition. It is suitable for signals that are already in the correct unit.

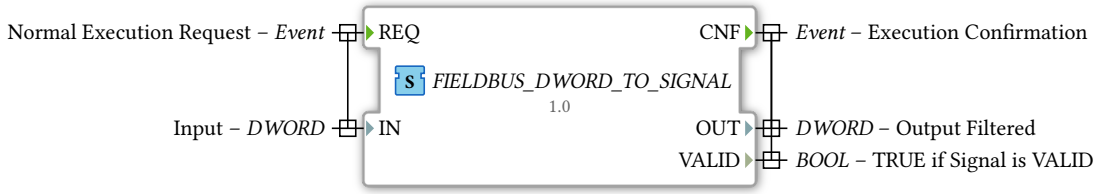
- **FIELDBUS_BYTE_TO_SIGNAL_SCALED** (existing block):

Additionally offers linear scaling and an offset. The user can flexibly adjust the conversion without changing the algorithm.

- **FIELDBUS_WORD_TO_SIGNAL_SCALED**:

Analog block for 16-bit values (WORD) with identical scaling logic, but a different input data type.

Conclusion



The function block `FIELDBUS_BYTE_TO_SIGNAL_SCALED` is a practical tool for processing fieldbus signals in byte format. It combines simple validity checking with freely configurable linear scaling. Thanks to the use of imported constants, it can be integrated into standardized signal processing pipelines. The clear separation of initialization and operation, along with the two event interfaces, makes it a robust and easy-to-understand building block for industrial automation solutions.

]

FIELDBUS_DWORD_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FIELDBUS_DWORD_TO_SIGNAL` mirrors and validates a DWORD input signal. If the input value is valid, it is passed unchanged to the output, and the `VALID` signal is set. Otherwise, the block returns a zero value, indicating invalidity.

Interface Structure

Event Inputs

Event	Comment
REQ	Normal execution trigger; processes the current value of `IN`.

Event Outputs

Event	Comment
CNF	Execution confirmation; sent after calculation.

Data Inputs

Variable	Type	Initial Value	Comment
IN	DWORD	`NOT_AVAILABLE_DWM`	Input signal

Data Outputs

Variable	Type	Initial Value	Comment
OUT	DWORD	`16#00000000`	Filtered output value
VALID	BOOL	`FALSE`	`TRUE`, if the signal is valid

Adapter

None.

Functionality

The function block is activated by an event at REQ. The associated algorithm compares the input value IN (as an unsigned integer) with a predefined threshold VALID_SIGNAL_DW:

- If DWORD_TO_UDINT(IN) <= DWORD_TO_UDINT(VALID_SIGNAL_DW), the signal is considered **valid**:
- OUT receives the value of IN.
- VALID is set to TRUE.
- Otherwise (signal invalid):
- OUT is set to DWORD#0.
- VALID is set to FALSE.

After the calculation is complete, the output event CNF is sent.

Technical Features

- The limit value VALID_SIGNAL_DW comes from the imported package eclipse4diac::signalprocessing::FIELDBUS_SIGNAL. It defines the maximum permissible value for a valid signal.
- The initial value of the input IN is NOT_AVAILABLE_DWM (also imported), so the function block already assumes an invalid state at startup.
- Converting DWORD to UDINT enables simple numerical comparison (≤) without sign issues.
- The function block is implemented as a **SimpleFB** with a single ECA state, REQ.

State Overview

State	Action	Output Event
REQ	Execute REQ Algorithm	CNF

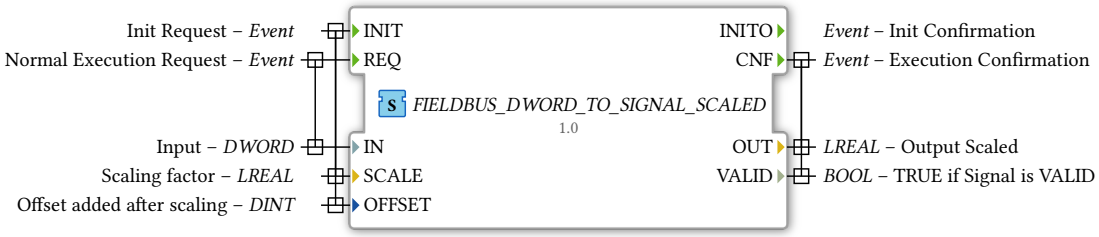
There is only one state; after its processing, the function block returns to the IDLE state (implicitly).

Application Scenarios

- **Fieldbus Signal Processing**: A DWORD value from a fieldbus (e.g., CANopen, Profibus) is validated before being used in the controller.
- **Data Validation**: This function block can be used as a filter to detect invalid or erroneous telegrams and replace them with a defined zero value.
- **Safety-Critical Systems**: The clear separation of valid and invalid signals allows for monitoring and further processing of signal quality.

Comparison with Similar Function Blocks

- A simple **MOVE** function block would pass the value through without validation; FIELDBUS_DWORD_TO_SIGNAL adds the validation logic.
- Function blocks like FIELDBUS_SIGNAL_TO_DWORD (if available) perform the opposite conversion – here, a DWORD signal is converted into a validated signal with a validity flag.
- This function block is specialized for DWORD values; corresponding variants for other data types (e.g., WORD, SINT) would be conceivable.



Conclusion

FIELDBUS_DWORD_TO_SIGNAL` is a compact yet essential function block for robust fieldbus connectivity. It combines signal transmission with simple validity checking and provides the validity as a separate Boolean signal. This allows downstream functions to quickly react to valid data or initiate error handling. The use of imported constants ensures a consistent definition of the validity threshold across multiple functions.

FIELDBUS_DWORD_TO_SIGNAL_SCALED

• – ◦ • – ◦ • – ◦ •

The function block **FIELDBUS_DWORD_TO_SIGNAL_SCALED** converts a fieldbus DWORD signal into a scaled LREAL value. It checks the validity of the input signal against a predefined range and, if the signal is valid, calculates the output value by multiplying it by a scaling factor and adding an offset. If the signal is invalid, the output is set to 0 and the validity flag is set to FALSE.

Event	Type	Description	
INIT	EInit	Initialization request; passes scaling parameters	
REQ	Event	Normal execution request for processing the input	
Event	Type	Description	
–––––	––	–––––––	
INITO	EInit	Initialization Acknowledgement	
CNF	Event	Execution Acknowledgement; returns scaled output and validity flag	
Name	Type	Initial Value	Description
————	———	—————————	———————
IN	DWORD	NOT_AVAILABLE_DWM	Input value from the fieldbus
SCALE	LREAL	LREAL#1.0	Scaling factor (multiplier)
OFFSET	DINT	DINT#0	Offset added after scaling
Name	Type	Initial Value	Description
———	———	———————	———————
OUT	LREAL	LREAL#0.0	Scaled output value
VALID	BOOL	FALSE	TRUE if the input signal is valid

Adapters

No adapters available.

Adapter

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

The function block has two states: **INIT** and **REQ**.

- **INIT state**: Triggered by the INIT event. The associated algorithm is empty, meaning no further actions are performed. The INITO output confirms the completion of the initialization.
- **REQ state**: Triggered by the REQ event. The REQ algorithm performs the following steps:

1. Checks whether the input value IN, interpreted as a UDINT, is less than or equal to the constant `VALID_SIGNAL_DW`.
2. If this condition is met, the signal is considered valid:

- `OUT` is calculated as: `UDINT_TO_LREAL(DWORD_TO_UDINT(IN)) * SCALE + DINT_TO_LREAL(OFFSET)`
- `VALID` is set to `TRUE`.

1. Otherwise (signal invalid):

- `OUT` is set to `0.0`.
- `VALID` is set to `FALSE`.

1. The CNF event is then triggered, providing the results (OUT, VALID).

The constants `NOT_AVAILABLE_DWM` and `VALID_SIGNAL_DW` are taken from imported libraries and define which DWORD values are considered "not available" and "valid," respectively.

- The function block uses a range check by comparing `DWORD_TO_UDINT(IN)` with `VALID_SIGNAL_DW`. This assumes that valid fieldbus signals lie within a specific range of numbers.
- The conversion is performed without floating-point errors because the DWORD is first converted to UDINT and then to LREAL.
- The scaling factor `SCALE` and the offset `OFFSET` can be set during initialization or runtime, but are only used in the REQ algorithm.
- The function block is implemented as a SimpleFB and is suitable for cyclic processing.

State	Trigger	Action	Output
INIT	INIT Event	INIT Algorithm (empty)	INITO
REQ	REQ Event	REQ Algorithm (calculation and validation)	CNF

The function block does not require state transitions between INIT and REQ – both states are triggered directly by their respective events.

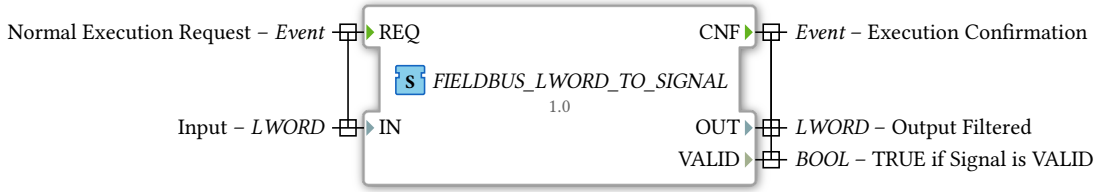
- **Agricultural Fieldbus Controllers**: Conversion of raw DWORD sensor values (e.g., rotational speeds, pressures) into physical units, taking sensor characteristics into account.
- **Scaling of Analog Values**: When a fieldbus device delivers a 32-bit raw value that must first be converted into a normalized value (e.g., 0-100%) using a factor and offset.
- **Signal Validation**: Only valid signals (within a defined range) are processed further; for invalid values, a defined zero value is output.
- **FIELDBUS_DWORD_TO_SIGNAL**: A similar function block without scaling capabilities, which outputs the raw value directly as LREAL.
- **FIELDBUS_DWORD_TO_SIGNAL_SCALED** additionally offers the parameters `SCALE` and `OFFSET` for flexible conversion.

- **Event-driven converters**: Other function blocks may use different validation logic (e.g., bitmasks) or support different fieldbus types.

This function block combines signal validation with a simple linear transformation, making it suitable for many applications.

The `FIELDBUS_DWORD_TO_SIGNAL_SCALED` is a compact and reusable function block for processing fieldbus signals. It enables reliable validity checking and simultaneous scaling in a single step. Due to the clear separation of initialization and processing, it is suitable for both one-time and cyclic calls in automation systems, particularly in agricultural technology.

Technical Features



State Overview

Application Scenarios

Comparison with Similar Function Blocks

Conclusion

FIELDBUS_LWORD_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FIELDBUS_LWORD_TO_SIGNAL** converts an LWORD value from a fieldbus system into a valid signal. It accepts an input value and passes it on unchanged only if its value lies within a defined valid range. Otherwise, a zero value is output, and the validity is signaled as `FALSE`.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Normal execution request (with data input `IN`)

Event Outputs

Name	Type	Comment
CNF	Event	Execution Confirmation (with data outputs `OUT` and `VALID`)

Data Inputs

Name	Type	Initial Value	Comment
IN	LWORD	`NOT_AVAILABLE_LWM`	Input value from the fieldbus

Note: `NOT_AVAILABLE_LWM` is a constant defined in the project (e.g., `LWORD#16#FFFFFFFFFFFFFFFF`) that represents an invalid or unavailable value.

Data Outputs

Name	Type	Initial Value	Comment
OUT	LWORD	`LWORD#16#0000000000000000`	Filtered output value (0 for invalid signal)

VALID	BOOL	FALSE	Validation flag (TRUE if signal is valid)

Adapters

No adapters available.

Functionality

The function block is activated by an event at the input REQ. The current value of IN is read and processed according to the following logic:

1. The incoming LWORD value is converted into an unsigned integer (ULINT).
2. This value is compared to a constant VALID_SIGNAL_LW, also interpreted as a ULINT.

- If the input value is **less than or equal to** this threshold, the signal is considered valid:
- OUT receives the value of IN.
- VALID is set to TRUE.
- Otherwise (value greater than threshold), the signal is considered invalid:
- OUT is set to zero (LWORD#16#0000000000000000).
- VALID is set to FALSE.

1. After processing is complete, the event CNF is output to confirm completion.

The constant VALID_SIGNAL_LW defines the upper limit of the valid value range. Common values are, for example, LWORD#16#0000FFFFFFFFFFFF or similar ranges specified by the fieldbus protocol.

Technical Features

- **Type Conversion:** The comparison is performed after converting both LWORD values to ULINT using LWORD_TO_ULINT. This interprets the values as unsigned 64-bit integers, enabling a consistent comparison independent of bit pattern-specific interpretations.
- **Use of project-wide constants:** The values NOT_AVAILABLE_LWM (initial value for IN) and VALID_SIGNAL_LW (limit value) are obtained via imports from a common signal processing package. They are not defined within the function block itself and can therefore be adjusted globally.
- **No additional state machine:** The function block has only a single state (REQ), which is exited immediately after the algorithm is executed. There are no internal delays or wait loops.

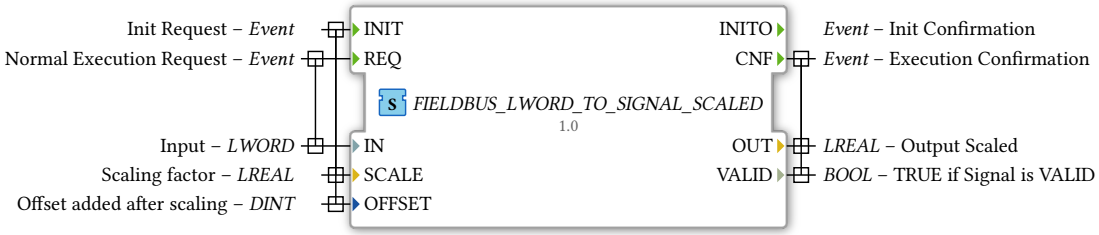
State Overview

State	Description	Action
REQ	Waits for an event at input REQ.	Executes the algorithm REQ (checking and, if necessary, filtering) and then sends the event CNF.

After each execution, the function block returns to the state REQ, so it is immediately ready for a new task after each processing cycle.

Application Scenarios

- **Fieldbus Signal Validation:** Used in automation systems where analog or digital signals are received via a fieldbus (e.g., PROFIBUS, CANopen). The function block filters out values that are outside the permissible range (e.g., error or initialization values) and outputs a defined zero value instead.
- **Safety-Related Applications:** If the fieldbus protocol specifies certain bit patterns for "signal not available" or "error," these can be detected by the limit check and marked as invalid.
- **Data preprocessing before logical operations:** The output VALID can be used directly as an enable signal for subsequent function blocks, so that they are only activated with valid input signals.



Comparison with similar function blocks

- **Simple filters (e.g., FIELDBUS_LWORD_FILTER):** These usually perform a simple limit check without a validity flag. The function block described here additionally offers the Boolean output VALID, which simplifies decision-making in the controller.
- **Signal converters (e.g., LWORD_TO_REAL):** These convert the data type but do not check the validity of the original value. The function block FIELDBUS_LWORD_TO_SIGNAL combines validation and optional conversion (here as a 1:1 pass-through on validity).
- **Monitor blocks (e.g., WATCHDOG):** These only monitor the signal's validity, not its value range. This block adds range checking.

Conclusion

The function block `FIELDBUS_LWORD_TO_SIGNAL` is a simple yet effective tool for processing fieldbus LWORD signals. The combination of range checking and outputting a validity flag ensures a clear separation of valid and invalid values. The use of project-wide constants provides flexibility, while the clear state logic guarantees reliable and fast processing. It is particularly suitable for applications where error signals or initialization values must be reliably detected and forwarded.

FIELDBUS_LWORD_TO_SIGNAL_SCALED

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FIELDBUS_LWORD_TO_SIGNAL_SCALED** converts a raw fieldbus signal in **LWORD** format into a scaled **LREAL** output value. It mirrors the input signal to the output, provided the signal is valid, and applies linear scaling. This function block is designed for use in industrial automation, particularly in the context of fieldbus systems.

Interface Structure

Event Inputs

Event	Type	Description	Accompanying Data
INIT	EInit	Initialization Request: Set Scale Factor (SCALE) and Offset (OFFSET)	SCALE, OFFSET
REQ	Event	Normal Execution Request: Process Input Signal (IN)	IN

Event Outputs

Event	Type	Description	Accompanying Data
INITO	EInit	Initialization Acknowledge	–
CNF	Event	Execution Acknowledge	OUT, VALID

Data Inputs

Name	Type	Initial Value	Description
IN	LWORD	NOT_AVAILABLE_LWM	Fieldbus Raw Signal (LWORD)
SCALE	LREAL	LREAL#1.0	Scaling Factor (Multiplication)
OFFSET	DINT	DINT#0	Offset added after scaling

Data Outputs

Name	Type	Initial Value	Description
OUT	LREAL	LREAL#0.0	Scaled Output Value (LREAL)
VALID	BOOL	FALSE	Indicates whether the input signal is valid (TRUE = valid)

Adapters

No adapters available.

Functionality

The module has two algorithms that are triggered by the **INIT** and **REQ** events.

- **INIT** (on event `INIT`): The algorithm is empty, but sets the output event `INITO`. This allows the scaling parameters (SCALE and OFFSET) to be initialized via the INIT call without immediate processing.
- **REQ** (on event `REQ`): Performs the actual signal processing:

1. The input signal `IN` (LWORD) is interpreted as an unsigned integer value (`LWORD_TO_ULINT`).
2. This value is compared to an internally defined valid threshold value, **VALID_SIGNAL_LW** (also an LWORD, imported constant). The comparison is performed at the ULINT level.
3. **Validity**: If `IN` ≤ `VALID_SIGNAL_LW`, the signal is considered valid:

- `OUT = (ULINT_TO_LREAL(IN)) * SCALE + DINT_TO_LREAL(OFFSET)`
- `VALID = TRUE`

1. **Invalidity**: Otherwise, the signal is considered invalid:

- `OUT = 0.0`
- `VALID = FALSE`

1. After the calculation, the output event `CNF` is sent.

The scaling is linear: `OUT = IN_als_LREAL * SCALE + OFFSET`. The default value of `SCALE` is 1.0, and that of `OFFSET` is 0, so identical transmission occurs without adjustment.

Technical Features

- **Validity Check**: The function block uses two imported constants:
- `NOT_AVAILABLE_LWM`: Initial value for the input `IN` (indicates "not available").
- `VALID_SIGNAL_LW`: Threshold up to which a signal is considered valid (inclusive).

The comparison is performed by converting both LWORD values to ULINT, so that negative values (as bit patterns) are also correctly interpreted.

- **Type Conversion**: The raw value is converted from LWORD to LREAL via ULINT (64-bit). Potential precision losses should be noted for very large ULINT values.
- **Scaling Parameters**: `SCALE` (LREAL) and `OFFSET` (DINT) are set only during the INIT event and remain unchanged for all subsequent REQ calls.
- **Event Control**: The function block has a simple state machine with two states and requires explicit initialization before first processing.

State Overview

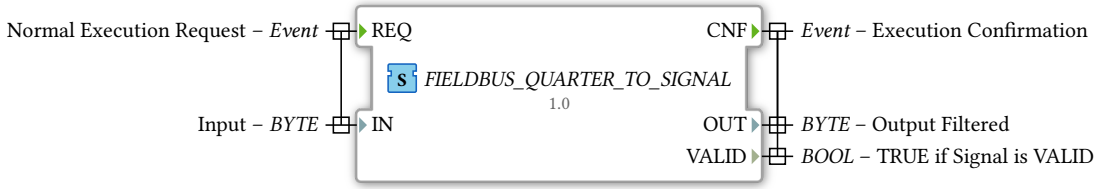
State	Triggered by	Output Algorithm	Event Output	Description
INIT	Event INIT	INIT	INITO	Initialization: Adopt Scaling Parameters
REQ	Event REQ	REQ	CNF	Signal Processing: Scaling and Validation Check

The function block switches between these two states only through the corresponding events. There is no explicit transition to a wait state after initialization; the function block remains in the last state until a new event arrives.

Application Scenarios

- **Analog Values from the Fieldbus**: A raw LWORD value from an analog input module (e.g., 0...10V, scaled as a raw value) is converted into a physical value (e.g., pressure, temperature) using SCALE and OFFSET.
- **Validation Filter**: Signals that are outside the permissible range (e.g., wire break or overflow) are detected by the validity check and marked as invalid, while the output is set to 0.
- **Parameter Initialization**: Scaling can be configured via the INIT event when the controller starts, without the actual processing having to run yet.

Comparison with Similar Function Blocks



- **FIELDBUS_LREAL_TO_SIGNAL_SCALED**: An analog function block for LREAL inputs that offers similar validation and scaling.
- **FIELDBUS_SINT_TO_SIGNAL_SCALED**: For signed 8-bit values.
- **Simple Scalers without Validation**: Function blocks like `SCALE` or `MUL_ADD` only offer the mathematical operation, but no fieldbus-specific validation.

This function block combines validation (via the threshold `VALID_SIGNAL_LW`) with linear scaling and is therefore particularly suitable for fieldbus applications where the validity of the signal must be ensured before further processing.

Conclusion

FIELDBUS_LWORD_TO_SIGNAL_SCALED is a compact yet powerful function block for processing fieldbus signals in LWORD format. It offers simple scaling, integrated validation, and a clean separation of initialization and execution. Through the use of standardized imports (`VALID_SIGNAL_LW`)It can be easily integrated into existing libraries and adapted to specific fieldbus protocols. The module is available under the Eclipse Public License 2.0 and is suitable for use in industrial control systems with IEC 61499-compliant runtime environments.

FIELDBUS_QUARTER_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FIELDBUS_QUARTER_TO_SIGNAL` serves as a signal validation and pass-through block. It checks whether an incoming BYTE value `IN` is within a valid range and, if so, passes it unchanged to `OUT`. Additionally, a Boolean signal `VALID` is set, indicating the validity status of the output. This block is suitable for filtering fieldbus signals where certain values are marked as invalid or “don’t care”.

Interface Structure

Event Inputs

Name	Type	Comment	With Variables
`REQ`	Event	Normal Execution Order	`IN`

Event Outputs

Name	Type	Comment	With Variables
`CNF`	Event	Execution Confirmation	`OUT`, `VALID`

Data Inputs

Name	Type	Comment	Initial Value
`IN`	`BYTE`	Input Signal	`NOT_AVAILABLE_2bit` (Imported Constant)

Data Outputs

Name	Type	Comment	Initial Value
`OUT`	`BYTE`	Filtered Output Signal	`16#00`

VALID	BOOL	TRUE, if the signal is valid	FALSE

Adapter

No adapters available.

Functionality

When an event occurs at input REQ, the algorithm REQ is executed:

1. The incoming value IN is compared to the imported constant DONT_CARE_2bit.
2. If IN is less than DONT_CARE_2bit, the value is considered valid:

- OUT receives the value of IN.
- VALID is set to TRUE.

1. Otherwise (if IN is greater than or equal to DONT_CARE_2bit), the signal is classified as invalid:

- OUT is reset to BYTE#0.
- VALID is set to FALSE.

1. After processing, the event CNF is triggered.

The comparison uses the semantics of the imported constants:
DONT_CARE_2bitdefines the threshold above which values are considered "irrelevant" or invalid. The initial value ofINis set toNOT_AVAILABLE_2bit`, which is typically above this threshold, so the function block outputs a defined invalid state upon startup.

Technical Features

- **Constant Import**: The values DONT_CARE_2bit and NOT_AVAILABLE_2bit are imported from a higher-level signal processing package. They must be defined in the target system and represent meaningful threshold values (e.g., 16#FC for "don't care").
- **Simple State Logic**: The function block has only a single EC state, REQ. Every event immediately triggers a calculation and output.
- **Compatibility**: Designed according to IEC 61499-1, usable in the 4diac IDE and other compliant runtime environments.

State Overview

Only one state exists:

State	Description	Output Event	Output Actions
REQ	Processes the input and updates outputs	CNF	Set OUT and VALID

Application Scenarios

- **Fieldbus Monitoring**: A sensor delivers 8-bit data on a fieldbus (e.g., CANopen, PROFIBUS), where certain values are coded as "not available" or "error." The function block extracts the valid measured values and displays their validity.
- **Signal Preprocessing**: Before further processing in a controller, invalid telegram segments are filtered out, so that subsequent blocks only work with plausible data.
- **Gateway Between Bus Systems**: Translation of a bus's "don't care" conventions into a uniform validity signal for the target system.

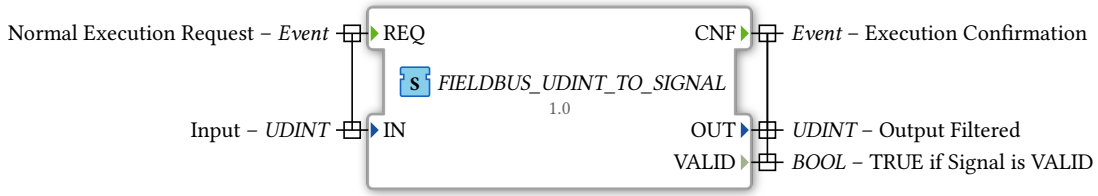
Comparison with Similar Function Blocks

- **FIELDBUS_QUARTER_TO_SIGNAL** specializes in distinguishing between valid and invalid values using a fixed threshold.
- A general **value filter** (e.g., F_BAND) could, on the other hand, query a lower and upper limit.
- A **validation checker** (e.g., VALIDITY_CHECK) often additionally sets Quality of Service flags.

This function block impresses with its simple logic, tailored to fieldbus types.

Conclusion

FIELDBUS_QUARTER_TO_SIGNAL` is a compact, efficient function block for validating 8-bit fieldbus signals. It reliably separates valid measured values from those marked as invalid and provides the validity



as a separate Boolean signal. Thanks to its streamlined state logic and the use of imported constants, it can be flexibly integrated into various signal processing chains.

]

FIELDBUS_UDINT_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FIELDBUS_UDINT_TO_SIGNAL** is used to check the validity of an incoming UDINT value and, if the check is successful, forward it unchanged to the output. If the value is invalid, the output is set to a defined error value (0) and the validity indicator is deactivated. This function block is typically used in fieldbus signal processing to ensure that only valid measurement or control values are passed on to subsequent logic.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution request; triggers the processing of the IN input.

Event Outputs

Event	Description
CNF	Confirms processing is complete. Triggered according to the algorithm.

Data Inputs

Name	Type	Initial Value	Description
IN	UDINT	`DWORD_TO_UDINT(NOT_AVAILABLE_DWM)`	The input value to be checked.

Data Outputs

Name	Type	Initial Value	Description
OUT	UDINT	`16#00000000`	The filtered output value. With a valid signal, it corresponds to IN; otherwise, it's 0.
VALID	BOOL	FALSE	TRUE if the signal is valid, i.e., IN is within the valid range.

Adapter

None.

Functionality

As soon as an event arrives at the **REQ** input, the algorithm is executed:

1. The value of **IN** is compared to the predefined threshold `VALID_SIGNAL_DW`.

2. If **IN** is less than or equal to this threshold, **OUT** is set to **IN** and **VALID** to `TRUE`.
3. Otherwise, **OUT** is set to `0` (UDINT) and **VALID** to `FALSE`.

The limit value `VALID_SIGNAL_DW` and the initial value `NOT_AVAILABLE_DWM` are imported as constants from the package `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL`. They represent a maximum permissible signal value and an "unavailable" marker, respectively.

Technical Features

- **Data Type** – The function block works exclusively with the type `UDINT` (Unsigned Double Integer, 32-bit).
- **Initial Value** – The input IN is set to the value `NOT_AVAILABLE_DWM` by default. This is converted from a previously defined DWORD using the function `DWORD_TO_UDINT`.
- **Limit Value** – The validity is determined by a simple comparison with the imported constant `VALID_SIGNAL_DW`. All values ≤ this limit are considered valid.
- **Simple State Logic** – The function block consists of exactly one state (REQ) and executes the algorithm on every request.

State Overview

The function block is implemented as a simple FB (SimpleFB) and has only one state:

State	Action	Output Event
REQ	Algorithm REQ	CNF

There is no state machine with multiple steps or branches.

Application Scenarios

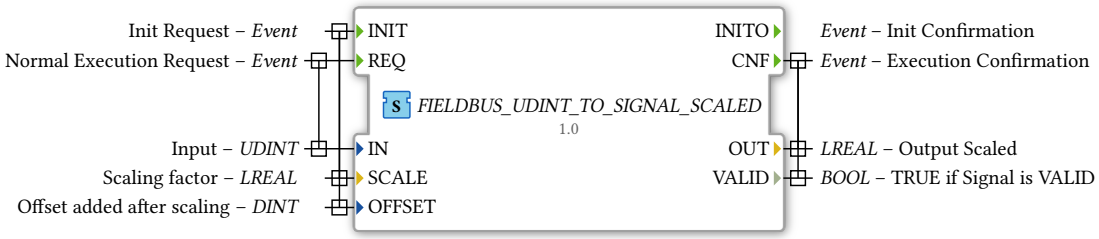
- **Fieldbus Signal Conditioning** – In automation systems where UDINT values are received via a fieldbus, the function block is used to filter invalid values or values outside the valid range (e.g., sensor data that must not exceed a maximum value).
- **Agricultural Technology** – Originally developed for use in agricultural control systems (e.g., HR Agrartechnik) to validate analog measurements such as rotational speeds or pressures.
- **Quality Assurance** – Preprocessing of measurement data before it is incorporated into control loops or logging.

Comparison with Similar Function Blocks

- **FIELDBUS_DINT_TO_SIGNAL** – Analog function block for signed 32-bit values (DINT).
- **FIELDBUS_BOOL_TO_SIGNAL** – Comparable function block for Boolean signals; threshold validation is omitted.
- **FIELDBUS_REAL_TO_SIGNAL** – For floating-point numbers, possibly with different tolerance logic.

This function block is specifically designed for the UDINT data type and uses a simple absolute limit for validation.

Conclusion



FIELDBUS_UDINT_TO_SIGNAL is a compact and efficient function block for filtering UDINT fieldbus signals. Its clear separation of valid and invalid values, along with its simple interface, makes it well-suited for robust automation solutions. The use of imported constants increases reusability and adaptability to various fieldbus protocols.

]

FIELDBUS_UDINT_TO_SIGNAL_SCALED

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FIELDBUS_UDINT_TO_SIGNAL_SCALED` processes a UDINT value received via the fieldbus. It mirrors the input `IN` to the output `OUT`, but only if the incoming signal is recognized as valid. Additionally, the value is scaled by a factor and an offset is applied. This function block is typically used in the signal processing chain of fieldbus protocols to convert raw integer values into physical quantities (e.g., as LREAL).

Interface Structure

Event Inputs

Event	Type	With Parameters	Description
`INIT`	EInit	`SCALE`, `OFFSET`	Initialization – sets scaling factor and offset.
`REQ`	Event	`IN`	Normal execution event – processes the current input value.

Event Outputs

Event	Type	With Parameters	Description
`INITO`	EInit	–	Confirmation of successful initialization.
`CNF`	Event	`OUT`, `VALID`	Processing confirmation – provides the scaled value and the validity signal.

Data Inputs

Name	Type	Initial Value	Description
`IN`	UDINT	`DWORD_TO_UDINT(NOT_AVAILABLE_DWM)`	Raw value from the fieldbus.
`SCALE`	LREAL	`LREAL#1.0`	Multiplicative scaling factor.
`OFFSET`	DINT	`DINT#0`	Additive Offset (after scaling).

Data Outputs

Name	Type	Initial Value	Description
`OUT`	LREAL	`LREAL#0.0`	Scaled output value.
`VALID`	BOOL	`FALSE`	`TRUE`, if the input value was recognized as valid.

Adapter

No adapters available.

Functionality

The function block has two states: `INIT` and `REQ`.

- **INIT State**: Upon a `INIT` event, the empty algorithm is executed (no action is taken), and subsequently, `INITO` is output. The parameters `SCALE` and `OFFSET` are passed to the function block but are only used during the next `REQ` processing.
- **REQ State**: On a `REQ` event, the following logic is executed:

1. The incoming value `IN` is compared to a predefined threshold `VALID_SIGNAL_DW` (from the import `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL::VALID_SIGNAL_DW`).
2. If `IN <= DWORD_TO_UDINT(VALID_SIGNAL_DW)` is true, the input is considered valid. Then `OUT` is calculated as:

OUT := UDINT_TO_LREAL(IN) * SCALE + DINT_TO_LREAL(OFFSET)`
and `VALID` is set to `TRUE`.

1. Otherwise, `OUT` is set to `0.0` and `VALID` to `FALSE`. This indicates that the transmitted fieldbus value is invalid (e.g., error value or communication failure).

The initial value of `IN` is preset to `DWORD_TO_UDINT(NOT_AVAILABLE_DWM)`, a constant from the same import that represents a special "not available" value.

Technical Features

- The validity check is based on two imported constants:
- `VALID_SIGNAL_DW`: Upper limit for valid values.
- `NOT_AVAILABLE_DWM`: Default value for unavailable signals (used as the initial value for `IN`).
- Scaling is performed in LREAL (double precision), allowing for precise processing of very large or small input values.
- The offset is defined as `DINT`, but is converted to `LREAL` before addition. The entire computational range is covered by the LREAL representation.

State Overview

The function block uses a simple state diagram with two states:

- **INIT**: Executed after the `INIT` event. The algorithm `INIT` is empty, and the output `INITO` is triggered.
- **REQ**: This event is executed after the `REQ` event. Here, the algorithm `REQ` is executed, which performs scaling and validation, and then outputs `CNF`.

There are no other states or loops.

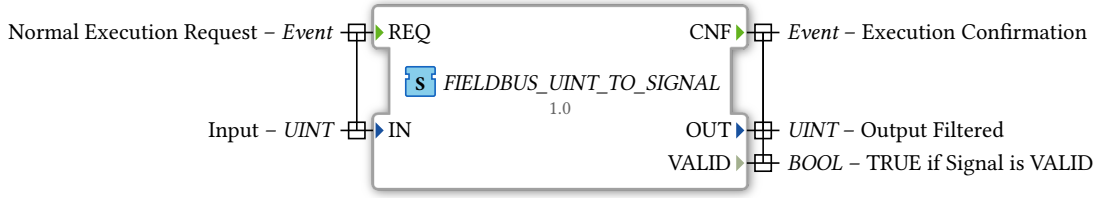
Application Scenarios

- **Scaling of Sensor Values**: A fieldbus device provides a raw UDINT value (e.g., 0 … 65535). `SCALE` converts a physical quantity (e.g., pressure in bar), and the offset accounts for zero-point shifts.
- **Validation Check**: Typical fieldbus protocols define certain bit patterns as "invalid." This function block automatically filters out these values and sets `VALID = FALSE`.
- **Initialization**: At system startup, the scaling factor can be set via `INIT`, while the `REQ` cycle regularly processes the current process values.

Comparison with Similar Function Blocks

Similar function blocks are often generic `SCALE` functions that do not include a validation check. This function block adds explicit validation of the fieldbus signal. Other implementations might make the validity range configurable as a parameter or via separate thresholds. This function block uses fixed constants defined in the import library, which simplifies configuration but is less flexible.

Conclusion



The `FIELDBUS_UDINT_TO_SIGNAL_SCALED` function block provides a robust and simple way to scale raw data from a fieldbus while simultaneously evaluating signal quality. The combination of scaling factor and offset, along with integrated validation, makes it particularly suitable for industrial automation applications where both the conversion and plausibility check of measured values are required.

FIELDBUS_UINT_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

The FIELDBUS_UINT_TO_SIGNAL function block is used to process fieldbus signals. It mirrors an incoming UINT value to the output, provided it is classified as valid. Validity is determined by comparing it to a configured threshold (VALID_SIGNAL_W). If the input value exceeds this threshold, the output is reset and the signal is marked as invalid.

Event	Data Type	Comment	
REQ	Event	Normal Execution Trigger (connected to IN)	
Event	Data Type	Comment	
–––––	–––––	———–	
CNF	Event	Execution confirmation (connected to OUT and VALID)	
Name	Data Type	Initial Value	Comment
——	–––––	———–	———–
IN	UINT	WORD_TO_UINT(NOT_AVAILABLE_WM)	Input value (raw fieldbus signal)
Name	Data Type	Initial Value	Comment
——	–––––	———–	———–
OUT	UINT	16#0000	Filtered Output Value
VALID	BOOL	FALSE	TRUE if the signal is recognized as valid

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

None.

Functionality

On each REQ event, the REQ algorithm is executed:

1. The incoming value IN is compared to the constant `VALID_SIGNAL_W`.
2. If `IN <= WORD_TO_UINT(VALID_SIGNAL_W)` is valid, the signal is considered valid:

- `OUT` receives the value of `IN`.
- `VALID` is set to TRUE.

1. Otherwise (signal invalid):

- `OUT` is reset to 0.
- `VALID` is set to FALSE.

1. The CNF event is then triggered.

The constants `NOT_AVAILABLE_WM` (for the initial value of IN) and `VALID_SIGNAL_W` (as the threshold) are obtained from external imports and define the valid range of the fieldbus signal.

- Use of type conversions (`WORD_TO_UINT`) for comparison with the imported constants.
- The function block imports two constants from the package `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL`: `NOT_AVAILABLE_WM` and `VALID_SIGNAL_W`. These must be defined or provided accordingly in the application.
- The function block is implemented as a simple FB, i.e., It has exactly one execution state.

The function block consists of a single state, **REQ**.

- **START → REQ**: The algorithm is executed as soon as the REQ event occurs. After processing, CNF is output, and the state remains in REQ (cyclic processing).
- Processing of analog sensor values from a fieldbus where a specific value range is defined as valid (e.g., 0–1000 for a pressure sensor).
- Filtering of communication errors or invalid telegrams by setting values outside the valid range to zero and marking them as invalid.
- Preprocessing of fieldbus signals before forwarding them to subsequent logic blocks.

Unlike simple pass-through blocks (e.g., `MOVE`), `FIELDBUS_UINT_TO_SIGNAL` performs a deliberate validity check and distinguishes between valid and invalid values. Other blocks, such as `LIMIT` or `SCALE`, offer range limits but no separate Boolean output for validity. This block is particularly suitable for applications requiring explicit signal status indication.

The FIELDBUS_UINT_TO_SIGNAL function block provides a simple and efficient way to check the validity of fieldbus signals and either pass them through or discard them. Its clear interface and the use of configurable constants make it versatile for use in IEC 61499 automation applications.

FIELDBUS_UINT_TO_SIGNAL_COMPOUND_SCALE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FIELDBUS_UINT_TO_SIGNAL_COMPOUND_SCALE` is used to process a 16-bit fieldbus signal (type `UINT`) into a scaled real value. The incoming word is split into an upper and a lower byte, each byte

is multiplied by its own scaling factor, and an offset is added. Additionally, a validity signal (`VALID`) is output, based on a predefined threshold. This function block is particularly suitable for protocols that encode two measured variables (e.g., temperature and pressure) in a single register.

Interface Structure

Event Inputs

Event	Type	Description
`INIT`	EInit	Initialization Request (Parameter Transfer)
`REQ`	Event	Normal Execution Request (Processing of `IN`)

Event Outputs

Event	Type	Description
`INITO`	EInit	Initialization Confirmation
`CNF`	Event	Execution Confirmation (after `REQ`)

Data Inputs

Variable	Type	Initial Value	Description
`IN`	UINT	`WORD_TO_UINT(NOT_AVAILABLE_WM)`	Raw value from fieldbus
`SCALE_HIGH`	REAL	`0.256`	Scaling factor for the upper byte
`SCALE_LOW`	REAL	`0.001`	Scaling factor for the lower byte
OFFSET`	DINT	`0`	Offset added after scaling (in REAL)

Data Outputs

Variable	Type	Initial Value	Description
`OUT`	REAL	`0.0`	Scaled Output Value
`VALID`	BOOL	`FALSE`	`TRUE`, if the input signal is recognized as valid

Adapter

None.

Functionality

1. **Initialization** (`INIT`):

The algorithm `INIT` is empty, but the parameters `SCALE_HIGH`, `SCALE_LOW`, and `OFFSET` are linked to the event via the `With` relationship and can thus be set when `INIT` is called.

1. **Normal Processing** (`REQ`):

- The input value `IN` is compared to a constant `VALID_SIGNAL_W` (from the imported name `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL::VALID_SIGNAL_W`):

IF (IN <= WORD_TO_UINT(VALID_SIGNAL_W)) THEN`

- If the condition is **true** (signal valid):
- The upper byte is extracted by right-shifting 8 bits and masking with `0x00FF`:

highByte := (IN >> 8) & 0xFF`

- The lower byte is obtained directly by masking:

lowByte := IN & 0xFF`

- Both bytes are converted to `REAL` and multiplied by the respective scaling factors. and the offset is added:

OUT := highByte * SCALE_HIGH + lowByte * SCALE_LOW + OFFSET`

- `VALID` is set to `TRUE`.
- If the condition is **false** (invalid signal):
- `OUT` is set to `0.0`.
- `VALID` is set to `FALSE`.
- The event `CNF` is then output.

Technical Features

- **Compound Scaling**: The function block allows separate scaling for the upper and lower bytes of a 16-bit word. This is useful when two different physical quantities are combined in one register.
- **Validity Check**: Comparison with `VALID_SIGNAL_W` defines a threshold. Values above this threshold are considered invalid – typical for fieldbus error codes (e.g., "Not Available").
- **Parameterization via `INIT`**: The scaling factors and offset can be set once via the `INIT` event so that they remain constant during operation.
- **Initial Values**: The predefined values (`SCALE_HIGH=0.256`, `SCALE_LOW=0.001`, `OFFSET=0`) are examples; they should be adapted to the specific application.

State Overview

The FB has two EC states:

- **INIT**: Executes the empty algorithm `INIT` and exits the state via the output `INITO`.
- **REQ**: Executes the algorithm `REQ`, which performs all signal processing, and exits the state via the output `CNF`.

The FB is implemented as a SimpleFB; there are no other states such as IDLE or WAIT.

Application Scenarios

- **Two-in-one Sensor Values**: A temperature sensor and a pressure sensor provide their values as 8-bit numbers each in a 16-bit register. The function block (FB) converts these values into physical units using separate scaling.
- **Fieldbus Error Detection**: If the fieldbus protocol specifies a particular bit code (e.g., all bits 1) for invalid measured values, validity can be detected using the threshold value `VALID_SIGNAL_W`.
- **Post-processing of Logging Data**: Raw data from a fieldbus logger is converted back into physical units using the original scaling.

Comparison with Similar Function Blocks

Function Block	Property	Difference
`SCALE` (e.g., according to IEC 61131)	Linear factor and offset on the entire value	No division into bytes, no validity check
`LINEAR` (Fieldbus Standard)	Moving average or simple linear transformation	No compound approach
`UINT_TO_REAL`	Direct type conversion	No scaling, no error detection

This function block is unique in combining byte separation with dual scaling and integrated validation, making it particularly suitable for special fieldbus protocols with compound registers.

Conclusion

The `FIELDBUS_UINT_TO_SIGNAL_COMPOUND_SCALE` is a powerful function block for processing 16-bit fieldbus signals that encode two independent measured values in a single register. Separate scaling of high and low bytes, along with integrated validation, allows for the efficient and reliable conversion of complex sensor registers into physical quantities. Parameterization via `INIT`The event and the clear separation of initialization and operation make the function block reusable and adaptable.

FIELDBUS_UINT_TO_SIGNAL_SCALED

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FIELDBUS_UINT_TO_SIGNAL_SCALED** processes a UINT value received via a fieldbus. It checks the validity of the input signal and, if valid, scales it to a REAL output using a multiplication constant (SCALE) and an additive offset (OFFSET). If the signal is invalid, the output is set to zero and a validity flag is set to FALSE. A typical application is the conversion of raw fieldbus data into physical quantities while simultaneously detecting exceptional conditions such as wire breaks or sensor errors.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization request. This event sets the parameters `SCALE` and `OFFSET`.
- **REQ** (Event): Normal execution request. This event processes the current value `IN`.

Event Outputs

- **INITO** (EInit): Initialization confirmation. Sent after processing the INIT event.
- **CNF** (Event): Execution confirmation. Sent after processing the REQ event and carries the output data `OUT` and `VALID`.

Data Inputs

Name	Type	Initial Value	Description
IN	UINT	WORD_TO_UINT(NOT_AVAILABLE_WM)	Raw value from the fieldbus to be scaled.
SCALE	REAL	REAL#1.0	Scaling factor (multiplication).
OFFSET	DINT	DINT#0	Additive offset to be added after scaling.

Data Outputs

Name	Type	Initial Value	Description
OUT	REAL	REAL#0.0	Scaled output value. 0.0 if the signal is invalid.
VALID	BOOL	FALSE	Validation flag: TRUE if the input signal is valid.

Adapter

None.

Functionality

The FB has two operating states, which are controlled by the corresponding events.

- **INIT state**: Upon receiving `INIT`, the parameters `SCALE` and `OFFSET` are adopted (the algorithm is empty; the transfer occurs implicitly via the `With` link). The event `INITO` is then sent.
- **REQ State**: Upon receiving `REQ`, the following algorithm is executed:

1. Check whether the input value `IN` is less than or equal to a predefined validity threshold. This threshold is given by the imported constant `VALID_SIGNAL_W` (from the namespace `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL`).
2. **Valid (`IN <= VALID_SIGNAL_W`)**:

- `OUT := UINT_TO_REAL(IN) * SCALE + DINT_TO_REAL(OFFSET)`
- `VALID := TRUE`

1. **Invalid (`IN > VALID_SIGNAL_W`)**:

- `OUT := 0.0`
- `VALID := FALSE`

1. Subsequently, the event `CNF` is sent with the current values of `OUT` and `VALID`.

The validity threshold is provided as part of the imported library and must be defined according to the fieldbus standard used. The initial value of `IN` is `WORD_TO_UINT(NOT_AVAILABLE_WM)`, which, by default, results in an invalid signal being detected if no data is passed.

Technical Features

- **Use of Imported Constants**: Validation is performed using constants from the `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL` namespace. These must be correctly defined in the target system (e.g., `VALID_SIGNAL_W` as the maximum valid UINT value, `NOT_AVAILABLE_WM` as an indicator for "not available").
- **Empty INIT Algorithm**: The INIT event is used solely for parameter passing. No explicit initialization logic exists – the values of `SCALE` and `OFFSET` are taken directly from the data inputs. Therefore, these parameters can also be set before the first INIT (see Initial Values).
- **Type Preservation**: The input is UINT, the output is REAL. Scaling is performed using REAL arithmetic after an explicit type conversion.
- **No State Machine Logic**: The FB is implemented as a SimpleFB, which only has the two states INIT and REQ. There are no time-based or repetitive processes; each execution is strictly event-driven.

State Overview

The FB has exactly two EC states:

State	Input	Algorithm	Output Event
INIT	INIT	– (empty)	INITO
REQ	REQ	REQ	CNF

There is no state loop or dwell time. After initialization, the function block (FB) starts in the INIT state and can then be executed any number of times via REQ. A subsequent INIT resets the parameters.

Application Scenarios

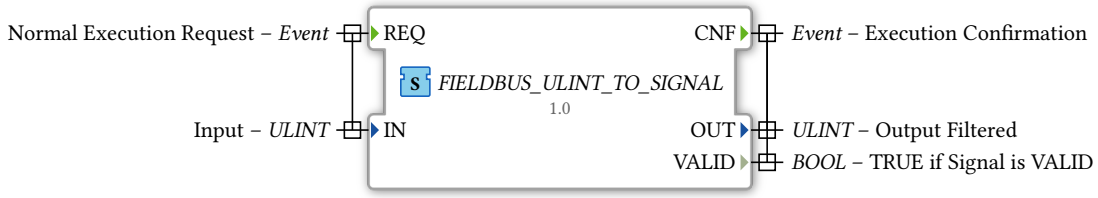
- **Scaling of Analog Values**: A fieldbus delivers a raw 16-bit measurement value (e.g., 0–4095). Using `SCALE = 0.001` and `OFFSET = -5.0`This results in, for example, a pressure in bar.
- **Error Value Detection**: Many fieldbus protocols define specific bit patterns for "sensor errors" or "wire breaks." The function block (FB) detects such values by classifying them as being above the validity threshold (e.g., 0xFFFE or 0x8000) and setting the output to zero.
- **Initialization Sequence**: After system startup, an INIT call can load the scaling parameters from a configuration file. Subsequently, REQ calls are sent in rapid succession for cyclical measurement processing.

Comparison with Similar Function Blocks

- **FIELDBUS_UINT_TO_SIGNAL (without scaling)**: A simpler FB that directly outputs the UINT value as a REAL and only performs the validity check. Scaling must be done externally.
- **FIELDBUS_UINT_TO_SIGNAL_FILTERED**: In addition to scaling, a low-pass or median filter is applied – suitable for noisy signals.
- **FIELDBUS_INT_TO_SIGNAL_SCALED**: Analog function block for signed inputs (INT), with corresponding adjustment of the validation logic.

This function block is characterized by its simplicity, clear separation of scaling and validation detection, and the use of imported constants, which allows for flexible adaptation to various fieldbus standards.

Conclusion



FIELDBUS_UINT_TO_SIGNAL_SCALED is a compact, event-driven function block for converting a UINT fieldbus signal into a scaled REAL value. The integrated validation check enables easy error detection. This block is particularly suitable for applications where raw bus data needs to be converted into physical quantities with minimal effort, while simultaneously monitoring signal quality. The clear interface and the use of imported constants facilitate reuse in different project contexts.

]

FIELDBUS_ULINT_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FIELDBUS_ULINT_TO_SIGNAL** serves as a filter block for fieldbus signals of type `ULINT`. It checks whether an incoming value lies within the valid signal range and, depending on the result, either outputs it unchanged or sets the output to a defined invalid value. The VALID output signal indicates the signal validity status. This block is particularly suitable for use in safety-critical or quality-monitoring applications where invalid or faulty fieldbus values must be reliably detected and handled.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution request – triggers the processing of the input value IN. The event output CNF is sent after the action is completed.

Event Outputs

Event	Description
CNF	Execution confirmation – sent after the calculation of OUT and VALID.

Data Inputs

Name	Type	Initial Value	Description
IN	ULINT	`LWORD_TO_ULINT(NOT_AVAILABLE_LWM)`	Input signal (raw value from the fieldbus)

Note: `NOT_AVAILABLE_LWM` is a constant imported from the library `FIELDBUS_SIGNAL`, representing an invalid or unavailable signal value.

Data Outputs

Name	Type	Initial Value	Description
OUT	ULINT	`16#0000000000000000`	Filtered output value – corresponds to IN if valid, otherwise 0.
VALID	BOOL	`FALSE`	Signal validity – `TRUE` if valid input, otherwise `FALSE`.

Adapter

This component has no adapter interfaces.

Functionality

After an event at the **REQ** input, the following algorithm is executed:

1. Check: **IN** ≤ `LWORD_TO_ULINT(VALID_SIGNAL_LW)`

VALID_SIGNAL_LWis an imported constant from theFIELDBUS_SIGNAL` library and defines the upper limit of the valid value range.

1. **Case – Valid Input** (Condition met):

- `OUT` := `IN`
- `VALID` := `TRUE`

1. **Case – Invalid Input** (Condition not met):

- `OUT` := `0`
- `VALID` := `FALSE`

The **CNF** event output is then triggered.

Technical Features

- The function block operates deterministically and requires only a single processing stage.
- The threshold values `NOT_AVAILABLE_LWM` and `VALID_SIGNAL_LW` are defined as external constants and stored centrally in the library `FIELDBUS_SIGNAL`. They can be adjusted without modifying the function block.
- The output value for an invalid signal is set to 0, which represents a defined "invalidity value" in many fieldbus systems.
- The initial value of `IN` is declared as "not available," so the function block provides a defined state even without a prior event.

State Overview

The function block is implemented as a **SimpleFB** and has only one state:

State	Description
REQ	Input state: Waiting for event REQ. Upon entry, the algorithm `REQ` is executed, and then the output `CNF` is sent. Afterward, the function block remains in the same state.

There are no further states or branches – the functionality is purely process-oriented.

Application Scenarios

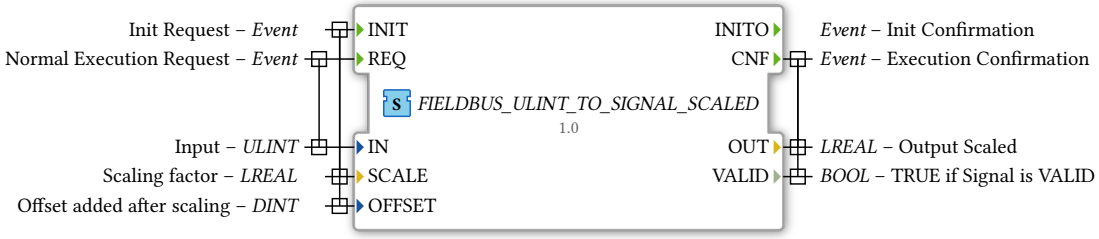
- **Fieldbus Signal Conditioning:** A sensor delivers a ULINT value that is only physically meaningful within a specific range (e.g., rotational speed, pressure). The function block filters out invalid measurements.
- **Safety Chain:** In a safety-related controller, faulty or deviating fieldbus values are detected and replaced by a defined substitute value (0). Simultaneously, a validity signal is provided for the downstream logic.
- **Quality Monitoring:** The VALID output can be used to monitor data integrity, e.g., to trigger alarms or switch to alternative signal sources.

Comparison with Similar Function Blocks

The 4diac framework includes other filter blocks for different data types, such as `FIELDBUS_DINT_TO_SIGNAL` or `FIELDBUS_REAL_TO_SIGNAL`. All of these share the principle of validity checking using a predefined upper limit. This particular block is specifically designed for the `ULINT` data type, enabling efficient and type-safe use in applications with 64-bit unsigned values.

Conclusion

The **FIELDBUS_ULINT_TO_SIGNAL** is a simple yet reliable function block for signal validation in fieldbus environments. Its clear distinction between valid and invalid values, along with the provision of a BOOL output for validity, makes it ideally suited for use in modular automation systems where data



quality and error detection are essential. The use of external constants allows for flexible adaptation to different signal ranges without modifying the component itself.

]

FIELDBUS_ULINT_TO_SIGNAL_SCALED

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FIELDBUS_ULINT_TO_SIGNAL_SCALED** is used to convert a raw ULINT value (e.g., from a fieldbus) into a scaled LREAL value. The validity of the input signal is checked against a constant threshold (`VALID_SIGNAL_LW`). If the input is valid, linear scaling is performed (multiplication by a factor and addition of an offset); otherwise, the output is set to 0,0 and the validity is negated.

Interface Structure

Event Inputs

Event	Type	Description	With Variables
INIT	EInit	Initialization Request	SCALE, OFFSET
REQ	Event	Normal Execution Request	IN

Event Outputs

Event	Type	Description	With Variables
INITO	EInit	Initialization Acknowledgement	–
CNF	Event	Execution Acknowledgement	OUT, VALID

Data Inputs

Variable	Type	Initial Value	Description
IN	ULINT	`LWORD_TO_ULINT(NOT_AVAILABLE_LWM)`	Raw value from the fieldbus
SCALE	LREAL	`1.0`	Scaling factor
OFFSET	DINT	`0`	Offset added after scaling

Data Outputs

Variable	Type	Initial value	Description
OUT	LREAL	`0.0`	Scaled output value (valid only if VALID = TRUE)
VALID	BOOL	`FALSE`	Validation signal: TRUE if IN ≤ `VALID_SIGNAL_LW`, otherwise FALSE

Adapters

No adapters available.

Functionality

The function block has two operating states, which are activated by the **INIT** and **REQ** events:

1. **INIT State**

When the INIT event arrives, the algorithm `INIT` is executed (currently empty). The **INITO** event is then sent.

The **SCALE** and **OFFSET** parameters can be set via the inputs connected to INIT.

1. **REQ State**

When a REQ event occurs, the algorithm `REQ` is executed:

- Check: `IN ≤ LWORD_TO_ULINT(VALID_SIGNAL_LW)`
- **Valid** (condition met):

OUT := ULINT_TO_LREAL(IN) * SCALE + DINT_TO_LREAL(OFFSET)`
VALID := TRUE`

- **Invalid** (condition not met):

OUT := 0.0`
VALID := FALSE`

- Subsequently, the **CNF** event is output with the new values of **OUT** and **VALID**.

The constants `NOT_AVAILABLE_LWM` and `VALID_SIGNAL_LW` are taken from the imported package `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL` and define the threshold for validation.

Technical Features

- The function block is implemented as a **SimpleFB** with two states, making it deterministic and eliminating the need for complex state machines.
- Validation is performed by comparing the result with the imported `VALID_SIGNAL_LW`. This allows for application-specific configuration of the valid value range.
- In the event of an invalid signal, the output **OUT** is reset to 0,0 – a defined error handling mechanism.
- Scaling and offset are passed as LREAL and DINT, respectively. The offset is internally converted to LREAL, enabling negative values.
- The initial value of **IN** (`NOT_AVAILABLE_LWM`) is chosen so that it is recognized as invalid on the first pass if no valid fieldbus value is present.

State Overview

State	Description	Trigger	Output Event
INIT	Initialization (no action)	INIT	INITO
REQ	Input signal processing (scaling or error handling)	REQ	CNF

Application Scenarios

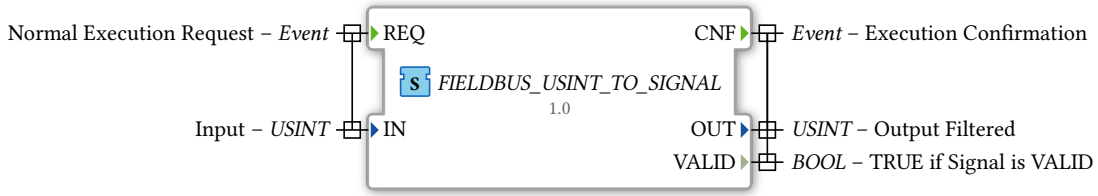
- **Fieldbus Sensors**: A 64-bit ULINT value from a pressure sensor is converted to bar using a factor (e.g., 0.001), and a zero-point offset is added. Validation prevents the processing of communication errors.
- **Error Handling**: If the value exceeds `VALID_SIGNAL_LW` (e.g., due to sensor failure), **VALID** is set to FALSE, preventing the higher-level controller from accepting the value.
- **Initialization**: During system startup, the scaling and offset can be loaded from a parameter set via INIT.

Comparison with Similar Function Blocks

- **FIELDBUS_SINT_TO_SIGNAL_SCALED** – same logic, but for signed 8-bit values (SINT). This block processes 64-bit unsigned values.
- **FIELDBUS_ULINT_TO_SIGNAL (without scaling)** – simple type conversion without scaling and without integrated validation.

- **GENERIC_SCALER** – a general scaling block where the validity check must be implemented externally.

Conclusion



The **FIELDBUS_ULINT_TO_SIGNAL_SCALED** function block offers a compact, configurable solution for the reliable conversion of raw fieldbus data into physical values. By combining validity checking, scaling, and offset, it is ideally suited for industrial automation tasks where data integrity and easy calibration are required.

]

FIELDBUS_USINT_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The FIELDBUS_USINT_TO_SIGNAL function block processes a USINT signal from a fieldbus. It checks whether the incoming value represents a valid signal range and, if so, mirrors it to the output. Otherwise, the output is set to a defined zero value, and the validity signal is reset.

Interface Structure

Event Inputs

Event	Description	With
REQ	Normal Execution Order	IN

Event Outputs

Event	Description	With
CNF	Execution Confirmation	OUT, VALID

Data Inputs

Name	Type	Comment	Initial Value
IN	USINT	Input Value from Fieldbus	BYTE_TO_USINT(NOT_AVAILABLE_B)

Data Outputs

Name	Type	Comment	Initial Value
OUT	USINT	Filtered Output Value	16#00
VALID	BOOL	TRUE if signal is valid	FALSE

Adapter

None.

Functionality

When a REQ event arrives, the algorithm is executed. The incoming value IN is compared to the constant threshold `VALID_SIGNAL_B` (interpreted as USINT). If `IN <= BYTE_TO_USINT(VALID_SIGNAL_B)` is true, the input value is directly transferred to the output OUT, and the validity signal VALID is set to TRUE. Otherwise, OUT is set to 0 and VALID to FALSE. The result is acknowledged with the CNF event.

The two constants `NOT_AVAILABLE_B` and `VALID_SIGNAL_B` are part of the package `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL` and define a reference value for "not available" and the upper limit for valid signals, respectively.

Technical Features

- The initial value of the IN input is set to `BYTE_TO_USINT(NOT_AVAILABLE_B)`, so that on the first call without a valid value, an invalid state is immediately signaled.
- The comparison uses the function `BYTE_TO_USINT` to convert the constant's byte value to the USINT data type.
- The function block is licensed under the Eclipse Public License 2.0.

State Overview

The function block has a single state, `REQ`. As soon as a REQ event arrives, the algorithm is executed and the CNF event is immediately sent. There are no internal state changes or delays.

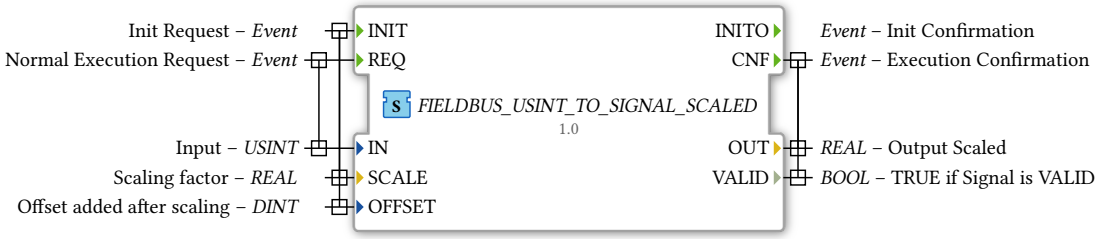
Application Scenarios

- **Fieldbus Signal Conditioning**: A sensor provides values in the range 0–127 as valid signals. The VALID_SIGNAL_B threshold is set to 127. Values above this threshold (e.g., 255 as an error code) are recognized as invalid.
- **Initialization**: At system startup, the input is preset to the "not available" value, so that until the first valid signal is received, the output remains at 0 and VALID is set to FALSE.
- **Error Detection**: Any permissible value range can be defined by adjusting the threshold.

Comparison with Similar Function Blocks

Similar function blocks such as `FIELDBUS_BYTE_TO_SIGNAL` or `FIELDBUS_SINT_TO_SIGNAL` operate on the same principle, but with different data types. This function block specializes in USINT. A simple "mirror" function block without validation would pass the value through unfiltered.

Conclusion



The `FIELDBUS_USINT_TO_SIGNAL` function block offers a simple and reliable way to check the validity of USINT fieldbus signals and only pass valid values on to subsequent processing. Its use of configurable limits (via package constants) makes it highly versatile.

FIELDBUS_USINT_TO_SIGNAL_SCALED

• – ○ • – ○ • – ○ •

Introduction

The function block **FIELDBUS_USINT_TO_SIGNAL_SCALED** converts an incoming USINT signal into a scaled REAL value, taking a validity check into account. It is typically used in fieldbus signal processing

to apply a scaling factor and an offset to raw fieldbus values (e.g., sensor data) and simultaneously evaluate the validity of the input signal. The block is structured according to the IEC 61499-1 standard.

Interface Structure

Event Inputs

Event	Type	Description
`INIT`	EInit	Initialization Request; linked to the parameters `SCALE` and `OFFSET`.
`REQ`	Event	Normal execution request; linked to the data input `IN`.

Event Outputs

Event	Type	Description
`INITO`	EInit	Initialization confirmation.
`CNF`	Event	Execution confirmation; linked to the outputs `OUT` and `VALID`.

Data Inputs

Name	Data Type	Initial Value	Description
`IN`	USINT	`BYTE_TO_USINT(NOT_AVAILABLE_B)`	Input signal as an unsigned 8-bit value. The initial value corresponds to the “not available” signal.
`SCALE`	REAL	`REAL#1.0`	Scaling factor (multiplication).
`OFFSET`	DINT	`DINT#0`	Offset added after scaling.

Data Outputs

Name	Data Type	Initial Value	Description
`OUT`	REAL	`REAL#0.0`	Scaled output value.
`VALID`	BOOL	`FALSE`	Validation flag: `TRUE`, if the input signal is valid.

Adapter

None available.

Functionality

The function block operates with two states: `INIT` and `REQ`.

- On a `INIT` event, the parameters `SCALE` and `OFFSET` are taken (the algorithm is empty, but the values are read in by the `With` binding). Then, `INITO` is output.
- On a `REQ` event, the algorithm `REQ` is executed:

If the input value `IN` is less than or equal to the predefined threshold `BYTE_TO_USINT(VALID_SIGNAL_B)`, the signal is considered valid. In this case, the value is scaled as follows:
OUT := USINT_TO_REAL(IN) * SCALE + DINT_TO_REAL(OFFSET) and `VALID` is set to `TRUE`.
If `IN` exceeds the threshold (i.e., the signal is invalid), `OUT` is set to `0.0` and `VALID` to `FALSE`.
This behavior mirrors the input 1:1 to the output, provided the signal is valid – with additional scaling and offset.

Technical Details

- The constants `NOT_AVAILABLE_B` and `VALID_SIGNAL_B` come from the external package `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL`. They define the boundaries between valid and invalid USINT values. `BYTE_TO_USINT(NOT_AVAILABLE_B)` is the initial state of the input and indicates an “unavailable” signal.

- The `INIT` algorithm contains no ST code – initialization is limited to providing the parameters via event binding. The function block expects a `INIT` call before the first `REQ` to set the scaling and offset.
- Scaling is always performed as REAL arithmetic; therefore, the offset is converted from DINT to REAL.

State Overview

The function block has two elementary states as simple FBs:

State	Action	Output Event
`INIT`	Execute algorithm `INIT` (empty)	`INITO`
`REQ`	Execute algorithm `REQ`	`CNF`

There are no further wait states – each incoming event immediately triggers the processing of the corresponding algorithm and the output of the associated result.

Application Scenarios

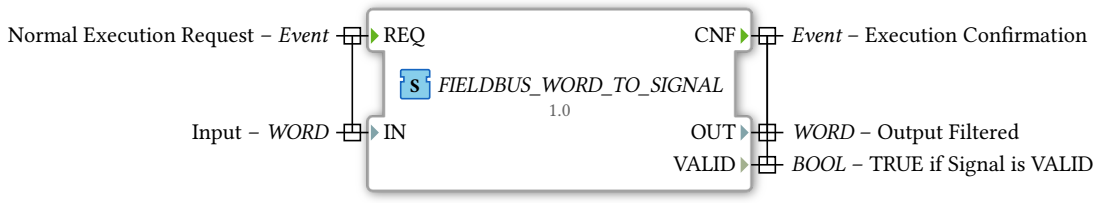
- **Fieldbus Sensor Evaluation**: A sensor delivers a raw USINT value (e.g., 0…200). The physical quantity (e.g., pressure in bar) is calculated from this using `SCALE` and `OFFSET`. The limit value `VALID_SIGNAL_B` separates valid measured values from error or initialization values.
- **Process Variable Update**: In PLC or control applications, the function block is triggered cyclically with `REQ` to process the latest fieldbus data and incorporate it into the control context.

Comparison with Similar Function Blocks

- **`FIELDBUS_USINT_TO_SIGNAL`**: A simpler function block without scaling or offset; it outputs the USINT value directly as REAL or as another data type.
- **`FIELDBUS_WORD_TO_SIGNAL_SCALED`**: Analog function block for WORD inputs – offers higher resolution but requires a different data type.

`FIELDBUS_USINT_TO_SIGNAL_SCALED` is characterized by the combination of validity checking (based on the constant `VALID_SIGNAL_B`) and simple linear scaling (multiplication + addition).

Conclusion



The function block `FIELDBUS_USINT_TO_SIGNAL_SCALED` is a compact yet powerful component for processing 8-bit fieldbus signals. It combines validity detection, scaling, and offset in a single logical unit and is particularly suitable for applications where raw values need to be converted into physical quantities and their plausibility checked simultaneously. Its simple state machine and clearly defined interfaces make it robust and easy to use.

FIELDBUS_WORD_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The FIELDBUS_WORD_TO_SIGNAL function block is used for simple signal filtering in fieldbus applications. It reflects an incoming WORD value at the output, provided the signal is classified as valid. A Boolean output indicates the validity status. Implementation is based on a comparison with an externally defined limit constant.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Normal execution command; triggered by the IN input.

Event Outputs

Name	Type	Comment
CNF	Event	Confirmation of execution; output after processing is complete.

Data Inputs

Name	Type	Initial Value	Comment
IN	WORD	NOT_AVAILABLE_WM	Input value that is checked for validity.

Data Outputs

Name	Type	Initial Value	Comment
OUT	WORD	16#0000	Filtered output value (only if the signal is valid).
VALID	BOOL	FALSE	TRUE if the input signal is recognized as valid.

Adapter

No adapters available.

Functionality

The module operates using a simple algorithm:

1. Upon arrival of the **REQ** event, the incoming value **IN** is read.
2. The value is converted to an unsigned integer using `WORD_TO_UINT`.
3. This is compared to the external constant `VALID_SIGNAL_W`.

– If the converted value is **less than or equal to** `VALID_SIGNAL_W`, **IN** is directly passed to **OUT** and **VALID** is set to `TRUE`.
Otherwise, **OUT** is reset to `16#0000` and **VALID** to `FALSE`.

1. The **CNF** event is then triggered.

The initial value of input `IN` is `NOT_AVAILABLE_WM`, so the function block signals an invalid signal in its default state.

Technical Features

- **External Constants:** The comparison limit `VALID_SIGNAL_W` and the default unavailable value `NOT_AVAILABLE_WM` are imported from the package `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL`. Their values are defined outside the function block.
- **Data Type Conversion:** The comparison is performed after converting `WORD` to `UINT` (`WORD_TO_UINT`) to enable an unsigned numerical comparison.
- **Initial Values:** The output `OUT` starts with `16#0000`, and `VALID` with `FALSE`. The input `IN` starts with the invalid value `NOT_AVAILABLE_WM`.
- **Simple State Machine:** There is only one execution state (REQ) – the function block is event-driven and does not remain in any other states.

Initial State Machine:

State Overview

The function block has exactly one state:

State	Description
REQ	Executes the algorithm, sets the outputs accordingly, and sends the confirmation event **CNF**.

There are no loops or branches in the state machine; each call to REQ is executed only once.

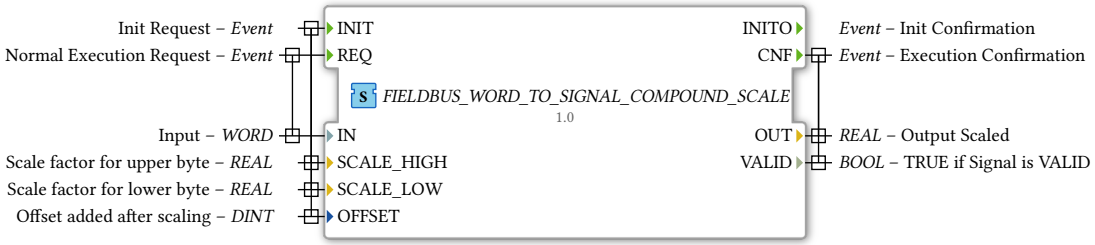
Application Scenarios

- **Fieldbus Signal Filtering:** Checks whether a WORD value originating from a fieldbus is within a valid range (e.g., sensor values, control commands).
- **Plausibility Check:** Suppresses values marked as "unavailable" or "erroneous" (represented by `NOT_AVAILABLE_WM`).
- **Data Consistency:** Used as a simple gate in industrial controllers, passing only valid data to subsequent logic.

Comparison with Similar Function Blocks

Similar function blocks such as **FIELDBUS_SIGNAL_FILTER** or **VALUE_CHECK** also perform comparisons using threshold values. The advantage of `FIELDBUS_WORD_TO_SIGNAL` lies in the direct integration of the validity identifier (`VALID`) and the use of predefined constants from the fieldbus library, which enables standardized handling of "unavailable" states. Unlike generic multiplex blocks, the logic here is optimized for specific use in the fieldbus context.

Conclusion



The function block `FIELDBUS_WORD_TO_SIGNAL` offers a compact and reliable way to check fieldbus signals for validity and forward only values recognized as valid. Using imported constants ensures a consistent definition of validity limits and unavailable values across the entire project. This component is particularly suitable for safety-critical applications where invalid data must be detected and suppressed.

]

FIELDBUS_WORD_TO_SIGNAL_COMPOUND_SCALE

• – ◦ • – ◦ • – ◦ •

Introduction

This function block maps a 16-bit word input to a scaled real value. The incoming word is first checked for validity. If the signal is valid, the upper and lower bytes are multiplied by their respective scaling factors and added with an offset. The result is output as the scale of the original fieldbus signal.

Interface Structure

Event Inputs

- **INIT** (EInit) – Initialization request; with the parameters `SCALE_HIGH`, `SCALE_LOW`, and `OFFSET`.
- **REQ** (Event) – Normal execution request; with the parameter `IN`.

Event Outputs

- **INITO** (EInit) – Confirmation of initialization.
- **CNF** (Event) – Confirmation of execution; with the parameters `OUT` and `VALID`.

Data Inputs

Name	Type	Initial Value	Description
IN	WORD	NOT_AVAILABLE_WM	The 16-bit fieldbus signal to be processed.
SCALE_HIGH	REAL	0.256	Scaling factor for the upper byte (high byte).
SCALE_LOW	REAL	0.001	Scaling factor for the lower byte (low byte).
OFFSET	DINT	0	Integer offset added after scaling.

Data Outputs

Name	Type	Initial Value	Description
OUT	REAL	0.0	Calculated scalar output value.
VALID	BOOL	FALSE	Indicates whether the input signal is valid (TRUE) or not (FALSE).

Adapters

No adapters available.

Functionality

The function block operates in two steps, controlled by events:

1. **Initialization (INIT)**

- The internal algorithm is empty; only the event output INIT0 is set.
- The scaling parameters (SCALE_HIGH, SCALE_LOW, OFFSET) are passed during the initialization event but are not used until the **REQ** cycle.

1. **Processing (REQ)**

- The incoming value IN is compared to the external constant VALID_SIGNAL_W.
- **Valid Signal** (IN ≤ VALID_SIGNAL_W):

1. The upper byte is extracted by right-shifting 8 bits and masking with 0x00FF.
2. The lower byte is obtained by masking with 0x00FF.
3. Both bytes are converted to REAL, multiplied by the corresponding scaling factors, and added to the offset:

OUT = (highByte * SCALE_HIGH) + (lowByte * SCALE_LOW) + OFFSET`

1. VALID is set to TRUE.

- **Invalid signal** (otherwise):
- OUT is set to 0.0.
- VALID is set to FALSE.

The following ST code illustrates the internal logic:
IF (WORD_TO_UINT(IN) <= WORD_TO_UINT(VALID_SIGNAL_W)) THEN temp := SHR(IN, SINT#8); highByte := temp AND WORD#16#00FF; lowByte := IN AND WORD#16#00FF; OUT := UINT_TO_REAL(WORD_TO_UINT(highByte)) * SCALE_HIGH

- UINT_TO_REAL(WORD_TO_UINT(lowByte)) * SCALE_LOW
- DINT_TO_REAL(OFFSET); VALID := BOOL#TRUE; ELSE OUT := REAL#0.0; VALID := BOOL#FALSE; END_IF;

Technical Features

- **Compound Scaling:** The two bytes of a word are scaled separately. This allows for the representation of measured values whose information is distributed across two bytes (e.g., different resolutions or units).
- **Fieldbus Constants:** The two external constants VALID_SIGNAL_W and NOT_AVAILABLE_WM define the valid value range and the "not available" state, respectively. They are taken from the package eclipse4diac::signalprocessing::FIELDBUS_SIGNAL.

- **Initial Values:** The default values `SCALE_HIGH = 0.256`, `SCALE_LOW = 0.001`, and `OFFSET = 0` are field-tested values for typical fieldbus signals (e.g., temperature measurement).
- **No State Dependency:** The component has no internal state machines beyond INIT/REQ – the response is purely combinatorial during the REQ event.

State Overview

The component has two simple states that directly correspond to the events:

State	Triggered by	Action performed	Output event
`INIT`	Event `INIT`	Algorithm `INIT` (empty)	`INITO`
`REQ`	Event `REQ`	Algorithm `REQ` (Scaling)	`CNF`

No further states or branches exist.

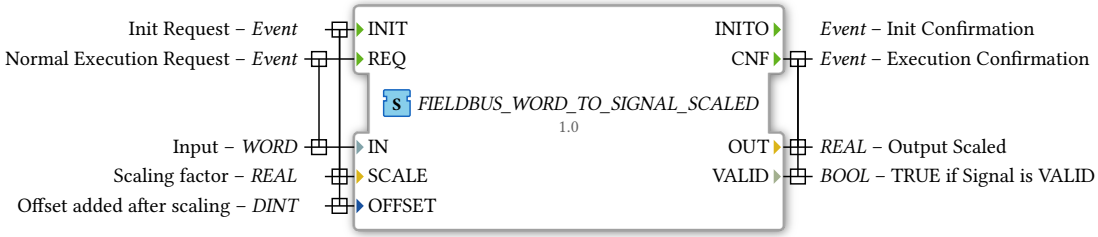
Application Scenarios

- **Temperature Measurement via Two Channels** – The high byte represents the integer part, the low byte the decimal part of a temperature (e.g., 0.256°C/LSB for high, 0.001°C/LSB for low).
- **Pressure or Level Sensors** – Provide a 16-bit raw value, which is decomposed into two differently scaled parts to determine the physical value.
- **Fieldbus Data Preprocessing** – In a logiBUS signal processing chain, this component can be used as the first stage for converting word values into real physical quantities.

Comparison with Similar Function Blocks

- **FIELDBUS_WORD_TO_SIGNAL** (without compound) – Applys only a single scaling factor to the entire word. Suitable when the high and low bytes have the same weight.
- **FIELDBUS_BYTE_TO_SIGNAL** – Processes only a single byte. Requires two instances to handle both bytes of a word.
- **FIELDBUS_WORD_TO_SIGNAL_COMPOUND_SCALE** is characterized by the separate scaling of the two bytes, which enables a more flexible and accurate representation of many sensor protocols.

Conclusion



The **FIELDBUS_WORD_TO_SIGNAL_COMPOUND_SCALE** function block is a specialized tool for processing 16-bit fieldbus signals where the two bytes have different physical meanings or resolutions. The clear separation of validation, byte extraction, and compound scaling makes it a reliable and configurable element in the signal processing chain. Externally defined fieldbus constants allow for easy adaptation to various protocols.

]

FIELDBUS_WORD_TO_SIGNAL_SCALED

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FIELDBUS_WORD_TO_SIGNAL_SCALED** is used to convert a digital fieldbus raw value (16-bit WORD) into a scaled physical signal value (REAL). A valid output is only provided if the

incoming value is recognized as a valid signal. The block checks the validity against a predefined constant (VALID_SIGNAL_W) and can reliably suppress unsafe or "unavailable" values.

Interface Structure

Event Inputs

Event	Description
INIT	Initialization request; sets the scaling factors (SCALE, OFFSET).
REQ	Normal processing request; evaluates the current input IN.

Event Outputs

Event	Description
INITO	Initialization confirmation.
CNF	Processing confirmation; signals that outputs OUT and VALID have been updated.

Data Inputs

Name	Data Type	Default Value	Description
IN	WORD	NOT_AVAILABLE_WM	Raw value from the fieldbus (e.g., 0…65535). The constant NOT_AVAILABLE_WM indicates an invalid starting value.
SCALE	REAL	1.0	Scaling factor (multiplied by the read value).
OFFSET	DINT	0	Integer offset added after scaling (converted to REAL).

Data Outputs

Name	Data Type	Default Value	Description
OUT	REAL	0.0	Scaled signal value. Valid only if VALID = TRUE.
VALID	BOOL	FALSE	Validation flag – TRUE, if the incoming raw value is recognized as a valid signal.

Adapter

No adapters available.

Functionality

The module operates in a state-controlled manner:

1. **INIT State**:

After the INIT event occurs, the initialization algorithm (empty) is executed and the INITO event is output. The scaling factors are then applied to the inputs SCALE and OFFSET (the values are already present at the inputs).

1. **REQ State** (Main Logic):

For each REQ event, the following algorithm is executed:

- The incoming IN (WORD) is first converted to UINT.
- If this value is **less than or equal to** the threshold defined in the global constant VALID_SIGNAL_W (also as WORD/UINT), the signal is considered **valid**.
- If valid:

OUT = UINT_TO_REAL(IN) * SCALE + DINT_TO_REAL(OFFSET)`
  VALID = TRUE`

- If invalid:

OUT = 0.0`
VALID = FALSE`

- Subsequently, the `CNF` event is triggered, which accompanies the updated outputs `OUT` and `VALID`.

The comparison value `VALID_SIGNAL_W` and the default input value `NOT_AVAILABLE_WM` are imported as constants in the namespace `eclipse4diac::signalprocessing::FIELDBUS_SIGNAL`.

Technical Features

- **Use of External Constants**: The validity threshold (`VALID_SIGNAL_W`) and the "Not Available" marker (`NOT_AVAILABLE_WM`) are retrieved from a global library. This enables consistent signal definition across multiple FB instances.
- **Scaling with REAL and DINT**: The offset is defined as `DINT`, but is converted to a floating-point number by `DINT_TO_REAL`. This can lead to minor rounding errors with large values, but is usually negligible in practice.
- **Validation Logic**: Unlike simple "word-to-real" converters, the value is only output if it lies within the defined valid range. This prevents misinterpretations of errors or invalid telegrams.
- **Initial Behavior**: The inputs `IN` have a default value of `NOT_AVAILABLE_WM`, so the function block immediately reports "invalid" after a reset or in case of no communication until a valid value is received.

State Overview

State	Content	Action	Output Event
`INIT`	Initialization (empty algorithm)	–	`INITO`
`REQ`	Signal Processing	Calculation of `OUT` and `VALID`	`CNF`

The function block (FB) has no further states; after each event, it returns to the corresponding start state. There is no explicit error handling or timeouts.

Application Scenarios

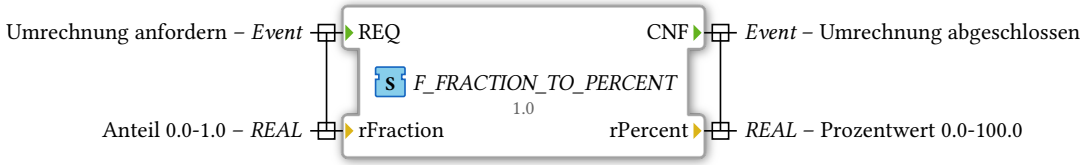
- **Agricultural Technology / Agricultural Control Systems**: A fieldbus device (e.g., ISOBUS) provides raw values for sensors (speed, temperature, pressure). The FB scales these to physical units and detects invalid measurement ranges.
- **Industrial Automation**: With Profibus/IO-Link connectivity, word codes can be converted into process-relevant quantities – e.g., 0…1000 ⟶ 0.0…10.0 V.
- **Diagnostic and Safety Functions**: Validation checks allow for easy detection of signal losses or range exceedances and the initiation of an error response.

Comparison with Similar Function Blocks

Function Block	Differences
FIELDBUS_WORD_TO_SIGNAL (without scaling)	Maps the raw value 1:1, without multiplication/addition.
WORD_TO_REAL (standard IEC function block)	Pure type conversion without validation or scaling.
SCALING_FB	Usually with separate validation and scaling branches; this function block combines both in one step.

The strength of `FIELDBUS_WORD_TO_SIGNAL_SCALED` lies in the **combination of validation, scaling, and offset** in a single, manageable function block.

Conclusion



This function block offers a compact and robust solution for processing fieldbus raw data. It integrates the typical task chain "Check ⟶ Scale ⟶ Offset" and, thanks to its fixed validity threshold, ensures a clear separation between normal measured values and error signals. The use of external constants allows for flexible adaptation without complicating the internal logic. Ideal for safety-critical or diagnostic applications in automation technology.

]

F_FRACTION_TO_PERCENT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **F_FRACTION_TO_PERCENT** is the counterpart to `F_PERCENT_TO_FRACTION`: it converts a fraction (REAL 0.0–1.0), such as one delivered by `MyLib::sys::F_PWM_RAW_TO_PERCENT`, into a percent value (REAL 0.0–100.0), e.g. for sending to a web client via OPC-UA publish.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Request conversion; processes the current value of `rFraction`.

Event Outputs

Event	Data Type	Comment
CNF	Event	Conversion complete; `rPercent` has been updated.

Data Inputs

Name	Data Type	Comment
rFraction	REAL	Fraction 0.0-1.0.

Data Outputs

Name	Data Type	Comment
rPercent	REAL	Percent value 0.0-100.0.

Adapter

None.

Functionality

On each `REQ` event, the `rFraction` input is multiplied by 100 without clamping:
`rPercent := rFraction * 100.0;`
The `CNF` event is then emitted.

Technical Details

- Implemented as a **SimpleFB** with a single execution state (`REQ`) — no multi-step state machine.
- Unlike its counterpart `F_PERCENT_TO_FRACTION`, it does **not clamp** the input value: since `rFraction` is already bounded to 0.0-1.0 by `RampLimitFS/F_PWM_RAW_TO_PERCENT` earlier in the PWM chain, an additional range check is not needed here.

- Deliberately kept separate from `MyLib::sys::F_PWM_RAW_TO_PERCENT`, which converts the fieldbus raw value (not percent!) into a fraction — together, the two blocks form the complete fieldbus-raw-value → fraction → percent chain.
- License: Eclipse Public License 2.0.

State Overview

State	Action	Output Event
REQ	Executes the **REQ** algorithm (multiplication by 100)	CNF

There are no further waiting or initialization states.

Application Scenarios

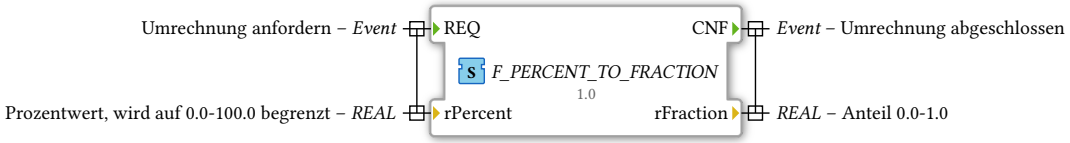
- Converting an internally processed fraction (0.0-1.0) back into the percent value expected by a web client via OPC-UA publish — e.g. in the PWM training example `RampLimitFS_TO_logiBUS_QDA_PWM_OPC`.
- In general: any interface that computes internally with a normalized 0.0-1.0 fraction while communicating externally in percent.

Comparison with Similar Blocks

- Its counterpart is `F_PERCENT_TO_FRACTION` (percent → fraction, for the forward direction, including clamping).
- The simplest conceivable scale converter with no range check at all, since the input is already guaranteed to arrive normalized.

Conclusion

F_FRACTION_TO_PERCENT is a pure multiplication by 100 that brings the internally used 0.0-1.0 fraction to the externally communicated 0.0-100.0 percent value — without any error handling of its own, since the input is already pre-normalized.



🛠️ Related Exercises

F_PERCENT_TO_FRACTION

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **F_PERCENT_TO_FRACTION** converts a percent value (REAL 0.0–100.0), such as one received via OPC-UA subscribe from a web client, into a fraction (REAL 0.0–1.0) as expected as input by `MyLib::sys::F_PWM_PERCENT_TO_RAW`. Values outside the valid range are clamped instead of producing an error.

Interface Structure

Event Inputs

Event	Data Type	Comment

REQ	Event	Request conversion; processes the current value of `rPercent`.

Event Outputs

Event	Data Type	Comment
CNF	Event	Conversion complete; `rFraction` has been updated.

Data Inputs

Name	Data Type	Comment
rPercent	REAL	Percent value, clamped to 0.0-100.0.

Data Outputs

Name	Data Type	Comment
rFraction	REAL	Fraction 0.0-1.0.

Adapter

None.

Functionality

On each `REQ` event, the `rPercent` input is checked and clamped to the valid range:

```
IF rPercent <= 0.0 THEN
    rFraction := 0.0;
ELSIF rPercent >= 100.0 THEN
    rFraction := 1.0;
ELSE
    rFraction := rPercent / 100.0;
END_IF;
```

- Values `<= 0.0` yield `rFraction = 0.0`, values `>= 100.0` yield `rFraction = 1.0`.
- All other values are divided linearly by 100.
- The `CNF` event is then emitted.

Technical Details

- Implemented as a **SimpleFB** with a single execution state (`REQ`) — no multi-step state machine.
- Clamps instead of error-handling: implausible percent values (e.g. from faulty web input) do not trigger an error state but are silently limited to 0-100 %.
- Deliberately kept separate from `MyLib::sys::F_PWM_PERCENT_TO_RAW`, which converts a fraction (not percent!) into the fieldbus raw value — together, the two blocks form the complete percent → fraction → fieldbus-raw-value chain.
- License: Eclipse Public License 2.0.

State Overview

State	Action	Output Event
REQ	Executes the **REQ** algorithm (clamping + division by 100)	CNF

There are no further waiting or initialization states.

Application Scenarios

- Converting a web setpoint received via OPC-UA subscribe (percent REAL) into the fraction expected by internal fieldbus conversion blocks — e.g. in the PWM training example `RampLimitFS_TO_logiBUS_QDA_PWM_OPC`.
- In general: any interface that communicates externally in percent while computing internally with a normalized 0.0-1.0 fraction.

Comparison with Similar Blocks

- Its counterpart is `F_FRACTION_TO_PERCENT` (fraction ⟶ percent, for the reverse direction).
- Unlike the `FIELDBUS_*_TO_SIGNAL` blocks (e.g. `FIELDBUS_BYTE_TO_SIGNAL`), this block does not validate against a constant but performs a pure, clamping scale conversion.

Conclusion

F_PERCENT_TO_FRACTION is a minimal, clamping scale converter that bridges the gap between the externally communicated percent value and the internally used 0.0-1.0 fraction — without any error handling of its own, since out-of-range values are simply clamped.

ILOCK_2_E

ECC: ILOCK_2_E

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ILOCK_2_E** is an event-driven bistable toggle block with dual interlock. It is used to control two mutually exclusive outputs (OUT1, OUT2). In addition to explicit set and reset functions, the block offers an edge-triggered toggle function that allows a single toggle per activation. The block is particularly suitable for control logics where both outputs must never be TRUE simultaneously and a repeated toggle command only takes effect after being released again (e.g., by setting the other channel or resetting).

Interface Structure

Event Inputs

Event	Comment
SET1	Sets OUT1 to TRUE and OUT2 to FALSE.
CLK1`	Toggles OUT1 (upon initial activation after a set/reset) and sets OUT2 to FALSE.
SET2`	Sets OUT2 to TRUE and OUT1 to FALSE.
CLK2`	Toggles OUT2 and sets OUT1 to FALSE.
R`	Resets both outputs to FALSE.

Event Outputs

Event	Comment
EO`	Triggered after every output change (SET, TOGGLE, or RESET). Stores the current values of OUT1 and OUT2.

Data Inputs

None (the function block is purely event-driven).

Data Outputs

Output	Type	Comment
OUT1	BOOL	First output (bistable value).
OUT2	BOOL	Second output (bistable value).

Adapters

None.

Functionality

The function block has six states: the initial idle state **STOP** and five action states (**SET1**, **SET2**, **TOGGLE1**, **TOGGLE2**, **RESET**). Upon the occurrence of an event, the block immediately switches to the corresponding state, executes the associated algorithm, and then outputs the event EO. Afterward, the block immediately returns to the **STOP** state (condition 1 on all transitions).

The internal logic provides **dual interlocking**: When one output is set, the other is forcibly set to FALSE. Similarly, when one output is toggled, the other output is reset.

The **toggle function** is edge-triggered: The internal variables EDGE1 and EDGE2 store whether a toggle has already been executed on the corresponding channel. Only after a reset or a set of the other channel (EDGE = FALSE) is the toggle actually executed and the flag set to TRUE. Repeated CLK events without an intermediate set/reset of the same or the other channel are ignored.

Technical Features

- **Edge Detection for Toggle** – The internal flags EDGE1/EDGE2 prevent multiple toggling events with the same enable signal.

- **Always Exclusive Outputs** – Each algorithm ensures that both outputs are never TRUE simultaneously.
- **No Data Inputs** – All control is exclusively event-based, enabling easy integration into event-driven automation systems.
- **Robust Reset Behavior** – A reset clears both the outputs and the internal edge flags, making the toggle function available again.

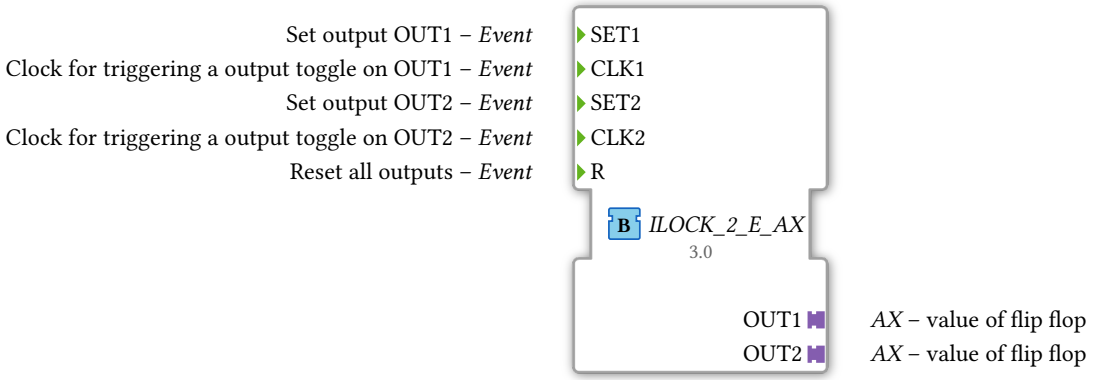
Status Overview

Status	Description	Trigger	Algorithm Effect (Simplified)	Output
STOP	Initial, waits for event	-	–	–
SET1	Set Output 1	SET1	OUT1=TRUE, OUT2=FALSE, EDGE1=FALSE, EDGE2=FALSE	E0
SET2	Set Output 2	SET2	OUT1=FALSE, OUT2=TRUE, EDGE1=FALSE, EDGE2=FALSE	E0
TOGGLE1	Toggle Output 1	CLK1	If EDGE1=FALSE: OUT1 = NOT OUT1; OUT2=FALSE; EDGE1=TRUE; EDGE2=FALSE	E0
TOGGLE2	Toggle Output 2	CLK2	OUT1=FALSE; if EDGE2=FALSE: OUT2 = NOT OUT2; EDGE1=FALSE; EDGE2=TRUE	E0
RESET	Reset all outputs	R	OUT1=FALSE, OUT2=FALSE, EDGE1=FALSE, EDGE2=FALSE	E0

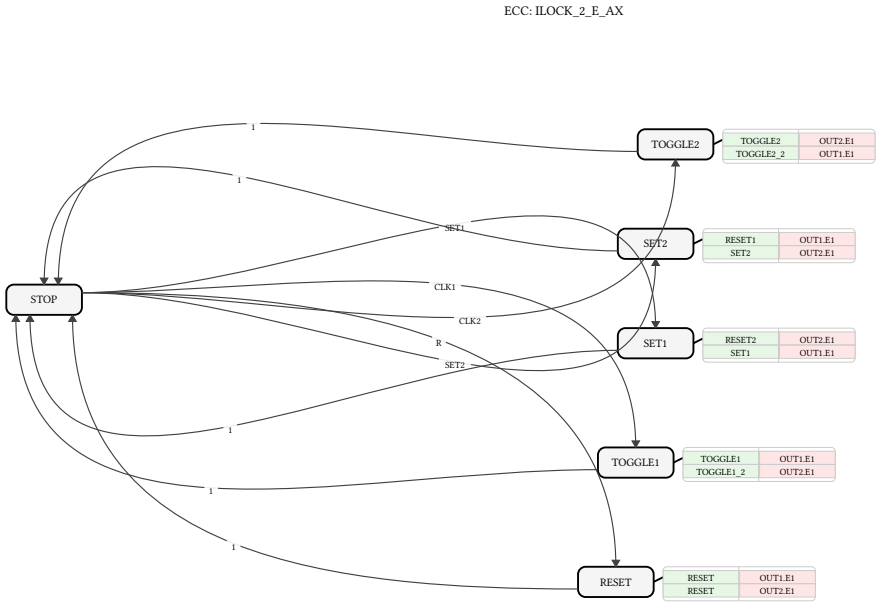
All action states immediately revert to STOP after the algorithm is executed.

Application Scenarios

- **Direction Control** (e.g., motor left/right) – both directions are never active simultaneously.
- **Pump Control with Priority** – two pumps, but only one may run at a time.
- **Mode Switching with Single Toggle** – e.g., "Start/Stop" behavior, where a repeated toggle command only takes effect after a reset or other action.
- **Interlocked Switching States in Safety Controllers** – guaranteed exclusivity of the outputs.



Comparison with Similar Function Blocks



Function Block	Properties
E_SR	Simple set/reset flip-flop, no toggle, no dual locking.
SR-Flipflop (two outputs)	Often only combinatorial or without edge detection.
ILOCK_2_E	Offers both: **Set** (exclusive) and **edge-triggered toggle** with automatic locking. Ideal for advanced requirements.

Conclusion

The ILOCK_2_E function block is a powerful function block for applications with two mutually exclusive states. The combination of explicit setting, edge-triggered toggle, and robust reset behavior makes it particularly suitable for control logics that require a clear separation of outputs and a defined response to repeated commands. Integration into event-based automation systems (e.g., IEC 61499) is achieved through the purely event-driven interface and the unified output E0.

ILOCK_2_E_AX

• – ○ • – ○ • – ○ •

Introduction

The function block **ILOCK_2_E_AX** provides two bistable outputs with mutual interlock and a toggle function. It is event-driven and outputs its states via two adapters (type `AX`). This block is suitable for applications requiring two mutually exclusive signals, such as controlling switches, valves, or motors.

Interface Structure

Event Inputs

Name	Description
`SET1`	Sets output `OUT1` to TRUE and `OUT2` to FALSE
`CLK1`	Toggles the state of `OUT1` if it is not already toggled
`SET2`	Sets output `OUT2` to TRUE and `OUT1` to FALSE
`CLK2`	Toggles the state of `OUT2` if it is not already toggled

R	Sets both outputs to FALSE (Reset)

Event Outputs

The function block has no dedicated event outputs. Output signals are transmitted exclusively via the **adapters** (see below).

Data Inputs

None.

Data Outputs

No direct data outputs. The current states of the flip-flops can be retrieved via the **adapters** (see below).

Adapters

Name	Type	Description
OUT1	AX	Provides the state of the first flip-flop (data output D1) and acknowledges changes via event output E1
OUT2	AX	Provides the state of the second flip-flop (data output D1) and acknowledges changes via event output E1

Functionality

This function block operates in an event-driven manner. An incoming event triggers a state change, which is immediately output to the corresponding adapters.

- **SET1**: Sets `OUT1.D1 = TRUE` and `OUT2.D1 = FALSE`. The internal edge buffers (`EDGE1`, `EDGE2`) are reset.
- **SET2**: Sets `OUT1.D1 = FALSE` and `OUT2.D1 = TRUE`. The edge buffers are reset.
- **CLK1**: Toggles `OUT1.D1` (if not already toggled by a previous `CLK1` event) and sets `OUT2.D1 = FALSE`. The edge buffer `EDGE1` prevents repeated toggling on the same event.
- **CLK2**: Toggles `OUT2.D1` (edge buffer `EDGE2`) and sets `OUT1.D1 = FALSE`.
- **R**: Sets both outputs to FALSE and clears the internal edge buffers.

The interlock ensures that only one of the two outputs can be TRUE at any given time. When one output is toggled, the other is always set to FALSE.

Technical Features

- The module uses **adapters** (type `AX`) as outputs. This allows for flexible connection to other modules that support the same adapter.
- An **internal edge detection** (variables `EDGE1`, `EDGE2`) prevents multiple toggling on a single event. The edge buffer is only reset after a reset or an explicit setting, allowing for further toggling.
- All algorithms are executed **atomically** in the ECC states; the module outputs an event via the adapters (`OUT1.E1` or `OUT2.E1`) after each action.
- The initial states of all outputs are **FALSE**.

State Overview

The following states underlie the ECC (Executive Control Cycle):

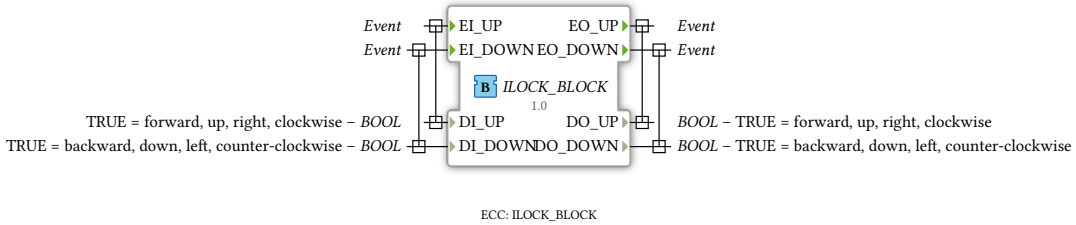
- **STOP** – Wait state (initial)
- **SET1** – Sets channel 1
- **SET2** – Sets channel 2
- **TOGGLE1** – Toggles channel 1, disables channel 2
- **TOGGLE2** – Toggles channel 2, disables channel 1
- **RESET** – Resets both channels

The transitions between states are triggered by the received events (`SET1`, `SET2`, `CLK1`, `CLK2`, `R`) and automatically return to state `STOP` after the actions are executed (transition condition). 1).

Application Scenarios

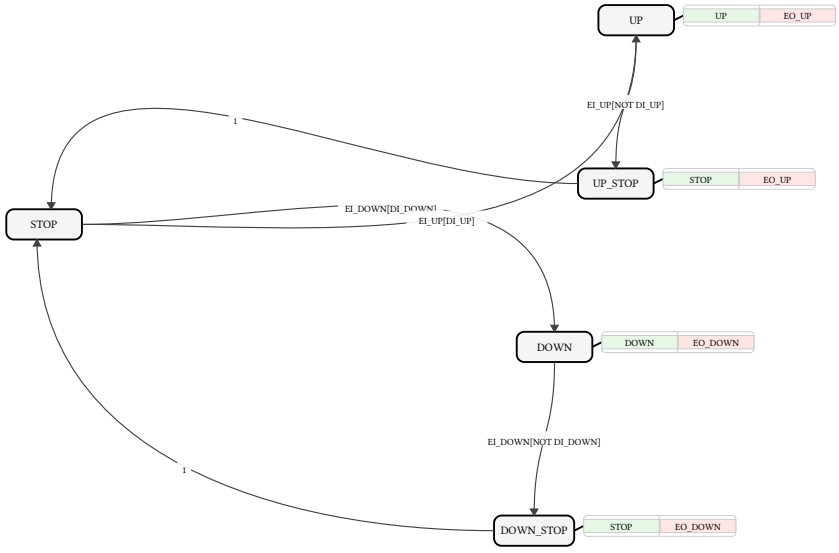
- **Alternating operation** of two consumers, e.g., feed/return valves, where both must never be active simultaneously.

- **Clock-controlled switching** between two states (e.g., direction change of a conveyor belt) using the toggle inputs.
- **Central reset function** for a group of bistable actuators via the `R` input.



Comparison with Similar Function Blocks

Compared to a simple set-reset flip-flop (e.g., `E_SR`), **ILOCK_2_E_AX** offers two outputs with integrated interlocking and a toggle function. While `E_SR` only switches a single output, this function block can control two coupled signals. The use of adapters instead of direct data ports allows for standardized and reusable coupling with other components.



Conclusion

The **ILOCK_2_E_AX** function block is a compact, event-driven component for implementing interlocked, bistable outputs with an optional toggle function. Thanks to its adapter-based interface and the clear separation of setting, toggling, and resetting, it is particularly suitable for safety-critical or logically linked control tasks in automation technology.

ILOCK_BLOCK

ECC: ILOCK_BLOCK

• – ○ • – ○ • – ○ •

Introduction

The function block **ILOCK_BLOCK** implements an interlock between two opposing signals. It prioritizes the first arriving active signal and ignores all subsequent conflicting signals until the initial signal is released. This ensures that two opposing actions (e.g., Up/Down, Right/Left) are never activated simultaneously.

Interface Structure

Event Inputs

Event	With Variable	Description
EI_UP	DI_UP	Event to Set UP Direction
EI_DOWN	DI_DOWN	Event to set the DOWN direction

Event Outputs

Event	With Variable	Description
EO_UP	DO_UP	Triggered when the UP direction is activated or deactivated
EO_DOWN	DO_DOWN	Triggered when the DOWN direction is activated or deactivated

Data Inputs

| Variable | Type | Comment | | |---|---|---| | DI_UP | BOOL | TRUE = forward, upward, right, clockwise | | DI_DOWN | BOOL | TRUE = backward, downward, left, counterclockwise |

Data Outputs

Variable	Type	Comment
DO_UP	BOOL	TRUE = forward, upward, right, clockwise
DO_DOWN	BOOL	TRUE = backward, downward, left, counterclockwise

Adapter

None.

Functionality

The module has two activation states (UP, DOWN) and two intermediate states (UP_STOP, DOWN_STOP) for deactivation. Control is achieved exclusively via the event inputs in conjunction with the data inputs.

- **In the idle state (STOP)**, both outputs are set to FALSE.
- **UP activation:** When the event EI_UP with DI_UP = TRUE arrives, the state changes to **UP**. In this state, DO_UP = TRUE and DO_DOWN = FALSE are set, and EO_UP is output.
- **DOWN Activation:** When the event EI_DOWN with DI_DOWN = TRUE occurs, the state changes to **DOWN**. DO_UP = FALSE and DO_DOWN = TRUE are set, and EO_DOWN is output.
- **Deactivation of an Active State:**
- In the UP state, another EI_UP with DI_UP = FALSE is expected (release). The state then immediately changes back to STOP via **UP_STOP** EO_UP is triggered once more (signaling the stop).
- Similarly, in the DOWN state, a new EI_DOWN followed by DI_DOWN = FALSE is required to return to STOP via **DOWN_STOP** this outputs EO_DOWN.
- **Ignoring Conflicting Signals:** As long as the function block is active (UP or DOWN), events in the opposite direction are completely ignored (no state change). This preserves the priority of the first signal.

Technical Features

- State transitions are event-driven and instantaneous (no delays).
- Unlike a simple set/reset function block, the second input direction is not accepted during the interlock; the interlock can only be released by the original event itself.
- All outputs are set back to FALSE after a stop.

State Overview

State	Description
STOP	Idle state. Both outputs FALSE. Waiting for activation.

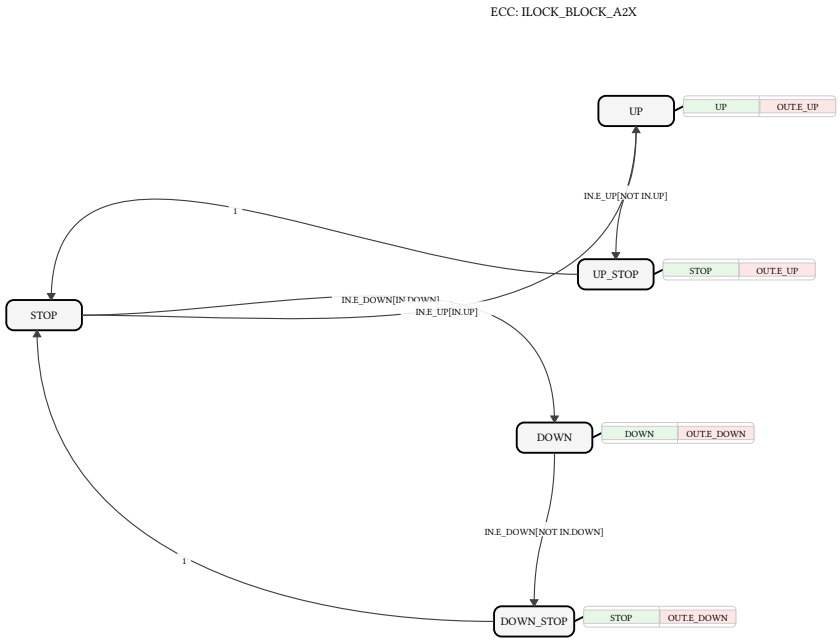
UP	UP direction active. DO_UP = TRUE, DO_DOWN = FALSE. Waiting for release by `EI_UP` with `DI_UP = FALSE`.
DOWN	DOWN direction active. DO_UP = FALSE, DO_DOWN = TRUE. Waiting for release by `EI_DOWN` with `DI_DOWN = FALSE`.
UP_STOP	Intermediate state after release of UP. Immediately executes the STOP algorithm, sends `EO_UP`, and switches back to STOP.
DOWN_STOP	Intermediate state after releasing DOWN. Immediately executes the STOP algorithm, sends `EO_DOWN`, and switches back to STOP.

DOWN_STOP **Transition Matrix (Simplified):**

- `STOP → UP` : `EI_UP` & `DI_UP = TRUE`
- `STOP → DOWN` : `EI_DOWN` & `DI_DOWN = TRUE`
- `UP → UP_STOP` : `EI_UP` & `DI_UP = FALSE`
- `DOWN → DOWN_STOP` : `EI_DOWN` & `DI_DOWN = FALSE`
- `UP_STOP → STOP` : always (immediately)
- `DOWN_STOP → STOP`: always (immediately)

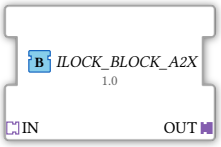
Application Scenarios

- **Motor control (e.g., lifting platform, crane):** Prevents simultaneous travel in opposite directions.
- **Valve control:** Protects against the simultaneous opening and closing of a process valve.
- **Directional interlock in conveyor systems:** Ensures that a belt only activates one direction of rotation at a time.
- **Safety-critical controls:** Enforces a clear, prioritized signal sequence.



Comparison with similar function blocks

- **Set/Reset (SR/R-SR):** Allows the simultaneous setting of both directions, which can lead to undefined states. The ILOCK_BLOCK prevents this through strict interlocking.
- **State timer (e.g., with multiple states):** Offers more flexibility but requires manual implementation of the prioritization logic. The ILOCK_BLOCK directly encapsulates this logic.
- **Simple Interlock via AND Gate:** Pure signal processing ignores the temporal sequence. The ILOCK_BLOCK reacts event-driven to the first valid activation.



Conclusion

The **ILOCK_BLOCK** is a specialized function block for interlock applications with prioritization of the first active input. Due to its clear state machine and event-driven processing, it is particularly suitable for time-critical and safety-related control systems where conflicting signals must be strictly excluded. It offers a robust alternative to classic set/reset logic and significantly reduces implementation effort.

ILOCK_BLOCK_A2X

Input for forward/up and backward/down direction – *A2X*

A2X – Output for forward/up and backward/down direction

• – ○ • – ○ • – ○ •

Introduction

The **ILOCK_BLOCK_A2X** is a basic function block (FB) that implements an interlock mechanism for directional commands (UP/DOWN) over a unidirectional A2X adapter. It prioritizes the *first* active input event and latches that direction until the corresponding input signal is withdrawn, ensuring that only one output direction can be active at a time. This makes it suitable for safety-related control of actuators such as hoists, sliding gates, or lifting platforms.

Interface Structure

The FB communicates exclusively through a single adapter pair of type `adapter::types::unidirectional::A2X`. The input socket `IN` receives events and data from the environment, while the output plug `OUT` forwards the latched state and corresponding event triggers.

Event Inputs

The events are carried by the input adapter `IN` and carry the data elements `UP` and `DOWN` as qualifiers (per IEC 61499 WITH semantics).

Event	Associated Data	Description
`IN.E_UP`	`IN.UP`	Request/trigger for the UP direction.
`IN.E_DOWN`	`IN.DOWN`	Request/trigger for the DOWN direction.

Event Outputs

The events are emitted on the output plug `OUT` together with the corresponding state data.

Event	Associated Data	Description

OUT.E_UP	OUT.UP, OUT.DOWN	Acknowledges the UP state or the UP release.
OUT.E_DOWN	OUT.UP, OUT.DOWN	Acknowledges the DOWN state or the DOWN release.

Data Inputs

The input data are accessed through the input socket IN and are only valid when the respective event is present.

Data	Type	Description
IN.UP	BOOL	Level signal requesting the UP direction.
IN.DOWN	BOOL	Level signal requesting the DOWN direction.

Data Outputs

The output data are provided on the output plug OUT and reflect the currently latched direction.

Data	Type	Description
OUT.UP	BOOL	TRUE while the UP direction is latched.
OUT.DOWN	BOOL	TRUE while the DOWN direction is latched.

Adapters

Adapter	Direction	Type	Description
IN	Socket	adapter::types::unidirectional::A2X	Receives UP/DOWN commands and events.
OUT	Plug	adapter::types::unidirectional::A2X	Sends the latched direction and events.

Functionality

The FB is implemented as a basic FB with an ECC (Execution Control Chart). It operates in a purely event-driven manner:

1. **From STOP state**
   - If IN.E_UP occurs and IN.UP is TRUE, the FB transitions to the UP state, sets OUT.UP := TRUE / OUT.DOWN := FALSE and emits OUT.E_UP.
   - If IN.E_DOWN occurs and IN.DOWN is TRUE, the FB transitions to the DOWN state, sets OUT.UP := FALSE / OUT.DOWN := TRUE and emits OUT.E_DOWN.
2. **In UP state**
   - The FB ignores any DOWN commands. If IN.E_UP occurs again while IN.UP is FALSE (the requesting signal has been released), it transitions to UP_STOP, resets both outputs to FALSE and emits OUT.E_UP to signal the release.
3. **In DOWN state**
   - Symmetrically, if IN.E_DOWN occurs while IN.DOWN is FALSE, the FB transitions to DOWN_STOP, resets both outputs to FALSE and emits OUT.E_DOWN.
4. **Stop handshake**
   - UP_STOP and DOWN_STOP are transient states; the FB immediately returns to STOP (unconditional transition), ready for the next command.

This behaviour ensures that the first active input (UP or DOWN) is prioritised and kept latched until it is explicitly withdrawn. The outputs OUT.UP / OUT.DOWN are never TRUE simultaneously, satisfying an interlock requirement.

Technical Features

- **IEC 61499-2 compliant** basic FB with ECC formalism.

- **Adapter-based interface** – uses the unidirectional `A2X` adapter type for both input and output, allowing direct connection to a partner FB via a single plug/socket pair.
- **Structured Text (ST)** algorithms for state actions.
- **Event-qualified data** – input data are sampled together with their associated event, avoiding glitches on the input line.
- **Deterministic state machine** – five ECC states (`STOP`, `UP`, `DOWN`, `UP_STOP`, `DOWN_STOP`) ensure reproducible behaviour.
- **Latched output** – the output direction is held until an explicit release event is received.
- **EPL-2.0 licensed** – can be freely used and modified in 4diac-based projects.

State Overview

State	Description	Actions / Outputs
`STOP`	Idle state, no direction latched.	none
`UP`	UP direction is latched and active.	`OUT.UP := TRUE`, `OUT.DOWN := FALSE`, emit `OUT.E_UP`
`DOWN`	DOWN direction is latched and active.	`OUT.UP := FALSE`, `OUT.DOWN := TRUE`, emit `OUT.E_DOWN`
`UP_STOP`	UP direction is being released; both outputs reset.	`OUT.UP := FALSE`, `OUT.DOWN := FALSE`, emit `OUT.E_UP`
`DOWN_STOP`	DOWN direction is being released; both outputs reset.	`OUT.UP := FALSE`, `OUT.DOWN := FALSE`, emit `OUT.E_DOWN`

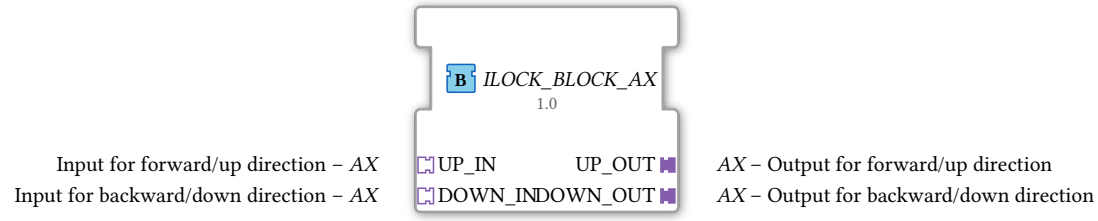
Transitions:

- `STOP` ⟶ `UP` : `IN.E_UP[IN.UP]`
- `STOP` ⟶ `DOWN` : `IN.E_DOWN[IN.DOWN]`
- `UP` ⟶ `UP_STOP` : `IN.E_UP[NOT IN.UP]`
- `DOWN` ⟶ `DOWN_STOP` : `IN.E_DOWN[NOT IN.DOWN]`
- `UP_STOP` ⟶ `STOP` : unconditional
- `DOWN_STOP` ⟶ `STOP` : unconditional

Application Scenarios

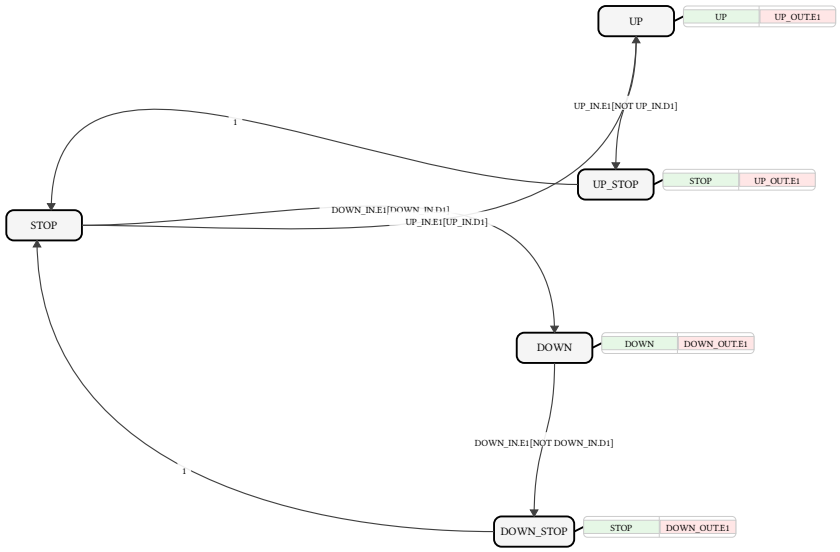
- **Actuator control** – controlling a single motor with forward/reverse (UP/DOWN) commands, e.g., roller shutters, conveyors, adjustable tables.
- **Interlocking in safety circuits** – preventing simultaneous activation of two contradictory commands (e.g., raise/lower) in manual control panels.
- **First-command priority logic** – when both directions are possible but only the first activated direction should be executed until it is released.
- **Adapter-chained signal chains** – because the FB uses unidirectional A2X adapters, it can be easily chained with other adapter-based logic blocks in a modular 4diac application.

Comparison with Similar Blocks



Feature	ILOCK_BLOCK_A2X	Classic SR Latch (RS-FF)	Plain A2X pass-through
Interface	A2X adapter (event + level)	Separate BOOL inputs	A2X adapter
Priority handling	First active input is latched	Set overrides Reset (or vice versa)	None (direct forwarding)
Direction exclusivity	Guaranteed (never both outputs `TRUE`)	Not guaranteed (can be both)	Not guaranteed
Release acknowledgement	Explicit event on stop (`E_UP` / `E_DOWN`)	None	None

Use in event-driven environment	Fully integrated (events with data)	Level-based, no events	Events forwarded, no latched state



Conclusion

The **ILOCK_BLOCK_A2X** is a robust, event-driven interlock component that elegantly enforces first-input priority and exclusive output direction. Its adapter-based design makes it highly reusable and easy to connect within IEC 61499 systems, while the explicit stop events provide clean handshaking with downstream logic. It is well suited for any application where conflicting directional commands must be safely serialised.

ILOCK_BLOCK_AX

ECC: ILOCK_BLOCK_AX

• — ○ • — ○ • — ○ •

Introduction

The function block **ILOCK_BLOCK_AX** implements an interlock for two opposing directions (up/down or forward/backward). It prioritizes the first active input and ensures that only one direction can be active at a time. The block is implemented as a basic function block (FB) according to IEC 61499-2.

Interface Structure

The function block uses adapter interfaces of type `adapter::types::unidirectional::AX`. Each adapter consists of an event input `E1` and a data input `D1` (BOOL).

Event Inputs

No discrete event inputs. Events are received via the adapter interfaces:

- `UP_IN.E1` – Upward/forward direction event
- `DOWN_IN.E1` – Downward/backward direction event

Event Outputs

No discrete event outputs. Outputs are provided via the adapter plugs:

- `UP_OUT.E1` – Event when the up direction is enabled/disabled
- `DOWN_OUT.E1` – Event when the down direction is enabled/disabled

Data Inputs

- `UP_IN.D1` (BOOL) – Validation signal for the up direction
- `DOWN_IN.D1` (BOOL) – Validation signal for the down direction

Data Outputs

- `UP_OUT.D1` (BOOL) – Validation signal for the up direction at the output
- `DOWN_OUT.D1` (BOOL) – Validation signal for the down direction at the output

Adapters

- **Sockets (Inputs):**
- `UP_IN` – Adapter for upward control
- `DOWN_IN` – Adapter for downward control
- **Plugs (Outputs):**
- `UP_OUT` – Adapter for upward output
- `DOWN_OUT` – Adapter for downward output

Functionality

The module operates using a finite state logic controller (ECC). It starts in the **STOP** state. As soon as one of the two events occurs and the corresponding `D1` signal is `TRUE`, it switches to the corresponding directional state. The state is maintained as long as `D1` of the active input remains `TRUE`. If the `D1` signal of the active input is set to `FALSE` (upon a subsequent event), the machine first switches to a **stop intermediate state** (UP_STOP or DOWN_STOP) and then automatically returns to **STOP**. The other input is ignored as long as one direction is active – the function block prioritizes the input that was active first.

The algorithms set the output signals:

- **UP**: `UP_OUT.D1 := TRUE`, `DOWN_OUT.D1 := FALSE`
- **DOWN**: `UP_OUT.D1 := FALSE`, `DOWN_OUT.D1 := TRUE`
- **STOP**: Both outputs set to `FALSE`

Technical Features

- **Prioritizing the first active input:** Only the first valid command received is executed; The other is blocked until the active one is deactivated.
- **Adapter-based interface:** The use of adapters of type `unidirectional::AX` allows flexible coupling with other components without direct event/data separation.
- **Interlocking at the automaton level:** The state transitions simulate hardware-level safety – `UP_OUT.D1` and `DOWN_OUT.D1 = TRUE` can never occur simultaneously.
- **Intermediate states:** The states `UP_STOP` and `DOWN_STOP` ensure that deactivation is properly acknowledged with an event on the corresponding output adapter.

State overview

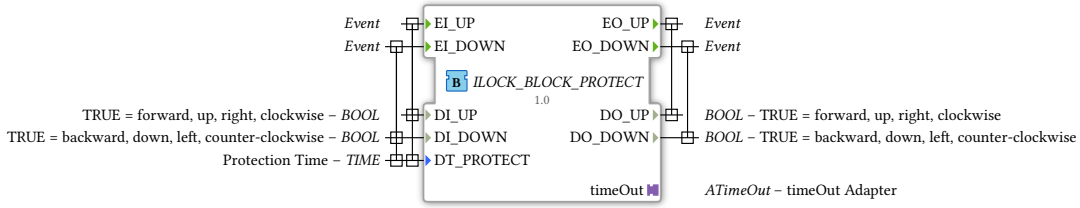
State	Description	Output signals
STOP	Idle state, no direction active	`UP_OUT.D1 = FALSE`, `DOWN_OUT.D1 = FALSE`
UP	Up direction active	`UP_OUT.D1 = TRUE`, `DOWN_OUT.D1 = FALSE`
DOWN	Down direction active	`UP_OUT.D1 = FALSE`, `DOWN_OUT.D1 = TRUE`
UP_STOP	Disable UP (exit immediately)	`UP_OUT.D1 = FALSE`, `DOWN_OUT.D1 = FALSE`
DOWN_STOP	Disable DOWN (exit immediately)	`UP_OUT.D1 = FALSE`, `DOWN_OUT.D1 = FALSE`

Transitions:

- `STOP` → `UP` on event from `UP_IN` to `UP_IN.D1 = TRUE`
- `STOP` → `DOWN` on event from `DOWN_IN` to `DOWN_IN.D1 = TRUE`
- `UP` → `UP_STOP` on event from `UP_IN` to `UP_IN.D1 = FALSE`
- `DOWN` → `DOWN_STOP` on event from `DOWN_IN` to `DOWN_IN.D1 = FALSE`
- `UP_STOP` → `STOP` automatically (Transition 1)
- `DOWN_STOP` → `STOP` automatic (Transition 1)

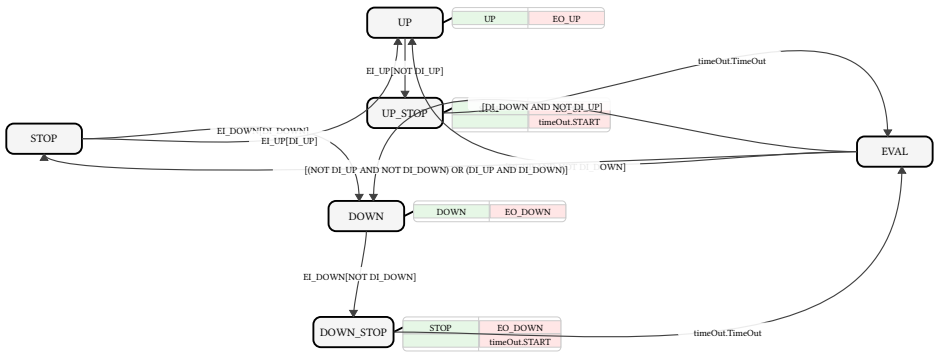
Application Scenarios

- **Traction control (e.g., lifting tables, conveyor belts):** Prevents simultaneous up/down movement.
- **Valve control:** Opening/closing a slide valve with mutual interlocking.
- **Safety-related logic:** Ensures that both drive directions are never activated simultaneously.
- **Control of switches or flaps:** Only one position may be active.



Comparison with similar function blocks

Compared to a simple RS flip-flop, `ILOCK_BLOCK_AX` offers explicit interlocking and the consideration of validation signals (`D1`). A conventional SR function block would allow simultaneous activation of both outputs without external logic. This function block guarantees mutual exclusivity at the state level.



Conclusion

ILOCK_BLOCK_AX` is a compact, safety-oriented functional block for interlocking two opposing directions. Its adapter-based interface and clearly defined mechanism make it easy to integrate and reliable in applications requiring exclusive directional control.

ILOCK_BLOCK_PROTECT

ECC: ILOCK_BLOCK_PROTECT

• – ○ • – ○ • – ○ •

Introduction

The function block `ILOCK_BLOCK_PROTECT` implements an interlock-protected direction control with an adjustable dead time. As soon as an active input (e.g., `EI_UP` with `DI_UP = TRUE`) is detected, it is prioritized, and all conflicting signals are ignored until the active input is reset. After resetting, a configurable protection time (`DT_PROTECT`) elapses before a new direction can be activated. This reliably prevents unwanted direction changes or short circuits.

Interface Structure

Event Inputs

Event	with variables	Description
`EI_UP`	`DI_UP`, `DT_PROTECT`	Event to activate forward direction
`EI_DOWN`	`DI_DOWN`, `DT_PROTECT`	Event to activate reverse direction

Event Outputs

Event	with variables	Description
`EO_UP`	`DO_UP`	Acknowledge active forward direction
`EO_DOWN`	`DO_DOWN`	Acknowledge active reverse direction

Data Inputs

Variable	Type	Initial Value	Description
`DI_UP`	BOOL	–	`TRUE` = forward, upward, right, clockwise
`DI_DOWN`	BOOL	–	`TRUE` = reverse, downward, left, counterclockwise
`DT_PROTECT`	TIME	`T#50ms`	Dead time after resetting a direction

Data Outputs

Variable	Type	Description
`DO_UP`	BOOL	`TRUE` = Forward direction active
`DO_DOWN`	BOOL	`TRUE` = Reverse direction active

Adapters

Adapter	Type	Description
`timeOut`	`iec61499::events::ATimeOut`	Adapter for the time-based control of dead time

Functionality

The function block operates according to the **first priority** principle:

1. **Initial state (`STOP`)**

Both outputs are `FALSE`. When an event with a valid condition is received (e.g., `EI_UP` for `DI_UP = TRUE`), the state changes in the corresponding direction (`UP` or `DOWN`).

1. **Directional States (`UP` / `DOWN`)**

The corresponding output (`DO_UP` or `DO_DOWN`) is set to `TRUE`, the other to `FALSE`.
As long as the active input remains active, new events are ignored (especially opposing ones).
A new event with the same input is only processed if the input previously fell to `FALSE` (falling edge) – see `UP_STOP`/`DOWN_STOP`.
... 3. **Reset to Protection Phase (`UP_STOP` / `DOWN_STOP`)**

If the active input is reset (e.g., DI_UP from TRUE to FALSE), the output is immediately set to FALSE and the timer timeOut is started. The dead time DT_PROTECT begins to run.

1. **Evaluation State (EVAL)**

After the dead time has elapsed, the function block leaves the protection phase and enters the EVAL state. The following decisions are made based on the current inputs:

- DI_UP = TRUE and DI_DOWN = FALSE ⟶ Transition to UP
- DI_DOWN = TRUE and DI_UP = FALSE ⟶ Transition to DOWN
- Both FALSE or both TRUE ⟶ Return to STOP

Important: As long as a new event arrives in the state UP/DOWN while the corresponding input is still TRUE, this event is ignored (no State transition). The stop phase is only initiated upon a falling edge.

Technical Features

- **Internal timer** via adapter timeOut (type ATimeOut) – the protection time is started by each state transition that deactivates a direction.
- **No simultaneous outputs** – DO_UP and DO_DOWN are never simultaneously TRUE. In the EVAL state, both outputs are FALSE.
- **Configurable dead time** via input DT_PROTECT (factory default 50 ms).
- **Compact implementation** as a Basic Function Block with a finite state machine (6 states).
- The interlock not only prevents conflicting commands but also enforces a minimum pause between two direction changes.

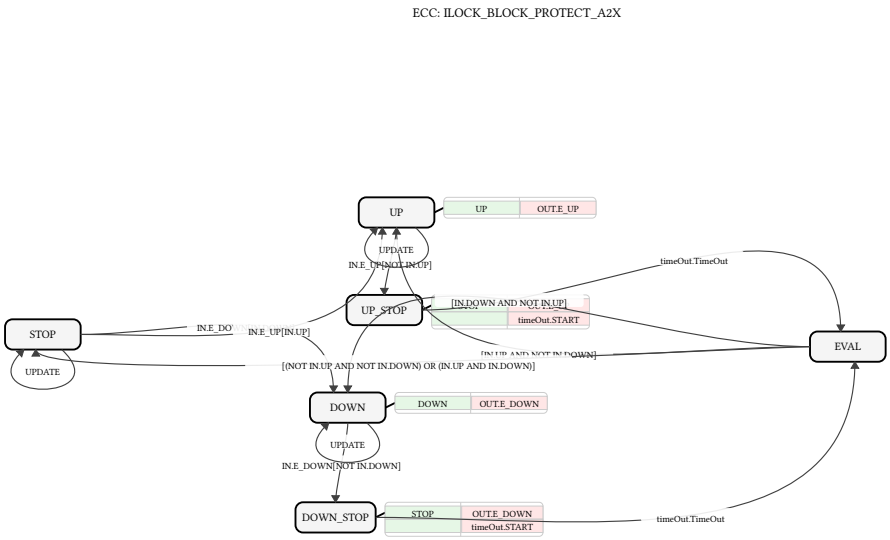
State Overview

State	Description
STOP	Idle state: both outputs FALSE, waiting for the first valid event
UP	Forward direction active: DO_UP = TRUE, DO_DOWN = FALSE
DOWN	Reverse direction active: DO_DOWN = TRUE, DO_UP = FALSE
UP_STOP	Protection phase after resetting the forward direction: DO_UP to FALSE, timer running
DOWN_STOP	Protection phase after resetting the reverse direction: DO_DOWN to FALSE, timer running
EVAL	Evaluation state after timer expiration: Decision on next direction or return to STOP

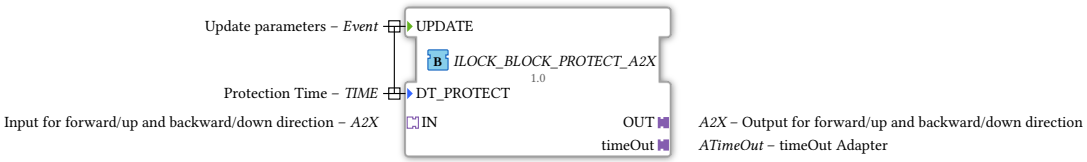
Application Scenarios

- **Directional control of motors** (e.g., conveyor belts, hoists, revolving gates) – prevents simultaneous control in both directions and enforces a dead time for the mechanical change of direction.
- **Interlocking of valves or flaps** – e.g., open/close control with protection against rapid switching to prevent mechanical stress.
- **Safety-related controls** – as part of a simple interlock logic when a safety-certified component is not required.
- **Control of feeders** in agricultural technology (see Copyright HR Agrartechnik GmbH) or in conveyor technology.

Comparison with similar components



Component	Properties
SR Flip-Flop	Simple set/reset logic, no dead time, no protection against simultaneous signals
ILOCK_BLOCK_PROTECT	Prioritizes the first active input, dead time after each direction change, both outputs never active simultaneously TRUE
Interlock Block without Timer	Blocking logic only, immediate switching possible, no protection time
RS Lock with Time Delay	Similar, but often less configurable and event-driven



The ILOCK_BLOCK_PROTECTIt offers an integrated, configurable dead time and is specifically optimized for event-driven systems according to IEC 61499.

Conclusion

The ILOCK_BLOCK_PROTECT is ideally suited for applications requiring reliable directional interlocking with adjustable protection time. Its clear state machine and use of the standard ATimeOut adapter make it easy to integrate into larger control projects. Prioritizing the first active input ensures deterministic behavior, and the enforced dead time protects both the mechanical components and the control logic from unwanted states.

ILOCK_BLOCK_PROTECT_A2X

• – ○ • – ○ • – ○ •

Introduction

The ILOCK_BLOCK_PROTECT_A2X function block implements an interlock mechanism for UP/DOWN control signals with a configurable protection dead-time. It prioritizes the first active input and suppresses conflicting commands during the protection interval, preventing rapid switching and potential mechanical or logical damage.

This block is an adapter-based version using the A2X type for unidirectional UP/DOWN signals, and a timer adapter for dead-time handling.

Interface Structure

Event Inputs

- **UPDATE** (Event) – Triggers an update of the protection time parameter (DT_PROTECT). While in any state, an UPDATE event causes the block to refresh its internal parameter without altering the current output state.

Event Outputs

None. The block does not produce direct event outputs. All state changes are reflected through the adapter outputs.

Data Inputs

- **DT_PROTECT** (TIME) – Protection dead-time. Default: T#50ms. This value defines the minimum time during which the output state is held after a change, ignoring conflicting input changes.

Data Outputs

None directly. Output data is provided via the OUT adapter.

Adapters

- **OUT** (Plug, type `adapter::types::unidirectional::A2X`) – Output adapter carrying the UP and DOWN boolean signals to the controlled device.
- **timeOut** (Plug, type `iec61499::events::ATimeOut`) – Timer adapter used to measure the protection dead-time. It receives the DT value and emits a TimeOut event when the interval expires.
- **IN** (Socket, type `adapter::types::unidirectional::A2X`) – Input adapter receiving the UP and DOWN commands from the source.

Functionality

The block acts as a priority interlock with dead-time protection:

1. **Idle (STOP)** – No active output. When either UP or DOWN becomes active (and the other is inactive), the block transitions to the corresponding active state (UP or DOWN) and sets the appropriate output.
2. **Active (UP or DOWN)** – The corresponding output is set. If the active input is released (goes FALSE) or the opposite input becomes active, the block enters a stop phase (UP_STOP or DOWN_STOP) while keeping the current output signal active for the protection time.
3. **Stop Phase (UP_STOP or DOWN_STOP)** – The output is cleared, but the timer is started. After the dead-time expires, the block evaluates the input conditions and moves to:
   - UP if only UP is active,
   - DOWN if only DOWN is active,
   - STOP if both are inactive or both active.
4. **Evaluation (EVAL)** – This state occurs after the dead-time and decides the next state based on the inputs.

The priority rule is: if both UP and DOWN are simultaneously active, the block goes to STOP (no output). If only one is active, that direction is selected. If none, it stays STOP.

The dead-time ensures that after a change, any subsequent changes within the protection time are ignored, preventing rapid toggling.

Technical Features

- Adapter-based design using A2X for propagation of UP/DOWN signals.
- Configurable dead-time via DT_PROTECT input.
- Handles input changes gracefully with a timer-based state machine.
- Supports runtime parameter updates via the UPDATE event.
- Meets IEC 61499 standard for function blocks.

State Overview

The block has six states:

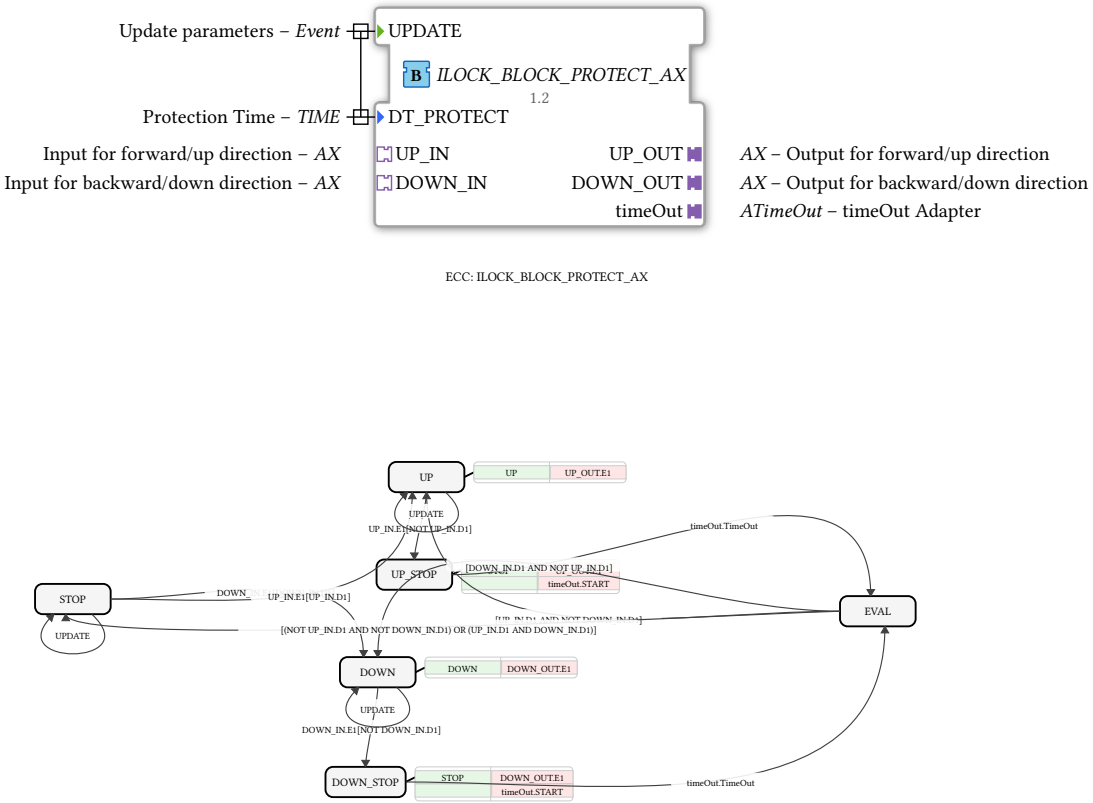
- **STOP**: No outputs active. Waits for valid UP/DOWN command.
- **UP**: UP output active, DOWN inactive.
- **DOWN**: DOWN output active, UP inactive.
- **UP_STOP**: Entered when UP input goes inactive or DOWN becomes active while in UP. Output is cleared and timer starts.
- **DOWN_STOP**: Entered when DOWN input goes inactive or UP becomes active while in DOWN. Output is cleared and timer starts.
- **EVAL**: After timer expiry, evaluates inputs to determine next state.

Transitions are based on input events (IN.E_UP, IN.E_DOWN) combined with the boolean values (IN.UP, IN.DOWN) and the timer TimeOut event.

Application Scenarios

This block is suitable for:

- Controlling bidirectional drives (e.g., motors, actuators) where conflicting commands must be avoided.
- Systems requiring a minimum dwell time between direction changes to protect mechanical components.
- Applications using adapter-based communication (A2X) in IEC 61499 distributed control systems.



Comparison with Similar Blocks

Compared to a simple interlock block without dead-time, this block adds a protection period to prevent rapid switching. The use of the A2X adapter allows easier integration with other A2X-compatible components, and the timer adapter makes the dead-time configurable. It is more robust than a direct logic block because it incorporates time-based state management.

Conclusion

The ILOCK_BLOCK_PROTECT_A2X provides a reliable interlock solution with adjustable dead-time, leveraging adapter-based communication in IEC 61499. Its state machine ensures safe operation by prioritizing the first active input and suppressing conflicting commands during the protection interval.

ILOCK_BLOCK_PROTECT_AX

• – ○ • – ○ • – ○ •

Introduction

The function block `ILOCK_BLOCK_PROTECT_AX` implements a prioritized interlock for two opposing directions (UP/DOWN) while taking into account a configurable protection dead time. The block is implemented as an adapter version, meaning that the inputs and outputs are provided via IEC 61499 adapters. The goal is the safe control of actuators where only one direction may be active at a time, for

example, during lifting or swiveling movements. The first activated input takes precedence; a change in direction only occurs after the protection time has elapsed and a new evaluation has been performed.

Interface Structure

Event Inputs

Name	Type	Data Carried	Description
`UPDATE`	Event	`DT_PROTECT`	Event for dynamically updating the protection time `DT_PROTECT`.

Event Outputs

The FB does not have any standalone event outputs. Events are provided via the adapters `UP_OUT`, `DOWN_OUT`, and `timeOut`, which are implemented as *plugs*.

Adapter Output	Event	Description
`UP_OUT`	`E1`	Triggered when the UP state is active or the UP_STOP state is reached.
`DOWN_OUT`	`E1`	Triggered when the DOWN state is active or the DOWN_STOP state is reached.
`timeOut`	`TimeOut`	Triggered when the set protection time has expired (generated by the adapter itself).

Data Inputs

Name	Type	Initial Value	Description
`DT_PROTECT`	TIME	`T#50ms`	Protection time that elapses after an input is deactivated before the inputs are re-evaluated.

Data Outputs

The FB does not have any standalone data outputs. Output data is provided via the adapters `UP_OUT`, `DOWN_OUT`, and `timeOut`.

Adapter Output	Data	Description
`UP_OUT`	`D1` (BOOL)	Signals the active UP state (`TRUE`) or inactive UP state (`FALSE`).
`DOWN_OUT`	`D1` (BOOL)	Signals the active DOWN state (`TRUE`) or inactive DOWN state (`FALSE`).
`timeOut`	`DT` (TIME)	Set by the algorithm to the value of `DT_PROTECT` and determines the timer duration.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AX`	`UP_IN`	Socket	Input for the UP direction. The rising edge event `E1` activates processing; `D1` (BOOL) specifies the desired state.
`adapter::types::unidirectional::AX`	`DOWN_IN`	Socket	Input for the DOWN direction. Analogous to `UP_IN`.
`adapter::types::unidirectional::AX`	`UP_OUT`	Plug	Output for the UP direction. Provides the event and data for the connected logic.
`adapter::types::unidirectional::AX`	`DOWN_OUT`	Plug	Output for the DOWN direction. Provides the event and data.

iec61499::events::ATimeOut	timeOut	Plug	Adapter for a timer. The function block sets the duration (DT) and starts the timer via the event START. The event TimeOut signals the completion of the timer.

Functionality

The function block operates as a state-controlled interlock with two priority inputs. The basic functionality is as follows:

1. **Initial state** (STOP): No direction is active. An incoming event at UP_IN.E1 or DOWN_IN.E1 is processed only if the corresponding data signal D1 has the value TRUE. The first input that meets this condition changes to the corresponding state (UP or DOWN). If both are TRUE simultaneously, neither is accepted – the function block remains in STOP.

The first input that meets this condition changes to the corresponding state (UP or DOWN). 2. **Active State** (UP or DOWN): The output adapter (UP_OUT or DOWN_OUT) signals the active direction via D1 = TRUE and triggers the event E1. The protection time is stored in the timer, but it is not yet active.

1. **Deactivation and Protection Time**: When the active input resets its data signal to FALSE (or the event without TRUE), the FB switches to the corresponding stop state (UP_STOP or DOWN_STOP). The output is set to FALSE, and the timer is started via the event timeOut.START. After the set protection time has elapsed (timeOut.TimeOut), the function block switches to the evaluation state (EVAL).

The function block is set to FALSE, and the timer is started via the event timeOut.START. 4. **Evaluation** (EVAL): In the evaluation state, the current data signals of both inputs are evaluated:

- Only UP_IN.D1 = TRUE ⟶ Switch to UP
- Only DOWN_IN.D1 = TRUE ⟶ Switch to DOWN
- Neither or both TRUE ⟶ Switch back to STOP

1. **Dynamic Update**: The event UPDATE allows the protection time DT_PROTECT to be changed during operation. The updated time takes effect the next time the timer is used (the timer is only started in the stop states). The event can be received in any state without changing the current control state.

Technical Features

- **Adapter Interface**: All data exchange takes place via adapters. This ensures a clean separation between control logic and peripherals, increases reusability, and improves encapsulation.
- **Dynamic Protection Time**: The dead time can be changed at runtime via the UPDATE event without restarting the function block. This is particularly useful in applications with variable switching times (e.g., temperature-dependent delays).
- **Dead Time Principle**: After an input is deactivated, the function block does not immediately switch to the other state, but enforces a minimal delay (DT_PROTECT). This prevents bounce or unwanted rapid switching.
- **Prioritization after first activation**: The logic only reacts to the first TRUE signal of an input event. Simultaneous activation of both inputs does not result in a change of direction.
- **Self-holding without external event**: As long as an active input maintains its D1 at TRUE, the corresponding output state is retained, even without further events.

State Overview

State	Description	Activities
STOP	Initial and idle state. No direction active.	–
UP	UP direction active.	Algorithm UP: setsUP_OUT.D1 = TRUE, DOWN_OUT.D1 = FALSE, transfers DT_PROTECT to timeOut.DT and sends UP_OUT.E1.
DOWN	DOWN direction active.	Algorithm DOWN: sets DOWN_OUT.D1 = TRUE, UP_OUT.D1 = FALSE, transfers DT_PROTECT to timeOut.DT and sends DOWN_OUT.E1.

UP_STOP	Wait time after deactivating UP.	Algorithm STOP: sets both outputs to FALSE, transfers DT_PROTECT to timeOut.DT, and starts the timer with timeOut.START.
DOWN_STOP	Wait time after deactivating DOWN.	Algorithm STOP (analogous to UP_STOP).
EVAL	Evaluation after the protection period expires.	No algorithm; the transitions determine the next state based on the current input data.

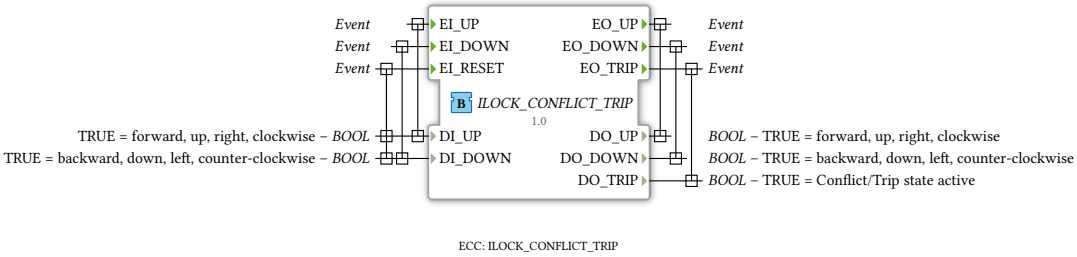
Transitions (Simplified):

- STOP → UP if UP_IN.E1 and UP_IN.D1 = TRUE
- STOP → DOWN if DOWN_IN.E1 and DOWN_IN.D1 = TRUE
- UP → UP_STOP if UP_IN.E1 and UP_IN.D1 = FALSE
- DOWN → DOWN_STOP if DOWN_IN.E1 and DOWN_IN.D1 = FALSE
- UP_STOP → EVAL if timeOut.TimeOut
- DOWN_STOP → EVAL if timeOut.TimeOut
- EVAL → UP if UP_IN.D1 = TRUE and DOWN_IN.D1 = FALSE
- EVAL → DOWN if DOWN_IN.D1 = TRUE and UP_IN.D1 = FALSE
- EVAL → STOP if both FALSE or both TRUE
- In any state, the event UPDATE can return to the same state (only used to update DT_PROTECT).

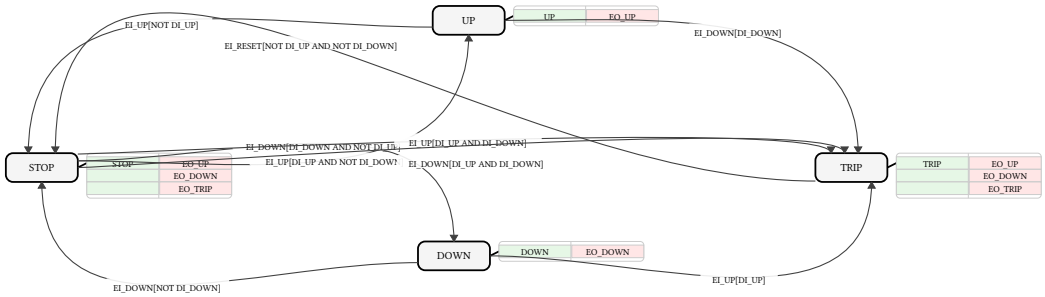
Application Scenarios

- **Lifting Platform Control**: Interlocking of lifting and lowering; after releasing the lifting command, a dead time of, for example, 100 ms is observed before lowering is possible.
- **Valve Control**: Switching between two media (e.g., heating/cooling) with a protection time to prevent pressure surges.
- **Robot Axes**: Collision prevention through simultaneous control of opposing movements.
- **Door Control**: Opening/closing with a delay when changing direction to protect end stops.

Comparison with Similar Function Blocks



Function Block / Property	ILOCK_BLOCK_PROTECT_AX	Simple Interlock (without dead time)	Interlock with fixed dead time
Dead Time	Dynamically configurable via UPDATE	None	Fixed (usually wired in the block)
Interface	Adapter (AX), loose coupling	Mostly direct inputs/outputs	Direct inputs/outputs
Priority	First active input	Often fixed priority	Varies
Evaluation after dead time	Yes, with a clear state machine	No	Partially
Flexibility	High (runtime change)	Low	Medium



The ILOCK_BLOCK_PROTECT_AX offers a particularly flexible solution thanks to its adapter interface and dynamically adjustable dead time. It is ideal for modular, reusable control projects according to IEC 61499.

Conclusion

The ILOCK_BLOCK_PROTECT_AX function block is a robust, state-controlled interlocking block for two opposing directions. The combination of prioritization of the first active input, a configurable protection dead time, and a full adapter interface makes it an excellent choice for safe and flexible control tasks in automation technology. Dynamic adjustment of the dead time via the UPDATE event increases adaptability to changing process conditions. Thanks to its clear state machine and compliance with IEC 61499 standards, the module can be used in both simple and complex distributed systems.

ILOCK_CONFLICT_TRIP

• – ○ • – ○ • – ○ •

Introduction

The **ILOCK_CONFLICT_TRIP** function block is used for **prioritized interlocking** with **conflict detection**. It evaluates two opposing binary signals (e.g., “Forward” and “Reverse”) and only actively passes on one of the two commands as long as they are not present simultaneously. If both inputs are active at the same time, a **trip state** (error/lock) is triggered, which can only be cleared by an explicit reset (with inactive inputs). This function block is specifically designed for safety-critical applications where conflicting control commands must be reliably detected.

Interface Structure

Event Inputs

Event	Description
EI_UP	Event for processing an “up” request (with data `DI_UP`)
EI_DOWN	Event for processing a “down” request (with data `DI_DOWN`)
EI_RESET	Event for resetting the trip state (reads both data inputs)

Event Outputs

Event	Description
EO_UP	Acknowledges the output of the “up” command (when the UP state is active)

EO_DOWN	Acknowledges the output of the “down” command (when the DOWN state is active)
EO_TRIP	Indicates that a trip state exists (when TRIP is active)

Data Inputs

Name	Type	Description
DI_UP	BOOL	TRUE = forward, up, right, clockwise
DI_DOWN	BOOL	TRUE = backward, down, left, counterclockwise

Data Outputs

Name	Type	Description
DO_UP	BOOL	TRUE = “Up” output active
DO_DOWN	BOOL	TRUE = Output “Down” active
DO_TRIP	BOOL	TRUE = Conflict/Trip state active

Adapters

No adapters available.

Functionality

The function block has four operating states: **STOP**, **UP**, **DOWN**, and **TRIP**.

- **STOP (Idle State):** Both data outputs are FALSE.
- With `EI_UP` with `DI_UP = TRUE` and `DI_DOWN = FALSE`, the block switches to the **UP** state.
- With `EI_DOWN` with `DI_DOWN = TRUE` and `DI_UP = FALSE`, it switches to **DOWN**.
- If `EI_UP` or `EI_DOWN`, and both data inputs are TRUE, it switches directly to **TRIP** (conflict).
- **UP (upward active):** `DO_UP = TRUE`, `DO_DOWN = FALSE`, `DO_TRIP = FALSE`.
- If `EI_UP` is encountered again, and `DI_UP = FALSE` is encountered again, it switches back to **STOP** (deactivation).
- If `EI_DOWN` is encountered, and `DI_DOWN = TRUE` is encountered, it switches to **TRIP** (an opposing request is detected during operation).
- **DOWN (Active Downward):** `DO_DOWN = TRUE`, `DO_UP = FALSE`, `DO_TRIP = FALSE`.
- On `EI_DOWN`, when `DI_DOWN = FALSE` occurs again, it switches to **STOP**.
- On `EI_UP`, when `DI_UP = TRUE` occurs, it switches to **TRIP**.
- **TRIP (Error/Lock):** `DO_TRIP = TRUE`, both direction outputs FALSE.
- **Only way to exit the trip:** A `EI_RESET` event where `DI_UP = FALSE` and `DI_DOWN = FALSE` are present. Then it returns to **STOP**.

Prioritization mechanism: The first valid input received is served until it is withdrawn or a conflict with the other input occurs. Simultaneous TRUE values on both data inputs immediately lead to the trip state.

Technical features

- **Reset only allowed in trip:** The function block can only be reset from the TRIP state to the STOP state by `EI_RESET`. A reset during normal states (UP/DOWN/STOP) has no effect.
- **Conditions for Trip Transitions:**
- From STOP: `(EI_UP UND DI_UP UND DI_DOWN)` OR `(EI_DOWN UND DI_UP UND DI_DOWN)`
- From UP: `(EI_DOWN UND DI_DOWN)`
- From DOWN: `(EI_UP UND DI_UP)`
- **Event Acknowledgment:** The event outputs are **always** output together with the data outputs (see `With` links), so the caller can immediately access the new state.
- **Use of 4diac (IEC 61499):** The FB is implemented as a Basic Function Block with its own ECC (Execution Control Chart).

State Overview

State	DO_UP	DO_DOWN	DO_TRIP	Description
STOP	FALSE	FALSE	FALSE	Idle state, no direction active
UP	TRUE	FALSE	FALSE	Upward direction active
DOWN	FALSE	TRUE	FALSE	Downward direction active
TRIP	FALSE	FALSE	TRUE	Conflict/lock active

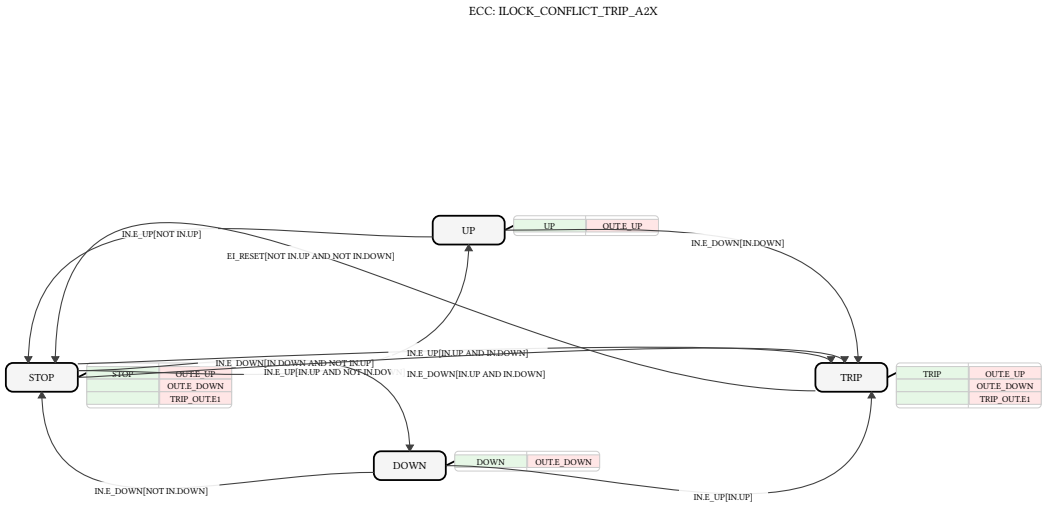
Application Scenarios

- **Motor control for linear units or rotary actuators:** Prevents simultaneous forward/reverse commands.
- **Hydraulic valve control:** Protection against conflicting switching commands (e.g., raising and lowering simultaneously).
- **Safety Interlock in Automation:** Detection of operator errors and triggering of a safe stop.
- **PLC Replication in Distributed Systems:** As part of a control logic that must avoid conflicting states.

Comparison with Similar Function Blocks

- **SR Latch / Flip-Flop:** A simple SR latch stores a state but does not detect conflicts with simultaneous "Set" and "Reset" signals. ILOCK_CONFLICT_TRIP enters the trip state instead of creating an undefined state.
- **F_TRIG / R_TRIG (Edge Detection):** These function blocks only detect signal edges but do not have any interlock logic.
- **Standard Interlock Function Blocks (e.g., from IEC 61131-3):** Many offer simple mutual interlocking (e.g., motor interlocking) but no dedicated trip state with a reset requirement. The ILOCK_CONFLICT_TRIP is more robust in fault situations.

Conclusion



The **ILOCK_CONFLICT_TRIP** is a compact, safety-oriented function block for the robust interlocking of two opposing control signals. It offers clear prioritization of the first activated input, detects conflicts through simultaneous activity, and forces an explicit reset after a fault. Its state machine is easy to understand and is ideally suited for applications where conflicting control commands must be reliably intercepted—for example, in machine or vehicle control.

ILOCK_CONFLICT_TRIP_A2X

• — ○ • — ○ • — ○ •

Introduction

The **ILOCK_CONFLICT_TRIP_A2X** function block implements an interlock mechanism for control applications requiring a safe handling of conflicting directional commands. It accepts two mutually exclusive direction signals (e.g., forward/up and backward/down) via a single bidirectional adapter and ensures that only one direction is ever active at a time. If both commands are present simultaneously, the block enters a **trip** state, setting a dedicated alarm output. Recovery from the trip state requires an explicit reset event, but only after both conflicting inputs have been released.

Interface Structure

The block communicates exclusively through adapter instances. There are no dedicated event or data ports other than the reset event input.

Event Inputs

Event	Description
`EI_RESET`	Clears the trip state when the conflict is resolved (i.e., both `IN.UP` and `IN.DOWN` are `FALSE`).

Event Outputs

There are no direct event output ports. All event-driven signalling is performed via the adapter outputs (`OUT.E_UP`, `OUT.E_DOWN`, `TRIP_OUT.E1`).

Data Inputs

There are no standalone data inputs. All data is read from the `IN` adapter (see below).

Data Outputs

There are no standalone data outputs. All data values are written to the OUT and TRIP_OUT adapters.

Adapters

Adapter	Type	Description
IN	adapter::types::unidirectional::A2X	Receives the directional commands. Carries the events E_UP, E_DOWN and the data signals UP, DOWN.
OUT	adapter::types::unidirectional::A2X	Mirrors the currently active and safe direction. Provides the events E_UP, E_DOWN and data UP, DOWN.
TRIP_OUT	adapter::types::unidirectional::AX	Outputs the trip status. Contains the event E1 and data D1 (trip indication, TRUE when tripped).

Functionality

The block operates as a state machine with four states: STOP, UP, DOWN, and TRIP. Its core logic is as follows:

- **STOP**: No direction is active. The block waits for a valid event on the IN adapter.
- **UP / DOWN**: A single direction is active. The corresponding output data and event are sent.
- **TRIP**: A conflict has been detected. The block deactivates both directions, sets TRIP_OUT.D1 to TRUE, and emits the trip event. It remains in this state until an EI_RESET event occurs while both IN.UP and IN.DOWN are FALSE.

The block prioritises the first active input: if only one of the two inputs is active, the block moves to the corresponding state. If both inputs become active simultaneously (or while a direction is already active and the other input arrives), the block immediately trips. This ensures that opposing commands can never be forwarded to the actuator.

Technical Features

- **State machine based on IEC 61499 ECC** – implemented as a basic function block.
- **Adapter-based I/O** – uses unidirectional adapters to separate input and output paths.
- **Conflict detection** – immediately reacts to simultaneous UP and DOWN signals.
- **Reset safety** – the trip state can only be cleared when the conflict has been fully removed (both inputs FALSE).
- **Event synchronisation** – transitions are triggered by events on the IN adapter, ensuring deterministic behaviour.

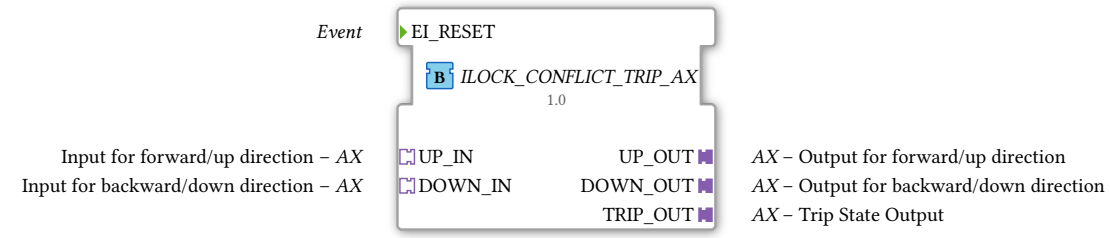
State Overview

State	Description	Transition Conditions
STOP	No direction active, all outputs FALSE.	⟶ UP on IN.E_UP if IN.UP and NOT IN.DOWN;⟶ DOWN on IN.E_DOWN if IN.DOWN and NOT IN.UP;⟶ TRIP on either event if both IN.UP and IN.DOWN are TRUE.
UP	Forward/up direction active.	⟶ STOP on IN.E_UP if NOT IN.UP;⟶ TRIP on IN.E_DOWN if IN.DOWN.
DOWN	Backward/down direction active.	⟶ STOP on IN.E_DOWN if NOT IN.DOWN;⟶ TRIP on IN.E_UP if IN.UP.
TRIP	Conflict detected, both directions deactivated, TRIP_OUT.D1 set to TRUE.	⟶ STOP on EI_RESET if NOT IN.UP and NOT IN.DOWN.

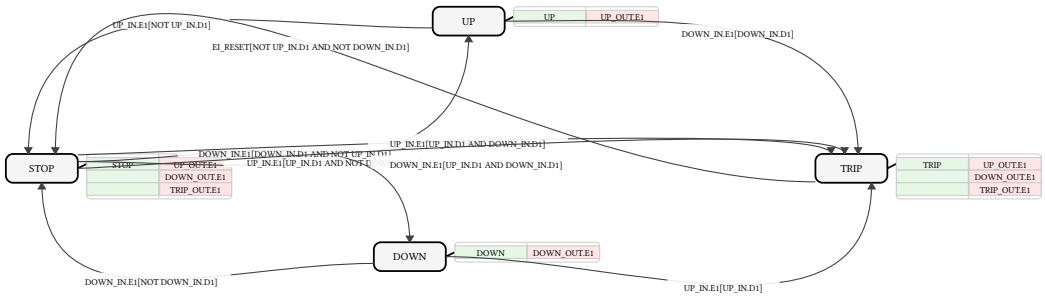
Application Scenarios

This block is well suited for safety-critical interlocking in machinery, conveyor systems, or any application where two opposing actuation commands must never be delivered simultaneously. Typical use cases include:

- Hoist or crane direction control.
- Hydraulic or pneumatic cylinder extension/retraction with safety interlocks.
- Motor control with forward/reverse operation and anti-conflict logic.
- Any system requiring a “trip” (fault) condition when conflicting commands are issued.



Comparison with Similar Blocks



Compared to a simple interlock that merely prioritises one input, the `ILOCK_CONFLICT_TRIP_A2X` adds an explicit trip state to signal a hardware or software conflict. This makes it more suitable for systems that require a visible alarm and a manual or logical reset after a fault. Unlike a pure priority encoder, it does not silently ignore the secondary input – it reacts to the conflict and forces the system into a safe state. The adapter-based design also simplifies integration with other 4diac components using the same adapter types.

Conclusion

The `ILOCK_CONFLICT_TRIP_A2X` function block provides a robust and safe interlocking solution for directional commands. Its clear state machine, conflict detection, and trip/reset behaviour make it a valuable component for automation projects that demand high reliability and fail-safe operation. By using standard adapters, it can be easily connected to existing I/O infrastructure and integrated into larger control applications.

ILOCK_CONFLICT_TRIP_AX

Introduction

The function block `ILOCK_CONFLICT_TRIP_AX` implements interlock logic for two opposing directions (UP and DOWN). It prioritizes the first active input signal and immediately switches to a trip state when both inputs are activated simultaneously. Resetting from the trip state is only possible via the event `EI_RESET` when both inputs are inactive. All communication takes place via adapters of type `unidirectional::AX`, enabling flexible and modular integration.

Interface Structure

Event Inputs

- **EI_RESET** – Event to reset the trip state (only effective if both data inputs of the adapters are FALSE).

Event Outputs

The FB has no direct event outputs. State changes are signaled via the event outputs of the output adapters (plugs):

- **UP_OUT.E1**
- **DOWN_OUT.E1**
- **TRIP_OUT.E1**

Data Inputs

The FB has no direct data inputs. The input data is provided via the adapter sockets:

- **UP_IN.D1** (BOOL) – Enables the up direction.
- **DOWN_IN.D1** (BOOL) – Enables the down direction.

Data Outputs

The FB has no direct data outputs. The output data is provided via the adapter plugs:

- **UP_OUT.D1** (BOOL) – Signal for the up direction.
- **DOWN_OUT.D1** (BOOL) – Signal for the down direction. - **TRIP_OUT.D1** (BOOL) – Signal for trip state.

Adapters

Sockets (Inputs)

Adapter	Type	Description
`UP_IN`	`adapter::types::unidirectional::AX`	Input for up-direction (event + data)
`DOWN_IN`	`adapter::types::unidirectional::AX`	Input for down-direction (event + data)

Plugs (Outputs)

Adapter	Type	Description
`UP_OUT`	`adapter::types::unidirectional::AX`	Output for Upward Direction
`DOWN_OUT`	`adapter::types::unidirectional::AX`	Output for Downward Direction
`TRIP_OUT`	`adapter::types::unidirectional::AX`	Trip State Output

Note: The interface `unidirectional::AX` is interpreted here as an adapter with one event (E1) and one BOOL data element (D1), which carries the activation state.

Functionality

The function block operates as a finite state machine with four states:

1. **STOP** – Idle state. All outputs are FALSE.

- On event `UP_IN.E1` with the condition `UP_IN.D1 AND NOT DOWN_IN.D1` ⟶ transition to **UP**.
- On event `DOWN_IN.E1` with condition `DOWN_IN.D1 AND NOT UP_IN.D1` ⟶ transition to **DOWN**.
- On event at either input with condition `UP_IN.D1 AND DOWN_IN.D1` ⟶ transition to **TRIP**.

1. **UP** – Upward direction active. `UP_OUT.D1 = TRUE`, all others FALSE.

- On event `UP_IN.E1` with `NOT UP_IN.D1` ⟶ return to **STOP**.

- On event `DOWN_IN.E1` with `DOWN_IN.D1` → **TRIP** (conflict).

1. **DOWN** – Downward direction active. `DOWN_OUT.D1 = TRUE`, all others FALSE.

- On event `DOWN_IN.E1` with `NOT DOWN_IN.D1` → return to **STOP**.
- On event `UP_IN.E1` with `UP_IN.D1` → **TRIP** (conflict).

1. **TRIP** – Error/conflict state. `TRIP_OUT.D1 = TRUE`, all others FALSE.

- Only output: Event `EI_RESET`, if `NOT UP_IN.D1 AND NOT DOWN_IN.D1` → return to **STOP**.

Prioritization is implicit: As long as there is no conflict, the first detected and valid request is executed. A change from UP to DOWN (or vice versa) without an intermediate stop is only possible via STOP, unless a conflict occurs that immediately triggers a trip.

Technical Features

- **Adapter-based communication:** All inputs and outputs are implemented as adapters, enabling loose coupling and easy reuse in complex systems.
- **Trip on conflict:** Simultaneous activation of both directions immediately triggers a separate trip state, which can only be exited by an explicit reset.
- **Reset condition:** The reset (`EI_RESET`) is only effective if both input data are FALSE – this prevents accidental release while a conflict persists.
- **No direct events/data:** The function block has no traditional event or data inputs/outputs, but uses only the adapter interfaces.

State overview

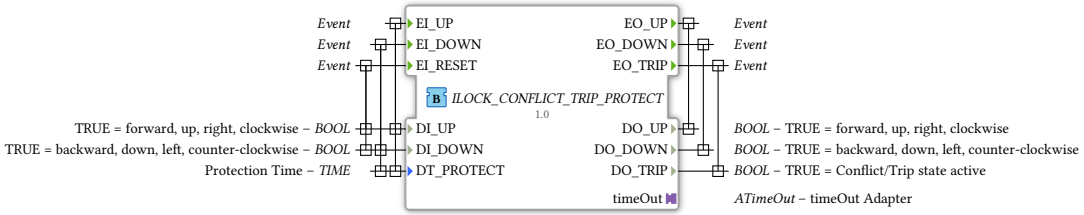
State	UP_OUT.D1	DOWN_OUT.D1	TRIP_OUT.D1	Description
`STOP`	FALSE	FALSE	FALSE	Resting position, no direction active
`UP`	TRUE	FALSE	FALSE	Upward direction active
`DOWN`	FALSE	TRUE	FALSE	Downward direction active
`TRIP`	FALSE	FALSE	TRUE	Conflict / Trip, requires reset

Important Transitions:

- STOP → UP: when UP_IN is active and DOWN_IN is inactive.
- STOP → DOWN: when DOWN_IN is active and UP_IN is inactive.
- STOP → TRIP: when both inputs are active simultaneously (conflict).
- UP → STOP: when UP_IN is deactivated.
- UP → TRIP: when DOWN_IN is active.
- DOWN → STOP: when DOWN_IN is deactivated.
- DOWN → TRIP: when UP_IN is active.
- TRIP → STOP: only via EI_RESET when both inputs are inactive.

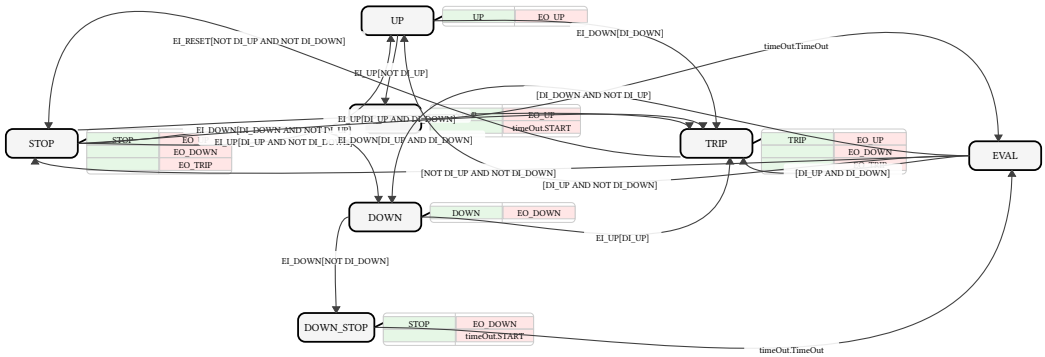
Application Scenarios

- **Interlock Control on Machines:** Prevents simultaneous movement in two opposite directions (e.g., raising/lowering, forward/backward).
- **Safety-Related Applications:** Detects critical conflict situations and enforces a defined error state that must be acknowledged.
- **Adapter-Based Systems:** Integration into modular automation solutions where components communicate via standardized adapters.



Comparison with Similar Function Blocks

- Simple interlock function blocks (e.g., `ILOCK`) often switch directly between directions without implementing a trip state.
- Function blocks with priority logic favor one direction, while this function block prioritizes the first arriving request and reports an error in case of a conflict.
- `ILOCK_CONFLICT_TRIP_AX` is distinguished by its explicit trip state and adapter interface – this enables a clean separation of control and diagnostic functions.



Conclusion

The ILOCK_CONFLICT_TRIP_AX is a robust interlock function block specifically designed for conflict situations. The trip state with external reset ensures safe handling of parallel requests. The adapter-based structure facilitates integration into larger automation projects and promotes reusability. This function block represents a reliable and flexible solution for safety-critical or fault-tolerant systems.

ILOCK_CONFLICT_TRIP_PROTECT

ECC: ILOCK_CONFLICT_TRIP_PROTECT

• – ○ • – ○ • – ○ •

Introduction

The function block ILOCK_CONFLICT_TRIP_PROTECT extends ILOCK_CONFLICT_TRIP with a configurable protection dead time (DT_PROTECT), analogous to how ILOCK_BLOCK_PROTECT extends the behavior of ILOCK_BLOCK. It still prioritizes the first active input, triggers a trip state when both directions are activated simultaneously, and requires an explicit EI_RESET thereafter. What's new is that after the active input is released, the dead time DT_PROTECT must elapse before the function block re-evaluates the current input signals – only then is the next direction (or, if applicable, a trip) taken.

Interface Structure

Event Inputs

Name	Carrying Data	Description
EI_UP	DI_UP, DT_PROTECT	Event for the up/forward direction.
EI_DOWN	DI_DOWN, DT_PROTECT	Down/Backward Direction Event.
EI_RESET	DI_UP, DI_DOWN	Reset Trip State; only effective if both data inputs are FALSE.

Event Outputs

Name	Carrying Data	Description
EO_UP	DO_UP	Triggered when the UP direction is enabled or disabled.
EO_DOWN	DO_DOWN	Triggered when the DOWN direction is enabled or disabled.
EO_TRIP	DO_TRIP	Sent in the TRIP state, it indicates the trip status.

Data Inputs

- DI_UP (BOOL) – TRUE = forward/upward/right/clockwise.
- DI_DOWN (BOOL) – TRUE = backward/downward/left/counterclockwise.
- DT_PROTECT (TIME, initial value T#50ms) – Protection dead time that must elapse after the active input is released before it can be re-evaluated.

Data Outputs

- DO_UP (BOOL) – Signals the active UP direction.
- DO_DOWN (BOOL) – Signals the active DOWN direction.
- DO_TRIP (BOOL) – Signals the trip/conflict state.

Adapters

Adapter	Type	Direction	Description
timeOut	iec61499::events::ATimeOut	Plug	Timer adapter for protection time. The function block sets timeOut.DT and starts it via timeOut.START; timeOut.TimeOut signals the execution.

Functionality

The function block operates as a finite state machine (ECC) with seven states:

1. **STOP** – Idle state, all outputs FALSE. At EI_UP with DI_UP AND NOT DI_DOWN → **UP** at EI_DOWN with DI_DOWN AND NOT DI_UP → **DOWN** if both data signals are TRUE at EI_UP or EI_DOWN → immediate **TRIP**.
2. **UP** – DO_UP = TRUE. At EI_UP[NOT DI_UP] → **UP_STOP** at EI_DOWN[DI_DOWN] (conflict during active UP) → immediate **TRIP**.
3. **DOWN** – DO_DOWN = TRUE. At EI_DOWN[NOT DI_DOWN] → **DOWN_STOP** at EI_UP[DI_UP] (conflict during active DOWN) → immediate **TRIP**.
4. **UP_STOP** / **DOWN_STOP** – Transition states after the active input is released. The algorithm STOP sets all outputs to FALSE, transfers DT_PROTECT to timeOut.DT, and starts the timer (timeOut.START). Upon expiration (timeOut.TimeOut) → **EVAL**.
5. **EVAL** – No separate algorithm. The current values of DI_UP/DI_DOWN are re-evaluated: only DI_UP TRUE → **UP** only DI_DOWN TRUE → **DOWN** both FALSE → **STOP** both TRUE → **TRIP**.
6. **TRIP** – DO_TRIP = TRUE, all other outputs FALSE. Exit only via EI_RESET if NOT DI_UP AND NOT DI_DOWN → **STOP**.

Trip detection itself still occurs immediately and independently of the dead time: A conflict during STOP, UP, or DOWN always directly triggers TRIP. The dead time DT_PROTECT only affects the period between the release of an active input and the acquisition of the next direction.

Trip detection itself continues to occur immediately and independently of the dead time: A conflict during STOP, UP, or DOWN always directly triggers TRIP. The dead time DT_PROTECT is only effective between the release of an active input and the acquisition of the next direction.

Technical Features

- **Combination of two patterns:** This function block combines the trip-on-conflict logic of ILOCK_CONFLICT_TRIP with the dead-time logic of ILOCK_BLOCK_PROTECT.

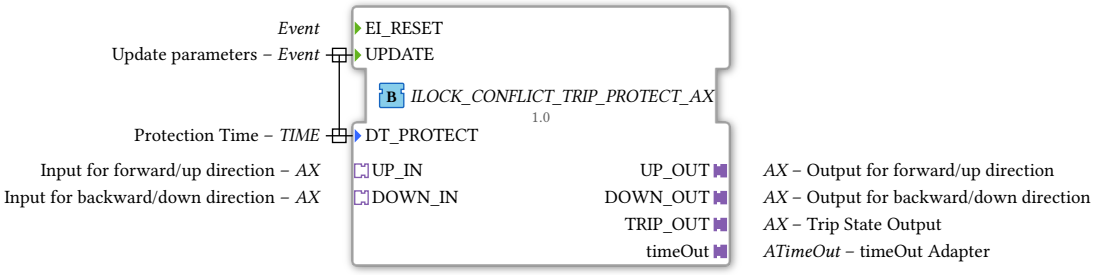
- **Immediate trip, delayed release:** Conflicts are detected without delay; only the return to a new valid state after release is delayed by `DT_PROTECT`.
- **Reset condition:** `EI_RESET` only takes effect if both data inputs are inactive – a reset while a conflict persists has no effect.
- **Timer restart in every intermediate stop state:** `timeOut.DT` is reused from `DT_PROTECT` upon each entry into `UP_STOP`/`DOWN_STOP`, so that any parameter change takes effect immediately in the next delay.

State Overview

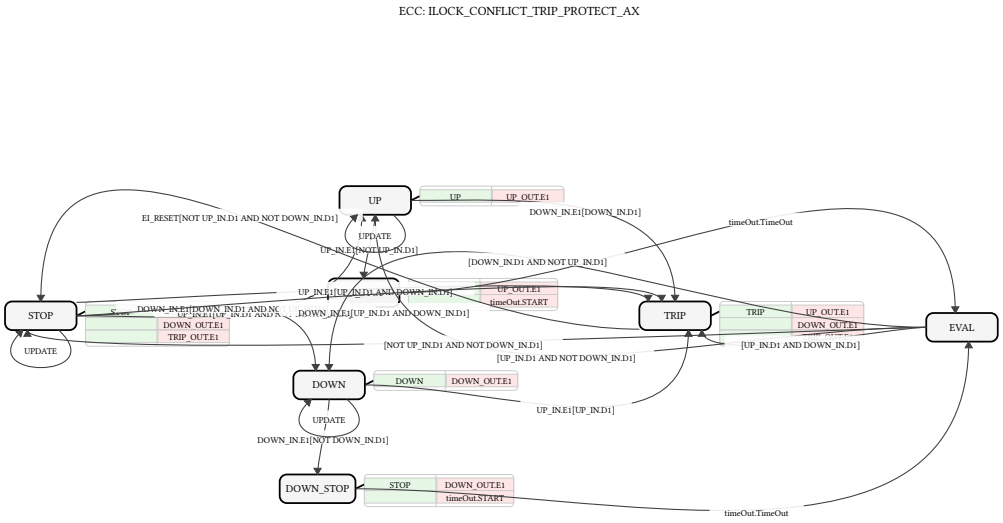
State	DO_UP	DO_DOWN	DO_TRIP	Description
`STOP`	FALSE	FALSE	FALSE	Idle state, no direction active.
`UP`	TRUE	FALSE	FALSE	Up direction active.
`DOWN`	FALSE	TRUE	FALSE	Downward direction active.
`UP_STOP`	FALSE	FALSE	FALSE	Waiting for `DT_PROTECT` to expire after UP is released.
`DOWN_STOP`	FALSE	FALSE	FALSE	Waiting for `DT_PROTECT` to expire after DOWN is released.
`EVAL`	–	–	–	No algorithm; decides the next state based on current inputs.
`TRIP`	FALSE	FALSE	TRUE	Conflict/Trip, requires `EI_RESET`.

Application Scenarios

- **Drives with Overrun:** When a mechanical or hydraulic overrun time must be observed after releasing a travel command before switching to the opposite direction is safe.
- **Safety-Oriented Interlock with Acknowledgement Required:** Applications where a simultaneous command in both directions is considered an error and must be explicitly acknowledged.
- **Valve or Flap Controls:** Protection against pressure surges or mechanical overload through a minimum pause between direction changes.



Comparison with Similar Function Blocks



Compared to `ILOCK_CONFLICT_TRIP`, this function block adds the states `UP_STOP`, `DOWN_STOP`, and `EVAL`, as well as the `timeOut` adapter – the trip logic itself remains identical. It differs from `ILOCK_BLOCK_PROTECT` in that a simultaneous command in both directions is not ignored, but rather treated as an explicit error condition (`TRIP`) that requires `EI_RESET`.

Conclusion

`ILOCK_CONFLICT_TRIP_PROTECT` combines the clear error detection of `ILOCK_CONFLICT_TRIP` with the protection dead time of `ILOCK_BLOCK_PROTECT`. It is suitable for applications that require both strict conflict detection with mandatory acknowledgment and a minimum pause between direction changes.

ILOCK_CONFLICT_TRIP_PROTECT_AX

• — ○ • — ○ • — ○ •

Introduction

The function block `ILOCK_CONFLICT_TRIP_PROTECT_AX` is the adapter version of `ILOCK_CONFLICT_TRIP_PROTECT`: It combines the trip-on-conflict logic of `ILOCK_CONFLICT_TRIP_AX` with the protection dead time of `ILOCK_BLOCK_PROTECT_AX`. The first active input is prioritized; simultaneous activation of both directions immediately triggers a trip, which can only be reset via `EI_RESET`. After the active input is released, the block additionally waits for the configurable time `DT_PROTECT` before re-evaluating the inputs. The process data (`UP_IN`/`DOWN_IN`/`UP_OUT`/`DOWN_OUT`/`TRIP_OUT`) is routed via adapters of type `unidirectional::AX`; the protection-time timer additionally uses the adapter `iec61499::events::ATimeOut` (`timeOut`).

Interface Structure

Event Inputs

Name	Carrying Data	Description
`EI_RESET`	–	Resets the trip state; only effective if `UP_IN.D1` and `DOWN_IN.D1` are both FALSE.
`UPDATE`	`DT_PROTECT`	Updates the protection time `DT_PROTECT` at runtime without changing the current state.

Event Outputs

No direct event outputs. State changes are signaled via the events of the output adapters (plugs):

- `UP_OUT.E1`, `DOWN_OUT.E1`, `TRIP_OUT.E1`

Data Inputs

`UP_IN`/`DOWN_IN` are not direct data inputs - they are provided via the socket adapters; `DT_PROTECT`, in contrast, is a direct data input carried by the `UPDATE` event:

- `UP_IN.D1` (BOOL) – Upward direction activation (socket adapter).
- `DOWN_IN.D1` (BOOL) – Downward direction activation (socket adapter).

- DT_PROTECT (TIME, initial value T#50ms) – Protection dead time after releasing the active input (direct data input, carried by UPDATE).

Data Outputs

No direct data outputs. Provided via the plug adapters:

- UP_OUT.D1 (BOOL) – Up signal.
- DOWN_OUT.D1 (BOOL) – Down signal.
- TRIP_OUT.D1 (BOOL) – Trip signal.

Adapters

Sockets (Inputs)

Adapter	Type	Description
UP_IN	adapter::types::unidirectional::AX	Up input.
DOWN_IN	adapter::types::unidirectional::AX	Down-direction input.

Plugs (Outputs)

Adapter	Type	Description
UP_OUT	adapter::types::unidirectional::AX	Up-direction output.
DOWN_OUT	adapter::types::unidirectional::AX	Down-direction output.
TRIP_OUT	adapter::types::unidirectional::AX	Trip state output.
timeOut	iec61499::events::ATimeOut	Timer adapter for the protection time; the module sets timeOut.DT and starts it via timeOut.START.

Functionality

The circuit is structurally identical to ILOCK_CONFLICT_TRIP_PROTECT, except that all signals are routed via adapters:

1. **STOP** – Idle state. At UP_IN.E1[UP_IN.D1 AND NOT DOWN_IN.D1] ⟶ **UP** at DOWN_IN.E1[DOWN_IN.D1 AND NOT UP_IN.D1] ⟶ **DOWN** if both data signals are TRUE at either event ⟶ immediate **TRIP**.
2. **UP** – UP_OUT.D1 = TRUE. At UP_IN.E1[NOT UP_IN.D1] ⟶ **UP_STOP** at DOWN_IN.E1[DOWN_IN.D1] (conflict) ⟶ immediate **TRIP**.
3. **DOWN** – DOWN_OUT.D1 = TRUE. At DOWN_IN.E1[NOT DOWN_IN.D1] ⟶ **DOWN_STOP** at UP_IN.E1[UP_IN.D1] (conflict) ⟶ immediate **TRIP**.
4. **UP_STOP** / **DOWN_STOP** – The algorithm STOP sets all adapter outputs to FALSE, transmits DT_PROTECT to timeOut.DT, and starts the timer. At timeOut.TimeOut ⟶ **EVAL**.
5. **EVAL** – No separate algorithm. Re-evaluation: only UP_IN.D1 TRUE ⟶ **UP** Only DOWN_IN.D1 is TRUE ⟶ **DOWN** both are FALSE ⟶ **STOP** both are TRUE ⟶ **TRIP**.
6. **TRIP** – TRIP_OUT.D1 = TRUE. Exit only via EI_RESET[NOT UP_IN.D1 AND NOT DOWN_IN.D1] ⟶ **STOP**.

Additionally, in states STOP, UP, and DOWN, there is a self-loop transition to the event UPDATE, which does not leave the respective state and serves solely to acquire a new DT_PROTECT value.

Technical Features

- **Pure Adapter Interface:** All process data is routed via unidirectional::AX adapters (the protection-time timer additionally via an iec61499::events::ATimeOut adapter). There are no traditional event/data ports except for EI_RESET, UPDATE, and DT_PROTECT.
- **Dynamic Dead Time:** The UPDATE event allows DT_PROTECT to be modified at runtime without exiting the automaton. The new value takes effect upon the next entry into UP_STOP/DOWN_STOP.
- **Immediate Trip in Case of Conflict:** As with the non-adapter variant, a simultaneous command in both directions is detected without delay.

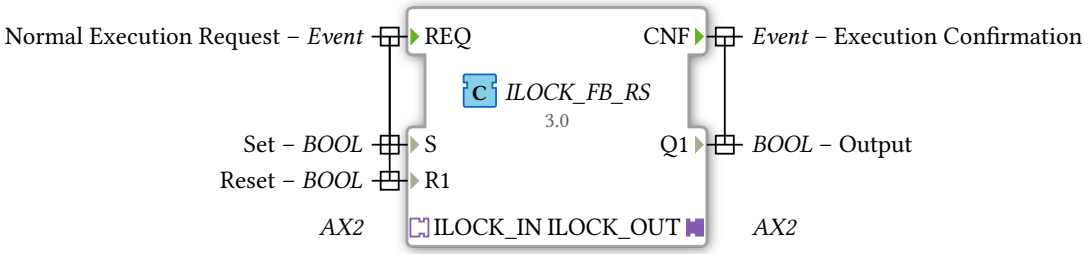
- **Reset Condition:** `EI_RESET` only takes effect if both input adapters report `D1 = FALSE`.

State Overview

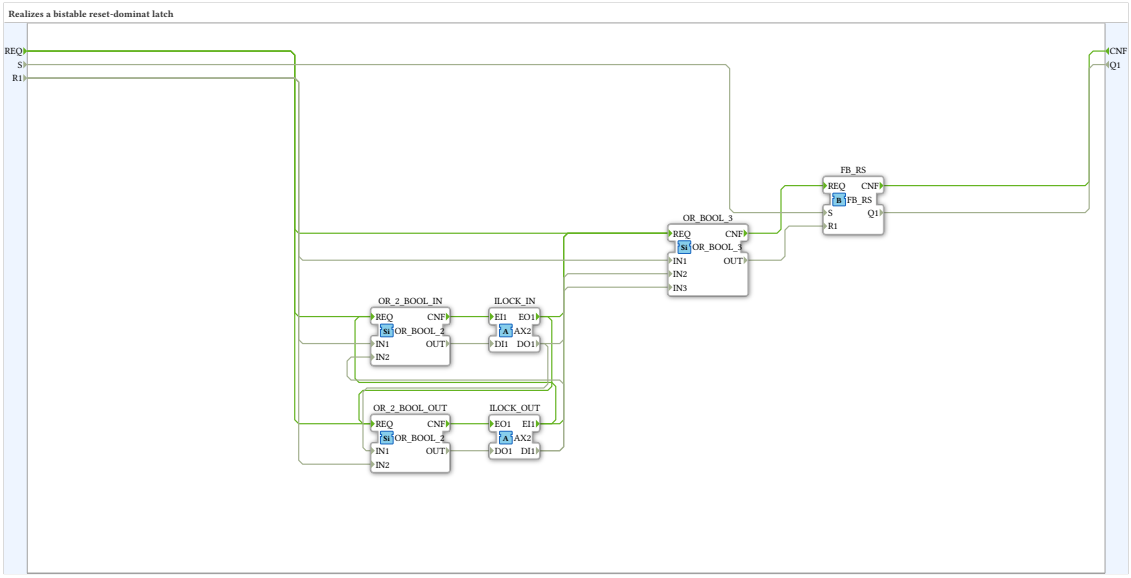
State	UP_OUT.D1	DOWN_OUT.D1	TRIP_OUT.D1	Description
`STOP`	FALSE	FALSE	FALSE	Idle state, no direction active.
`UP`	TRUE	FALSE	FALSE	Up direction active.
`DOWN`	FALSE	TRUE	FALSE	Downward direction active.
`UP_STOP`	FALSE	FALSE	FALSE	Waiting for `DT_PROTECT` to expire after UP is released.
`DOWN_STOP`	FALSE	FALSE	FALSE	Waiting for `DT_PROTECT` to expire after DOWN is released.
`EVAL`	–	–	–	No algorithm; decides on the next state.
`TRIP`	FALSE	FALSE	TRUE	Conflict/Trip, requires `EI_RESET`.

Application Scenarios

- **Adapter-Based Drive Controls:** Modular systems where direction signals are already routed through the system via `unidirectional::AX` adapters.
- **Safety-Oriented Interlocking with Overrun Time:** Applications requiring both strict conflict detection with mandatory acknowledgement and a minimum pause between direction changes.
- **Runtime Parameterization:** Systems where the protection time must be adjusted via `UPDATE` depending on the operating state (e.g., temperature, load).



Comparison with similar building blocks



Compared to `ILOCK_CONFLICT_TRIP_AX`, this building block adds the states `UP_STOP`, `DOWN_STOP`, `EVAL`, as well as the `timeOut` adapter and the `UPDATE` event. Compared to `ILOCK_BLOCK_PROTECT_AX`, it differs in that a simultaneous command in both directions is not silently ignored, but rather treated as an explicit `TRIP` state, which requires an `EI_RESET` response. Compared to the non-adapter variant `ILOCK_CONFLICT_TRIP_PROTECT`, the interface is fully adapter-based, which facilitates integration into modular, adapter-oriented systems.

Conclusion

`ILOCK_CONFLICT_TRIP_PROTECT_AX` combines adapter-based conflict detection with mandatory acknowledgment and a configurable protection dead time in a single module. It is suitable for modular automation solutions that require strict mutual exclusivity of two directions combined with overrun time and runtime parameterization.

ILOCK_FB_RS

• – ○ • – ○ • – ○ •

Introduction

The function block `ILOCK_FB_RS` implements a bistable reset-dominant RS latch (reset-dominant flip-flop). It extends a simple RS flip-flop with a bidirectional coupling interface, enabling multiple such blocks to be chained together in an interlock chain. The output state is set by the Set input (S) and reset by the Reset input (R1) – also taking into account signals from adjacent blocks.

Interface Structure

Event Inputs

Event	Comment
`REQ`	Normal execution request (linked to data S and R1)

Event Outputs

Event	Comment
`CNF`	Execution Acknowledgement (linked to data output Q1)

Data Inputs

Variable	Type	Comment
`S`	BOOL	Set (active high)
`R1`	BOOL	Reset (active high) – Reset-dominant

Data Outputs

Variable	Type	Comment
`Q1`	BOOL	Flip-flop output

Adapter

Name	Direction	Type	Description
`ILOCK_IN`	Socket	bidirectional::AX2	Receives signals from the previous component in the chain (event EO1, data DO1)
`ILOCK_OUT`	Plug	bidirectional::AX2	Sends signals to the next component in the chain (event EI1, data DI1)

The adapters of type AX2 each provide two logic channels:

- Event channel: EI1 (input) / EO1 (output)
- Data channel: DI1 (input) / DO1 (output)

Functionality

Internally, the component consists of an RS flip-flop (FB_RS, reset-dominant), two OR gates, and a 3-OR gate. The logic links the external inputs to the adapter signals:

- **Set:** The input S goes directly to the set input of the internal flip-flop. With S active and the reset input inactive, Q1 = TRUE is used.
- **Reset:** The reset input R1 is connected to the data outputs of the two adapters (ILOCK_IN.DO1 and ILOCK_OUT.DI1) via a 3-factor OR gate. The result controls the reset input of the internal flip-flop. As soon as **one** of these three sources becomes active, the output Q1 is reset (reset dominance).

Reset dominance: - **Coupling:** The internal reset (R1) is additionally routed to the adapter outputs via OR gates:

- At ILOCK_OUT.DO1, R1 is ORed with the received signal from ILOCK_IN.DO1 (OR_2_BOOL_OUT), so that a reset is passed on.
- At ILOCK_IN.DI1, R1 is ORed with the received signal from ILOCK_OUT.DI1 (OR_2_BOOL_IN), so that a reset from the other side is also passed on.
- **Event Control:** All events (REQ, as well as the adapter events) are collected and forwarded to the internal flip-flop via OR logic. The acknowledgment (CNF) is output after the flip-flop has processed.

Technical Features

- **Reset Dominance:** In case of conflict (S and R1 active simultaneously), the reset takes precedence → Q1 = FALSE.
- **Cascading:** Multiple ILOCK_FB_RS units can be cascaded using the adapters. A reset occurring at one point propagates through the chain.
- **Bidirectional Coupling:** The adapters enable both forward and reverse communication, allowing the device to receive and forward set and reset signals from both sides.
- **Compatibility:** Implemented according to IEC 61499-1 and utilizes subapplications from the iec61131 library.

State Overview

The internal RS flip-flop has the following state table (reset-dominant):

S	R1_eff	Q1 (new)	Description
0	0	Q1_old	Hold
1	0	1	Set
0	1	0	Reset
1	1	0	Reset dominant

The output R1_eff is the result of the OR operation on R1, ILOCK_IN.DO1, and ILOCK_OUT.DI1. The output Q1 is only set if none of these three reset sources are active.

Application Scenarios

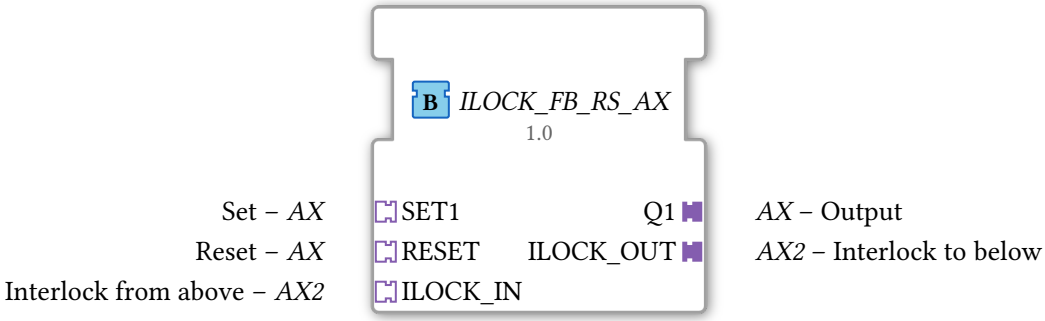
- **Interlock Chains** in safety controllers: Several components are chained together. A fault or reset at one point resets all subsequent outputs.
- **Priority Logic:** Reset-dominant latch structures where a specific event (e.g., emergency stop) takes precedence over set signals.
- **Signal Interlocking** in redundant systems where multiple conditions for setting and resetting must be combined.

Comparison with Similar Components

Component	Properties
FB_RS (IEC 61131)	Simple reset-dominant RS flip-flop without adapter, no cascading

ILOCK_FB_RS	Same core function, but with bidirectional adapters for cascading and additional reset signal linking

The ILOCK_FB_RS thus adds the ability to operate multiple such flip-flops in a chain, with a reset signal being passed from one link to the others.



Conclusion

The ILOCK_FB_RS is a versatile component for implementing reset-dominant interlock logic. Its integrated bidirectional coupling makes it particularly suitable for modular, expandable safety and interlock circuits, eliminating the need for additional external logic.

ILOCK_FB_RS_AX

Introduction

The function block **ILOCK_FB_RS_AX** implements a bistable, reset-dominant RS latch with an AX interface for set and reset signals, as well as a bidirectional AX2 interface for chaining multiple interlock blocks in a hierarchy. The block is designed for use in safety-related and interlock-based control environments.

Interface Structure

The block does not have separate event or data ports, but rather encapsulates all signal types via **adapters**. The following list groups the events and data received via the individual adapters.

Event Inputs

- **SET1.E1** (via socket adapter `SET1`): Set event, triggers the latch function.
- **RESET.E1** (via socket adapter `RESET`): Reset event, triggers the reset logic.
- **ILOCK_IN.EO1** (via socket adapter `ILOCK_IN`): Event from a parent or neighboring interlock instance (bidirectional side).
- **ILOCK_OUT.EI1** (via plug adapter `ILOCK_OUT`): Event from a child interlock instance.

Event Outputs

- **Q1.E1** (via plug adapter `Q1`): Output event after each update of the latch state.
- **ILOCK_IN.EI1** (via socket adapter `ILOCK_IN`): Event sent to the connected partner adapter of `ILOCK_IN`.
- **ILOCK_OUT.EO1** (via plug adapter `ILOCK_OUT`): Event sent to the connected partner adapter of `ILOCK_OUT`.

Data Inputs

- **SET1.D1** (via socket adapter `SET1`): Set signal (Boolean value, TRUE sets the latch).
- **RESET.D1** (via socket adapter `RESET`): Reset signal (Boolean value, TRUE resets the latch, overrides Set).
- **ILOCK_IN.DO1** (via socket adapter `ILOCK_IN`): Interlock status from above (Boolean value, TRUE blocks the latch).
- **ILOCK_OUT.DI1** (via plug adapter `ILOCK_OUT`): Interlock status from below (Boolean value, TRUE blocks the latch).

Data Outputs

- **Q1.D1** (via plug adapter `Q1`): Latch output state (Boolean value).
- **ILOCK_IN.DI1** (via socket adapter `ILOCK_IN`): Forwards the reset signal upwards.
- **ILOCK_OUT.DO1** (via plug adapter `ILOCK_OUT`): Forwards the reset signal downwards.

Adapter

Adapter	Type	Direction	Description
`SET1`	Unidirectional AX	Socket	Set Input
`RESET`	Unidirectional AX	Socket	Reset Input
`ILOCK_IN`	Bidirectional AX2	Socket	Interlock Input (from top)
`Q1`	Unidirectional AX	Plug	Latch Output
`ILOCK_OUT`	Bidirectional AX2	Plug	Interlock Output (downward)

Functionality

The function block executes the algorithm `REQ` upon each incoming event (via `SET1.E1`, `RESET.E1`, `ILOCK_IN.EO1`, or `ILOCK_OUT.EI1`). The internal logic calculates the new output value `Q1.D1` using the reset-dominant formula:

Q1.D1 := (SET1.D1 OR Q1.D1) AND NOT (RESET.D1 OR ILOCK_IN.DO1 OR ILOCK_OUT.DI1);`

- If the reset signal (`RESET.D1`) or one of the interlock inputs (`ILOCK_IN.DO1` or `ILOCK_OUT.DI1`) is TRUE, the latch is immediately reset (Q = FALSE), regardless of the set signal.
- If no reset or interlock block is present, the latch is set by a set signal (`SET1.D1` = TRUE) and remains self-latching.
- The interlock signals of the AX2 interface are propagated:
- `ILOCK_IN.DI1` (upwards) = `RESET.D1 OR ILOCK_OUT.DI1`
- `ILOCK_OUT.DO1` (downwards) = `RESET.D1 OR ILOCK_IN.DO1`

This creates a cascade in which a reset signal is passed on in both directions (upwards and downwards), blocking all subordinate and superior latch components.

Technical Features

- **Adapter-based interfaces**: Instead of individual ports, the component uses standardized AX/AX2 adapters, enabling a modular and reusable connection with other components.

- **Cascadable Interlock Chain**: Multiple ILOCK_FB_RS_AX instances can be connected in series using the bidirectional `ILOCK_IN/ILOCK_OUT` adapters. A reset signal is automatically propagated in both directions, blocking the entire chain.
- **Reset Dominance**: The reset signal always takes precedence over the set signal. This meets typical requirements for safety interlocks that demand a defined priority for the reset signal.
- **Continuous Event Processing**: The function block reacts to every incoming event (set, reset, up/down interlock) and immediately updates all outputs. There are no state changes in the ECC (only one state, `REQ`); the logic is purely combinational with feedback via the stored latch value.

Reset Dominance:

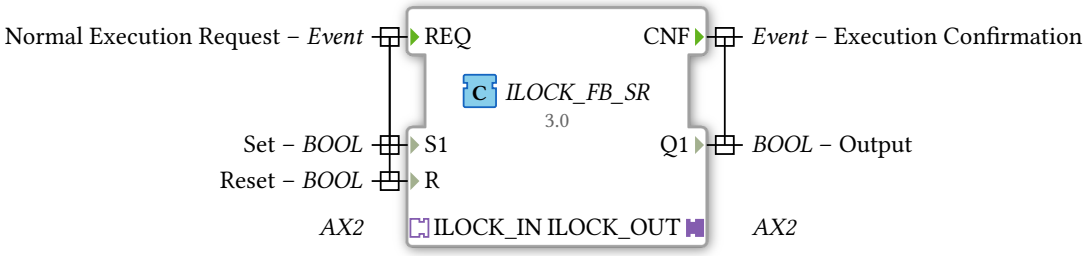
State Overview

The component has only one state, `REQ`, in its ECC, which is always active. The internal latch state is represented by the boolean value `Q1.D1`.The state overview therefore describes the behavior of the internal memory cell:

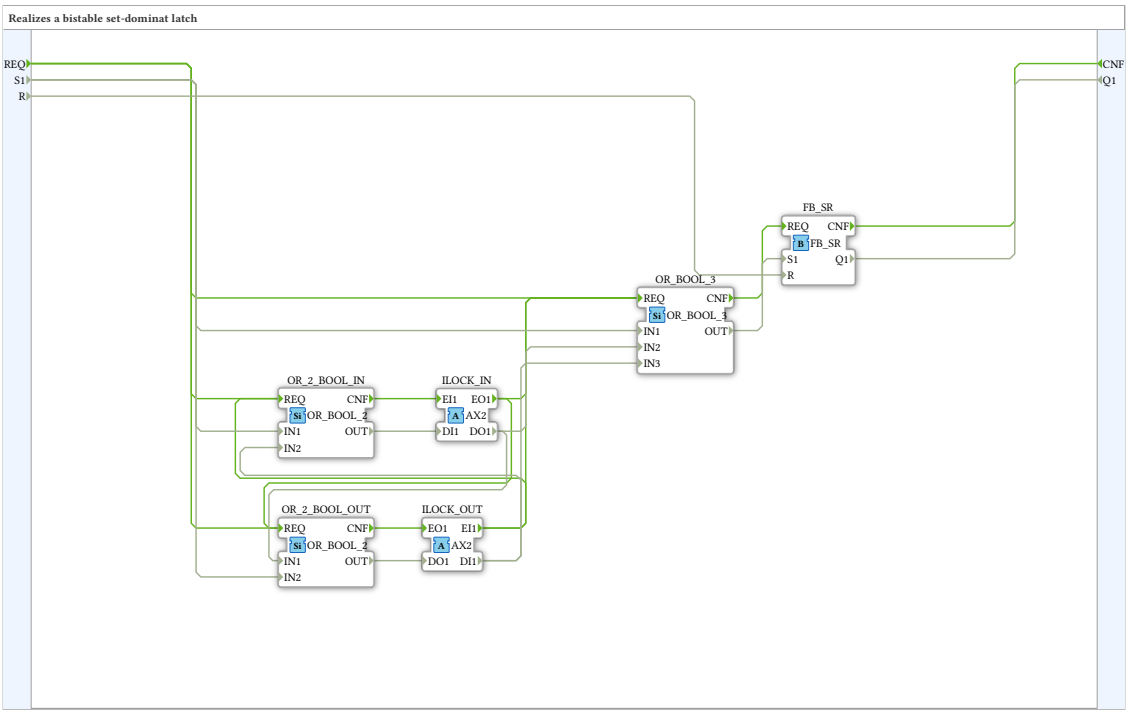
Current Q	SET1.D1	RESET.D1	Interlock active?	Next Q	Description
FALSE	FALSE	FALSE	NO	FALSE	Latch remains reset
FALSE	TRUE	FALSE	NO	TRUE	Latch is set
FALSE	TRUE	TRUE	YES/NO	FALSE	Reset dominates
TRUE	FALSE	FALSE	NO	TRUE	Latch remains set (self-latching)
TRUE	TRUE	FALSE	NO	TRUE	Latch remains set
TRUE	FALSE	TRUE	YES/NO	FALSE	Reset dominates
TRUE	TRUE	TRUE	YES/NO	FALSE	Reset dominates
arbitrary	arbitrary	arbitrary	YES (ILOCK)	FALSE	Interlock blockage sets or holds latch

Application Scenarios

- **Machine Safety**: Interlocking drives or tools where a reset signal (e.g., emergency stop) takes precedence and also blocks adjacent modules.
- **Process Control with Hierarchy**: In a cascade of control modules, a higher-level signal can reset the subordinate blocks to their default state.
- **Redundant Interlocking**: Multiple ILOCK_FB_RS_AX instances can be arranged in a ring or line to create a distributed interlocking system without central logic.
- **Latch with External Blocking**: External conditions (e.g., sensor values or enable/disable) can block the latch via the interlock adapters without affecting the set/reset function.



Comparison with Similar Function Blocks



- **Standard RS Latch (e.g., SR_FF)**: A typical RS latch has equal set and reset inputs. The ILOCK_FB_RS_AX is reset-dominant and additionally offers an interlock function for cascading.
- **Reset-Dominant Latch without Interlock**: A simple RS latch with reset dominance only has set/reset ports. The function block described here extends this to include bidirectional interlocking via AX2 adapters.
- **Interlock Function Blocks with Dedicated Ports**: Some libraries offer interlock function blocks with individual Boolean inputs for “InterlockFromAbove” and “InterlockFromBelow.” The ILOCK_FB_RS_AX encapsulates these channels in adapters, thus simplifying the connection between instances.

Conclusion

The **ILOCK_FB_RS_AX** is a specialized function block for interlock-based control tasks. Its reset-dominant logic ensures a defined priority for the reset signal. The use of AX/AX2 adapters enables a clean, modular structure and easy cascading of multiple function blocks. This makes it particularly suitable for hierarchical or distributed safety and locking systems in automation technology.

ILOCK_FB_SR

• – ○ • – ○ • – ○ •

Introduction

The ILOCK_FB_SR function block implements a bistable set-dominant SR latch, specifically designed for use in interlock circuits. It extends a simple SR latch with bidirectional adapters for coupling with other function blocks, enabling the implementation of complex interconnections and priority logic.

Interface Structure

Event Inputs

Event	Description	Accompanying Data
`REQ`	Execution Request for Processing the Set and Reset Signals	`S1`, `R`

Event Outputs

Event	Description	Carrying Data
`CNF`	Execution Confirmation, outputs the current output value	`Q1`

Data Inputs

Name	Data Type	Description
`S1`	`BOOL`	Set Input

R	BOOL	Reset Input

Data Outputs

Name	Data Type	Description
Q1	BOOL	Latch Output (set-dominant)

Adapters

Adapter	Type	Direction	Description
ILOCK_IN	adapter::types::bidirectional::AX2	Socket	Receives data and events from an upstream interlock block
ILOCK_OUT	adapter::types::bidirectional::AX2	Plug	Sends data and events to a downstream interlock block

The adapters enable bidirectional chaining of interlock blocks by allowing both the reception of enable/lock signals and the transmission of states.

Functionality

The core of the block is an internal SR latch (FB_SR) that operates in a **set-dominant** manner: If both Set (S1) and Reset (R) are active simultaneously, the block sets the output Q1 to TRUE.

The logic is supplemented by three OR gates:

- **OR_3_BOOL** combines the signals from the Set input (S1) with the feedback signals from the adjacent Interlock devices (ILOCK_IN.DO1 and ILOCK_OUT.DI1). The result is fed to the Set input of the internal SR latch.
- **OR_2_BOOL_IN** combines the Set signal (S1) and the signal from the downstream Interlock device (ILOCK_OUT.DI1). The result is sent to the upstream device via the adapter ILOCK_IN.DI1.
- **OR_2_BOOL_IN** combines the Set signal (S1) and the signal from the downstream Interlock device (ILOCK_OUT.DI1). - **OR_2_BOOL_OUT** combines the set signal (S1) and the signal of the upstream interlock block (ILOCK_IN.DO1). The result is sent to the downstream block via the adapter ILOCK_OUT.DO1.

This structure allows multiple interlock blocks to be cascaded: A set signal can be blocked or forwarded by an upstream block. Simultaneously, the release of its own latch is reported to the adjacent blocks.

Technical Features

- **Set-Dominant Behavior**: In case of conflict (S1=TRUE, R=TRUE), the set signal takes precedence.
- **Adapter-Based Coupling**: The bidirectional adapters ILOCK_IN and ILOCK_OUT allow for modular interconnection without the need to manually establish direct data or event connections between the components.
- **Feedback**: The internal logic processes both external set and reset signals as well as the states of adjacent components, creating a dynamic interlocking chain.

State Overview

The internal SR latch has four states based on the (combined) inputs:

S1 (after logic)	R	Q1 (previous)	Q1 (new)
0	0	0	0
0	0	1	1
0	1	0	0
0	1	1	0
1	0	0	1
1	0	1	1

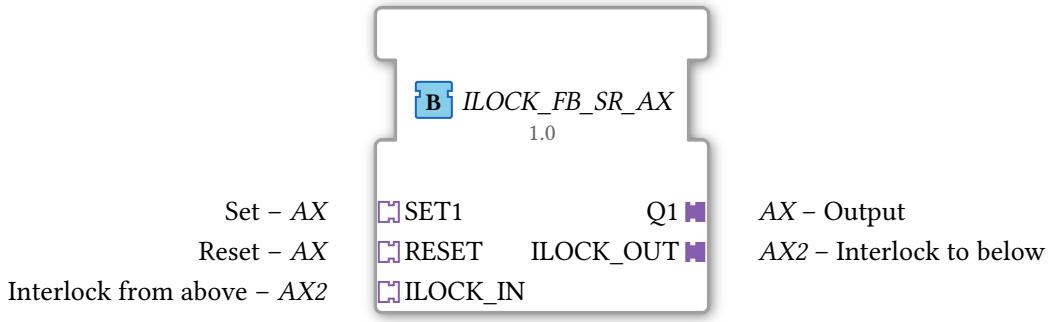
1	1	0	1
1	1	1	1

The effective values for S1 (Set) result from the OR operation of `S1`, `ILOCK_IN.DO1`, and `ILOCK_OUT.DI1`.

Application Scenarios

- **Safety Interlocks**: In systems where multiple conditions must be met simultaneously before a process is enabled (e.g., safety gates, emergency stop).
- **Cascaded Controls**: Superior and subordinate interlock units that interact via adapters (e.g., in production lines).
- **Priority-Based Sets**: Used in systems where a set signal must take precedence over a reset signal to enforce safety-critical states.

Comparison with Similar Devices



- **IEC 61131 SR (reset-dominant)**: Standard SR latch where the reset signal takes precedence in case of a conflict. The ILOCK_FB_SR reverses this priority.
- **IEC 61131 RS (set-dominant)**: Similar behavior at its core, but without the adapter-based interconnection and the logic for chaining multiple devices.
- **D Flip-Flop**: Clocked memory cell that only takes over on a rising edge – this is an asynchronous, clock-independent latch.

The ILOCK_FB_SR is specifically optimized for interlock chains, while simple SR latches operate in isolation.

Conclusion

The ILOCK_FB_SR offers a flexible and robust solution for set-dominant interlock circuits. By combining an SR latch with bidirectional adapters and OR logic, arbitrarily complex interconnections can be built without the need for extensive wiring of signals between the components. The set-dominant behavior is particularly advantageous in safety-critical applications where a set signal must take precedence.

ILOCK_FB_SR_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ILOCK_FB_SR_AX** implements a set-dominant (set-priority) bistable flip-flop (RS latch) with interlock functionality. It is designed for use in safety and interlocking chains where a set signal can be propagated and fed back through multiple stages. The interface consists of two unidirectional AX adapters (SET1, RESET) and one AX2 bidirectional adapter pair (ILOCK_IN / ILOCK_OUT), as well as an output adapter Q1. The block operates in an event-driven manner and recalculates the output values with each incoming event.

Interface Structure

Event Inputs

Event	Data Source	Description
`SET1.E1`	Socket SET1	Sets output Q1 (set-dominant)
`RESET.E1`	Socket RESET	Resets output Q1 (only effective if SET1 = 0)
`ILOCK_IN.EO1`	Socket ILOCK_IN	Receives the propagation event from the parent interlock stage
`ILOCK_OUT.EI1`	Plug ILOCK_OUT	Receives an event from the child interlock stage (e.g., acknowledgment)

Event Outputs

Event	Data Source	Description
`Q1.E1`	Plug Q1	Output event after each Q1 update
`ILOCK_IN.EI1`	Socket ILOCK_IN	Sends propagation event to the parent stage
`ILOCK_OUT.EO1`	Plug ILOCK_OUT	Sends propagation event to the child stage

Data Inputs

Data	Type	Description
SET1.D1	BOOL	Set input (dominant)
RESET.D1	BOOL	Reset input (active when SET1=0)
ILOCK_IN.DO1`	BOOL	Data from the parent interlock stage (propagation signal)
ILOCK_OUT.DI1`	BOOL	Data from the child interlock stage (feedback)

Data Outputs

Data	Type	Description
Q1.D1`	BOOL	Latch output (set by Set or Interlock)
ILOCK_IN.DI1`	BOOL	Propagated Set signal to the parent stage
ILOCK_OUT.DO1	BOOL	Propagated Set signal to the subordinate stage

Adapter

Adapter	Type	Direction	Description
Q1	AX (unidirectional)	Plug	Latch output
ILOCK_OUT	AX2 (bidirectional)	Plug	Interlock interface to the subordinate stage
SET1	AX (unidirectional)	Socket	Set input
ax (unidirectional)	Socket	Reset input	
ILOCK_IN	AX2 (bidirectional)	Socket	Interlock interface to the higher-level interface

Functionality

The function block implements an algorithm that performs the following calculations on each incoming event:

1. **Q1.D1 (Latch Output):**

Q1.D1 := SET1.D1 OR ILOCK_IN.DO1 OR ILOCK_OUT.DI1 OR ((NOT RESET.D1) AND Q1.D1)`

- The output is set if **SET1.D1**, **ILOCK_IN.DO1** (from above), or **ILOCK_OUT.DI1** (from below) has the value TRUE.
- If no set signal is active and **RESET.D1** = **FALSE**, the current value of Q1 is retained (memory behavior).
- Set is dominant: An active set overrides a reset.

1. **ILOCK_IN.DI1 (Propagation Upwards):**

ILOCK_IN.DI1 := SET1.D1 OR ILOCK_OUT.DI1`

- The set signal is propagated upwards when either its own set input or the signal of the lower stage is active.

1. **ILOCK_OUT.DO1 (Propagation Downwards):**

ILOCK_OUT.DO1 := SET1.D1 OR ILOCK_IN.DO1`

- The set signal is propagated downwards when either its own set input or the signal of the upper stage is active.

After each calculation, the event outputs Q1.E1, ILOCK_IN.EI1, and ILOCK_OUT.EO1 are activated.

Technical Features

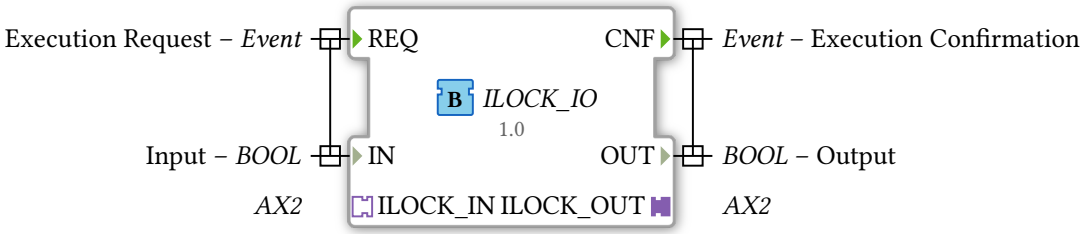
- **Interlock Cascade:** The function block can be used in a chain of multiple identical blocks. The AX2 adapter (ILOCK) propagates a set signal both upwards and downwards. This enables mutual interlocking across multiple stages.
- **Bidirectional Communication:** The AX2 adapter allows both sending and receiving events and data in both directions, enabling feedback from subordinate stages.
- **Set Dominance:** An active set input immediately sets the output and blocks a reset. This function block is therefore an **SR flip-flop with set signal priority**.
- **Pure Event Control:** The function block has no cyclical execution; every change is triggered only by a corresponding event.

State Overview

The function block has a single internal state, **REQ**, in which it always resides. The algorithm is executed upon each incoming event (SET1.E1, RESET.E1, ILOCK_IN.EO1, ILOCK_OUT.EI1), and then the system returns to the REQ state. There are no other states; the function block (FB) is essentially stateless (combinatorically with memory via feedback from Q1.D1).

Application Scenarios

- **Safety Interlock in Agricultural Engineering:** Cascading multiple ILOCK_FB_SR_AX functions to create a continuous interlock chain (e.g., for machine axes). A set signal from any point blocks all subsequent stages.
- **Production Systems with Release Chains:** Setting and resetting release signals in a hierarchical control system, where higher stages override lower ones.
- **Redundant Control Systems:** Utilizing the interlock function for mutual monitoring and interlocking of multiple control channels.



Comparison with Similar Function Blocks

- **Standard RS Flip-Flop (SR):** A simple SR function block has no interlock mechanism and no bidirectional data propagation. It can only be set or reset locally.
- **ILOCK_FB_SR_AX** extends the classic RS flip-flop with cascading capability via the AX2 interfaces. The dominance of the set signal and the bidirectional propagation make it particularly suitable for safety chains.
- **Monostable Function Blocks:** Unlike monostable functions, this function block retains its state until the next reset or set (bistable).

Conclusion

The ILOCK_FB_SR_AX is a specialized function block for building interlock chains with a set-dominant latch function. By combining unidirectional set/reset inputs and bidirectional interlock adapters, it is ideally suited for safety-related applications requiring cascading and mutual interlocking of multiple stages. Its simple, event-driven logic enables efficient and deterministic processing in automation technology.

ILOCK_IO

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ILOCK_IO** implements a cascadable, momentary (non-resettable) interlock with a BOOL interface. It is used to ensure that, in a chain of multiple function blocks, only one block sets its output to TRUE at a time, as long as its input is active and no other block in the chain is already active. This function block is particularly suitable for controllers where competing requirements must be handled exclusively.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Execution Request (triggers the processing of the IN input)

Event Outputs

Event	Data Type	Comment
CNF	Event	Execution Confirmation (signals that the output OUT has been updated)

Data Inputs

Variable	Data Type	Comment
IN	BOOL	Input Value (Set Request)

Data Outputs

Variable	Data Type	Comment
OUT	BOOL	Output Value (Enabled/Disabled)

Adapters

Label	Type	Direction	Description
ILOCK_IN	adapter::types::bidirectional::AX2	Socket	Input adapter for receiving locking information from the chain (from the predecessor)
ILOCK_OUT	adapter::types::bidirectional::AX2	Plug	Output adapter for sending locking information to the chain (to the successor)

The adapters of type `AX2` are bidirectional and contain the data points `DI1` (Data Input 1) and `DO1` (Data Output 1). In the chain, `ILOCK_OUT.DO1` and `ILOCK_IN.DI1`, as well as `ILOCK_OUT.DI1` and `ILOCK_IN.DO1`, are connected in pairs to implement the interlock logic.

Functionality

The function block operates as a **momentary latch with interlock**. The following algorithm is executed each time the event `REQ` is called:

1. The output `OUT` is set to TRUE if the input `IN` is TRUE **and** no other function block in the chain is active. The activity of other blocks is queried via the adapters:

- `ILOCK_IN.DO1`: Signal from the predecessor (whether it is active)
- `ILOCK_OUT.DI1`: Signal from the successor (whether it is active)
- Logic: `OUT := IN AND NOT (ILOCK_IN.DO1 OR ILOCK_OUT.DI1)`

1. Subsequently, the current state is propagated to its neighbors via the adapters:

- `ILOCK_IN.DI1 := OUT` – writes the state back to the predecessor
- `ILOCK_OUT.DO1 := OUT` – writes the state to the successor

The chain is structured so that only one block can be active at a time. If `IN` goes to FALSE, `OUT` immediately goes to FALSE, and the interlock is released.

Technical Features

- **Cascading**: Any number of `ILOCK_IO` blocks can be connected in series using the bidirectional adapters. Each block checks whether its predecessor or successor is already active before it becomes active itself.
- **Instantaneous Behavior**: The output is only TRUE as long as the input is active. There is no memory function – the block is not a flip-flop.
- **Exclusive Release**: Even with multiple simultaneous set requests, only one block can be activated. The priority is determined by the order of the `REQ` events (the one processed first blocks the others).

State Overview

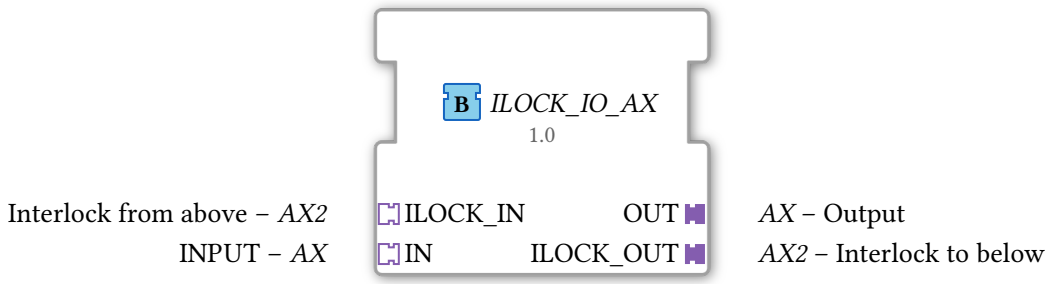
The block has a single **algorithmic state** `REQ`. Each time `REQ` is called, the algorithm is executed, and the system immediately transitions back to the same state. There is no state storage – the logic is purely combinatorial with feedback via the adapters.

State	Action	Output
REQ	Execute algorithm `REQ`	`CNF` is sent after calculation

Application Scenarios

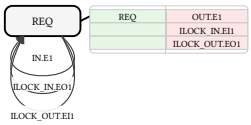
- **Traffic light control with multiple request buttons**: Each button is connected to a `ILOCK_IO`; only the first button pressed receives the enable signal.
- **Exclusive machine control**: Multiple control panels compete for control of a machine – only the active panel receives the authorization.
- **Safety Interlock**: In a conveyor system, several safety doors block each other; only one door can be open at a time.

Comparison with Similar Components



- **SR Flip-Flop (`SR`)** – stores a state, `ILOCK_IO` does not store (instantaneously).
- **Monostable Flip-Flop (`RTRIG`, `FTRIG`)** – reacts only to edges, `ILOCK_IO` operates on a level-controlled basis.

- **Simple `AND` Gate Component** – only local logic, no networking with other components. `ILOCK_IO` offers this networking via adapters.



Conclusion

The `ILOCK_IO` function block is a specialized block for implementing exclusive release chains. Its simple interface and cascadability make it ideal for modular controllers where multiple competing requirements need to be managed. The bidirectional adapters enable flexible and expandable wiring.

ILOCK_IO_AX

ECC: ILOCK_IO_AX

• – ○ • – ○ • – ○ •

Introduction

The function block **ILOCK_IO_AX** implements a chainable momentary latch with interlock functionality. It ensures that only one element in a chain is active at any given time – as soon as another function block in the chain becomes active, it is reset. The function block is specifically designed for use with AX/AX2 adapter interfaces.

Interface Structure

The block does not have any traditional event or data inputs/outputs at the function block level. All communication takes place via **adapter interfaces**. The signals transmitted via the adapters are detailed below.

Event Inputs

Signal	Adapter	Description
`IN.E1`	IN (AX)	Trigger for processing the input signal.
`ILOCK_IN.EO1`	ILOCK_IN (AX2)	Event from the parent function block in the chain (e.g., when a different output becomes active there).
`ILOCK_OUT.EI1`	ILOCK_OUT (AX2)	Event from the child function block in the chain (e.g., when it becomes active).

Event Outputs

Signal	Adapter	Description
`OUT.E1`	OUT (AX)	Confirmation that processing is complete.
`ILOCK_IN.EI1`	ILOCK_IN (AX2)	Event sent to the parent FB (sent with each processing cycle).
`ILOCK_OUT.EO1`	ILOCK_OUT (AX2)	Event sent to the child FB (sent with each processing cycle).

Data Inputs

Signal	Adapter	Description
`IN.D1`	IN (AX)	Set input (BOOL) – if TRUE and no other FB in the chain is active, the output becomes active.
`ILOCK_IN.DO1`	ILOCK_IN (AX2)	State of the parent FB (TRUE means that the output is active there).
`ILOCK_OUT.DI1`	ILOCK_OUT (AX2)	State of the child function block (TRUE means that its output is active).

Data Outputs

Signal	Adapter	Description
`OUT.D1`	OUT (AX)	Output signal (BOOL) – active when `IN.D1` is set and no other function block in the chain is active.
`ILOCK_IN.DI1`	ILOCK_IN (AX2)	Passes its own output signal to the parent function block.
`ILOCK_OUT.DO1`	ILOCK_OUT (AX2)	The output signal is passed on to the subordinate function block.

Adapter

Adapter	Direction	Type	Description
`IN`	Socket (Input)	`adapter::types::unidirectional::AX`	Input signal from the user (set input and event).
`OUT`	Plug (Output)	`adapter::types::unidirectional::AX`	Output signal to the user (output value and confirmation).
`ILOCK_IN`	Socket (Input)	`adapter::types::bidirectional::AX2`	Connection to the **parent** function block in the chain.
`ILOCK_OUT`	Plug (Output)	`adapter::types::bidirectional::AX2`	Connection to the **subordinate** FB in the chain.

Functionality

The FB operates as a **momentary switch with interlock** (also known as an "exclusive latch"). In state `REQ`, the following logic is executed:

- The output `OUT.D1` is only **TRUE** if the input `IN.D1` is active **and** no other FB in the chain is currently active (`ILOCK_IN.DO1` from the predecessor and `ILOCK_OUT.DI1` from the successor must be FALSE).
- The active state of the function block (`OUT.D1`) is passed on via the adapters `ILOCK_IN.DI1` (to the predecessor) and `ILOCK_OUT.DO1` (to the successor).
- Each triggering event input (whether from `IN.E1`, `ILOCK_IN.EO1`, or `ILOCK_OUT.EI1`) leads to a recalculation of the logic and the output of all events (`OUT.E1`, `ILOCK_IN.EI1`, `ILOCK_OUT.EO1`).

Due to the bidirectional state transmission via the ILOCK adapters, all function blocks in the chain are aware of each other, so only one can be active at a time.

Technical Features

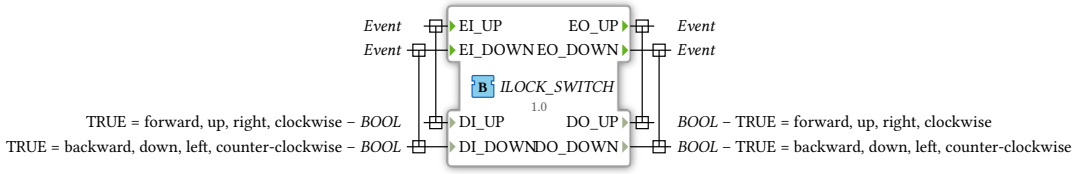
- **Chainable Interlock Structure**: Multiple ILOCK_IO_AX function blocks can be chained together by connecting `ILOCK_OUT` of one function block to `ILOCK_IN` of the next. The chain can be of any length.
- **No Own Events/Data at the Function Block Level**: All signal transmission takes place via the standardized AX/AX2 adapters. This allows for easy integration into existing adapter-based systems.
- **Only One Processing at a Time**: Since only one state (`REQ`) exists, the same logic is executed for each event. There are no internal state changes.

State Overview

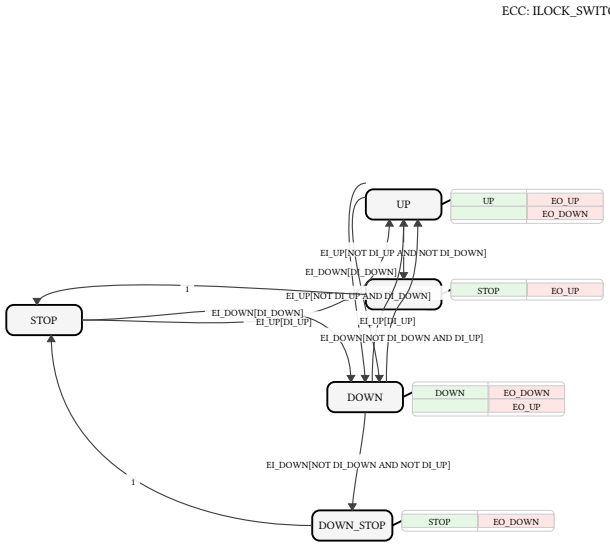
The function block has only one state:
+---+ | REQ | (Standardzustand) +---+ | ^ | | (Ereignisse: IN.E1, ILOCK_IN.EO1, ILOCK_OUT.EI1) +-+ In state `REQ`, the algorithm `REQ` and the event outputs are executed. This state is never exited.

Application Scenarios

- **Control of switching devices** (e.g., valves, motors) in a line where only one may be active at a time.
- **Non-priority selection** from multiple sources (e.g., a push-button panel with interlock).
- **Chained safety controllers** where activating a subsequent stage must deactivate the previous one (or vice versa).



Comparison with Similar Function Blocks



Function Block	Description	Difference to ILOCK_IO_AX
SR Flip-Flop	Sets output on SET, resets on RESET.	No interlock – multiple function blocks (FBs) can be active simultaneously.
Simple Latch (e.g., LATCH_AX)	Holds the value until triggered again.	No coupling with other FBs.
ILOCK_IO_AX	Exclusive activation in a chain.	Enforces that only one FB is active – ideal for line control systems.

Conclusion

The **ILOCK_IO_AX** is a specialized function block for exclusive activation in chained configurations. By using AX/AX2 adapters and bidirectional status feedback, robust interlock logic is implemented without separate wiring. It is particularly suitable for modular control structures where multiple actuators may only be active sequentially or individually.

ILOCK_SWITCH

• – ○ • – ○ • – ○ •

Introduction

The function block **ILOCK_SWITCH** serves as a priority-controlled switch with an interlock function. It evaluates two event signals (**EI_UP** and **EI_DOWN**) in combination with associated Boolean data values and sets the outputs **DO_UP** and **DO_DOWN** accordingly. The last active input is always prioritized – simultaneous activation of both outputs is impossible. The logic prevents oscillations and ensures a defined state even with invalid or conflicting input assignments.

Interface Structure

Event Inputs

Event	with Data	Description
EI_UP	DI_UP	Event for requesting the up/forward direction.
EI_DOWN	DI_DOWN	Event for requesting the down/backward direction.

Event Outputs

Event	with data	Description
EO_UP	DO_UP	Triggered when the up direction is activated or when exiting the UP state.
EO_DOWN	DO_DOWN	Triggered when the down direction is activated or when exiting the DOWN state.

Data Inputs

Name	Type	Comment
DI_UP	BOOL	TRUE = forward, up, right, clockwise
DI_DOWN	BOOL	TRUE = backward, down, left, counterclockwise

Data Outputs

Name	Type	Comment
DO_UP	BOOL	TRUE = forward, up, right, clockwise
DO_DOWN	BOOL	TRUE = backward, down, left, counterclockwise

Adapter

None.

Functionality

This component implements a finite automaton with six states. The basic idea: **The last valid instruction received sets the output state.** A command is only considered valid if the corresponding Boolean data value is **TRUE**.

- **STOP** (Idle State): Both outputs are **FALSE**.
- **UP**: DO_UP = TRUE, DO_DOWN = FALSE.

This is reached when **EI_UP** occurs with **DI_UP = TRUE** while the STOP state is in the STOP state.

- **DOWN**: DO_UP = FALSE, DO_DOWN = TRUE.

This is reached when **EI_DOWN** occurs with **DI_DOWN = TRUE** while the STOP state is in the STOP state.

- **UP_STOP**: An intermediate state that occurs when **EI_UP** occurs during the UP state, but **DI_UP = FALSE** (and also **DI_DOWN = FALSE**).

In UP_STOP, both outputs are set to FALSE, and the system immediately returns to STOP.

- **DOWN_STOP**: Analogous to UP_STOP for the DOWN state when **EI_DOWN** is **DI_DOWN = FALSE**.
- Direct switching is possible:

From **UP → DOWN** when **EI_DOWN** is **DI_DOWN = TRUE** or **EI_UP** is **DI_UP = FALSE** and **DI_DOWN = TRUE** (implicit request for the opposite direction).

From **DOWN → UP** analogously.

This logic ensures that only one direction is active at any given time and that the module cleanly returns to its idle state when invalid signals (FALSE values) are received.

Technical Features

- **Interlocking via state machines**: It is not possible to set both outputs to TRUE simultaneously – even with simultaneous events, switching occurs sequentially.
- **Intermediate States (UP_STOP, DOWN_STOP)**: These prevent unwanted flickering of the outputs by immediately resetting them and transitioning to STOP upon receiving invalid signals.
- **Implicit Switching**: An event whose data value requests the opposite direction (e.g., EI_UP with DI_UP=FALSE and DI_DOWN=TRUE) directly causes the direction change without requiring a separate EI_DOWN event.

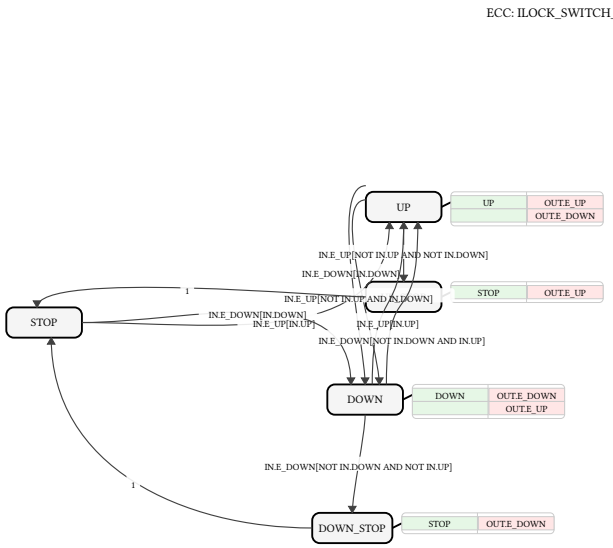
State Overview

State	DO_UP	DO_DOWN	Achieved by
STOP	FALSE	FALSE	Start / after UP_STOP and DOWN_STOP
UP	TRUE	FALSE	EI_UP with DI_UP=TRUE from STOP or DOWN
DOWN	FALSE	TRUE	EI_DOWN with DI_DOWN=TRUE from STOP or UP
UP_STOP	FALSE	FALSE	EI_UP with DI_UP=FALSE and DI_DOWN=FALSE in the UP state
DOWN_STOP	FALSE	FALSE	EI_DOWN with DI_DOWN=FALSE and DI_UP=FALSE in the DOWN state

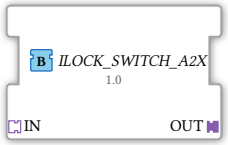
The transitions between states always occur via an incoming event and the evaluation of the current data values.

Application Scenarios

- **Motor control for linear actuators, swivel arms, or lifting devices**, where simultaneous movement in both directions must be prevented mechanically or for safety reasons.
- **Interlocking of valve actuators** (open/close) with feedback via limit switches.
- **Operator interfaces with pushbuttons for "Up" and "Down"**, where the last button press takes precedence and permanent blockage is avoided.



Comparison with Similar Function Blocks



- A simple **AND/OR gate** cannot implement interlocking and would activate both outputs with simultaneous TRUE signals.
- An **RS flip-flop** stores one state, but may allow both set/reset inputs to be activated simultaneously (metastable). ILOCK_SWITCH avoids this through its rigid transition logic.
- A **mux** would only pass through one data value, but cannot implement event-driven prioritization with intermediate states. ILOCK_SWITCH offers a solution specifically optimized for drive interlocks.

Conclusion

The **ILOCK_SWITCH** is a robust, event-driven function block for interlocked direction control. The combination of a state machine, data dependency, and explicit intermediate states reliably prevents typical problems such as simultaneous activation of both outputs or oscillations. It is particularly suitable for safety-critical controls in automation technology, where a clear and resettable priority logic is required.

ILOCK_SWITCH_A2X

Input for forward/up and backward/down direction – *A2X* *A2X* – Output for forward/up and backward/down direction

• — ○ • — ○ • — ○ •

Introduction

The `ILOCK_SWITCH_A2X` is an event-driven basic function block that implements a two-directional interlock switch for an A2X adapter signal. It accepts UP/DOWN requests through an `IN` adapter and forwards

the interlocked result through an OUT adapter. Only one direction can be active at a time. If both directions are requested, the last active input wins.

Interface Structure

The FB does not expose ordinary IEC 61499 event or data inputs/outputs. All control information is exchanged through two A2X adapter instances.

Event Inputs

None at the FB interface.

The FB receives events through the IN adapter:

- IN.E_UP — up-direction event, evaluated together with IN.UP.
- IN.E_DOWN — down-direction event, evaluated together with IN.DOWN.

Event Outputs

None at the FB interface.

The FB sends events through the OUT adapter:

- OUT.E_UP — up-direction output event, accompanied by OUT.UP.
- OUT.E_DOWN — down-direction output event, accompanied by OUT.DOWN.

Data Inputs

None at the FB interface.

The IN adapter supplies the boolean data:

- IN.UP — indicates whether the up direction is requested.
- IN.DOWN — indicates whether the down direction is requested.

Data Outputs

None at the FB interface.

The OUT adapter supplies the boolean data:

- OUT.UP — TRUE while the up direction is active.
- OUT.DOWN — TRUE while the down direction is active.

Adapters

Adapter	Direction	Type	Description
IN	Socket	adapter::types::unidirectional::A2X	Input for forward/up and backward/down direction.
OUT	Plug	adapter::types::unidirectional::A2X	Output for forward/up and backward/down direction.

Functionality

The FB is a basic FB controlled by an ECC. It evaluates the A2X input events and data and produces an interlocked A2X output.

- In the STOP state, both OUT.UP and OUT.DOWN are FALSE; no direction is active.
- If an IN.E_UP event arrives with IN.UP = TRUE, the FB enters UP and activates OUT.UP.
- If an IN.E_DOWN event arrives with IN.DOWN = TRUE, the FB enters DOWN and activates OUT.DOWN.
- If a direction event arrives that requests the other direction while one direction is active, the FB switches to the other direction. This ensures last-active-input priority.
- If the active direction is released and no other direction is requested, the FB passes through a stop state and returns to STOP.
- If the active direction is released but the other direction is still requested, the FB switches directly to the remaining direction.

The algorithms used by the states are:

Algorithm	OUT.UP	OUT.DOWN
UP	TRUE	FALSE

DOWN	FALSE	TRUE
STOP	FALSE	FALSE

The output events are generated together with these data values, so a receiving block can react both to a direction change and to the release of the opposite direction.

Technical Features

- IEC 61499 basic FB with ECC-based, event-driven behavior.
- No external event/data inputs or outputs; all signals are transported by the unidirectional A2X adapters.
- Interlocked output: `OUT.UP` and `OUT.DOWN` can never be `TRUE` at the same time.
- Last-event priority when both input directions are active.
- Automatic stop handling through transient `UP_STOP` and `DOWN_STOP` states.
- Suitable for integration in `logiBUS::signalprocessing::interlock` signal-processing chains.

State Overview

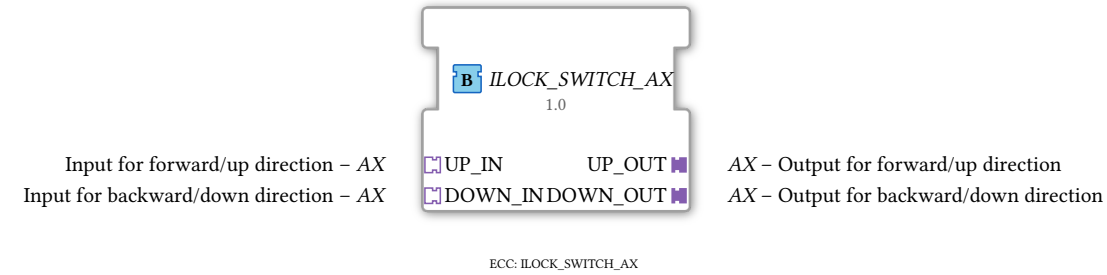
State	Output Data	Output Events	Meaning
STOP	OUT.UP = FALSE, OUT.DOWN = FALSE	—	No direction active.
UP	OUT.UP = TRUE, OUT.DOWN = FALSE	OUT.E_UP, OUT.E_DOWN	Up direction active.
DOWN	OUT.UP = FALSE, OUT.DOWN = TRUE	OUT.E_DOWN, OUT.E_UP	Down direction active.
UP_STOP	OUT.UP = FALSE, OUT.DOWN = FALSE	OUT.E_UP	Transient stop from up direction.
DOWN_STOP	OUT.UP = FALSE, OUT.DOWN = FALSE	OUT.E_DOWN	Transient stop from down direction.

The ECC transitions are:

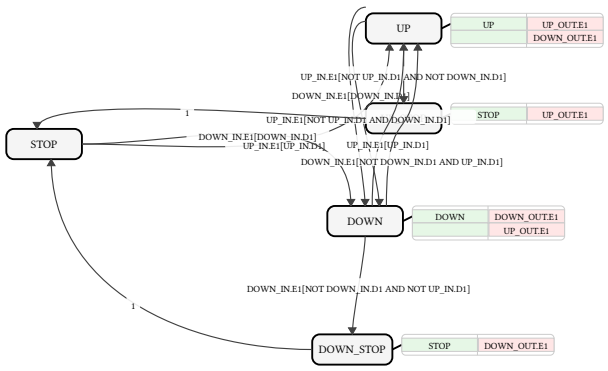
From	Condition	To
STOP	IN.E_UP[IN.UP]	UP
STOP	IN.E_DOWN[IN.DOWN]	DOWN
UP	IN.E_DOWN[IN.DOWN]	DOWN
UP	IN.E_UP[NOT IN.UP AND IN.DOWN]	DOWN
UP	IN.E_UP[NOT IN.UP AND NOT IN.DOWN]	UP_STOP
DOWN	IN.E_UP[IN.UP]	UP
DOWN	IN.E_DOWN[NOT IN.DOWN AND IN.UP]	UP
DOWN	IN.E_DOWN[NOT IN.DOWN AND NOT IN.UP]	DOWN_STOP
UP_STOP	1	STOP
DOWN_STOP	1	STOP

Application Scenarios

- Direction control of hydraulic or electric actuators that must not run in two directions simultaneously.
- Interlocking of forward/backward or up/down control signals on a logiBUS A2X connection.
- Conversion of a raw A2X input into a clean, interlocked A2X output for downstream control logic.
- Use as an adapter-based replacement for a conventional two-input interlock FB where UP/DOWN signals are fed from a single A2X input/output.



Comparison with Similar Blocks



- Compared with a non-adapter `ILOCK_SWITCH`, this variant uses an A2X adapter for both input and output. This simplifies wiring when the surrounding system already uses A2X signals.
- Compared with an SR latch, this FB provides two separate direction outputs with associated events and an explicit stop state. It does not use a fixed set/reset priority; instead, the last active input wins.
- Compared with a fixed-priority direction selector, this FB can react to event/data combinations that indicate “one direction released, other still active” and switch to the remaining direction.

Conclusion

`ILOCK_SWITCH_A2X` is a compact, adapter-based interlock element for two-direction control signals. It combines a simple state machine with A2X adapter input/output, provides last-active-input prioritization, and guarantees that the output never activates both directions at the same time. It is especially useful in logiBUS signal-processing applications where UP/DOWN commands are transported over a single A2X connection.

ILOCK_SWITCH_AX

(No image available)

• – ○ • – ○ • – ○ •

Introduction

The function block **ILOCK_SWITCH_AX** implements interlocking switch control for bidirectional axes. It prioritizes the last active input and ensures that both directions are never activated simultaneously. Communication occurs exclusively via adapter interfaces of type `adapter::types::unidirectional::AX`. This version is specifically designed for use in modular control systems with standardized adapters.

Interface Structure

Event Inputs
None (all events are transmitted via the adapter sockets).

Event Outputs
None (all events are transmitted via the adapter plugs).

Data Inputs
None (all data is transmitted via the adapter sockets).

Data Outputs
None (all data is transmitted via the adapter plugs).

Adapters

Name	Type	Direction	Comment
UP_IN	adapter::types::unidirectional::AX	Socket	Input for forward/upward direction
DOWN_IN	adapter::types::unidirectional::AX	Socket	Input for reverse/downward direction
UP_OUT	adapter::types::unidirectional::AX	Plug	Output for forward/upward direction
DOWN_OUT	adapter::types::unidirectional::AX	Plug	Output for reverse/downward direction

Each adapter provides an event output `E1` and a data input/output `D1` (of type BOOL). The sockets receive requests, and the plugs pass on the switched states.

Functionality
The logic is implemented using a finite state machine (ECC). The function block is initially in state `STOP`. A change to the states `UP` or `DOWN` occurs when the corresponding socket returns an event `E1` with the data value `D1` set (i.e., `UP_IN.E1[UP_IN.D1]` or `DOWN_IN.E1[DOWN_IN.D1]`).

- In the state `UP`, `UP_OUT.D1` is set to `TRUE` and `DOWN_OUT.D1` is set to `FALSE`.
- In the state `UP`, `UP_OUT.D1` is set to `TRUE` and `DOWN_OUT.D1` to `FALSE`.
- In state `DOWN`, `DOWN_OUT.D1` is set to `TRUE` and `UP_OUT.D1` to `FALSE`.

A change from the current state to the other is only possible when the other socket becomes active (prioritization of the last active input). The conditions are differentiated as follows:

- **UP → DOWN**: either directly via `DOWN_IN.E1[DOWN_IN.D1]` or when the current input is deactivated and the other is active (`UP_IN.E1[NOT UP_IN.D1 AND DOWN_IN.D1]`).
- **DOWN → UP**: analogously via `UP_IN.E1[UP_IN.D1]` or `DOWN_IN.E1[NOT DOWN_IN.D1 AND UP_IN.D1]`.

If the active input is lost without the other becoming active, an intermediate state (`UP_STOP` or `DOWN_STOP`) is reached. In this state, the outputs are set to `FALSE`, and then the state machine immediately transitions to the `STOP` state.

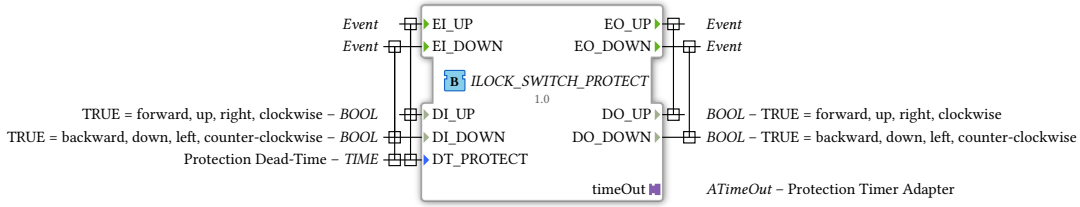
Technical Features
- **Adapter-based interface**: The function block uses only adapters of type `unidirectional::AX`, which enables clean encapsulation of event and data communication and facilitates reuse in different contexts.
- **Prioritization of the last active input**: Unlike a simple state machine that only reacts to rising edges, this system considers the last valid signal sent.
- **Secure Interlock**: The ECC structure prevents both outputs from becoming `TRUE` simultaneously.
- **Explicit Stop Intermediate States**: The states `UP_STOP` and `DOWN_STOP` ensure a defined response to the disappearance of a control signal before returning to the idle state.

State Overview

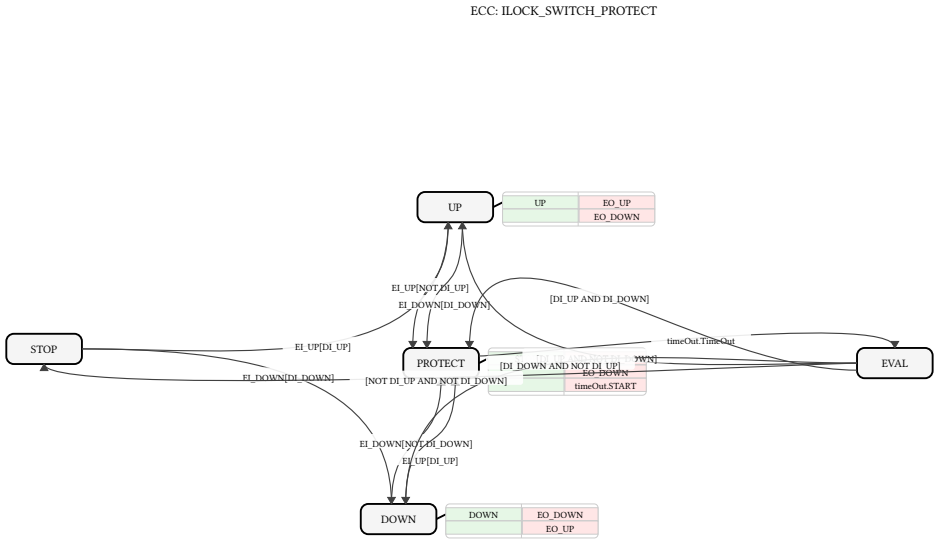
State	UP_OUT.D1	DOWN_OUT.D1	Description
`STOP`	FALSE	FALSE	Idle state, no direction active
`UP`	TRUE	FALSE	Forward/Upward Direction Active
DOWN`	FALSE	TRUE	Backward/Downward Direction Active
UP_STOP`	FALSE	FALSE	Intermediate State After Exiting UP
DOWN_STOP`	FALSE	FALSE	Intermediate State After Exiting DOWN

Application Scenarios

- **Control of lifting/lowering drives** (e.g., hoists, hydraulic cylinders) – prevents simultaneous lifting and lowering.
- **Interlocking of switches** in conveyor systems – prioritizes the most recent request.
- **Safety-oriented switching** in modular automation systems using an adapter-based data model (e.g., logiBUS).



Comparison with similar function blocks



- **ILOCK_SWITCH** (without adapter): Offers similar interlock logic but uses direct event and data ports. The adapter version `ILOCK_SWITCH_AX` allows for easier coupling to standardized interfaces and is better suited for hierarchical architectures.
- **SR-Flipflop** (Set-Reset): Can also lock two states, but always prioritizes the set or reset input (depending on the implementation) and not the last active one.

Conclusion

The function block `ILOCK_SWITCH_AX` offers robust, adapter-based interlocking for bidirectional controllers. Due to the state automation, only one direction is active at a time, with priority assigned to the last received command. The clean separation of event and data channels, as well as the defined stop states, make it a reliable component in safety-critical applications.

ILOCK_SWITCH_PROTECT

• – ○ • – ○ • – ○ •

Introduction

The **ILOCK_SWITCH_PROTECT** function block implements a prioritized interlock between two switching directions – e.g., up/down, forward/backward, or right/left. It features a configurable dead-time delay that prevents immediate re-switching after a change of direction. The block evaluates the two binary inputs and outputs a switching signal only if the last active input is still active after the dead-time has expired. This prevents momentary oscillations and protects connected actuators.

Interface Structure

Event Inputs

Name	With Parameters	Description
EI_UP	`DI_UP`, `DT_PROTECT`	Event requesting the “Up” direction
EI_DOWN	`DI_DOWN`, `DT_PROTECT`	Event requesting the “Down” direction

Event Outputs

Name	With Parameters	Description
EO_UP	`DO_UP`	Confirmation that the “Up” direction has been activated
EO_DOWN	`DO_DOWN`	Confirmation that the “Down” direction has been activated

Data Inputs

Name	Data Type	Initial Value	Description
DI_UP	BOOL	–	TRUE = forward, up, right, clockwise
DI_DOWN	BOOL	–	TRUE = backward, down, left, counterclockwise
DT_PROTECT	TIME	T#50ms	Protection delay (dead time) before a change of direction

Data Outputs

Name	Data Type	Description
DO_UP	BOOL	TRUE = Output active for direction “Up”
DO_DOWN	BOOL	TRUE = Output active for direction “Down”

Adapter

Name	Type	Description
timeOut	`iec61499::events::ATimeOut`	Adapter for implementing the protection delay

Functionality

The module operates as a finite state machine with five states:

1. **STOP** – Idle state. Both outputs are FALSE.

- Upon an event with a valid input (`EI_UP[DI_UP]` or `EI_DOWN[DI_DOWN]`), the module switches directly to the corresponding state.

1. **UP** – The “Up” direction is active. `DO_UP = TRUE`, `DO_DOWN = FALSE`.

- A repeat `EI_UP` with an inactive request (`NOT DI_UP`) or a `EI_DOWN` with an active request (`DI_DOWN`) triggers the protection state.

1. **DOWN** – The “Down” direction is active. `DO_UP = FALSE`, `DO_DOWN = TRUE`.

Similarly: `EI_DOWN[NOT DI_DOWN]` or `EI_UP[DI_UP]` initiates the protection state.

1. **PROTECT** – Protection state. Both outputs are immediately reset (FALSE) and the timer of the adapter `timeOut` is started.

- Only after the configured time (`DT_PROTECT`) has elapsed does the evaluation state begin.

1. **EVAL** – Evaluation after the protection time.

- Based on the current inputs, the following is determined:
- `DI_UP AND NOT DI_DOWN` ⟶ **UP**
- `DI_DOWN AND NOT DI_UP` ⟶ **DOWN**
- `NOT DI_UP AND NOT DI_DOWN` ⟶ **STOP**
- `DI_UP AND DI_DOWN` (both active simultaneously) ⟶ **PROTECT** again (invalidation case)

The event outputs are triggered along with the respective executed algorithm. In the UP, DOWN, and PROTECT states, **both** event outputs (EO_UP and EO_DOWN) are sent sequentially – this is a specific behavior of this function block.

Technical Features

- **Adapter-Based Timer Implementation**: The protection delay is implemented using the standardized IEC61499 adapter `ATimeOut`. This makes the time control platform-independent and allows it to be used in various runtime environments.
- **Dead Time Preset**: The time `DT_PROTECT` is set in the algorithms for the UP, DOWN, and STOP states before the timer is started, if applicable. This ensures that the current time configuration always applies, even if the protection state is repeatedly entered.
- **Lockout for Simultaneous Requests**: If both inputs (`DI_UP` and `DI_DOWN`) are simultaneously requested, the timer is locked.If both conditions are TRUE, the function block remains in the protection state until the request is resolved.

State Overview

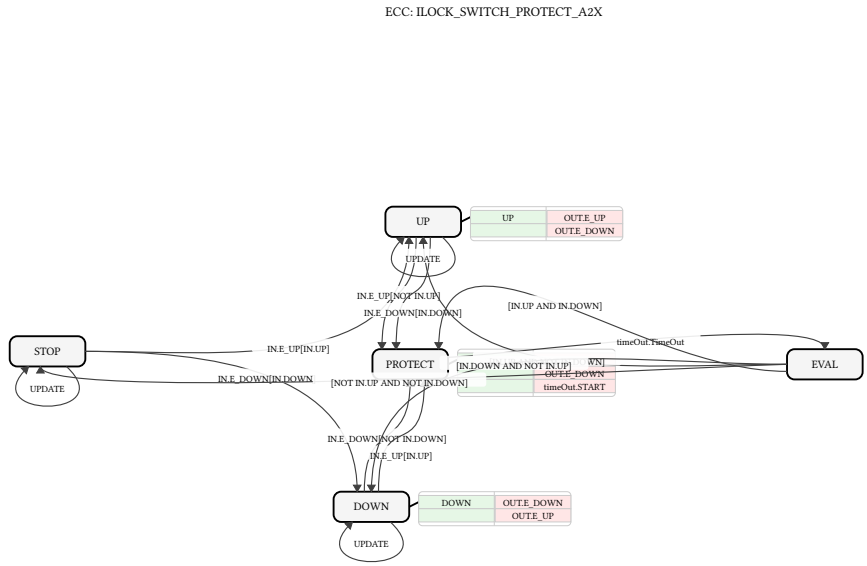
State	Description	DO_UP	DO_DOWN	Triggered Event Outputs
STOP	Waiting for a valid request; outputs inactive	FALSE	FALSE	–

UP	Up direction active; switching blocked without intermediate step	TRUE	FALSE	EO_UP, EO_DOWN
DOWN	Down direction active; switching blocked without intermediate step	FALSE	TRUE	EO_DOWN, EO_UP
PROTECT	Protection delay in progress; all outputs disabled	FALSE	FALSE	EO_UP, EO_DOWN, timeOut.START
EVAL	After the protection time has elapsed, the inputs are evaluated	–	–	– (state change)

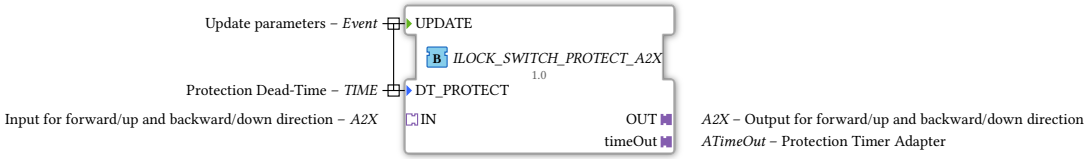
Application Scenarios

- **Drive Control**: Prevents rapid changes of direction in motors that require a mechanical or electrical dead time (e.g., fans, conveyor belts, sliding gates).
- **Valve or Damper Control**: Ensures that a defined pause is observed before a change of direction (opening/closing) to prevent pressure surges or cavitation.
- **Safety-Oriented Interlock**: The function block can be used to debounce competing control signals and only accept the last pending command after a defined hold time.

Comparison with Similar Function Blocks



Function Block	Special Feature
SR Latch	Simple set-reset flip-flop with no delay
Interlock (simple)	Switches instantly, no dead time
ILOCK_SWITCH_PROTECT	Configurable protection delay, evaluation after the delay, handling of simultaneous requests



Compared to simple latches, **ILOCK_SWITCH_PROTECT** offers controlled switching, which is particularly advantageous with inductive loads or mechanically slow systems.

Conclusion

The **ILOCK_SWITCH_PROTECT** function block is a robust IEC 61499 component for applications requiring time-delayed, prioritized switching between two states. Its adjustable dead time, adapter-based timer implementation, and clear state logic make it particularly suitable for industrial control systems where reliability and protection mechanisms are paramount. The simultaneous activation of both event outputs in the action states should be considered during integration.

ILOCK_SWITCH_PROTECT_A2X

• – ○ • – ○ • – ○ •

Introduction

The **ILOCK_SWITCH_PROTECT_A2X** function block is an adapter-based implementation of a protective interlock switch. It takes forward/up and backward/down commands via a single `A2X` input adapter, prioritizes the most recent active command, and applies a configurable dead-time (`DT_PROTECT`) before actually switching the output direction. This prevents rapid or accidental direction changes that could damage mechanical systems.

The block is designed for applications where a controlled directional actuation (e.g., a motor, valve, or shutter) must be protected against abrupt reversals. It uses an internal state machine to manage the protective delay and outputs the resulting direction via an `A2X` output adapter.

Interface Structure

Event Inputs

Event	With	Comment
`UPDATE`	`DT_PROTECT`	Updates the protection dead-time parameter. The new value is taken from the associated data input.

Event Outputs

The block does not have direct event outputs. Instead, events are emitted through its output adapters:

- `OUT.E_UP` – signals the active upward/forward direction (via `OUT` adapter).
- `OUT.E_DOWN` – signals the active downward/backward direction (via `OUT` adapter).
- `timeOut.START` – starts the protective timer (via `timeOut` adapter).

Data Inputs

Name	Type	Initial Value	Comment
DT_PROTECT	TIME	T#50ms	Protection dead-time, i.e., the minimum delay between a command change and the actual output transition.

Data Outputs

The block does not have direct data outputs. Direction data is provided via the OUT adapter:

- OUT.UP – boolean indicating upward/forward direction is active.
- OUT.DOWN – boolean indicating downward/backward direction is active.

Adapters

Adapter	Type	Direction	Comment
IN	adapter::types::unidirectional::A2X	Socket (input)	Provides input commands: events E_UP/E_DOWN and data UP/DOWN.
OUT	adapter::types::unidirectional::A2X	Plug (output)	Outputs the resulting direction: events E_UP/E_DOWN and data UP/DOWN.
timeOut	iec61499::events::ATimeOut	Plug (output)	Timer adapter used for the protective dead-time. It receives a DT data value and a START event. The TimeOut event is used internally to trigger evaluation after the delay.

Functionality

The block operates as a directional interlock with a configurable protection delay. It continuously monitors the input adapter IN for two command types:

- UP (forward/upward)
- DOWN (backward/downward)

When a command is received and there is no current movement, the block sets the output direction immediately (after a short internal evaluation). However, if a direction change is requested while the opposite direction is already active, the block does **not** switch directly. Instead, it enters a PROTECT state, stops all output, and starts the protection timer with DT_PROTECT. Once the timer expires, the block evaluates the current input conditions and decides the next state:

- If only UP is active, it switches to the UP state.
- If only DOWN is active, it switches to the DOWN state.
- If neither is active, it returns to STOP.
- If both are active, it remains in PROTECT and restarts the timer (this ensures that the last active command eventually wins, but no direction is set while both are given).

The UPDATE event can be used anytime to change the dead-time value. The new value is applied immediately, even if a protection cycle is already running (the timer uses the updated DT_PROTECT value).

Technical Features

- **Adapter-based I/O**: Uses standard A2X adapters for both input and output, making it easy to interface with other blocks and reuse in different contexts.
- **Configurable dead-time**: The DT_PROTECT parameter (via UPDATE) allows the user to adjust the minimum delay before a direction change takes effect.
- **Priority handling**: The block resolves simultaneous UP and DOWN commands by staying in protective mode until only one direction remains active.
- **Transparent state machine**: The internal ECC clearly defines the states and transitions, ensuring deterministic behavior.
- **Timer integration**: Uses a standard ATimeOut adapter for timing, which simplifies integration with other timing resources.

State Overview

The internal ECC consists of five states:

State	Description
STOP	Idle state. No output direction is active. The block waits for an input command.
UP	Upward/forward direction is active. Outputs OUT.UP = TRUE and OUT.DOWN = FALSE. Emits OUT.E_UP.
DOWN	Downward/backward direction is active. Outputs OUT.UP = FALSE and OUT.DOWN = TRUE. Emits OUT.E_DOWN.
PROTECT	Protection delay active. All outputs are cleared (OUT.UP = FALSE, OUT.DOWN = FALSE). The timer is started with DT_PROTECT.
EVAL	Evaluation state after the delay. Determines the next direction based on current input values.

Transitions:

- From STOP to UP if IN.E_UP occurs and IN.UP is true.
- From STOP to DOWN if IN.E_DOWN occurs and IN.DOWN is true.
- From UP to PROTECT if IN.E_UP occurs with IN.UP false (i.e., release) or IN.E_DOWN occurs with IN.DOWN true (request opposite direction).
- From DOWN to PROTECT if IN.E_DOWN occurs with IN.DOWN false or IN.E_UP occurs with IN.UP true.
- From PROTECT to EVAL when the timer expires (timeOut.TimeOut).
- From EVAL to UP, DOWN, STOP, or PROTECT based on the combination of IN.UP and IN.DOWN.
- From any state back to itself on UPDATE (parameters are refreshed without changing the operating state).

Application Scenarios

The **ILOCK_SWITCH_PROTECT_A2X** block is suitable for any system that requires safe direction control with a mandatory dwell time between reversals. Typical examples include:

- **Electric motors** driving conveyor belts or winches where sudden reversal can cause mechanical stress.
- **Roller shutters, blinds, or gates** that must not change direction abruptly.
- **Valves or actuators** with inherent mechanical limits that require a short settling time.
- **Robotic axes** where a reversal must be delayed to avoid overcurrent or overshoot.
- **Pumps or fans** that should not be toggled rapidly.

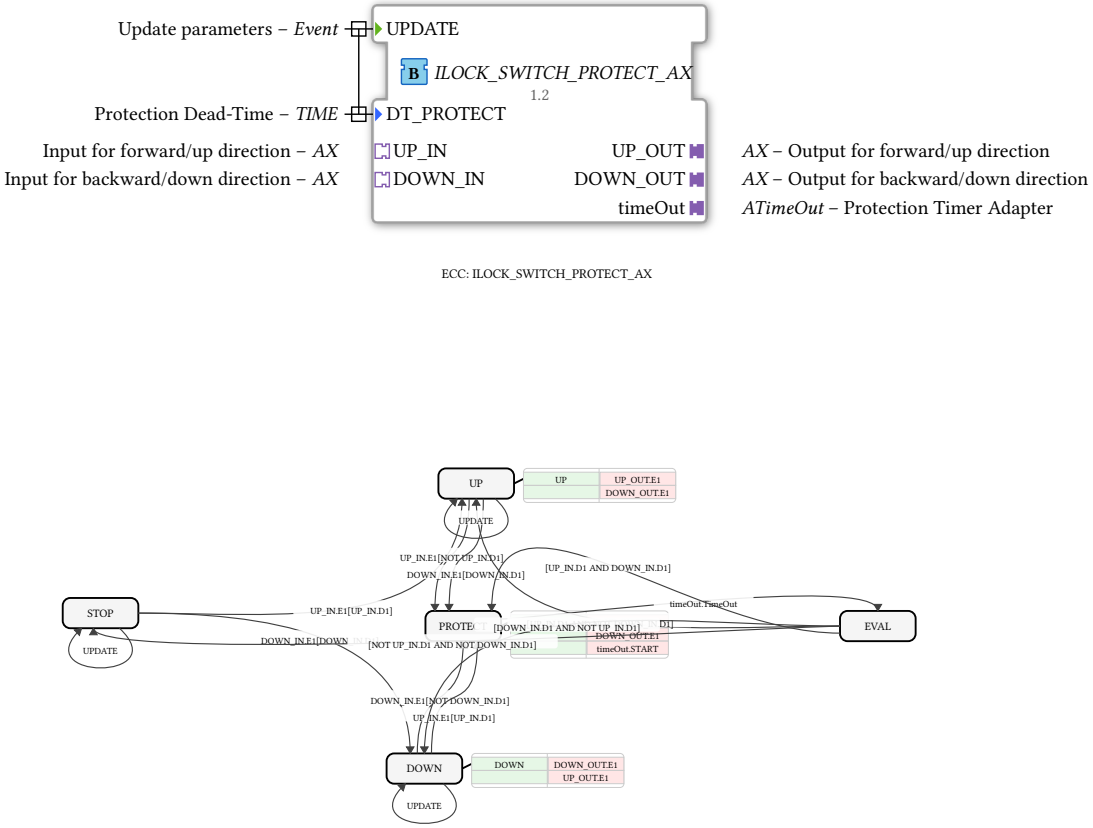
The block is especially useful in safety-critical applications where a defined delay is mandated by regulations.

Comparison with Similar Blocks

Compared to a simple interlock switch (that switches direction immediately), this block adds a **protective dead-time**. This feature is essential when:

- The driven load has significant inertia and can be damaged by rapid direction changes.
- The control system must prevent simultaneous activation of both directions (e.g., to avoid short-circuiting a bridge).
- The application requires a minimum delay for settling or safety reasons.

The adapter version (A2X) offers a clean interface that separates control commands from the actual output, making it more modular than a version with direct I/O ports. It also simplifies integration with other adapter-based systems. The use of a standard timer adapter (ATimeOut) allows the dead-time to be synchronized with global timing resources.



In contrast to blocks without a prioritization mechanism, this block handles the case where both UP and DOWN are given simultaneously by waiting in PROTECT until one command disappears. This ensures that the last active input eventually wins, preventing an undefined state.

Conclusion

The **ILOCK_SWITCH_PROTECT_A2X** function block provides a robust and configurable solution for interlocked direction control with a protective delay. Its adapter-based interface makes it easy to integrate into larger IEC 61499 applications, while the internal state machine guarantees deterministic behavior under all input conditions. The ability to dynamically update the dead-time via the UPDATE event adds

flexibility for changing operational requirements. This block is particularly suited for applications where mechanical or electrical protections demand a minimum time between direction reversals.

ILOCK_SWITCH_PROTECT_AX

• – ○ • – ○ • – ○ •

Introduction

The function block `ILOCK_SWITCH_PROTECT_AX` is used for interlocked switching between two input channels (UP/DOWN) with an adjustable protection dead time. It prioritizes the last active input and, through the dead time, prevents uncontrolled switching back and forth (bouncing) in the case of simultaneous or rapidly changing demands. The interface is provided via standardized unidirectional adapters (type `AX`) and a timer adapter.

Interface Structure

Event Inputs

Event	Description
`UPDATE`	Parameterization event; The current value of `DT_PROTECT` is assigned to the timer.

Event Outputs

No direct event outputs. Output is implicit via the adapters:

- `UP_OUT.E1` – Event output of the Up adapter
- `DOWN_OUT.E1` – Event output of the Down adapter
- `timeOut.TimeOut` – Event of the Timer adapter (internal use)

Data Inputs

Name	Type	Initial Value	Description
DT_PROTECT	TIME	T#50ms	Protection dead time that is activated after a state change.

Data Outputs

No direct data outputs. State output is provided via the adapters:

- UP_OUT.D1 – Boolean value for the up output (TRUE when active)
- DOWN_OUT.D1 – Boolean value for the down output (TRUE when active)

Adapters

Direction	Name	Type	Description
Socket	UP_IN	adapter::types::unidirectional::AX	Input for the "Up/Forward" request. Contains event E1 and Boolean data D1.
Socket	DOWN_IN	adapter::types::unidirectional::AX	Input for the "Down/Backward" request.
Plug	UP_OUT	adapter::types::unidirectional::AX	Output for the Up direction.
Plug	DOWN_OUT	adapter::types::unidirectional::AX	Output for the Down direction.
Plug	timeOut	iec61499::events::ATimeOut	Timer adapter for implementing dead time. Controls the event TimeOut after DT_PROTECT has elapsed.

Functionality

This module implements a **latched two-channel circuit with dead time**:

- The two inputs UP_IN and DOWN_IN can never be active simultaneously.
- As soon as an input becomes active (i.e., its event E1 occurs and the corresponding data D1 is TRUE), the module switches to the corresponding state (UP or DOWN) after a short dead time.
- If a direction change occurs, the **protection state PROTECT** is first entered, in which all outputs are set to FALSE and the timer is started with DT_PROTECT. After the dead time has elapsed, the system switches to state EVAL, which determines the final state based on the current input signals.
- The dead time prevents crosstalk or signal bounce, e.g., with mechanical switches or overlapping requirements.

Technical Features

- **Adapter-based interface**: The function block communicates exclusively via standardized adapters (AX for Boolean control, ATimeOut for timers). This allows for easy reuse in various container blocks.
- **Integrated Protection Logic**: In state PROTECT, all outputs are deactivated before a new direction is activated – this protects connected hardware (e.g., motors, valves) from short circuits or mutual blocking.
- **Parameter Update**: The event UPDATE allows dynamic adjustment of the dead time at runtime without having to reset the function block.
- **Dead Time on Every State Change**: Every transition (Stop→Up, Down→Up, etc.) always goes through the protection phase, regardless of the previous direction.

State Overview

State	Description
STOP	Idle state. No output active. Waiting for an input to be activated.

UP	Output UP_OUT.D1 = TRUE, DOWN_OUT.D1 = FALSE. Activates when UP_IN.D1 is present and DOWN_IN.D1 is inactive.
DOWN	Output DOWN_OUT.D1 = TRUE, UP_OUT.D1 = FALSE. Activates when DOWN_IN.D1 is present and UP_IN.D1 is inactive.
PROTECT	Protection phase. Both outputs are immediately set to FALSE, and the timer is started. After DT_PROTECT expires, the process switches to EVAL.
EVAL	Evaluation status. Based on the current input data, a decision is made as to which final state (STOP, UP, DOWN) or PROTECT (in case of simultaneous requests) will be applied.

The transitions defined in the ECC are:

- STOP ⟶ UP (at UP_IN.E1 and UP_IN.D1)
- STOP ⟶ DOWN (at DOWN_IN.E1 and DOWN_IN.D1)
- UP ⟶ PROTECT (at UP_IN.E1 and NOT UP_IN.D1 OR DOWN_IN.E1 and DOWN_IN.D1)
- DOWN ⟶ PROTECT (analogous)
- PROTECT ⟶ EVAL (after timeOut.TimeOut)
- EVAL ⟶ UP (at UP_IN.D1 AND NOT DOWN_IN.D1)
- EVAL ⟶ DOWN (at DOWN_IN.D1 AND NOT UP_IN.D1)
- EVAL ⟶ STOP (at NOT UP_IN.D1 AND NOT DOWN_IN.D1)
- EVAL ⟶ PROTECT (at UP_IN.D1 AND DOWN_IN.D1)
- In each state, an UPDATE event can re-evaluate the state and Update the dead time.

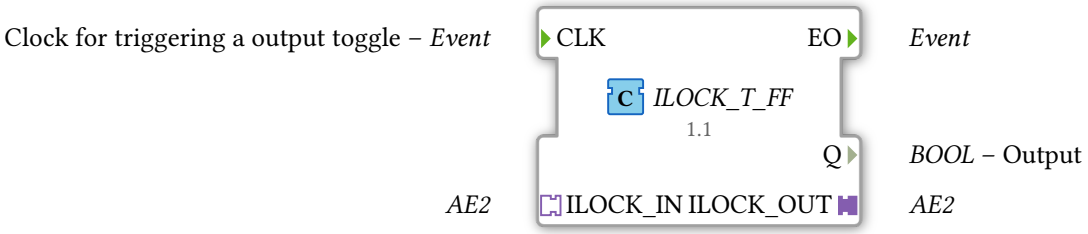
Application Scenarios

- **Interlocking of drives**: For example, in a lifting table or conveyor belt that may only be active in one direction at a time.
- **Short-circuit protection** in H-bridge circuits: Before the polarity of a motor is switched, both outputs are briefly deactivated.
- **Switching safety logic** in agricultural technology or automation, where mechanical limit switches or proximity sensors require time-based debouncing.
- **Interface between two control systems**: If both systems control a common axis, the function block prevents collisions by prioritizing the last active input.

Comparison with similar function blocks

- **Simple RS flip-flop**: Offers no dead time and switches instantly – can oscillate with overlapping signals.
- **SWITCH (without protection)**: Standard toggle switch also switches without delay and without debouncing.
- **SR Latch with Timer**: Similar function, but usually implemented as a composite function block. ILOCK_SWITCH_PROTECT_AX encapsulates all the logic, including the timer and evaluation, in a single Basic Function Block.
- **Interlock Function Blocks in IEC 61499**: Many libraries offer interlock function blocks, but often without an adapter interface or with fixed delays. This block is specifically designed for use with unidirectional AX adapters.

Conclusion



ILOCK_SWITCH_PROTECT_AX`This robust and flexible component for interlocked switching with adjustable protection dead time. The adapter-based interface enables seamless integration into modular 4diac architectures. The clear state machine ensures deterministic behavior and provides protection against faulty switching in time-critical applications. Ideal for applications in agricultural technology, automation, and drive technology where reliable direction changes are required.

ILOCK_T_FF

• – ○ • – ○ • – ○ •

Introduction

The **ILOCK_T_FF** is a composite function block (FB) that implements a lockable toggle flip-flop (T flip-flop). It extends a simple T flip-flop with a bidirectional interlock interface, allowing multiple blocks to be chained together in an interlock chain. This block is particularly suitable for safety-related control systems where states that have been switched must be blocked and passed on to subsequent elements.

Interface Structure

Event Inputs

Name	Type	Description
CLK	Event	Trigger signal to toggle the output.

Event Outputs

Name	Type	Description
EO	Event	Triggered as soon as the internal set/reset latch changes its state.

Data Inputs

No data inputs (control is achieved solely through events and the adapters).

Data Outputs

Name	Type	Description

Q	BOOL	Current state of the flip-flop (0 or 1).

Adapter

Name	Type	Direction	Description
ILOCK_IN	`adapter::types::bidirectional::AE2`	Socket	Receives and sends lock signals to and from upstream components in the chain.
ILOCK_OUT	`adapter::types::bidirectional::AE2`	Plug	Sends and receives lock signals to and from downstream components.

Functionality

Internally, the component consists of an **E_SWITCH** (event branch) and an **E_SR** (set-reset latch):

1. **Normal Operation (No Lock)**

- An event at the **CLK** is forwarded to the **E_SWITCH**.
- The output **Q** of the internal latch serves as the control signal **G** for the **E_SWITCH**:
- If **Q** = **FALSE**, the **E_SWITCH** switches the event to **E_SR.S** (Set) – **Q** becomes **TRUE**.
- If **Q** = **TRUE**, the **E_SWITCH** switches the event to **E_SR.R** (Reset) – **Q** becomes **FALSE**.
- This ensures a clean toggle (edge transition) with every **CLK**.

1. **Lock Mechanism (Interlock)**

- Lock events can be fed into the chain via the adapters **ILOCK_IN** and **ILOCK_OUT**.
- A lock event (e.g., from an upstream component via **ILOCK_IN.EO1** or from a downstream component via **ILOCK_OUT.EI1**) is applied to the **Reset** (**R**) of the latch.
- This immediately resets **Q** to **FALSE**. The toggle operation is interrupted because the **E_SWITCH** now remains in the **Q** = **FALSE** state and would attempt to set it on the next **CLK** event – however, the lock signal can take effect again.
- **Lock Propagation**: Each incoming lock event is simultaneously propagated to the other adapter output:
- **ILOCK_IN.EO1 → ILOCK_OUT.EO1** (to subsequent devices)
- **ILOCK_OUT.EI1 → ILOCK_IN.EI1** (to previous devices)
- This allows a lock to propagate in both directions (**Multi-Hop Chain Propagation**).

1. **Result**

- As long as no lock is active, the device operates like a normal T flip-flop.
- As soon as a lock becomes active, it forces **Q** = **FALSE** and blocks further toggle attempts until the lock is released.

Technical Features

- **Bidirectional Lock Propagation**: The device can both receive and propagate lock signals, enabling a daisy chain of multiple ILOCK_T_FF devices.
- **Feedback of its own state**: The output signal **Q** is used internally as a control signal for the **E_SWITCH** and determines the toggle direction.
- **No dedicated ECC**: All logic is implemented using the two included basic modules (E_SR, E_SWITCH).

State Overview

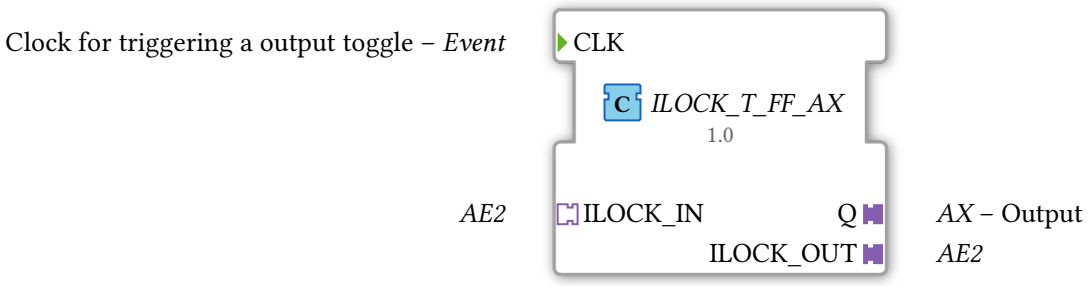
Since the module does not have its own state diagram, the states are derived from the internal **E_SR**:

State **Q**	Meaning in normal operation	Meaning when Lock is active
0	On the next CLK, it toggles to 1.	Lock has set Q to 0 and holds it there.
1	On the next CLK, it toggles to 0.	Lock immediately resets Q to 0.

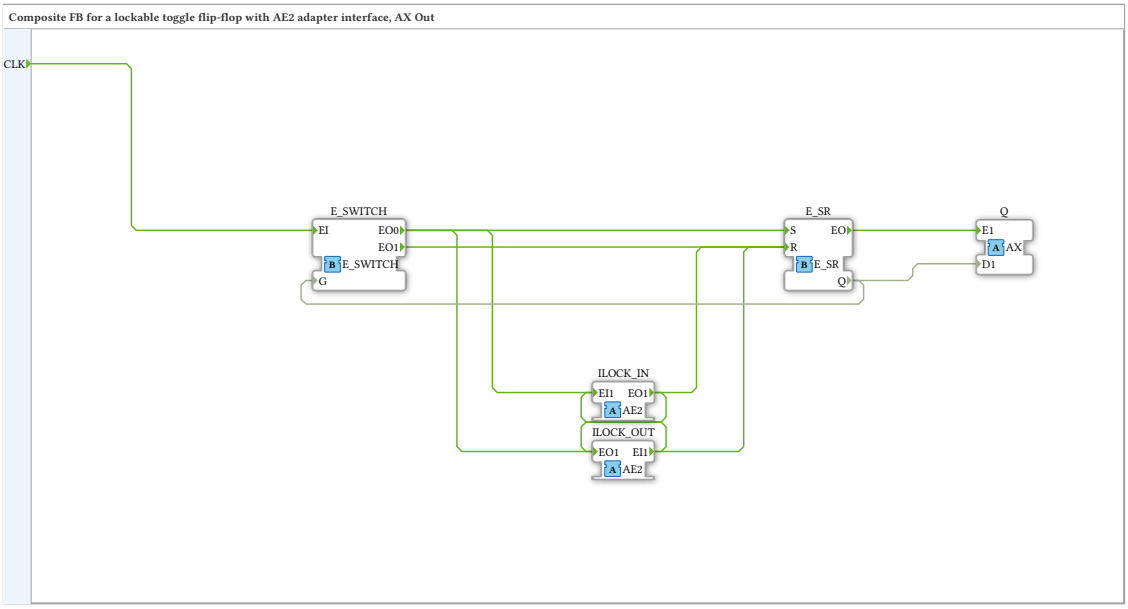
An active lock is present as soon as one of the adapter events (ILOCK_IN.EO1 or ILOCK_OUT.EI1) is received. The lock is maintained until no further lock events are present (the exact resolution depends on the external signal control).

Application Scenarios

- **Safety interlocks in agricultural technology** (e.g., control of implements): Once activated, a lock state blocks all subsequent switching operations and is propagated to all other components in the chain.
- **Chained emergency stop systems**: Allows the propagation of a stop signal along multiple stations, while each station manages its own state.
- **Protocol adaptation for interlock signals**: The function block can be used as a universal link in an interlock chain where the output Q represents a switching operation.



Comparison with similar function blocks



Function block	Properties	Difference from ILOCK_T_FF
T Flip-Flop (e.g., `E_TOGGLE`)	Pure toggle function without locking logic.	Lacks lock/interlock capability, no adapter interface.
RS Flip-Flop (e.g., `E_SR`)	Set/reset with two inputs, no toggle.	Can be extended with external logic to enable toggle functionality, but without integrated lock propagation.
Simple Interlock Block	Only lock propagation, no toggle.	The ILOCK_T_FF combines toggle and lock propagation in a single block.

Conclusion

The **ILOCK_T_FF** combines the functionality of a clocked T-flip-flop with efficient, bidirectional interlock propagation. Thanks to its integrated multi-hop propagation, it is ideally suited for networked safety circuits where a switching state must be blocked and simultaneously propagated to the entire circuit. Its compact design as a composite function block makes it easy to understand and reusable.

ILOCK_T_FF_AX

• – ○ • – ○ • – ○ •

Introduction

The function block `ILOCK_T_FF_AX` is a composite function block that implements a lockable toggle flip-flop. It features an AE2 adapter interface for connecting to a higher-level interlocking logic and outputs the current switching state via a unidirectional AX adapter. The function block is designed for use in safety-related or interlocked control applications where the switching of an output must be influenced by external conditions.

Interface Structure

Event Inputs

Event	Type	Description
`CLK`	Event	Clock signal that triggers a state change (toggle).

Event Outputs

This function block does not have its own event outputs. Events are passed through the adapter interfaces.

Data Inputs

No direct data inputs.

Data Outputs

No direct data outputs. The current state is provided via the AX adapter.

Adapters

Adapter	Type	Direction	Description
`Q`	`adapter::types::unidirectional::AX`	Plug/Output	Unidirectional output adapter that provides the current state (Boolean value) as data and outputs an event upon a state change.
`ILOCK_IN`	`adapter::types::bidirectional::AE2`	Socket	Bidirectional adapter (input) for receiving locking signals.

ILOCK_OUT	adapter::types::bidirectional::AE2	Plug	Bidirectional adapter (output) for forwarding locking events to the higher-level logic.

The AE2 adapters each have two event pairs (EI1/EO1, EI2/EO2) and two associated data ports. Only the first two ports (EI1/EO1) are used in this module.

Functionality

The internal structure consists of two IEC 61499 standard components: E_SR (set-reset flip-flop) and E_SWITCH (event switch). The toggle behavior is implemented as follows:

1. An incoming CLK event is fed to the event switch E_SWITCH.
2. The switch input G is connected to the output Q of the SR flip-flop.

If G = false is present, the event is forwarded to the output EO0 (set path).

- If G = true is present, the event is forwarded to output EO1 (reset path).

1. The set path (EO0) sets the SR flip-flop (E_SR.S) and simultaneously generates an event on ILOCK_OUT.EO1 and ILOCK_IN.EI1 to inform the adapters of the locking mechanism.
2. The reset path (EO1) resets the SR flip-flop (E_SR.R). This reset can also be triggered externally via ILOCK_IN.EO1 or ILOCK_OUT.EI1, enabling a **latched reset**.
3. The output of the SR flip-flop (E_SR.Q) is written to the AX adapter Q.D1, and the event Q.E1 is triggered with each state change.
4. Additionally, events between ILOCK_IN and ILOCK_OUT are passed through in both directions to allow communication with neighboring devices in the same latching array.

The device thus implements an edge-triggered toggle flip-flop that can be reset by external latching signals (via the AE2 adapters).

Technical Features

- **Composite Implementation:** The function block is built as a network of standard FBs (E_SR and E_SWITCH) and can therefore be easily adapted or integrated into other projects.
- **Bidirectional Interlocking Interface:** The AE2 adapters allow both the reception and transmission of interlocking events, enabling modular cascading of multiple function blocks.
- **Unidirectional AX Output:** The state is output as a clean Boolean signal with event provisioning; no additional data conversion is required on the receiver side.
- **Use of Only the First AE2 Ports:** The second ports of the AE2 adapters remain unused and can be added in a derived version if needed.

State Overview

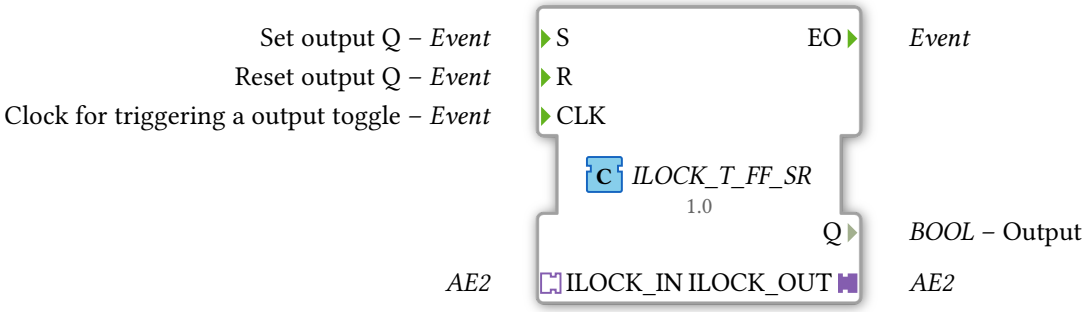
The internal state of the flip-flop is binary:

State	Description
0 (false)	Output Q is inactive. The block will be set on the next CLK event.
1 (true)	Output Q is active. The block will be reset on the next CLK event.

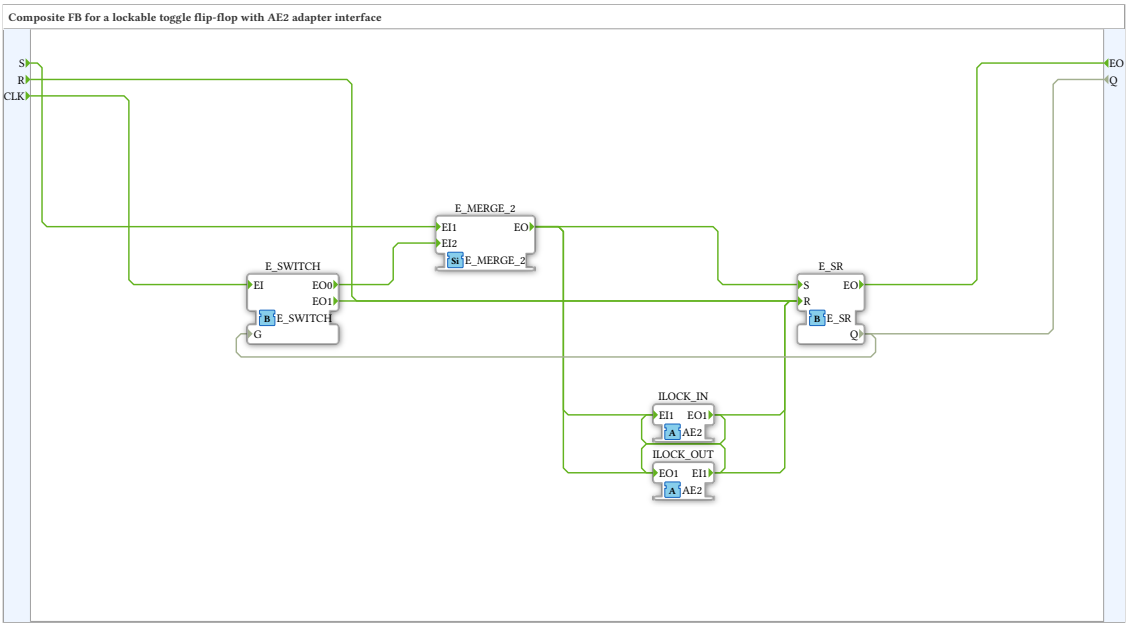
State transitions occur exclusively on a CLK event (Toggle) or on a lock reset via ILOCK_IN.EO1 or ILOCK_OUT.EI1. Simultaneous setting and resetting are resolved by the logic of the SR flip-flop (reset takes priority if both events occur).

Application Scenarios

- **Interlocked Output Control:** In machine controls where an output may only be switched under specific safety conditions. The interlock signals (e.g., from emergency stop circuits or light curtains) are read via ILOCK_IN and suppress the toggle.
- **Cascaded Interlock Chains:** Multiple ILOCK_T_FF_AX blocks can be connected via the AE2 adapters to create a tiered interlock hierarchy.
- **Clock Synchronous Switching State Management:** This block is suitable for applications requiring clocked state changes, e.g., in step sequencers or sequential control systems.



Comparison with Similar Components



- **Standard Toggle Flip-Flop (e.g., our own IEC 61499 component `E_TOGGLE`):** A simple toggle flip-flop has no external latching interface and cannot be reset by external conditions. `ILOCK_T_FF_AX` extends this basic principle with bidirectional AE2 communication.
- **Set-Reset Flip-Flop (e.g., `E_SR`)):** An SR flip-flop has separate set and reset inputs, but no toggle mechanism. This component combines toggle and SR behavior with interlock logic.
- **Components with AX output:** The AX adapter is a common standard for unidirectional Boolean outputs. Other components often use separate data ports, whereas this one uses an encapsulated adapter interface.

Conclusion

ILOCK_T_FF_AX` offers a compact, standards-compliant solution for a interlockable toggle flip-flop in the IEC 61499 environment. Its use of AE2 adapter interfaces allows for seamless integration into modern, modular automation architectures. The composite design facilitates maintenance and customization, while the clear separation of event and data flows simplifies troubleshooting. The component is specifically optimized for safety-related or interlock-dependent switching tasks and provides a solid basis for the development of more complex control logics.

ILOCK_T_FF_SR

• – ○ • – ○ • – ○ •

Introduction

The function block `ILOCK_T_FF_SR` is a composite function block (FB) that implements a latchable toggle flip-flop with set and reset functionality. It has an adapter interface (AE2) that enables bidirectional communication with other instances and serves for interlock chaining. The flip-flop toggles its output `Q`

on every rising edge of the clock input CLK, provided no reset or set event is present. Latching is achieved via the adapters, which can be set by external function blocks.

Interface Structure

Event Inputs

Name	Type	Description
S	Event	Sets output Q to TRUE
R	Event	Sets output Q to FALSE
CLK	Event	Clock event – triggers a toggle on output Q

Event Outputs

Name	Type	Description
EO	Event	Triggered after every change of the internal state (Set, Reset, or Toggle)

Data Inputs

None.

Data Outputs

Name	Type	Description
Q	BOOL	Current state of the flip-flop (TRUE = set, FALSE = reset)

Adapter

Name	Type	Direction	Description
ILOCK_IN	AE2 (bidirectional)	Socket (input)	Allows the reception of latching signals from upstream devices
ILOCK_OUT	AE2 (bidirectional)	Plug (output)	Sends interlock signals to downstream components

The adapters ILOCK_IN and ILOCK_OUT are of type AE2 (general, bidirectional adapter). They are used to cascade multiple instances of the component, allowing a set state in one component to reset other components (interlock).

Functionality

The component is based on an internal network consisting of three primitive functional blocks: a E_SR (set/reset flip-flop), a E_SWITCH (event-driven toggle switch), and a E_MERGE_2 (event merger).

- **Set (S):** An event at S is routed via E_MERGE_2 directly to the Set input of E_SR. The output Q is set to TRUE. Simultaneously, the events are passed on to the connected function blocks via the adapters.
- **Reset (R):** An event at R goes directly to the Reset input of E_SR. The output Q is set to FALSE. Reset signals received from the adapters (via ILOCK_IN.EO1 and ILOCK_OUT.EI1) also trigger a reset.
- **Toggle (CLK):** An event at CLK is routed to E_SWITCH. Its control input, G, is connected to the current output, Q.
- If Q = FALSE is active, the clock event is forwarded via the output EO0 to E_MERGE_2.EI2 and from there to the set input of E_SR. Thus, Q is set to TRUE.
- If Q = TRUE is set to TRUE, the clock event is routed directly to the reset input of E_SR via the output EO1. Q is set to FALSE.

This results in the toggle behavior: Each clock pulse reverses the current state of Q.

- **Interlock:** The adapters ILOCK_IN and ILOCK_OUT are interconnected such that an incoming event from ILOCK_IN (e.g., from a previous block) triggers the reset input and is simultaneously passed on to the next block via ILOCK_OUT. This allows for the creation of a chain of flip-flops, where only one may be active at any given time.

After each state change, the event output EO is triggered.

Technical Features

- **Composite FB:** The block is implemented as a network of IEC 61499 elementary modules. This ensures transparent and traceable behavior.
- **Bidirectional Adapters:** Using the adapter type AE2 allows for flexible coupling as both a socket (input) and a plug (output).
- **Conflict Handling:** If a set and a reset event occur simultaneously (e.g., S and R), the reset event takes precedence because the reset input of E_SR has multiple sources and is treated with priority. The exact priority is determined by the E_SR implementation (default: reset takes precedence over set).
- **No Data Inputs:** The function block operates purely event-driven; its state is only changed by events.

No Data Inputs:

State Overview

The internal flip-flop E_SR has two states:

- **State FALSE** (Q = FALSE): The output is reset. A clock event causes it to be set.
- **State TRUE** (Q = TRUE): The output is set. A clock event causes it to be reset.

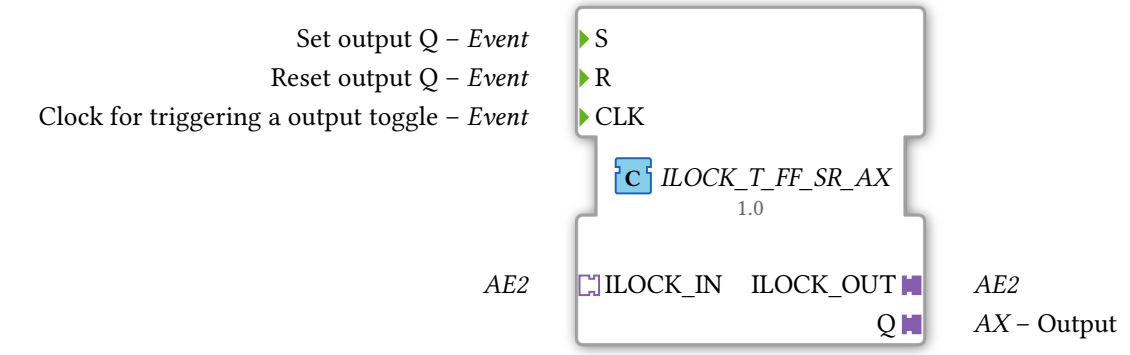
A set event (S) always results in the state TRUE, regardless of the current state.
A reset event (R) always results in the state FALSE, regardless of the current state.

Current State	Event	New State	Output Actions
FALSE	S	TRUE	EO is triggered
FALSE	R	FALSE	EO is triggered
FALSE	CLK	TRUE	EO is triggered
TRUE	S	TRUE	EO is triggered
TRUE	R	FALSE	EO is triggered
TRUE	CLK	FALSE	EO is triggered

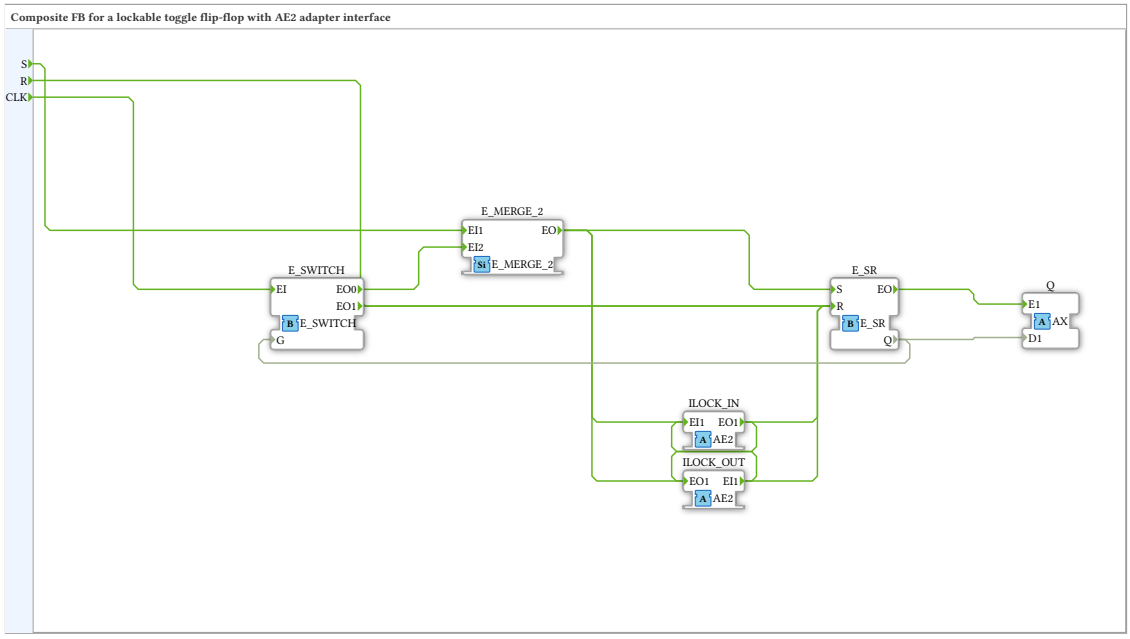
The adapter events act like an external reset and set the state to FALSE.

Application Scenarios

- **Interlock Control in Safety Circuits:** Several machines or drives should interlock with each other. Only one may be active at any given time. By chaining multiple ILOCK_T_FF_SR devices, it can be ensured that only one flip-flop is set at any given time.
- **State Machines with Changing Modes:** This component is suitable as a toggle flip-flop that can be overridden by external set/reset signals, e.g., for manual intervention.
- **Cascaded Circuits with Feedback:** The adapter interface allows for easy integration into existing AE2-based communication structures.



Comparison with Similar Components



- **Standard T-FF (IEC 61499)E_T_FF):** Offers only toggle functionality without separate set/reset inputs. The ILOCK_T_FF_SR extends this to include set and reset control.
- **Standard SR flip-flop (e.g., E_SR):** Has only set and reset, no toggle. This component combines toggle with SR.
- **Interlock component:** Many manufacturer-specific blocks implement interlock via buses; this component uses standardized adapters (AE2) and is therefore more portable.

Conclusion

The ILOCK_T_FF_SR is a versatile function block that combines a toggle flip-flop with set/reset and an interlock interface. The clear separation between logic and adapter connections allows for the construction of safe, cascadable circuits. By using IEC 61499 standard components, the behavior remains traceable and expandable.

ILOCK_T_FF_SR_AX

• – ○ • – ○ • – ○ •

Introduction

The function block **ILOCK_T_FF_SR_AX** is a composite function block (FB) for a latching toggle flip-flop with set/reset functionality and an AE2 adapter interface. It enables the targeted setting, resetting, and clocking of an output signal, taking into account latching states that are read and output via bidirectional adapters.

Interface Structure

Event Inputs

Name	Type	Comment
S	Event	Sets output Q (if not latched)
R	Event	Resets output Q
CLK	Event	Clock input for toggling the output

Event Outputs

This function block does not have explicit event outputs. Output is provided via adapters.

Data Inputs

There are no direct data inputs. The interlock information is exchanged via the adapters `ILOCK_IN` and `ILOCK_OUT`.

Data Outputs

Name	Type	Comment
Q	Adapter AX (unidirectional)	Output signal of the internal SR flip-flop

Adapters

Direction	Name	Type	Comment
Socket	ILOCK_IN	AE2 (bidirectional)	Receives lock signals from external components
Plug	ILOCK_OUT	AE2 (bidirectional)	Sends lock signals to external components
Plug	Q	AX (unidirectional)	Outputs the current state of the flip-flop

Functionality

This component implements an SR flip-flop with a toggle function and a lock mechanism.

- **Set (S)**: An event at `S` causes the internal SR flip-flop `E_SR` to be set via a merge (E_MERGE_2). Output Q is set to `true` unless a locking reset occurs at `ILOCK_IN` or `ILOCK_OUT`.
- **Reset (R)**: An event at `R` sets output Q to `false`. Additionally, both input adapter `ILOCK_IN` and output adapter `ILOCK_OUT` can also trigger a reset – this serves as an interlock.
- **Toggle (CLK)**: The current state of Q is evaluated on each clock event at `CLK`. A switch (E_SWITCH) is used to:
- Generate a set pulse when Q = `false` (Q ⟶ `true`).
- Generate a reset pulse when Q = `true` (Q ⟶ `false`).

Thus, the output toggles with every CLK event, unless a latch prevents this.

The latch is implemented using the bidirectional AE2 protocol: The signals from `ILOCK_IN` and `ILOCK_OUT` are passed through each other and can both reset the internal flip-flop and be exchanged with each other. This allows for a secure lock (e.g., mutual exclusion).

Technical Features

- **Composite Architecture**: The function block consists of the embedded functions `E_SR`, `E_SWITCH`, and `E_MERGE_2`, which are logically linked.
- **Bidirectional Interlocking**: The adapters `ILOCK_IN` and `ILOCK_OUT` are of type AE2, which enables bidirectional exchange of events and data. This allows for interlocking with other function blocks.
- **Toggle Only on State Change**: The toggle mechanism evaluates the output Q, so a toggle only occurs if the flip-flop has not already been set by S or R.
- **No Direct Data Inputs**: Control is achieved exclusively via events and adapters, which facilitates integration into event-driven systems.
-

State Overview

The internal state of the flip-flop can take the values `false` (0) or `true` (1). The possible transitions are:

Current	Event	New State	Conditions
0	S	1	No locking via ILOCK
0	R	0	–
0	CLK	1	No locking
0	ILOCK_IN/ILOCK_OUT	0	–
1	S	1	–
1	R	0	No locking (R takes precedence)

1	CLK	0	No Interlock
1	ILOCK_IN/ILOCK_OUT	0	–

Application Scenarios

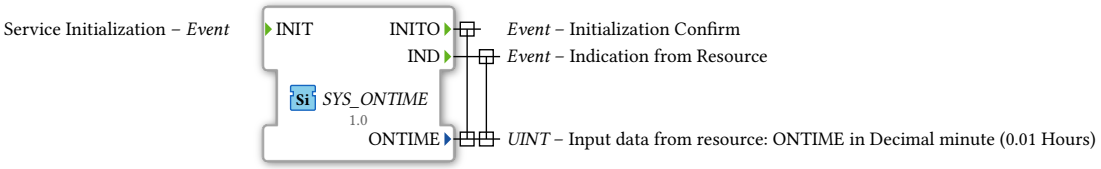
- **Machine Control**: Switching an output (e.g., valve or motor) at a specific time, where a higher-level safety controller can lock the output in case of danger.
- **Mutual Interlock**: Multiple `ILOCK_T_FF_SR_AX` function blocks can be interconnected via bidirectional adapters so that only one of its outputs is active at any given time (e.g., in turnout or drive control).
- **Clock-Controlled Signal Generation**: Generating a periodic square wave signal by applying a clock signal to `CLK`, where setting and resetting can be controlled externally.

Comparison with Similar Function Blocks

- **Simple SR Flip-Flop**: Has no toggle function and no interlock adapters.
- **TcFF (Toggle Flip-Flop)**: Allows toggling only on a clock event, but has no separate set/reset inputs and no interlock interface.
- **Standard Interlock Devices**: Often limited to binary signals, while `ILOCK_T_FF_SR_AX` combines toggle, SR, and bidirectional interlock functionality in a single device.

Conclusion

The `ILOCK_T_FF_SR_AX` function block offers a flexible and safe way to control an output that can be switched on a clock signal and influenced via separate set/reset inputs as well as an expandable interlock interface. The combination of SR flip-flop and toggle logic makes it particularly suitable for safety-critical applications in automation technology.



measurement

SYS_ONTIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SYS_ONTIME` is a Service Interface Function Block (SIFB). Its main task is to read and provide the uptime (ontime) of the resource in which it is executed. It serves as a standardized interface between the application logic and the system-level services of the runtime environment.

Interface Structure

Event Inputs

- **`INIT`**: This event initializes the function block. It must be triggered before the block can begin its service.

Event Outputs

- **`INITO`**: This event confirms the successful initialization of the function block. It is triggered along with the first valid `ONTIME` value.
- **`IND`**: This event signals that a new, updated `ONTIME` value has been provided by the system resource manager.

Data Inputs

- This function block has no data inputs.

Data Outputs

- **`ONTIME` (UINT)**: This output provides the cumulative uptime of the resource. The unit is “decimal minutes,” which is equal to 0.01 hours (e.g., a value of 150 equals 1.5 hours).

Adapters

- This function block does not use adapters.

Functionality

The `SYS_ONTIME` block acts as a client for an internal system service. After receiving the `INIT` event, it registers with the resource manager to gain access to the uptime data. Once initialization is complete, the `INITO` event is triggered along with the current uptime value.

The block then continuously monitors the system resource. As soon as the uptime changes (typically due to a system tick or similar mechanism), the resource manager triggers an indication. The `SYS_ONTIME` block receives this, updates its internal `ONTIME` value, and forwards the `IND` event, along with the new value, to the connected application logic.

The block then continuously monitors the system resource. As soon as the uptime changes (typically due to a system tick or similar mechanism), the resource manager triggers an indication.

Technical Features

- **Service Interface FB**: As a SIFB, its implementation is specific to the respective 4diac runtime (FORTE) and the underlying hardware/platform. The exact method of time measurement (e.g., based on processor startup time or the runtime environment) is runtime-defined.
- **Unit**: The operating time is provided in the unusual but practical unit for control tasks: the decimal minute (1/100 of an hour). This facilitates calculations in the decimal system, e.g., for maintenance intervals or energy consumption estimates.
- **Read-Only Access**: The block provides read-only access to an internal system value. Resetting the operating time is not possible via this interface.

Status Overview

1. **Inactive**: The block has been created but not yet initialized. No communication with the system resource is taking place.
2. **Initialized**: After receiving `INIT`, the block is registered with the resource manager and awaits data. The state changes immediately after successful initialization, followed by the output of `INITO`.
3. **Ready**: The block has received the first `ONTIME` value and is ready for operation. It now awaits indication events (`IND`) from the system to output updated values.

Application Scenarios

- **Predictive Maintenance**: Monitoring the operating time of machines or plant components to trigger maintenance intervals based on actual usage.
- **Energy Management**: Recording the operating hours of consumers (e.g., motors, heaters) to calculate energy consumption or for load profiles.
- **Production Data Acquisition (PDA)**: Logging of production or machine runtimes for Overall Equipment Effectiveness (OEE) analysis.
- **Lifetime Monitoring**: Checking whether critical components have reached or exceeded their specified lifespan (in operating hours).

⚖️ Comparison with similar modules

- **`E_CYCLE` / `E_DELAY`**: These modules themselves generate periodic events or delays. `SYS_ONTIME`, on the other hand, *reads* a passively existing, cumulative time value from the system.
- **`E_SR` (Set-Reset) with counter**: A manually configured counter for power-on processes could provide similar data, but would be implemented application-side and not persistent system-wide. `SYS_ONTIME` provides a reliable, system-maintained value that is usually persistent even after a restart.
- Other SYS_ *blocks** (such as `SYS_TIME`): While `SYS_TIME` provides the current time and date, `SYS_ONTIME` specifically provides the pure uptime of a resource.

🛠️ Related Exercises

- Exercise_140

Conclusion

The `SYS_ONTIME` function block is an essential tool for all applications that rely on recording and analyzing uptime. As a standardized service interface, it abstracts away the platform-specific implementation and

provides application logic with simple, reliable access to this important system metric. Its use is particularly recommended in the areas of maintenance, energy efficiency, and operational data acquisition.

2.10.3.10 stations

Computers

Introduction

The global constants `Computers` provide a collection of predefined network addresses (IP addresses and ports) as strings (`WSTRING`). They serve to centrally manage connection information for various computers or stations within a logiBUS project. Using these constants improves the maintainability and readability of the code, as changes to network addresses only need to be made in one central location.

Interface Structure

Global constants are not function blocks in the traditional sense; therefore, no event or data interfaces exist. Instead, constant declarations are provided that are available project-wide.

Data Inputs

Not applicable. Constants are fixed values and have no inputs.

Data Outputs

Not applicable. Constants are directly incorporated into expressions or assignments.

Adapters

Not applicable.

Functionality

The constants are defined when the project is compiled. Each constant is assigned a fixed, unchanging value of type `WSTRING` (Wide String). Once the program is running, these constant names (`C_LO`, `C_ET`, etc.) can be used instead of the hard-coded strings in any part of the program that imports or recognizes these constants.

Technical Specifications

- **Type:** All constants are of type `WSTRING`, which supports Unicode strings.
- **Scope:** As global constants, they are available within the declared package (`logiBUS::stations`).
- **Initialization:** The values are assigned directly upon declaration and are read-only at runtime.
- **Usage:** They are typically intended for configuring communication modules (e.g., `PUBLISH`, `SUBSCRIBE`, `CLIENT`, `SERVER`) where the address of the communication partner is required.

State Overview

Not applicable. Constants have no state.

Application Scenarios

1. **Simplified Address Configuration:** In a distributed control system with multiple controllers (e.g., main controller, floor controller), the IP addresses of the individual devices can be stored centrally here. 2. **Portability between environments:** By simply swapping the values in this constant file, a program can be quickly adapted between different network environments (e.g., development local host, test network, production network).
2. **Typo prevention:** Using the constant name `C_ET` is less error-prone than repeatedly typing the string `"192.168.5.1:61499"`.

⚖️ Comparison with similar components

- **`VAR_GLOBAL` (Global variables):** Unlike global variables, constants (`CONSTANT`) cannot be changed after initialization. They therefore offer greater program security.
- **`VAR_CONFIG` (Configuration variables):** Configuration variables are also constants, but they can be configured per resource. The global constants defined here have a fixed, project-wide value.
- **Direct Value Specification:** While it's possible to directly use string literals in the code, this leads to poorer maintainability and a higher susceptibility to errors compared to using central constants.

Conclusion

The global constants `Computers` are a simple yet extremely useful tool for structuring and maintaining network connection data in 4diac projects. They promote clean programming practices, reduce redundancy, and make the code more adaptable to changes in the network topology. Their use is particularly recommended in larger or distributed automation systems.

2.10.3.11 storage

Const

storageStatusMessages

• – ◦ • – ◦ • – ◦ •

Introduction

`storageStatusMessages` is a **GlobalConstants** element from the `logiBUS::storage::const` package. It is not an executable function block, adapter, or subapplication. Instead, it provides a centralized collection of `STRING` constants used by storage-related function blocks to report status and error information.

The constant set is designed for storage modules that work with initialization (INI) and non-volatile storage (NVS) systems. It contains human-readable messages for successful operations, missing or invalid data, initialization state, and common NVS error cases.

Interface Structure

Because `storageStatusMessages` is a GlobalConstants definition, it does not provide an IEC 61499 event or data interface. It has no inputs, no outputs, and no adapters. The declared constants are globally visible to other elements in the same library or project.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The main purpose of `storageStatusMessages` is to define a single source of truth for storage status strings. Instead of using hard-coded literals in multiple function blocks, storage-related FBs can reference these global constants. This reduces typing errors, simplifies translations or adjustments, and makes the behavior of different storage blocks more consistent.

The following table lists all constants exposed by this element.

Constant Name	Type	Value
OK	STRING	OK
NO_CHANGE	STRING	Value was not stored. Old is new
INITIALISED	STRING	initialized
NOT_INITIALISED	STRING	Not initialized
ERR	STRING	ERROR
ERR_NVS_NOT_FOUND	STRING	ESP_ERR_NVS_NOT_FOUND
ERR_NVS_DEFAULT_SET	STRING	Default Value was used
ERR_SECTION_EMPTY	STRING	SECTION empty
ERR_KEY_EMPTY	STRING	KEY empty
ERR_SECTION_WHITESPACE	STRING	SECTION contains whitespace
ERR_KEY_WHITESPACE	STRING	KEY contains whitespace
ERR_READ_ONLY	STRING	Key is read-only

The constants cover the following categories:

- General success and error states: OK, ERR.
- Initialization states: INITIALISED, NOT_INITIALISED.
- No-operation result: NO_CHANGE.
- NVS-related errors: ERR_NVS_NOT_FOUND, ERR_NVS_DEFAULT_SET.
- Validation errors for storage sections and keys: empty or whitespace.
- Access restriction error: ERR_READ_ONLY.

Technical Features

- Defined as GLOBALCONSTANTS in the package logiBUS::storage::const.
- Contains 12 STRING constants.
- All constants are read-only and cannot be modified at runtime.
- The values are globally accessible, avoiding local duplication of status strings.
- The names follow a consistent prefix style: ERR_ for error constants.
- The message set is versioned, allowing controlled evolution of the status vocabulary.
- Supports both human-readable logging and comparison in application logic.

State Overview

storageStatusMessages is not an FB and therefore has no state machine. It does not process events, maintain runtime variables, or transition between states. The element has exactly one static condition: all declared constants are defined and available as soon as the containing library is loaded.

Application Scenarios

This GlobalConstants element is useful wherever storage services need to report their result in a standardized way.

Typical scenarios include:

- Function blocks that access NVS storage and need to return ERR_NVS_NOT_FOUND when a stored key does not exist.
- Initialization routines that distinguish between INITIALISED and NOT_INITIALISED.
- Write operations that detect that the new value is identical to the old one and return NO_CHANGE.
- Validation logic that checks section and key names for empty strings or whitespace.
- Error handling for read-only keys using ERR_READ_ONLY.
- Logging or HMI displays that show status messages from storage operations.

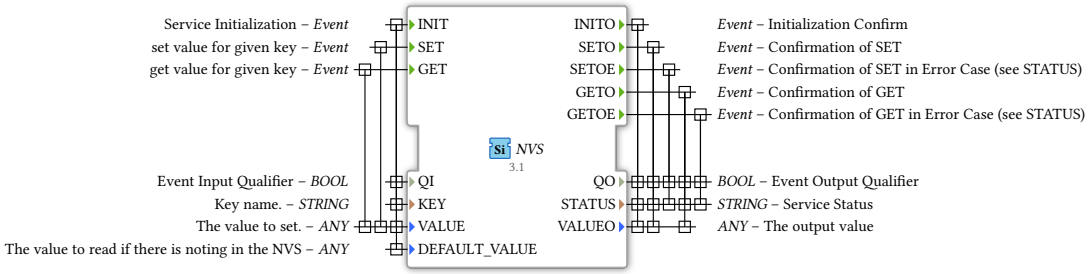
Comparison with Similar Blocks

Since storageStatusMessages is a passive constant container rather than a function block, it cannot be compared directly to executable FBs. However, it can be compared with common alternatives:

- Compared to hard-coded literals, it provides a central, reusable message catalog and avoids inconsistent wording.
- Compared to local constants inside individual FBs, it makes the same messages available across an entire library or project.
- Compared to integer error codes, it delivers readable text directly, but it does not provide numeric encoding for binary protocols.
- Compared to a function block that generates status strings, it requires no runtime processing and has no execution overhead.

Conclusion

`storageStatusMessages` is a compact global constant set that standardizes status and error reporting for storage-related function blocks. It is especially suited for INI and NVS handling on platforms such as ESP32, where storage errors need to be communicated consistently. By using these global constants, applications become more readable, maintainable, and robust against inconsistent status strings.



esp32_nvs

NVS

• – ◦ • – ◦ • – ◦ •

Introduction

The NVS (Non-Volatile Storage) function block enables persistent storage and loading of data on an ESP32 microcontroller. It utilizes the ESP32's non-volatile storage (NVS) to store values under a defined key and retrieve them as needed. This block is particularly suitable for applications where configuration data, calibration values, or status information must be retained across device restarts.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block. Triggers the read operation of the value specified by `KEY`. If no value is stored, `DEFAULT_VALUE` is returned.
- **SET**: Saves the value passed to `VALUE` under the previously configured key (`KEY`) in the NVS.
- **GET**: Reads the value stored under the configured key (`KEY`) in the NVS.

Event Outputs

- **INITO**: Confirms the execution of the initialization (INIT) and returns the result.
- **SETO**: Confirms the execution of the write operation (SET) and returns the status.
- **SETOE**: Confirmation of SET in the error case (see `STATUS`); carries `QO` and `STATUS`.
- **GETO**: Confirms the execution of the read operation (GET) and returns the read value.
- **GETOE**: Confirmation of GET in the error case (see `STATUS`); carries `QO` and `STATUS`.

Data Inputs

- **QI** (BOOL): Qualifies the INIT event input. The service is activated by `TRUE` and deactivated by `FALSE`.
- **KEY** (STRING): The unique key name under which the value is stored in the NVS or from which it is read. This value must be set during the INIT phase.
- **VALUE** (ANY): The data record to be stored. It can be any elementary data type (e.g., BOOL, INT, REAL, STRING).
- **DEFAULT_VALUE** (ANY): The default value returned during a read operation (INIT or GET) if no value is yet stored in the NVS under the specified key.
•

Data Outputs

- **QO** (BOOL): Reflects the current operating state of the function block (`TRUE` = ready/successful, `FALSE` = not ready/error).
- **STATUS** (STRING): Contains a status message describing the success or type of error of the last operation (e.g., "OK", "Key not found", "Storage full").
- **VALUEO** (ANY): The value actually read from the NVS or, if no value was present, the value from `DEFAULT_VALUE`.

Adapters

This function block does not use adapters.

Operation

The NVS block operates based on its state. During initialization (INIT with `QI=TRUE`), the specified `KEY` is set. The system then automatically attempts to read the corresponding value from the NVS (Non-Volatile Storage). The result (stored value or `DEFAULT_VALUE`) is output along with the status via `INITO`.

Afterward, the block can perform two main operations:

1. **Write (SET)**: The value assigned to `VALUE` is stored in the NVS under the specified key (`KEY`). Confirmation is provided via `SETO`.
2. **Read (GET)**: The value currently stored under the key is read from the NVS and made available via `VALUEO` at output `GETO`.

The data types of the inputs and outputs `VALUE`, `DEFAULT_VALUE`, and `VALUEO` must be consistent. The block is designed for repeated access to the same key.

Technical Features

- **ESP32-Specific**: This block directly uses the NVS API of the ESP32-IDF and is therefore only compatible with ESP32-based target platforms.
- **Type Flexibility**: The use of the generic data type `ANY` allows for the storage of various elementary data types. The specific type is set during initial use (INIT) and must be retained for all subsequent operations.

Persistence: Data in the NVS survives a microcontroller restart and is also retained after a power failure (depending on the NVS memory configuration).

State Overview

1. **Not Initialized**: The block is inactive after startup. The key (`KEY`) is not set.
2. **Initialized/Ready**: After a successful `INIT` event, the block is ready for operation. The key is configured, and an initial value (from NVS or default) has been loaded. The block is waiting for `SET` or `GET` events.
3. **Write Operation**: During the processing of a `SET` event.
4. **Read Operation**: During the processing of a `GET` event or the implicit read operation during `INIT`.

Application Scenarios

- **Device Configuration**: Saving network credentials (SSID, password), IP addresses, or other parameters to be retained after a reset.
- **Operational Data Acquisition**: Persistently counting operating hours, cycle counts, or units produced.
- **Calibration Data**: Storing sensor- or actuator-specific calibration values.
- **Last Known State**: Saving the system state before an unexpected shutdown to restore it upon the next startup.

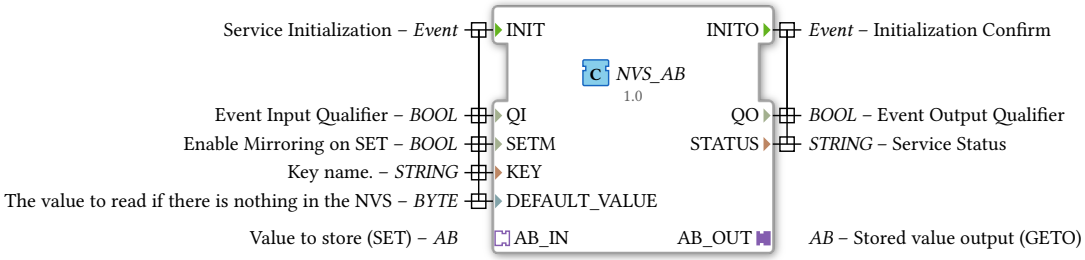
⚖️ Comparison with similar building blocks

- **E_R_TRIG / F_TRIG**: These are purely event triggers and do not offer persistent data storage.
- **BLINK / DELAY**: Time-based blocks without memory functionality.
- **E_EEPROM**: A generic EEPROM block. The NVS block is specific to the ESP32 platform and utilizes its optimized, wear-leveling file system (NVS), while a generic E_EEPROM block would be hardware-dependent and often operate on simpler memory.

🛠️ Related Exercises

- Exercise_012
- Exercise_012a_sub
- Exercise_020c2_sub

Conclusion



The NVS function block provides a simple and robust interface to the ESP32's non-volatile memory. Its clear separation of read and write operations, along with its type-flexible data processing, makes it ideal for a wide range of applications requiring persistent data on embedded ESP32 systems. Its integration into the 4diac IDE enables platform-specific functionality within the portable IEC 61499 model.

NVS_AB

• – ○ • – ○ • – ○ •

Introduction

`NVS_AB` loads and stores a `BYTE` value under a key (`KEY`) in the ESP32's non-volatile storage (NVS). Unlike the bidirectional NVS_AB2, it uses two separate unidirectional `AB` adapters: a socket for writing (`AB_IN`) and a plug for reading/confirming (`AB_OUT`).

Interface Structure

Event Inputs

- **INIT**: initializes the block and reads the value stored under `KEY` (or `DEFAULT_VALUE` if none exists yet). Carries `QI`, `SETM`, `KEY`, `DEFAULT_VALUE`.

Event Outputs

- **INITO**: confirms initialization and the initial read, carries `QO` and `STATUS`.

Data Inputs

- **QI** (BOOL): qualifier for the `INIT` event.
- **SETM** (BOOL): enables mirroring (confirmation) on write (`SET`).
- **KEY** (STRING): name of the key in the NVS.
- **DEFAULT_VALUE** (BYTE): value returned when nothing is stored under `KEY` yet.

Data Outputs

- **QO** (BOOL): success qualifier, carried with `INITO` and the internal adapter confirmations.
- **STATUS** (STRING): status message of the NVS access.

Adapters

- **AB_IN** (Socket, type `AB`): new value to store – an adapter event on `AB_IN.E1` triggers a `SET` on the internal NVS block, `AB_IN.D1` carries the value to write.
- **AB_OUT** (Plug, type `AB`): outputs the most recently read value – both after the automatic initial read on `INIT` and after each confirmed write (`AB_OUT.D1`/`AB_OUT.E1`).

Functionality

`NVS_AB` wraps an internal instance of `logiBUS::storage::esp32_nvs::NVS` plus an `E_PERMIT` gate (`SET_PERMIT`). On `INIT`, the internal NVS instance is initialized (`NVS.INIT`) and a `GET` is triggered automatically, returning the value stored under `KEY` (or `DEFAULT_VALUE`); the result is output via `AB_OUT`, and `INITO` confirms completion.

To write, the block connected to `AB_IN` fires an adapter event (`AB_IN.E1`) carrying the new value (`AB_IN.D1`), which triggers `NVS.SET`. Whether the successful write is additionally reported back via `AB_OUT` is controlled by `SETM`: if `SETM` is set, `SET_PERMIT` releases the `AB_OUT.E1` event after a successful `SET` ("mirroring").

Technical Details

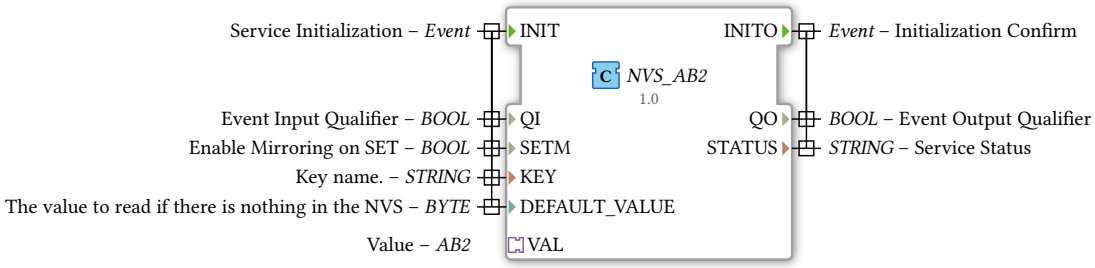
- Pure composite FB with no ECC of its own – the actual flash logic lives in the internal `NVS` instance; `NVS_AB` only wires events and data between it and the two `AB` adapters.
- Two separate unidirectional adapters (`AB_IN`/`AB_OUT`) instead of a single bidirectional one – this lets the read and write paths connect to different peers, which NVS_AB2 (a single shared `AB2` socket) cannot do.
- `SETM` only controls whether a write is additionally mirrored back via an `AB_OUT` adapter event – the value is stored either way.

State Overview

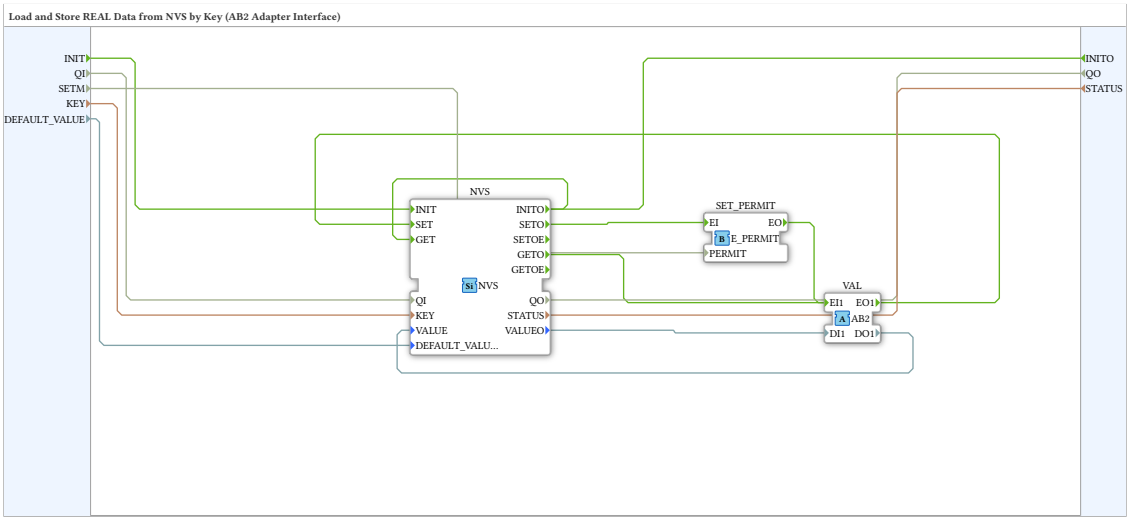
The block is stateless in terms of its own ECC: on `INIT` it runs through initialization plus an initial read once, then reacts to every `AB_IN` adapter event with an NVS write and, optionally, a confirmation via `AB_OUT`.

Application Scenarios

- Persisting individual `BYTE` configuration values (e.g. operating mode, channel selection) on the ESP32
- Building a read/write pair where the read and write sides need to connect to different blocks
- Restoring a last-stored `BYTE` value after a restart via `AB_OUT`



⚖️ Comparison with Similar Blocks



Compare with NVS_AB2, which serves the same purpose through a single bidirectional `AB2` adapter instead of two unidirectional `AB` adapters, and with INI_AB, which provides the same interface for the text-based `settings.ini` instead of the NVS flash storage.

Conclusion

NVS_AB provides simple, unidirectionally wired access to a persistent BYTE value in the ESP32's NVS, and fits anywhere the read and write paths need to be kept separate.

NVS_AB2

• – ○ • – ○ • – ○ •

Introduction

The function block **NVS_AB2** enables the loading and saving of BYTE data in non-volatile storage (NVS) using a string key. It encapsulates NVS access in a convenient, asynchronous interface and communicates with the environment via a bidirectional **AB2** adapter. This makes the block particularly suitable for scenarios where configuration values or status data need to be permanently stored on an ESP32.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initializes the function block. The input data (QI, SETM, KEY, DEFAULT_VALUE) are transferred when this event occurs.

Event Outputs

Event	Type	Description
INITO	EInit	Confirmation of successful initialization and the first read operation.

Data Inputs

Name	Type	Description
QI	BOOL	Qualifier for the initialization event (e.g., enabling processing).

SETM	BOOL	Enable mirroring on SET.
KEY	STRING	Name of the key under which the value is stored in the NVS.
DEFAULT_VALUE	BYTE	Value returned if no value exists in the NVS for the specified key.

Data Outputs

Name	Type	Description
QO`	BOOL	Qualifier for the output event – signals success (TRUE) or failure (FALSE).
STATUS	STRING	Detailed status message (e.g., error text or confirmation).

Adapter

Name	Type (AB2 adapter)	Description
VAL	adapter::types::bidirectional::AB2	Bidirectional interface for the data value. Reading and writing are performed via the adapter channels (events: EI1, EO1; data: DI1, DO1).

Functionality

Upon arrival of the **INIT** event, the internal NVS module is initialized. Immediately after successful initialization, a **read operation** (GET) is automatically initiated, which reads the value corresponding to the key KEY from the NVS. If no value is found, DEFAULT_VALUE is used. The read value is output via the adapter (VAL.DI1), and the event INITO signals completion.

After initialization, the function block can process asynchronous read and write requests via the adapter:

- **Read**: An event received at the adapter port VAL.EO1 triggers another read operation (GET) in the NVS. The read value is again made available via VAL.DI1, and the acknowledgment (VAL.EI1) is sent.
- **Write**: The value to be saved is made available via the adapter on VAL.DO1. An event at VAL.EO1 triggers the **write operation** (SET) in the NVS. Acknowledgement is sent via VAL.EI1 after successful saving.

The outputs QO and STATUS are set to the current status of the NVS module upon each of the output events (INITO, as well as the internal adapter acknowledgments).

Technical Features

- **NVS Access on the ESP32**: The module utilizes the function block defined at logiBUS::storage::esp32_nvs::NVS, which encapsulates the ESP32's flash memory management.
- **Bidirectional Adapter Interface**: The AB2 adapter allows the function block to process both read and write requests from the environment without requiring separate trigger events on the function block itself.
- **Automatic First Read Access**: After initialization, the stored value is read immediately, so that the current data value is available via the adapter after INITO.
- **Error Handling**: The status (STATUS) and the qualifier (QO) indicate the success or failure of each NVS operation.

State Overview

The function block does not have explicit state machines, as it uses the behavior of the internal NVS function block as a composite function block. The following phases can be distinguished:

1. **Initialization** – triggered by INIT
2. **Ready** – after successful initialization, the module waits for adapter events
3. **Read/Write Operation** – brief access to the NVS during the processing of an adapter event

Application Scenarios

- **Configuration storage** for device parameters (e.g., setpoints, calibration data) on ESP32-based controllers.
- **Persistent state maintenance**, e.g., last operating mode or counter readings across a restart.

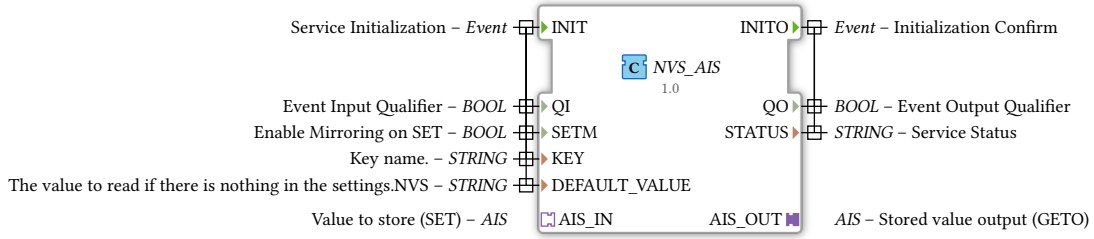
- **Data exchange via AB2 protocol** with other modules that support the AB2 adapter interface – easy integration into existing automation solutions.

Comparison with Similar Function Blocks

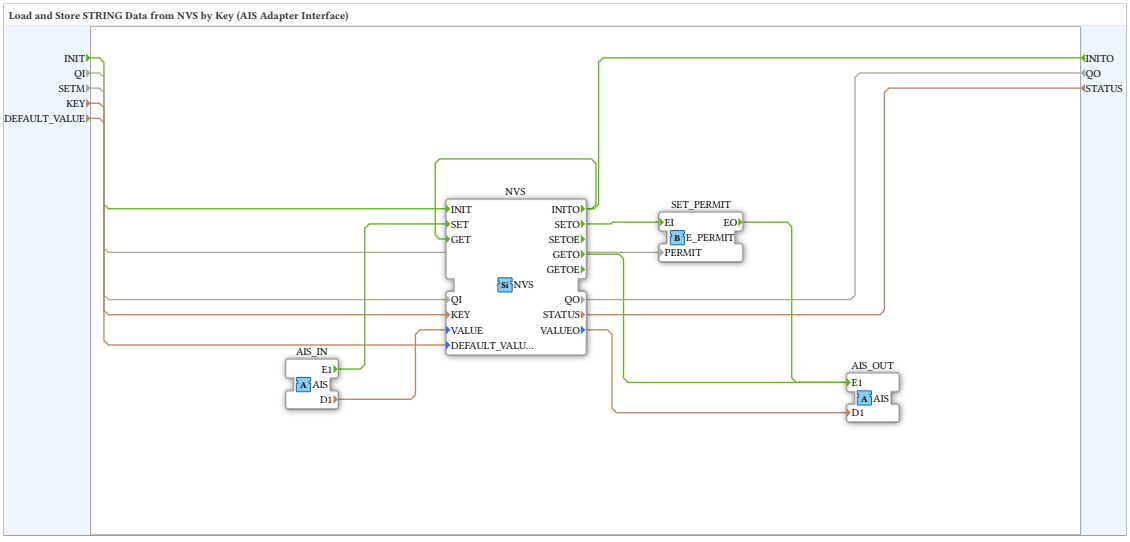
Compared to simpler read/write function blocks (e.g., direct NVS FBs without an adapter), **NVS_AB2** offers:

- **Asynchronous, event-driven communication** via the AB2 adapter – decouples data access from the main control flow.
- **Automatic initialization and first read** reduces programming effort.
- **Uniform error signaling** via `QO` and `STATUS`.

In contrast, function blocks without an adapter require separate event inputs for reading and writing and do not offer a standardized bidirectional interface.



Conclusion



NVS_AB2 is a practical function block for reliable, asynchronous access to the non-volatile memory of an ESP32. By encapsulating the NVS logic in a composite module and providing an AB2 adapter interface, it can be flexibly integrated into automation projects requiring persistent data storage. The combination of automatic initialization, read/write support, and clear status feedback makes it an efficient solution for embedded controllers.

NVS_AIS

• – ○ • – ○ • – ○ •

Introduction

The function block `NVS_AIS` is used to store and load strings (STRING) in the non-volatile storage (NVS) of an ESP32 microcontroller. The data is addressed via a key (KEY) and exchanged via AIS (Acyclic

Information Service) adapters. The block encapsulates the NVS initialization as well as the basic read and write operations and provides a standardized interface for integration into industrial control applications.

Interface Structure

Event Inputs

Event	Type	Description	Data Carried
INIT	EInit	**Service Initialization** – Starts the function block and communication with the NVS.	QI, SETM, KEY, DEFAULT_VALUE

Event Outputs

Event	Type	Description	Carrying Data
INITO	EInit	**Initialization Confirm** – Confirms successful initialization or signals an error.	QO, STATUS

Data Inputs

Name	Data Type	Description
QI	BOOL	**Event Input Qualifier** – Controls the behavior during the INIT phase (e.g., activation).
SETM	BOOL	Enable Mirroring on SET: if TRUE, the confirmation of a SET (SETO) is additionally forwarded to the output adapter (mirrored)
KEY	STRING	**Key name** – The key under which the value is stored/retrieved in the NVS.
DEFAULT_VALUE	STRING	**Default value** – Value that is read if no entry exists in the NVS for the specified KEY.

Data Outputs

Name	Data type	Description
QO	BOOL	**Event Output Qualifier** – Indicates the success of the last operation.
STATUS	STRING	**Service Status** – Feedback on the NVS driver status (e.g., error messages).

Adapters

Adapter	Type	Description
AIS_IN	`adapter::types::unidirectional::AIS` (Socket)	**Value to store (SET)** – Receives a STRING value to be stored via the AIS protocol.
AIS_OUT	`adapter::types::unidirectional::AIS` (Plug)	**Stored value output (GETO)** – Sends the read STRING value from the NVS via the AIS protocol.

Functionality

1. **Initialization**

An event at the `INIT` input starts the internal logic. The function block calls the embedded `NVS` function block, which prepares the non-volatile memory. The supplied data (`QI`, `SETM`, `KEY`, `DEFAULT_VALUE`) are forwarded to the internal function block.

1. **Read Operation**

After a successful INIT phase (event `INITO` of the internal NVS), the `GET` event input of the internal NVS is automatically activated. The read value (or the `DEFAULT_VALUE` entry if no entry exists) is output via the `AIS_OUT` adapter as the `E1` event and `D1` data.

1. **Write Operation**

A new value can be received via the `AIS_IN` adapter. The associated `SET` event (E1) is routed to the internal NVS module, which stores the received value (D1) under the previously set `KEY`. The acknowledgment (`SETO`) is then sent via the `AIS_OUT` adapter.

1. **Feedback**

After both reading and writing, the module outputs the status (`QO`, `STATUS`) as well as the `INITO` event. The status can be used for error diagnosis.

Technical Features

- **NVS for ESP32** – The module is specifically designed for the ESP32's non-volatile memory and uses the corresponding driver API.
- **Adapter Interface** – Communication with the outside world is exclusively via AIS adapters (unidirectional). This decouples the module from specific bus or application protocols.
- **Automatic Read Operation After INIT** – After initialization, a read operation is started immediately, so the stored value is instantly available at the output.
- **Unified Status** – All relevant status information is reported back via the outputs `QO` and `STATUS`.

State Overview

The function block `NVS_AIS` itself does not have an explicit state machine. Its behavior is entirely controlled by the embedded function block `NVS`, which cycles through the typical states of an NVS driver (e.g., initialization, ready, error). The events `INIT` and `INITO` represent the start-stop cycle. The adapter events `E1` initiate the read/write requests.

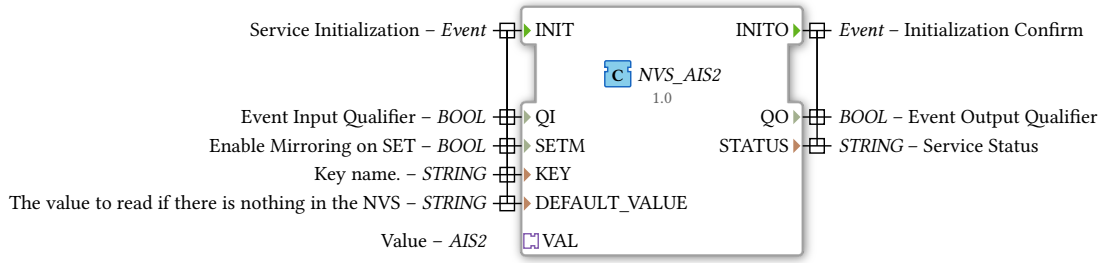
Application Scenarios

- **Configuration Memory** – Persistent storage of device settings (e.g., network parameters, operating modes) as strings.
- **Data Exchange with Other Devices** – Using the AIS adapters for easy integration into an IEC 61499 application without having to program direct bus or memory accesses.
- **Recovery After Restart** – The combination of INIT, automatic reading, and default values ensures that a defined initialized state is reached.

Comparison with Similar Devices

- **`NVS` (direct)**: The direct NVS device offers more detailed control options (dedicated events for GET/SET) but requires manual connection of the interfaces. `NVS_AIS` simplifies the application by embedding the read/write logic and using standardized adapters.
- **Additional memory modules (e.g., for SD cards)**: These usually operate with different protocols (SPI, I²C) and offer different memory schemes. `NVS_AIS` is optimized for the specific characteristics of the ESP32-NVS (key-value pairs, low latency).

Conclusion



NVS_AIS`is a practical function block that encapsulates the saving and loading of strings in the ESP32's non-volatile memory and provides it via a clean adapter interface. With its automated initialization and integrated read and write operations, it is particularly well-suited for applications requiring simple, reliable persistence of configuration data. The adapter interface enables loose coupling with other components and increases reusability across various IEC 61499 projects.

NVS_AIS2

• – ○ • – ○ • – ○ •

Introduction

The **NVS_AIS2** function block is used to load and store STRING data in non-volatile storage (NVS) of an ESP32 via an adapter. It encapsulates initialization and access to a single NVS entry identified by a KEY.

Interface Structure

Event Inputs

Event	Type	Comment	Associated Variables
INIT	EInit	Service Initialization	QI, SETM, KEY, DEFAULT_VALUE

Event Outputs

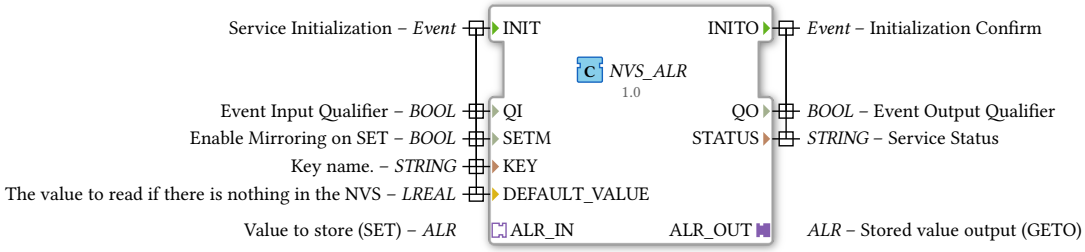
Event	Type	Comment	Associated Variables
INITO	EInit	Initialization Confirm	QO, STATUS

Data Inputs

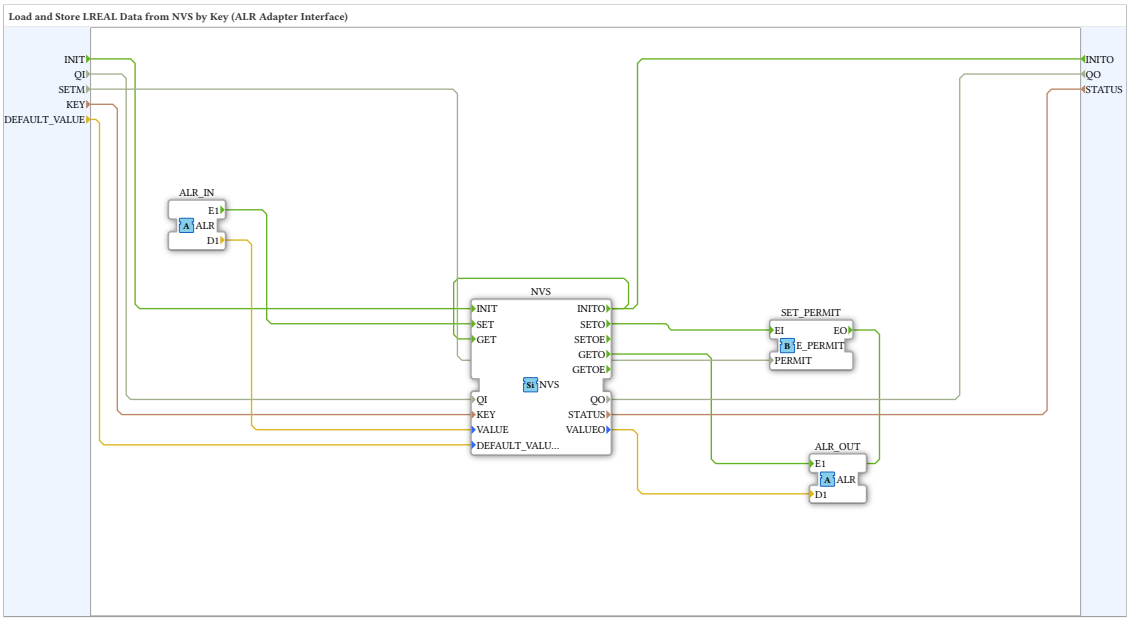
Name	Type	Comment
QI	BOOL	Event Input Qualifier
SETM	BOOL	Enable mirroring on SET
KEY	STRING	Key name for NVS entry
DEFAULT_VALUE	STRING	Default value if key does not exist in NVS (Default: ’’)

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service status



Adapters



Adapter	Type	Comment
VAL	adapter::types::bidirectional::AIS2 (Socket)	Value (STRING)

Functionality

1. **Initialization**: An INIT event initializes the internal NVS block.
2. **Read value**: The read value is output via VAL.DI1.
3. **Store value**: An external block sends E01 via VAL to write a new value (D01) to NVS.

NVS_ALR

• – ○ • – ○ • – ○ •

Introduction

The function block **NVS_ALR** is used to load and store values of type LREAL in non-volatile storage (NVS) using a key. It is specifically designed for connection via the unidirectional **ALR adapter**. The block combines an initialization phase, in which the memory contents are read, with a subsequent read and write operation via the adapter.

Interface Structure

Event Inputs

Event	Description	Associated Variables
INIT	Initializes the function block and performs an initial read operation from the NVS.	QI, SETM, KEY, DEFAULT_VALUE

Event Outputs

Event	Description	Included Variables
INITO	Confirmation of initialization and feedback of the result.	QO, STATUS

Data Inputs

Variable	Type	Description
QI	BOOL	Control for initialization (TRUE = active).
SETM	BOOL	Enable mirroring on SET.
KEY	STRING	Key name for NVS access.
DEFAULT_VALUE	LREAL	Value to be read if no entry exists in the NVS under the specified key.

Data Outputs

Variable	Type	Description
QO	BOOL	Initialization confirmation (TRUE = successful).
STATUS	STRING	Status message (e.g., error message for failed access).

Adapters

Adapter	Direction	Type	Description
ALR_IN	Socket	`adapter::types::unidirectional::ALR`	Receives write commands (stores value).
ALR_OUT	Plug	`adapter::types::unidirectional::ALR`	Sends read values after a read operation.

Functionality

1. **Initialization**

After an event at the **INIT** input, the internal function block `NVS` is called with the specified key (`KEY`), the default value (`DEFAULT_VALUE`), and the activation (`QI`). The initialization process opens the NVS area and immediately reads the existing value. This value is output via the **ALR_OUT** adapter as an event with the corresponding data value (`D1`). Simultaneously, the **INITO** event output is triggered with the acknowledgments (`QO`, `STATUS`).

1. **Write via ALR_IN**

An event at the **ALR_IN.E1** input (connected to the socket) triggers a **SET** operation. The supplied data value (`ALR_IN.D1`) is written to the NVS under the previously stored key. After successful writing, the event is passed to **ALR_OUT.E1**, and the written value is output there.

1. **Read via ALR_IN?**

In this network, a **GET** command is automatically triggered after initialization. An explicit read call via the adapter is not included in the design; the function block always outputs the current value via **ALR_OUT** after each NVS operation (INIT, SET).

Technical Features

- **Adapter Interface**

Communication with the outside world occurs exclusively via the unidirectional ALR adapter. This makes the module particularly suitable for modular architectures where data flows are handled via standardized interfaces.

- **Internal NVS Module**

The FB `NVS` (from the library `logiBUS::storage::esp32_nvs`) is used in the network. This encapsulates the actual read and write logic on the ESP32-NVS.

- **Automatic Read Operation**

After initialization, a GET request is executed immediately, so the user receives the current value (default value or stored value) right away.

- **Error Handling**

The outputs `QO` and `STATUS` allow for easy verification of initialization success. Errors are reported as a string.

State Overview

The function block does not cycle through explicitly modeled states, but is event-driven. The following behavior occurs:

- **Idle State** – No INIT is performed. No actions are executed.
- **Initializing** – INIT is received; NVS operations are started; upon completion, INITO is triggered and a GET request is initiated.
- **Ready** – After successful initialization, the function block waits for events via **ALR_IN.E1** (write) or internal GET requests (only triggered automatically initially).
- **Write** – At ALR_IN.E1, the value is saved and the result is sent to ALR_OUT.

Application Scenarios

- **ESP32 Configuration Parameters**

Storage of LREAL values such as calibration factors, thresholds, or PID parameters that should be retained after a restart. The ALR adapter enables easy integration with other function blocks that use the same adapter type.

- **Encapsulated Data Access**

If a function block needs to read and write LREAL values from the NVS, but directly using the NVS function block seems too complex, NVS_ALR offers an abstracted interface.

- **Modular Automation**

Use in Industry 4.0 applications where devices communicate via standardized adapter services (e.g., via an ALR configuration layer).

Comparison with Similar Function Blocks

- **NVS (Direct)**

The `NVS` function block offers more flexibility (e.g., random access, different data types), but requires more complex wiring and explicit GET/SET calls. NVS_ALR reduces the complexity to an adapter interface.

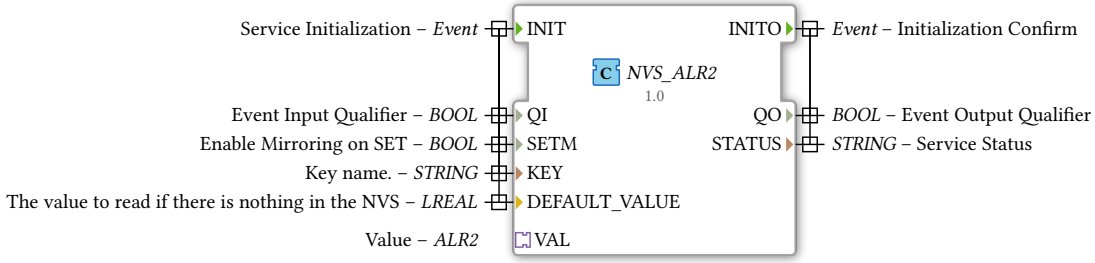
- **BOOL_NVS, INT_NVS (Hypothetical)**

Analogous function blocks for other data types. NVS_ALR is specifically designed for LREAL and utilizes the ALR adapter, which is typically intended for LREAL data.

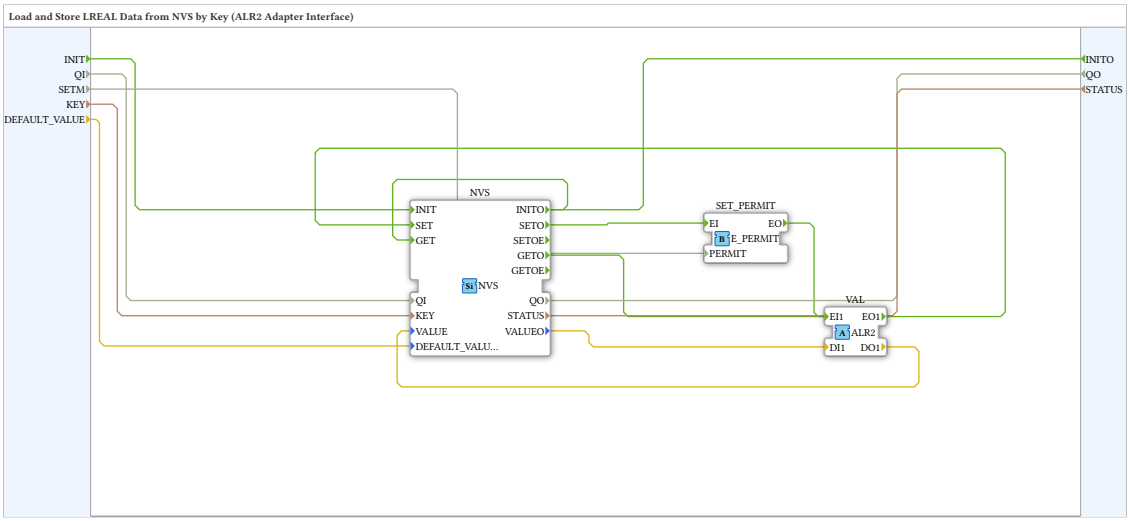
- **Retentive Variables**

In some systems, retentive variables can be used directly in the function block model. However, NVS_ALR is explicitly designed for use with an external flash memory (NVS) and is therefore more portable.

Conclusion



The **NVS_ALR** function block offers a compact and user-friendly way to persistently store LREAL values in an NVS and exchange them via a unidirectional adapter. By combining initialization, automatic reading,



and adapter-based writing, it is particularly well-suited for modular and reusable ESP32-based control applications. Its design adheres to the IEC 61499 standard and enables a clean separation of memory logic and application.

NVS_ALR2

• – ○ • – ○ • – ○ •

Introduction

The **NVS_ALR2** function block is used to load and store LREAL data in non-volatile storage (NVS) of an ESP32 via an adapter. It encapsulates initialization and access to a single NVS entry identified by a KEY.

Interface Structure

Event Inputs

Event	Type	Comment	Associated Variables
`INIT`	EInit	Service Initialization	QI, SETM, KEY, DEFAULT_VALUE

Event Outputs

Event	Type	Comment	Associated Variables
`INITO`	EInit	Initialization Confirm	QO, STATUS

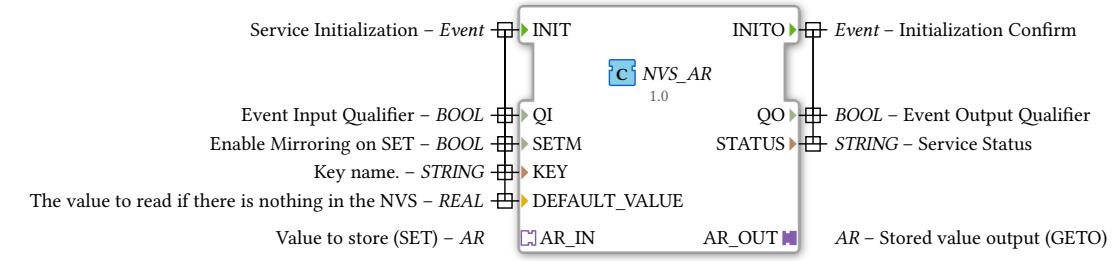
Data Inputs

Name	Type	Comment

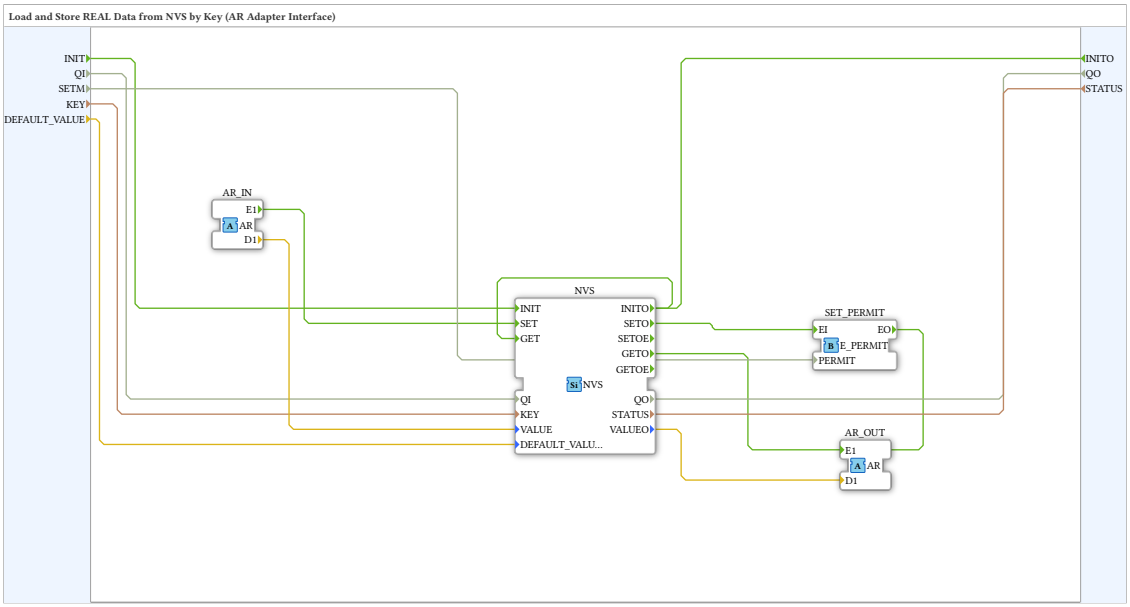
QI	BOOL	Event Input Qualifier
SETM	BOOL	Enable Mirroring on SET: if TRUE, the confirmation of a SET (SETO) is additionally forwarded to the output adapter (mirrored)
KEY	STRING	Key name for NVS entry
DEFAULT_VALUE	LREAL	Default value if key does not exist in NVS (Default: 0.0)

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service status



Adapters



Adapter	Type	Comment
VAL	adapter::types::bidirectional::ALR2 (Socket)	Value (LREAL)

Functionality

1. **Initialization**: An INIT event initializes the internal NVS block.
2. **Read value**: The read value is output via VAL.DI1.
3. **Store value**: An external block sends E01 via VAL to write a new value (D01) to NVS.

NVS_AR

• — ○ • — ○ • — ○ •

Introduction

The function block NVS_AR is used to load and store REAL data in non-volatile storage (NVS) using a key. It provides unidirectional communication with other IEC 61499 function blocks via two AR adapter interfaces. The block encapsulates the internal NVS function block and extends its functionality with a standardized adapter connection.

Interface Structure

Event Inputs

- **INIT** (EInit) – Initializes the function block. Upon this event, the data inputs QI, SETM, KEY, and DEFAULT_VALUE are accepted.

Event Outputs

- **INITO** (EInit) – Confirms successful completion of the initialization. After this event, the outputs QO and STATUS are valid.

Data Inputs

- **QI** (BOOL) – Input qualifier; controls the execution of the initialization.
- **SETM** (BOOL) – Enable mirroring on SET.
- **KEY** (STRING) – Key name under which the value is stored/retrieved in the NVS.
- **DEFAULT_VALUE** (REAL) – Default value that is returned if no entry with the specified key exists in the NVS.

Data Outputs

- **QO** (BOOL) – Output qualifier; indicates successful initialization.
- **STATUS** (STRING) – Status message for error diagnosis or confirmation.

Adapters

- **AR_IN** (Adapter type adapter::types::unidirectional::AR) – Receives a value to be stored (SET event and data).
- **AR_OUT** (Adapter type adapter::types::unidirectional::AR) – Makes the read value available to other function blocks (GETO event and data).

Functionality

The function block operates as follows:

1. **Initialization**: An event at INIT starts the initialization of the internal NVS function block. The inputs QI, SETM, KEY, and DEFAULT_VALUE are forwarded to NVS.
2. **After Initialization**: Once NVS completes initialization (event INITO), a **read command** (GET) is automatically sent to NVS. The read value (or the default value) is then output via the adapter output AR_OUT. … 3. **Save**: An event received via the adapter input AR_IN (AR_IN.E1) triggers a **save command** (SET) in the internal NVS. The value to be saved is taken from the adapter data channel (AR_IN.D1).
3. **Feedback**: After both a read and a save operation, the result (success/error) is reported via the adapter event AR_OUT.E1 and via the data outputs QO/STATUS.

Technical Features

- The module uses the unidirectional AR adapter, which enables loose coupling between function blocks.
- It is specifically designed for REAL data; other data types cannot be processed.
- The implementation is based on the generic NVS block from the logiBUS::storage::esp32_nvs library.
- The event control ensures that the current value is automatically read from the NVS and made available after initialization.

State Overview

The NVS_AR block does not have an explicit state engine in its XML definition. Its functional behavior is determined by the event chaining:

- **Idle State**: The block waits for an event on INIT or AR_IN.E1.
- **Initialization Phase**: After INIT, the internal NVS block is started. The outputs are not yet active during this phase.

- **Operation Phase**: After `INITO`, the block is ready to read values (automatically) and have them saved via `AR_IN`.

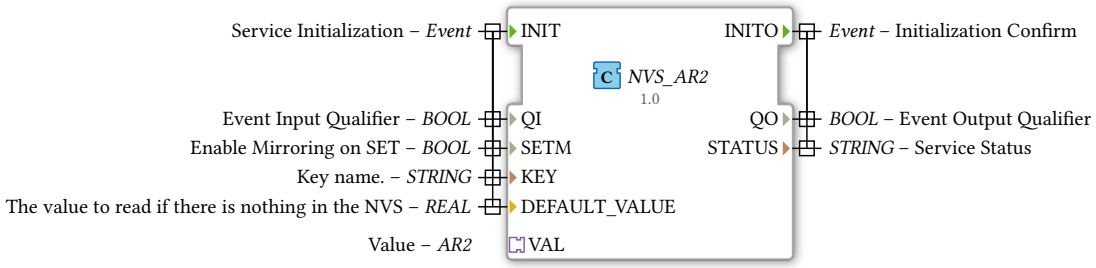
Application Scenarios

- **Configuration Memory**: Storing and retrieving real-world configuration parameters (e.g., limits, factors) in an ESP32-NVS.
- **Calibration Data**: Storing calibration values for sensors or actuators.
- **Persistent Operational Data**: Storing count values or totals that should be retained during power outages.

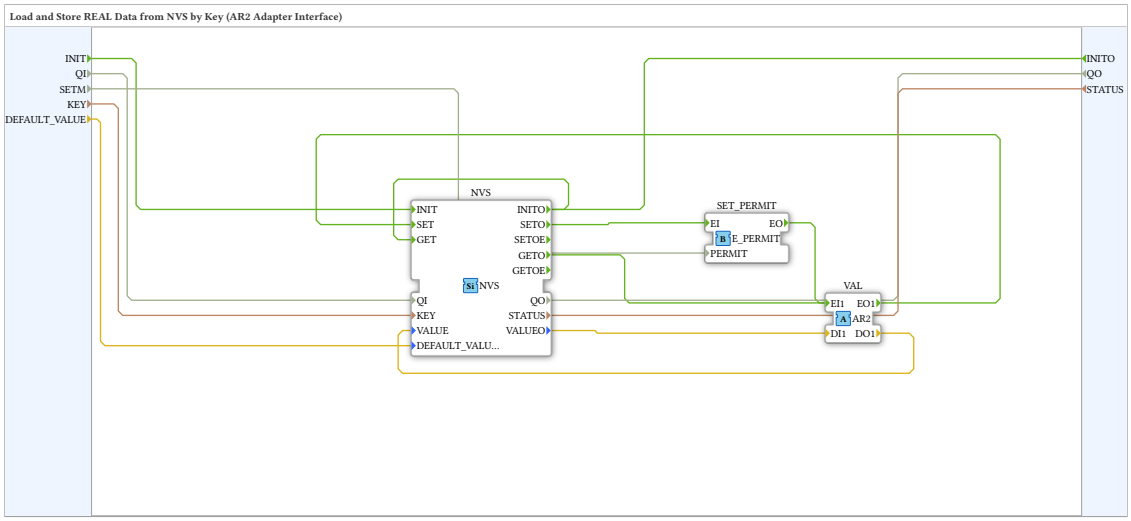
Comparison with Similar Blocks

Feature	`NVS_AR`	Direct `NVS` block
Interface	AR adapter (unidirectional)	Standard event/data inputs
Intended use	Easy integration into adapter-based networks	Flexible, but more complex wiring
Data type	REAL	Multiple types (via generic parameter)

The `NVS_AR` simplifies integration by standardizing the adapter connection, while the pure `NVS` block offers broader type support.



Conclusion



The `NVS_AR` function block offers a compact, adapter-based solution for loading and storing real data in non-volatile memory. Thanks to the AR adapter, it can be easily integrated into existing IEC 61499 networks without requiring detailed connections. Automatic initial readout after initialization simplifies its use in typical real-time control scenarios.

NVS_AR2

• – ○ • – ○ • – ○ •

Introduction

The NVS_AR2 function block is used to store and load real values (floating-point numbers) into non-volatile storage (NVS) using a key. It encapsulates the logic of the underlying NVS block and provides a bidirectional AR2 adapter interface for asynchronous communication. This allows the block to be integrated into an event-driven environment where read and write operations are triggered asynchronously.

Interface Structure

Event Inputs

- **INIT**: Initializes the block. This event passes the parameters QI (Qualifier), SETM (mirroring on SET), KEY (Key), and DEFAULT_VALUE (Default Value). After successful initialization, the INITO output is triggered.

Event Outputs

- **INITO**: Initialization confirmation. This event signals that the function block is ready. It is also triggered after a read or write operation via the adapter (since the events are chained).

Data Inputs

- **QI** (BOOL): Input qualifier for controlling execution. Typically, this is set to TRUE to activate initialization.
- **SETM** (BOOL): Enable mirroring on SET.
- **KEY** (STRING): The key name under which the value is to be stored or read in the NVS.
- **DEFAULT_VALUE** (REAL): The value returned if no entry exists in the NVS under the specified key.

Data Outputs

- **QO** (BOOL): Output qualifier. Displays the status of the executed operation.
- **STATUS** (STRING): Status message of the operation (e.g., success, error code).

Adapter

- **VAL** (of type `adapter::types::bidirectional::AR2`): Bidirectional adapter for asynchronous reading and writing of values. The adapter has two events (EO1 – from the module to the adapter; EI1 – from the adapter to the module) and two data ports (DO1 – data from the module to the adapter; DI1 – data from the adapter to the module). External components can send read and write requests to the NVS_AR2 and receive results via this adapter.

Functionality

The NVS_AR2 acts as an intermediary between the actual NVS memory module (`logiBUS::storage::esp32_nvs::NVS`) and a higher-level controller via the bidirectional adapter. Upon

receipt of the INIT event, the parameters are forwarded to the internal NVS module. The NVS module performs initialization and acknowledges with INITO.

After initialization, a read operation (GET) is automatically triggered: The NVS block reads the value under the specified key. If no entry exists, DEFAULT_VALUE is used. The read result is sent to the connected component via the adapter output (VAL.DI1) and the event VAL.EI1.

A write operation occurs when the external component sends a write command via the adapter (VAL.EO1). The desired value is then passed to NVS_AR2 via VAL.DO1, which forwards it to the NVS block (SET). After a successful write, the NVS block acknowledges with SETO, which in turn triggers the event VAL.EI1 to send the confirmation back to the external component.

Technical Features

- **Asynchronous Communication**: The block supports asynchronous read and write operations via the AR2 adapter, allowing it to be integrated into concurrent systems without blocking calls.
- **Default Value**: Specifying a DEFAULT_VALUE ensures that a defined value is returned even when a key is used for the first time.
- **Error Handling**: STATUS and QO indicate the success or failure of the operation.
- **Reusability**: The function block encapsulates the general NVS function block and adds a standardized adapter interface, facilitating reuse in various control logics.

State Overview

The function block does not have an explicitly defined state machine in the XML, as it is controlled via the internal NVS function block and event chaining. The state is determined by the sequence of events:

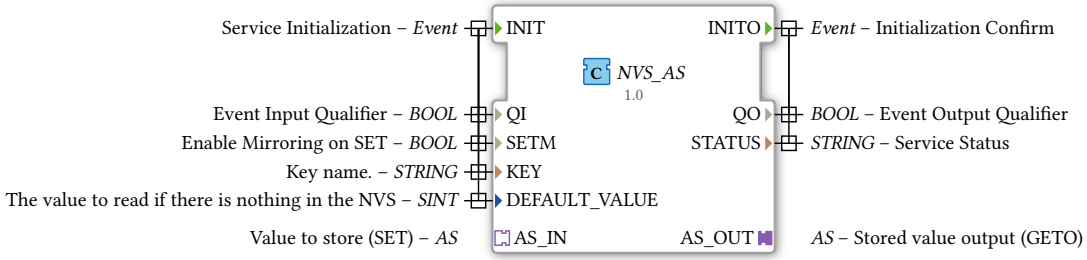
1. Waiting for INIT → Initialization runs → INITO and GET are triggered.
2. After GET: Waiting for read result → Value sent to adapter.
3. Waiting for write request via adapter → SET executed → Confirmation returned.
4. After each step, the function block is ready for new requests.

Application Scenarios

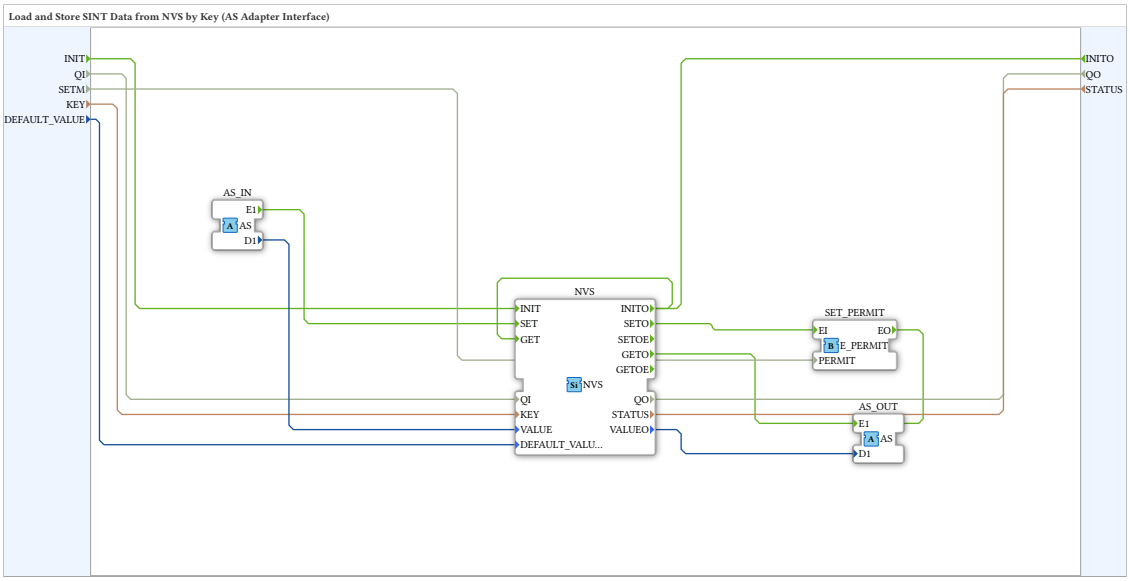
- **Persistent Configuration Memory**: Saving and retrieving settings (e.g., setpoints, parameters) in an embedded system with NVS (such as ESP32 NVS).
- **Data Logging**: Asynchronously storing measured values in NVS.
- **Load Initial Default Values**: Loading a saved value at system startup or using a default value if it has never been saved.

Comparison with Similar Devices

- **NVS**: The basic NVS device without an adapter has direct event interfaces (INIT, REQ, etc.) and requires a direct connection. NVS_AR2 adds a bidirectional adapter interface, enabling a more flexible, protocol-independent connection.
- **Other Memory Devices (e.g., EEPROM, file system)**: These devices often have different data types and access methods. NVS_AR2 is specifically optimized for REAL values and NVS access.



Conclusion



The NVS_AR2 function block offers a clean, adapter-based interface for asynchronously reading and writing real data to non-volatile memory. Thanks to the encapsulation of the NVS block and the integration of the AR2 adapter, it is ideally suited for modular, event-driven control systems that require persistent data management.

NVS_AS

• – ○ • – ○ • – ○ •

The function block **NVS_AS** serves as an interface for reading and writing SINT (signed integer) data in non-volatile storage (NVS). Storage is performed using a user-defined key (KEY). The block extends access to the NVS with an adapter interface (unidirectional AS type), allowing values to be received and sent via standardized adapter connections. This enables modular and reusable connectivity to storage functions in IEC 61499 applications.

Event	Description	Associated Variables
INIT	Initializes the NVS and triggers the first loading of a stored value.	QI, SETM, KEY, DEFAULT_VALUE
Event	Description	Associated Variables
–––––	–––––	–––––––
INITO	Confirmation of initialization and the first loading process.	QO, STATUS
Variable	Type	Description
–––––	–––	–––––––
QI	BOOL	Enables initialization (TRUE = enable).
SETM	BOOL	Enable Mirroring on SET: if TRUE, the confirmation of a SET (SETO) is additionally forwarded to the output adapter (mirrored)
KEY	STRING	Key under which the value is stored in the NVS.

DEFAULT_VALUE	SINT	Default value, read if no value exists under the key.
Variable	Type	Description
-----	----	-------
QO	BOOL	Confirms successful initialization and operational readiness.
STATUS	STRING	Status message (e.g., “Success” or error message).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Adapter	Type	Direction	Description
AS_IN	AS	SOCKET	Receives a SINT value to be stored via a unidirectional adapter protocol (Event + Data).
AS_OUT	AS	PLUG	Sends the read SINT value to connected blocks via a unidirectional adapter protocol.

Functionality

The **NVS_AS** block encapsulates an instance of the **NVS** block (from the `logiBUS::storage::esp32_nvs` library). The function operates in two modes:

1. **Initialization and First Read Operation**

After an INIT event, the internal NVS block is initialized. Immediately afterward (automatic chaining of `INIT0` to `GET`), the value stored under the specified KEY is read. If no value exists, `DEFAULT_VALUE` is returned. The read or specified value is sent to downstream function blocks via the **AS_OUT** adapter (event `E1` and data `D1`).

1. **Writing and Reading via Adapters**

- An event (`E1`) with an associated data value (`D1`) received via the **AS_IN** adapter triggers a **SET** operation in the NVS. The value is stored under the KEY specified during INIT.
- After a successful SET, the stored value is automatically output via **AS_OUT** (through the connection between `NVS.SET0` and `AS_OUT.E1`).
- Similarly, a reread can be triggered by an INIT event or by the internal process after a successful SET. A separate external read event is not provided; the value is always updated after a change or during initialization.

The function block therefore operates as a **read and write memory access with automatic feedback of the current value**.

- **Adapter-Based Input/Output**

The use of unidirectional AS adapters allows for loose coupling: **AS_IN** receives write requests, **AS_OUT** outputs the stored value. This corresponds to a publisher/subscriber or client/server pattern at the adapter level.

- **Automatic Initialization**

After the INIT event, a GET request is executed immediately, so the function block provides the current or default value immediately after initialization.

- **Type Restriction to SINT**

The function block stores and loads only SINT values. Separate versions are required for other data types (e.g., INT, REAL, STRING).

- **Error Handling**

Errors during NVS operations (e.g., invalid key, memory error) are output as an error message via the STATUS output, and QO is set to FALSE.

The internal NVS module has its own state machine. The following processes are relevant for the user:

Phase	State
1	Waiting for INIT event.
2	INIT executed ⟶ NVS initialized ⟶ GET started.
3	GET completed ⟶ Value sent via AS_OUT ⟶ Ready for write operations via AS_IN.
4	Event via AS_IN ⟶ SET executed ⟶ Value saved ⟶ Value sent via AS_OUT ⟶ Return to Phase 3.

A new INIT event can force a re-initialization at any time.

- **Persistent Device Parameters**

Storing configuration values (e.g., brightness, delay time) in the non-volatile memory of an ESP32, automatically loading them on restart.

- **State Markers for Automation**

Remembering the last state (e.g., counter reading, production parameters) even after a power failure.

- **Adapter-Based Data Nodes**

Integration into a chain of adapters where one module sets values and another reads them.

- **NVS (Direct)**

The `NVS` module offers the same functionality, but without an adapter interface. It requires separate event and data lines. `NVS_AS` simplifies integration into adapter-oriented architectures.

- **NVS_AS_REAL, NVS_AS_STRING**

Analogous modules for other data types. The interface and behavior are identical; only the data type varies.

- **Retain Values**

In some systems, retain variables are also persistent. `NVS_AS` relies on low-level NVS (e.g., on ESP32) and is therefore platform-specific, but offers higher performance and optimized capacity.

The **NVS_AS** function block provides a practical, adapter-based encapsulation of non-volatile memory for SINT values. By combining initialization logic, automatic value feedback, and an adapter interface, it is ideally suited for modular IEC 61499 projects that require persistent storage with minimal wiring. The limitation to the SINT type and the automatic GET post-initialization should be noted, but simultaneously simplify handling in many standard applications.

NVS_AS2

• – ○ • – ○ • – ○ •

Introduction

The **NVS_AS2** function block is used to load and store SINT data in non-volatile storage (NVS) of an ESP32 via an adapter. It encapsulates initialization and access to a single NVS entry identified by a KEY.

Interface Structure

Event Inputs

Event	Type	Comment	Associated Variables
`INIT`	EInit	Service Initialization	QI, SETM, KEY, DEFAULT_VALUE

Event Outputs

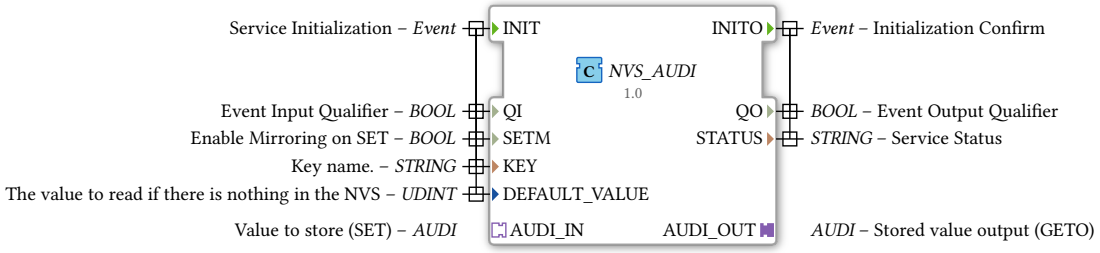
Event	Type	Comment	Associated Variables
`INITO`	EInit	Initialization Confirm	QO, STATUS

Data Inputs

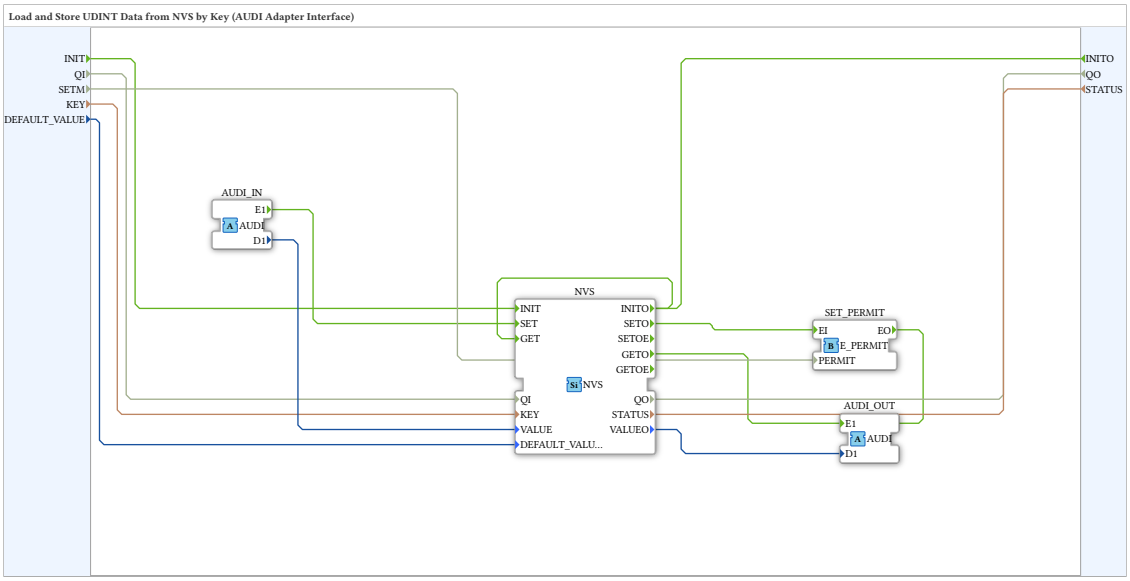
Name	Type	Comment
QI	BOOL	Event Input Qualifier
SETM	BOOL	Enable mirroring on SET
KEY	STRING	Key name for NVS entry
DEFAULT_VALUE	SINT	Default value if key does not exist in NVS (Default: 0)

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service status



Adapters



Adapter	Type	Comment
VAL	adapter::types::bidirectional::AS2 (Socket)	Value (SINT)

Functionality

1. **Initialization**: An INIT event initializes the internal NVS block.
2. **Read value**: The read value is output via VAL.DI1.
3. **Store value**: An external block sends E01 via VAL to write a new value (D01) to NVS.

NVS_AUDI

• – ○ • – ○ • – ○ •

Introduction

The **NVS_AUDI** function block enables the storage and loading of **UDINT** data in the **Non-Volatile Storage (NVS)** of an ESP32 microcontroller. The data is addressed using a unique **key (KEY)**. The block uses a **unidirectional AUDI adapter interface** to communicate with the NVS: The value to be stored is received via an input adapter (socket), and the read value is provided via an output adapter (plug).

Interface Structure

Event Inputs

Name	Type	Data Carried	Comment
INIT	EInit	QI, SETM, KEY, DEFAULT_VALUE	Initializes the service

Event Outputs

Name	Type	Carried Data	Comment
INITO	EInit	QO, STATUS	Initialization Confirmation

Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier
SETM	BOOL	Enable mirroring on SET
KEY	STRING	Key Name for NVS Access
DEFAULT_VALUE	UDINT	Default value if no value exists in NVS

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service Status (Error/OK)

Adapter

Name	Type	Comment
AUDI_IN	adapter::types::unidirectional::AUDI	Value to be stored (SET)
AUDI_OUT	adapter::types::unidirectional::AUDI	Stored/loaded value (GETO)

Functionality

Upon arrival of the **INIT** event, the internal NVS module is initialized (QI, SETM, KEY, and DEFAULT_VALUE are passed). After successful initialization, **INITO** fires, and simultaneously a **GET** request is sent to the NVS to load the stored value. The result of the GET operation is provided via **AUDI_OUT** (data on D1, event on E1).

If an event (E1) with a value (D1) is received via the **AUDI_IN** adapter, a **SET** request is sent to the NVS to store the value under the current KEY. After saving, **SETO** fires, and the result is also acknowledged via **AUDI_OUT**.

The status (QO, STATUS) is updated via the outputs after both loading and saving.

Technical Features

- The function block uses the **unidirectional AUDI adapter**, which allows for simple, stream-based data transfer: A value is sent (SET), and a value is received (GETO).
- Internally, the function block `logiBUS::storage::esp32_nvs::NVS` is used, which executes the actual NVS operation on the ESP32.

- The default data type is **UDINT** (unsigned 32-bit).
- No additional states or timers are required; the function block operates purely event-driven.
- The **TypeHash** attribute is set to an empty string – it can be used for integrity checks.

State Overview

Since no explicit state machine is defined in the XML, the process is derived from the events:

1. **Initialization Phase** – INIT received ⟶ NVS-INIT ⟶ NVS-GET triggered.

Afterwards: Ready (waiting for SET or another GET by re-INIT).

1. **Storage Phase** – Event via AUDI_IN (E1) ⟶ NVS-SET ⟶ Value is written.
2. **Read Operation** – Automatically after INIT or by re-INIT.

Output via AUDI_OUT occurs after each read or write operation.

Application Scenarios

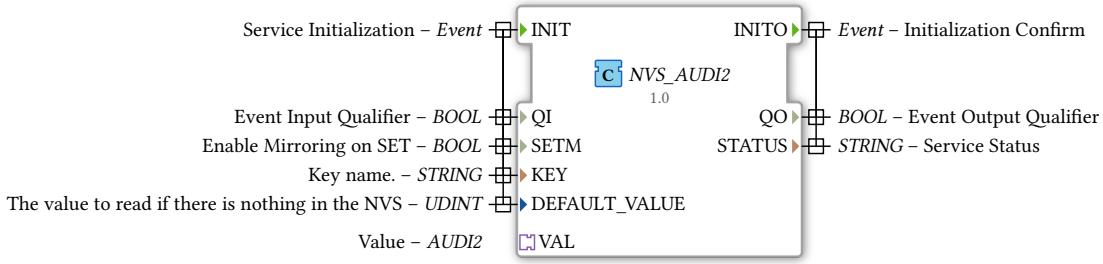
- Storing **configuration parameters** (e.g., limits, operating modes) in the NVS, which are retained even after a power failure.
- **Meter readings** or **calibration data** in ESP32-based industrial controllers.
- **Persistent states** of automation processes, uniquely identified by a key.
- Exchanging data between different FBs via the AUDI adapter without directly accessing the NVS.

Comparison with Similar Function Blocks

- **NVS (without adapter)**: Provides direct access to the NVS via individual events and data ports, but requires more wiring.
- **NVS_AUDI** encapsulates the NVS operations behind a standardized adapter interface. This makes the module easier to replace and standardizes data transfer (e.g., with other memory modules that also use AUDI adapters).

Other memory modules (e.g., Retain, SD card) differ in their hardware interface and latency; NVS is specifically optimized for the ESP32.

Conclusion



The NVS_AUDI function block provides an elegant solution for persistent storage of UDINT data on the ESP32. The integration of the AUDI adapter interface simplifies connectivity to other modules and results in clearer code structure. It is particularly suitable for applications requiring standardized data exchange between storage and processing components.

NVS_AUDI2

• — ○ • — ○ • — ○ •

Introduction

The **NVS_AUDI2** function block is used to load and store UDINT data in non-volatile storage (NVS) of an ESP32 via an adapter. It encapsulates initialization and access to a single NVS entry identified by a KEY.

Interface Structure

Event Inputs

Event	Type	Comment	Associated Variables
INIT	EInit	Service Initialization	QI, SETM, KEY, DEFAULT_VALUE

Event Outputs

Event	Type	Comment	Associated Variables
INITO	EInit	Initialization Confirm	QO, STATUS

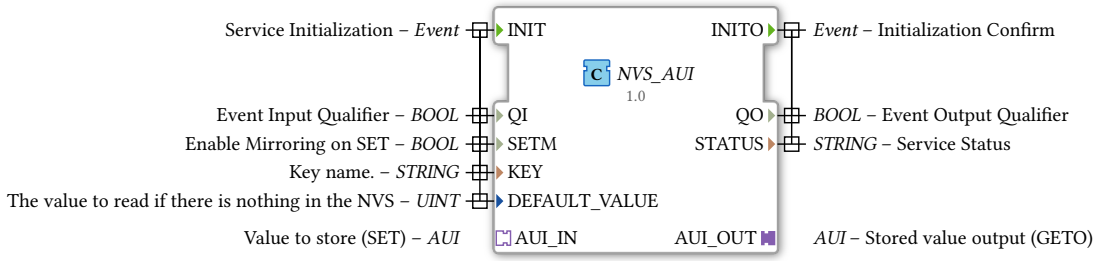
Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier
SETM	BOOL	Enable Mirroring on SET: if TRUE, the confirmation of a SET (SETO) is additionally forwarded to the output adapter (mirrored)
KEY	STRING	Key name for NVS entry
DEFAULT_VALUE	UDINT	Default value if key does not exist in NVS (Default: 0)

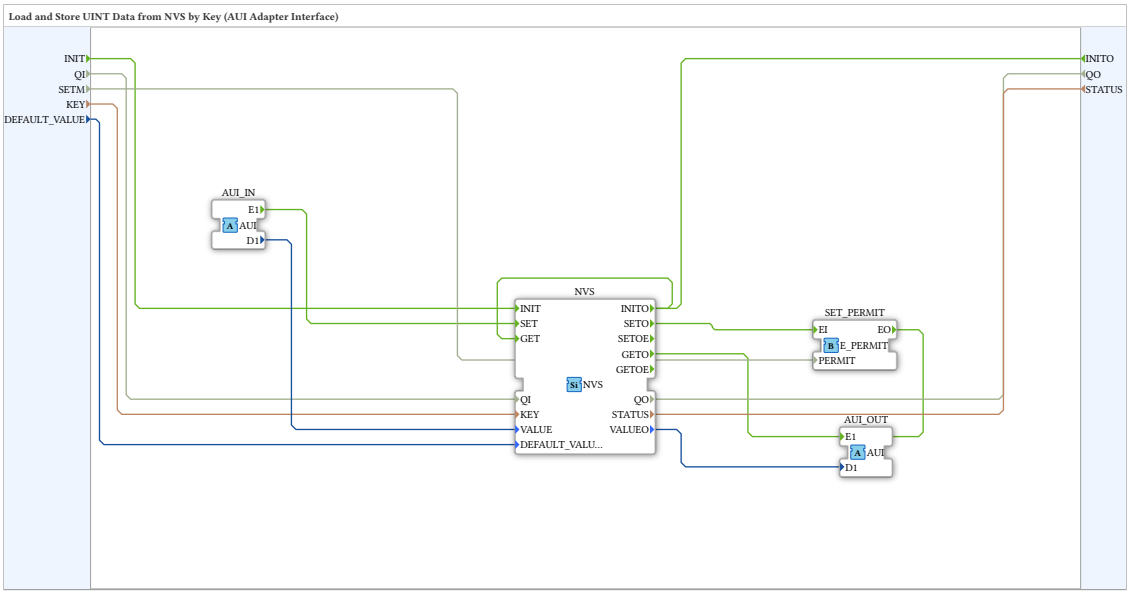
Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service status

Adapters



Adapter	Type	Comment



VAL	adapter::types::bidirectional::AUDI2 (Socket)	Value (UDINT)

Functionality

1. **Initialization**: An INIT event initializes the internal NVS block.
2. **Read value**: The read value is output via VAL.DI1.
3. **Store value**: An external block sends E01 via VAL to write a new value (D01) to NVS.

NVS_AUI

• — ○ • — ○ • — ○ •

Introduction

The function block **NVS_AUI** is used to load and store UINT data in non-volatile memory (NVS) using a key. It encapsulates access to the NVS and provides a standardized AUI adapter interface for outputting read values and receiving values to be stored. Typical applications include embedded systems that need to persistently store configuration or status data.

Interface Structure

Event Inputs

Event	Comment	Accompanying Data
INIT	Service Initialization	QI (BOOL), SETM (BOOL), KEY (STRING), DEFAULT_VALUE (UDINT)

Event Outputs

Event	Comment	Carrying Data
INITO	Initialization Acknowledgement	QO (BOOL), STATUS (STRING)

Data Inputs

Name	Type	Comment
QI	BOOL	Qualifier for the input event
SETM	BOOL	Enable mirroring on SET
KEY	STRING	Key name for NVS access
DEFAULT_VALUE	UDINT	Value to be read if no entry exists in the NVS

Data Outputs

Name	Type	Comment
QO	BOOL	Qualifier for the output event
STATUS	STRING	Service status message

Adapters

Adapter	Type / Direction	Comment
AUI_IN	**Socket** (Input) – Type: adapter::types::unidirectional::AUI	Returns the value to be stored (SET)
AUI_OUT	**Plug** (Output) – Type: adapter::types::unidirectional::AUI	Returns the retrieved value (GETO)

Functionality

1. **Initialization**

A INIT event triggers the connection to the non-volatile memory. The key (KEY) and the default value (DEFAULT_VALUE) are passed. After successful initialization, INITO is acknowledged with the result (QO / STATUS).

1. **Reading Data**

After initialization, the stored value for the specified key is automatically read internally and provided as an event (E1) and data (D1) via the output adapter AUI_OUT. If no entry exists, DEFAULT_VALUE is output.

1. **Storing Data**

A new value can be received via the input adapter AUI_IN. An incoming event (E1) with the associated data (D1) is forwarded to the internal NVS function block, which persistently stores the value under the initialized key.

The entire data and event flow is implemented by the embedded function block NVS (from the library logiBUS::storage::esp32_nvs).

Technical Features

- **AUI Adapter Interface**

The unidirectional adapters AUI_IN and AUI_OUT enable loose coupling between the NVS module and other components that use standardized AUI interfaces.

- **Automatic Read Operation After Initialization**

Immediately after initialization, the value is read and made available via AUI_OUT – without a separate "Get" event.

- **Error Handling**

Errors during initialization or memory accesses are signaled via STATUS.

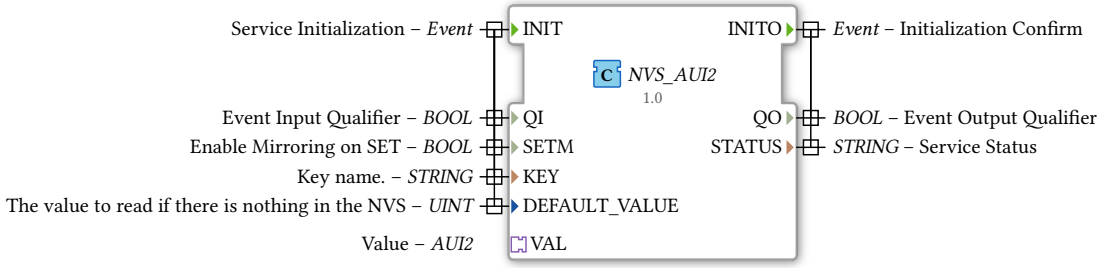
Status Overview

The FB is in **idle state** after startup.

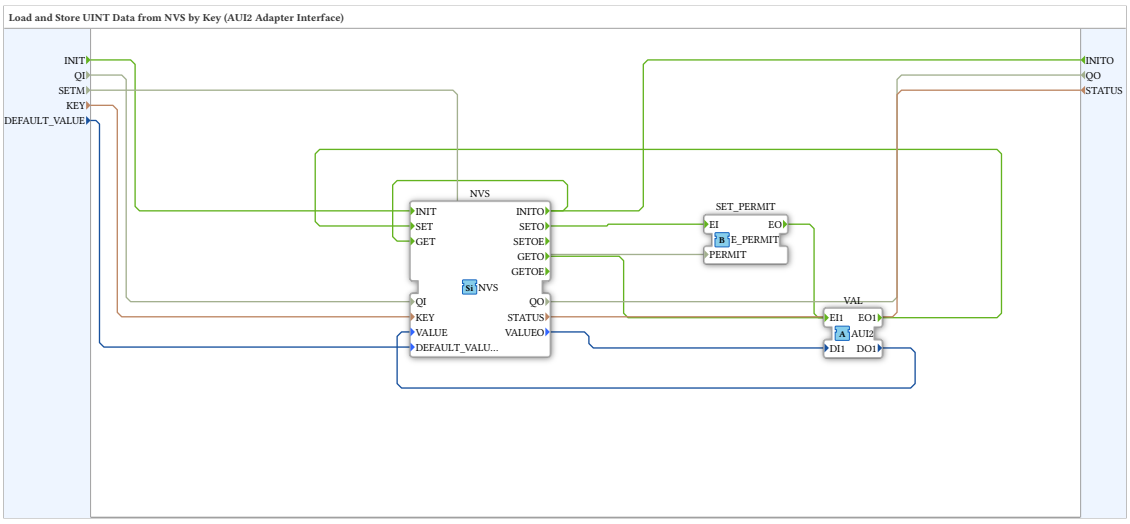
- **Initialization** (upon arrival of `INIT`): Establishing the NVS connection, reading the existing value.
- **Ready** (after successful `INITO`): Waiting for incoming data via `AUI_IN` to save or for external requests via `AUI_OUT`.
- **Save operation** (upon event at `AUI_IN`): Value is persisted; then returns to the ready state.
- **Error state** (in case of unsuccessful initialization): `QO` = FALSE, `STATUS` contains error text.

Application Scenarios

- **Configuration Memory** in IoT devices: Storing network settings, calibration data, or user settings.
- **Status Monitoring**: Saving the last operating state (e.g., counter readings) before a power failure.
- **Parameter Transfer** between different automation components that communicate via AUI adapters.



Comparison with Similar Function Blocks



Compared to the direct **NVS** function block, `NVS_AUI` offers a higher level of abstraction through its adapter interface. While the basic function block requires separate events for reading (`GET`) and writing (`SET`), `NVS_AUI` simplifies data flow through unidirectional adapters and automatic read operation after INIT. Other memory modules (e.g., `F_MMAP`, `F_FILE`) typically use file-based or memory-mapping methods; `NVS_AUI` is specifically optimized for non-volatile memory with key-value pairs.

Conclusion

NVS_AUI` is a practical functional block for persistent data storage in automation systems. The combination of NVS memory and an AUI adapter allows for easy integration into existing IEC 61499 applications, reduces wiring effort, and ensures a clear separation between memory logic and communication.

NVS_AUI2

• – ○ • – ○ • – ○ •

Introduction

The **NVS_AUI2** function block is used to load and store UINT data in non-volatile storage (NVS) of an ESP32 via an adapter. It encapsulates initialization and access to a single NVS entry identified by a KEY.

Interface Structure

Event Inputs

Event	Type	Comment	Associated Variables
INIT	EInit	Service Initialization	QI, SETM, KEY, DEFAULT_VALUE

Event Outputs

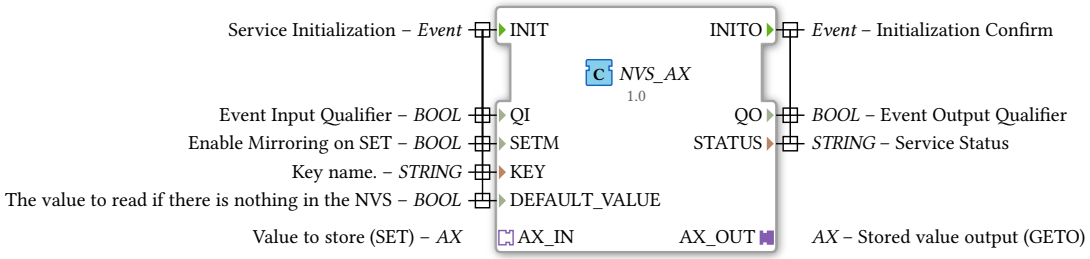
Event	Type	Comment	Associated Variables
INITO	EInit	Initialization Confirm	QO, STATUS

Data Inputs

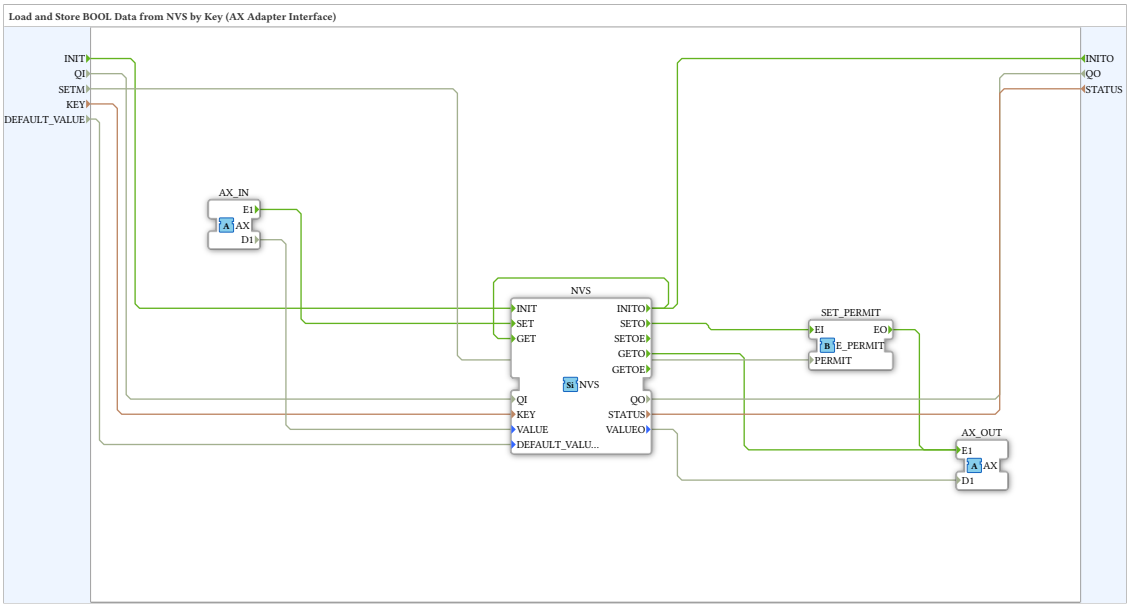
Name	Type	Comment
QI	BOOL	Event Input Qualifier
SETM	BOOL	Enable mirroring on SET
KEY	STRING	Key name for NVS entry
DEFAULT_VALUE	UINT	Default value if key does not exist in NVS (Default: 0)

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service status



Adapters



Adapter	Type	Comment
VAL	adapter::types::bidirectional::AUI2 (Socket)	Value (UINT)

Functionality

1. **Initialization**: An INIT event initializes the internal NVS block.
2. **Read value**: The read value is output via VAL.DI1.
3. **Store value**: An external block sends E01 via VAL to write a new value (D01) to NVS.

NVS_AX

• – ○ • – ○ • – ○ •

Introduction

`NVS_AX` loads and stores a `BOOL` value under a key (`KEY`) in the ESP32's non-volatile storage (NVS). It is the Boolean counterpart to NVS_AB and uses the same two-adapter architecture, but with unidirectional `AX` adapters instead of `AB`.

Interface Structure

Event Inputs

- **INIT**: initializes the block and reads the value stored under `KEY` (or `DEFAULT_VALUE` if none exists yet). Carries `QI`, `SETM`, `KEY`, `DEFAULT_VALUE`.

Event Outputs

- **INITO**: confirms initialization and the initial read, carries `QO` and `STATUS`.

Data Inputs

- **QI** (BOOL): qualifier for the `INIT` event.
- **SETM** (BOOL): enables mirroring (confirmation) on write (`SET`).
- **KEY** (STRING): name of the key in the NVS.
- **DEFAULT_VALUE** (BOOL): value returned when nothing is stored under `KEY` yet.

Data Outputs

- **QO** (BOOL): success qualifier, carried with `INITO` and the internal adapter confirmations.
- **STATUS** (STRING): status message of the NVS access.

Adapters

- **AX_IN** (Socket, type `AX`): new value to store – an adapter event on `AX_IN.E1` triggers a `SET` on the internal NVS block, `AX_IN.D1` carries the value to write.
- **AX_OUT** (Plug, type `AX`): outputs the most recently read value – both after the automatic initial read on `INIT` and after each confirmed write (`AX_OUT.D1`/`AX_OUT.E1`).

Functionality

`NVS_AX` wraps an internal instance of `logiBUS::storage::esp32_nvs::NVS` plus an `E_PERMIT` gate (`SET_PERMIT`). On `INIT`, the internal NVS instance is initialized (`NVS.INIT`) and a `GET` is triggered automatically, returning the value stored under `KEY` (or `DEFAULT_VALUE`); the result is output via `AX_OUT`, and `INITO` confirms completion.

To write, the block connected to `AX_IN` fires an adapter event (`AX_IN.E1`) carrying the new value (`AX_IN.D1`), which triggers `NVS.SET`. Whether the successful write is additionally reported back via `AX_OUT`

is controlled by SETM: if SETM is set, SET_PERMIT releases the AX_OUT.E1 event after a successful SET ("mirroring").

Technical Details

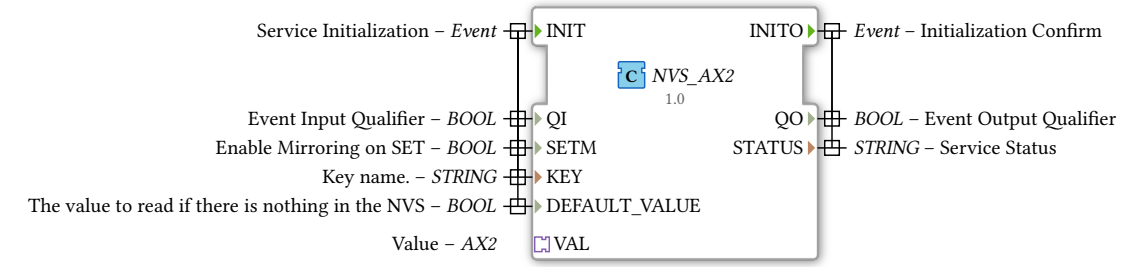
- Pure composite FB with no ECC of its own – the actual flash logic lives in the internal NVS instance; NVS_AX only wires events and data between it and the two AX adapters.
- Two separate unidirectional adapters (AX_IN/AX_OUT) – this lets the read and write paths connect to different peers.
- SETM only controls whether a write is additionally mirrored back via an AX_OUT adapter event – the value is stored either way.

State Overview

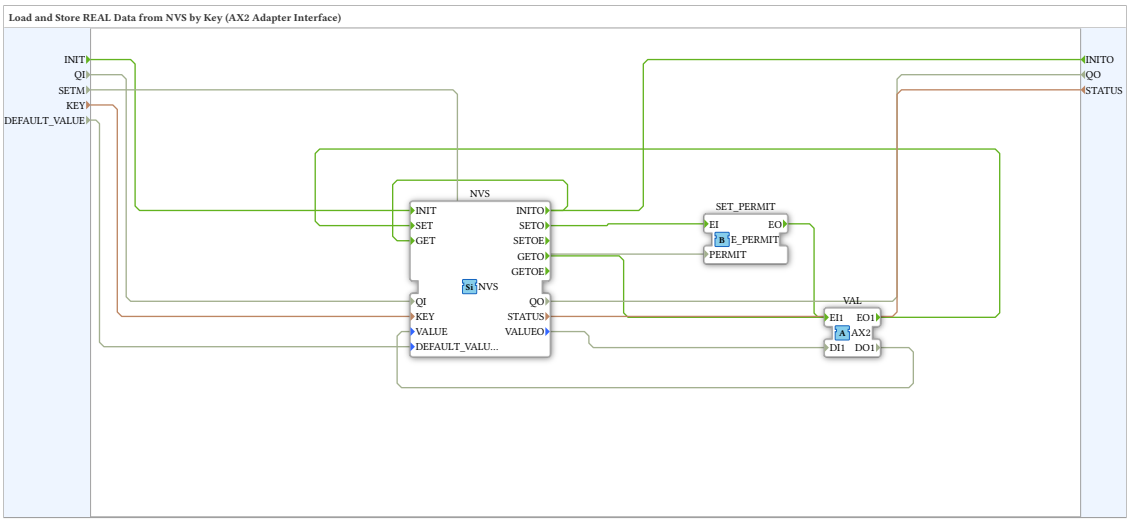
The block is stateless in terms of its own ECC: on INIT it runs through initialization plus an initial read once, then reacts to every AX_IN adapter event with an NVS write and, optionally, a confirmation via AX_OUT.

Application Scenarios

- Persisting individual BOOL configuration values (e.g. enable flags, operating-mode switches) on the ESP32
- Building a read/write pair where the read and write sides need to connect to different blocks
- Restoring a last-stored BOOL value after a restart via AX_OUT



⚖️ Comparison with Similar Blocks



Compare with NVS_AB, which uses the same architecture for BYTE instead of BOOL values, and with INI_AX, which provides the same interface for the text-based settings.ini instead of the NVS flash storage.

Conclusion

NVS_AX provides simple, unidirectionally wired access to a persistent BOOL value in the ESP32's NVS, and fits anywhere the read and write paths need to be kept separate.

NVS_AX2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **NVS_AX2** is used to load and save REAL data to the non-volatile memory (NVS) of an ESP32 via an adapter. It encapsulates the initialization and access to a single NVS entry, which is identified by a key. The function block provides an initializing event interface and a bidirectional adapter interface through which the stored value can be accessed externally. The block is modeled according to IEC 61499 and optimized for use in distributed automation systems.

Interface Structure

Event Inputs

Event	Type	Comment	Carried Variables
INIT	EInit	Service Initialization	QI, SETM, KEY, DEFAULT_VALUE

Event Outputs

Event	Type	Comment	Carried Variables
INITO	EInit	Initialization Confirm	QO, STATUS

Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier (Initialization Enabled)
SETM	BOOL	Enable Mirroring on SET: if TRUE, the confirmation of a SET (SETO) is additionally forwarded to the output adapter (mirrored)
KEY	STRING	Key name for the NVS entry
DEFAULT_VALUE	BOOL	Default value if the key does not exist in the NVS (default: FALSE)

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service status

Adapters

Adapter	Type	Comment
VAL	adapter::types::bidirectional::AX2 (Socket)	Value (REAL)

The **VAL** adapter establishes a bidirectional connection to an external component. The stored REAL value can be read and written via this adapter. The AX2 adapter type defines an event and data protocol for data transfer.

Functionality

1. **Initialization**: An event at input INIT triggers the initialization of the internal NVS component. The values QI, SETM, KEY, and DEFAULT_VALUE are passed. After successful initialization, the event INITO is sent at the output. Simultaneously, a read operation (GET) for the specified key is automatically initiated.
2. **Read Value**: The read value is output via the adapter VAL as DI1 (data output of the adapter), and an event EI1 is triggered on the adapter. The outputs QO and STATUS reflect the result of the read operation.

3. **Save Value**: An external function block can send an event `EO1` via the adapter `VAL` to write a new value (provided as `DO1`) to the NVS. The internal NVS function block then performs a SET operation and confirms it via `SETO`. The event `EI1` is then triggered on the adapter to signal completion to the sender.
4. **Status Signaling**: The outputs `QO` and `STATUS` are updated after each read or write operation and output with the event `INITO`.

Technical Features

- **Persistence on ESP32**: The function block uses the ESP32 microcontroller's NVS (Non-Volatile Storage) to permanently store data. The data is retained even after a restart.
- **Adapter-Based Communication**: The interface to the user is via a bidirectional adapter (AX2), which enables flexible and standardized connectivity to other components. The data type is set to REAL.
- **Error Handling**: Error messages (e.g., NVS error, insufficient memory) can be queried via the output `STATUS`. The output `QO` indicates the success of the operation.
- **Standard Compliance**: The function block (FB) is implemented according to IEC 61499 and uses the block class `logiBUS::storage::esp32_nvs::NVS`.

State Overview

The FB does not have an explicit state machine, but the following logical sequence occurs:

1. **Idle**: No `INIT` event is received.
2. **Initializing**: After `INIT` – the internal NVS block is started and a GET request is executed.
3. **Ready**: After `INITO` – the module waits for read/write requests via the adapter.
4. **Write Operation**: A `EO1` event on the adapter triggers a SET operation.
5. **Read**: A subsequent read operation can only be performed by another `INIT` event or internal logic (the module reads once at startup and subsequently only during write operations).

Application Scenarios

- **Configuration Storage**: Saving user settings (e.g., setpoints, operating modes) to an ESP32 device.
- **Calibration Data**: Permanent storage of calibration values for sensors.
- **State Storage**: Saving the last operating state (e.g., counter readings, switch positions) in the event of a power failure.
- **Data Logging**: Targeted saving of individual measured values via the adapter.

Comparison with Similar Function Blocks

Unlike simple memory function blocks (e.g., `CTUO` or generic `R_TRIG` blocks), `NVS_AX2` is specifically designed for persistent storage on ESP32 hardware. While other function blocks only process volatile data, this block ensures permanent data retention. Using an adapter offers more flexibility than a fixed input/output because the data type and communication direction are clearly defined. Compared to direct NVS API calls in IEC 61499, this function block simplifies integration through its fully declarative description.

Conclusion

The function block `NVS_AX2` is an efficient and standards-compliant solution for persistently storing a REAL value in the NVS of an ESP32. Its clear interface structure with event control and bidirectional adapter facilitates integration into complex automation projects. Thanks to integrated initialization and error logging, the block is robust and suitable for industrial applications.

Introduction

The INI function block enables the loading and saving of data to a `settings.ini` file. It provides a simple interface for persistently managing values using a section name (SECTION) and a key (KEY). The block is particularly useful for configuration management in 4diac FORTE applications, for example, for setting and retrieving parameters such as IP addresses, thresholds, or operating modes.

Interface Structure

Event Inputs

- **INIT**: Service initialization. Used during startup or reconfiguration. Triggers the initialization of the block and, optionally, the first read/write of a value.
- **SET**: Sets the value for the configured key in the INI file.
- **GET**: Reads the value for the configured key from the INI file.

Event Outputs

- **INITO**: Initialization confirmation. Triggered after processing the INIT event.
- **SETO**: Write confirmation. Triggered after processing the SET event.
- **GETO**: Read confirmation. Triggered after processing the GET event.

Data Inputs

- **QI (BOOL)**: Event input qualifier. Controls whether the operation is enabled (`TRUE`) or disabled (`FALSE`) upon INIT.
- **SECTION (STRING)**: The name of the section within the `settings.ini` file.
- **KEY (STRING)**: The name of the key within the specified section.
- **VALUE (ANY_ELEMENTARY)**: The value to be written. This data type can be any elementary type (e.g., BOOL, INT, REAL, STRING).
- **DEFAULT_VALUE (ANY_ELEMENTARY)**: The default value returned if the requested key does not exist in the INI file.

Data Outputs

- **QO (BOOL)**: Event output qualifier. Returns the status of the operation (`TRUE` for success, `FALSE` for error or deactivation).
- **STATUS (STRING)**: Detailed status of the executed operation (e.g., “OK”, “ERROR”).
- **VALUEO (ANY_ELEMENTARY)**: The value read or written. For GET requests, this is either the value read from the file or the DEFAULT_VALUE.

Adapters

This function block does not use adapters.

Functionality

The INI block acts as an interface between the IEC 61499 application and a persistent `settings.ini` file on the file system. Upon a `INIT` event with `QI=TRUE`, the block is configured for the specified `SECTION` and `KEY`. Optionally, a value (`VALUE`) can be written immediately, or a default (`DEFAULT_VALUE`) can be set.

A `SET` event writes the current value of the `VALUE` input under the configured key to the file. A `GET` event reads the value from the file. If the key does not exist, `DEFAULT_VALUE` is returned instead. Each operation (`INIT`, `SET`, `GET`) is acknowledged by a corresponding output event (`INITO`, `SETO`, `GETO`), with `QO`, `STATUS`, and `VALUEO` indicating the result status.

…

Technical Features

- **Type Flexibility**: The data inputs/outputs `VALUE`, `DEFAULT_VALUE`, and `VALUEO` use the generic data type `ANY_ELEMENTARY`. This allows the storage of various elementary data types (e.g., numbers, Boolean values, strings) using the same function block.

- **Persistence**: The data is stored in text-based INI files (`settings.ini` for writable values, `settingsReadOnly.ini` for read-only factory settings).
- **Write Protection & Factory Defaults**: Keys in `settingsReadOnly.ini` override values in `settings.ini` and reject write attempts (`SET`) (`STATUS = "Key is read-only"`). For details, see Read-Only Settings (settingsReadOnly.ini) .
- **Error Handling**: The output of `STATUS` provides textual feedback on the success or failure of the operation, facilitating debugging.
- **Package**: The block is included in the package `eclipse4diac::storage`.

State Overview

The block does not have an explicit, complex state machine in the user-accessible sense. Its behavior is event-driven: After initialization (`INIT`), it waits for requests (`SET` or `GET`), processes them, and then returns to a waiting state. The internal state (configured section/key) is retained after `INIT`.

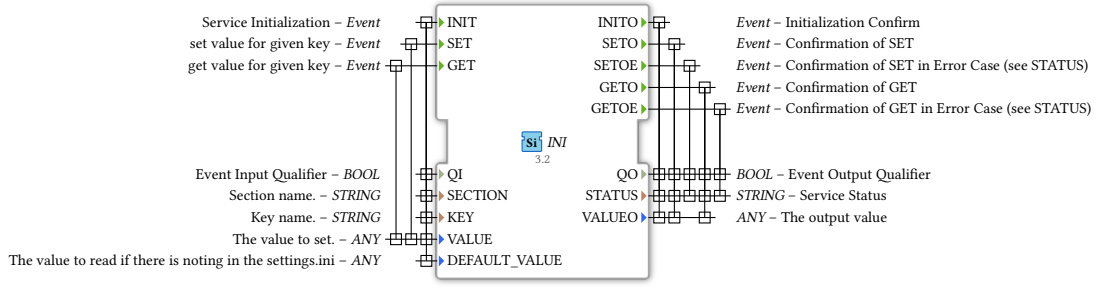
Application Scenarios

- **Configuration Management**: Loading device IP addresses, communication ports, or network settings when an application starts.
- **Parameterization**: Saving plant- or product-specific parameters (e.g., setpoints, times) that should be retained between restarts.
- **Operational Data Acquisition**: Persistently saving simple operating states or counter readings.
- **User Settings**: Managing language settings or other user preferences.
-

⚖️ Comparison with similar building blocks

- **`E_SR` (SR flip-flop) / `E_RS` (RS flip-flop)**: These blocks store a binary state (`BOOL`) in memory only during runtime. The INI block stores arbitrary data types permanently in non-volatile memory.
- **`E_DEMUX` / `E_MUX`**: These are used for event and data distribution, not persistent storage.
- **`FB_RETAIN` (from `eclipse4diac::core`)**: Stores data persistently, but typically uses device-specific, non-directly accessible retain memory. The INI block uses a standardized, readable text file.
- **Database or File I/O Blocks**: More general blocks for file access offer greater flexibility but are also more complex to use. The INI block is a specialized, simple solution for the common use case of key-value storage.

Conclusion



The INI function block is a practical and straightforward tool for persistently storing configuration and parameter data in 4diac FORTE applications. Its strengths lie in its ease of use via sections and keys, the flexibility provided by the `ANY_ELEMENTARY` type, and the human-readability of the stored INI file. It is an excellent choice for applications that require a simple, persistent key-value database.

INI

• – ○ • – ○ • – ○ •

Introduction

The **INI** function block is used for the secure reading and writing of configuration data in a `settings.ini` file. It allows access to values via a section and key name and provides both initialization and read/write operations as separate events. Its use of generic data types (`ANY`) makes it flexible.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initializes the function block and opens the INI file
SET	Event	Writes the value of `VALUE` for the current key
GET	Event	Reads the value of the current key

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirmation
SETO	Event	Write Confirmation
SETOE	Event	Confirmation of SET in error case (see `STATUS`)
GETO	Event	Read Confirmation
GETOE	Event	Confirmation of GET in error case (see `STATUS`)

Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier (controls execution)
SECTION	STRING	Section Name in the INI File
KEY	STRING	Key name within the section
VALUE	ANY	Value to be set (for SET)
DEFAULT_VALUE	ANY	Default value if key does not exist (for GET)

Data Outputs

Name	Type	Comment
QO	BOOL	Event output qualifier (indicates success/failure)
STATUS	STRING	Status information (e.g., error message)
VALUEO	ANY	Value retrieved (for GET) or confirmed set value

Adapters

No adapters defined.

Functionality

The function block operates on a file `settings.ini`, which contains a simple key-value structure in sections (`[Section]`). Its use involves three steps:

1. **INIT** – The INIT event passes the parameters `SECTION` and `KEY`. The function block opens or loads the INI file and prepares the read/write operations. Successful initialization is signaled by the INITO event.
2. **SET** – After initialization, a new value can be written to the previously defined key using SET. The passed value `VALUE` is stored in `settings.ini`, provided the key is not write-protected. If the parameter

is read-only and located in `settingsReadOnly.ini`, the write attempt is rejected, triggering the error event **`SETOE`**, and `STATUS` reports `"Key is read-only"`.

3. **GET** – The GET function reads the current value of the key. For read-only parameters, the value from `settingsReadOnly.ini` is always returned. If a normal key does not exist in `settings.ini`, the default value specified via `DEFAULT_VALUE` is returned. The read value appears at output `VALUEO`.

The execution of each event is acknowledged by the respective output (INITO, SETO/SETOE, GETO). The function block `QO` indicates whether the operation was successful, and `STATUS` provides textual feedback.

Technical Features

- **Generic Data Types** – `VALUE` and `DEFAULT_VALUE` are declared as `ANY`. The function block can therefore work with various data types (e.g., BOOL, INT, REAL, STRING), provided the runtime environment supports them.
- **Write Protection (Factory Default)** – In addition to `settings.ini`, the system also supports the write-protected default file `settingsReadOnly.ini`. Parameters from this file override modifiable values and reject write attempts using `STATUS = "Key is read-only"`. See also Read-only settings (`settingsReadOnly.ini`).
- **Event-based control** – All actions are triggered by events. The function block can therefore be fully integrated into an event-driven system (e.g., IEC 61499).
- **Error handling** – The output qualifier `QO` and the `STATUS` string enable easy error diagnosis (e.g., for read-only keys, missing file, or invalid section).

State overview

The function block goes through the following main states:

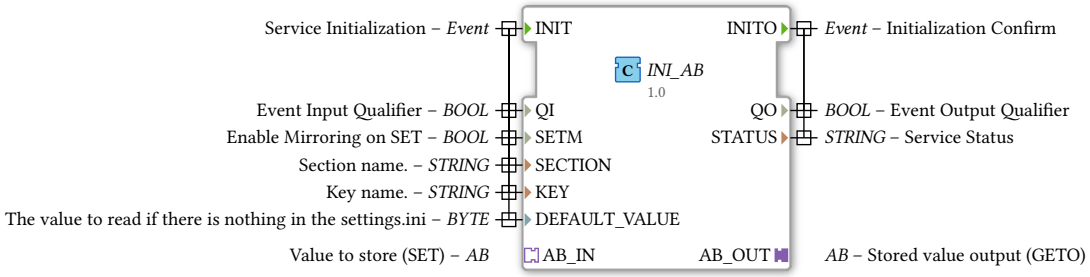
- **Idle** – Waiting for INIT.
- **Initialized** – After successful INIT; ready for SET or GET.
- **Error** – In case of failed initialization or operation; only a new INIT can exit this state.

State transitions are controlled by the INIT, SET, and GET events and their corresponding acknowledgment outputs.

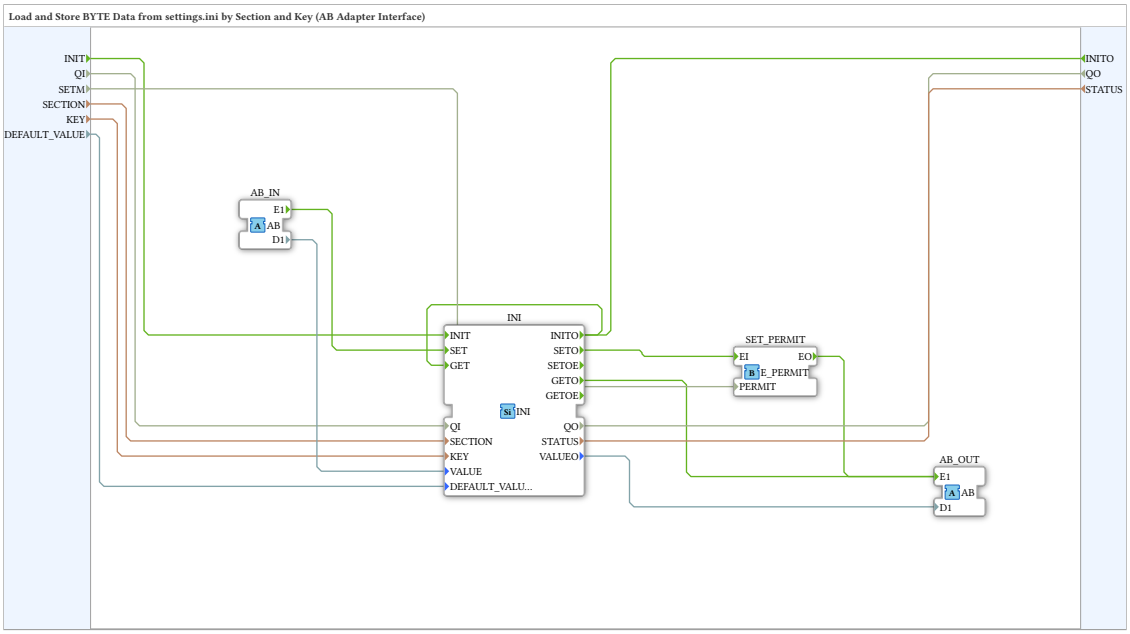
Application Scenarios

- **Machine Configuration** – Saving and retrieving parameters such as speed, temperature limits, or operating modes in a central INI file.
- **Plant Initialization** – Loading settings once when the controller starts via the INIT event.
- **Online Parameterization** – Dynamically changing values during operation using SET and immediately retrieving them with GET.

Comparison with Similar Function Blocks



Function Block	Data Source	Type Support	Event Interface
INI	settings.ini	ANY (generic)	INIT, SET, GET
FILE_READ	Text File	STRING	REQ, CNF
PARAM_DB	Database	Type-specific	Complex



The INI function block stands out due to its simplicity and direct connection to INI files, without the need for additional drivers or databases. Other function blocks either offer more flexibility (database) or are limited to simple text input/output.

Conclusion

The INI function block provides a compact and reliable solution for the persistent storage of configuration data in IEC 61499 systems. Its generic data type definition and clear event handling make it versatile. Thanks to its integrated error handling, it is suitable for both development and production environments.

INI_AB

• – ○ • – ○ • – ○ •

Introduction

`INI_AB` loads and stores a `BYTE` value in the `settings.ini` file, addressed by section (`SECTION`) and key (`KEY`). It is the `settings.ini` counterpart to NVS_AB and uses the same two-adapter architecture with unidirectional `AB` adapters.

Interface Structure

Event Inputs

- **INIT**: initializes the block and reads the value stored under `SECTION/KEY` (or `DEFAULT_VALUE` if none exists yet). Carries `QI`, `SETM`, `SECTION`, `KEY`, `DEFAULT_VALUE`.

Event Outputs

- **INITO**: confirms initialization and the initial read, carries `QO` and `STATUS`.

Data Inputs

- **QI** (BOOL): qualifier for the `INIT` event.
- **SETM** (BOOL): enables mirroring (confirmation) on write (`SET`).
- **SECTION** (STRING): name of the section in `settings.ini`.
- **KEY** (STRING): name of the key within the section.
- **DEFAULT_VALUE** (BYTE): value returned when nothing is stored under `SECTION/KEY` yet.

Data Outputs

- **QO** (BOOL): success qualifier, carried with `INITO` and the internal adapter confirmations.
- **STATUS** (STRING): status message of the file access.

Adapters

- **AB_IN** (Socket, type AB): new value to store – an adapter event on AB_IN.E1 triggers a SET on the internal INI block, AB_IN.D1 carries the value to write.
- **AB_OUT** (Plug, type AB): outputs the most recently read value – both after the automatic initial read on INIT and after each confirmed write (AB_OUT.D1/AB_OUT.E1).

Functionality

INI_AB wraps an internal instance of eclipse4diac::storage::INI plus an E_PERMIT gate (SET_PERMIT). On INIT, the internal INI instance is initialized (INI.INIT) and a GET is triggered automatically, returning the value stored under SECTION/KEY (or DEFAULT_VALUE); the result is output via AB_OUT, and INITO confirms completion.

To write, the block connected to AB_IN fires an adapter event (AB_IN.E1) carrying the new value (AB_IN.D1), which triggers INI.SET. Whether the successful write is additionally reported back via AB_OUT is controlled by SETM: if SETM is set, SET_PERMIT releases the AB_OUT.E1 event after a successful SET ("mirroring").

Technical Details

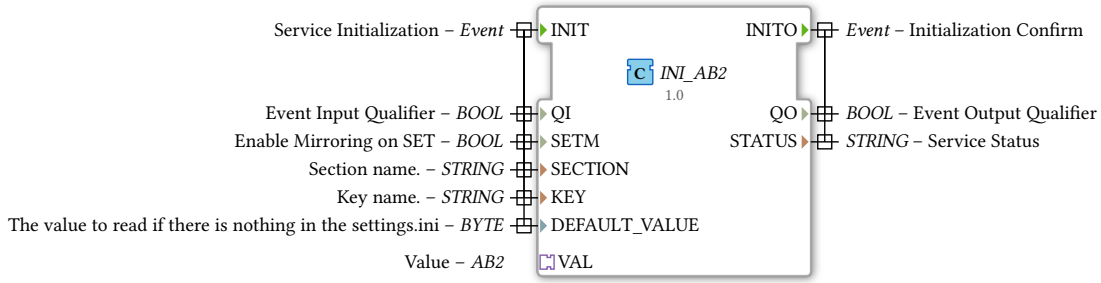
- Pure composite FB with no ECC of its own – the actual file access logic lives in the internal INI instance; INI_AB only wires events and data between it and the two AB adapters.
- Two separate unidirectional adapters (AB_IN/AB_OUT) instead of a single bidirectional one – this lets the read and write paths connect to different peers, which INI_AB2 (a single shared AB2 socket) cannot do.
- Addressing via SECTION **and** KEY (rather than just KEY for the NVS_* blocks) matches the classic INI file format.

State Overview

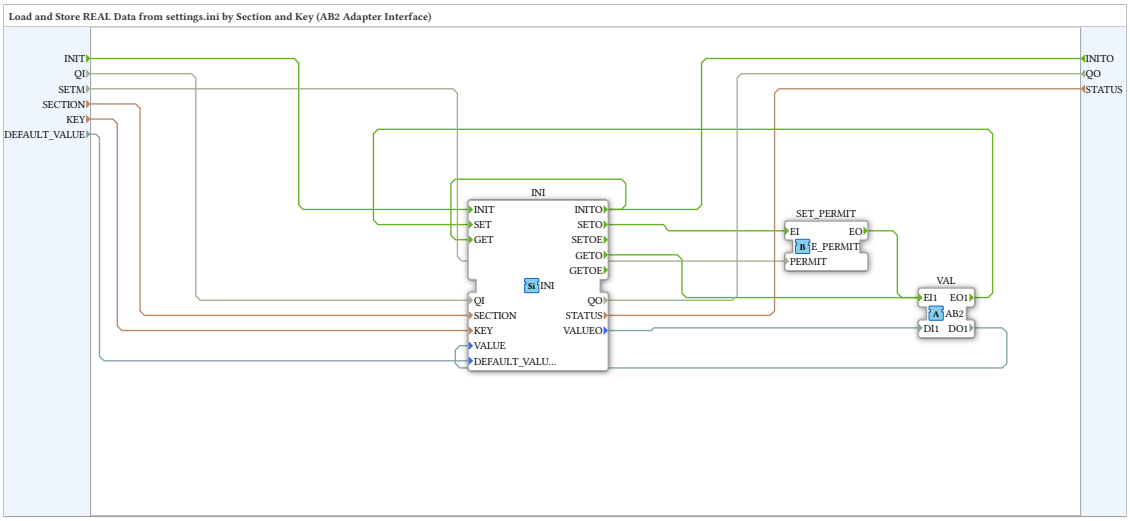
The block is stateless in terms of its own ECC: on INIT it runs through initialization plus an initial read once, then reacts to every AB_IN adapter event with an INI write and, optionally, a confirmation via AB_OUT.

Application Scenarios

- Persisting individual BYTE configuration values (e.g. operating mode, channel selection) in a human-readable settings.ini
- Building a read/write pair where the read and write sides need to connect to different blocks
- Configuration files that also need to be viewable/editable outside the controller (e.g. with a text editor)



⚖️ Comparison with Similar Blocks



Compare with INI_AB2, which serves the same purpose through a single bidirectional AB2 adapter instead of two unidirectional AB adapters, and with NVS_AB, which provides the same interface for the ESP32 NVS flash storage instead of settings.ini.

Conclusion

INI_AB provides simple, unidirectionally wired access to a persistent BYTE value in settings.ini, and fits anywhere the read and write paths need to be kept separate.

INI_AB2

• – ○ • – ○ • – ○ •

Introduction

The function block `INI_AB2` is used to read and write BYTE values to or from a `settings.ini` file. Access is via a combination of section name and key name. Communication with external systems is via a bidirectional **AB2 adapter**, which allows values from the INI file to be passed to other function blocks or values from other function blocks to be received and stored in the file. The function block was developed according to the IEC 61499-2 standard.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initialization event; starts the read or write operation depending on the connected adapter logic. The data passed specifies the mirroring on SET (`SETM`), section, key, and a default value.

Event Outputs

Event	Type	Description
INITO	EInit	Initialization confirmation. Triggered after the read/write access is complete.

Data Inputs

Variable	Type	Description
QI	BOOL	Qualifier for the event input; controls its execution.
SETM	BOOL	Enable mirroring on SET.
SECTION	STRING	Name of the section in `settings.ini`.
KEY	STRING	Name of the key within the section.
DEFAULT_VALUE	BYTE	The value returned if the key does not exist in `settings.ini`.

Data Outputs

Variable	Type	Description
QO	BOOL	Output qualifier; indicates successful execution.

STATUS	STRING	Service status message (e.g., error messages or “OK”).

Adapters

Adapter	Type	Description
VAL	adapter::types::bidirectional::AB2	Bidirectional adapter for exchanging BYTE values. The incoming value (`DO1`) is written to the INI file; the outgoing value (`DI1`) is read from the INI file and passed on.

Functionality

The `INI_AB2` block internally contains an instance of the function block `eclipse4diac::storage::INI`. Communication with `settings.ini` occurs exclusively via this internal instance.

1. **Initialization (Read Operation):** An INIT event at the input sets the internal parameters (Section, Key, Default Value) and activates the internal INI instance (`INI.INIT`). After successful reading, the read value is sent to the connected module via the adapter output (`VAL.DI1`). Simultaneously, outputs `INITO`, `QO`, and `STATUS` are updated.
2. **Write Operation:** The connected module can provide a new value via the adapter input (`VAL.DO1`). As soon as the event `VAL.EO1` arrives, the value is saved in the INI instance (`INI.SET`). The confirmation (`INI.SETO`) is returned to the adapter via `VAL.EI1`.
3. **Write Operation:** The connected module can provide a new value via the adapter input (`VAL.DO1`). 3. **Cyclic Reading:** After each INIT operation, the internal GET command is automatically triggered, allowing the current value to be read from the file and output via the adapter.

The circuitry ensures that both read and write accesses can be handled bidirectionally via the adapter. The module thus implements persistent data storage with external control.

Technical Features

- **Bidirectional Adapter Connection:** The AB2 adapter allows both reading and writing to the INI file via a single connection.
- **Default Value:** If a specified key is not present in `settings.ini`, the value passed via `DEFAULT_VALUE` is used and output as the read value.
- **Use of `eclipse4diac::storage::INI`:** The function block encapsulates the actual INI access logic and provides robust error handling (status output).
- **IEC 61499-2 compliant:** The function block adheres to the standard for function blocks, which increases interoperability and reusability.

State Overview

The `INI_AB2` function block itself does not have explicit states (no ECC states), as the logic is fully implemented through the internal INI instance and the event/data flows. However, the interaction can be described as a simple sequential process:

1. **Idle State** – Waiting for INIT or data from the adapter.
2. **Initialize** – INIT is processed, the internal INI is started.
3. **Read** – The INI reads the value and outputs it via the adapter.
4. **Write** – Value from the adapter is saved to the INI file.
5. **Return** – Confirmation via INITO or adapter event.

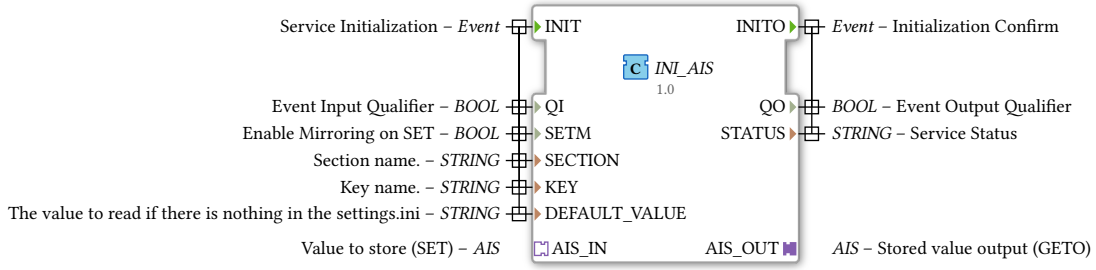
Application Scenarios

- **Configuration Management:** Saving and retrieving machine parameters (e.g., setpoint temperatures, limit values) in a central `settings.ini` file.
- **Plant Parameterization:** Multiple control components access the same INI file via the AB2 adapter and can thus exchange parameters.
- **Data Exchange Between Heterogeneous Systems:** The standardized adapter enables integration into any 4diac architecture.

Comparison with Similar Function Blocks

- **INI_AB (Unidirectional):** Uses a unidirectional adapter that allows either read-only or write-only access. `INI_AB2` is more flexible due to its bidirectional interface.
- **INI_CFB (Composite FB):** A similar function block without an adapter, addressed directly via events and data. `INI_AB2` abstracts the connection and enables modular coupling.
- **eclipse4diac::storage::INI (direct):** The basic function block does not offer an adapter interface; `INI_AB2` encapsulates this and adds bidirectional communication.

Conclusion



The `INI_AB2` function block is a practical extension for IEC 61499-based automation solutions. It simplifies access to INI configuration files through a standardized adapter interface and enables both read and write operations. Its ease of use and clear separation of logic and interface make it a useful tool for modular and reusable control applications.

]

INI_AIS

• – ○ • – ○ • – ○ •

Introduction

The function block **INI_AIS** is used to load and save strings (STRING) from a `settings.ini` file. The desired value is accessed via a section name and a key. The interface is implemented using unidirectional AIS adapters, allowing the block to both read and write values.

Interface Structure

Event Inputs

Name	Type	Description
INIT	EInit	Service Initialization

Event Outputs

Name	Type	Description
INITO	EInit	Initialization Confirmation

Data Inputs

Name	Type	Description
QI	BOOL	Qualifier for the event input
SETM	BOOL	Enable Mirroring on SET: if TRUE, the confirmation of a SET (SETO) is additionally forwarded to the output adapter (mirrored)
SECTION	STRING	Name of the section in the configuration file
KEY	STRING	Name of the key in the specified section
DEFAULT_VALUE	STRING	Default value if the entry does not exist

Data Outputs

Name	Type	Description
QO	BOOL	Qualifier for the event output
STATUS	STRING	Status message (e.g., error text)

Adapter

Name	Type	Direction	Description
AIS_OUT	adapter::types::unidirectional::AIS	Plug	Output for the read value (GETO)
AIS_IN	adapter::types::unidirectional::AIS	Socket	Input for the value to be stored (SET)

Functionality

The function block internally contains an instance of the function block `INI` (from the library `eclipse4diac::storage`). The process is as follows:

1. **Initialization (INIT)**

- The data `QI`, `SETM`, `SECTION`, `KEY`, and `DEFAULT_VALUE` are forwarded to the internal INI block.
- The INIT event pulse starts the INI block.
- Upon completion, INI returns the event `INITO`, which is output externally as `INITO` of the INI_AIS. Simultaneously, the outputs `QO` and `STATUS` are also received.
- Immediately after initialization, the `GET` service is automatically triggered in the INI block to read the value from `settings.ini`.

1. **Reading a Value (via AIS_OUT)**

- The read value appears at the data output `VALUEO` of the INI block and is assigned to the data output `D1` of the adapter plug `AIS_OUT`.
- The event `GETO` of the INI block is transferred to the event input `E1` of `AIS_OUT`, allowing the receiving block to retrieve the value.

1. **Writing a Value (via AIS_IN)**

- An external function block can send a value (event `E1` with data `D1`) to the INI_AIS via the adapter socket `AIS_IN`.
- This event triggers the `SET` service of the internal INI function block. The incoming value is passed to the data input `VALUE` of INI.
- After successful writing, INI sends the event `SETO`, which is forwarded to the event output `E1` of `AIS_OUT`. The written value is simultaneously returned via `VALUEO`, so the writing block receives confirmation of the value.

Technical Features

- **Internal Networking:** This block utilizes the existing `INI` block and encapsulates its complex interface in a simpler, adapter-based form.
- **Unidirectional AIS Adapters:** Data exchange occurs via AIS interfaces, which enable loose coupling between the blocks. The `AIS_IN` socket is responsible for receiving write commands, and the `AIS_OUT` plug is responsible for sending read results.
- **Automatic Read Access:** After initialization, the stored value is immediately read and made available via the output – without a separate GET request.
- **Automatic Read Access: - Error Handling:** Status messages are communicated via the `STATUS` output (e.g., file not found, section/key missing).

State Overview

The function block has no explicitly programmed states. The internal INI block handles state management. From the user's perspective, the following operating phases occur:

- **Initialized (after INIT – INITO):** The function block is ready to read and write values. The value of the specified key has already been read once and is available at the `AIS_OUT` output.
- **Write Operation (via AIS_IN):** An external command triggers a write access. After completion, the new value can be retrieved via `AIS_OUT`.
- **Read Access:** Occurs implicitly after each INIT and is not explicitly controlled.

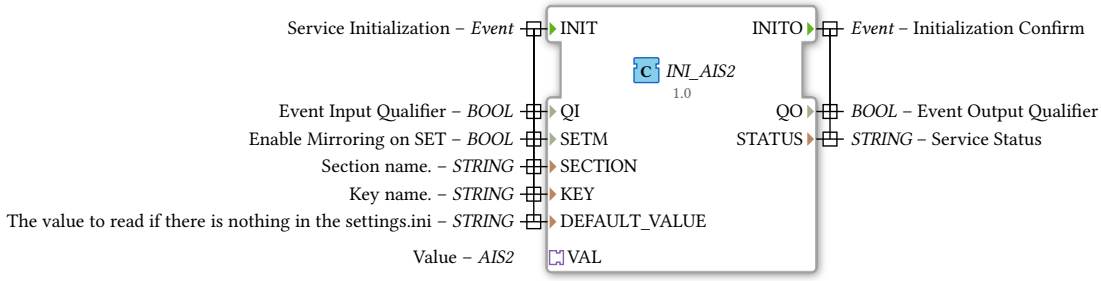
Application Scenarios

- **Persistent Configuration Data:** Saving parameters such as device addresses, limits, or operating modes in an INI file.
- **Plug-and-Play Modules:** Modules that read their configuration via the AIS adapter and overwrite it as needed – without hardwiring the data paths.
- **Initialization Values:** Reading default values at system startup, which can be customized via the `settings.ini` file.

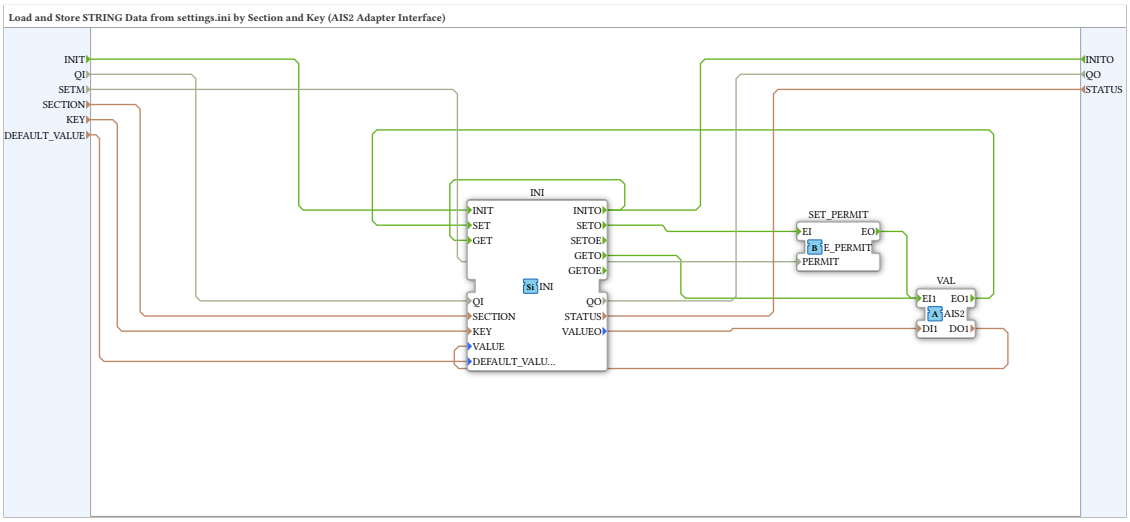
Comparison with Similar Modules

Module	Description
INI	Direct access to INI files with separate GET and SET events.
INI_AIS	INI extends the INI function block with an adapter-based interface that simplifies the coupling of other function blocks and integrates the handling of read and write operations.

- Unlike the basic `INI` function block, INI_AIS provides a unified, event-driven interface for read and write components.
- The use of adapters enables flexible connectivity in larger automation networks without the need for individual data wiring.



Conclusion



The **INI_AIS** function block is a practical extension of the basic `INI` function block.A module that significantly simplifies the use of configuration files in automation projects. By integrating read and write operations into a single adapter interface, system design becomes more modular and streamlined. This module is particularly suitable for scenarios where multiple components need to access the same data storage.

INI_AIS2

• – ○ • – ○ • – ○ •

Introduction

The INI_AIS2 function block is used to read and write STRING data from a settings.ini file via an AIS2 adapter. It combines the INI block with a bidirectional AIS2 adapter to read values from or write them back to a configuration file. Initialization is performed via the INIT event, where the section and key are specified. The read value is offered via the adapter, and a write operation is triggered via the adapter event.

Interface Structure

Event Inputs

Name	Description
INIT	Initialization event to start the read operation. Expects the parameters QI, SECTION, KEY, and DEFAULT_VALUE.

Event Outputs

Name	Description
INITO	Initialization confirmation. Sent after the read operation is complete. Status information is available via QO and STATUS.

Data Inputs

Name	Type	Description

QI	BOOL	Input qualifier for controlling processing.
SETM	BOOL	Controls confirmation/mirroring after a successful write. Regardless of SETM, VAL.EO1 always triggers INI.SET; however, the SETO confirmation reaches VAL.EI1 only when SETM=TRUE (suppressed when SETM=FALSE).
SECTION	STRING	Name of the section in the settings.ini file.
KEY	STRING	Name of the key within the section.
DEFAULT_VALUE	STRING	Default value read if the key is not present in the file. Default: ''.

Data Outputs

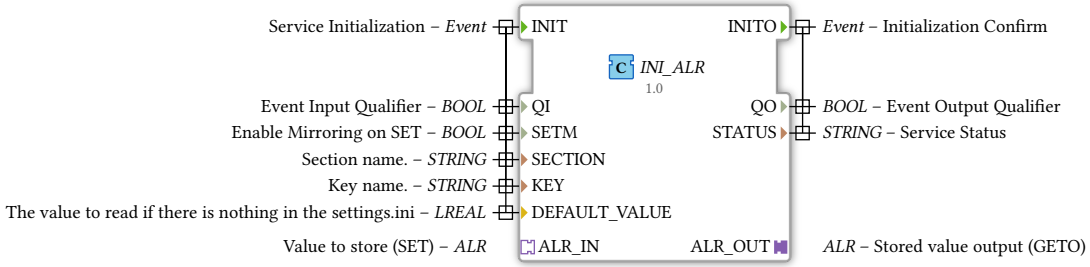
Name	Type	Description
QO	BOOL	Output qualifier, indicates successful processing.
STATUS	STRING	Service status message (e.g., error messages).

Adapters

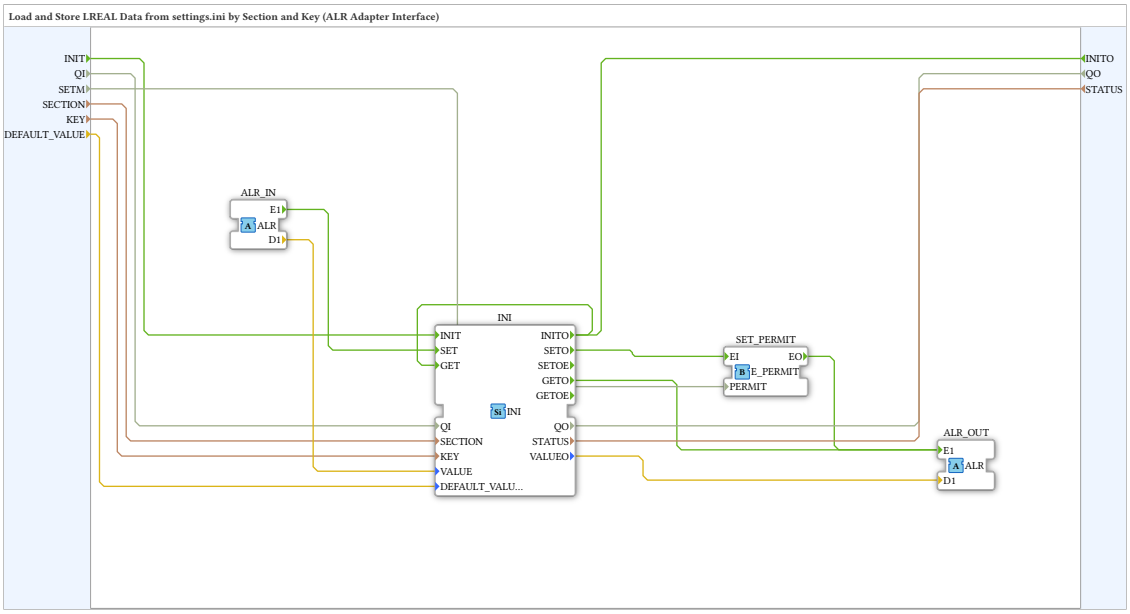
Name	Type	Description
VAL	adapter::types::bidirectional::AIS2	Bidirectional adapter for exchanging values. This adapter provides the read value as an output (DI1) and receives a write value as an input (DO1).

Functionality

The INI_AIS2 function block contains an internal INI function block (eclipse4diac::storage::INI) that performs the actual file operation. The network connections implement the following processes:



- Upon arrival of INIT, QI, SECTION, KEY, and DEFAULT_VALUE are forwarded to the INI function block.
- The INI function block performs a read operation and passes the result (via VALUEO) to the adapter output (VAL.DI1).
- Simultaneously, after a successful read, the GET event is triggered, which activates the adapter input (VAL.EI1) to transmit the value.
- A write operation is initiated as soon as the adapter sends an EO1 event. This event triggers the SET event on the INI function block, setting the value received via VAL.DO1 as the new VALUE.
- The INI block confirms the write operation with SETO. If SETM=TRUE, this confirmation is routed back to the adapter (VAL.EI1), whereas SETM=FALSE suppresses this mirror.
- The QO and STATUS outputs are directly taken from the INI block.



Thus, read and write access to the settings.ini file can be controlled via the AIS2 adapter.

Technical Features

- The block uses a bidirectional AIS2 adapter that can both send and receive values.
- A STRING value is used as the default value.

INI_ALR

• – ○ • – ○ • – ○ •

Introduction

The function block **INI_ALR** is used to read and write floating-point values of type LREAL to and from a `settings.ini` file. It accesses a configuration file that is parameterized via a section name and a key. The block encapsulates the use of the internal `INI` function block and additionally provides a standardized **ALR** adapter interface (unidirectional) through which values can be both set and read.

Interface Structure

Event Inputs

Event	Type	Comment	With Variables
INIT	EInit	Initializes the function block and triggers a read operation	QI, SETM, SECTION, KEY, DEFAULT_VALUE

Event Outputs

Event	Type	Comment	With variables
INITO	EInit	Confirms initialization	QO, STATUS

Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier (Allow)
SETM	BOOL	Enable mirroring on SET
SECTION	STRING	Section name in the INI file
KEY	STRING	Key name within the section
DEFAULT_VALUE	LREAL	Fallback value if the key is missing in the INI file

Data Outputs

Name	Type	Comment

QO	BOOL	Event Output Qualifier
STATUS	STRING	Status message (e.g., error text)

Adapters

Adapter	Type	Comment
ALR_IN	adapter::types::unidirectional::ALR	Socket – Value to store (SET)
ALR_OUT	adapter::types::unidirectional::ALR	Plug – Read value (GET)/Confirmation

Functionality

1. **Initialization and First Read**

An event at the input `INIT` triggers the initialization of the internal `INI` block. The parameters `QI`, `SETM`, `SECTION`, `KEY`, and `DEFAULT_VALUE` are forwarded to the `INI` block. After its acknowledgment (`INITO`), the GET operation of the `INI` block is automatically triggered. The read value appears at the data output of the adapter `ALR_OUT.D1` and is simultaneously signaled via the event `ALR_OUT.E1`. The outputs `QO` and `STATUS` of the `INI` block are directly passed through to the corresponding outputs of the `INI_ALR` block.

... 2. **Write via ALR-IN**

A set event at the adapter socket `ALR_IN.E1` is forwarded to the SET input of the internal `INI` module. The value to be saved is located at `ALR_IN.D1` and is set via `INI.VALUE`. After successful writing, the `INI` module acknowledges with `SETO`, which in turn triggers `ALR_OUT.E1`.

1. **Reading via ALR-IN** (implicit)

The currently read value is always available at output `ALR_OUT` via the initial GET sequence and the forwarding of `GETO`. A new read can be triggered by another `INIT` pulse.

Technical Features

- **Reuse** of the standardized `INI` block (`eclipse4diac::storage::INI`) for file access.
- **ALR adapter interface** – allows unidirectional coupling with other blocks that use the same adapter type. This simplifies integration into modular control applications.
- **Asynchronous processing**: Read and write operations are event-driven and performed asynchronously. Acknowledgement is provided via the corresponding event outputs.
- **Compliant with IEC 61499-2 standard** – all inputs and outputs are defined with standard types.
- **Error handling** is provided via the STATUS output (e.g., for missing files or corrupted data).

State Overview

The `INI_ALR` itself does not have its own state machines. State management is fully implemented by the internal `INI` block. Typical phases are:

- **Idle** – Waiting for an INIT event.
- **Initialize** – Processing of INIT, forwarding data to `INI`.
- **Ready** – A read result is available after successful INIT acknowledgment.
- **Write Operation** – triggered by `ALR_IN.E1`.
- **Error State** – in case of faulty INI accesses, STATUS is set accordingly.

Application Scenarios

- **Machine Configuration** – Loading parameters (e.g., maximum speed, limits) from a central INI configuration file.
- **Calibration Values** – Storing and reading calibration data in automation technology.
- **Interface to ALR-based Components** – If a function block provides or expects an LREAL value via an ALR adapter, `INI_ALR` can be used as a link for persistent storage.

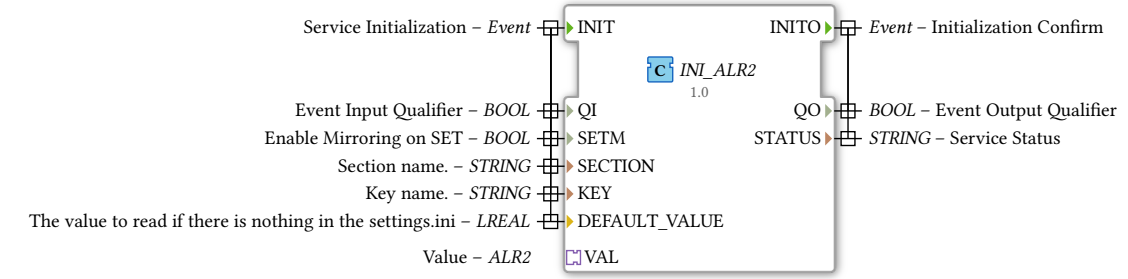
Comparison with Similar Function Blocks

Function Block	Description	Advantage of INI_ALR
`INI`	Direct access to INI files (without ALR)	No adapter interface, manual coupling required

INI_ALR	Encapsulates INI and provides an ALR adapter interface	Easy integration into ALR-based architectures

The INI_ALR combines the proven INI file functionality with a standardized adapter interface, thereby reducing the effort required for integration into a service-oriented control system.

Conclusion



The INI_ALR is a practical function block that extends access to settings.ini for LREAL data with a flexible adapter interface. It is particularly suitable for applications that require consistent ALR-based communication while also needing simple, file-based persistence. By encapsulating the complex INIThe use of modular components and the automatic chaining of event and data flows reduces development effort and increases reusability.

INI_ALR2

• – ○ • – ○ • – ○ •

Introduction

The INI_ALR2 function block is used to read and write LREAL data from a settings.ini file via an ALR2 adapter. It combines the INI block with a bidirectional ALR2 adapter to read values from or write them back to a configuration file. Initialization is performed via the INIT event, where the section and key are specified. The read value is offered via the adapter, and a write operation is triggered via the adapter event.

Interface Structure

Event Inputs

Name	Description
INIT	Initialization event to start the read operation. Expects the parameters QI, SECTION, KEY, and DEFAULT_VALUE.

Event Outputs

Name	Description
INITO	Initialization confirmation. Sent after the read operation is complete. Status information is available via QO and STATUS.

Data Inputs

Name	Type	Description
QI	BOOL	Input qualifier for controlling processing.
SETM	BOOL	Controls confirmation/mirroring after a successful write. Regardless of SETM, VAL.EO1 always triggers INI.SET; however, the SETO confirmation reaches VAL.EI1 only when SETM=TRUE (suppressed when SETM=FALSE).
SECTION	STRING	Name of the section in the settings.ini file.
KEY	STRING	Name of the key within the section.
DEFAULT_VALUE	LREAL	Default value read if the key is not present in the file. Default: 0.0.

Data Outputs

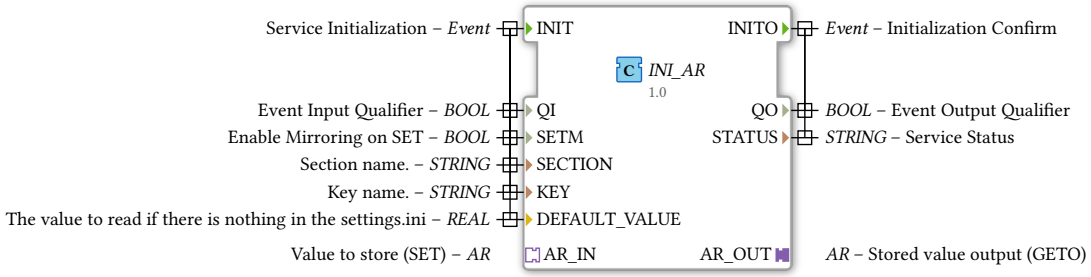
Name	Type	Description
QO	BOOL	Output qualifier, indicates successful processing.
STATUS	STRING	Service status message (e.g., error messages).

Adapters

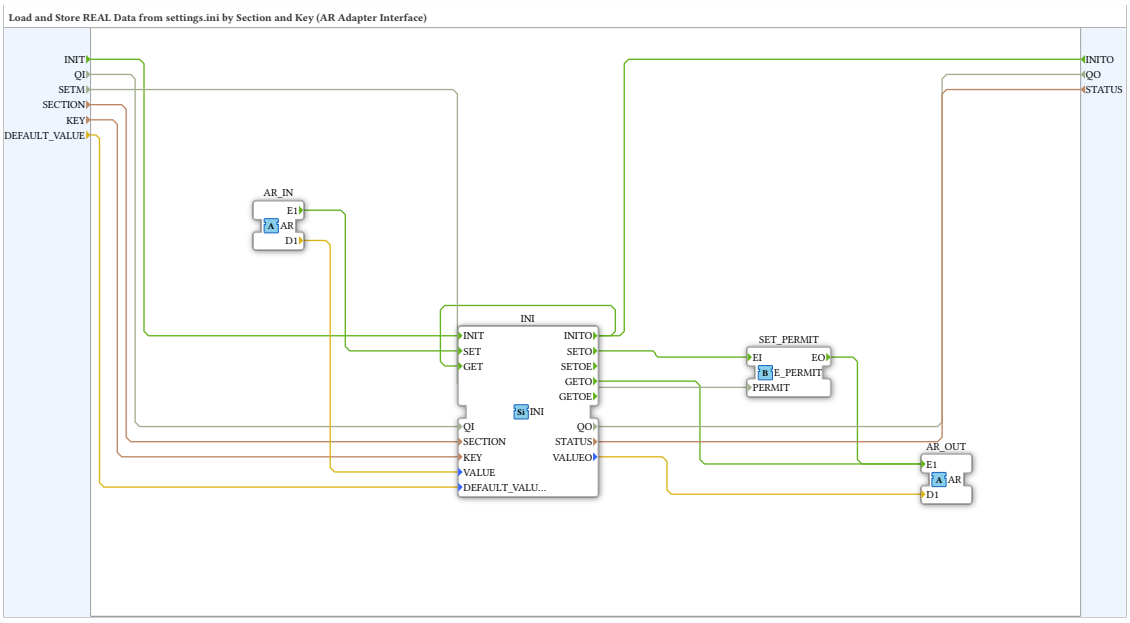
Name	Type	Description
VAL	adapter::types::bidirectional::ALR2	Bidirectional adapter for exchanging values. This adapter provides the read value as an output (DI1) and receives a write value as an input (DO1).

Functionality

The INI_ALR2 function block contains an internal INI function block (eclipse4diac::storage::INI) that performs the actual file operation. The network connections implement the following processes:



- Upon arrival of INIT, QI, SECTION, KEY, and DEFAULT_VALUE are forwarded to the INI function block.
- The INI function block performs a read operation and passes the result (via VALUEO) to the adapter output (VAL.DI1).
- Simultaneously, after a successful read, the GET event is triggered, which activates the adapter input (VAL.EI1) to transmit the value.
- A write operation is initiated as soon as the adapter sends an EO1 event. This event triggers the SET event on the INI function block, setting the value received via VAL.DO1 as the new VALUE.
- The INI block confirms the write operation with SETO. If SETM=TRUE, this confirmation is routed back to the adapter (VAL.EI1), whereas SETM=FALSE suppresses this mirror.
- The QO and STATUS outputs are directly taken from the INI block.



Thus, read and write access to the settings.ini file can be controlled via the ALR2 adapter.

Technical Features

- The block uses a bidirectional ALR2 adapter that can both send and receive values.
- A LREAL value is used as the default value.

INI_AR

• – ○ • – ○ • – ○ •

Introduction

The INI_AR function block is used to load and save real data from a settings.ini file. It accesses the configuration file via a section and key name and provides the read or saved values via a unidirectional adapter. This allows for flexible integration into modular storage and control architectures.

Interface Structure

Event Inputs

- `INIT` (EInit): Service initialization. Triggers the loading of the current value and processes the associated data inputs.

Event Outputs

- `INITO` (EInit): Initialization confirmation. Sent after a successful read or write operation.

Data Inputs

- `QI` (BOOL): Qualifier for the event input.
- `SETM` (BOOL): Enable mirroring on SET.
- `SECTION` (STRING): Name of the section in the INI file.
- `KEY` (STRING): Name of the key within the section.

- `DEFAULT_VALUE` (REAL): Value to be used if no entry is found in the settings.ini file.

Data Outputs

- `QO` (BOOL): Qualifier for the event output.
- `STATUS` (STRING): Status message of the service (e.g., success, error).

Adapter

- **AR_OUT** (Plug, type `adapter::types::unidirectional::AR`): Adapter output through which the read value (GETO) is sent to other function blocks.
- **AR_IN** (Socket, type `adapter::types::unidirectional::AR`): Adapter input through which a value to be stored (SET) can be received.

Functionality

After an INIT pulse, the internal function block `INI` (of type `eclipse4diac::storage::INI`) is triggered. This reads the current value from the specified section and the key from the settings.ini file. If no entry exists, `DEFAULT_VALUE` is used. After the read operation is complete, the GET event is triggered, and the read value is passed on via the adapter output `AR_OUT` (event GETO, data VALUEO).

Simultaneously, a new value (event E1, data D1) can be received via the adapter input `AR_IN`. This triggers the SET event in the INI block, which writes the value to the INI file. After writing, an acknowledgment is sent via `SETO`, which is also forwarded to the adapter output. The GETO and SET events are combined into the same output event `AR_OUT.E1`. The qualified outputs `QO` and `STATUS` are taken directly from the internal INI block.

Technical Features

- The function block uses the internal INI function block from the library `eclipse4diac::storage`.
- The adapters `AR_IN` and `AR_OUT` must be of type `adapter::types::unidirectional::AR`.
- The function block is licensed under the Eclipse Public License 2.0 (EPL-2.0).
- Author: Franz Höpfinger, Version 1.0, Date: April 24, 2026.

State Overview

The function block does not have an explicit state machine. The logic is controlled entirely via the event chaining of the internal INI function block:

- The value is read (GET) after `INIT`.
- Each `SET` pulse via `AR_IN` writes a new value to the INI file.

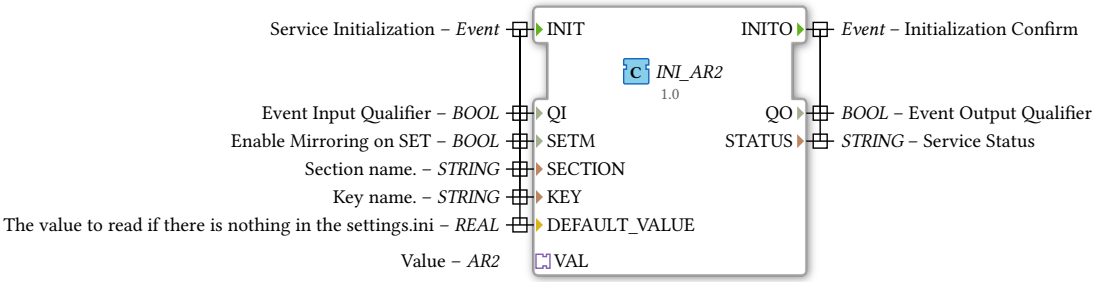
Application Scenarios

- Persistent storage of configuration parameters (REAL) in an INI file for automation projects.
- Exchange of runtime parameters between different function blocks via the adapter interface.
- Initializing plant parameters from a central configuration file.

Comparison with Similar Blocks

- **Standard INI Block** (`INI`): Provides direct read/write access to INI files via data inputs and outputs without an adapter.
- **INI_AR** extends this with the adapter interface, allowing values to be passed modularly to other blocks via events and data without having to encapsulate all the logic in a single block.
- Analogous building blocks exist for other data formats (JSON, XML), but these use different libraries.

Conclusion



The INI_AR function block encapsulates access to an INI file for real values and simultaneously provides a standardized adapter interface for integration into distributed control networks. It simplifies saving and loading configuration data and allows for a clear separation between memory logic and data flows.

INI_AR2

• – ○ • – ○ • – ○ •

Introduction

The INI_AR2 function block is used to read and write real values to and from a settings.ini file using a section and key name. It encapsulates an INI function block and provides a bidirectional AR2 adapter interface. Upon initialization, the value for the specified section and key name is read and output via the adapter. Simultaneously, new values can be received via the adapter and written back to the file.

Interface Structure

Event Inputs

- **INIT** (EInit): Service initialization. Triggers the loading of the value from settings.ini and initializes the function block.

Event Outputs

- **INITO** (EInit): Initialization confirmation. Sent after successful processing of the INIT event.

Data Inputs

- **QI** (BOOL): Input qualifier. Controls execution (e.g., activation/deactivation).
- **SETM** (BOOL): Enable Mirroring on SET: if TRUE, the confirmation of a SET (SETO) is additionally forwarded to the output adapter (mirrored).
- **SECTION** (STRING): Section name in the settings.ini file (e.g., “[MySection]”).
- **KEY** (STRING): Key name in the section (e.g., “MyKey”).
- **DEFAULT_VALUE** (REAL): Default value returned if the key is not present in the file.

Data Outputs

- **QO** (BOOL): Output qualifier. Indicates the processing status.
- **STATUS** (STRING): Service status message (e.g., error message or “OK”).

Adapters

- **VAL** (AR2): Bidirectional adapter of type `adapter::types::bidirectional::AR2`. This adapter provides the read values (output) and receives new values (input) for writing back to the INI file. The adapter has the events EO1 (output) and EI1 (input) as well as data DO1 (output) and DI1 (input).

Functionality

The FB INI_AR2 is a composite function block that internally uses an INI function block (`eclipse4diac::storage::INI`). The process is as follows:

1. **Initialization**: Upon arrival of the INIT event, the parameters QI, SETM, SECTION, KEY, and DEFAULT_VALUE are passed to the internal INI block.
2. **Reading**: After INIT, the INI block automatically performs a GET operation (controlled by the event connection from INI.INITO to INI.GET). It reads the value from the settings.ini file for the specified section and key. If no entry exists, the DEFAULT_VALUE is used.
3. **Output via Adapter**: The read value is passed to the adapter output via the data connection INI.VALUEO -> VAL.DI1 and the event INI.GETO -> VAL.EI1.
4. **Write via Adapter**: When a new value arrives at VAL.DO1 via the adapter (triggered by VAL.EO1), the event VAL.EO1 -> INI.SET is sent. The INI block then writes the new value back to the file. After writing, INI.SETO -> VAL.EI1 is sent, which returns the acknowledgment to the adapter.
5. **Completion**: After the initial read operation, the INITO event is output, along with the status information QO and STATUS. After write operations via the adapter, no INITO is sent, only an acknowledgment via VAL.EI1.

Technical Features

- The function block uses the Eclipse 4diac infrastructure and imports types from `eclipse4diac::storage` and `adapter::types::bidirectional::AR2`.
- The AR2 adapter enables a clear separation between read and write accesses via a single adapter socket.
- By default, the file `settings.ini` is expected in the application's working directory. The exact path can be adjusted via the INI block configuration (not directly visible in INI_AR2).
- The function block is designed for REAL data; corresponding variants would need to be created for other data types.
- Error handling is handled via the STATUS output and QO.
- The INITO event is only triggered after the initial read operation, not after write operations via the adapter. Write operations are only acknowledged via the adapter.
-

State Overview

Since this is a composite function block, there is no explicit internal state machine. The process is determined by the event network:

- Receive INIT ⟶ Execute INI.INIT.
- After INI.INITO: Execute INI.GET automatically.
- After INI.GETO: Trigger VAL.EI1 (value output) and send INITO.
- Upon receiving VAL.EO1 (new value from an external source): Execute INI.SET, then INI.SETO ⟶ VAL.EI1 (acknowledgment to the adapter, no INITO).

Application Scenarios

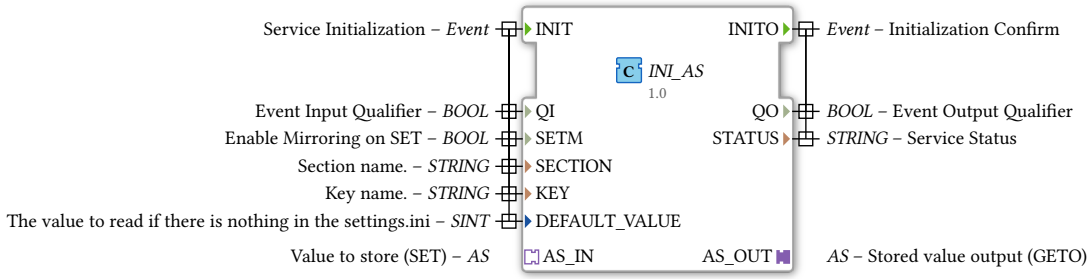
- **Parameter Management**: Saving and loading settings (e.g., PID controller parameters, setpoints) from a configuration file.
- **Initial Configuration**: When an application starts, predefined values are loaded from the settings.ini file.
- **Online Parameterization**: New values can be written at runtime via the AR2 adapter using an HMI or a control system. The block immediately saves and confirms these values in the file.
- **Redundancy**: If no file exists, the DEFAULT_VALUE is used, allowing the application to start even without configuration.

Comparison with Similar Blocks

- **INI (eclipse4diac::storage::INI)**: The INI_AR2 extends the basic INI block with an adapter interface, making it easier to integrate into a higher-level structure. The standard INI block requires separate event connections for reading and writing; INI_AR2 simplifies this with its bidirectional adapter.

- Other storage blocks (e.g., for databases or OPC UA): INI_AR2 is limited to simple INI files but is very lightweight and has no additional runtime dependencies.

Conclusion



The INI_AR2 function block offers a compact and easy-to-integrate solution for persistently storing and loading REAL configuration values. Using an AR2 adapter standardizes the connection to other components. This block is particularly suitable for embedded controllers with low data storage requirements, where a single INI file is sufficient.

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

]

INI_AS

• — ○ • — ○ • — ○ •

Introduction

The function block **INI_AS** is used to load and save SINT data from a `settings.ini` file. It accesses a configuration value via a section name (`SECTION`) and a key (`KEY`). The value can be both read and written via the adapter interface `AS`. The block encapsulates the internal `INI` function block and extends it with a standardized adapter interface.

Interface Structure

Event Inputs

| Event | Type | With Vars | Description | | Event | Type | With Vars | Description | |-----|----|-----|-------| | `INIT` | EInit | QI, SETM, SECTION, KEY, DEFAULT_VALUE | Service Initialization: Reads the value from the INI file and outputs it via the adapter. |

Event Outputs

Event	Type	With Vars	Description
`INITO`	EInit	QO, STATUS	Confirmation of initialization.

Data Inputs

Name	Data Type	Description
`QI`	BOOL	Input qualifier (e.g., enable).
`SETM`	BOOL	Enable mirroring on SET
`SECTION`	STRING	Name of the section in the INI file.
`KEY`	STRING	Name of the key within the section.
`DEFAULT_VALUE`	SINT	Value returned if the key is not present in the INI file.

Data Outputs

| Name | Data Type | Description | | |-----|-----|-------| | `QO` | BOOL | Output qualifier (indicates successful operation). | | `STATUS` | STRING | Status message (e.g., error messages). |

Adapter

Name	Type	Direction	Description
`AS_IN`	`adapter::types::unidirectional::AS`	Input (Socket)	Receives a new value to be stored (SET operation).
`AS_OUT`	`adapter::types::unidirectional::AS`	Output (Plug)	Outputs the currently read or stored value (GET operation).

Functionality

1. **Initialization and First Read (INIT Event)**

The parameters `SECTION`, `KEY`, and `DEFAULT_VALUE` are passed via the `INI` event. The internal `INI` block is started, reads the value from `settings.ini`, and outputs it via the adapter output `AS_OUT`. Simultaneously, the `INITO` event is triggered, reporting the completion of the initialization.

Subsequently (possibly within the same cycle), a `GET` event is automatically executed on the `INI` block, so that the read value is immediately available at the adapter.

1. **Writing a Value (via the Adapter Input)**

A new value (event `E1` and data `D1`) can be sent to the block via the socket `AS_IN`. This event is forwarded to the `SET` input of the internal `INI` block, which saves the value to the INI file. After successful saving, the `SETO` event of the `INI` block is triggered, which in turn serves the adapter output `AS_OUT` (event `E1`) and outputs the saved value via `D1`.

... 3. **Feedback**

The internal `INI` module provides the output signals `QO` and `STATUS`, which are directly routed to the corresponding outputs of the `INI_AS` module.

Technical Features

- **Adapter Interface `AS`**: The module uses a unidirectional adapter (`adapter::types::unidirectional::AS`). This enables standardized connectivity to other modules that support the same adapter type.

- **Data Type SINT**: The read and stored value is of the “Short Integer” (SINT, 8-bit) type. This makes the module particularly suitable for small integer configuration values.
- **Reuse of the `INI` block**: All logic for accessing the INI file is taken over from the proven `eclipse4diac::storage::INI` block. The `INI_AS` block encapsulates this and extends the adapter interface.
- **Automatic GET after INIT**: After initialization, a read operation is started immediately, so the current value is available at the adapter output without a separate event.

State Overview

The block does not have an explicit state machine (ECC). Its behavior is controlled purely via event chaining within the internal FB network:

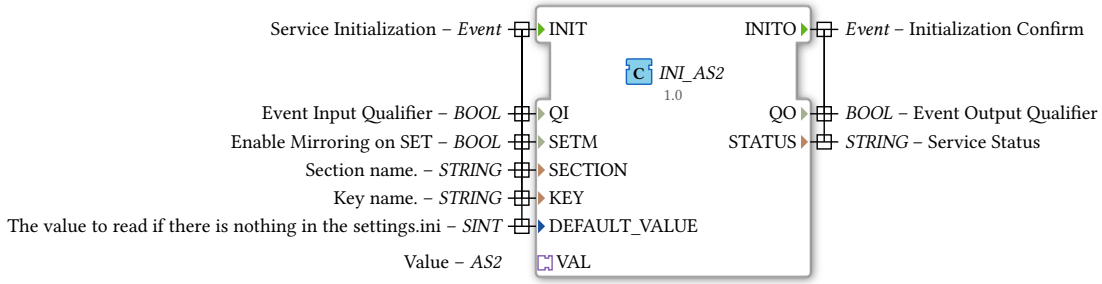
- After `INIT`, the sequence is: INIT of the `INI` block ⟶ INITO ⟶ GET (automatic) ⟶ VALUO at the adapter output.
- After a SET event from the adapter input: SET of the `INI` block ⟶ SETO ⟶ adapter output with the new value.

Application Scenarios

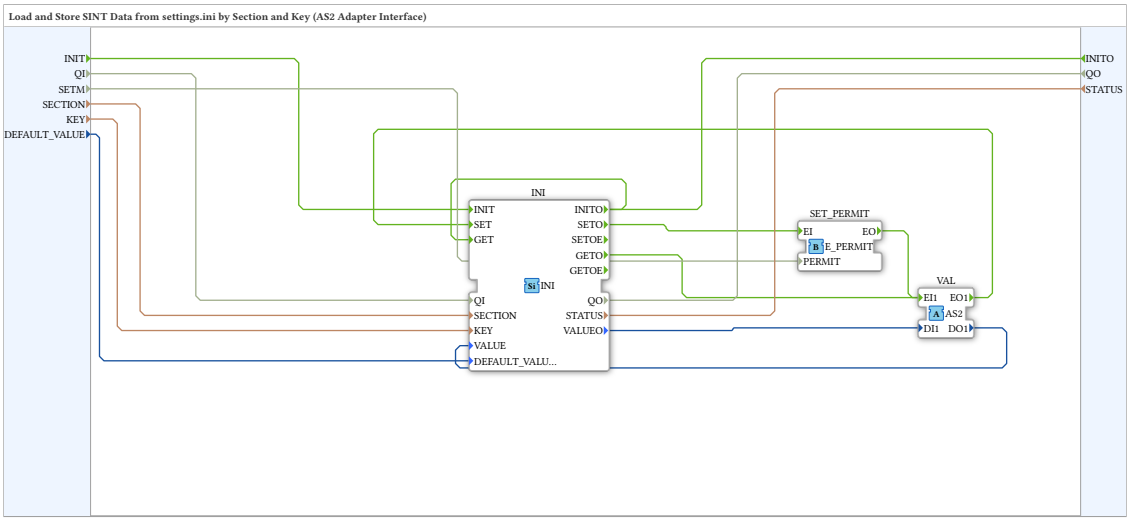
- **Persistent Configuration**: Saving and reading settings such as thresholds, mode flags, or device addresses in a `settings.ini` block.
- **Parameterization of Control Applications**: When a PLC or other automation system needs to load or modify values from a configuration file at runtime.
- **Adapter-Based Communication**: Integration into a higher-level adapter structure that groups several such read/write blocks.

Comparison with Similar Function Blocks

- **INI_STRING, INI_INT, INI_BOOL**: These function blocks also use the internal `INI` function block, but support different data types (STRING, INT, BOOL) and often have a different interface structure (no adapters). The `INI_AS` function block offers a uniform and reusable interface through its adapter.
- **Direct `INI` Function Block**: The `INI` function block itself has several event inputs (INIT, GET, SET) and requires manual wiring of read and write operations. The `INI_AS` simplifies handling by standardizing typical usage (reading on startup, writing via adapters).



Conclusion



The function block `INI_AS` is a convenient building block for persistently reading and writing SINT values from an INI file. Its adapter interface allows for easy integration into existing architectures and reduces wiring effort. It is particularly suitable for configuration tasks where a single integer value needs to be cached.

INI_AS2

• – ○ • – ○ • – ○ •

Introduction

The INI_AS2 function block is used to read and write SINT data from a settings.ini file via an AS2 adapter. It combines the INI block with a bidirectional AS2 adapter to read values from or write them back to a configuration file. Initialization is performed via the INIT event, where the section and key are specified. The read value is offered via the adapter, and a write operation is triggered via the adapter event.

Interface Structure

Event Inputs

Name	Description
INIT	Initialization event to start the read operation. Expects the parameters QI, SECTION, KEY, and DEFAULT_VALUE.

Event Outputs

Name	Description
INITO	Initialization confirmation. Sent after the read operation is complete. Status information is available via QO and STATUS.

Data Inputs

Name	Type	Description
QI	BOOL	Input qualifier for controlling processing.
SETM	BOOL	Controls confirmation/mirroring after a successful write. Regardless of SETM, VAL.EO1 always triggers INI.SET; however, the SETO confirmation reaches VAL.EI1 only when SETM=TRUE (suppressed when SETM=FALSE).
SECTION	STRING	Name of the section in the settings.ini file.
KEY	STRING	Name of the key within the section.
DEFAULT_VALUE	SINT	Default value read if the key is not present in the file. Default: 0.

Data Outputs

Name	Type	Description

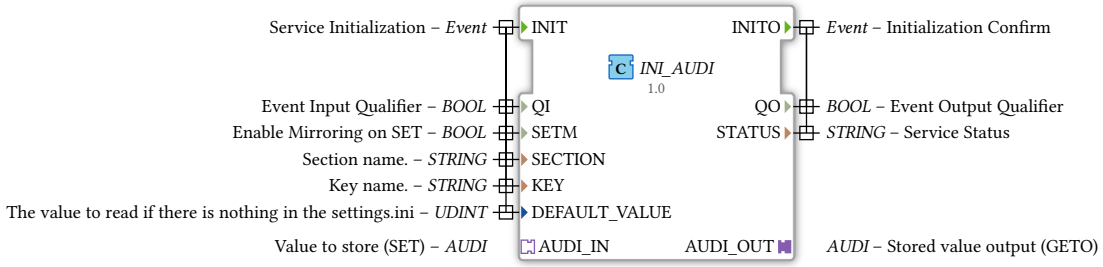
QO	BOOL	Output qualifier, indicates successful processing.
STATUS	STRING	Service status message (e.g., error messages).

Adapters

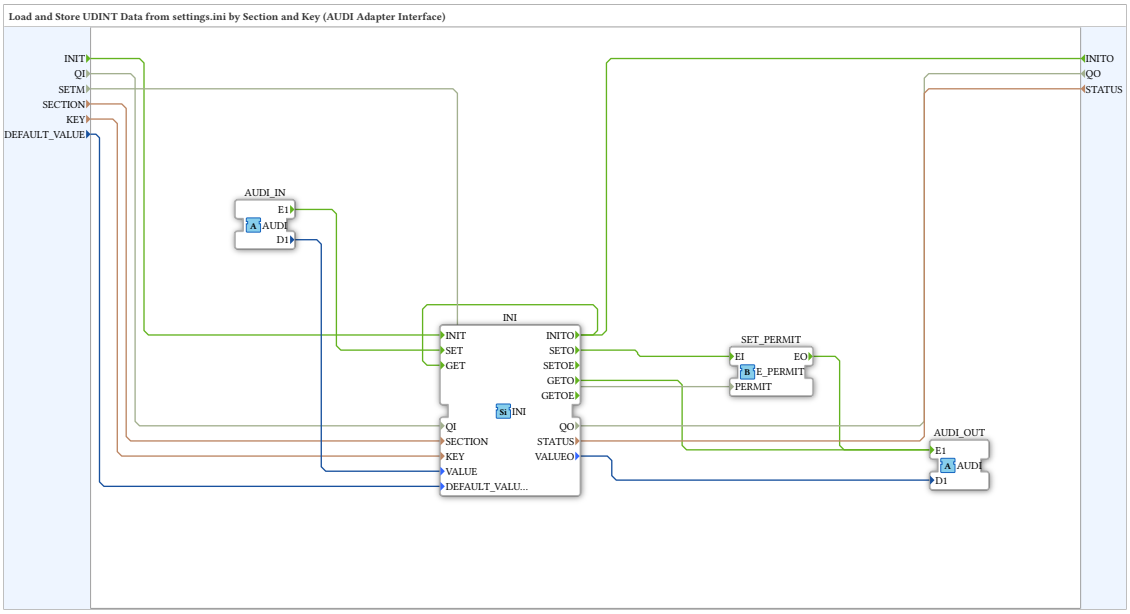
Name	Type	Description
VAL	adapter::types::bidirectional::AS2	Bidirectional adapter for exchanging values. This adapter provides the read value as an output (DI1) and receives a write value as an input (DO1).

Functionality

The INI_AS2 function block contains an internal INI function block (eclipse4diac::storage::INI) that performs the actual file operation. The network connections implement the following processes:



- Upon arrival of INIT, QI, SECTION, KEY, and DEFAULT_VALUE are forwarded to the INI function block.
- The INI function block performs a read operation and passes the result (via VALUEO) to the adapter output (VAL.DI1).
- Simultaneously, after a successful read, the GET event is triggered, which activates the adapter input (VAL.EI1) to transmit the value.
- A write operation is initiated as soon as the adapter sends an EO1 event. This event triggers the SET event on the INI function block, setting the value received via VAL.DO1 as the new VALUE.
- The INI block confirms the write operation with SETO. If SETM=TRUE, this confirmation is routed back to the adapter (VAL.EI1), whereas SETM=FALSE suppresses this mirror.
- The QO and STATUS outputs are directly taken from the INI block.



Thus, read and write access to the settings.ini file can be controlled via the AS2 adapter.

Technical Features

- The block uses a bidirectional AS2 adapter that can both send and receive values.
- A SINT value is used as the default value.

INI_AUDI

• – ○ • – ○ • – ○ •

Introduction

The **INI_AUDI** function block enables reading and saving UDINT data from a `settings.ini` file. Access to the file is implemented via an internal `INI` function block. Communication with the environment is handled via two **AUDI adapters** (unidirectional), implemented as a plug (`AUDI_OUT`) and a socket (`AUDI_IN`). This allows for modular integration with other function blocks that use the same adapter type.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Service Initialization

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirm

Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier
SETM	BOOL	Enable mirroring on SET
SECTION	STRING	Section name in settings.ini
KEY	STRING	Key name in settings.ini
DEFAULT_VALUE	UDINT	Fallback value if the key is not found

Data Outputs

Name	Type	Comment
QO	BOOL	Output Qualifier

STATUS	STRING	Service Status

Adapter

Name	Type	Direction	Comment
AUDI_OUT	AUDI	Plug (Output)	Output of the read value
AUDI_IN	AUDI	Socket (Input)	Input of the value to be stored

Functionality

This function block works in conjunction with the internal `INI` function block. The basic sequence is:

1. **Initialization (`INIT` event)**

- The input data associated with `INIT` (`QI`, `SETM`, `SECTION`, `KEY`, `DEFAULT_VALUE`) is forwarded to the internal `INI` module.
- `INI` is started and acknowledged with `INITO`.

1. **Reading a Value**

- After INIT confirmation, the `GET` command of the `INI` block is automatically triggered.
- The read value (or `DEFAULT_VALUE`) is output to the `AUDI_OUT.D1` adapter via `INI.VALUEO`.
- Simultaneously, the event `AUDI_OUT.E1` is sent to notify the connected block.

1. **Writing a Value**

- If the adapter `AUDI_IN` receives an event `E1` with a data value `D1`, `INI_AUDI` forwards this to the `INI` block as a `SET` command.
- The internal `INI` block stores the value in the INI file under the specified section and key and acknowledges it with `SETO`.
- The acknowledgment event is output via `AUDI_OUT.E1`.

... 4. **Feedback**

- The status outputs `QO` and `STATUS` are directly inherited from the internal `INI` block and are available at the output.

Technical Features

- The block uses the **adapter `adapter::types::unidirectional::AUDI`**, which is specifically designed for the directed communication of values and events.
- The data is processed as **UDINT (Unsigned Double Integer)**, enabling efficient storage and transmission.
- The internal `INI` block is from the `eclipse4diac::storage` library and supports standard INI file formats.
- The block uses the **adapter `adapter::types::unidirectional::AUDI`**, which is specifically designed for the directed communication of values and events. - The fallback mechanism via `DEFAULT_VALUE` ensures that a defined value is returned even if entries are missing in the INI file.

State Overview

Since the function block operates in an event-driven manner, the following logical states result:

- **Idle**: Waiting for a `INIT` event.
- **Initialize**: After `INIT` – internal forwarding to the INI function block.
- **Read** (automatically after `INITO`): The `INI` function block executes a GET command.
- **Write**: Upon receiving an event via `AUDI_IN.E1`.
- **Confirm**: Output of the corresponding OUT event and update of the status outputs.

The function block is stateless in the sense of a continuous data flow; each action is triggered by an event and terminates synchronously.

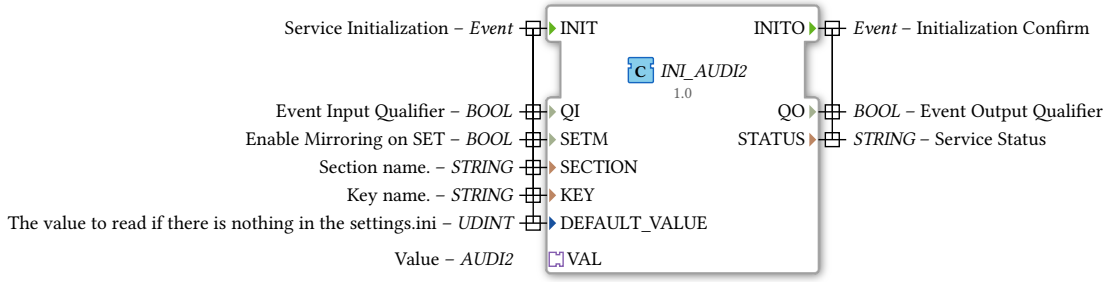
Application Scenarios

- **Configuration Management** in automation systems: Reading settings (e.g., limits, parameters) from a central `settings.ini` and writing back changed values.

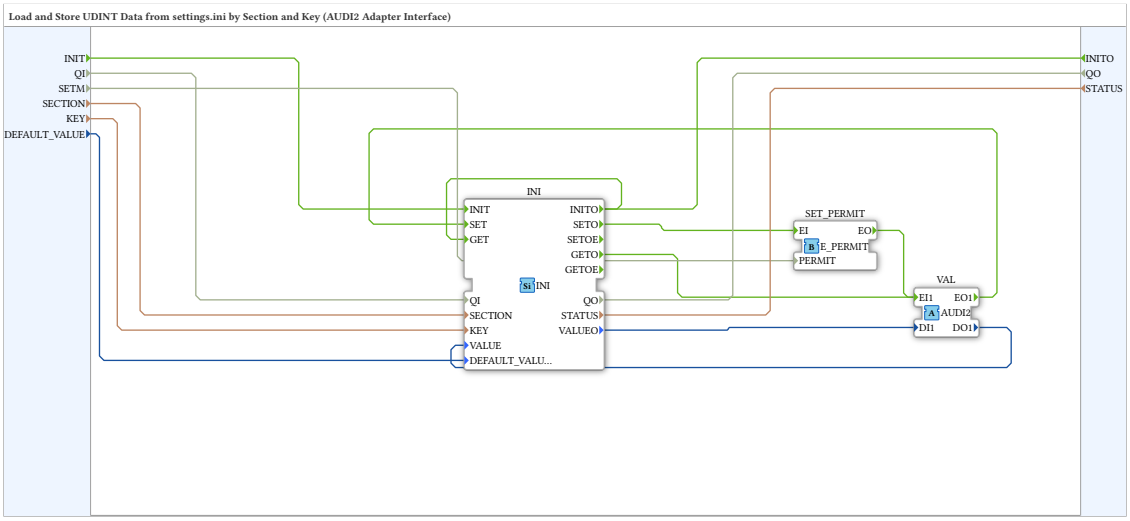
- **Adapter-based sensor/actuator coupling**: Connecting a function block that reads or sets values via the AUDI adapter without having to implement the file access logic itself.
- **Persistent Data Storage**: Saving counter readings or machine states to an INI file while simultaneously communicating via standardized adapters.

Comparison with Similar Function Blocks

- **Compared to a pure `INI` function block**: `INI_AUDI` encapsulates the adapter communication and offers a higher level of abstraction. The user does not have to directly handle events and data connections between multiple components.
- **Compared to Function Blocks with Other Data Types**: This function block is specifically designed for `UDINT`. Separate versions are required for other data types (e.g., `STRING`, `REAL`). However, the basic structure remains the same.
- **Advantage**: By using adapters (AUDI), the function block can easily be replaced with other interfaces, provided they implement the same adapter type.



Conclusion



The `INI_AUDI` function block provides a compact and reusable solution for reading and writing UDINT values from an INI file, connecting to the environment via standardized AUDI adapters. Its clear separation of initialization, reading, and writing, along with the inclusion of a fallback value, makes it particularly suitable for robust configuration and data storage tasks in automation environments. Its simple structure facilitates integration into complex 4diac networks.

INI_AUDI2

• – ○ • – ○ • – ○ •

Introduction

The INI_AUDI2 function block is used to read and write UDINT data from a settings.ini file via an AUDI2 adapter. It combines the INI block with a bidirectional AUDI2 adapter to read values from or write them back to a configuration file. Initialization is performed via the INIT event, where the section and key are specified. The read value is offered via the adapter, and a write operation is triggered via the adapter event.

Interface Structure

Event Inputs

Name	Description
INIT	Initialization event to start the read operation. Expects the parameters QI, SECTION, KEY, and DEFAULT_VALUE.

Event Outputs

Name	Description
INITO	Initialization confirmation. Sent after the read operation is complete. Status information is available via QO and STATUS.

Data Inputs

Name	Type	Description
QI	BOOL	Input qualifier for controlling processing.
SETM	BOOL	Controls confirmation/mirroring after a successful write. Regardless of SETM, VAL.EO1 always triggers INI.SET; however, the SETO confirmation reaches VAL.EI1 only when SETM=TRUE (suppressed when SETM=FALSE).
SECTION	STRING	Name of the section in the settings.ini file.
KEY	STRING	Name of the key within the section.
DEFAULT_VALUE	UDINT	Default value read if the key is not present in the file. Default: 0.

Data Outputs

Name	Type	Description
QO	BOOL	Output qualifier, indicates successful processing.
STATUS	STRING	Service status message (e.g., error messages).

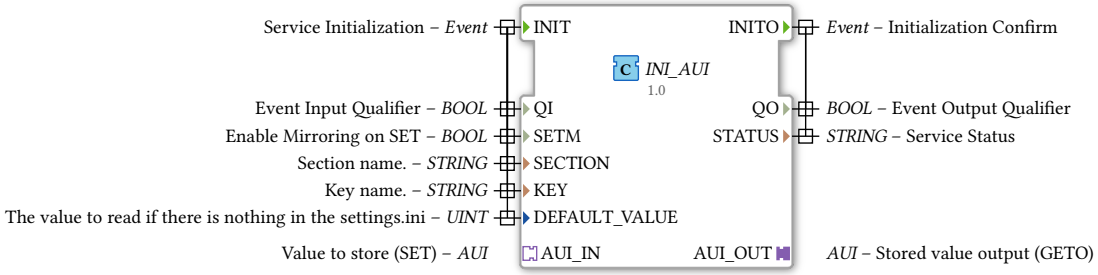
Adapters

Name	Type	Description
VAL	adapter::types::bidirectional::AUDI2	Bidirectional adapter for exchanging values. This adapter provides the read value as an output (DI1) and receives a write value as an input (DO1).

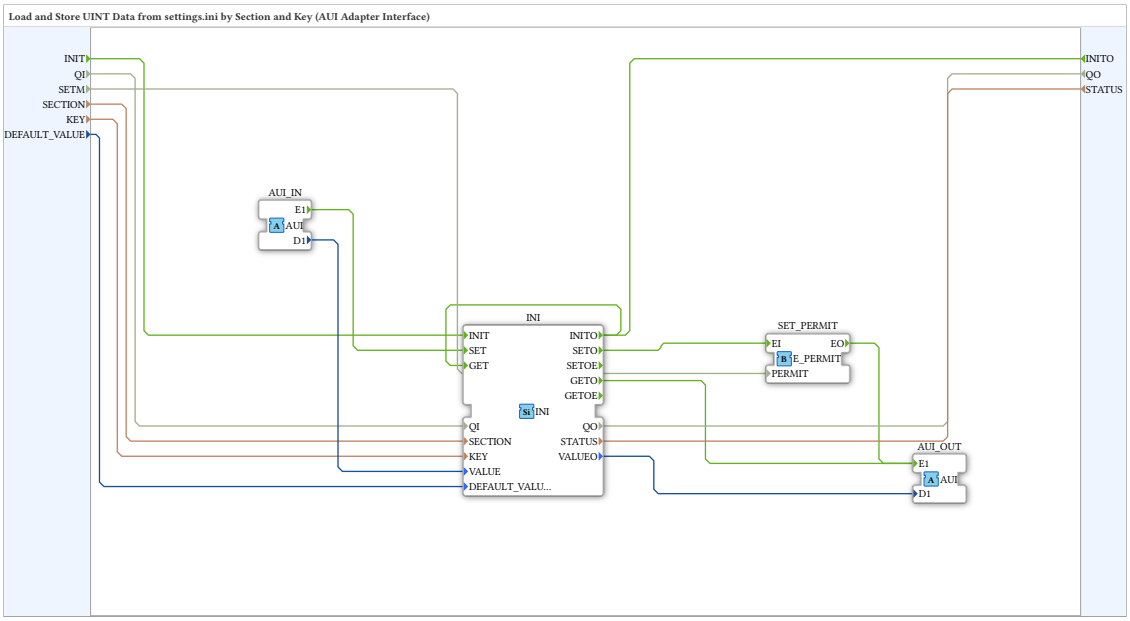
Functionality

The INI_AUDI2 function block contains an internal INI function block (eclipse4diac::storage::INI) that performs the actual file operation. The network connections implement the following processes:

- Upon arrival of INIT, QI, SECTION, KEY, and DEFAULT_VALUE are forwarded to the INI function block.
- The INI function block performs a read operation and passes the result (via VALUEO) to the adapter output (VAL.DI1).



- Simultaneously, after a successful read, the GET event is triggered, which activates the adapter input (VAL.EI1) to transmit the value.
- A write operation is initiated as soon as the adapter sends an EO1 event. This event triggers the SET event on the INI function block, setting the value received via VAL.DO1 as the new VALUE.
- The INI block confirms the write operation with SETO. If SETM=TRUE, this confirmation is routed back to the adapter (VAL.EI1), whereas SETM=FALSE suppresses this mirror.
- The QO and STATUS outputs are directly taken from the INI block.



Thus, read and write access to the settings.ini file can be controlled via the AUDI2 adapter.

Technical Features

- The block uses a bidirectional AUDI2 adapter that can both send and receive values.
- A UDINT value is used as the default value.

INI_AUI

• – ○ • – ○ • – ○ •

Introduction

The function block `INI_AUI` is used to read and store **UINT data** (more precisely: `UDINT` values) from a `settings.ini` file. The parameters **Section** and **Key** determine which value is read. Additionally, a **Default Value** can be specified if no entry exists in the INI file. The function block offers both direct access via its inputs and an **Adapter Interface (AUI)** for unidirectional communication with other function blocks.

Interface Structure

Event Inputs

Event	Type	Short Description

INIT	EInit	Service Initialization: Triggers loading the value from the INI file

Event Outputs

Event	Type	Short Description
INITO	EInit	Initialization Acknowledgement (sent after completion of read/write operations)

Data Inputs

Name	Type	Short Description
QI	BOOL	Qualifier for the event input (enables processing)
SETM	BOOL	Enable Mirroring on SET: if TRUE, the confirmation of a SET (SETO) is additionally forwarded to the output adapter (mirrored)
SECTION	STRING	Name of the section in `settings.ini` (e.g., `[MySection]`)
KEY	STRING	Key name within the section
DEFAULT_VALUE	UDINT	Value returned if no entry exists

Data Outputs

Name	Type	Short Description
QO	BOOL	Qualifier for the event output (indicates successful execution)
STATUS	STRING	Status message (e.g., Error or Success)

Adapters

Direction	Adapter Type	Short Description
Plug	`adapter::types::unidirectional::AUI`	**Output (OUT):** Provides the read/written value via the adapter
Socket	`adapter::types::unidirectional::AUI`	**Input (IN):** Receives the value to be stored via the adapter

Functionality

The `INI_AUI` function block encapsulates an internal `INI` function block (`eclipse4diac::storage::INI`). The essential processes are:

1. **Reading a Value**

- An **INIT** event at the input triggers the internal `INI.INIT`.
- The data `QI`, `SETM`, `SECTION`, `KEY`, and `DEFAULT_VALUE` are forwarded to the `INI` function block.
- After successful processing, `INI.INITO` sends the confirmation event and internally triggers `INI.GET` to load the value from the file.
- The read value appears at `INI.VALUEO` and is output via the **AUI_OUT** adapter (plug) as `D1`.
- Simultaneously, `QO` and `STATUS` are taken from the internal function block.

1. **Writing a Value**

- An event at the **AUI_IN.Socket** (via the input adapter) triggers the internal `INI.SET`.
- The value provided via the adapter (D1) is passed to `INI.VALUE` and written to `settings.ini`.
- After writing, `INI.SETO` sends the confirmation event, which is output via the **AUI_OUT.Plug** as `E1`.
- Here too, the outputs `QO` and `STATUS` are updated.

> **Note:** The adapter **AUI_IN** acts as a socket (receiving), and **AUI_OUT** as a plug (providing). Both use the same unidirectional AUI type.

Technical Features

- **Adapter-based communication:** The function block enables the exchange of configuration data via a unidirectional adapter (AUI) without requiring direct data connections. This simplifies module communication in distributed systems.
- **Dual operation:** The value can be set via the classic data inputs (`SECTION`, `KEY`, `DEFAULT_VALUE`) as well as via the adapter (`AUI_IN.D1`).
- **Default Value:** If an entry is missing in the INI file, `DEFAULT_VALUE` is used – this prevents undefined states.
- **Status Information:** The user can check the success of each operation via `STATUS` and `QO`.

State Overview

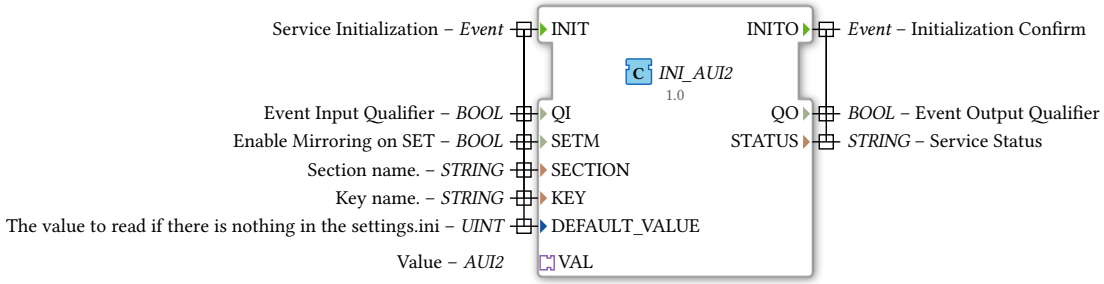
The function block `INI_AUI` does **not have its own state machine**. The entire process control is implemented by the integrated `INI` function block and the defined event connections (e.g., INIT → INI.INIT, INI.INITO → INITO, INI.INITO → INI.GET). Therefore, the function block operates strictly event-driven and executes read/write operations sequentially.

Application Scenarios

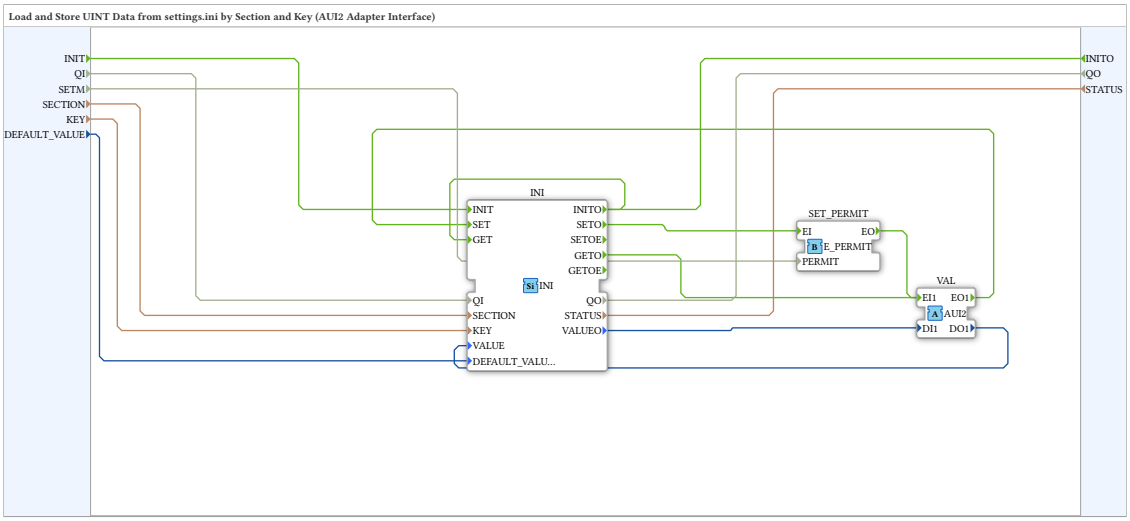
- **Parameter Management** in modular automation systems where multiple components access shared configuration data via an adapter.
- **Initialization** of control functions with a default value that can be overwritten from an INI file if needed.
- **Exchange of settings** between different function blocks connected via the AUI adapter (e.g., a higher-level manager block and multiple worker blocks).

Comparison with Similar Blocks

- **`INI` (Basic Function Block):** The `INI_AUI` extends the simple `INI` function block with a standardized adapter interface. While the `INI` only has direct inputs/outputs, the `INI_AUI` allows loose coupling via AUI.
- **Other memory blocks (e.g., `Memory`, `Persist`):** These usually work with internal variables or files, but often lack an adapter interface and dedicated `settings.ini` integration.



Conclusion



The `INI_AUI` function block is a flexible solution for reading and saving configuration values in a `settings.ini`-file. By combining direct data inputs and a unidirectional AUI adapter interface, it is ideally suited for both simple initialization tasks and modular, adapter-based system architectures. The integration of a default value and clear status feedback increase the robustness and maintainability of the control software.

INI_AUI2

• – ○ • – ○ • – ○ •

Introduction

The INI_AUI2 function block is used to read and write UINT data from a settings.ini file via an AUI2 adapter. It combines the INI block with a bidirectional AUI2 adapter to read values from or write them back to a configuration file. Initialization is performed via the INIT event, where the section and key are specified. The read value is offered via the adapter, and a write operation is triggered via the adapter event.

Interface Structure

Event Inputs

Name	Description
INIT	Initialization event to start the read operation. Expects the parameters QI, SECTION, KEY, and DEFAULT_VALUE.

Event Outputs

Name	Description
INITO	Initialization confirmation. Sent after the read operation is complete. Status information is available via QO and STATUS.

Data Inputs

Name	Type	Description
QI	BOOL	Input qualifier for controlling processing.
SETM	BOOL	Controls confirmation/mirroring after a successful write. Regardless of SETM, VAL.EO1 always triggers INI.SET; however, the SETO confirmation reaches VAL.EI1 only when SETM=TRUE (suppressed when SETM=FALSE).
SECTION	STRING	Name of the section in the settings.ini file.
KEY	STRING	Name of the key within the section.
DEFAULT_VALUE	UINT	Default value read if the key is not present in the file. Default: 0.

Data Outputs

Name	Type	Description

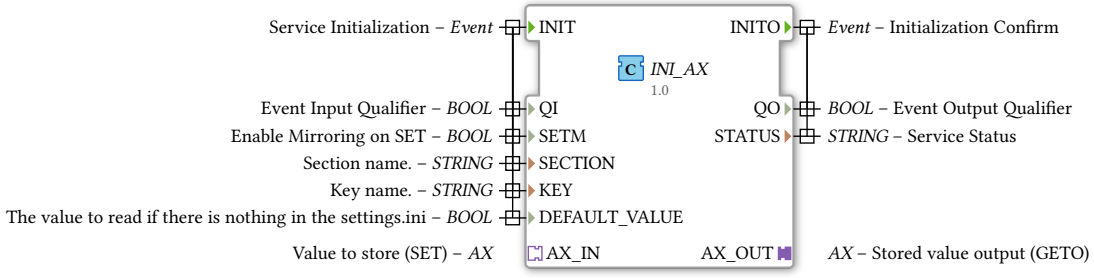
QO	BOOL	Output qualifier, indicates successful processing.
STATUS	STRING	Service status message (e.g., error messages).

Adapters

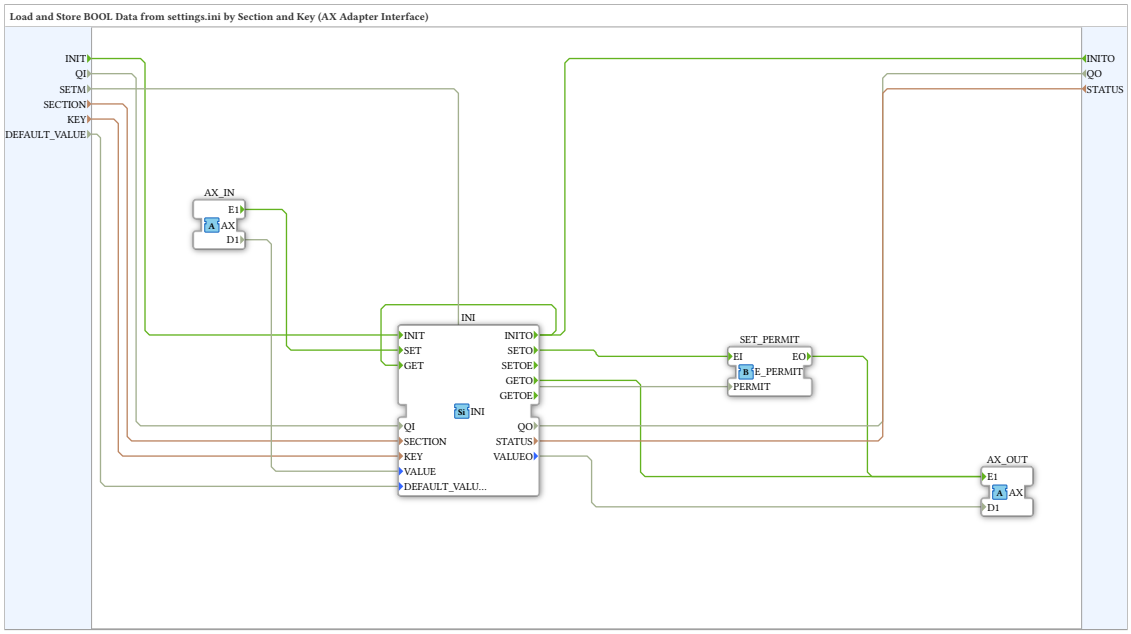
Name	Type	Description
VAL	adapter::types::bidirectional::AUI2	Bidirectional adapter for exchanging values. This adapter provides the read value as an output (DI1) and receives a write value as an input (DO1).

Functionality

The INI_AUI2 function block contains an internal INI function block (eclipse4diac::storage::INI) that performs the actual file operation. The network connections implement the following processes:



- Upon arrival of INIT, QI, SECTION, KEY, and DEFAULT_VALUE are forwarded to the INI function block.
- The INI function block performs a read operation and passes the result (via VALUEO) to the adapter output (VAL.DI1).
- Simultaneously, after a successful read, the GET event is triggered, which activates the adapter input (VAL.EI1) to transmit the value.
- A write operation is initiated as soon as the adapter sends an EO1 event. This event triggers the SET event on the INI function block, setting the value received via VAL.DO1 as the new VALUE.
- The INI block confirms the write operation with SETO. If SETM=TRUE, this confirmation is routed back to the adapter (VAL.EI1), whereas SETM=FALSE suppresses this mirror.
- The QO and STATUS outputs are directly taken from the INI block.



Thus, read and write access to the settings.ini file can be controlled via the AUI2 adapter.

Technical Features

- The block uses a bidirectional AUI2 adapter that can both send and receive values.
- A UINT value is used as the default value.

INI_AX

• – ○ • – ○ • – ○ •

Introduction

`INI_AX` loads and stores a `BOOL` value in the `settings.ini` file, addressed by section (`SECTION`) and key (`KEY`). It is the Boolean counterpart to INI_AB and the `settings.ini` counterpart to NVS_AX.

Interface Structure

Event Inputs

- **INIT**: initializes the block and reads the value stored under `SECTION`/`KEY` (or `DEFAULT_VALUE` if none exists yet). Carries `QI`, `SETM`, `SECTION`, `KEY`, `DEFAULT_VALUE`.

Event Outputs

- **INITO**: confirms initialization and the initial read, carries `QO` and `STATUS`.

Data Inputs

- **QI** (BOOL): qualifier for the `INIT` event.
- **SETM** (BOOL): enables mirroring (confirmation) on write (`SET`).
- **SECTION** (STRING): name of the section in `settings.ini`.
- **KEY** (STRING): name of the key within the section.
- **DEFAULT_VALUE** (BOOL): value returned when nothing is stored under `SECTION`/`KEY` yet.

Data Outputs

- **QO** (BOOL): success qualifier, carried with `INITO` and the internal adapter confirmations.
- **STATUS** (STRING): status message of the file access.

Adapters

- **AX_IN** (Socket, type `AX`): new value to store – an adapter event on `AX_IN.E1` triggers a `SET` on the internal INI block, `AX_IN.D1` carries the value to write.
- **AX_OUT** (Plug, type `AX`): outputs the most recently read value – both after the automatic initial read on `INIT` and after each confirmed write (`AX_OUT.D1`/`AX_OUT.E1`).

Functionality

`INI_AX` wraps an internal instance of `eclipse4diac::storage::INI` plus an `E_PERMIT` gate (`SET_PERMIT`). On `INIT`, the internal INI instance is initialized (`INI.INIT`) and a `GET` is triggered automatically, returning the value stored under `SECTION`/`KEY` (or `DEFAULT_VALUE`); the result is output via `AX_OUT`, and `INITO` confirms completion.

To write, the block connected to `AX_IN` fires an adapter event (`AX_IN.E1`) carrying the new value (`AX_IN.D1`), which triggers `INI.SET`. Whether the successful write is additionally reported back via `AX_OUT` is controlled by `SETM`: if `SETM` is set, `SET_PERMIT` releases the `AX_OUT.E1` event after a successful `SET` ("mirroring").

Technical Details

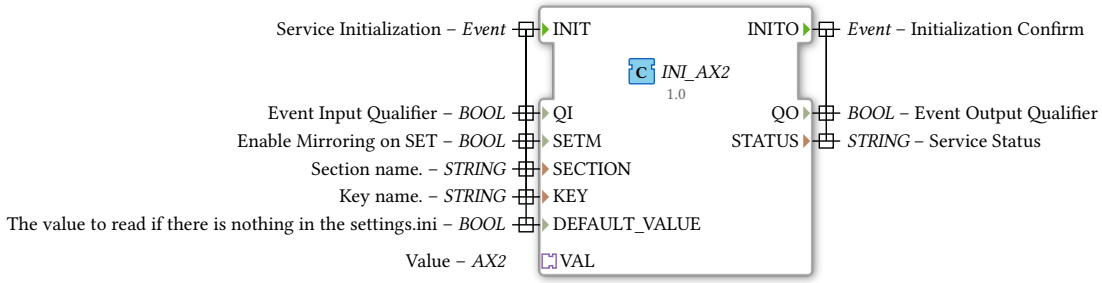
- Pure composite FB with no ECC of its own – the actual file access logic lives in the internal `INI` instance; `INI_AX` only wires events and data between it and the two `AX` adapters.
- Two separate unidirectional adapters (`AX_IN`/`AX_OUT`) – this lets the read and write paths connect to different peers.
- Addressing via `SECTION` **and** `KEY` (rather than just `KEY` for the `NVS_*` blocks) matches the classic INI file format.

State Overview

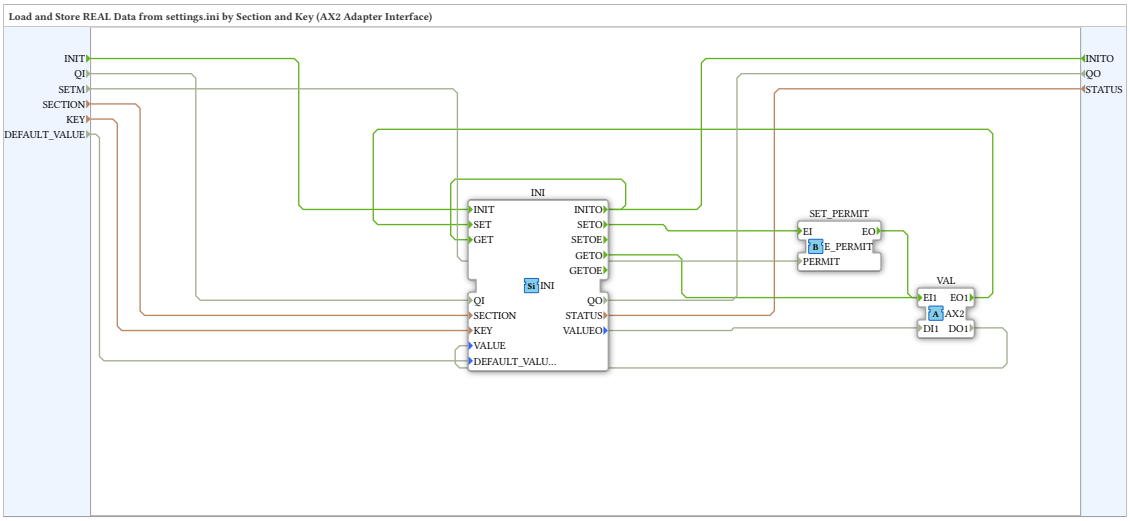
The block is stateless in terms of its own ECC: on `INIT` it runs through initialization plus an initial read once, then reacts to every `AX_IN` adapter event with an INI write and, optionally, a confirmation via `AX_OUT`.

Application Scenarios

- Persisting individual `BOOL` configuration values (e.g. enable flags, operating-mode switches) in a human-readable `settings.ini`
- Building a read/write pair where the read and write sides need to connect to different blocks
- Configuration files that also need to be viewable/editable outside the controller (e.g. with a text editor)



⚖️ Comparison with Similar Blocks



Compare with INI_AB, which uses the same architecture for `BYTE` instead of `BOOL` values, and with NVS_AX, which provides the same interface for the ESP32 NVS flash storage instead of `settings.ini`.

Conclusion

`INI_AX` provides simple, unidirectionally wired access to a persistent `BOOL` value in `settings.ini`, and fits anywhere the read and write paths need to be kept separate.

INI_AX2

• – ○ • – ○ • – ○ •

Introduction

The INI_AX2 function block is used to read and write real data from a settings.ini file via an AX2 adapter. It combines the INI block with a bidirectional AX2 adapter to read values from or write them back to a configuration file. Initialization is performed via the INIT event, where the section and key are specified. The read value is offered via the adapter, and a write operation is triggered via the adapter event.

Interface Structure

Event Inputs

Name	Description
INIT	Initialization event to start the read operation. Expects the parameters QI, SETM, SECTION, KEY, and DEFAULT_VALUE.

Event Outputs

Name	Description
INITO	Initialization confirmation. Sent after the read operation is complete. Status information is available via QO and STATUS.

Data Inputs

Name	Type	Description
QI	BOOL	Input qualifier for controlling processing.
SETM	BOOL	Enable mirroring on SET
SECTION	STRING	Name of the section in the settings.ini file.
KEY	STRING	Name of the key within the section.
DEFAULT_VALUE	BOOL	Default value read if the key is not present in the file. Default: FALSE.

Data Outputs

Name	Type	Description
QO	BOOL	Output qualifier, indicates successful processing.
STATUS	STRING	Service status message (e.g., error messages).

Adapters

Name	Type	Description
VAL	adapter::types::bidirectional::AX2	Bidirectional adapter for exchanging values. This adapter provides the read value as an output (DI1) and receives a write value as an input (DO1).

Functionality

The INI_AX2 function block contains an internal INI function block (eclipse4diac::storage::INI) that performs the actual file operation. The network connections implement the following processes:

- Upon arrival of INIT, QI, SETM, SECTION, KEY, and DEFAULT_VALUE are forwarded to the INI function block.
- The INI function block performs a read operation and passes the result (via VALUEO) to the adapter output (VAL.DI1).
- Simultaneously, after a successful read, the GET event is triggered, which activates the adapter input (VAL.EI1) to transmit the value.
- A write operation is initiated as soon as the adapter sends an EO1 event. This event triggers the SET event on the INI function block, setting the value received via VAL.DO1 as the new VALUE.
- The INI block confirms the write operation with SETO and sends this back to the adapter (VAL.EI1).
- The QO and STATUS outputs are directly taken from the INI block.

Thus, read and write access to the settings.ini file can be controlled via the AX2 adapter.

Technical Features

- The block uses a bidirectional AX2 adapter that can both send and receive values.
- A BOOL value is used as the default, although the comment indicates REAL data. The actual value type is determined by the adapter.
- The internal INI block is part of the eclipse4diac standard library for file access.
- The connections in the FBNetwork are configured so that event control is synchronized between read and write operations.

State Overview

The block itself does not have explicit states, as it is implemented as a pure network of subordinate blocks. The state logic is determined by the internal INI block and the adapter. Typical states are:

- **Initialization**: Waiting for an INIT event.
- **Read**: Processing the read operation via the INI block.
- **Write**: Processing a write command via the adapter.
- **Wait**: After completing an operation, waiting for the next event.

Application Scenarios

- Reading configuration parameters from an INI file in an automation application, where the values are passed to other components via an AX2 adapter.
- Writing modified parameters back to the file, e.g., after user input or an algorithm.
- Combining with other blocks for persistent storage of settings in an IEC 61499 system.

Comparison with Similar Blocks

- The simple **INI** block offers direct read/write access to INI files, but without adapter connectivity. INI_AX2 extends this with a standardized AX2 interface for value exchange.

Other memory blocks, such as **CSV** or **JSON** blocks, serve different file formats; INI_AX2 is specific to the INI format with a bidirectional adapter.

Conclusion

The INI_AX2 function block is a useful component for IEC 61499 applications that require easy access to configuration files via an AX2 adapter. By encapsulating the INI block and using event-driven control, it enables both read and write operations to a settings.ini file. The use of a bidirectional adapter allows for flexible integration into complex networks.

Read-Only Settings (`settingsReadOnly.ini`)

In logiBUS® systems, configuration values and parameters are managed in INI files on the ECU's file system. In addition to the freely writable standard configuration file (`settings.ini`), the system supports a read-only settings file: **`settingsReadOnly.ini`**. This feature is used to permanently freeze factory settings, manufacturer-defined system parameters, fixed communication addresses, or critical hardware and security options. This prevents important parameters from being accidentally changed by operators or by the control system itself

---

Introduction

Concept of the Two Configuration Files

The ECU distinguishes between two levels of configuration storage:

File	Purpose	Writable?	Typical Contents
`settingsReadOnly.ini`	Factory Settings & System Defaults	❌ No (Write-protected)	ISOBUS source addresses (Node SAs), hardware pin assignments, fixed boot times
`settings.ini`	User & Runtime Settings	✅ Yes (Read & Write)	User preferences, dynamic operating parameters, selectable limit scaling

1. **Factory Settings Priority**: During boot, the control unit first reads the file `settingsReadOnly.ini`. All sections (`[Section]`) and keys (`KEY`) defined within it are loaded in read-only mode.
2. **Automatic Purge:** If a key is located in both `settingsReadOnly.ini` and the writable `settings.ini`, the duplicate key is automatically **removed** from `settings.ini` at system startup. This ensures that no conflicting values exist and the user file remains uncluttered.
3. **Additional Loading:** All parameters that are *not* located in `settingsReadOnly.ini` are loaded from `settings.ini` and behave normally as writable files.

Parameters are read transparently. If a key is stored in `settingsReadOnly.ini`, its immutable value is always returned.

If an attempt is made to change a read-only key (whether via control functions or 4diac IEC 61499 function blocks), the following occurs:

- The **write attempt is rejected**.
- The value defined in `settingsReadOnly.ini` **remains unchanged**.
- The rejection of the write operation is logged and reported back to the calling block logic.

Schreibzugriffe (`SET`)

Lesezugriffe (`GET`)

Verhalten im Betrieb (Lesen & Schreiben)

Functionality & Priorität beim Start

Behavior in 4diac FORTE (IEC 61499 INI Blocks)

For users of 4diac FORTE control programs, the INI function blocks (`INI`, `INI_AX`, `INI_AUI`, `INI_AR`, etc.) behave as follows with read-only parameters:

- **Read event (`GET`)**: Signals the confirmation event `GETO` as usual. The protected value is present at output `VALUEO`, and `STATUS` reports `"OK"`.
- **Write Event (`SET`)**:
- The **normal success event (`SETO`)** is not triggered, but rather the error event **`SETOE`** (*Set Output Error*).

- The data output **STATUS** provides the understandable message: **"Key is read-only"**.
- The output **QO** indicates the error state.

!!! note “Note for Application Developers” By evaluating the output event SETOE or the status string "Key is read-only", the 4diac application can react specifically to read-only parameters (e.g., displaying a note on the visualization).

The file settingsReadOnly.ini is located on the ECU's memory under: /data/settingsReadOnly.ini

Importing or updating the factory settings is easily done via the ECU's integrated **Web Interface** (File Server):

1. Connect to the ECU's web interface using a web browser.
2. Navigate to the file management (/data).
3. Upload your prepared settingsReadOnly.ini file.
4. After restarting the ECU, the read-only parameters will take effect.

If settingsReadOnly.ini is not present on the ECU, the system will start normally without any limitations. All keys in settings.ini remain fully writable, as before.

Praktisches Beispiel

Verhalten bei fehlender Datei

Übertragung auf das Steuergerät

Einspielen und Verwalten der Werkseinstellungen

Example file settingsReadOnly.ini (factory settings)

[CF-A] UserLanguage = DE
[User] OperatorID = 42
Result in operation:

- NODE1_SA (128), bootTimeVT (90), and DeviceName ("LOGIBUS-NODE-01") are protected and cannot be modified.
- UserLanguage ("DE") and OperatorID (42) can be freely modified and permanently saved by the controller.
- If an old value, NODE1_SA = 130, was accidentally present in settings.ini, the control unit will automatically delete it during boot, ensuring that the default value, 128, is always used.

Beispieldatei settings.ini (Benutzereinstellungen)

Summary & Best Practices

Goal	Recommended Procedure
Save Factory Settings	Create all immutable parameters (e.g., bus addresses, security limits) in settingsReadOnly.ini and upload them to the control unit.
Allow User Settings	Keep parameters that the operator is allowed to adjust (e.g., language, operating modes, counter readings) exclusively in settings.ini.
Enable Parameters	To make a parameter writable again, remove the corresponding key from settingsReadOnly.ini and restart the control unit.

assembling

ARR08X_TO_BYTE

• — ○ • — ○ • — ○ •

Introduction

The function block `ARR08X_TO_BYTE` converts an array of eight Boolean values (`BOOL`) into a single byte value (`BYTE`). Each bit in the resulting byte corresponds to an element of the input array. This operation is useful for bundling multiple binary signals (e.g., switch states or error flags) to save space and preparing them for further processing or communication.

Interface Structure

Event Inputs

- `REQ` (Request): Triggers the conversion operation. Upon receiving an event at this input, the current value of the input array `IN` is read and converted into a byte.

Event Outputs

- `CNF` (Confirm): Triggered as soon as the conversion is complete. This event signals that the output value (the byte) is valid and current.

Data Inputs

- `IN` (Array[0..7] of BOOL): The input array containing the eight Boolean values to be converted. The index `0` corresponds to the least significant bit (LSB, bit 0) of the resulting byte, and the index `7` corresponds to the most significant bit (MSB, bit 7).

Data Outputs

- `OUT` (BYTE): The output value composed of the eight Boolean inputs. The data output is not explicitly named (empty name in the interface) but is accompanied by the event output `CNF`.

Adapters

This function block does not use any adapters.

Operation

Upon receiving a `REQ` event, the block performs a bitwise assignment. Each bit of the internal result byte (`ARR08X_TO_BYTE`) is directly assigned to the corresponding element of the input array `IN`. After these assignments are complete, the `CNF` event is generated, and the calculated byte value is available at the output.

The underlying ST code logic is:
ARR08X_TO_BYTE.0 := IN[0]; ARR08X_TO_BYTE.1 := IN[1]; ... ARR08X_TO_BYTE.7 := IN[7];

Technical Features

- **Hard-wired size:** This block is specifically designed for converting exactly 8 Boolean values. Different blocks are required for other array sizes.
- **Direct bit mapping:** The mapping is deterministic and performed without any arithmetic operations, enabling very fast and resource-efficient execution.
- **Index bit mapping:** It is critical to observe the mapping of array index to bit position in the byte: `IN[0]` ⟶ Bit 0 (LSB), `IN[7]` ⟶ Bit 7 (MSB).

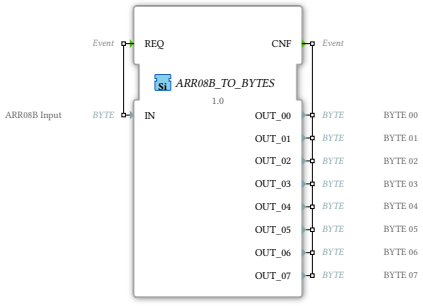
State overview

This function block is stateless. It has no internal memory between calls. Its output at any given time is solely a direct function of the current input values when the `REQ` event occurs.

Application Scenarios

- **Communication Protocols:** Bundling multiple binary device statuses into a single data byte for transmission via serial interfaces or fieldbuses (e.g., PROFIBUS, CANopen).
- **Memory Optimization:** More compact storage of up to 8 switching states or alarm conditions in a single byte variable.
- **PLC Internal Data Handling:** Preparing data for blocks or functions that expect byte or word data types instead of individual Boolean values.

⚖️ Comparison with Similar Building Blocks



- **`BOOL_TO_BYTE` blocks:** Many libraries offer blocks that combine eight individual `BOOL` inputs (e.g., `IN0`...`IN7`) into a `BYTE`. `ARR08X_TO_BYTE`, on the other hand, uses an array as its input, which often makes wiring clearer when dealing with many signals from a common source (e.g., a previous array output).
- **`MERGE`/`PACK` blocks:** More general blocks can combine different data types. `ARR08X_TO_BYTE` is more specialized, simpler, and more efficient for its specific purpose.
- **Bitwise Shifting (`SHL`, `OR`):** The same function could be implemented using a loop and bitwise operations in ST. This pre-built block offers a standardized, ready-to-use, and less error-prone solution.

Conclusion

The `ARR08X_TO_BYTE` function block is a simple yet extremely useful tool for signal processing in IEC 61499 systems. It provides an elegant and efficient method for converting eight Boolean values from an array into a compact byte. Its clear interface and deterministic operation make it a reliable component for automation applications, especially where data needs to be prepared for communication or space-optimized storage.

forwarding

ARR08B_TO_BYTES

• – ○ • – ○ • – ○ •

The function block `ARR08B_TO_BYTES` is used to decompose an 8-element byte array (`ARR08B`) into eight individual byte outputs. It is a utility block for data conversion and forwarding within control applications, especially when structured data from an array needs to be split into discrete signals.

- **REQ**: This incoming event triggers the processing of the function block. Upon its arrival, the data at input `IN` is read and distributed to the individual outputs.

- **CNF**: This outgoing event signals the completion of processing. It is generated simultaneously with the output of the new values at data outputs `OUT_00` to `OUT_07`.
- **IN** (`ARRAY[0..7] OF BYTE`): The input for the 8-byte array to be split. The array has a fixed index range from 0 to 7.
- **OUT_00** (`BYTE`): Contains the value of the array element with index 0 (`IN[0]`).
- **OUT_02** (`BYTE`): Contains the value of the array element with index 2 (`IN[2]`).
- **OUT_03** (`BYTE`): Contains the value of the array element with index 3 (`IN[3]`).
- **OUT_04** (`BYTE`): Contains the value of the array element with index 4 (IN[4]) ... * **OUT_05** (`BYTE`): Contains the value of the array element with index 5 (`IN[5]`).
- **OUT_06** (`BYTE`): Contains the value of the array element with index 6 (`IN[6]`).
- **OUT_07** (`BYTE`): Contains the value of the array element with index 7 (`IN[7]`).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block has no adapter interfaces.

The operation is deterministic and simple: Upon each occurrence of the `REQ` event, the function block reads the entire input array `IN`. Each element of the array is then assigned to a specific byte output. The assignment is made directly according to the array index. After all assignments have been completed, the `CNF` event is triggered to report the successful completion of the operation to subsequent blocks.

The included ST (Structured Text) code shows the direct implementation:
OUT_00 := IN[0]; OUT_01 := IN[1]; ... OUT_07 := IN[7];

- **Fixed Size:** The block is specifically designed for arrays with exactly 8 elements (`ARR08B`). Separate blocks are required for arrays of other lengths.
- **Synchronous Processing:** Processing occurs in a single cycle without delay. The latency between `REQ` and `CNF` is minimal.
- **No Internal State:** The block has no internal memory. The output is a direct function of the current input at any given time.

The function block has no internal states in the sense of a state machine. Its behavior is purely combinatorial and is entirely controlled by the interface events:

1. **Idle State:** Waiting for the `REQ` event.
2. **Execution State:** At `REQ`, the data is transferred and the `CNF` event is immediately generated. The block then returns to its idle state.

- **Data Distribution:** Splitting a received data packet (e.g., from a communication interface) into its individual byte components for further processing in the application.
- **Interface Adapter:** Connecting function blocks that work with array structures to blocks that expect individual byte inputs.
- **Data Logging and Visualization:** Separating array data to selectively display or store individual bytes in HMIs or logging systems.
-
- **`SEL_n` / `MUX` blocks:** These blocks select an element from an array based on an index. `ARR08B_TO_BYTES`, on the other hand, extracts **all** elements simultaneously and in parallel.
- **`BYTES_TO_ARR08B`:** This is the inverse block, which combines eight individual byte inputs into an 8-byte array.
- **Generic Array Splitting Blocks:** More generic blocks might exist that take the array length as a parameter. `ARR08B_TO_BYTES`, due to its fixed size, is simpler, faster, and requires no configuration.

•

The `ARR08B_TO_BYTES` function block is a specialized, efficient, and reliable building block for the fundamental operation of array decomposition. Its strength lies in its simplicity and unambiguity for the specific use case of an 8-byte array. For control applications where this data structure is common, it offers an optimized and maintainable solution compared to manual indexing in more complex blocks.

Conclusion

ARR08B_TO_DWORDS

This function block converts an 8-byte array into two 32-bit data words (DWORDs). It is used to split a contiguous 8-byte data block into two 4-byte integer values.

• – ○ • – ○ • – ○ •

Introduction

The **ARR08B_TO_DWORDS** is a pure conversion function block that creates two separate DWORD values from an incoming 8-byte array. The conversion is performed byte by byte, with the first four bytes assigned to the first output (OUT_00) and the last four bytes to the second output (OUT_01). The function block is triggered by an event (REQ) and outputs a confirmation event (CNF) after the conversion is complete.

Interface Structure

Event Inputs

Event	Description	Data Carried
REQ	Starts the conversion of the input array.	IN (8-byte array)

Event Outputs

Event	Description	Data Carried
CNF	Confirms the completed conversion.	OUT_00, OUT_01

Data Inputs

Name	Data Type	Array Dimension	Description
IN	BYTE	[0..7]	8-byte input array that is split into two DWORDs.

Data Outputs

Name	Data Type	Description

OUT_00	DWORD	First DWORD (bytes 0–3 of the array).
OUT_01	DWORD	Second DWORD (bytes 4–7 of the array).

Adapters

No adapters available.

Functionality

This function block performs a direct byte-by-byte copy from the input array to the output variables:

1. Bytes **IN[0]** to **IN[3]** are assigned to the least significant to most significant bytes of **OUT_00**.
2. Bytes **IN[4]** to **IN[7]** are assigned to **OUT_01**.

The assignment is performed in the structured text body:
OUT_00.%B0 := IN[0]; OUT_00.%B1 := IN[1]; OUT_00.%B2 := IN[2]; OUT_00.%B3 := IN[3]; OUT_01.%B0 := IN[4]; OUT_01.%B1 := IN[5]; OUT_01.%B2 := IN[6]; OUT_01.%B3 := IN[7]; The function block operates without delay or state memory; the outputs are updated immediately upon arrival of the REQ event, and the CNF event is triggered instantly.

Technical Features

- **Endianness**: The function block interprets the array in little-endian format – the first byte (index 0) is assigned to the least significant byte of the DWORD. This assumption is typical for many industrial protocols and systems.
- **No Array Length Check**: The array is assumed to be exactly 8 bytes. A different input size would lead to undefined behavior.
- **Functional Function Block**: The function block is purely functional and has no internal states.

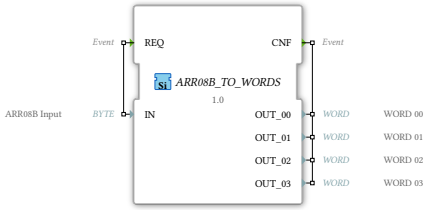
State Overview

The function block has no internal state machine. It operates event-driven and immediately returns the CNF signal after each activation. The outputs remain active until the next REQ activation.

Application Scenarios

- **Data Packet Decomposition**: Separation of an 8-byte telegram into two 32-bit values, e.g., for communication with industrial field devices (CANopen, Modbus, etc.).
- **Sensor Value Processing**: Splitting an 8-byte raw data block from sensors that deliver two physical measured values (4 bytes each).
- **Conversion in the logiBUS Environment**: Within the `logiBUS::utils::conversion::arr::forwarding` package, this is a standard function block for forward conversion of array data.

Comparison with Similar Function Blocks



Function Block	Function	Difference
BYTE_TO_DWORD	Converts a single 4-byte array into a DWORD.	Requires separate calls for each 4-byte segment.
ARR08B_TO_DWORDS	Converts an 8-byte array into two DWORDs at once.	Integrated splitting in a single step reduces the number of calls and code.

This function block thus offers a more compact solution than combining several basic conversion blocks.

Conclusion

The **ARR08B_TO_DWORDS** is a simple yet useful function block for quickly and directly splitting an 8-byte array into two DWORDs. Thanks to its clear byte-to-byte mapping and event handling, it integrates well into dataflow-oriented control applications. Its use requires a little-endian format. Adjustments are necessary for other endianness requirements. Overall, the component is an efficient solution for preprocessing binary data.

ARR08B_TO_WORDS

• – ○ • – ○ • – ○ •

Introduction

The function block **ARR08B_TO_WORDS** is used to divide an 8-byte array into four 16-bit words (WORDs). It is typically used in data preprocessing when raw byte data from sensors or communication interfaces needs to be converted into integer values. The conversion is performed byte-wise, taking the little-endian byte order into account.

Interface Structure

Event Inputs

Event	Description
REQ	Trigger the conversion; The function block processes the current value of `IN` and outputs the results.

Event Outputs

Event	Description
CNF	Confirmation that the conversion is complete and the output values are valid.

Data Inputs

Name	Type	Array Size	Description
IN	BYTE	0...7	Input array of 8 bytes, which is split into four words.

Data Outputs

Name	Type	Description
OUT_00	WORD	Word formed from bytes IN[0] and IN[1] (least significant).
OUT_01	WORD	Word formed from bytes IN[2] and IN[3].
OUT_02	WORD	Word formed from bytes IN[4] and IN[5].
OUT_03	WORD	Word formed from bytes IN[6] and IN[7] (most significant).

Adapter

No adapters available.

Functionality

When the event `REQ` is triggered, the 8-byte array `IN` is processed sequentially. Each pair of consecutive bytes is combined into a 16-bit word, with the first byte (`IN[0]`) being the least significant byte (`%B0`) and the second byte (`IN[1]`) being the most significant byte (`%B1`) of the word (little-endian format). The resulting four words are made available at outputs `OUT_00` to `OUT_03`. The event `CNF` is then sent.

Technical Features

- **Byte Order:** Conversion always occurs in little-endian format, meaning the first byte in the array becomes the least significant part of the word.
- **No Buffering:** The function block is purely combinational and does not store any states. Each `REQ` call processes the current input value.
- **Typing:** Inputs are defined as an array of `BYTE` (0 indexing), outputs as `WORD`. The function block does not require any further type conversions.

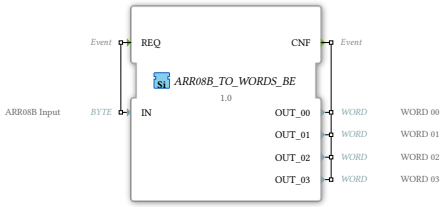
State Overview

The function block does not have an internal state machine. Processing is strictly event-driven:

1. Wait for `REQ`.
2. For `REQ`: Copy the bytes into the output words.
3. Send `CNF` and return to wait mode.

Application Scenarios

- **Sensor Readout:** A temperature sensor provides 8 raw bytes, which must be split into four 16-bit measured values (e.g., two channels with one word each).
- **Protocol Decoding:** A serial protocol transmits user data as a byte array; the function block extracts four 16-bit register values from it.
- **Data Preprocessing in PLC Systems:** Combine multiple byte-oriented interfaces (e.g., Profibus, CAN) into uniform word signals for further processing.



Comparison with Similar Function Blocks

- **`BYTE_TO_WORD`:** Converts only two bytes into a single word; requires four calls for 8 bytes.
- **`ARRAY_TO_WORD` (general):** Usually configurable, e.g., with start index and number of words – `ARR08B_TO_WORDS`, on the other hand, is fixed to 8 bytes and 4 words and is therefore simpler and more performant in this specific case.
- **`WORD_TO_ARR08B` (if present):** The inverse function that packs four words back into an 8-byte array.

Conclusion

The function block **ARR08B_TO_WORDS** offers a lean, specialized solution for decomposing an 8-byte array into four 16-bit words. The hardwired byte mapping ensures high execution speed and ease of use, especially in time-critical environments or for recurring conversion tasks. Little-endian interpretation is the standard for many industrial and embedded systems, so the component requires no additional parameters.

ARR08B_TO_WORDS_BE

• — ○ • — ○ • — ○ •

Introduction

The function block `ARR08B_TO_WORDS_BE` extracts four 16-bit words (WORD) from an 8-byte array (big-endian). It is primarily used to convert binary data streams stored in an ascending byte array and interpret them as an ordered word sequence. This block belongs to the package group `logiBUS::utils::conversion::arr::forwarding`.

Interface Structure

Event Inputs

Event	Description

REQ	Starts the conversion: The incoming byte array IN is converted into the four output words.

Event Outputs

Event	Description
CNF	Confirms successful conversion and indicates that the output values are valid.

Data Inputs

Name	Type	Array Size	Description
IN	BYTE	0..7 (8 bytes)	Input array – the raw data from which the words are extracted.

Data Outputs

Name	Type	Description
OUT_00	WORD	Word from byte 0 (high) and byte 1 (low)
OUT_01	WORD	Word from byte 2 (high) and byte 3 (low)
OUT_02	WORD	Word consisting of byte 4 (high) and byte 5 (low)
OUT_03	WORD	Word consisting of byte 6 (high) and byte 7 (low)

Adapter

No adapters available.

Functionality

Upon arrival of a REQ event, the eight bytes of the input array IN are encoded into four 16-bit words in strict **big-endian order**:

- OUT_00 = (IN[0] << 8) | IN[1]
- OUT_01 = (IN[2] << 8) | IN[3]
- OUT_02 = (IN[4] << 8) | IN[5]
- OUT_03 = (IN[6] << 8) | IN[7]

The output event is then The event CNF is triggered, indicating the validity of all output values. This is implemented directly in the structured text portion of the function block, without an internal state machine.

Technical Features

- **Big-Endian Convention:** The first byte of a word (IN[0], IN[2], ...) is the higher-order byte (%B1), and the second byte (IN[1], IN[3], ...) is the lower-order byte (%B0).
- **Fixed Array Size:** Exactly 8 bytes are expected; the array is declared as ARRAY[0..7] OF BYTE.
- **No side effects:** The function block is purely combinatorial – it requires no internal state and operates within a single event cycle.
- **Typical use:** Converting data from binary protocols (e.g., CAN messages, Modbus registers, or serial streams) that are stored as byte arrays.

State overview

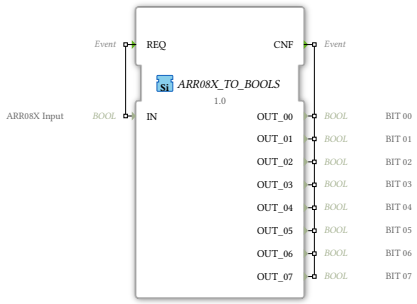
The function block does not have its own state machine. It is triggered by the **event REQ** and outputs **CNF** after data processing. Execution occurs within a single cycle.

State	Description
Idle	Waiting for REQ; outputs retain the last value.
Processing	REQ received – data is being processed.
Completed	CNF is being sent, outputs are valid. The module immediately returns to idle state.

Application Scenarios

1. **Modbus Communication:** An 8-byte register block (e.g., holding register) is received as a byte array and must be split into four 16-bit values.
2. **CAN Messages:** An 8-byte CAN frame contains multiple 16-bit sensor values transmitted in big-endian format.
3. **Serial Data Analysis:** Summarizing consecutive bytes from a serial interface into usable WORD sizes for further processing.
4. **Gateway Functions:** Conversion of binary to general-purpose data in automation processes based on IEC 61499.

Comparison with Similar Building Blocks



Building Block	Difference
`ARR08B_TO_WORDS_LE`	Uses little-endian order (Byte[0] = low byte).
`ARR04B_TO_WORD`	Works with a 4-byte array and creates only one WORD.
`BYTE_TO_WORD`	Converts two individual bytes into one WORD; requires separate concatenation.

ARR08B_TO_WORDS_BE` focuses on the efficient, predefined partitioning of an 8-byte array into four words in big-endian order – ideal for standardized protocols.

Conclusion

The `ARR08B_TO_WORDS_BE` function block offers a simple and reliable method for converting an 8-byte array into four big-endian words. Its compact interface (`REQ`/`CNF` + one input, four outputs) allows for easy integration into existing IEC 61499 applications. Thanks to its direct ST implementation, there are no latencies from state machines, making it particularly suitable for time-critical applications in automation technology.

ARR08X_TO_BOOLS

• – ○ • – ○ • – ○ •

Introduction

The **ARR08X_TO_BOOLS** function block converts an 8-element BOOL array into eight individual BOOL signals. It extracts each bit from the input array and makes it available via its own named data output. This block is particularly useful for breaking down compact array data from higher-level systems or communication interfaces into individual, easily processed logical signals.

Interface Structure

The block has a simple, unidirectional interface with a request/acknowledgment event pair.

Event Inputs

REQ: This event triggers the processing. Upon its arrival, the values of the input array `IN` are read and distributed to the individual outputs `OUT_00` to `OUT_07`.

Event Outputs

- **CNF**: This event is triggered as soon as the extraction of the Boolean values is complete. It confirms the execution of the function block and transmits the new values to all eight data outputs (`OUT_00` to `OUT_07`).

Data Inputs

- **IN** (ARRAY[0..7] OF BOOL): The input array containing the eight Boolean values to be extracted. Index 0 corresponds to the least significant bit (LSB) and is mapped to `OUT_00`.

Data Outputs

- **OUT_00** (BOOL): Extracted bit 0 (LSB) of input array `IN`.
- **OUT_01** (BOOL): Extracted bit 1 of input array `IN`.
- **OUT_02** (BOOL): Extracted bit 2 of input array `IN`.
- **OUT_03** (BOOL): Extracted bit 3 of input array `IN`.
- **OUT_04** (BOOL): Extracted bit 4 of input array `IN`.
- **OUT_05** (BOOL): Extracted bit 5 of the input array `IN`.
- **OUT_06** (BOOL): Extracted bit 6 of the input array `IN`.
- **OUT_07** (BOOL): Extracted bit 7 (MSB) of the input array `IN`.

Adapters

This function block does not use any adapters.

Operation

The operation is deterministic and stateless. Upon each occurrence of the `REQ` event, the function block performs a direct assignment. Each element of the input array `IN` is assigned to its corresponding, individually named output variable. The logic corresponds to the following ST assignment:
```
  iec61131-3 OUT_00 := IN[0]; OUT_01 := IN[1]; OUT_02 := IN[2]; OUT_03 := IN[3]; OUT_04 := IN[4]; OUT_05 := IN[5]; OUT_06 := IN[6]; OUT_07 := IN[7]; Immediately after this operation is completed, the CNF`` event is generated with the new values.
```

Technical Features

- **Real-time behavior:** The function block only performs assignments and causes no significant latency. Execution is completed in one cycle.
- **Memory:** No internal state is stored between calls. The output is a pure function of the current input.
- **Array limits:** The function block is specifically defined for arrays of a fixed size of 8 (indices 0 to 7). Using an array of a different size will result in a compilation error.

State overview

The function block has no internal state (stateless). Its behavior is identical for each call and depends solely on the current values at the data input `IN`.

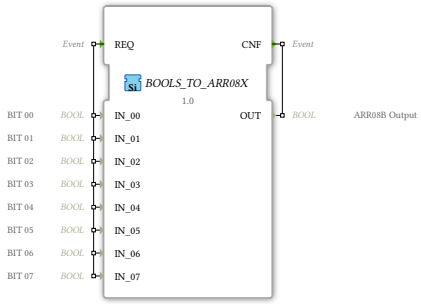
Application Scenarios

- **Bus Telegram Unpacking:** Extracting individual status or control bits from a byte received via field-buses (e.g., CAN, PROFIBUS) or industrial networks.
- **Interface to Bit-Oriented Components:** Preparing array data for controlling individual lamps, valves, or relays addressed via discrete BOOL outputs.
- **Simplified Visualization:** Providing individually addressable signals for HMIs or alarm systems instead of having to work with array indices.
- **Decoding:** Converting a simple 8-bit binary number into its individual logical values.

⚖️ Comparison with Similar Function Blocks

- **`SEL` / `MUX` Function Blocks:** These select a single element from an array based on an index. `ARR08X_TO_BOOLS`, on the other hand, extracts **all** elements simultaneously and in parallel.
- **`BYTE_TO_BOOLS` / `WORD_TO_BOOLS`:** These building blocks decompose a byte or word data element into its individual bits. `ARR08X_TO_BOOLS` operates directly on an array of BOOLs, which is semantically clearer if the source is already a BOOL array. However, the functional effect on the bits is equivalent.
- **Manual Indexing:** Instead of using this building block, one could directly access `IN[0]`, `IN[1]`, etc., in the surrounding algorithm. However, the function block provides a clearer interface description, improves the readability of the FBD network, and encapsulates the functionality.

🛠️ Related Exercises



- Exercise_054

Conclusion

The ARR08X_TO_BOOLS is a specialized, yet very useful conversion module. It provides a simple and efficient method for unpacking a compact 8-bit BOOL array into eight discrete signals. Its clear, stateless operation and the explicit labeling of all outputs significantly improve the readability and maintainability of control applications that use array-based data structures.

reversing

BOOLS_TO_ARR08X

• — ○ • — ○ • — ○ •

Introduction

The function block BOOLS_TO_ARR08X converts eight individual Boolean (BOOL) input signals into a Boolean array (ARRAY[0..7] OF BOOL). It is a fundamental building block for signal aggregation and data structuring in control applications, especially when discrete digital signals need to be bundled for compact processing or transmission.

Interface Structure

Event Inputs

- REQ (Request): Triggers the conversion operation. Upon this event, the current values at the eight IN_xx inputs are read and written to the output array OUT.

Event Outputs

- CNF (Confirm): Triggered as soon as the conversion is complete and the output array OUT is ready with the new values.

Data Inputs

Eight individual Boolean inputs (BOOL), each corresponding to a bit in the resulting array:

- IN_00: Value for bit 00 / Array index 0.
- IN_01: Value for bit 01 / Array index 1.
- IN_02: Value for bit 02 / Array index 2.
- IN_03: Value for bit 03 / Array index 3.
- IN_04: Value for bit 04 / Array index 4.
- IN_05: Value for bit 05 / Array index 5.
- IN_06: Value for bit 6 / array index 6.
- IN_07: Value for bit 7 / array index 7.

Data Outputs

- OUT: The output signal of type ARRAY[0..7] OF BOOL. After the REQ event is triggered, it contains the values present at the inputs at that time, where IN_00 is mapped to OUT[0] and IN_07 to OUT[7].

Adapters

This function block has no adapter interfaces.

Functionality

The functionality is deterministic and simple. Whenever an event arrives at the `REQ` input, the contained ST code is executed. This code directly assigns the value of the corresponding individual `IN_xx` input to each element of the output array `OUT`. The mapping is hardwired:
OUT[0] := IN_00; `OUT[1] := IN_01;` ... OUT[7] := IN_07;`Immediately after this assignment, the`CNF` event is generated to signal the successful completion of the operation. There is no buffering, delay, or logical combination of the input values.

Technical Features

- **Real-time Behavior:** The operation is atomic and very fast, as it consists only of direct assignments. It introduces no significant latency into the control cycle.
- **Size Definition:** The output array is defined with the fixed size `[0..7]`, which corresponds to exactly eight elements.
- **Synchronous Processing:** All input values are acquired synchronously at the time of the `REQ` event. Changes to the inputs during processing have no effect on the current cycle.

State Overview

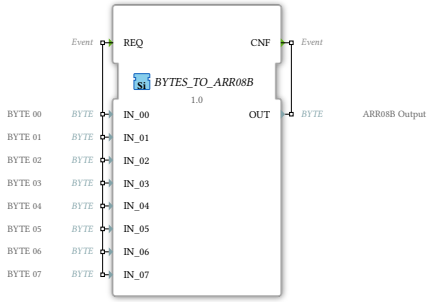
The function block is stateless. It has no internal memory. Its output at any given time is solely a function of the current input values at the time of the last `REQ` event.

Application Scenarios

- **Bundling of Switching States:** Combining the states of multiple limit switches, pushbuttons, or valves into a single array for transmission over a network or to a higher-level control module.
- **Preprocessing for Array-Based Blocks:** Providing input data for function blocks that perform their operations on entire arrays (e.g., logic operations, shift operations).
- **Structuring of I/O Data:** Organizing distributed digital input signals from a PLC into a defined data structure for improved program readability and maintainability.
- **Interface to Visualization Systems:** Easier mapping of many individual signals to a composite symbol or status display in an HMI.

⚖️ Comparison with Similar Blocks

- **`BOOL_TO_xxx` Blocks:** Blocks like `BOOL_TO_INT` or `BOOL_TO_BYTE` also convert multiple Boolean values into a more compact data set. `BOOLS_TO_ARR08X`, on the other hand, explicitly creates an array, which preserves indexed access to each individual bit and maintains the semantic meaning of its position.
- **Manual Wiring:** The alternative would be to directly wire each individual bit to the indices of an array variable block. `BOOLS_TO_ARR08X` encapsulates this operation, improving clarity in the FBD/LD editor and reducing wiring effort.
- **`MERGE`/`CONCAT` blocks:** General-purpose merge blocks can combine various data types. `BOOLS_TO_ARR08X` is specialized and type-safe for exactly eight BOOL inputs and a BOOL array as an output.



🛠️ Related Exercises

- Exercise_054

Conclusion

The `BOOLS_TO_ARR08X` is a specialized, robust, and efficient function block for a common task in industrial automation: bundling discrete signals. Its strength lies in its simplicity, deterministic execution time, and clear interface definition. It is the first choice when eight Boolean signals need to be provided in an ordered array structure for further processing.

BYTES_TO_ARR08B

• — ◦ • — ◦ • — ◦ •

Introduction

The function block `BYTES_TO_ARR08B` converts eight individual `BYTE` values into an array of type `BYTE` with eight elements. It is part of a collection of helper functions for data conversion and array operations.

Interface Structure

Event Inputs

- **REQ**: This event triggers the processing of the function block. Upon its arrival, the values at the data inputs are read and written to the output array.

Event Outputs

- **CNF**: This event is generated after successful processing and assignment of the values to the output array. It indicates the availability of the result. ...

Data Inputs

- **IN_00** (`BYTE`): Value for the array element at index 0.
- **IN_01** (`BYTE`): Value for the array element at index 1.
- **IN_02** (`BYTE`): Value for the array element at index 2.
- **IN_03** (`BYTE`): Value for the array element at index 3.
- **IN_04** (`BYTE`): Value for the array element at index 4.
- **IN_05** (`BYTE`): Value for the array element at index 5.
- **IN_06** (`BYTE`): Value for the Array element at index 6.
- **IN_07** (`BYTE`): Value for the array element at index 7.

Data Outputs

- **OUT** (`ARRAY[0..7] OF BYTE`): The resulting byte array. Indices 0 through 7 contain the values from `IN_00` to `IN_07`, sequentially.

Adapters

This function block does not use any adapters.

Operation

When triggered by the `REQ` event, the block copies the values of the eight `BYTE` inputs directly into the corresponding positions of the output array `OUT`. The assignment is sequential: `IN_00` ⟶ `OUT[0]`, `IN_01` ⟶ `OUT[1]`, and so on, up to `IN_07` ⟶ `OUT[7]`. Immediately after this assignment, the `CNF` event is triggered.

The internal implementation is in Structured Text (ST) and consists of a simple series of assignments.

Technical Features

- **Deterministic Runtime:** The operation has a constant and very short execution time because it consists only of direct assignments.
- **No Buffering:** There is no intermediate storage of the input values. Processing occurs exclusively upon the arrival of a `REQ` event.
- **Fixed Size:** The block is specifically designed for a combination of exactly eight bytes.

State Overview

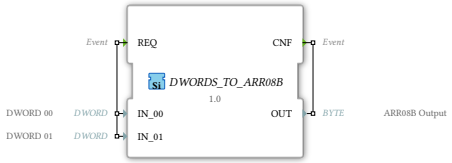
The function block is stateless. Each `REQ` call is independent of previous calls and processes only the currently available input values.

Application Scenarios

- **Data Aggregation:** Combining individual byte values (e.g., from various sources or sensors) into a compact array for further processing or transmission.
- **Protocol and Interface Adaptation:** Preparing data structures for communication protocols or function blocks that expect a byte array instead of individual bytes.
- **Data Restructuring:** Converting between different data representations within a control application.

⚖️ Comparison with Similar Blocks

- **`CONCAT` Blocks:** General-purpose blocks for concatenating strings are not directly comparable, as they are designed for the `STRING` data type.
- **Manual Assignment in ST:** The functionality could be implemented directly in an ST program using assignments. However, the function block encapsulates this logic for improved reusability, readability, and maintainability within FBD/LD diagrams.
- **Custom Array Blocks:** Unlike general-purpose array blocks that have index inputs, `BYTES_TO_ARR08B` is optimized for a specific, fixed task and is therefore easier and faster to use.
-



🛠️ Related Exercises

- Exercise_12x_sub

Conclusion

The `BYTES_TO_ARR08B` is a specialized and efficient utility module for a common data manipulation task. It offers a clear, event-driven interface and saves the user from repeatedly implementing array mapping manually. Its strength lies in its simplicity and unambiguity for the specific use case of combining eight bytes.

DWORDS_TO_ARR08B

• — ○ • — ○ • — ○ •

Introduction

The function block **DWORDS_TO_ARR08B** converts two 32-bit DWORD values into an eight-byte array (BYTE). The conversion is performed in little-endian format (Intel standard), meaning the least significant byte of a DWORD is written to the lowest index position of the output array. The function block is optimized for use on PC-based controllers (e.g., Beckhoff, Wago, B&R, Raspberry Pi).

Interface Structure

Event Inputs

Event	Description
`REQ`	Starts the conversion. The current values of `IN_00` and `IN_01` are read.

Event Outputs

Event	Description

CNF	Sent as soon as the output OUT has been updated.

Data Inputs

Variable	Type	Description
IN_00	DWORD	First 32-bit word (lower order).
IN_01	DWORD	Second 32-bit word (higher order).

Data Outputs

Variable	Type	Description
OUT	ARRAY[0..7] OF BYTE	Output array with 8 bytes (bytes 0–3 from IN_00, bytes 4–7 from IN_01).

Adapters

No adapters available.

Functionality

When a rising edge is detected at the event input REQ, the following logic is executed:

1. The two input DWORDs IN_00 and IN_01 are read byte by byte.
2. The system's internal byte accesses (e.g., IN_00.%B0 for the least significant byte) are used.
3. The bytes are copied into the output array OUT in **little-endian order**:

- OUT[0] ⟵ least significant byte of IN_00
- OUT[1] ⟵ second byte of IN_00
- OUT[2] ⟵ third byte of IN_00
- OUT[3] ⟵ most significant byte of IN_00
- OUT[4] ⟵ least significant byte of IN_01
- OUT[5] ⟵ second byte of IN_01
- OUT[6] ⟵ third byte of IN_01
- OUT[7] ⟵ most significant byte of IN_01

1. After the assignments are complete, the event CNF is sent.

Technical Details

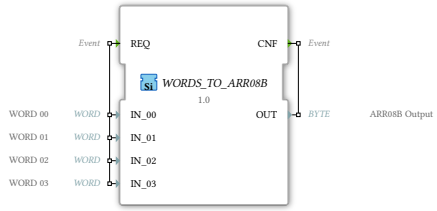
- The byte order follows the **Little-Endian format** (Intel standard), which is natively used on most PC-based controllers (Windows-based systems, Raspberry Pi).
- The function block is implemented as **structured text (ST)** and does not require a state machine – processing occurs linearly with each REQ event.
- The package logiBUS::utils::conversion::arr::reversing used in the ST code indicates a reusable library for conversions.

State Overview

The function block does not have its own state machine. It performs a single, deterministic calculation with each REQ event and signals completion with CNF. There are no internal memory states that persist across multiple calls.

Application Scenarios

- **Data Protocol Preparation**: Conversion of control data (e.g., position values, timer counters) stored as two DWORDs into a byte array for serial transmission (RS-232, CAN, Ethernet).
- **Communication with Endian-Sensitive Devices**: Ensuring the correct byte order when exchanging data with sensors or actuators that expect little-endian.
- **Memory Mapping / Union Replacement**: In languages without union types, this function block serves as a portable method for decomposing DWORD values byte by byte.



Comparison with Similar Function Blocks

- **WORD_TO_ARR04B**: Converts a WORD into a 4-byte array – here, the same approach is extended to two DWORDs.
- **DWORDS_TO_ARR08B_BIGENDIAN**: Alternative function block for big-endian systems (Motorola standard) with reversed byte order.
- **SWAP_BYTES**: Swaps the bytes of a DWORD, but does not return an array. This function block directly creates the complete 8-byte array.

Conclusion

The function block `DWORDS_TO_ARR08B` offers a simple and efficient way to combine two little-endian DWORDs into a byte array. Its consistent focus on PC-based controllers and its clear, maintainable ST implementation make it a reliable tool for data conversion in automation technology.

WORDS_TO_ARR08B

• – ○ • – ○ • – ○ •

Introduction

The function block **WORDS_TO_ARR08B** is used to concatenate four 16-bit words (type `WORD`) into a byte array of length 8 (type `ARRAY[0..7] OF BYTE`). It uses the little-endian format (Intel standard), which stores the least significant bytes first. The block is controlled via an event input and is particularly suitable for PC-based controllers (e.g., Beckhoff, Wago, B&R, Raspberry Pi).

Interface Structure

Event Inputs

Name	Type	Description
`REQ`	Event	Triggers the conversion; all input variables are read and the result is calculated.

Event Outputs

Name	Type	Description
`CNF`	Event	Sent after successful calculation, indicating that valid data is present at output `OUT`.

Data Inputs

Name	Type	Description
`IN_00`	WORD	First Word (Bytes 0 and 1)
`IN_01`	WORD	Second Word (Bytes 2 and 3)
`IN_02`	WORD	Third Word (Bytes 4 and 5)
`IN_03`	WORD	Fourth Word (Bytes 6 and 7)

Data Outputs

Name	Type	Description
`OUT`	ARRAY[0..7] OF BYTE	Result array, containing the 8 bytes in little-endian order.

Adapters

No adapters defined.

Functionality

When a rising edge is detected at the event input `REQ`, the function block performs the following mapping (described in the Structured Text Implementation):

Index `OUT`	Source	Meaning
`OUT[0]`	`IN_00.%B0`	Low-order byte of word 0
`OUT[1]`	`IN_00.%B1`	High-order byte of word 0
`OUT[2]`	`IN_01.%B0`	Low-order byte of word 1
`OUT[3]`	`IN_01.%B1`	Higher-order byte of word 1
`OUT[4]`	`IN_02.%B0`	Low-order byte of word 2
`OUT[5]`	`IN_02.%B1`	Higher-order byte of word 2
`OUT[6]	`IN_03.%B0`	Low-order byte of word 3
`OUT[7]`	`IN_03.%B1`	Higher-order byte of word 3

After the assignments are complete, the output pulse `CNF` is generated.

Technical Features

- **Little-Endian Format**: The bytes of each word are stored in ascending memory address order, with the least significant byte first. This corresponds to the Intel byte order and is common for many PC-based controllers and communication protocols (e.g., Modbus, CANopen, serial interfaces).
- **No Reversal of Overall Order**: The words themselves are inserted into the array in the order `IN_00` to `IN_03`; only within each word is the byte order reversed. If a different implementation is required to also reverse the word order (e.g., Big-Endian at the word level), this is necessary.
- **Immediate Execution**: The function block is purely combinatorial – after the event `REQ`, the result is available in the next execution cycle. No internal state is stored.

State Overview

The function block does not have an explicit state machine. Its behavior is purely event-driven:

1. **Idle**: Waiting for `REQ`.
2. **Processing**: Upon `REQ`, the input values are read and the output calculation is performed.
3. **Complete**: `CNF` is sent; the function block returns to the idle state.

The implementation is deterministic and requires only one execution step.

Application Scenarios

- **Communication with Peripherals**: A microcontroller or IPC sends 16-bit sensor data (e.g., analog-to-digital converter, encoder) via a byte-oriented serial bus. The device packs the words into a byte array that can be transmitted directly.
- **Data Logging**: Combining multiple 16-bit measurements into a buffer for storage or transmission (e.g., CSV, binary format).
- **Protocol Conversion**: Adapting data to the byte order required by a specific protocol (e.g., OPC UA, MQTT binary payload).

Comparison with Similar Function Blocks

- **WORDS_TO_ARR08B** expects exactly four words and creates an array of length 8. For other word/byte counts, related function blocks exist, such as `WORDS_TO_ARR04B`, `WORDS_TO_ARR16B`, or for big-endian.
- Unlike a general-purpose block like `MERGE`, which concatenates arbitrary data types, this function block is specifically optimized for 2-byte-per-word conversion and guarantees the correct byte order.
- Compared to simple variable assignment using `MOVE` or a pure function like `WORD_TO_BYTE`, this block avoids manual index calculations and improves readability.

Conclusion

The function block **WORDS_TO_ARR08B** is a compact, specialized module for converting four 16-bit words into a little-endian byte array. Its clear, event-driven interface and simple implementation make it ideal for use in control applications where data needs to be prepared at the byte level for communication or storage. It belongs to the `logiBUS::utils::conversion::arr::reversing` package family and adds a useful conversion capability to the 4diac toolbox.

]

WORDS_TO_ARR08B_BE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **WORDS_TO_ARR08B_BE** combines four 16-bit words (WORD) into an 8-byte array. The conversion is performed in **Big-Endian format** (Network Byte Order), where the most significant byte is stored first in the output array. This corresponds to the standard representation in network protocols such as Modbus TCP, Siemens S7 communication, or Ethernet headers.

Interface Structure

Event Inputs

Event	Description
`REQ`	Starts the conversion of all four input words.

Event Outputs

Event	Description
`CNF`	Sent once the output array has been fully calculated.

Data Inputs

Name	Type	Comment
`IN_00`	WORD	Word 00 (first word)
`IN_01`	WORD	Word 01 (second word)
`IN_02`	WORD	Word 02 (third word)
`IN_03`	WORD	Word 03 (fourth word)

Data Outputs

Name	Type	Comment
`OUT`	ARRAY[0..7] OF BYTE	8-byte array in big-endian format

Adapters

No adapters available.

Functionality

After receiving the event `REQ`, the values of the four inputs `IN_00` to `IN_03` are read. For each word, the **high byte** (BYTE 1) and then the **low byte** (BYTE 0) are written to the output array. The order in the array is:

- `OUT[0]` = High byte of `IN_00`
- `OUT[1]` = Low byte of `IN_00`
- `OUT[2]` = High byte of `IN_01`
- `OUT[3]` = Low byte of `IN_01`
- `OUT[4]` = High byte of `IN_02`
- `OUT[5]` = Low byte of `IN_02`
- `OUT[6]` = High byte of `IN_03`
- `OUT[7]` = Low byte of `IN_03`

The event `CNF` is then triggered.

Technical Features

- **Big-Endian Format** (Network Byte Order) – the bytes are stored in order, with the most significant byte first. This is required for many industrial communication protocols and network stacks.
- The function block operates **event-driven**: The conversion is only performed when a `REQ` event occurs, so no cyclical calculation takes place.
- The internal implementation uses **Structured Text (ST)** with direct bit element access (`%B1` and `%B0`), ensuring efficient and deterministic conversion.

State Overview

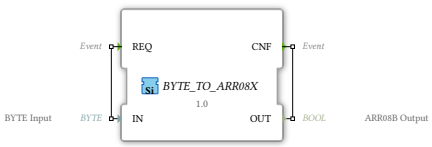
The function block has no explicit internal state (stateless). It immediately performs the calculation upon each `REQ` and signals completion with `CNF`. No blocking is expected during the calculation.

Application Scenarios

- **Network Communication**: Preparation of data for protocols that expect big-endian, e.g., Modbus TCP, Siemens S7 over Industrial Ethernet, or raw Ethernet frames.
- **Data Preprocessing**: Conversion of sensor values or control commands stored as WORD registers into a byte-oriented format.
- **Gateway Functions**: Translation between little-endian controllers and big-endian networks.

Comparison with Similar Components

Component	Special Feature
WORDS_TO_ARR08B_BE	Big-endian, 4 WORDS ⟶ 8 bytes
WORDS_TO_ARR08B_LE	Little-endian (low byte first)
BYTES_TO_WORDS_BE / LE	Reverse conversion
WORDS_TO_ARR16B_BE	Big-Endian, 8 WORDS ⟶ 16 Bytes
WORDS_TO_ARR08N	Possibly unspecified endianness



This function block is specifically optimized for big-endian applications and is kept compact.

Conclusion

WORDS_TO_ARR08B_BE` is a precise, event-driven function block for the big-endian conversion of four WORDS into an 8-byte array. It is ideally suited for all applications that require byte-wise representation in Network Byte Order and simplifies the interface between control logic and communication protocols.

splitting

BYTE_TO_ARR08X

• – ◦ • – ◦ • – ◦ •

Introduction

The function block BYTE_TO_ARR08X converts a single byte value into an array of eight Boolean values (BOOL). Each bit of the input byte is assigned to a separate element in the output array. This block is particularly useful for breaking down compact digital information stored in a byte for individual processing or visualization.

Interface Structure

Event Inputs

- REQ (Request): This event triggers the conversion function. Upon its arrival, the current value at data input IN is processed.

Event Outputs

- CNF (Confirm): This event signals the completion of the conversion. It is output along with the calculated data at output OUT.

Data Inputs

- IN (BYTE): The input for the byte value to be decomposed into Boolean bits.

Data Outputs

- OUT (ARRAY[0..7] OF BOOL): The output array with eight BOOL elements. Element OUT[0] corresponds to the least significant bit (LSB, bit 0) of the input byte, and OUT[7] corresponds to the most significant bit (MSB, bit 7).

Adapter

This function block has no adapter interfaces.

Functionality

When triggered by the REQ event, the block reads the value at the IN input. Then, each individual bit (0 to 7) of the BYTE data type is extracted and assigned to the corresponding index in the BOOL array OUT. The assignment is performed directly:

- OUT[0] receives the value of IN.0 (bit 0)
- OUT[1] receives the value of IN.1 (bit 1)
- ...
- OUT[7] receives the value of IN.7 (bit 7)

After these assignments are complete, the CNF event is output along with the populated array OUT.

- OUT[7] receives the value of IN.7 (bit 7)
- OUT[0] receives the value of IN.0
- OUT[1] receives the value of IN.1
- OUT[1] receives the value of IN.1 ...

Technical Features

- **Direct Bit Access:** The implementation uses the direct bit addressing common in IEC 61131-3 ST (Structured Text) syntax (e.g., IN.0), enabling efficient and readable operation.
- **Fixed Array Size:** The output array is defined with the fixed size [0..7], which corresponds exactly to the bit length of a byte (8 bits).
- **Real-Time Capable:** The block performs a deterministic, stateless operation and is therefore suitable for real-time applications.

State Overview

The function block is stateless. Its behavior is identical for every REQ event and depends solely on the current value at the data input IN. There are no internal variables stored between calls.

Application Scenarios

- **Control Byte Unpacking:** Processing a status or control byte received from a field device or higher-level controller to evaluate individual status bits (e.g., “Motor on,” “Valve open,” “Fault active”) separately.
- **Visualization:** Preparing data for visualization systems (HMIs), which often display individual switching states as separate Boolean lamps or indicators.
- **Interface to Bit-Oriented Logic:** Providing individual bits for subsequent function blocks that operate with Boolean logic (AND, OR, NOT, flip-flops) instead of entire bytes.

⚖️ Comparison with Similar Blocks

- **`BYTE_TO_BOOL` (or similarly named blocks):** Many libraries offer blocks that convert one byte into eight separate BOOL outputs. `BYTE_TO_ARR08X` differs in that it outputs the bits in a structured **array**, which simplifies the wiring in the 4diac IDE, as only one data output is required. Handling in ST code is also more compact.
- **Bitwise reading using `AND` & comparisons:** The same functionality could be achieved through a series of comparisons (`((IN AND 16#01) = 1`, etc.). The `BYTE_TO_ARR08X` block encapsulates this logic in a reusable, easy-to-understand block.
- **Counterpart `ARR08X_TO_BYTE`:** A complementary block that combines an array of eight BOOLs into one byte would perform the reverse operation.

Conclusion

The `BYTE_TO_ARR08X` function block is a simple, specialized, and highly practical conversion module. It elegantly solves a common problem in automation technology by abstracting bit extraction from a byte and providing the results in a manageable array. Its deterministic and stateless nature makes it a reliable and high-performance component for applications where digital bit information needs to be transferred compactly and then processed decentrally.

GET_ANY

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_ANY** function block reads an arbitrary value (type `ANY`) from an InOut variable and provides it as a buffered output value. It serves to capture the current value of a variable source at a specific point in time and temporarily store it for subsequent processing steps.

Interface Structure

Event Inputs

Name	Type	With Variables	Description
REQ	Event	IN	Normal execution request; reads the current value of IN.

Event Outputs

Name	Type	With Variables	Description
CNF	Event	IN, OUT	Confirmation after successful execution; the values of IN and OUT are then valid.

Data Inputs

The function block has no separate data inputs. The source data is provided via the InOut variable.

Data Outputs

Name	Type	Description
OUT	ANY	Buffered output value. Contains the value read from IN at the time of the last REQ execution.

Adapter

None.

Functionality

1. An event at **REQ** triggers the internal algorithm `REQ`.
2. The algorithm executes the assignment `OUT := IN`.

- **IN** is an InOut variable that can be both read and written – here it is used only as a source.
- **OUT** receives the current value of **IN** and stores it temporarily.

1. After the assignment is complete, the **CNF** event is sent. At this point, both **IN** (unchanged) and **OUT** are valid.

Technical Features

- The function block uses an **InOut variable** (`IN`) as its source. This allows direct access to another block output or a global variable without requiring a separate connection via a data input.

IN receives the current value of **IN** and stores it temporarily. - The **type `ANY`** makes the function block generic; it can be used with any data type (e.g., INT, REAL, BOOL, STRING).

- There is only one state, therefore execution is deterministic and occurs in a single step.

State Overview

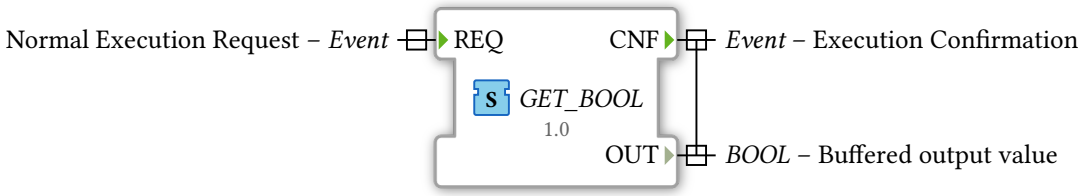
The function block is implemented as a **SimpleFB** with exactly one state:

State	Description
REQ	Executes the algorithm `REQ` and sends CNF. After the action, the function block returns to this state (default).

No other states (e.g., Wait, Error) are defined.

Application Scenarios

- **Value Sampling**: At a specific point in time (event), a current value from a sensor or calculation should be captured, e.g., for later logging or comparison.
- **Signal Decoupling**: If an output needs to be read multiple times without the value changing during processing, GET_ANY buffers the value.
- **Type-Independent Interface**: As a generic buffer in libraries that work with different data types.



Comparison with Similar Function Blocks

- **`GET` Function Blocks** (e.g., `GET_INT`): These are type-specific and require explicit data types. In contrast, `GET_ANY` offers **type flexibility** at the expense of type safety at design time.
- **`MOVE`-FB**: A `MOVE` function block typically copies from an input to an output but does not use an InOut variable. `GET_ANY`, on the other hand, reads directly from an existing variable without requiring a separate input connection.

Conclusion

GET_ANY` is a simple yet powerful function block for **caching any value** from an InOut source. Its generic type design and direct connection to existing variables reduce wiring complexity and increase flexibility in the control logic. It is particularly suitable for applications where a value needs to be frozen at a specific event time.

GET_BOOL

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_BOOL** function block reads a BOOL value from a variable declared as `InOut` and provides it as a buffered output value. This simple encapsulation allows a Boolean signal to be passed from any context without requiring direct read/write access to the source in the calling function block.

Interface Structure

Event Inputs

Event	Description	With Variables
REQ	Normal Execution Request	IN

Event Outputs

Event	Description	With Variables
CNF	Execution Confirmation	OUT, IN

Data Inputs

There are no declared data inputs (*InputVars*). Access to the source variable is exclusively via an InOut parameter.

Data Outputs

Variable	Type	Initial Value	Description
OUT	BOOL	FALSE	Buffered Output Value

Adapters

No adapters are available.

Operation

1. Processing is started at the **event input REQ**.
2. The internal algorithm **REQ** performs the simple assignment `OUT := IN` – the current value of the InOut variable `IN` is copied to the output `OUT`.
3. After the successful copy operation, the **CNF** event is triggered. It passes both the new value `OUT` and the (unchanged) value of `IN` to the subsequent logic.

The output `OUT` remains at the last read value until a new pulse `REQ` updates the value.

Technical Features

- **In/Out Parameter** `IN`: This parameter allows bidirectional access to the connected variable. The function block reads the value but does not modify it. This allows direct access to a variable from the parent application without having to define a separate input variable.
- **Buffering**: The value is buffered locally in the output `OUT`. Changes to the source variable between two `REQ` calls are only applied with the next `REQ` call.
- **Initial Values**: Both `IN` and `OUT` are pre-assigned to `FALSE`, so the function block exhibits defined behavior even without prior initialization.

Buffering:**

State Overview

The function block has a single state:

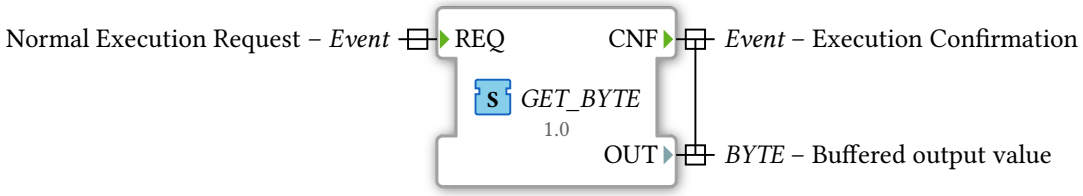
State	Action	Output Event
REQ	`OUT := IN`	CNF

After the algorithm is executed, the initial state is immediately exited (no hold state). The function block is therefore event-driven and waits for the next request after processing.

Application Scenarios

- **Signal Acquisition**: A Boolean sensor value (e.g., from a switch or limit switch) is to be used in the application and simultaneously passed to a higher-level display function block.
- **Decoupling**: A variable from another function block is to be read without the source function block establishing a direct connection. `GET_BOOL` handles the reading.
- **Buffering and Synchronization**: In clocked systems, a `REQ` pulse can be used to sample the current value and hold it for the duration of a cycle.

Comparison with Similar Function Blocks



Function Block	Purpose	Data Type
GET_BOOL	Read a BOOL value via InOut	BOOL
GET_INT	Read an INT value via InOut	INT
GET_REAL	Read a REAL value via InOut	REAL
SET_BOOL	Write a BOOL value via InOut (write)	BOOL

All `GET_*` function blocks share the use of an InOut parameter and event-driven value transfer. The only difference lies in the data type used. Unlike `SET_BOOL`, `GET_BOOL` does not modify the source variable.

Conclusion

The **GET_BOOL** block is a minimalist yet useful component for reading and buffering a single Boolean value. Its strength lies in the clean decoupling of the signal source from the rest of the application code and its ease of use thanks to a single event pulse. It is particularly well-suited for modular and reusable automation solutions that require a clearly defined data flow.

GET_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_BYTE** function block is used to read a variable `BYTE`, which is provided via an **InOut** parameter. The read value is buffered at the output `OUT` and is available after execution. This function block is typically used to retrieve a current `BYTE` value from an external source (e.g., a shared data area) without modifying the source itself.

Interface Structure

Event Inputs

Name	Type	Comment	With Variables
REQ	Event	Normal execution trigger	IN

Event Outputs

Name	Type	Comment	With variables
CNF	Event	Execution confirmation	OUT, IN

Data Inputs

This function block does not have traditional data inputs, but instead uses an **InOut parameter** that can be used as both an input and an output:

Name	Type	Initial value	Comment
IN	BYTE	0	Source variable (read via InOut)

Data Outputs

Name	Type	Initial value	Comment
OUT	BYTE	0	Buffered output value

Adapters

No adapters available.

Functionality

The function block is activated by an event at input `REQ`. The current value of the variable at the **InOut** parameter `IN` is then read and copied to output `OUT`. Finally, event `CNF` is triggered, confirming successful execution. The algorithm is very simple:

OUT := IN; Since `IN` is declared as an InOut parameter, the calling application must provide a BYTE variable that can be both read and (in the case of other function blocks) written. However, `GET_BYTE` only performs a read operation.

Technical Features

- **InOut Parameter**: The function block accesses an external variable directly without connecting it via a separate data input. This enables efficient, direct data binding and saves network resources.
- **Buffered Output**: The read value is buffered in `OUT` and remains until the next execution – even if the source variable changes in the meantime.
- **No State Machine**: The function block consists of a single state, which makes the implementation lean and deterministic.

State Overview

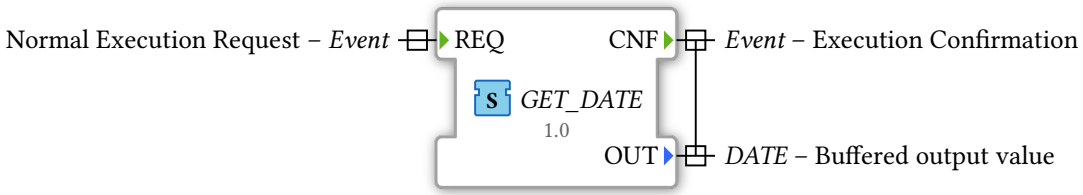
The function block has exactly one internal state:

State	Description	Output Event
REQ	No waiting; immediate execution of the read operation	CNF

There are no wait states or branches.

Application Scenarios

- **Reading Configuration Values**: A `BYTE` value from a central data block (e.g., a global configuration) is transferred to a local buffer.
- **Synchronization Between Function Blocks**: Another function block writes a `BYTE` value to a shared InOut variable, and `GET_BYTE` reads this value as needed.
- **Safe Data Transfer**: The buffered output prevents subsequent logic from reacting to a changing source value – it always works with the value valid at the time of the request.



Comparison with Similar Function Blocks

Function Block	Description	Difference to GET_BYTE
GET_VALUE	Reads a value from an InOut parameter (type-independent)	GET_BYTE is specific to the data type `BYTE` and is therefore more type-safe.
MOVE	Copies a value from an input to an output	MOVE requires separate inputs and does not provide a buffer – GET_BYTE uses InOut.
READ_BYTE	Reads a byte via a hardware address	GET_BYTE operates at the variable level, not at hardware addresses.

Conclusion

GET_BYTE is a simple yet useful building block for reading a `BYTE` value from an external source via an InOut parameter and buffering it. Thanks to its streamlined design (one state, minimal interface), it is particularly suitable for resource-critical applications and for integration into existing communication or storage concepts where direct access to a shared variable is desired.

GET_DATE

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_DATE** function block reads a DATE value from an InOut variable and provides it as a buffered output. When requested by an event, the current value of the source is copied into an internal buffer and then output to the output as well as to the InOut variable itself.

Interface Structure

Event Inputs

Name	Type	Comment	With Variables
REQ	Event	Normal Execution Request	IN

Event Outputs

Name	Type	Comment	With Variables
CNF	Event	Execution Confirmation	OUT, IN

Data Inputs

Name	Type	Comment

IN	DATE	Source Variable (InOut)

Data Outputs

Name	Type	Comment
OUT	DATE	Buffered Output Value
IN	DATE	Source Variable (InOut) – also output with CNF

Adapters

No adapters available.

Functionality

The function block has a simple execution state **REQ**:

1. An incoming event at the **REQ** input triggers processing.
2. The internal algorithm copies the current value of the InOut variable **IN** to the output signal **OUT**.
3. Subsequently, the **CNF** event is sent. This passes both the value of **OUT** and the (unchanged) value of **IN** to the output.

The functionality corresponds to a simple value transfer without further processing or state storage across multiple calls.

Technical Features

- The use of an **InOut** variable allows direct access to an external variable without declaring a separate data input.
- Buffering occurs only during the execution of the algorithm; the current value of **IN** is read again with each new **REQ**.
- The function block is implemented as a **SimpleFB** and has no internal state transitions – processing is purely combinatorial in a single step.

State Overview

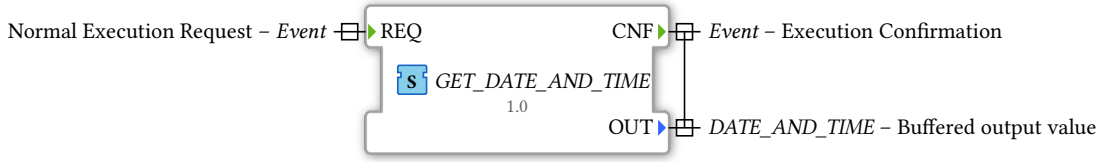
The function block consists of exactly one state:

- **REQ**: Upon entering this state, the algorithm that converts **OUT** to **IN** is executed, and the **CNF** event is sent.

There are no other states or conditional transitions.

Application Scenarios

- **Reading a Global Date**: When a system time or date needs to be read from a central variable and used locally.
- **Buffering for Subsequent Processing**: To hold a DATE value at a specific point in time and pass it to other function blocks.
- **Cascading InOut Accesses**: In combination with other function blocks that access the same InOut variable to ensure consistent data.



Comparison with Similar Function Blocks

- **GET_BOOL**, **GET_INT**, **GET_STRING**, etc.: These function blocks operate on the same principle but with different data types. They all use an InOut variable as a source and a buffered output.
- **SET_DATE**: The counterpart – it writes a value to an InOut variable instead of reading it.
- All these function blocks have a simple structure and are suitable for standardized access to shared data.

Conclusion

GET_DATE is a minimalist yet useful function block for reading a DATE value via an InOut variable. Its simple state logic and direct value copying make it reliable and easy to understand. It is particularly suitable for modular automation solutions where data needs to be exchanged between function blocks using a shared variable.

GET_DATE_AND_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_DATE_AND_TIME** function block is used to read a value of type `DATE_AND_TIME` from a variable declared as InOut and provide it as a buffered output. On each request, the current value of the source (InOut variable) is copied to the output.

Interface Structure

Event Inputs

Event	With	Description
REQ	IN	Normal execution request; triggers the reading of the source data.

Event Outputs

Event	With	Description
CNF	OUT, IN	Confirmation of execution; signals that the output has been updated.

Data Inputs

Name	Type	Description
IN	DATE_AND_TIME	InOut variable as the data source. It is read but not modified.

Data Outputs

Name	Type	Description
OUT	DATE_AND_TIME	Buffered output value that is taken from the InOut source on every REQ.

Adapter

None.

Functionality

The component has a simple internal state **REQ**. When this state occurs (triggered by the event `REQ`), the following algorithm is executed:

OUT := IN;

The event `CNF` is then sent. The value of the InOut variable `IN` is not modified; it is simply read and copied to the output `OUT`. Thus, the function block acts as a **buffer** for any `DATE_AND_TIME` value.

Technical Features

- The use of an **InOut variable** (`IN`) allows direct access to an external variable without having to declare it as a separate input or output. The function block accesses it in read mode.
- The output `OUT` stores the value present at the time of `REQ`. If the source changes between two `REQ` calls, the new value is only applied with the next `REQ` call (buffered provisioning).
- This is a **simple function block** (SimpleFB) without complex state management – only a single execution state.

State Overview

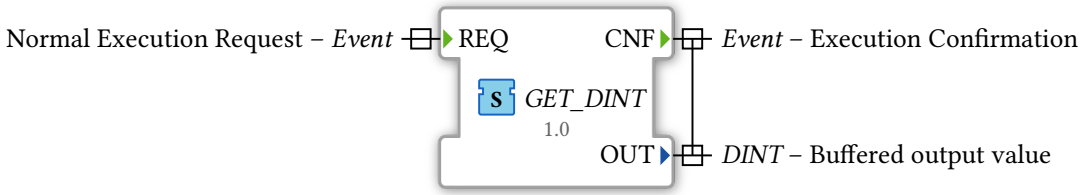
State	Action	Output Event
REQ	`OUT := IN;`	CNF

There is no initial state or other states; the function block waits for the `REQ` event and immediately executes the algorithm.

Application Scenarios

- **Timestamp Acquisition**: Retrieving the current time from a system clock, provided as an InOut variable, at a defined control point.
- **Buffering of Date/Time Values**: Temporarily storing a current date/time value for later processing steps.
- **Synchronization**: Transferring a common time value from a central source to various function blocks.

Comparison with Similar Function Blocks



- **GET_DATE_AND_TIME**, unlike function blocks such as `E_GET_TIME` (real-time clock query) or `TIME_GET` (current system time): This function block does not use a built-in clock but reads from any InOut variable. This makes it more flexible, e.g., for accessing application-specific time values.

GET_DATE_AND_TIME Compared to a simple assignment block (e.g., `MOVE` with `DATE_AND_TIME`), it offers an event-driven, explicit request and explicit acknowledgment (`REQ`/`CNF`), which is advantageous for time-critical control applications.

Conclusion

GET_DATE_AND_TIME is a lean, clearly structured function block that allows reading and buffering a `DATE_AND_TIME` value from an InOut variable. Its ease of use and explicit event control make it a useful tool for reliably acquiring time data in automation applications.

GET_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **GET_DINT** reads a DINT value from an InOut variable and provides it as a buffered output value. The variable itself is not modified; the block serves purely as a read and buffer block.

Interface Structure

Event Inputs

- **REQ** – Normal execution command (activates reading the InOut variable).

Event Outputs

- **CNF** – Confirmation of execution (sent after successful value transfer).

Data Inputs

There are no traditional data inputs. The value source is provided via the InOut variable described below.

Data Outputs

- **OUT** (Type: DINT, Initial Value: 0) – Buffered output value containing the current value of the InOut variable.

Adapter

None.

Special Feature: The function block uses an **InOut variable** named **IN** (Type: DINT, Initial Value: 0). This variable serves as the source for the read operation. It is neither a pure data input nor a pure data output, but allows direct access to a memory location within the caller context. The function block accesses this variable for reading.

Functionality

When the **REQ** event input is activated, the function block performs the following steps:

1. The current value of the InOut variable **IN** is read.
2. This value is copied (buffered) to the data output **OUT**.
3. The event output **CNF** is then sent to signal successful execution.

Since this is a single action, the function block is deterministic and requires no further state transitions.

Technical Features

- **Direct Memory Access:** By using an InOut variable, the function block can access a variable outside its own instance. This allows data sharing between different function blocks without additional input connections.
- **Buffering:** The **OUT** output holds the read value until the next activation of **REQ**. This allows the value to be used multiple times without re-querying the source.
- **No Side Effects:** The function block does not modify the InOut variable **IN** it only reads its value.

State Overview

The function block has a single state, **REQ**. When this state is activated, the algorithm's action (copying the value) is executed, and the state is exited, sending **CNF**.

- – **REQ** (Start state and only state)
- Action: `OUT := IN;`
- Output event: **CNF**

There are no branches, loops, or wait times.

Application Scenarios

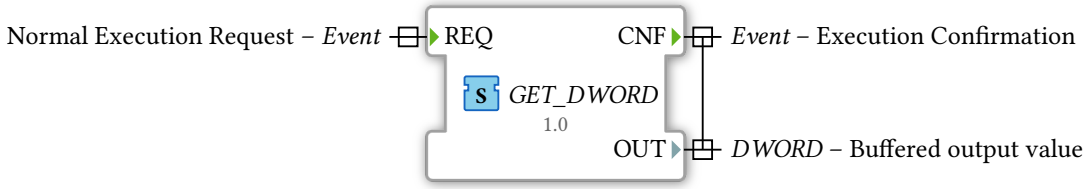
- **Buffering a DINT Value:** In a control application, a measured value (e.g., from a sensor) should only be read on request and temporarily stored for further processing.
- **Reading Shared Variables:** If multiple function blocks need access to a shared variable, **GET_DINT** can provide the current value without requiring the variable to be used as a data input for each function block.
- **Interface Decoupling:** Separating the read time from the actual processing through event-driven buffering.

Comparison with Similar Function Blocks

In the 4diac IDE, analogous function blocks exist for other data types (e.g., `GET_INT`, `GET_BOOL`). The basic mechanism is identical; only the data type differs.

Unlike a **MOVE** function block, which copies a value from an input to an output, **GET_DINT** reads the value from an InOut variable and buffers it. This allows reading variables that cannot be directly connected as data inputs.

Conclusion



GET_DINT is a simple yet useful function block for event-driven reading and buffering of a DINT value from an InOut variable. Its strength lies in its ability to access shared variables and provide the read value without any side effects. Its clear structure and low complexity make it a reliable tool for many control tasks.

]

GET_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `GET_DWORD` is used to read the current value of a variable of type `DWORD`, provided as an InOut parameter, and to provide this value as a buffered output. The read operation is controlled by an event.

Interface Structure

Event Inputs

Event	Data Type	Comment
`REQ`	`Event`	Request to read the InOut variable and provide the output value

Event Outputs

Event	Data Type	Comment
`CNF`	`Event`	Confirmation that the read operation has completed and the output has been updated

Data Inputs

Name	Data Type	Comment
`IN`	`DWORD`	Source variable (InOut). The current value of this variable is read at `REQ`. Initial value: 0

Data Outputs

Name	Data Type	Comment
`OUT`	`DWORD`	Buffered output value. Contains the value read during the last execution. Initial value: 0

Adapter

No adapters available.

Functionality

When an event occurs at input `REQ`, the algorithm `REQ` is executed. This assigns the current value of the input variable `IN` to the output variable `OUT`. The event `CNF` is then sent.

The function block buffers the read value; that is, `OUT` retains its value until a subsequent `REQ` updates it. The InOut variable `IN` is directly bound to a parent variable, so each read operation returns the actual current value of this variable.

Technical Details

- **InOut Parameters:** `IN` is declared as an InOut variable. This means it serves as a reference to an external variable. The function block reads the value of this referenced variable but does not modify it (no feedback).
- **Initial Values:** Both `IN` and `OUT` are initialized to `0`. The initial value of `IN` only takes effect if the referenced variable is not explicitly set or is used in an environment without an external value.

- **No State Machine Complexity:** The function block is implemented as a simple SimpleFB with only one state. There are no internal state transitions other than executing the action.

State Overview

The function block has a single state, `REQ`:

State	Description
`REQ`	Waits for the event `REQ`. Upon its occurrence, the action `REQ` (OUT := IN) is executed, and then the event `CNF` is sent. After `CNF`, the function block remains in the same state.

Application Scenarios

- **Buffering a Sensor Signal:** A DWORD sensor value (e.g., counter reading) is to be sampled at specific times and temporarily stored for further processing.
- **Decomposing DWORD Data:** In combination with other function blocks such as `EXTRACT_BYTE` or `SPLIT_DWORD`, the read value can be decomposed into individual bytes or bits.
- **Updating the Process Image:** This function block is suitable for transferring the current value of an external global variable (e.g., from an industrial fieldbus) to a local buffer in a controlled manner.

Comparison with Similar Function Blocks

- **GET_DWORD with Simple Input:** A hypothetical function block with a normal data input (`VarInput`) would not pass the value by reference, but would use the current input value with each event. In contrast, `GET_DWORD` with InOut offers a fixed binding to a specific variable, which is more consistent in scenarios with multiple accesses to the same variable.
- **SET_DWORD:** The symmetric function block `SET_DWORD` would *set* the value of an InOut variable, while `GET_DWORD` only reads it. Both use the InOut concept, but with opposite actions.
-

Conclusion

GET_DWORDis a simple yet useful building block for the controlled retrieval of a DWORD value from an externally referenced variable. Its strength lies in buffering the value and separating the source (InOut) from the output (OUT). Thanks to its simple state machine and the standardizedREQ/CNF` interface pattern, it can be easily integrated into existing 4diac applications.

GET_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_INT** function block is used to read the current value of an INT variable (defined as an InOut parameter) and provide it as a buffered value at the output. Buffering occurs with each execution cycle, ensuring the output value remains stable until the next request.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution request; triggers the reading of the InOut variable **IN**.

Event Outputs

Event	Description
CNF	Execution confirmation; indicates that the value of **IN** is buffered and available at output **OUT**.

Data Inputs

– *No standalone data inputs available.*
The input value is provided via the InOut parameter **IN** (see next section).

Data Outputs

Output	Type	Description
OUT	INT	Buffered output value containing the last read value from **IN**. Initial value: 0.

Adapters

– *No adapters available.*

InOut Variables (Implicit)

Variable	Type	Description
IN	INT	Source of the value to be read. Can be used as both input and output (read-only here). Initial value: 0.

Functionality

The FB operates as a simple read buffer:

1. Upon arrival of the **REQ** event, the **ST** algorithm `REQ` is executed:

``structured text OUT := IN;

1. The current value of the InOut variable **IN** is copied to the output **OUT**.
2. The **CNF** event is then issued to signal the completion of the operation.

Since **IN** is declared as an InOut parameter, the function block directly accesses the memory location of the parent application. The value is not modified, but simply read and temporarily stored.

Technical Features

- **InOut Parameter**: Using an InOut variable allows direct access to the data source without separate data inputs and outputs. This reduces the number of connections and saves resources.
- **Buffering**: The output **OUT** retains its value until the next **REQ** call. This ensures that the output value is independent of any changes to the source between two read cycles.
- **Initial Values**: Both **IN** and **OUT** start with 0, so defined values are available even without prior execution.

State Overview

The function block (FB) has a single state: **REQ**

- **REQ**: When activated, the algorithm `REQ` is executed, followed by the **CNF** event. The state persists (no transition to another state).

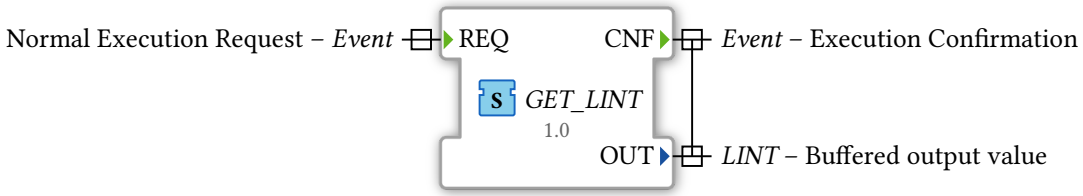
State	Entry Condition	Action	Output Event

REQ	Event **REQ** received	`OUT := IN;`	CNF

Application Scenarios

- **Data Buffering**: An INT value used by multiple function blocks should be stably available without each block having to directly access the source.
- **Synchronization**: In time-critical control systems, the current value of a variable can be "frozen" at a specific point in time and processed later.
- **Replacement of a MOVE function block**: If direct memory access via InOut is preferred for performance reasons, **GET_INT** replaces the classic MOVE function block with separate input and output.

Comparison with similar function blocks



Function block	Input type	Buffering	Special feature
GET_INT	InOut (INT)	Yes (one-time read on REQ)	Accesses the original variable, no additional variable required
MOVE (e.g., IEC 61131-3)	Input (INT)	Yes (on every execution)	Copies the value from an explicit input to an output
F_TRIG / R_TRIG	Input (BOOL)	No (edge detection only)	Works with Boolean values

The main difference lies in the elimination of a separate data input through the use of an InOut parameter.

Conclusion

GET_INT is a simple yet effective function block for buffered readout of an INT variable. By using an InOut parameter, it reduces connection overhead and is particularly suitable for applications requiring a stable instantaneous value. Its clear, low-state structure makes it reliable and easy to understand.

GET_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **GET_LINT** reads a value of type **LINT** from an InOut variable and makes this buffered value available at its output. The block is part of the library `logiBUS::utils::conversion::provide` and implements a simple read-buffer functionality.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Normal Execution Command

The event input REQ triggers the execution of the function block. The current value of the InOut variable **IN** is read and temporarily stored in the output **OUT**.

Event Outputs

Name	Type	Comment

CNF	Event	Execution Confirmation

The CNF event is sent after successful processing of the REQ event. It signals that the OUT output contains the current value of the InOut variable IN.

Data Inputs

Name	Type	Comment
IN	LINT	Source Variable (InOut) – Initial Value: 0

IN is declared as an InOut variable. It can be both read and written, but in this function block, it is only read. The passed value is copied to the OUT output with each REQ event.

Data Outputs

Name	Type	Comment
OUT	LINT	Buffered Output Value – Initial Value: 0

The output **OUT** holds the last value read from the InOut variable **IN**. It is updated with each REQ event.

Adapter

This function block has no adapter interfaces.

Functionality

The GET_LINT function block implements a simple buffer function. It has a single entry state **REQ**, which is activated by an event at the corresponding input. In this state, the algorithm `REQ` is executed:

OUT := IN;

The confirmation event **CNF** is then sent. The output **OUT** then contains the current value of the InOut variable **IN**. The function block then waits for the next REQ pulse.

Technical Features

- **InOut Variable**: The function block uses an InOut parameter (`IN`). This allows direct access to a variable that can be both read and written. In the case of GET_LINT, however, the value is only read and not modified.
- **LINT Data Type**: The function block works exclusively with the 64-bit integer type LINT (Long Integer). It is intended for environments where large integer values are processed.
- **Simplest State Machine**: There is only one state with one direct action and one output. This makes the function block deterministic and resource-efficient.
- **No Error Handling**: The function block does not contain any plausibility checks or timeouts. It assumes that the InOut variable provides valid data.

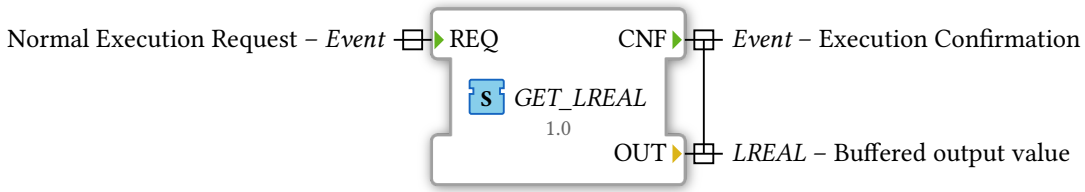
State Overview

State	Action	Output
REQ	Copy from IN to OUT	CNF

The function block starts in the **REQ** state and returns to the same state after executing the action and sending CNF (endless loop on each event).

Application Scenarios

- **Caching a LINT Value**: When a LINT value needs to be read from a global variable or another function block and held constant for a specific period (e.g., for subsequent processing).
- **Synchronization**: The function block can be used to capture the current value of an InOut variable at a specific clock cycle and pass it to other function blocks.
- **Decoupling**: The buffer decouples the reading function block from the source – changes to the source only take effect after the next REQ pulse.
- **Simple Value Transfer**: In control systems, GET_LINT can be used to retrieve an external measured value or a parameter from another function block.



Comparison with Similar Function Blocks

- **GET_DINT / GET_BOOL**: Analogous function blocks for other data types (DINT, BOOL). The functionality is identical; only the data type differs.
- **MOVE (e.g., MOVE_INT)**: A MOVE function block also copies a value but uses input and output variables by default instead of InOut. InOut variables allow a direct reference to the source without additional data flow.
- **LINT_READER** (fictitious): A hypothetical function block that offers additional functions such as buffer timeout or read lock. GET_LINT, on the other hand, is minimalist and fast.

Conclusion

The GET_LINT function block offers a lean and reliable method for reading a LINT value from an InOut variable and buffering it. Thanks to its simple state machine and clear interface, it is ideally suited for basic synchronization tasks in IEC 61499-based systems. The use of InOut parameters keeps the implementation flexible without requiring additional data lines or protocols.

GET_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `GET_LREAL` provides read access to a `LREAL` variable (64-bit floating-point number) which is passed as an InOut parameter. The read value is buffered internally and made available at the output `OUT`. Execution is triggered by an event.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Normal Execution Trigger; Reads the value of `IN`

Event Outputs

Event	Data Type	Comment
CNF	Event	Confirmation of execution; sent after reading

Data Inputs

This function block does not have its own data inputs. The source data is provided via the InOut parameter `IN`.

Data Outputs

Output	Data Type	Initial Value	Comment
OUT	LREAL	0.0	Buffered Output Value

Adapter

No adapters available.

Functionality

1. An event at input `REQ` triggers processing.

2. The function block executes the ST instruction `OUT := IN;`. The current value of the InOut variable `IN` is read and temporarily stored in the local output variable `OUT`.
3. After successful reading, the event `CNF` is output. The value of `OUT` is retained until the next execution.

Technical Features

- The source `IN` is declared as an **InOut variable**. It must be linked to an actual variable (e.g., a global or hardware resource) by the calling environment.
- The function block buffers the read value: as long as no new `REQ` pulse is received, `OUT` returns the last read state.
- Both parameters (`IN` and `OUT`) are initialized with the value `0.0`.

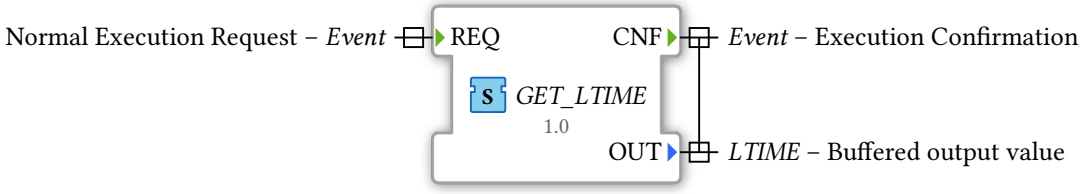
State Overview

Since this is a simple function block (SimpleFB), there is only one ECC state:

State	Action	Output Event
REQ	`OUT := IN;`	CNF

Application Scenarios

- **Buffered reading of a high-frequency process variable** (e.g., temperature or pressure) to keep the value constant during the control cycle.
- **Accessing a shared memory variable** in a multitasking environment where decoupled read speed is desired.
- **Preparing data for downstream calculations** that rely on a stable, buffered floating-point value.



Comparison with Similar Components

Components such as `GET_REAL` or `GET_INT` operate on the same principle, but with shorter data types. `GET_LREAL` is specifically designed for applications requiring high numerical accuracy (64-bit). Unlike pure read blocks without buffering (e.g., direct variable linking), the buffered output guarantees deterministic delivery that is independent of the time of the read.

Conclusion

GET_LREAL`is a simple, reliable block for buffered reading of a`LREAL` source. It is particularly suitable for decoupling read and processing logic and ensures that the provided value remains constant throughout a complete execution cycle.

GET_LTIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **GET_LTIME** is used to read the current value of an LTIME variable and provide it as a buffered output value. It accesses the source via an InOut interface and makes the read value available at the output as soon as an event occurs. This enables controlled, one-time reading of a time variable.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Normal execution command. Associated with the input value IN.

Event Outputs

Event	Data Type	Comment
CNF	Event	Execution confirmation. Connected to the outputs OUT and IN.

Data Inputs

This function block does not have traditional data inputs. Access to the source value is exclusively via the InOut variable.

Data Outputs

Name	Data Type	Comment
OUT	LTIME	Buffered output value (initial value LT#0s).

Adapter

None.

Functionality

This function block implements simple, event-driven copy logic:

1. An incoming **REQ** event triggers the execution of the internal algorithm.
2. The algorithm assigns the current value of the InOut variable **IN** to the output **OUT** (`OUT := IN;`).
3. After successful assignment, the output event **CNF** is sent to signal completion to the calling instance.

Thus, the value of the external LTIME variable is only read when the REQ event arrives and is buffered in the output until the next read.

Technical Features

- **InOut Variable**: The source is accessed via an InOut interface, which represents a direct reference to an external variable. Changes to the external variable between two REQ calls are only applied during the next read operation.
- **Buffering**: The read value remains in the output OUT until another REQ event arrives. This protects against asynchronous changes to the source during processing.
- **Reading Back the Input**: The **CNF** event is connected not only to OUT but also to IN. This can be used in certain runtime environments to control the forwarding of the InOut value, but it has no additional functional significance in the standard behavior.

State Overview

The function block is implemented as a SimpleFB and has exactly one internal state:

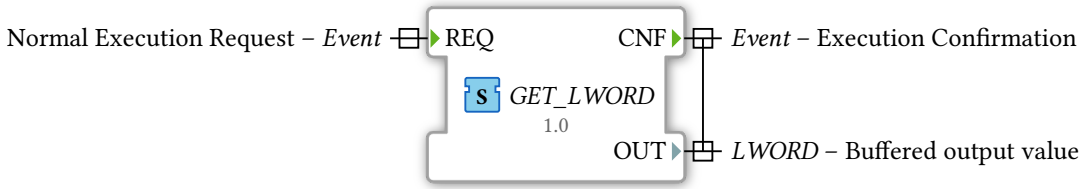
State	Action	Output Event
REQ	Algorithm REQ (OUT := IN)	CNF

After receiving **REQ**, the state is traversed once and the output is generated. There are no further states or branches.

Application Scenarios

- **Timestamp Capture**: Freezing a current system time value (LTIME) once at a specific event, e.g., an alarm signal.
- **Synchronization of Time Measurements**: Reading a shared timer in an industrial controller to pass consistent time data to various downstream function blocks.
- **Buffering of Time Values** in data-driven architectures where an LTIME variable is used multiple times but must be read at precisely the same time.

Comparison with Similar Function Blocks



- **GET_VALUE (for other data types)**: Functions analogously, but for scalar data types such as INT, REAL, etc. GET_LTIME is specialized for the LTIME data type.

- **Latch Function Blocks**: While latch blocks store and hold a value upon an event, GET_LTIME additionally generates an acknowledgment event and reads from an InOut variable instead of a normal data input.
- **MOVE Block**: A MOVE block also copies a value from an input to an output, but without event control and without InOut support. GET_LTIME offers an event-driven, buffered version.

Conclusion

The **GET_LTIME** function block is a simple yet effective component for the controlled reading of an LTIME variable via an InOut interface. Its event-driven operation and buffering of the output value make it particularly suitable for time-critical applications where a consistent time value is required at a defined point in time. The clear interface and simple state logic facilitate integration into larger control applications.

GET_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_LWORD** function block is used for the consistent retrieval of an LWORD value from an **InOut variable**. It buffers the current value of the source variable and makes it available at the output `OUT`. This is particularly useful when the content of a shared variable needs to be saved at a defined point in time without being affected by subsequent write operations from other function blocks.

Interface Structure

Event Inputs

Event	Description
`REQ`	Starts the read operation. The current value of `IN` is transferred to `OUT`.

Event Outputs

Event	Description
`CNF`	Confirms successful completion of the operation. Triggered after the copy operation.

Data Inputs

This function block does not have traditional data inputs but uses an **InOut parameter** that functions as a bidirectional interface.

Data Outputs

Variable	Type	Description
`OUT`	`LWORD`	Buffered output value. Contains the copy of the value of `IN` at the time of the last `REQ`. Initial value = `0`.

Adapter

None available.

Functionality

The function block implements a simple sequence:

1. **Event `REQ`** triggers the execution of algorithm `REQ`.
2. **Algorithm `REQ`**: The instruction `OUT := IN;` copies the current value of the InOut variable `IN` to the output buffer `OUT`. The InOut interface ensures direct read access to the source variable.
3. After the assignment is complete, the output event **`CNF`** is sent. The event outputs `CNF` are linked to both `OUT` and `IN`, allowing subsequent function blocks to use both the new value and the reference to the InOut variable.

Buffering ensures that the value of `OUT` remains stable during a run cycle, even if the source `IN` is modified by other function blocks in the meantime.

Technical Features

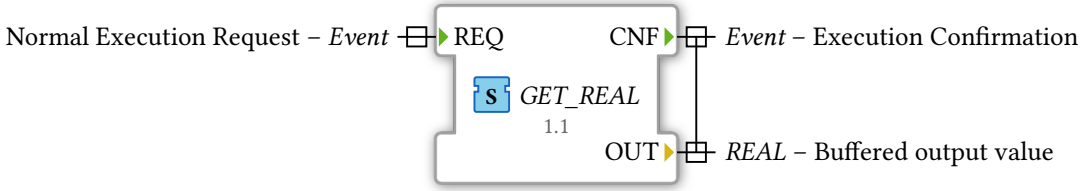
- **InOut Parameter**: The variable `IN` is declared as `InOutVar`. This allows the function block to directly access an external memory location without requiring an additional connection as a data input. The function block reads this value but does not modify it.
- **Simple State Logic**: The component has only a single state, `REQ`. Therefore, exactly one action is executed for each `REQ` event – execution is deterministic and instantaneous.
- **Variable Type**: `LWORD` (64-bit logarithmic or bifield value) is treated as a safe buffer.

State Overview

State	Description
`REQ`	Initial and only state. Upon receiving `REQ`, the algorithm is executed and `CNF` is sent. The state is retained, so the process is repeated upon receiving `REQ` again.

Application Scenarios

- **Consistent Sampling**: A `GET_LWORD` function block can be used to read the value of a cyclically updated sensor at a defined time and store it for further processing (e.g., a calculation chain).
- **Preventing Race Situations**: In systems with multiple parallel function blocks accessing the same memory location, buffering prevents a function block from receiving an inconsistent value in the interim.
- **Data Logging**: A snapshot can be created using `GET_LWORD` before a measurement is stored in a log memory.



Comparison with Similar Components

- **`GET_INT`, `GET_DWORD`, `GET_BOOL`** etc.: These components follow the same principle but differ in data type. `GET_LWORD` is specifically designed for 64-bit values.
- **Simple Input Variable**: A pure data input would require the connecting component to buffer the value itself or constantly update the connection. The InOut mechanism provides a reference to the original, which is more direct and memory-efficient in some architectures.
- **`MUX` Components**: A multiplexer could also select a value but requires additional control lines. `GET_LWORD` is optimized for one-time, deterministic reading.

Conclusion

The function block `GET_LWORD` is a simple yet effective building block for the safe and time-controlled querying of an InOut variable of type `LWORD`. Its minimal state machine and direct copy logic make it ideal for real-time applications requiring consistent data retrieval. By utilizing the InOut concept, efficient coupling to existing memory locations is achieved without increasing the complexity of the connection structure.

GET_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_REAL** function block is used to read a REAL value from an **InOut variable** and make it available in a buffered output. The read value is obtained from the InOut variable `IN` when an event is received at input `REQ` and output at output `OUT`. After execution, the acknowledgment event `CNF` is sent.

Interface Structure

Event Inputs

Event	Description	With Variables
REQ	Normal execution request – triggers reading the InOut variable.	`IN`

Event Outputs

Event	Description	With Variables
CNF	Execution Acknowledgement – sent after processing `REQ`.	`OUT`, `IN`

Data Inputs

Variable	Type	Initial Value	Description
IN	REAL	0.0	InOut variable whose current value is read.

> **Note:** `IN` is declared as an *InOut variable* – it can be both read and written. However, in this function block, it is only read.

Data Outputs

Variable	Type	Initial Value	Description
OUT	REAL	0.0	Buffered output – holds the read value of `IN` until the next update.

Adapters

No adapters available.

Functionality

1. An incoming event at input `REQ` triggers the execution of the internal algorithm `REQ`.
2. In the algorithm, the current value of the input variable `IN` is copied to the output variable `OUT`:

```
OUT := IN;
```

1. The confirmation event `CNF` is then sent. The outputs `OUT` and `IN` are associated with the event, so they are valid simultaneously.
2. The output value is retained until another `REQ` event arrives and `OUT` is rewritten.

Technical Features

- **InOut Usage:** The function block uses an InOut variable (`IN`). This can be written to or read from externally; here, it serves exclusively as a source.
- **Initialization:** Both REAL variables are pre-assigned to `0.0`.
- **Minimal Overhead:** The function block (FB) has only one state (`REQ`) and a simple assignment algorithm – it operates without delay or additional logic.
- **Standard Compliance:** The function block is defined according to IEC 61499-1 and is intended for use in automation environments such as 4diac IDE.

State Overview

The FB has only one state:

- **State `REQ`:**

Upon entry, the algorithm `REQ` is executed (OUT := IN) and the event `CNF` is sent. The FB remains in this state and is always ready for the next request.

There are no further states or branches – the function block is deterministic and reacts immediately to every `REQ` event.

Application Scenarios

- **Reading a Process Value:** In a PLC, `GET_REAL` can be used to read a current sensor value, which is available as an InOut variable, and pass it to a subsequent function block (e.g., for calculations or visualization).
- **Value Comparison Between Function Blocks:** If another function block provides an InOut interface with a REAL value, `GET_REAL` can retrieve this value and make it available as a buffered output.
- **Testing and Simulation:** The function block is suitable for debugging to capture and log the current value of a variable at a specific point in time.

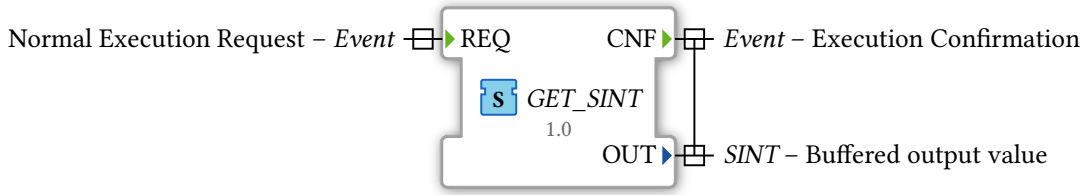
Comparison with Similar Function Blocks

Similar function blocks exist for other data types, e.g., `GET_BOOL`, `GET_INT`, `GET_LREAL`, etc. They all share the same principle: reading an InOut variable and providing it as a buffered output. The difference lies solely in the data type and the associated precision or value range.

Function Block	Data Type	Application Area
GET_BOOL	BOOL	Binary Signals
GET_INT	INT	Integers (16 bits)
GET_REAL	REAL	Floating-Point Numbers (32 bits)
GET_LREAL	LREAL	Precise Floating-Point Numbers (64 bits)

All these function blocks can be used analogously and offer a uniform interface for accessing InOut variables.

Conclusion



The `GET_REAL` function block is a lean and reliable block for reading a REAL InOut variable. It fulfills a fundamental task in the IEC 61499 world: forwarding a value from a bidirectional interface to a buffered output. Its simplicity and clear semantics make it suitable for both production and testing purposes. Its combination with parallel function blocks of other data types makes it a flexible tool in automation technology.

GET_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_SINT** function block is used to read a value of the data type `SINT` (signed short integer) from a variable declared as `InOut` and provide it as a buffered output. It is typically used to access a shared variable or a physical input without modifying the original value. The function block operates according to the **IEC 61499** standard.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Normal execution request. Triggers the reading of the InOut variable.

- **With Link**: The event input REQ is linked to the data variable IN.

Event Outputs

Event	Data Type	Comment
CNF	Event	Confirmation of execution. Sent after a successful copy operation.

- **With Link**: The event output CNF is linked to the data variables OUT and IN.

Data Inputs

This function block does not have traditional data inputs. Instead, it uses a variable named InOut.

Data Outputs

Variable	Data Type	Initial Value	Comment
OUT	SINT	0	Buffered output value. Contains the copy of IN after a successful REQ execution.

Adapter

None.

Functionality

The function block performs a simple copy operation:

1. An event at the input REQ triggers the execution of the stored algorithm.
2. The algorithm assigns the current value of the InOut variable IN to the output OUT: `OUT := IN;`.
3. After the assignment is complete, the event CNF is sent to signal completion to the calling function block.

The InOut variable IN allows direct access to an external variable or memory location without requiring it to be defined as a separate input or output. The function block buffers the read value, ensuring that the output OUT remains stable even after changes to the source, until the next request is made.

Technical Features

- **Use of InOut Variables**: IN is declared as InOut, meaning it can be both read and written. In this case, it is only read, allowing for flexible coupling with the calling network.
- **Buffering**: The output OUT stores the read value until the next update by REQ. This prevents unwanted side effects from changes to the source.
- **No State Logic**: The function block consists of a single state (REQ) that reacts immediately to each incoming event. No delay, no waiting for conditions.
- **Initial Values**: Both IN and OUT are initialized with 0, ensuring a defined start state.

State Overview

The function block uses a simple ECA state machine with exactly one state:

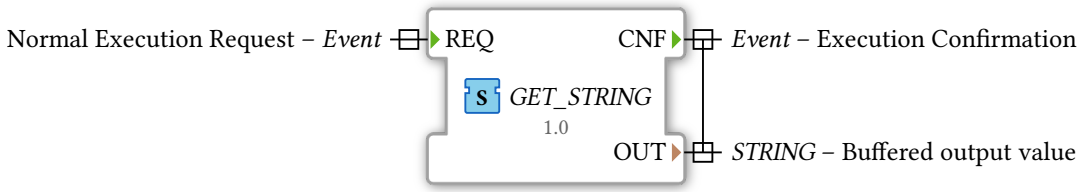
State	Action	Outgoing Event
REQ	REQ Algorithm (OUT := IN)	CNF

- Every incoming REQ event triggers an immediate action and sends CNF. There are no branches, error states, or timing issues.

Application Scenarios

- **Reading Hardware Inputs**: When a SINT value needs to be read from an analog input chip or a programmable logic controller (PLC), `GET_SINT` can be used as an interface to capture the current value at a specific point in time.
- **Accessing Shared Variables**: In a distributed control system, `GET_SINT` can be used to transfer the value of a global or peripheral variable into a local processing chain.
- **Data Consistency**: Buffering ensures that the read value remains stable throughout the entire processing of the subsequent network, even if the source is updated asynchronously.

Comparison with Similar Building Blocks



Building Block	Data Type	Special Feature
`GET_BOOL`	BOOL	Same functionality, but for Boolean values.
`GET_INT`	INT	Similar to `GET_SINT`, but with 16-bit integers.
`GET_REAL`	REAL	For floating-point numbers.
`MOVE` (generic)	Any	A generic MOVE building block can also copy values, but requires separate inputs and outputs. In contrast, `GET_SINT` uses InOut variables, which can be more practical when coupling to peripheral addresses.

All `GET_*` function blocks have in common that they read a value from an InOut source and provide it as a buffered output. In contrast, `SET_*` overwrites the value of the source.

Conclusion

GET_SINT`is a minimalist and reliable function block for reading a`SINT` value from an InOut variable. Its simplicity makes it an ideal function block for reading peripheral or shared data in IEC 61499 applications. The use of the InOut interface reduces wiring complexity and promotes a clean separation between data access and processing logic.

GET_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `GET_STRING` is used to read a string value from an InOut variable and provide it as a buffered output. It is typically used to capture the current value of an external variable at a specific time and make it available for further processing.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Normal execution request. Triggers the reading of the InOut variable.

Event Outputs

Event	Data Type	Comment
CNF	Event	Confirmation of execution. Sent after the value has been read and passed to the output.

Data Inputs

Name	Data Type	Comment
IN	STRING	InOut variable that serves as the source. Its current value is read and buffered on REQ.

Data Outputs

Name	Data Type	Comment
OUT	STRING	Buffered output value. Contains the string read from IN at the time of the last REQ.

Adapter

None.

Functionality

The function block has a state `REQ`. An incoming event at `REQ` executes the algorithm, which copies the value of the InOut variable `IN` directly to the output `OUT`. Then, the event `CNF` is sent. The InOut variable `IN` is not modified, but only read. The buffered value remains until another `REQ` reads a new value.

Technical Features

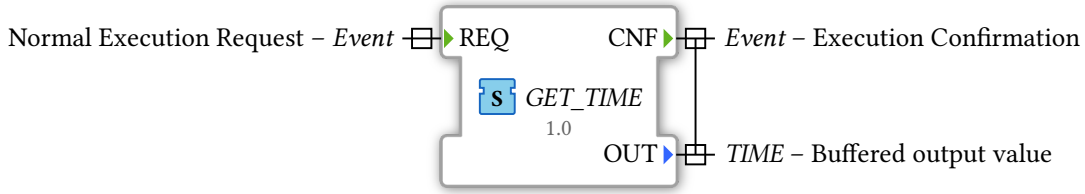
- The variable `IN` is declared as **InOut**, meaning it is passed by reference. This allows direct access to the memory of the passed string variable without first copying the value locally.
- The function block is specialized for the data type `STRING`. Corresponding variants (e.g., `GET_ANY`) are required for other data types.
- No initial values are set. The output `OUT` is undefined after the first cycle until `REQ` has been received.

State Overview

The function block has a single state:
| State Name | Description | | State Name | Description | |-------|-------| | REQ | Waits for an event at `REQ`. Executes the algorithm (copies `IN` ⟶ `OUT`) and sends `CNF`. |
There are no start or end states; the block returns to state `REQ` after each iteration.

Application Scenarios

- **Caching**: A string value from an external source (e.g., a data block) is sampled and cached for subsequent processing without affecting the source.
- **Logging**: Snapshot of a changing string at specific event times.
- **Synchronization**: Provides a consistent value for multiple downstream blocks when the source is to be read from several locations simultaneously.



Comparison with similar blocks

- **MOVE / ASSIGN**: Simple assignment blocks for arbitrary types, often without explicit event handling. `GET_STRING`, on the other hand, is specifically designed for `STRING` and uses an InOut interface.
- **GET_ANY**: A generic block for arbitrary data types. `GET_STRING` is type-safe and avoids parameterization overhead for reading strings.
- **READ_REF**: Also a block for passing by reference, but often implemented as a function block without event handling. `GET_STRING` integrates event handling and is therefore suitable for sequential control systems.

Conclusion

GET_STRING` is a simple yet specialized function block for buffering a string value from an InOut variable. Its event-driven approach allows for precise use in time-critical processes. Using an InOut interface saves memory and processing time, as no value copy is required on the caller side. For most applications that need to sample strings, this function block offers a clean and resource-efficient solution.

GET_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **GET_TIME** allows you to read a TIME value from an InOut variable and provide it as a buffered output value. It serves as a simple interface for incorporating an external time value into the block structure.

Interface Structure

Event Inputs

Name	Type	Comment	With Variables
REQ	Event	Normal Execution Request	IN

Event Outputs

Name	Type	Comment	With Variables
CNF	Event	Execution Confirmation	OUT, IN

Data Inputs

No dedicated data inputs available.

Data Outputs

Name	Type	Comment	Initial Value
OUT	TIME	Buffered Output Value	T#0s

Adapters

No adapters available.

Functionality

GET_TIME implements a simple, event-driven process. An event at the **REQ** input triggers the execution of the algorithm. The current value of the InOut variable **IN** is copied to the data output **OUT** and temporarily stored. An event is then generated at the output **CNF** to acknowledge the successful transfer. The InOut variable **IN** serves solely as a readable source and retains its value.

Technical Features

- The variable **IN** is declared as **InOut**. It can be externally linked to another variable or output without the function block accessing it for writing. This allows for flexible integration with external timers or signals.
- The output **OUT** buffers the read value. After a **REQ** event, the current **IN** value is available at the output until the next request.
- The function block does not have its own timer or buffer for delays.

State Overview

State	Description	Action Performed

REQ	Waits for an event at the **REQ** input. Upon receipt, the algorithm is executed and a **CNF** event is sent.	`OUT := IN;`

Application Scenarios

- **Time Measurement**: Acquisition of a current system time (e.g., `TIME()` or a clock signal) into an output for further processing.
- **Signal Forwarding**: Buffered forwarding of an external TIME signal to decouple asynchronous changes in the source from the rest of the process.
- **Initialization**: Setting a start time value in a control logic.

Comparison with Similar Function Blocks

Compared to a pure **MOVE** function block for TIME data, **GET_TIME** uses an **InOut** interface, which allows a direct connection to the source even without an additional data input. It is specifically designed for TIME values and does not offer a general data copy function. Other time function blocks such as **E_TIME** or **TIME_IN** often work with their own timer or event counter, while **GET_TIME** passively retrieves an external value.

Conclusion

GET_TIME is a lean, clear function block for reading and buffering a TIME value. Its simple event handling and the use of an InOut variable make it particularly suitable for scenarios in which an external time value needs to be selectively incorporated into control logic.

GET_TIME_OF_DAY

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `GET_TIME_OF_DAY` is used to read a time of day value (type `TIME_OF_DAY`) from an InOut variable. The read value is buffered internally and made available via a data output. In this way, a consistent, uniquely read time of day is passed on – even if the source variable changes in the meantime.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Execution Request; reads the current value of IN

Event Outputs

Event	Data Type	Comment
CNF	Event	Confirmation after successful read and buffering

Data Inputs

There are no pure inputs. The source data is provided via the InOut input `IN`.

Data Outputs

Output	Data Type	Comment
OUT	TIME_OF_DAY	Buffered time of day value

Adapters

No adapters are available.

Functionality

A call to the event `REQ` triggers the internal associated action: The current value of the InOut variable `IN` is read and copied to the output variable `OUT`. The event `CNF` is then sent. The time of day is then consistently available at the output `OUT` until the next `REQ` – regardless of any interim changes to `IN`.

Technical Features

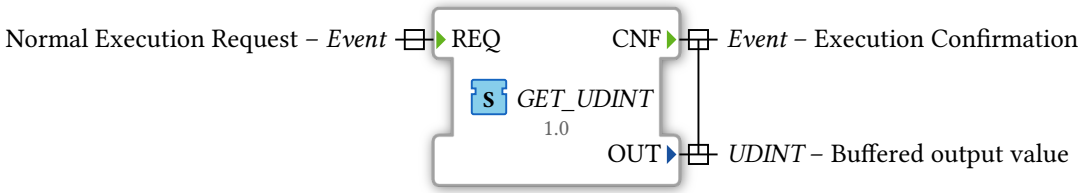
- **InOut variable as source:** The function block uses an InOut parameter that is directly linked to an external variable in the IEC 61499 model. This allows the function block to read the value "from the outside" without having to define a data input itself.
- **Buffering:** The read value is temporarily stored in the output variable `OUT`, so that subsequent queries always return the same value until `REQ` is triggered again.
- **Simple State Machine:** The function block consists of only one state, which executes the action and immediately outputs the confirmation event.

State Overview

The simple function block has only the state `REQ`. As soon as the event `REQ` is received, the action `REQ` is executed (OUT := IN) and the event `CNF` is sent. There are no further states or branches.

Application Scenarios

- **Timestamping in Controllers:** A one-time capture of a time value from a higher-level clock, for example, to document operating hours or switching times.
- **Buffering for Asynchronous Evaluation:** An external timer (e.g., a system clock) changes continuously; the function block freezes its value at the time of the call and makes it available to a slower consumer or logic.
- **Communication Across Boundaries:** In distributed systems, the current time of day can be retrieved from a component and cached locally for consistent output later.



Comparison with Similar Function Blocks

- **Unlike a pure data connector** (e.g., MOVE or simple data copy), `GET_TIME_OF_DAY` uses an InOut parameter, which allows direct coupling to the source variable and thus cleanly separates the signal paths in the IEC 61499 model.
- **Unlike time function blocks**, which independently generate ticks or real-time values, this function block only accesses an externally provided value – it is purely read and buffer logic.
- **Similar function blocks** exist for other data types (e.g., `GET_BOOL`, `GET_REAL`) and follow the same design pattern.

Conclusion

GET_TIME_OF_DAY` is a compact yet useful function block that reads a time of day from an InOut variable, buffers it, and passes it on as a controlled output value. Its clear, low-state logic and buffering make it particularly suitable for tasks where a recorded time must be available in the same format at a later time.

GET_UDINT

• – ◦ • – ◦ • – ◦ •

The **GET_UDINT** function block reads the current value of a variable of type **UDINT** declared as InOut and provides it as a buffered output. Buffering ensures that the output value remains stable during a cycle, even if the source data changes later.

Name	Type	Comment
REQ	Event	Normal Execution Request

Associated Data:

- **IN** (InOut variable) is read on REQ.

Name	Type	Comment
CNF	Event	Execution Confirmation

Associated Data:

- **OUT** (Output Value) is provided after a successful read.
- **IN** (InOut Variable) is also associated, meaning its value can be read at the output after the event.

Name	Type	Default Value	Comment
IN	UDINT (InOut)	0	Source Variable to be Read
Name	Type	Default Value	Comment
––	––	–––––	–––––
OUT	UDINT	0	Buffered Output Value

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

None.

Functionality

Upon an event at the **REQ** input, the function block executes the algorithm and sends an acknowledgment event to **CNF**. The algorithm copies the current value of the InOut variable **IN** to the output variable **OUT**. This freezes the value at the time of the request and makes it stably available at the output until the next request.

- **InOut Variable:** The parameter **IN** is declared as InOut. This allows direct access to the memory address of the source variable, which can be useful for communication over distributed systems (e.g., fieldbuses). However, the function block only reads the value; it does not write back.
- **No Side Effects:** The function block does not modify the InOut variable.

The function block has only one state:

- **REQ:** The algorithm is executed. After copying the value, the output **CNF** is immediately set.

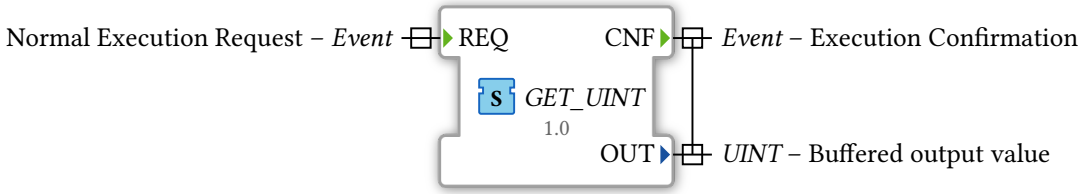
There are no other states; the function block is always ready to process a request.

- **Buffering of Process Values:** In automation systems where a measured value or manipulated variable (e.g., a counter reading or speed) needs to be frozen at a specific interval before being passed on to other function blocks.
- **Decoupling of Cycles:** When an InOut variable is read by multiple function blocks and a stable value is required within a cycle.
- **Replacement for direct access:** Instead of directly reading an InOut variable, the function block (FB) provides a clear interface (event input, output) and improves system readability.

- **MUX (Multiplexer):** A MUX selects between multiple inputs, while **GET_UDINT** buffers exactly one defined value from an InOut variable.
- **GET_DINT / GET_REAL:** Analogous function blocks for other data types that implement the same principle of buffered output of InOut values.
- **Latch function blocks:** These store values and output them upon an event; **GET_UDINT**, on the other hand, overwrites the output with the current value of the source on every request.

The **GET_UDINT** function block is a simple yet useful tool for stably and event-drivenly caching the value of an InOut variable of type UDINT. It is particularly suitable for applications where access to external or shared variables should occur in controlled steps, thus contributing to clean and predictable signal processing.

Technical Features



State Overview

Application Scenarios

Comparison with Similar Function Blocks

Conclusion

GET_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_UINT** function block reads the current value of a source `UINT` passed as an InOut variable and provides it as a buffered output value. It serves to capture a consistent snapshot of an external or internal UINT value at a defined point in time and make it available for further processing in the workflow.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution command; triggers reading the InOut variable and updating the output.

Event Outputs

Event	Description
CNF	Confirms the successful execution of REQ and signals that the outputs are valid.

Data Inputs

Variable	Type	Description
IN	UINT	Source variable provided as an InOut parameter. The value is read during REQ and passed unchanged to the output. Default value: `0`.

Note: `IN` is declared as an InOut variable, but is only used for reading within the function block.

Data Outputs

Variable	Type	Description
OUT	UINT	Buffered output value containing the value read from `IN` during the last REQ execution. Default value: `0`.

Adapter

None.

Functionality

The function block has a single execution state (`REQ`). When the event input `REQ` is activated, it performs the following action:

1. **Read** the current value of the InOut variable `IN`.

None.
The function block has a single execution state (`REQ`). 2. **Copy** this value to the output variable `OUT`.

1. **Trigger** the event output `CNF` to signal completion.

Processing is strictly sequential and instantaneous.

Technical Features

- **InOut variable as source:** Although `IN` is declared as an InOut variable, it is used for reading only. The function block does not write back, so the source remains unchanged.
- **Buffering:** The output `OUT` holds the value until the next output, `REQ`, is executed. This achieves decoupling between the source and the subsequent logic.
- **Simple state model:** The function block consists of only one state, so no complex sequence controls are required.

State Overview

State	Description
REQ	Waits for the arrival of event `REQ` and then performs the assignment `OUT := IN`. Subsequently, `CNF` is sent.

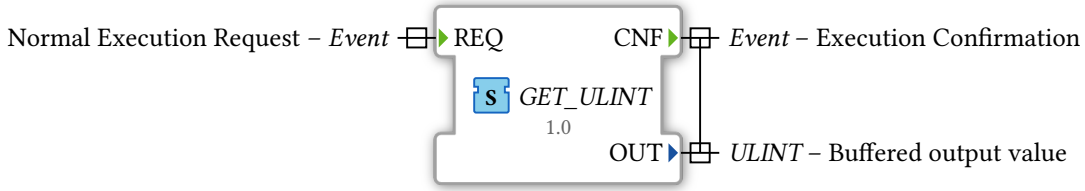
There is no explicit start or end state; after execution, the function block remains in state `REQ`, ready for the next task.

Application Scenarios

- **Safe Value Transfer:** A UINT value from a global variable or another function block should be frozen at a defined point in time to maintain consistency throughout a process.

Safe Value Transfer: - **Sampling of Measured Values:** In a cyclic control system, the current value of a counter or sensor is read and temporarily stored.

- **Data Transfer Between Tasks:** This function block can serve as a simple buffer layer between asynchronous communication paths.



Comparison with Similar Function Blocks

Unlike a pure input function block, which uses a fixed data port, **GET_UINT** allows the use of an **InOut variable** as a source. This allows the variable to be both written to and read from external sources without requiring a separate connection to an input. Pure read function blocks (e.g., UINT input) do not offer this flexibility but have a clearer interface. Compared to a memory function block (e.g., `R_TRIG` or `SR`), **GET_UINT** does not store states, but only the last read value.

Conclusion

GET_UINT is a simple yet useful function block that buffers a UINT value from an InOut variable. Its minimalist design—one event, one action—makes it ideal for situations requiring clean, time-defined value transfer. It is particularly well-suited for applications that need a consistent data set within a flow without affecting the source.

GET_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_ULINT** function block reads the current value of a variable of type `ULINT` (unsigned 64-bit integer) provided as an InOut parameter and makes it available as a buffered value at a data output. Upon a request (REQ), the value from the source is read and output at `OUT`. The acknowledgment (CNF) is then sent. Thus, GET_ULINT is a simple read function block for InOut variables.

Interface Structure

Event Inputs

Name	Type	Comment	With Data
`REQ`	Event	Normal Execution Request	`IN`

Event Outputs

Name	Type	Comment	With Data
`CNF`	Event	Execution Confirmation	`OUT`, `IN`

Data Inputs

Name	Type	Comment
-	-	-

Data Outputs

Name	Type	Comment	Initial Value
`OUT`	ULINT	Buffered output value	0

Adapters

No adapters available.

Internal Input/Output Variables

In addition to the inputs/outputs, the function block has an input/output variable:
| Name | Type | Comment | Initial Value | | |—|—|—|—| | `IN` | ULINT | Source variable (InOut) | 0 |

Functionality

This function block processes a single action:

1. An incoming event at input `REQ` triggers the execution of algorithm `REQ`.
2. In the algorithm, the current value of the InOut variable `IN` is copied directly to the output `OUT`:

OUT := IN;`

1. After the assignment is complete, the event `CNF` is output. The outputs `OUT` and `IN` are associated with the event `CNF`, allowing calling blocks to process the updated value.

By using an InOut variable, the block can access memory outside its own context without obtaining it via a conventional input. The value is read fresh with each request, making the block suitable as a read buffer.

Technical Features

- **InOut Variable:** The function block uses a variable named `IN` with the property `InOut`. This allows linking to a parent variable (e.g., from a resource or global data space) without the function block having to obtain the variable via a normal data input. Access is reference-based.
- **ULINT Type:** Both `IN` and `OUT` are declared as unsigned 64-bit integers (ULINT) – suitable for large count values, timestamps, or other values in the range 0 ... 2^{64}-1.
- **Instant Read:** The algorithm is extremely short (one assignment), making the execution time negligible.

State Overview

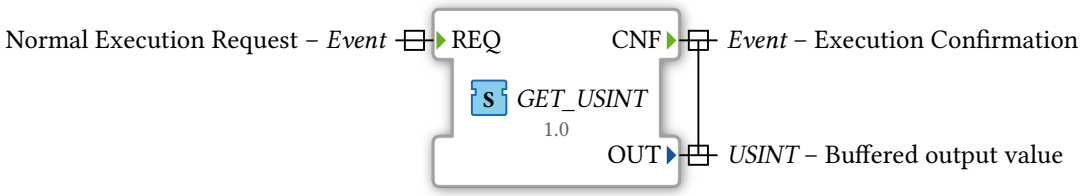
The function block is implemented as a SimpleFB with a single ECC state:

State	Action	Output Event	Meaning
`REQ`	`REQ` (OUT := IN)	`CNF`	Upon a request, the value is read and acknowledged.

There are no other states, no branches, and no internal memory variables (except for the output `OUT` itself, which buffers the last read value).

Application Scenarios

- **Safe Read Operation:** A higher-level function block wants to retrieve the current value from a shared variable (e.g., a sensor value written by another control component) without permanently referencing the value.
- **Value Buffer for Asynchronous Processing:** In a time-controlled process, `GET_ULINT` can be called to take a snapshot of a global counter variable and buffer it.
- **Parameterization via InOut Interfaces:** If the function block is embedded in a higher-level component, the InOut variable can be directly connected to a data connection of the parent function block, so that read requests point to this variable.



Comparison with Similar Function Blocks

- **GET_DINT / GET_LINT / GET_UINT:** Analogous function blocks for other integer types (DINT, LINT, UINT, etc.). The functionality is identical; the only difference is the data type.
- **READ_ULINT (hypothetical):** A function block that uses a separate data input for the source value instead of an InOut variable. This would have the advantage of loose coupling, but the disadvantage that the source value would have to be carried along as a data stream. The InOut approach of `GET_ULINT` allows a direct reference to a shared variable, which is preferred in some architectures.
- **SAMPLE_ULINT:** A function block that samples and buffers the current value of an input on each event – also similar, but with a normal data input instead of InOut.

Conclusion

The `GET_ULINT` function block provides a simple and efficient way to read the current value of an InOut variable of type `ULINT` and output it as a buffered output. Using an InOut variable allows direct, reference-based access to external memory locations without additional data copying during the call. Thanks to its minimalist state machine, it is ideally suited for time-critical applications where a fast, unobtrusive value read is required.

GET_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `GET_USINT` is used to read a `USINT` value from an InOut variable. It buffers the read value and makes it available via an output. This function block is particularly suitable when the value of a variable from a higher-level context (e.g., a group) needs to be queried once and then used as a constant intermediate value in subsequent processes.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Normal execution request. Trigger to read the current value of `IN` and pass it to `OUT`.

Event Outputs

Event	Data Type	Comment
CNF	Event	Confirmation of successful execution. Sent after reading and buffering.

Data Inputs

This function block does not have traditional data inputs. Instead, the value to be read is provided via the InOut variable `IN`.

Variable	Data Type	Comment
IN	USINT	Source variable (InOut). The current value of this variable is read and buffered upon a `REQ` event. The variable can be written to and read from external sources; within the function block, access is read-only.

Data Outputs

Variable	Data Type	Comment
OUT	USINT	Buffered output value. Contains the value read during the last execution of `IN`. Initial value: 0.

Adapter

None.

Functionality

1. The function block waits for a `REQ` event.
2. Upon arrival of `REQ`, the current value of the InOut variable `IN` is read and copied to the local output variable `OUT` (`OUT := IN;`).
3. Subsequently, the acknowledgment event `CNF` is sent.
4. The value of `OUT` is retained until another `REQ` event triggers a new read operation.

Since this is a simple function block, there are no branches or timed sequences – the action is executed in a single step.

Technical Features

- **InOut Variable `IN`** – The interface uses a variable `InOut`, which functions as both an input and an output. This is typical for 4diac function blocks that access variables of a parent group. The block does **not** modify the value of `IN`; it only reads it.
- **Buffering** – Without re-reading `REQ`, the output value remains stable, even if the source variable changes later. This decouples the value from the time it is read.
- **No State Machines** – The block consists of only one state, `REQ`, making the implementation trivial and resource-efficient.

State Overview

The block has exactly one state:

State	Action	Initial Event
REQ	Execute algorithm `REQ` (`OUT := IN;`)	CNF

A start state is not explicitly defined; after initialization, the function block is activated by the first `REQ`.

Application Scenarios

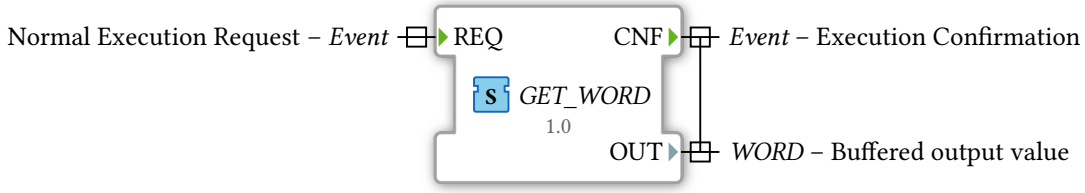
- **One-Time Query of a Configuration Variable** – A `USINT` value defined in a parent resource should be read exactly once at the beginning of the process and then used as a local constant.
- **Decoupling of Read and Write Access** – If a variable is both written to and read from multiple function blocks, `GET_USINT` prevents the read side from being constantly updated, as buffering only occurs on demand.
- **Testing Tool** – This function block can be used to display the current value of an InOut variable in a diagnostic branch.

Comparison with Similar Function Blocks

Function Block	Type	Special Feature
`GET_USINT`	Custom Function Block	Reads an InOut variable and buffers the value. The output remains stable until the next request.
`USINT_TO_*` (e.g., Converter)	Conversion Function Block	Converts a USINT to another type, but does not necessarily read from an InOut.
Direct data access	No function block	A value can be read over data connections without buffering, but without decoupling and without event control.

GET_USINT` is specialized for reading InOut variables with explicit buffering and event control – a task that cannot be accomplished with standard converters or direct connections.

Conclusion



The `GET_USINT` function block offers a simple and efficient way to read a `USINT` value from an InOut variable and provide it as a buffered output. Its clear, event-driven interface and minimal state machine make it a useful tool for decoupling and initialization tasks in 4diac applications. It is ideally suited when the value of a variable should only be retrieved on demand and any changes to the source in the meantime must be ignored.

GET_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The **GET_WORD** function block is used to read a WORD value from an InOut variable and make it available as a buffered output. It is typically used to capture a current value from a hardware peripheral or a shared memory location and make it available for further processing in the control program.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution request; clears the read operation and outputs the result at output `OUT`.

Event Outputs

Event	Description
CNF	Execution confirmation; signals that the value from `IN` was successfully transferred to `OUT`.

Data Inputs

The function block (FB) does not have explicit data inputs in the traditional sense, but uses an **InOut variable**:

Variable	Type	Description
IN	WORD	Source variable (InOut) from which the read value originates. The FB accesses it for reading.

Data Outputs

Output	Type	Description
OUT	WORD	Buffered output value – Copy of `IN` at the time of the last `REQ` execution.

Adapter

No adapters available.

Functionality

1. The function block starts with a **REQ** event at the input.
2. The **REQ** algorithm is executed:

- The current value of the input variable `IN` is copied to the output `OUT`.

1. After successful assignment, the **CNF** event is sent at the output.

Thus, the value read once remains at the output `OUT` until another **REQ** pulse triggers an update. This corresponds to a buffered read operation.

Technical Features

- **InOut Usage** – The function block reads an InOut variable, which is typically connected to a memory or hardware register.
- **Buffering** – The read value is held in the output `OUT`, even if the source `IN` changes later. Only a subsequent **REQ** call updates the buffer.
- **Initialization** – `IN` and `OUT` are pre-set to 0 by default.

State Overview

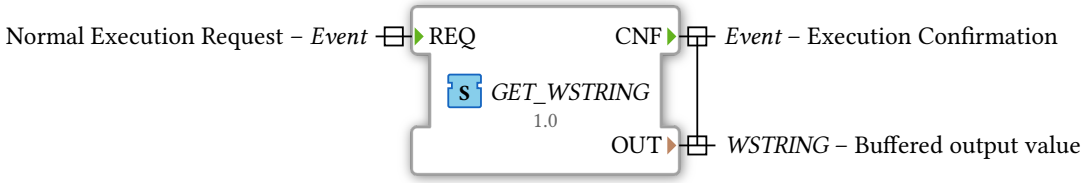
The function block implements a simple state machine with only one state:

State	Description
REQ	Always active when **REQ** is received; Performs the assignment `OUT := IN` and sends **CNF**.

There are no other states such as IDLE or WAIT, as the logic is strictly event-driven without branching.

Application Scenarios

- **Reading a Hardware Register** – For example, reading an analog-to-digital converter value or a counter value stored as a WORD.
- **Saving a Volatile Value** – If the source is only stable for a short time (e.g., after an interrupt), the function block can freeze the value at a defined moment.
- **Accessing Shared Variables** – In multi-call environments, the current value of a global WORD variable is retrieved and processed locally.



Comparison with Similar Function Blocks

Function Block	Difference
MOVE	Copies a value from a data input to an output. `GET_WORD`, on the other hand, reads from an InOut variable, which often represents a connection to an external resource.
READ	Often standardized for IEC 61499, reads from a process image. `GET_WORD` is more specific for a buffered WORD takeover from an InOut location.
LATCH	Holds a value after a set pulse. `GET_WORD` only updates on each **REQ**, thus resembling a clocked latch, but is not set/resettable.

Conclusion

GET_WORD is a simple but useful function block for selectively reading and buffering a WORD value from an InOut variable. It is particularly suitable for applications where the current state of a source needs to be captured at a specific event time and then made available in a stable manner. The function block (FB) is easy to understand, resource-efficient, and can be seamlessly integrated into event-driven processes.

GET_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **GET_WSTRING** is used to read a WSTRING variable via an InOut parameter and provides the buffered value as a data output. It is typically used to transfer an external WSTRING value into the internal processing of an application module without modifying the original value.

Interface Structure

Event Inputs

Event	Data Type	Description
REQ	Event	Normal execution request – triggers the reading of the InOut variable.

Event Outputs

Event	Data Type	Description
CNF	Event	Confirmation of execution – sent after successful copying.

Data Inputs

Variable	Data Type	Description
IN	WSTRING	InOut source variable whose value is read. (The variable is not modified.)

Data Outputs

Variable	Data Type	Description
OUT	WSTRING	Buffered output value – contains the content of IN read at the time of the REQ event.

Adapter

No adapters available.

Functionality

The function block has a single real-time step (EC state) called `REQ`. As soon as a pulse arrives at the **REQ** event input, the defined algorithm is executed:

1. The current value of the InOut variable **IN** is read and directly assigned to the output variable **OUT** (`OUT := IN`).
2. The **CNF** event is then triggered to signal successful transfer to the calling network.

The InOut variable remains unchanged; only a read access takes place.

Technical Features

- **Input/Output Usage**: The variable `IN` is formally declared as `InOut`. This allows the function block (FB) to access the memory address of the connected source without requiring a separate input variable. The variable can therefore be written to externally as well as read from within the FB.
- **Buffered Output**: The value of `OUT` remains stable until the FB is updated by another **REQ**. This ensures that downstream parts of the application always have access to a consistent value.
- **Type Consistency**: The FB works exclusively with the data type `WSTRING`. Separate function blocks (e.g., `GET_STRING`, `GET_DINT`) are required for other data types.

State Overview

The FB has only one active state:

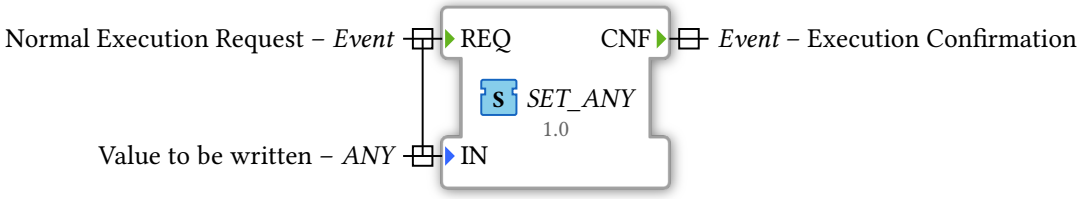
State	Description
REQ	Initial and operating state. The algorithm is executed and a CNF is sent on every **REQ** event. There are no further branches or wait states.

Application Scenarios

- **Data retrieval from an external WSTRING source** – e.g., reading a global configuration string or a WSTRING value provided by another function block.
- **Decoupling of read and write accesses** – The value from a shared variable can be safely buffered before being processed further in the internal logic.
- **Implementation of a "Get" function block** in an InOut-based architecture, as commonly used in **EC-61499** networking.

Comparison with Similar Function Blocks

Function Block	Data Type	Special Feature
GET_STRING	STRING	Analog function block for ASCII strings (not Unicode).
GET_DINT	DINT	For 32-bit integers.
FORCE	Any type	Forces a value regardless of the source, often with an additional reset mechanism.



GET_WSTRING differs from these by its specific support for the wide character type (WSTRING), used for Unicode strings (UTF-16). It is a simple function block limited to reading and buffering, with no side effects.

Conclusion

The **GET_WSTRING** function block is a lean, easy-to-understand function block that performs a fundamental task in IEC 61499 environments: the safe reading of a WSTRING InOut variable and the provision

of a buffered output value. Its simple structure and the absence of state branches make it ideal for use in data-driven control tasks where values from an external source need to be retrieved once or cyclically.

SET_ANY

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_ANY** is used to write any value from input `IN` to a variable `OUT`, declared as an InOut parameter. The operation is triggered by an event at input `REQ` and acknowledged with the output event `CNF` after successful assignment. The function block is generic and can work with any data type, as long as the types of `IN` and `OUT` are compatible.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Normal execution request – triggers the assignment. Associated with the variables `IN` and `OUT`.

Event Outputs

Event	Data Type	Comment
CNF	Event	Confirmation of successful execution. Associated with the variable `OUT`.

Data Inputs

Name	Data Type	Comment
IN	ANY	Value written to the target variable.
OUT	ANY	**InOut Parameter** – used as both an input and an output (see Data Outputs).

Note: `OUT` is declared as InOut. It functions as a data input (the original variable is read if necessary) and as a data output (overwritten with the value of `IN`).

Data Outputs

Name	Data Type	Comment
OUT	ANY	**InOut Parameter** – contains the value of the input `IN` after execution. The variable can also be used outside the function block.

Adapter

None.

Functionality

The module has a single processing state, `REQ`. If an event occurs at the event input `REQ`, the algorithm `REQ` is executed:

OUT := IN; After assignment, the output event `CNF` is sent. Execution is atomic – no further state logic is applied.

Technical Features

- **Generic Data Type `ANY`:** The function block can be used with any IEC 61499 data type (e.g., BOOL, INT, REAL, STRING, structures). Type compatibility between `IN` and `OUT` must be ensured by the user.
- **InOut Mechanism:** `OUT` is declared as an InOut parameter. This means that the variable serves as both input (e.g., for read operations) and output. In the 4diac IDE, InOut is typically implemented as a reference to an external variable.
- **Simple State Machine:** The function block contains only one state, making it very lightweight and resource-efficient.

State Overview

State	Description
REQ	Waits for a `REQ` event. Upon occurrence, the algorithm is executed, then `CNF` is sent, and the state remains active.

There are no other states, no branches, and no time monitoring.

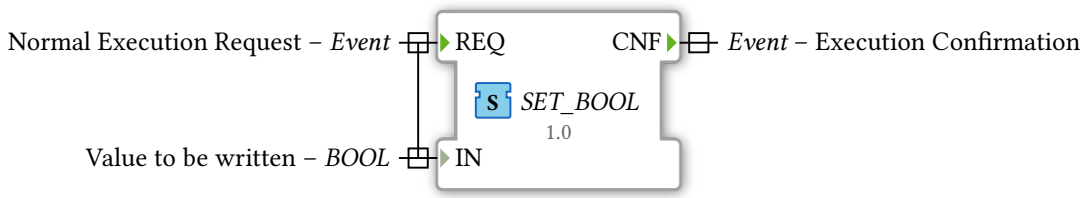
Application-Specific Scenarios

- **Variable Initialization:** A one-time initial value is set for a globally or instance-specific variable.
- **Parameter Override:** At runtime, an existing value is overwritten with a new one, e.g., to change setpoints or configuration parameters.
- **Point-to-Point Data Transfer:** When a value needs to be copied from a source to a directly connected destination without requiring separate logic.

Comparison with Similar Function Blocks

Function Block	Difference
SET	Is fixed to a specific data type (e.g., SET_BOOL, SET_INT). `SET_ANY` is generic.
MOVE	Also copies a value from an input to an output, but uses standard outputs. `SET_ANY` uses an InOut parameter that references a persistent variable.
SELECT	Selects between two input values and requires a control signal. `SET_ANY` operates without a condition.

Conclusion



SET_ANY`is a simple yet flexible function block for selectively overwriting variables in IEC 61499. The use of the generic type`ANY` and the InOut parameter makes it universally applicable, especially in scenarios where values need to be written to existing memory locations at runtime. Thanks to its minimal state logic, it is suitable for time-critical applications or as a basic building block for more complex data flow structures.

SET_BOOL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block SET_BOOL is used to write a Boolean input value (IN) to an InOut variable (OUT). It provides simple assignment logic for BOOL data and is controlled by an event.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Normal Execution Trigger

Event Outputs

Name	Type	Comment
CNF	Event	Execution Confirmation

Data Inputs

Name	Type	Initial Value	Comment
IN	BOOL	FALSE	Value to be written to the target variable

Data Outputs

No separate data outputs. The output value is provided via the InOut variable OUT.

Adapters

None.

Functionality

When the event REQ is received, the function block executes the assignment OUT := IN. The current value of input IN is copied to the InOut variable OUT. Then, the confirmation event CNF is sent. The InOut variable OUT can be externally assigned to any BOOL variable, allowing the value to be written directly to the corresponding location in the system.

Technical Features

- The function block uses an **InOut variable** (OUT) that functions as both an output and an input. This allows the value to be written directly to an external variable without requiring a separate data output.
- The initial values of IN and OUT are both FALSE, which ensures a defined state even without initialization.
- There is only one algorithm and one state; therefore, the execution logic is deterministic and unconcurrency-free.

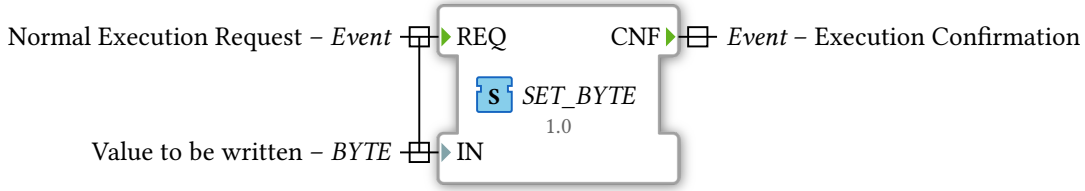
State Overview

State	Action	Event Output	Description
REQ	OUT := IN	CNF	On the REQ event, the input value is written to the InOut variable, and execution is confirmed.

The function block has only one active state. After execution, it waits for the next REQ event.

Application Scenarios

- **Setting a Global Flag**: A Boolean flag can be set in another function block or a global variable via an InOut variable.
- **Assigning Values from a Sensor**: A Boolean sensor value (e.g., from a switch) is directly assigned to a control variable.
- **Initializing BOOL Variables**: A defined value can be written to a variable at system startup using REQ.



Comparison with Similar Function Blocks

- **`MOVE` (e.g., ANY to ANY)**: `MOVE` copies values of any data type but requires separate inputs and outputs. `SET_BOOL` is BOOL-based and uses an InOut variable, enabling more compact connections.
- **`SET_BOOL` vs. direct assignment in ST**: This function block abstracts the assignment as an event-driven block and can be used in graphical editors (e.g., FBD) where direct assignment is not possible.
- **`R_TRIG` / `F_TRIG`**: These function blocks detect edges and only change the output on signal transitions. In contrast, `SET_BOOL` performs an unconditional assignment on every `REQ` event.

Conclusion

SET_BOOL` is a simple yet practical function block for directly assigning a Boolean value to a variable using an InOut interface. It is ideally suited for control tasks where a Boolean state needs to be set and integrates seamlessly into the event-driven paradigm of IEC 61499.

SET_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_BYTE** is used to easily overwrite a BYTE variable. It reads the value of the data input `IN` and writes it to the InOut variable `OUT` as soon as an event arrives at the input `REQ`. The event `CNF` is then output.

Interface Structure

Event Inputs

Name	Type	Comment
`REQ`	Event	Normal execution job (start write operation)

Event Outputs

Name	Type	Comment
`CNF`	Event	Confirmation of successful assignment

Data Inputs

Name	Type	Value Range	Initial Value	Comment
`IN`	BYTE	0…255	0	Value to be written to the target variable

Data Outputs

The function block uses an **InOut** variable. Therefore, there are no separate data outputs – the output value is identical to the value of the InOut variable `OUT`.

Adapter

None present.

Functionality

When an event occurs at input `REQ`, the algorithm `REQ` is executed. This assigns the value of `IN` to the InOut variable `OUT`:

OUT := IN; Immediately after the assignment, the event `CNF` is sent. The InOut variable can be both read and written from outside the function block (e.g., via a connection in the application model). After the write operation, it has the value `IN`.

Technical Features

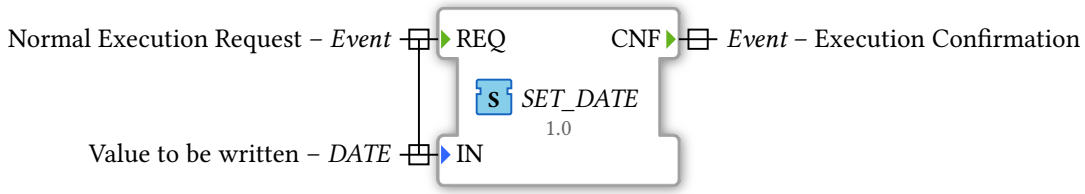
- **Simplest Assignment**: The algorithm consists of only one line – no delays, conditions, or filters.
- **InOut Variable**: `OUT` is declared as InOut, meaning it can be connected externally to a variable that can be both read and written. This allows direct manipulation of a global or linked BYTE variable.
- **No State Machine**: The function block has only one implicit state (`REQ`) and requires no additional state logic.

State Overview

The function block (FB) has no explicit states. Action is initiated immediately upon the event `REQ`. There are neither error nor delay states.

Application Scenarios

- **Initialization or Reset**: A specific initial value is to be written to an existing byte variable.
- **Switching/Setting Bit Patterns**: An external signal (e.g., from a communication block) is passed to an output or memory location via `IN`.
- **Testing/Diagnostics**: Temporarily overwriting a value in a control application.



Comparison with Similar Function Blocks

- **MOVE** (general): The simple MOVE function block for arbitrary data types usually works with an input and an output, not with InOut. `SET_BYTE` is specifically optimized for BYTE and uses InOut, so the value is written directly to the target variable (no separate output is needed).
- **SET_BOOL** (if available): Analogous for BOOL – both function blocks follow the same simple principle but are limited to their respective data types.

Conclusion

SET_BYTE` is a minimalist, clearly defined function block for writing to a BYTE variable once. Its strength lies in its simplicity and the use of an InOut interface, which allows for direct value assignment without additional wiring of a data output. It is particularly suitable for applications where a predefined value needs to be written to a persistent variable at a specific time.

SET_DATE

• – ◦ • – ◦ • – ◦ •

Introduction

The **SET_DATE** function block is used to write a date value (data type `DATE`) from an input to an InOut variable. The InOut variable is written directly and is available with the new value after execution. This enables efficient transfer of date values without an additional output variable.

Interface Structure

Event Inputs

Event	Description	With Variables
REQ	Normal Execution Request	IN, OUT

Event Outputs

Event	Description	With Variables
CNF	Execution Confirmation	OUT

Data Inputs

Variable	Type	Description
IN	DATE	Value to be written to the target variable
OUT	DATE	Target variable (InOut) – initial value can be read but will be overwritten

Data Outputs

Variable	Type	Description
OUT	DATE	Target variable (InOut) – contains the value of IN after execution

Adapter

None.

Functionality

When the **REQ** event is triggered, the function block executes the algorithm `REQ`:

- The value of the input `IN` is assigned to the InOut variable `OUT` (`OUT := IN;`).
- The **CNF** event is then sent to signal successful completion.

The InOut variable `OUT` serves as both an input and an output. The current value can be read before execution, and the new value is available after execution.

Technical Features

- **InOut Variable:** The function block uses an InOut variable that is referenced directly in the calling environment. Changes take effect immediately on the connected variable without any additional data output.
- **Data Type:** Designed exclusively for the data type `DATE`.
- **Simple State Logic:** The function block consists of only one state, which directly performs the assignment.

State Overview

State	Description
REQ	Executes the value assignment `OUT := IN` and sends CNF

No other state exists; the function block is immediately ready for execution.

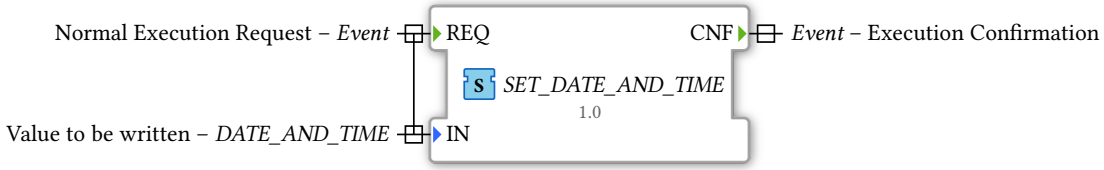
Application Scenarios

- Setting a date value in a PLC controller, e.g., initializing a current date.
- Transferring a calculated or parent date to a global or parent variable.
- Switching between different date values by repeated calls with different `IN` values.

Comparison with similar function blocks

Similar function blocks exist for other data types:

- **SET_TIME** (for `TIME`)
- **SET_DT** (for `DATE_AND_TIME`)



The main difference lies in the data type used. The functionality and the InOut interface are identical.

Conclusion

SET_DATE is a simple yet useful function block for directly setting a date variable. By using an InOut variable, memory and communication overhead are kept to a minimum. The function block is particularly

suitable for standardization tasks in automation technology where date values need to be transferred efficiently and reliably.

SET_DATE_AND_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The SET_DATE_AND_TIME function block is used to write an incoming DATE_AND_TIME value to a target variable. The target variable is passed as an InOut parameter, allowing it to be both read and written. The function block implements a simple assignment operation triggered by an event.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution request; starts writing the input value to the InOut variable.

Event Outputs

Event	Description
CNF	Confirmation of successful execution.

Data Inputs

Name	Type	Description
IN	DATE_AND_TIME	The value to be written to the target variable.

Data Outputs

This function block does not have explicit data outputs. The updated value is made visible externally via the InOut parameter `OUT`.

Adapters

None.

Functionality

As soon as an event occurs at input `REQ`, the ST instruction `OUT := IN` is executed. The value of input `IN` is copied directly into the InOut variable `OUT`. Upon successful completion, output `CNF` is triggered to signal completion. Using an InOut variable allows the function block to be inserted into an existing data connection without requiring a separate output variable.

Technical Features

- **InOut Variable:** The parameter `OUT` is declared as InOut. This allows the function block to directly overwrite the value of the associated variable while remaining externally readable.
- **Simple Assignment:** This is a simple copy operation without type conversion or validation checks.
- **No State Machines:** The function block is implemented as a SimpleFB with only one EZ state (REQ). Execution occurs strictly within a single cycle.

State Overview

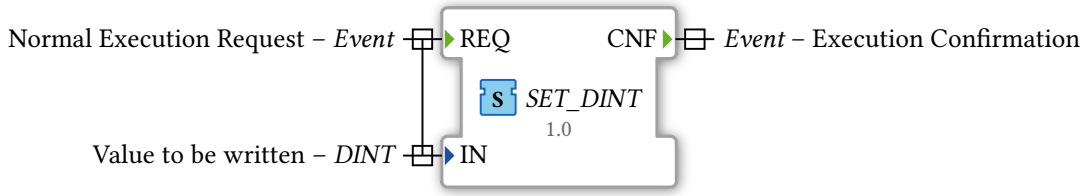
The function block has a single state:

State	Action	Output Event
REQ	`OUT := IN`	CNF

The state machine starts in this state upon receiving `REQ`, executes the action, and immediately sends `CNF`.

Application Scenarios

- **Initializing a System Time:** A higher-level function block can provide the current time (e.g., from an interface) via `IN` and write it to a globally or persistently stored time variable (InOut) via `SET_DATE_AND_TIME`.
- **Resetting a Time Variable:** When setting a reference time, the function block can be used to assign a predefined value to a higher-level variable.
- **Parameterization:** In control/regulation applications, the function block can be used to write target time values to data blocks.



Comparison with Similar Function Blocks

Simple assignment function blocks for other data types (e.g., `SET_VALUE` for integer or boolean) follow the same pattern. The `SET_DATE_AND_TIME` function block is specifically designed for use with the `DATE_AND_TIME` type and does not offer advanced functions such as addition or subtraction. Unlike a `MOVE` block (which maps an input to an output), this block uses an InOut variable, eliminating the need to separate the source and destination.

Conclusion

The `SET_DATE_AND_TIME` function block is a simple yet useful block for overriding a date and time variable within an IEC 61499 system. Its use of an InOut interface allows for easy integration into existing data flows. Due to its straightforward structure, it is efficient and suitable for all scenarios requiring the targeted assignment of a date and time value.

SET_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SET_DINT` is used to write a DINT value from a data input to an InOut variable. It thus implements a simple assignment operation for the data type `DINT`. The block is triggered by an event and acknowledges successful execution with a confirmation event.

Interface Structure

Event Inputs

Name	Type	Comment	With Variables
REQ	Event	Normal Execution Trigger	IN, OUT

Event Outputs

Name	Type	Comment	With Variables
CNF	Event	Execution Confirmation	OUT

Data Inputs

Name	Type	Comment	Initial Value
IN	DINT	Value to be written	0

Data Outputs

This function block does not have traditional data outputs, but rather an InOut parameter (see below). The acknowledgment event `CNF` is linked to the output `OUT`, so that after execution, the updated value is available at the output.

Adapter

None.

Functionality

When an event occurs at the input `REQ`, the algorithm `REQ` is executed. This copies the current value of the data input `IN` directly into the InOut variable `OUT`. The acknowledgment event `CNF` is then sent.

The logic in Structured Text is:
OUT := IN; Execution is atomic: The value is applied immediately and without delay.

Technical Features

- The function block uses an **InOut variable** (`OUT`). This variable is both an input and an output and can be read and written externally. This allows the function block to overwrite the value of an existing variable in place without using an additional output.
- The function block is stateless – there is only one execution state. Every call performs the same simple assignment.
- All variables are initially predefined with `0`.

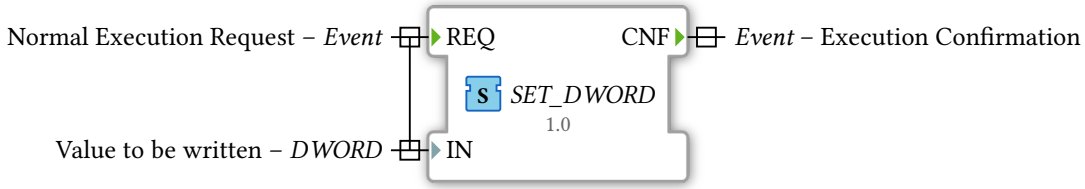
State Overview

State	Action	Output Event
REQ	OUT := IN	CNF

The function block has no other states (no wait loops, no branches). After the action, it immediately returns to standby mode for the next `REQ`.

Application Scenarios

- **Parameter Passing:** An external value (e.g., from a configuration interface) is written to a local variable in an application.
- **Signal Routing:** A digital integer value is redirected from one signal path to another, while preserving the original value.
- **Initialization:** At system startup, a defined start value can be written to a state variable via `SET_DINT`.
- **Testing and Debugging:** Manually setting a DINT value via an HMI or a script.



Comparison with Similar Function Blocks

- **MOVE/DINT**: Standardized function blocks such as `MOVE` from IEC 61131-3 also perform assignments. `SET_DINT` is specialized for the type `DINT` and offers a reduced interface (only one input event, no additional outputs).
- **SET_BOOL, SET_REAL, SET_SINT**: Analogous function blocks for other data types exist in the `logiBUS` library. They differ only in data type; their functionality is identical.
- **Direct Assignment in the Network**: In IEC 61499, an assignment could also be implemented without a function block via a direct data connection. The function block `SET_DINT`, however, offers explicit, event-driven encapsulation that can be monitored and triggered at runtime.

Conclusion

SET_DINT` is a simple yet useful function block for the targeted assignment of DINT values. By using an InOut variable, the interface remains streamlined, and the block can be directly integrated into existing data flows. Its clear, stateless logic makes it reliable and easy to understand – ideal for basic transfer operations in automation projects.

SET_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SET_DWORD` is used to write a DWORD value to a target variable declared as InOut via an input. It provides a simple and efficient way to set values during operation without requiring a separate assignment in the program.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Normal Execution Request – triggers the write operation

The event `REQ` simultaneously provides the data `IN` and `OUT`.

Event Outputs

Name	Type	Comment
CNF	Event	Execution Confirmation – sent after successful execution

The output `CNF` references the modified variable `OUT`.

Data Inputs

Name	Type	Comment
IN	DWORD	Value to be written to the target variable (initial value: 0)

Data Outputs

Name	Type	Comment
OUT	DWORD	Target variable (InOut) – the value of `IN` is written here (initial value: 0)

Note: `OUT` is declared as an InOut variable, meaning it can be referenced externally and its memory location is directly modified by the function block. It appears in the function block network as both an output and an input.

Adapters

No adapters available.

Functionality

The function block has a single action that is executed when the event `REQ` occurs:

```structured text
OUT := IN;
```

The event `CNF` is then sent. The function block is stateless and executes the assignment on every `REQ` event, regardless of the current value.

Technical Features

- **InOut Variable**: Using an InOut variable allows direct access to the memory location of an external variable. This reduces data copying overhead and enables the modification of variables that are also used elsewhere in the system.

- **No State Logic**: The function block does not implement a state machine with multiple states – it always reacts the same way to the input event.
- **Initial Values**: Both variables are initially set to 0, but are usually overwritten at runtime.

State Overview

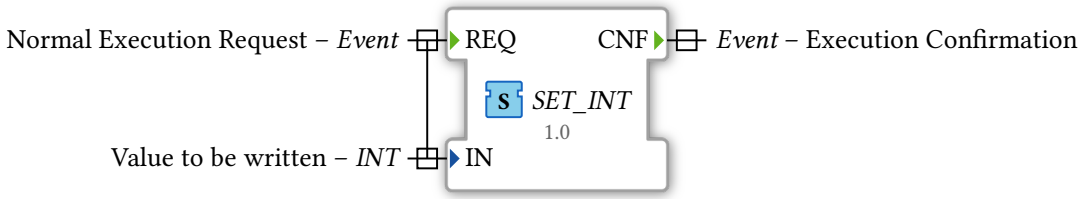
The function block consists of a simple state machine with exactly one state:

State	Triggering Event	Action	Output
REQ	REQ	OUT := IN;	CNF

There are no wait states or branches.

Application Scenarios

- **Peripheral Configuration**: Setting a DWORD register in a module (e.g., time base, threshold).
- **Parameter Passing**: Passing a constant or calculated value to a globally available variable (e.g., via an InOut data type).
- **Testing and Debugging**: Temporarily overwriting a value during operation without modifying the source code.
- **Plain Text Assignment Migration**: Replacing a simple `OUT := IN` instruction in an IEC 61499 network with a reusable function block.



Comparison with Similar Function Blocks

- **MOVE / MV**: Available in many libraries, but usually work with simple input/output variables and require explicit buffering. `SET_DWORD`, on the other hand, directly accesses an existing variable (InOut).
- **SET_BOOL / SET_INT / SET_REAL**: Analogous function blocks for other data types; the principle is identical, only the data type varies.
- **WRITE_DWORD**: Some libraries offer a function block that writes via an address bus. `SET_DWORD` is simpler and does not require address logic.

Conclusion

SET_DWORD` is a minimal but very useful function block for directly assigning values to a DWORD InOut variable. Its simplicity makes it error-resistant, and the absence of state logic ensures predictable real-time behavior. It is particularly suitable for configuration and initialization tasks where fast, straightforward value assignment is required.

SET_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_INT** is used to write a value of data type `INT` from an input directly into an InOut variable. This block is a simple, event-driven function block and is typically used to set global parameters or variables of other function blocks via a defined event pulse. Its functionality is reduced to the minimal task of value assignment.

Interface Structure

Event Inputs

Event	Data Type	Description	With Data
REQ	Event	Normal Execution Request. Triggers the transfer of the value from IN to OUT.	IN, OUT

Event Outputs

Event	Data Type	Description	With Data
CNF	Event	Execution Confirmation. Sent after the value has been successfully written to OUT.	OUT

Data Inputs

Variable	Data Type	Description	Initial Value
IN	INT	The value to be copied to the InOut variable.	0

Data Outputs

The function block does not have a dedicated data output. Output is provided via the InOut variable (see below).

Adapter

None.

InOut Variable

Variable	Data Type	Description	Initial Value
OUT	INT	Target variable into which the value of IN is written. This variable is declared as InOut, meaning it is referenced from outside the function block and can be directly manipulated.	0

Functionality

The function block operates according to a very simple, direct principle:

1. An event is received at input REQ.
2. The algorithm REQ executes the assignment `OUT := IN`. The current value of the data input IN is thus copied into the InOut variable OUT.
3. After successful assignment, the event CNF is sent to signal completion to the calling environment. The CNF event is linked to the InOut variable OUT, ensuring data consistency.

Execution occurs without delay or conditions – the value is overwritten immediately upon each REQ event.

Technical Features

- **InOut Variable**

The function block uses an InOut parameter (OUT) that represents a direct reference to an external variable (e.g., a global data block or a variable of a parent function block). This eliminates the need for an explicit connection back to another function block. The function block writes its value directly to the referenced memory location.

- **No Buffering**

The function block (FB) does not buffer data. The value is immediately overwritten with each REQ-Ereignis event.

- **Initial Values**

The data inputs and InOut variables are initialized with 0. This value is used in case of a lost connection.

State Overview

The FB has a single ECC state (REQ) that executes the action and immediately triggers the output event CNF. There are no branches, timers, or error states.

State	Action	Trigger
REQ	Execution of the algorithm REQ (OUT := IN) and sending of CNF	Event REQ

Application Scenarios

- **Setting a Constant Value**

An external sensor or logic provides a setpoint (`IN`), which is transferred to a global setpoint variable (`OUT`) at a clock signal (`REQ`).

- **Initializing Variables**

When an application starts, `SET_INT` can be used to set multiple InOut variables to defined initial values.

- **Parameter Override**

A higher-level controller or user interface overrides the current value of another function block upon a specific event, without having to modify the function block itself (the InOut connection allows direct access).

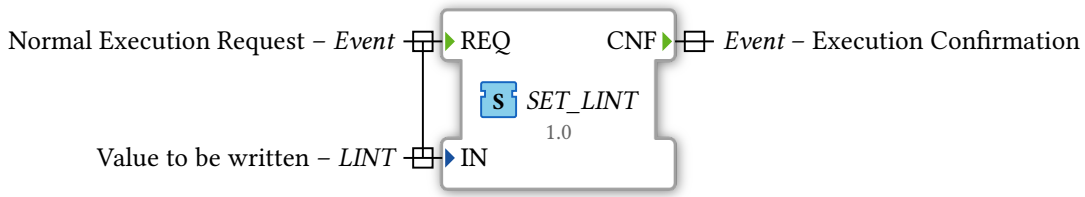
Comparison with Similar Function Blocks

- **SET_BOOL / SET_REAL**

Similar to `SET_INT`, but for the data types `BOOL` and `REAL`, respectively. The functionality is identical.

- **MOVE**

A general MOVE function block copies a value from a data input to a data output. In contrast, `SET_INT` uses an InOut variable and writes directly to an external location, resulting in tighter coupling. `MOVE` requires a separate connection from the output to the destination.



- **LATCH**

A latch function block can store a value and output it when needed. In contrast, `SET_INT` overwrites without a hold function – each call overwrites the previous value.

Conclusion

The `SET_INT` function block is a minimalist yet effective building block for directly setting an INT variable via an InOut interface. Its strength lies in its simple logic and the ability to access external variables. It is particularly suitable for flat control structures where fast and direct value assignments are required. Due to its simplicity, it is robust and reliable, but requires a well-thought-out variable concept to avoid unwanted side effects.

SET_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_LINT** is used to write a value of type `LINT` (64-bit integer) from a data input to a variable declared as an InOut parameter. It is typically used to explicitly set the value of a variable defined outside the block. The block complies with the IEC 61499-1 standard and provides simple, event-driven write access.

Interface Structure

Event Inputs

Name	Type	Description	With Variables
REQ	Event	Triggers Write Operation	IN, OUT

Event Outputs

Name	Type	Description	With Variables
CNF	Event	Confirmation after successful write	OUT

Data Inputs

Name	Type	Initial Value	Description
IN	LINT	0	The value to be written

Data Outputs

This function block does not have traditional data outputs, but rather an **InOut parameter** `OUT`, which functions as both an input and an output. This parameter is the target memory location for the value of `IN`.

Adapter

None.

Functionality

The behavior of the function block is reduced to a single step:

1. An event at the **REQ** input triggers the internal processing.
2. The algorithm executes the assignment `OUT := IN`. This copies the value of the data input `IN` to the InOut variable `OUT`.
3. After the assignment is complete, the **CNF** event is sent to signal successful execution.

The InOut variable `OUT` must be bound to a memory location (e.g., a global or device-specific variable) in the application. The function block overwrites the value stored there with the value of `IN`.

Technical Features

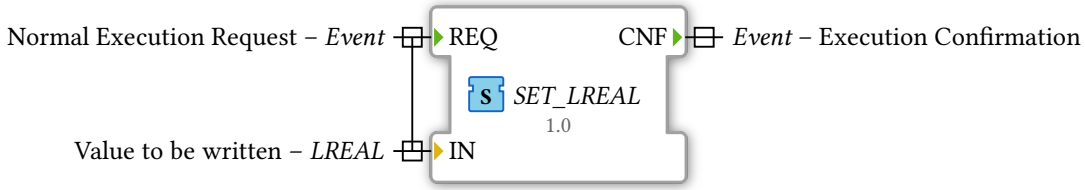
- The function block uses an **InOut parameter** instead of a separate data output. This allows direct writing to an external variable without requiring additional wiring via a data output.
- The data type `LINT` (64-bit signed integer) is platform-dependent; the implementation requires that the target system supports this type.
- There is no error handling or range checking – the assignment always occurs as soon as `REQ` is triggered.
- The function block is a **SimpleFB** with only one ECR state; therefore, its behavior is deterministic and fast.

State Overview

The function block has only one state, `REQ`. After the algorithm executes, it automatically returns to its initial state (implicitly). A state machine in the classical sense does not exist – the function block is stateless. Exactly one write operation is performed after each `REQ` event.

Application Scenarios

- **Initializing LINT Variables**: Setting a global configuration variable to a defined initial value.
- **Changing Control Parameters**: Dynamically overriding a parameter (e.g., setpoint or limit value) by a higher-level function block.
- **Test and Debug Interfaces**: Enables manual setting of variables at runtime via an HMI or script.
- **Message Header/Payload Setting**: In communication, `IN` can contain the value of a message, which is written to a buffer (`OUT`).



Comparison with Similar Function Blocks

- **SET_DINT / SET_INT**: Analogous function blocks for `DINT` (32-bit) and `INT` (16-bit), respectively. The only difference is the data type.
- **MOVE**: A more general function block for copying arbitrary values, often also with InOut parameters. `SET_LINT` is specialized for `LINT` and offers no further data or event inputs.
- **WRITE_LINT (hypothetical)**: A function block that explicitly writes an address via a pointer. `SET_LINT` operates without addressing and expects a directly linked variable.

Conclusion

SET_LINTis a minimalist function block that reliably performs a single task: assigning aLINT` value to an InOut variable. Due to its simplicity, it is particularly suitable for performance-critical or manageable control tasks where no complex logic is required. The absence of error handling makes it transparent and predictable, but requires the user to correctly link the InOut variable.

SET_LREAL

• – ◦ • – ◦ • – ◦ •

The function block **SET_LREAL** is used to pass a value of type LREAL to an InOut variable. The input value is written to the target variable on a rising edge of the REQ event, and the operation is acknowledged via the CNF event.

Event	With Variables	Description	
REQ	IN, OUT	Normal execution request. Triggers writing the input value to the target variable.	
Event	With Variables	Description	
–––––	–––––	–––––	
CNF	OUT	Confirmation of successful execution. The target variable has been updated.	
Name	Type	Initial Value	Description
––	–––	–––––	–––––––––––––––
IN	LREAL	0.0	Value to be written to the target variable.
OUT	LREAL	0.0	(InOut) Input side of the target variable. The current value can be read.
Name	Type	Initial Value	Description
––	–––	–––––	–––––––––––––––––
OUT	LREAL	0.0	(InOut) Output side of the target variable. After execution, the value of IN is output here.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter
No adapters available.

Functionality
When an event occurs at the **REQ** input, the algorithm is executed, copying the value of the input variable **IN** to the InOut variable **OUT**. The **CNF** event is then sent. The function block operates purely combinatorially and has no internal state maintenance beyond execution.

- The function block uses an InOut variable. This allows direct access to an external variable without requiring an additional connection between the input and output.
- The algorithm is implemented in Structured Text (ST) and is very simple (`OUT := IN;`).

The function block consists of a single state, **REQ**:

- **REQ**: Waits for the arrival of the REQ event. Then executes the algorithm and sends CNF. After sending, it returns to the REQ state (implicitly, as no other states are defined).

There are no branches or timing controls.

- **Copying an LREAL value** to a global or cross-instance variable when a direct connection is not possible or desired.
- **Setting a setpoint** in a controller, e.g., for a PID controller where the value is received via an analog input.
- **Initialization** of variables during operation, without having to restart the entire application.
- **SET_INT** or **SET_BOOL**: Functionally equivalent function blocks for other data types.
- **MOVE**: A general MOVE function block (e.g., in IEC 61131-3) copies values without event control. SET_LREAL, on the other hand, uses event-driven execution and InOut variables.
- **WRITE_LREAL**: Some libraries offer separate function blocks for writing to an address. SET_LREAL is simpler and operates at the variable level.

The **SET_LREAL** function block is a simple yet useful tool for writing an LREAL value to an InOut variable. Its event-driven operation makes it easy to integrate into IEC 61499 applications. The clear interface with only one event input and output, one data input and one InOut variable reduces complexity and facilitates reuse.

Conclusion

SET_LTIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_LTIME** is used to write an input value of type `LTIME` to a variable declared as InOut. This allows you to directly set the value of an external reference (e.g., an instance variable or another function block). Using an InOut variable allows for efficient data transfer without requiring a separate data output.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Normal execution trigger. Associated with the data `IN` and `OUT`.

Event Outputs

Name	Type	Comment
CNF	Event	Confirmation of successful execution. Associated with data `OUT`.

Data Inputs

Name	Type	Initial Value	Comment
IN	LTIME	LT#0s	Value to be written to the target variable.

Data Outputs

Name	Type	Initial Value	Comment
OUT	LTIME	LT#0s	**InOut Variable** – Target variable that receives the passed value. The function block writes the value of `IN` to this variable. As an InOut variable, it can be both read from and written to externally.

Adapter

None.

Functionality

When an event occurs at the **REQ** input, the algorithm `REQ` is executed:

- The value of the data input `IN` is copied directly into the InOut variable `OUT`.

- The **CNF** event is then output to signal the successful assignment.

The logic is very simple and consists of a single assignment:
OUT := IN;

Technical Features

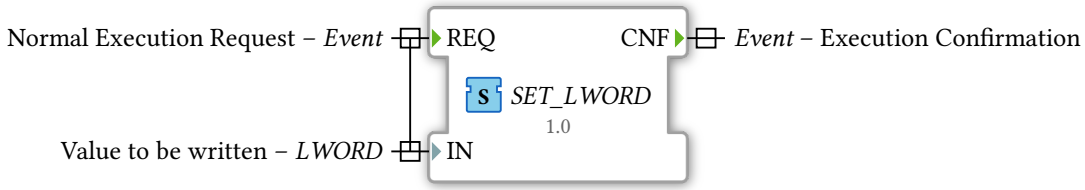
- The function block (FB) works exclusively with the **LTIME** data type (high-resolution time, according to IEC 61499).
- The target variable `OUT` is declared as **InOut**. This means that it is passed externally as a reference. Changes made by the FB to `OUT` immediately affect the referenced variable.
- Initially, both `IN` and `OUT` are set to `LT#0s` to prevent undefined states.
- The function block is a **simple FB** with only one state, which reacts immediately to a REQ event.

State Overview

The FB has exactly one state:
| State | Action | Output | | State | Action | Output | |———|————|———| | REQ | `REQ` (OUT := IN) | CNF |
There are no branches or timers. The function block is essentially combinatorial, as it reacts immediately to the input event.

Application Scenarios

- **Setting a Central Time Base**: If multiple function blocks access a common LTIME variable, `SET_LTIME` can update this variable.
- **Runtime Configuration**: In a control application, target time values from a configuration interface can be written to the corresponding InOut parameters.
- **Testing and Simulation**: This function block is suitable for selectively writing values to an observable variable in test environments.



Comparison with Similar Function Blocks

- **SET_TIME**: Works analogously, but with the data type `TIME` (second resolution). `SET_LTIME` offers higher time resolution (nanoseconds) and is therefore suitable for precise applications.
- **MOVE Function Blocks**: Many IEC 61499 libraries contain generic MOVE function blocks that copy values from an input to an output. `SET_LTIME` specializes in `LTIME` and uses an InOut reference instead of a separate output, which can be advantageous in certain architectures.

Conclusion

SET_LTIME` is a minimalist yet useful function block for precisely setting an LTIME variable. Its clear interface and the use of an InOut reference make it an efficient tool in timing and configuration scenarios. The component is easy to understand and straightforward to use.

SET_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_LWORD** is used to transfer an LWORD value (64-bit integer) from a data input to an InOut variable. It allows the direct setting of a target value that simultaneously functions as an input and output. This makes the block suitable for use in systems where a specific memory location or a connection variable needs to be updated.

Interface Structure

Event Inputs

Event	Data Type	Comment
REQ	Event	Normal Execution Trigger

Event Outputs

Event	Data Type	Comment
CNF	Event	Execution Confirmation

Data Inputs

Name	Data Type	Initial Value	Comment
IN	LWORD	0	Value to be written

Data Outputs

Name	Data Type	Initial Value	Comment
OUT	LWORD	0	Destination variable (declared as InOut)

Note: OUT is declared in the XML as `<InOutVars>`. It is a combined input/output variable that serves both as a source (read) and a destination (write).

Adapter

None.

Functionality

When an event is received at the **REQ** input, the function block executes the following algorithm:

OUT := IN; The value of the data input **IN** is directly transferred to the InOut variable **OUT**. The **CNF** event is then sent to confirm successful execution.

The function block is a simple, stateless function block – there are no delays or concurrency issues.

Technical Features

- **InOut Variable:** The variable `OUT` is declared as InOut. This means it can be used in the network as both an input (to read an existing value) and an output (to set a new value). The algorithm overwrites the contents of the connected variable with the input value.
- **Type LWORD:** The function block is designed for 64-bit values. When used with shorter data types (e.g., DWORD), an explicit type conversion is required.
- **Initial Value:** Both `IN` and `OUT` are preset to 0.

State Overview

The function block has only one EC state:

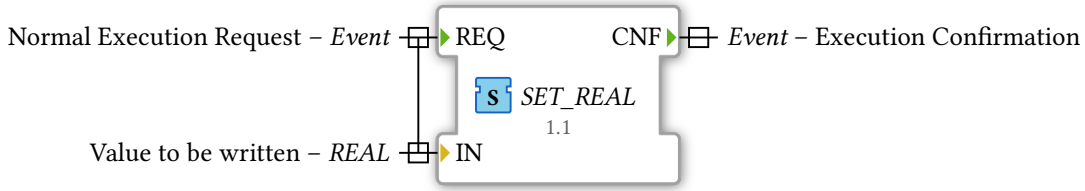
- **REQ:** Executes the algorithm and then sends the CNF event.

There are no wait states or loops.

Application Scenarios

- **Initializing Memory Locations:** Setting a 64-bit register or a global variable to a defined initial value.
- **Copying Values in InOut Connections:** If another function block provides an LWORD variable as an InOut, SET_LWORD can selectively overwrite it.
- **Test and Debugging Environments:** Manually specifying values in data paths to verify system behavior.

Comparison with Similar Function Blocks



- **SET_BOOL / SET_DWORD / SET_SINT:** Analogous function blocks for other basic data types (BOOL, DWORD, SINT, etc.). SET_LWORD covers the 64-bit integer range.

- **MOVE:** A general function block that copies values between any data type, but often without InOut support. SET_LWORD specifically uses the InOut declaration and is therefore optimized for direct variable assignments.
- **WRITE_***: Some libraries contain function blocks for writing to peripheral addresses. SET_LWORD is more abstract and operates at the logical variable level.

Conclusion

The function block **SET_LWORD** is a lean but essential tool for setting a 64-bit value to an InOut variable. Its simple semantics ("write IN to OUT") and support for the standard LWORD data type make it versatile for use in IEC 61499-based automation systems – especially where direct manipulation of variables via event control is required.

SET_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_REAL** is used to write a REAL value from a data input to an InOut variable. It is a simple, event-driven function block that, upon receiving a request (REQ), passes the current input value IN to the referenced variable OUT and acknowledges the operation with a confirmation event (CNF).

Interface Structure

Event Inputs

Name	Type	Description
REQ	Event	Normal execution request (connected to IN and OUT)

Event Outputs

Name	Type	Description
CNF	Event	Execution Confirmation (connected to OUT)

Data Inputs

Name	Type	Initial Value	Description
IN	REAL	0.0	Value to be written
OUT	REAL (InOut)	0.0	Target variable (InOut – read and write)

Data Outputs

No separate data outputs are available. The InOut parameter OUT also functions as an output and is updated after assignment.

Adapters

None.

Functionality

The FB has a single execution state **REQ**. As soon as an event arrives at the **REQ** input, the defined algorithm is executed:

OUT := IN; The current value of IN is assigned to the InOut variable OUT. The **CNF** event is then triggered to signal the completion of the operation. The process is atomic and requires no further state transitions.

Technical Features

- **InOut Parameter OUT**: The variable OUT is both readable and writable. It is directly referenced by the calling environment, so the assignment immediately changes the value at the original address.
- **Initial Values**: Both IN and OUT are initialized to 0.0. This prevents undefined states before the first execution.
- **Simplicity**: The function block consists of only one state and one algorithm, guaranteeing very low runtime complexity.

State Overview

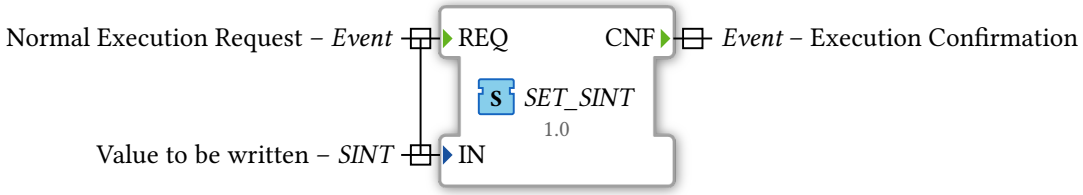
State	Description	Action	Output
REQ	Wait for execution request	Execute algorithm REQ ⟶ OUT := IN	CNF

No further state exists; the function block immediately returns to the waiting REQ state after execution.

Application Scenarios

- **Parameter setting**: Passing a REAL value to a global configuration variable, e.g., for scaling or setpoints.
- **Initialization**: Setting an InOut variable to a defined start value during commissioning.
- **Value copy within an application**: Easily overwriting an existing REAL variable with a different value, triggered by an event.

Comparison with similar function blocks



FB	Type	Difference
SET_BOOL	BOOL	Writes Boolean values, analogous functionality
SET_INT	INT	Writes integers, identical event control
MOVE (generic)	ANY	Can copy any data type, but requires type matching and often has multiple states
SET_REAL	REAL	Specifically optimized for REAL, minimal states and clear semantics

Compared to a generic MOVE block, SET_REAL offers a leaner implementation and is tailored to the frequently used REAL type.

Conclusion

The **SET_REAL** function block is a simple yet effective block for setting a REAL variable. Thanks to its minimal state machine and direct use of InOut parameters, it is ideally suited for event-driven assignments in IEC 61499 applications. It reduces complexity and increases the readability of the control code.

SET_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_SINT** is used to write a SINT value from its data input **IN** to an InOut variable **OUT**. It is used to set a SINT value at a specific point in the control sequence. The block implements a simple, event-driven assignment.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution request. Triggers the assignment from **IN** to **OUT**.

Event Outputs

Event	Description
CNF	Execution confirmation. Sent after successful assignment.

Data Inputs

Name	Type	Initial Value	Description
IN	SINT	0	The value to be written.

Data Outputs

The function block has no separate data outputs. The target value is returned via the InOut variable **OUT**.

Adapters

No adapters are available.

Functionality

A **REQ** event starts the execution of the algorithm. Within the algorithm, the current value of **IN** is directly assigned to the InOut variable **OUT**:

OUT := IN; After the assignment is complete, the **CNF** event is triggered. The InOut variable **OUT** serves as both input and output – its value is overwritten and then available for subsequent function blocks.

Technical Features

- **InOut Variable**: The variable **OUT** is declared as `InOut`. It can be both read and written. The function block overwrites the existing value of **OUT** with the value of **IN**.
- **Simplest Algorithm**: The function block performs only a single assignment. There are no conditions, loops, or additional logic.
- **Type Safety**: Both **IN** and **OUT** are of type `SINT`, ensuring a direct, type-compliant assignment.

State Overview

The function block has a single state (ECState) named **REQ**:

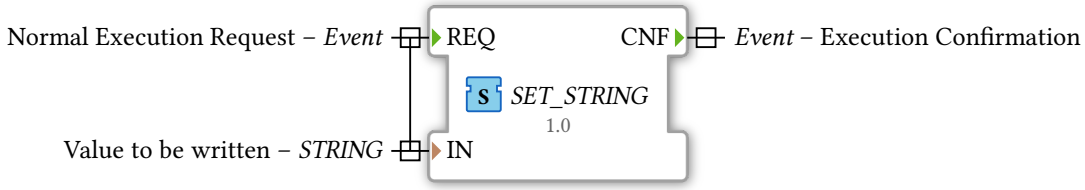
State	Action	Output Event
REQ	`OUT := IN`	CNF

There is only this one state; after execution, the function block returns to its initial state. It is not an explicit state machine with multiple states.

Application Scenarios

- **Setting a SINT value at runtime**: For example, overwriting a limit value or a counter in a controller.
- **Initializing SINT variables** in a specific step of the control sequence.
- **Passing a constant or calculated value** to another function block via the InOut variable, provided there is a connection to a global variable or another InOut port.

Comparison with Similar Function Blocks



- **SET_BOOL**: Analogous function for the data type `BOOL`. Works identically, but with Boolean values.
- **SET_INT**: Corresponding function block for `INT`. The structure (event REQ/CNF, assignment) is identical.

- **MOVE (e.g., MOVE_SINT)**: A MOVE function block copies a value from an input to an output without the target variable being implemented as an InOut. **SET_SINT**, on the other hand, writes directly to an existing variable, which in some architectures offers the advantage that the variable can also be read by other function blocks without requiring a separate connection to an output.

Conclusion

SET_SINT is a minimal and reliable function block for setting a SINT variable to a desired value. Its simplicity makes it ideal for situations where a value needs to be overwritten directly without additional logic. Using an InOut variable saves on separate output variables and allows direct chaining with other function blocks that read the same variable. It is an efficient solution for simple value assignments.

SET_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SET_STRING` is used to write a string value (STRING) provided via the data input `IN` to an input-output variable `OUT`. Execution is triggered by an event at the input `REQ`. After writing, an acknowledgment event is sent at the output `CNF`.

Interface Structure

Event Inputs

Name	Type	Comment	With Variables
REQ	Event	Normal execution command	IN, OUT

Event Outputs

Name	Type	Comment	With variables
CNF	Event	Execution confirmation	OUT

Data Inputs

Name	Type	Comment
IN	STRING	The value to be written

Data Outputs

Name	Type	Comment
OUT	STRING	Target variable (In-Out) – identical to IN after execution

Note: `OUT` is declared as an In-Out variable. It serves simultaneously as an input (the current value before execution) and as an output (the new value after execution). When `REQ` is received, `OUT := IN` is set, overwriting the previous value.

Adapters

No adapters are available.

Functionality

1. An incoming event at input `REQ` starts the processing.
2. The code stored in algorithm `REQ` is executed:

- `OUT := IN;`

The value of the input variable `IN` is copied to the input-output variable `OUT`.

1. Subsequently, the event at output `CNF` is sent to signal successful execution.

Technical Features

- The function block contains only a single state (`REQ`) in which all processing takes place. It is a **simple function block** (SimpleFB) without sequential state machines.

1. The event is then sent at output `CNF` to signal successful execution. - The input-output variable `OUT` allows the function block to be directly linked to a persistently writable variable (e.g., a global data object or a linked hardware address) without requiring a separate output variable.

- The algorithm is trivial and performs no type or range checks.

State Overview

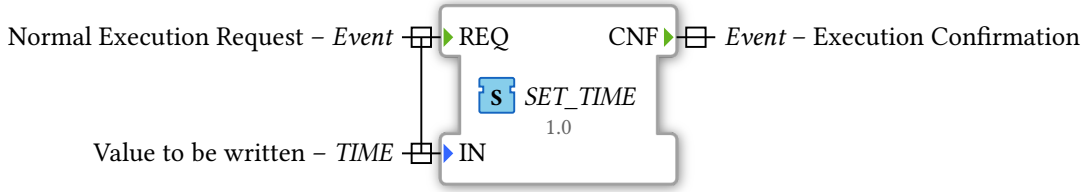
The function block has exactly one state:

State	Action	Output Event	Description
`REQ`	`OUT := IN`	`CNF`	Copies the input value to the input-output variable and acknowledges

A start state is not explicitly defined; The function block expects an external event pulse on `REQ`.

Application Scenarios

- **String Parameterization in Controllers**: Setting a string value in a global variable, e.g., a device name or IP address.
- **Initialization of Text Blocks**: Overwriting a standard string in a higher-level function block network.
- **Test and Debugging Environments**: Precisely specifying values for subsequent processing steps.



Comparison with Similar Function Blocks

- **SET_BOOL, SET_INT, SET_REAL**: Similarly structured function blocks for other data types. `SET_STRING` differs from `STRING` only in its data type.
- **MOVE**: A generic function block that can copy values of different data types. In contrast, `SET_STRING` is strictly specialized for `STRING` and works with an input/output variable, while `MOVE` uses separate inputs and outputs.
- **WRITE_STRING**: Blocks with similar functionality found in some libraries, but often equipped with additional control or error outputs.

Conclusion

The `SET_STRING` function block is a simple yet effective tool for precisely setting a string value to an input/output variable. It is particularly suitable for applications where a value needs to be written directly to an existing variable without requiring any readback or comparison logic. Due to its minimal interface and clear semantics, it can easily be integrated into more complex automation solutions.

SET_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_TIME** is used to write a time value (type TIME) provided via the data input IN to a variable OUT passed as an InOut parameter. The block is implemented as a simple, event-driven block and confirms execution via the event output CNF.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution request. Trigger the algorithm that copies the value from IN to OUT. Associated data: IN, OUT.

Event Outputs

Event	Description
CNF	Confirmation of successful execution. Sent after the algorithm completes. Associated data: OUT.

Data Inputs

Name	Type	Initial Value	Description
IN	TIME	T#0s	The time value to be written to the target variable.

Data Outputs

Name	Type	Initial Value	Description
OUT	TIME (InOut)	T#0s	Target variable passed as an InOut parameter during the call. The value of IN is copied into this variable.

> **Note:** OUT is an **InOut** parameter, meaning it serves as both an input and an output. The caller must provide a writable variable.

Adapter

None available.

Functionality

1. The function block waits for an event at input REQ.
2. When REQ occurs, the algorithm is executed: The current value of the data input IN is assigned to the InOut variable OUT (OUT := IN).
3. After successful assignment, the event CNF is triggered to signal completion to the calling function block.

Execution takes place in a single EC state (REQ), which runs the algorithm exactly once.

Technical Features

- **InOut Parameter:** OUT is an InOut data point. This allows the function block to write directly to a variable provided by the caller without requiring an additional data output. The caller must ensure that the referenced variable exists and is writable.
- **Simple Logic:** The function block consists of only one EC state and one ST algorithm. There are no branches, timers, or internal state machines.
- **Typing:** Both IN and OUT are of type TIME, meaning only time values are processed.

State Overview

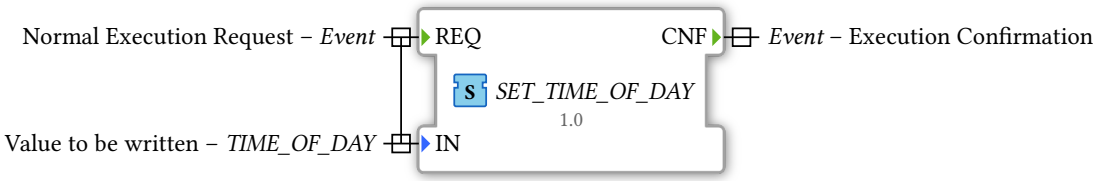
The function block has exactly one state:

State	Description
REQ	Initial state upon initialization. Activated when REQ occurs. Executes the algorithm and sends CNF.

There are no other states. The function block returns to the initial state after completing the algorithm and waits for the next REQ event.

Application Scenarios

- **Setting Timer Parameters:** A higher-level control block passes a specific delay time (e.g., for a TON or TOF block) via an InOut parameter.
- **Initializing Time Variables:** In a startup sequence, predefined time values are written to global or instance-specific variables.
- **Copying Time Values:** A time variable is overwritten once with a calculated or configured value.
- **Real-Time Parameter Updates:** Dynamically changes a time reference shared by multiple blocks.



Comparison with Similar Blocks

- **Simple MOVE blocks (e.g., MOVE for generic types):** SET_TIME is specifically optimized for the TIME type and uses an InOut parameter, which saves memory and makes data transfer more efficient.
- **Direct assignment via IEC 61499 connections:** A simple connection from a OUT port of another block to the IN port of a target block could also set a value, but often requires additional event coupling. SET_TIME simplifies this through explicit REQ/CNF control.
- **Setting via global variables:** Other blocks write directly to global variables via service interfaces. SET_TIME, on the other hand, typically operates on instance-specific InOut parameters, which improves encapsulation.

Conclusion

The **SET_TIME** function block is a simple yet useful building block for writing a TIME value to a variable referenced as an InOut. Its clear event handling, minimal resource consumption, and direct coupling of input and output via the InOut mechanism make it ideal for time-critical assignment tasks in automation technology. The use of standard IEC 61499 mechanisms ensures interoperability and easy integration into existing control projects.

SET_TIME_OF_DAY

• – ◦ • – ◦ • – ◦ •

Introduction

The function block SET_TIME_OF_DAY is used to write a time of day value provided via the data input IN to a target variable OUT, which is declared as an InOut variable. The block is implemented as a simple FB (SimpleFB) and complies with the IEC 61499-1 standard.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Normal execution request (bound to IN and OUT)

Event Outputs

Name	Type	Comment

CNF	Event	Execution confirmation (bound to `OUT`)

Data Inputs

Name	Type	Comment
IN	TIME_OF_DAY	The time of day value to be written

Data Outputs

No explicit data outputs are available. The target value is stored as an InOut variable.

Adapters

None.

Functionality

When an event arrives at input `REQ`, the algorithm `REQ` is executed:

- The value of `IN` is assigned to the InOut variable `OUT`: `OUT := IN`.
- After successful assignment, the event `CNF` is output to acknowledge the completion of the operation.

Technical Details

- The target variable `OUT` is declared as an **InOut variable**. This means that it serves as both input and output and must be passed externally by reference. The value of `OUT` is overwritten by the assignment.
- The function block contains only one state and one algorithm, ensuring very simple, deterministic execution.
- The data type `TIME_OF_DAY` follows the IEC 61499 data type definition for times of day (e.g., `TOD#12:30:00`).

State Overview

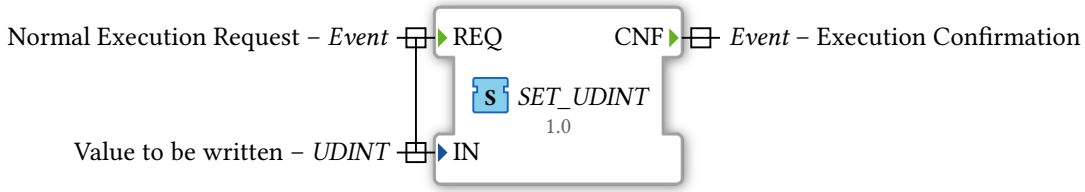
The function block has a single state:

- **REQ**: Activated on the event `REQ`. After the algorithm is executed, `CNF` is sent, and the state remains active (no state change).

State	Action	Output Event
REQ	Algorithm `REQ`	CNF

Application-Specific Scenarios

- **Setting a Global Time of Day**: In a controller, the current time can be retrieved from a higher-level system and written to a central InOut variable.
- **Configuring Time Parameters**: A user enters a time of day via an HMI, which is then written to a configuration variable using `SET_TIME_OF_DAY`.
- **Passing Time Values**: If a time value needs to be read from a source and passed to multiple subsequent function blocks, this function block can serve as a simple write access.



Comparison with Similar Function Blocks

- **MOVE for Elementary Types**: Similar function blocks exist for basic types such as `BOOL`, `INT`, `REAL`, etc. `SET_TIME_OF_DAY` is the specific variant for `TIME_OF_DAY`.
- **Standard MOVE Blocks**: Many IEC 61499 libraries contain generic function blocks such as `MOVE` or `ASSIGN`. The block presented here is a dedicated and type-safe implementation for `TIME_OF_DAY`.

Conclusion

SET_TIME_OF_DAY`is a minimal yet useful function block for overriding a`TIME_OF_DAY` InOut variable. Its simple structure makes it reliable and easy to understand. It can be effectively used in combination with other function blocks in timing and configuration applications.

SET_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_UDINT** is used to write a value from the data input `IN` to the InOut variable `OUT`. The operation is triggered by an event at the input `REQ`, and after successful assignment, the output `CNF` is activated. The function block is specifically designed for the UDINT data type, thus enabling efficient and type-safe data transfer to a shared variable.

Interface Structure

Event Inputs

Event	Data Type	Comment
`REQ`	Event	Normal execution job; triggers writing the input value to the output variable.

Data associated with `REQ`: `IN`, `OUT`

Event Outputs

Event	Data Type	Comment
`CNF`	Event	Execution confirmation; outputs once the value has been successfully assigned.

Data associated with `CNF`: `OUT`

Data Inputs

Identifier	Data Type	Initial Value	Comment
`IN`	UDINT	0	Value to be written to the target variable.
`OUT` (InOut)	UDINT	0	Target variable that functions as both an input (readable) and an output (writable).

Data Outputs

Identifier	Data Type	Comment
`OUT` (InOut)	UDINT	Same variable as the input; after execution, it contains the value of `IN`.

Adapters

No adapters available.

Functionality

The function block works very simply:

1. An event at the input `REQ` starts the processing.
2. The ST code implemented in the algorithm `REQ` executes the assignment `OUT := IN;`.
3. After the assignment, the event at the output `CNF` is sent to signal successful completion.

The InOut variable `OUT` is both readable and writable. The assigned value remains until another `REQ` assigns a new value or the variable is modified externally.

Technical Features

- **Using an InOut Variable**: `OUT` is declared as an InOut variable. This allows the function block to directly access and modify an external variable without requiring a separate data output. The value is visible both inside and outside the function block after the write operation.
- **Simple Logic**: No intermediate storage, no delays – the process is atomic and occurs in a single step.
- **Type Binding**: The function block is defined exclusively for the type `UDINT` (unsigned 32-bit integer), guaranteeing type-safe operation.

State Overview

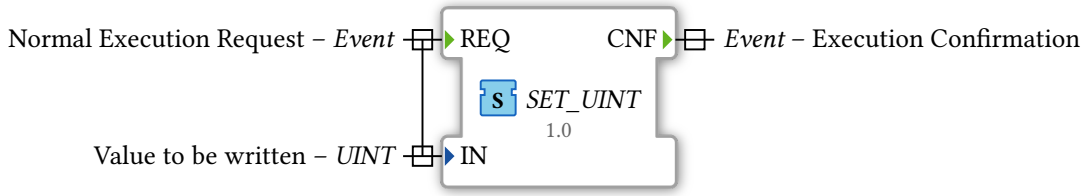
The function block contains a single state, `REQ` (event handling):

State	Action	Output Event
`REQ`	Execute algorithm `REQ` (OUT := IN)	CNF

After `CNF` is executed, the function block returns to its initial state and waits for the next `REQ` event.

Application Scenarios

- **Variable Initialization**: Setting a UDINT value to a predefined starting value at runtime.
- **Parameter Control**: Overriding configuration values in a running application (e.g., setpoints, counter values).
- **Data Passing Between Logic Blocks**: Using a shared InOut variable to update data without additional intermediate storage.
- **Replacement for Simple Move Functions**: Similar to a MOVE block, but with explicit UDINT focus and InOut mechanics.



Comparison with Similar Blocks

- **MOVE (Generic)**: A general-purpose MOVE block can copy values of any type, but requires separate inputs and outputs. `SET_UDINT`, on the other hand, uses InOut, which reduces wiring and allows access to the original variable.
- **SET_BOOL, SET_INT, etc.**: Type variants of the same concept for different data types. `SET_UDINT` is specifically optimized for 32-bit unsigned integers.
- **R_TRIG / F_TRIG**: These edge detections do not set values, but rather detect changes. `SET_UDINT` directly writes values.

Conclusion

The function block `SET_UDINT` is a lean, reliable component for writing an InOut variable with a UDINT value. Its simple structure (one event, one assignment) makes it easy to understand and debug. Using an InOut interface saves on wiring and allows direct manipulation of external variables. Typical of IEC 61499, it is ideal for automation projects where fast and type-safe value assignments are required.

SET_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The SET_UINT function block is used to write a UINT value, which is present at a data input, into a variable declared as an InOut parameter. This simple but fundamental operation allows data to be copied from the FB context into an external or referenced variable.

Interface Structure

Event Inputs

Name	Type	Description
REQ	Event	Normal Execution Command

Event Outputs

Name	Type	Description
CNF	Event	Execution Confirmation

Data Inputs

Name	Type	Initial Value	Description
IN	UINT	0	Value to be written

Data Outputs

No separate outputs available. The target value is provided via the InOut variable `OUT`.

Adapters

No adapters.

Operation

Processing occurs in one step:

1. An event at the input `REQ` triggers the execution of the algorithm.
2. The algorithm copies the value of the data input `IN` to the InOut variable `OUT`.
3. Upon completion, the event `CNF` is output.

The InOut variable `OUT` is interpreted as a referenced variable – the function block writes directly to the memory location connected to the `OUT` interface during the call.

Technical Features

- **InOut Variable as Target:** The function block uses an InOut variable (`OUT`) instead of a simple output. This allows the function block to directly access and overwrite an existing variable in call environments (e.g., within resources or other function blocks).
- **Single-line algorithm:** The assignment `OUT := IN` is performed in a single ST instruction; no further calculations or intermediate storage are carried out.
- **No state machines:** The function block (FB) has only one entry state (`REQ`); state changes or loops are not implemented.

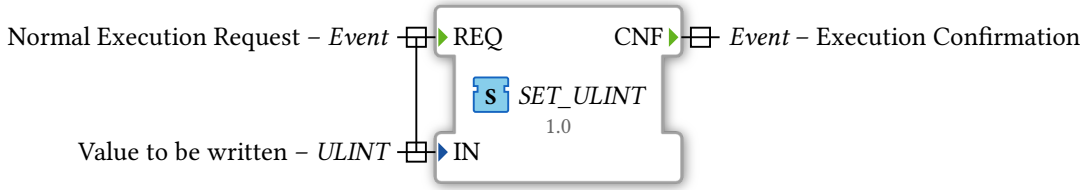
State overview

State	Action	Output
REQ	`OUT := IN`	CNF

After execution, the FB remains in an implicit end state; it is ready for each new request `REQ`.

Application Scenarios

- **Setting a Configuration Value:** A setpoint or parameter (e.g., a threshold in a control block) is input externally and written to the corresponding internal variable.
- **Copying UINT Data to a Central Memory Location:** In a controller, `SET_UINT` can be used to transfer measured values or calculation results to a global data block.
- **Exchanging Data Between Function Blocks:** Two different function blocks can access the same variable via the InOut variable – the `SET_UINT` function block is used for targeted overwriting.



Comparison with Similar Function Blocks

- **SET_BOOL / SET_INT / SET_*:** These function blocks differ only in the data type used. Their functionality – "writing the value from IN to OUT" – is identical.
- **MOVE (e.g., `MOVE` in IEC 61131-3):** A general copy function, which is usually implemented as a standard function (without its own event interface). The `SET_UINT` function block provides explicit event control for its execution.
- **Special Case InOut:** Unlike pure output blocks, `SET_UINT` allows direct access to the target variable, which offers advantages when passing data across hierarchy boundaries.

Conclusion

The `SET_UINT` function block is a minimal but useful block for writing a UINT value to a referenced variable. Its simple structure—an event triggers an assignment—makes it particularly useful in environments where explicitly "setting" a variable via an event is required. If it does not meet any further conditions, it is suitable as a template for similar data type-specific set functions.

SET_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The **SET_ULINT** function block is used to write an unsigned 64-bit integer value (ULINT) from a data input to an InOut variable. It is typically used to set values to linked variables or global memory locations that can also be read by other function blocks.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution command. The value of `IN` is transferred to the InOut variable `OUT`, and upon completion, the event output `CNF` is sent.

Event Outputs

Event	Description
CNF	Execution confirmation. Triggered as soon as the assignment of `IN` to `OUT` is completed.

Data Inputs

Name	Data Type	Description
IN	ULINT	The value to be written. Default: `0`.

Data Outputs

Name	Data Type	Description
OUT	ULINT	InOut variable – target of the assignment. It can be both read and written and is set to the new value after execution.

Adapter

None.

Functionality

The function block is implemented as a simple state machine (SimpleFB). A single state, `REQ`, executes the algorithm `REQ` when activated:

OUT := IN; The event output `CNF` is then sent. The passed value `IN` is therefore copied directly into the InOut variable `OUT`. Since `OUT` is declared as InOut, the function block cannot read the previous value of `OUT` – it is simply overwritten.

Technical Features

- The function block uses an **InOut variable** (`OUT`), which functions as both an input and output port in the IEC 61499 model. This allows direct connections to variables shared by multiple function blocks.
- The `logiBUS::utils::conversion::provide` package in the CompilerInfo indicates that the function block (FB) is intended for use in the logiBUS ecosystem.
- The algorithm is very simple – just a single ST assignment – and therefore extremely fast to execute.
- The initial value of `OUT` is `0`, so a defined starting value is available upon first use without prior initialization.

State Overview

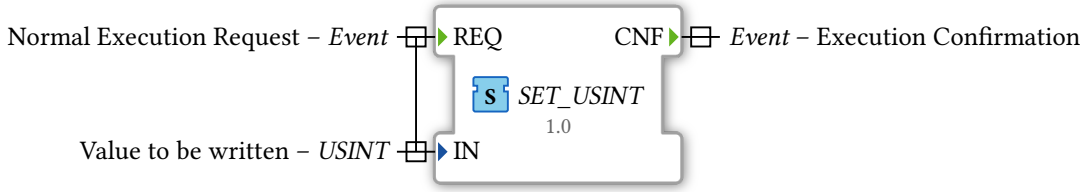
The FB has exactly one EC state:

State	Action	Output
REQ	`REQ` (OUT := IN)	CNF

After startup or reset, the function block (FB) is in state `REQ`. Each `REQ` event pulse triggers the action and subsequently generates `CNF`.

Application Scenarios

- **Parameterized by Real-Time Systems**: Setting setpoints or configuration parameters in a variable monitored by multiple function blocks.
- **Global Status Variables**: Writing error codes or operating states to a central `ULINT` variable.
- **Testing and Diagnostic Purposes**: Targeted overwriting of values in a running controller for analysis purposes.



Comparison with Similar Function Blocks

- **SET_INT, SET_DINT, SET_LINT**: Similar function blocks for other integer types (INT, DINT, LINT). The functionality is identical; only the data type differs.
- **MOVE_ULINT**: Many libraries include a MOVE block that copies a value from an input to an output. `SET_ULINT` differs by using an **InOut variable**, which allows direct access to an existing variable without having to use a pure output.

Conclusion

The **SET_ULINT** function block is a simple yet effective tool for setting ULINT values in shared variables. Its InOut interface makes it particularly suitable for applications where values need to be overwritten without evaluating the previous state. Its lean implementation makes it well-suited for time-critical control applications.

SET_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_USINT** is used to write a value of type **USINT**, provided via the data input **IN**, directly into the variable **OUT**, which is declared as InOut. The block performs a simple assignment and confirms execution with the **CNF** event.

Interface Structure

Event Inputs

Event	Description
REQ	Normal execution request – takes the value from **IN** to **OUT** and sends **CNF**.

Event Outputs

Event	Description
CNF	Confirmation of successful execution (sent after assignment).

Data Inputs

Name	Data Type	Initial Value	Description
IN	USINT	0	Value to be written to the target variable.

Data Outputs

Name	Data Type	Initial Value	Description
OUT	USINT (InOut)	0	Target variable (declared as InOut, meaning it can be both read and written). After execution, **OUT** contains the value of **IN**.

Adapter

None.

Functionality

When the **REQ** event is received, the function block executes the **REQ** algorithm. This assigns the current value of the **IN** input to the **OUT** variable (`OUT := IN;`). The **CNF** event is then sent to signal the completion of the operation. The function block operates without delay or further conditions.

Technical Features

- The use of an **InOut** variable allows **OUT** to be used as both a target (output) and a source (input) in other function blocks.
- The function block is fixed to the **USINT** data type (8-bit unsigned integer) – direct conversion is not supported.
- Only one state exists; the function block is **event-driven** and performs exactly one assignment per **REQ**.

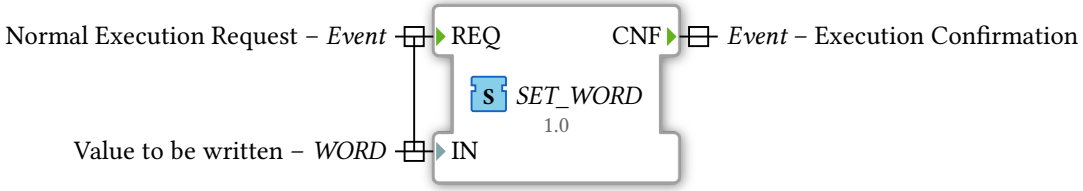
State Overview

State	Action	Output Event
REQ	Execute the **REQ** (`OUT := IN;`) algorithm	**CNF**

The FB has no explicit start state – it waits for an event in the **REQ** state.

Application Scenarios

- **Initializing** variables or peripherals that require a specific USINT value.
- **Parameterizing** devices or function blocks via an InOut variable.
- **Simply setting a value** in control logic when no calculation or condition is required.



Comparison with Similar Function Blocks

- **MOVE (ANY)**: A more general function block for copying arbitrary data types, often without InOut capability.
- **SET_INT**, **SET_BYTE**, etc.: Analogous function blocks for other integer types – SET_USINT is specialized for USINT.
- Unlike **LATCH** or **SR flip-flops**, SET_USINT does not store state but performs a one-time assignment.

Conclusion

SET_USINT is a minimalist and reliable function block for directly assigning a value to an InOut variable of type USINT. Its simple structure is particularly suitable for clear, sequential control tasks where a value must be set without side effects.

SET_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The SET_WORD function block writes a WORD value from its data input IN to an InOut variable OUT. It is used to overwrite an output or a globally accessible WORD variable with a specific value.

Interface Structure

Event Inputs

- **REQ** (Event): Normal execution command. The block is triggered when an event arrives at this input.

Connected to the variables `IN` and `OUT`.

Event Outputs

- **CNF** (Event): Confirmation of execution. Sent after successful assignment.

Connected to the variable `OUT`.

Data Inputs

- **IN** (WORD): The value to be written to the target variable. Initial value: `0`.

Data Outputs

No data outputs are available. Output is exclusively via the InOut variable `OUT`.

Adapters

None.

Functionality

When an event occurs at the **REQ** input, the following algorithm is executed:
OUT := IN;`Subsequently, an acknowledgment event is sent at the **CNF** output. The function block overwrites the current value ofOUTwith the value ofIN`.

Technical Features

- `OUT` is declared as an **InOut variable**. It serves as both input (read) and output (write). The previous value of `OUT` is overwritten by the assignment.
- There are no separate data outputs – the change directly affects the associated variable.
- The function block is type-specific to `WORD`. Corresponding variants are available for other data types.

State Overview

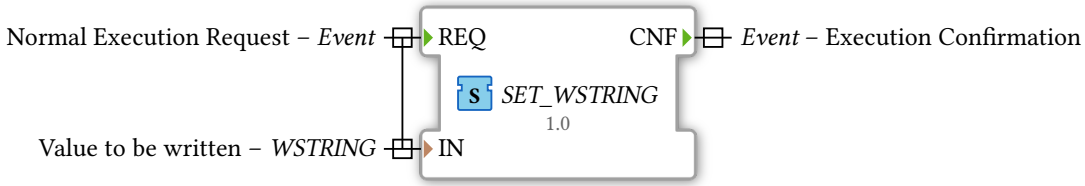
The function block has one active state:

- **REQ**: Upon entering this state, the assignment `OUT := IN` is executed, and the **CNF** event is triggered.

There are no other states or branches.

Application Scenarios

- Setting a WORD output to a calculated or fixed value.
- Overwriting a global WORD variable in a PLC.
- One-time initialization of a WORD variable by an external function block.



Comparison with similar function blocks

- **MOVE**: Copies a value from an input to an output (separate inputs/outputs). SET_WORD uses an InOut variable instead.
- **SET_BOOL**: Analogous functionality for the BOOL data type.
- **F_MOVE**: Function block for general data transfer, often with multiple inputs/outputs. SET_WORD is more specific and direct.

Conclusion

SET_WORD is a simple and efficient function block for writing a WORD value directly to an InOut variable. By using an InOut parameter, it reduces the number of variables required and is particularly useful in scenarios where a value needs to be overwritten without using a separate output.

SET_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SET_WSTRING** is used to transfer a value of data type `WSTRING` to an InOut parameter. It is typically used to write a calculated or externally specified string value to a higher-level variable (e.g., of another instance or a higher-level function block).

Interface Structure

Event Inputs

Event	Description
`REQ`	Normal execution call: The assignment of the input value to the InOut variable is triggered.

Event Outputs

Event	Description
`CNF`	Execution confirmation. Sent after successful assignment.

Data Inputs

Name	Data Type	Description
`IN`	`WSTRING`	Source value to be written to the target variable.

Data Outputs

This function block does not have traditional data outputs. The value is passed via the **InOut variable** `OUT`.

Adapters

None.

Functionality

If the event input REQ is activated, the function block executes the following assignment:
OUT := IN; The value WSTRING, which is present at input IN, is copied unchanged to the InOut variable OUT. Then, the event CNF is sent to signal the completion of the operation to the calling function block.

Technical Features

- **InOut Variable**: OUT is declared as an InOut parameter. This means that the variable can be both read and written, and its lifetime is outside the function block. The function block overwrites the current content of OUT with the value of IN.
- **Data type WSTRING**: This is a string type that supports wide characters (Unicode). The function block does not perform any length checks or conversions – the assignment is direct.
- **Simplest State Machine**: The state machine consists of a single state (REQ) that covers all functionality. There are no branches or time delays.

State Overview

The function block contains exactly one state:

State	Description
REQ	Becomes active after the event REQ occurs. Executes the assignment OUT := IN and sends CNF. The function block then returns to its initial state.

Application Scenarios

- **Passing a Formatted String**: Suppose a function block generates an error message as WSTRING and wants to write it to a parent variable. SET_WSTRING handles this assignment upon a trigger.
- **Parameterization**: In a controller, an external parameter (e.g., a product name) can be copied to a global data block using SET_WSTRING.
- **Debugging**: Temporarily setting a WSTRING variable using test or initialization logic.

Comparison with Similar Function Blocks

- **SET_BOOL**: Works analogously, but with the data type BOOL. Both use an InOut to write values to external variables.
- **MOVE (IEC Function Block)**: The standard MOVE function block copies data from an input to an output. In contrast, SET_WSTRING uses an InOut parameter, which allows connection to existing variables without an additional output port.
- **WRITE_STRING**: Some libraries offer special Write function blocks with length checks. SET_WSTRING is deliberately kept simple and does not include any checks.

Conclusion

The **SET_WSTRING** function block is a minimalist yet effective solution for writing to a WSTRING InOut variable. Its simple state machine and clear interface make it easy to understand and use wherever a trivial assignment to an event is needed. For tasks with additional functions (conversion, length constraints), specialized building blocks are preferable.

assembling

ST08X_TO_BYTE

• – ○ • – ○ • – ○ •

Introduction

The function block `ST08X_TO_BYTE` converts a special data structure containing eight individual Boolean values (BOOL) into a single byte value (BYTE). This operation is useful for bundling compact digital signals for transmission or storage, or for connecting them to systems that expect data in byte format.

Interface Structure

Event Inputs

- **REQ**: This event triggers the conversion function. Upon its arrival, the current values at the data input `IN` are read and converted to the byte output `OUT`.

Event Outputs

- **CNF**: This event signals the successful completion of the conversion. It is generated simultaneously with the output of the calculated byte value at data output `OUT`.

Data Inputs

- **IN** (Type: `ST08X`): The input for the data structure to be converted. Type `ST08X` is a user-defined structure type (STRUCT) containing eight individual BOOL elements named `X_00` through `X_07`.

Data Outputs

- **OUT** (Type: `BYTE`): The output where the result of the conversion is provided. The eight bits of the byte (bits 0 to 7) directly correspond to the eight BOOL values of the input structure.

Adapter

This function block has no adapter interfaces.

Functionality

When triggered by the `REQ` event, the block performs a bitwise assignment. Each bit of the output byte `OUT` is set to the value of the corresponding Boolean element in the input structure `IN`. The assignment follows the following predefined scheme:

- `OUT`.0 (least significant bit, LSB) = `IN.X_00`
- `OUT`.1 = `IN.X_01`
- `OUT`.2 = `IN.X_02`
- `OUT`.3 = `IN.X_03`
- `OUT`.4 = `IN.X_04`
- `OUT`.5 = `IN.X_05`
- `OUT`.6 = `IN.X_06`
- `OUT`.7 (most significant bit, MSB) = `IN.X_07`

After these assignments are complete, the `CNF` event is output along with the new value of `OUT`.

Technical Features

- **Deterministic Mapping**: The assignment of individual BOOL elements to specific bit positions in the byte is hardcoded and not configurable.

- **Simple Logic**: The block contains no state machines or complex algorithms. Its functionality is limited to direct, parallel assignment.
- **Type Dependency**: The block is specific to the user-defined data type `ST08X`. Different blocks may be required for other structures or a different number of bits.

State Overview

The function block does not have an internal state in the sense of a state machine. It behaves purely combinatorially with respect to the data and sequentially with respect to event handling: An incoming `REQ` is always followed by an outgoing `CNF`.

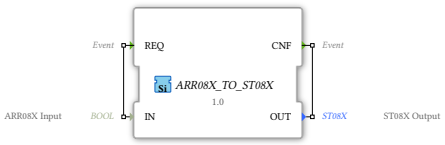
Application Scenarios

- **Communication with Byte-Oriented Interfaces**: Preparing data for transmission via serial bus systems (e.g., Modbus, Profibus), networks, or communication protocols that expect data in byte blocks.
- **Compact Storage**: Bundling multiple digital switching states (e.g., from limit switches, machine states) into a single byte to optimize storage space.
- **Data Preparation for Visualization or Logging**: Converting structured BOOL signals into a byte format that is easier for display systems or data storage to handle.
-

⚖️ Comparison with Similar Blocks

- **`BOOL_TO_BYTE` (or similar blocks from standard libraries)**: Many IEC 61499 or IEC 61131-3 libraries offer blocks that directly convert eight separate `BOOL` inputs into a single `BYTE`. `ST08X_TO_BYTE` differs in that the input values are already bundled into a structured variable (`ST08X`), which can simplify wiring in the application diagram.
- **`PACK` / `UNPACK` blocks**: More general blocks for packing and unpacking data. `ST08X_TO_BYTE` is a specialized and type-safe implementation for precisely this one use case.
- **Manual Bit Operations**: The function could also be implemented through direct assignments in Structured Text (ST). The function block encapsulates this logic and provides a standardized, reusable interface with clear event handling.

Conclusion



The `ST08X_TO_BYTE` function block is a specialized and efficient tool for converting a structured group of eight Boolean signals into a compact byte. Its clear, well-defined interface and simple operation make it ideal for applications where digital signals need to be bundled for efficient communication or storage. Its use promotes the reusability and readability of control programs compared to manually implemented bit operations.

converting

Numeric Index (converting)

Here you will find all exercises from the `converting` workspace, listed in ascending order. ...

ARR08X_TO_ST08X

• – ○ • – ○ • – ○ •

This function block (FB) is used to convert an array of 8 BOOL values (ARR08X) into a corresponding structure of 8 BOOL values (ST08X). It enables easy conversion between these two data formats.

- **REQ**: An event that triggers the conversion. When REQ is received, the value of input `IN` is processed, and the result is provided at output `OUT`.
- **CNF**: An acknowledgment event that is triggered once the conversion is complete and the output `OUT` has been updated.
- **IN**: An array of 8 BOOL values (BOOL[0..7]) representing the source data for the conversion.

- **OUT**: A structure of type `logiBUS::utils::conversion::types::ST08X` containing the converted 8 BOOL values.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block has no adapters.

The function block `ARR08X_TO_ST08X` performs a direct, element-by-element assignment of values from the input array `IN` to the corresponding fields of the output structure `OUT`. On each `REQ` event, the value of the `IN` array is read, and the individual elements of the array `IN[0]` to `IN[7]` are assigned to the fields `X_00` to `X_07` of the `ST08X` structure. After the assignment, the `CNF` event is triggered.

The assignments are made as follows:

- `OUT.X_00 := IN[0];`
- `OUT.X_01 := IN[1];`
- `OUT.X_02 := IN[2];`
- `OUT.X_03 := IN[3];`
- `OUT.X_04 := IN[4];`
- `OUT.X_05 := IN[5];`
- `OUT.X_06 := IN[6];`
- `OUT.X_07 := IN[7];`
- **Data Type Conversion**: This function block specializes in converting a generic BOOL array into a specific BOOL structure of type `ST08X`. This structure type must be known to the system (via `IMPORT logiBUS::utils::conversion::types::ST08X;`).
- **Data Type Conversion**: This function block specializes in converting a generic BOOL array into a specific BOOL structure of type `ST08X`. * **Fixed Size**: This function block is designed for arrays and structures with exactly 8 BOOL elements. It is not variable for other array sizes.
- **Determinism**: The conversion is direct and deterministic. Execution occurs immediately upon receiving the `REQ` event.

The `ARR08X_TO_ST08X` function block is a stateless function block. It does not store any internal states between calls. Each execution of the function block is independent of previous executions and is based solely on the current input values.

- **Interface Adaptation**: Ideal for adapting data formats between different system components, especially when one component prefers or expects an array and another a structure.
- **Standardized Data Access**: Enables access to individual Boolean values via named fields (`X_00`, `X_01`, etc.) instead of array indices, which can improve code readability.
- **Visualization**: Simplifies integration with visualization systems that may prefer a structured representation of Boolean signals over an array.
- **Legacy Systems**: Can serve as a bridge between older systems that may use Boolean arrays and newer components that work with structures.
- **Manual Assignment**: The functionality could also be implemented through direct assignments in the control program's code (e.g., in a `ST` block). The `ARR08X_TO_ST08X` function block encapsulates this logic in a reusable function block, increasing modularity and clarity.
- **Generic Converters**: Unlike a generic converter that could handle arbitrary array sizes or types, this block is specifically designed for 8-element BOOL arrays and the `ST08X` structure. This simplifies implementation but makes it less flexible for other sizes.

The `ARR08X_TO_ST08X` function block is a useful, specialized block for efficiently and clearly converting 8-element BOOL arrays into an 8-element BOOL structure. It contributes to improved code readability and modular architecture in 4diac applications, especially in scenarios requiring data format adaptation.

ST08X_TO_ARR08X

• — ○ • — ○ • — ○ •

Introduction

This function block (FB) is used to convert a specific structure of type `ST08X`, which contains eight individual BOOL values, into an array of eight BOOL values. It enables seamless adaptation of the data representation in automation applications.

Interface Structure

Event Inputs

- **REQ**: This event is used to initiate the conversion operation. Upon receiving this event, the data from input `IN` is processed and written to output `OUT`.

Event Outputs

- **CNF**: This event is triggered after the data from the `IN` input has been successfully converted to the `OUT` array and the output has been updated.

Data Inputs

- **IN** (`logiBUS::utils::conversion::types::ST08X`): This is the input for the structure of type `ST08X`. This structure contains eight named BOOL fields (X_00 to X_07) to be converted.

Data Outputs

- **OUT** (`BOOL[0..7]`): This is the output for the array of BOOL values. The array has a fixed size of 8 elements containing the converted data from the input structure.

Adapters

This function block does not use any adapters.

Functionality

The function block `ST08X_TO_ARR08X` performs a direct and deterministic transformation of the input data. When the `REQ` event is received, the individual BOOL fields of the input structure `IN` are assigned to the corresponding index of the `OUT` array:

- `IN.X_00` is assigned to `OUT[0]`.
- `IN.X_01` is assigned to `OUT[1]`.
- ...
- `IN.X_07` is assigned to `OUT[7]`.

After these assignments are complete, the `CNF` event is thrown to indicate that the output `OUT` has been updated and the converted data is available.

Technical Features

- **Specific Types**: The function block is specifically designed for converting between the user-defined type `logiBUS::utils::conversion::types::ST08X` and a `BOOL[0..7]` array.
- **Fixed Mapping**: The mapping of structure fields to array indices is static and cannot be configured at runtime.
- **Atomic Operation**: The conversion is a single, self-contained operation triggered by an input increment event.

State Overview

The `ST08X_TO_ARR08X` function block is stateless. It does not store any internal state or data between executions. Each execution triggered by a `REQ` event processes the data currently assigned to `IN` completely and independently of previous operations.

Application Scenarios

- **Interface Adaptation**: Ideal for adapting data from a component that provides 8 BOOL values as a structure (`ST08X`) to another component that expects a `BOOL` array with 8 elements (e.g., for visualizations, external devices, or generic loop processing).
- **Data Format Standardization**: If a project uses different conventions for grouping 8 BOOL values, this function block can help bring the data into a consistent format.
- **Compatibility with legacy systems**: Can be used to convert data from more modern structures into array-based formats that are easier for older or simpler systems to process.

⚖️ Comparison with similar function blocks

While 4diac-IDE and the IEC 61499 standard provide generic data conversion mechanisms and array manipulation functions, the `ST08X_TO_ARR08X` is a highly specialized function block. General conversion function blocks might offer more flexible handling of different data types or array sizes, but often require configuration or additional logic. This function block provides a dedicated, simple, and efficient solution for this specific conversion case without any configuration overhead.

Conclusion

The `ST08X_TO_ARR08X` function block is a precise tool for converting an 8-BOOL structure into an 8-BOOL array. Its simplicity and specialization make it an efficient solution for interface adaptation and data formatting in 4diac-based automation applications that require such conversion.

ARR08B_TO_ST08B

• – ○ • – ○ • – ○ •

Introduction

This function converts an 8-byte array into an 8-byte structure. It is used to convert linear byte data into a structured format.

Interface Structure

Event Inputs

- **REQ**: A rising event at this input triggers the conversion of the data from input `IN` to output `OUT`.
- Associated with: `IN`

Event Outputs

- **CNF**: An event at this output signals the completion of the conversion and that the output data at `OUT` has been updated.
- Associated with: `OUT`

Data Inputs

- **IN** (Type: `BYTE`, Array Size: `[0..7]`): The input data array containing the 8 bytes to be converted.
- Comment: `ARR08B Input`

Data Outputs

- **OUT** (Type: `logiBUS::utils::conversion::types::ST08B`): The output structure containing the converted 8 bytes.
- Comment: `ST08B Output`

Adapters

No adapters are defined for this function block.

Functionality

The function block `ARR08B_TO_ST08B` performs a direct byte-by-byte assignment. When a `REQ` event is received, the individual elements of the input array `IN` are assigned to the corresponding components of the output structure `OUT`:

- `OUT.B_00` is assigned to `IN[0]`.
- `OUT.B_01` is assigned to `IN[1]`.
- `OUT.B_07` is assigned to `IN[7]`.

After these assignments are complete, a `CNF` event is triggered to indicate that the conversion is finished and the new data is available at the `OUT` output.

Technical Details

- **Data Types:** The input array is of type `BYTE`, and the output structure `ST08B` is a user-defined type consisting of 8 individual `BYTE` components (e.g., `B_00` to `B_07`).
- **Direct Assignment:** No data manipulation or conversion takes place; the bytes are copied directly from the array position to the structure component.
- **Stateless:** The function block has no internal state and always produces the same result for the same input.

State Overview

The `ARR08B_TO_ST08B` function block is **stateless**. It performs a purely functional transformation: On each trigger event (`REQ`), the current input values (`IN`) are converted, and the result (`OUT`) is output. No values are stored between calls.

Application Scenarios

This function block is useful in scenarios where:

- Raw data received as a byte array (e.g., via communication interfaces such as CAN, SPI, UART) needs to be converted into a structured format to improve readability and further processing.
- Data is exchanged between systems that use different representations for the same 8-byte data set (array vs. structure).
- A clear and explicit type conversion from a linear to a named structure is required to improve program logic.

⚖️ Comparison with Similar Function Blocks

- **Generic Copy Functions (e.g., `MEMCPY`):** Unlike a generic memory copy function that copies memory areas byte by byte, `ARR08B_TO_ST08B` provides a type-safe and explicit assignment of array elements to structured fields. This can help avoid errors in resizing or type matching and improve code readability.
- **Manual Assignments:** The functionality could also be achieved through eight individual assignment lines in ST code. However, this function block encapsulates this logic in a reusable and easily integrated unit, promoting modularity and maintainability.
- **Type Casting:** While a type cast might enable a similar conversion in some languages, this function block provides an explicit, event-driven interface that fits well into the 4diac model and allows for clear triggering of the conversion.

Conclusion

The `ARR08B_TO_ST08B` function block is a specialized and efficient building block for converting an 8-byte array into a predefined 8-byte structure. It improves code structure, readability, and maintainability by encapsulating a frequently used conversion task in a clear and reusable unit. Its stateless nature ensures predictable and reliable operation.

ST08B_TO_ARR08B

• — ○ • — ○ • — ○ •

Introduction

The function block `ST08B_TO_ARR08B` converts an 8-byte structured data type (`ST08B`) into an 8-byte array. This conversion allows for the easy adaptation of structured data to interfaces or protocols that require a sequential arrangement of bytes.

Interface Structure

Event Inputs

- **REQ**: An event input that triggers the execution of the conversion. This event is linked to the data input `IN` to ensure that the conversion is performed using the current input data.

Event Outputs

- **CNF**: An event output that signals that the conversion was successful and the output `OUT` has been updated. This event is linked to the data output `OUT`.

Data Inputs

- **IN**: A data input of type `logiBUS::utils::conversion::types::ST08B`. This input expects a structure consisting of 8 bytes (e.g., `B_00` to `B_07`).

Data Outputs

- **OUT**: A data output of type `BYTE` as an array with size `0..7`. This array contains the 8 bytes that were converted from the input structure.

Adapters

This function block does not use any adapters.

How it Works

The operation of `ST08B_TO_ARR08B` is direct and straightforward. Upon receiving a `REQ` event, the individual byte elements of the input structure `IN` are directly assigned to the corresponding elements of the output array `OUT`. Each element `B_xx` of the structure `IN` is assigned to the element `OUT[xx]` of the array.

Specifically, the assignment is as follows:

- `OUT[0]` is assigned to `IN.B_00`.
- `OUT[1]` is assigned to `IN.B_01`.
- ...
- `OUT[7]` is assigned to `IN.B_07`.

After these assignments are complete, the `CNF` event is triggered to signal the completion of the operation.

Technical Features

- **Data Types:** The function block works with a specific user-defined structure type, `ST08B`, and a standard `BYTE` array.
- **Direct Mapping:** No complex logic, transformation, or calculation takes place; instead, the bytes are directly mapped one-to-one.
- **Transparency:** The implementation in ST (Structured Text) is clear and easy to understand, ensuring high transparency of the function.

State Overview

The function block `ST08B_TO_ARR08B` is a pure data conversion block without internal state in the sense of a state machine. It executes its operation deterministically on each `REQ` event and returns a result based on the current input data.

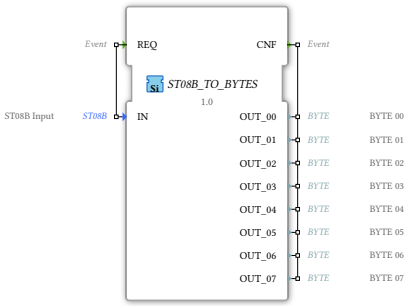
Application Scenarios

- **Data Preparation for Communication:** To prepare structured data for serial communication protocols (e.g., Modbus RTU, SPI, I2C), Ethernet frames, or other byte-oriented interfaces.
- **Connecting External Devices:** If external devices or libraries expect data as a pure byte array, this block can convert internal structured data accordingly.
- **Type Conversion and Interoperability:** Improves compatibility between different parts of an application or between different systems that use different data representations.
- **Archiving and Logging:** Stores structured data in a generic byte format for archiving or logging purposes.

⚖️ Comparison with Similar Blocks

Compared to other conversion blocks, `ST08B_TO_ARR08B` stands out due to its specialization in converting an 8-byte structure to an 8-byte array. General type conversion functions might be more complex and offer more configuration options, while this block performs a highly optimized and specific task. Blocks for array-to-structure conversion (e.g., `ARR08B_TO_ST08B`) would be the inverse function of this block.

Conclusion



The `ST08B_TO_ARR08B` function block is a simple yet effective way to convert an 8-byte structure into an 8-byte array. It provides a reliable solution for scenarios requiring direct and transparent adaptation of structured data to byte-oriented interfaces or formats. Its clear functionality and implementation make it a valuable tool in the 4diac development environment.

forwarding

ST08B_TO_BYTES

• – ○ • – ○ • – ○ •

Introduction

This function block extracts the individual 8 bytes of a specific 8-byte structure (`ST08B`) and provides them as separate byte outputs. It enables detailed segmentation and further processing of structured 8-byte data.

Interface Structure

Event Inputs

- **REQ**: Triggers the function and initiates the extraction of the bytes from the data input `IN`.

Event Outputs

- **CNF**: Sent after successful execution and updating of all output bytes. This event is associated with all `OUT_xx` data outputs.

Data Inputs

- **IN** (`logiBUS::utils::conversion::types::ST08B`): The input containing the 8-byte structure from which the bytes are to be extracted.

Data Outputs

- **OUT_00** (`BYTE`): The first extracted byte (byte 00).
- **OUT_01** (`BYTE`): The second extracted byte (byte 01).
- **OUT_02** (`BYTE`): The third extracted byte (byte 02).
- **OUT_03** (`BYTE`): The fourth extracted byte (byte 03).
- **OUT_04** (`BYTE`): The fifth extracted byte (Byte 04).
- **OUT_05** (`BYTE`): The sixth extracted byte (Byte 05).
- **OUT_06** (`BYTE`): The seventh extracted byte (Byte 06).
- **OUT_07** (`BYTE`): The eighth extracted byte (Byte 07).

Adapter

This function block has no adapter interfaces.

Operation

As soon as a `REQ` event is received, the function block reads the input structure `IN`. It extracts each individual byte of the structure (`IN.B_00` to `IN.B_07`) and assigns it to the corresponding output parameter (`OUT_00` to `OUT_07`). Upon completion of these assignments, the `CNF` event is triggered to signal the successful operation. The internal logic is direct and transparent:

OUT_00 := IN.B_00; OUT_01 := IN.B_01; OUT_02 := IN.B_02; OUT_03 := IN.B_03; OUT_04 := IN.B_04; OUT_05 := IN.B_05; OUT_06 := IN.B_06; OUT_07 := IN.B_07;

Technical Features

This function block specializes in decomposing the user-defined structure `ST08B`. Type assignment is performed directly without additional conversion logic, as both the source and target types (members of the structure and outputs) are of type `BYTE`. This ensures efficient and lossless data splitting. The block is deterministic and stateless, as it does not store any internal states that could influence the outcome of future executions.

State Overview

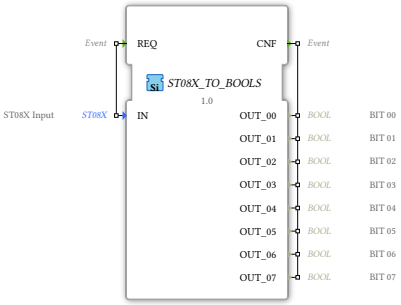
The function block `ST08B_TO_BYTES` is a pure converter without internal state. Each execution is independent of previous executions and always delivers the same result for identical input data.

Application Scenarios

- **Data Logging and Analysis**: When an 8-byte structure is received, the individual bytes can be extracted for separate logging, monitoring, or use in specific analyses.
- **Interface Adaptation**: Adapting data formats when an external interface provides an 8-byte structure, but subsequent components expect individual bytes.
- **Bit-Level Manipulation**: Preparing data for bit-level operations where each byte must be addressed individually.
- **Debugging**: Simplifies debugging data in 8-byte structures by making the contents of individual bytes visible.

⚖️ Comparison with Similar Components

Similar functionality could be achieved in other systems through explicit type conversions or pointer operations. In the 4diac context, this component represents an event-driven, clearly defined, and reusable solution for this specific structure-to-byte partitioning. The advantage lies in the direct connection to the 4diac event model and the explicit declaration of the interface, which improves readability and maintainability. Alternatively, the assignments would have to be made directly in the `ST` code of a Composite Function Block, which would limit reusability.



Conclusion

The `ST08B_TO_BYTES` function block is a useful tool for decomposing a specific 8-byte structure into its individual byte components. Its simplicity, clear interface, and deterministic functionality make it a reliable building block for applications that require precise control and analysis of 8-byte data. It promotes modularity and reusability in 4diac applications.

ST08X_TO_BOOLS

• — ○ • — ○ • — ○ •

Introduction

This function block extracts eight individual BOOL values from a single input structure of type `ST08X`. It allows for the easy decomposition of a bundled 8-BOOL structure into its individual components.

Interface Structure

Event Inputs

- **REQ**: An event at this input requests conversion. It signals the function block to process the data from input `IN`.

Event Outputs

- **CNF**: This event is output once the conversion is complete and all output BOOL values (`OUT_00` to `OUT_07`) have been updated.

Data Inputs

- **IN** (Type: `logiBUS::utils::conversion::types::ST08X`): The input structure containing the eight BOOL values to be extracted.

Data Outputs

- **OUT_00** (Type: `BOOL`): The first extracted BOOL value (bit 00).
- **OUT_01** (Type: `BOOL`): The second extracted BOOL value (bit 01).
- **OUT_02** (Type: `BOOL`): The third extracted BOOL value (Bit 02).
- **OUT_03** (Type: `BOOL`): The fourth extracted BOOL value (Bit 03).
- **OUT_04** (Type: `BOOL`): The fifth extracted BOOL value (Bit 04).
- **OUT_05** (Type: `BOOL`): The sixth extracted BOOL value (Bit 05).
- **OUT_06** (Type: `BOOL`): The seventh extracted BOOL value (Bit 06).
- **OUT_07** (Type: `BOOL`): The eighth extracted BOOL value (Bit 7).

Adapter

No adapters available.

Functionality

As soon as an event is received at input `REQ`, the function block directly assigns the individual BOOL components of the input structure `IN` to the corresponding output variables. Specifically, `IN.X_00` is assigned to output `OUT_00`, `IN.X_01` to output `OUT_01`, and so on, up to `IN.X_07` to `OUT_07`. After successful assignment, a confirmation event `CNF` is output to indicate that the results are available.

Technical Features

- **Direct Mapping:** The function block implements a simple and direct 1:1 mapping from the fields of the `ST08X` structure to the individual BOOL outputs.

- **Type Safety:** The use of the specific type `ST08X` ensures a clear and type-safe interface.
- **Efficiency:** The conversion is highly efficient because no complex logic or calculations are required.

State Overview

This function block is stateless. It does not store any internal data between calls, and its output depends solely on the current input values. Each execution is independent of previous executions.

•

Application Scenarios

- **Decomposition of Combined Signals:** Ideal for splitting a logically grouped 8-bit structure into its individual, independent BOOL signals.
- **Interface Adaptation:** Enables connection to other function blocks or systems that expect individual BOOL inputs instead of a structure.
- **Visualization and Diagnostics:** Simplifies the separate display or monitoring of each individual bit of a `ST08X` structure.

⚖️ Comparison with Similar Blocks

This function block is specifically designed for the `ST08X` structure. While generic bit extraction functions (e.g., from a BYTE or WORD) might produce similar results, `ST08X_TO_BOOLS` provides a clearly defined, typed interface for the specific `ST08X` structure. This improves readability and avoids potential errors during manual bit indexing. It is simpler and more specific than function blocks that support complex bit field operations or variable bit counts.

Conclusion

The function block `ST08X_TO_BOOLS` is a useful tool for decomposing `ST08X` structures into individual BOOL signals. It impresses with its simplicity, efficiency, and clear, type-safe interface, which simplifies the development and maintenance of 4diac applications.

reversing

BOOLS_TO_ST08X

• – ○ • – ○ • – ○ •

This function block (FB) is used to combine eight individual BOOL values into a structure of type `ST08X`. It enables the clear grouping and transfer of eight binary pieces of information as a single structured variable.

- **REQ** (Event): This event triggers the conversion and assignment of the input values to the output. All data inputs are connected to this event and are read upon its arrival.
- **CNF** (Event): This confirmation event is triggered after the conversion is successfully completed and the output `OUT` has been updated. The data output `OUT` is associated with this event.
- **IN_00** (BOOL): The value for bit 0 of the output structure.
- **IN_01** (BOOL): The value for bit 1 of the output structure.

- **IN_02** (BOOL): The value for bit 2 of the output structure.
- **IN_03** (BOOL): The value for bit 3 of the output structure.
- **IN_04** (BOOL): The value for bit 4 of the output structure.
- **IN_05** (BOOL): The value for bit 5 of the output structure.
- **IN_06** (BOOL): The value for bit 6 of the output structure.
- **IN_07** (BOOL): The value for bit 7 of the output structure.
- **OUT** (logiBUS::utils::conversion::types::ST08X): The resulting structure containing the values of the eight binary inputs in their respective fields (`X_00` to `X_07`).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block has no adapters.

Functionality

The function block `BOOLS_TO_ST08X` is activated by an incoming `REQ` event. With each activation, the current values of the eight data inputs (`IN_00` to `IN_07`) are directly assigned to the corresponding fields (`X_00` to `X_07`) of the output structure `OUT`. After successful assignment, the `CNF` event is triggered at the output to signal the completion of the operation and make the updated `OUT` value available. The assignment is one-to-one, where `IN_00` corresponds to the field `X_00`, `IN_01` to the field `X_01`, and so on, until `IN_07` is assigned to the field `X_07`.

- **Direct Assignment:** The logic consists of a direct one-to-one assignment of the Boolean inputs to the fields of the `ST08X` structure.
- **Typing:** The `ST08X` type is a user-defined structure specifically designed for aggregating eight Boolean values and can be used in a type-safe manner.
- **Direct Assignment:** * **Efficiency:** Due to its simple implementation, this function block is very efficient and resource-saving.
- **Stateless:** The function block does not store any internal states and processes each request independently of previous calls.

The function block `BOOLS_TO_ST08X` is a stateless function block. This means that it does not store any information about previous executions that could influence its current behavior. Each activation by the `REQ` event results in a recalculation of the output `OUT` based on the values of the data inputs valid at that time.

- **Sensor Data Acquisition:** Combining eight individual digital sensor states (e.g., limit switches, light barriers) into a single structure for more compact data processing or visualization.
- **Interface Communication:** Prepare binary data for transmission via serial interfaces or communication protocols that expect data in structured formats.
- **Programming Logic:** Simplify the logic in more complex function blocks by combining eight separate signals into a single, more manageable variable.

This function block specializes in converting eight BOOL values to the user-defined `ST08X` type. Compare to:

- **`BOOLS_TO_BYTE` or `BOOL_TO_WORD`:** These blocks convert individual BOOL values to a primitive integer type (byte, word), where individual bits must be accessed via bitwise operations. In contrast, `BOOLS_TO_ST08X` offers a structured variable whose fields are directly accessible via names (`OUT.X_00`, `OUT.X_01`, etc.), which improves code readability.
- **Logical Operators (AND, OR, XOR):** These operators combine Boolean values, but not into a structure; instead, they combine them into a single Boolean result. `BOOLS_TO_ST08X` is used for aggregation, not logical combination.

The main advantage of `BOOLS_TO_ST08X` lies in its use of a specific structure type, which offers higher type safety and better code organization compared to generic integer types.

- **Logical Operators (AND, OR, XOR):** These operators combine Boolean values, but not into a structure; rather, they combine them into a single Boolean result.

The `BOOLS_TO_ST08X` function block is a simple yet extremely useful building block for converting eight individual BOOL signals into a standardized `ST08X` structure. It enhances the modularity and readability of 4diac applications by providing a clean and type-safe method for grouping bit information. This simplifies data handling and transmission in complex control systems.

BYTES_TO_ST08B

• – ○ • – ○ • – ○ •

Introduction

This function block combines eight individual byte values into a single 8-byte structure of type `ST08B`. It enables the orderly conversion of discrete byte values into a structured data format.

Interface Structure

Event Inputs

- **REQ** (Type: `Event`)
- Connects the activation of the function block to the data inputs: `IN_00`, `IN_01`, `IN_02`, `IN_03`, `IN_04`, `IN_05`, `IN_06`, `IN_07`.
- Triggers the conversion of the input bytes to the `ST08B` structure.

Event Outputs

- **CNF** (Type: `Event`)
- Triggered after successful conversion.
- Signals the availability of the converted value at data output `OUT`.

Data Inputs

- **IN_00** (Type: `BYTE`)
- Comment: BYTE 00

- **IN_01** (Type: BYTE)
- Comment: BYTE 01
- **IN_02** (Type: BYTE)
- Comment: BYTE 02
- **IN_03** (Type: BYTE)
- Comment: BYTE 03
- **IN_04** (Type: BYTE)
- Comment: BYTE 04
- **IN_05** (Type: BYTE)
- Comment: BYTE 05
- **IN_06** (Type: BYTE)
- Comment: BYTE 06
- **IN_07** (Type: BYTE)
- Comment: BYTE 07

Data Outputs

- **OUT** (Type: logiBUS::utils::conversion::types::ST08B)
- Comment: ST08B Output
- Outputs the 8-byte structure created from the eight input bytes.

Adapters

This function block does not have any adapter interfaces.

Functionality

Upon receiving a REQ event, the function block directly assigns the values of the eight data inputs IN_00 to IN_07 to the corresponding fields (B_00 to B_07) of the output structure OUT. After this assignment is complete, a CNF event is triggered, signaling that the OUT structure has been updated with the new values and is ready for further processing.

Technical Features

The function block uses the user-defined data type logiBUS::utils::conversion::types::ST08B as its output format. This type must be defined in the system for the function block to function correctly. The bytes are assigned positionally: IN_00 becomes OUT.B_00, IN_01 becomes OUT.B_01, and so on.

State Overview

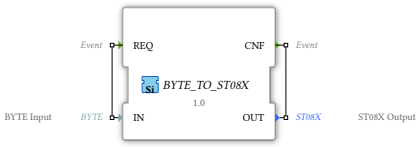
The BYTES_TO_ST08B function block is a purely combinational function block. It has no internal states that are stored for extended periods. Each execution triggered by a REQ event processes the current input values independently of previous executions and produces a corresponding output result.

Application Scenarios

- **Data Packet Assembly:** Combining individual byte components into a predefined data packet, e.g., for communication via serial interfaces or networks.
- **Interfacing with Protocols:** Adapting data to communication protocols that expect specific 8-byte structures.
- **Data Type Conversion:** Converting raw byte data into a higher-level, structured data type for improved handling and readability within the application.
- **Hardware Interconnection:** When data from sensors or actuators is read byte by byte and needs to be aggregated into a fixed structure.

⚖️ Comparison with Similar Blocks

Compared to general type conversion or array manipulation blocks, BYTES_TO_ST08B offers a specialized solution for converting exactly eight bytes into a predefined ST08B structure. This eliminates the need for manual indexing or looping and simplifies handling for this specific use case. Other function blocks might be more flexible (e.g., able to process a variable number of bytes), but this block is optimized for its fixed size.



Conclusion

The function block BYTES_TO_ST08B is a useful tool for converting eight individual byte inputs into a defined 8-byte structure ST08B. It contributes to the modularization and simplification of control

programs, especially when it comes to preparing discrete byte data for structured communication tasks or internal data processing. Its direct and event-driven operation makes it reliable and easy to integrate.

splitting

BYTE_TO_ST08X

• — ◦ • — ◦ • — ◦ •

Introduction

This function block (FB) is used to break down a single byte value into a structure of eight individual BOOL values. Each bit of the input byte is assigned to a separate BOOL field in the output structure, which simplifies the handling of bitwise information.

Interface Structure

Event Inputs

- **REQ**: An event input that triggers the execution of the function block. It is associated with the data input `IN`.

Event Outputs

- **CNF**: An event output that signals that the conversion is complete. It is associated with the data output `OUT`.

Data Inputs

- **IN**: Type `BYTE`. This is the byte value whose eight bits are to be split into individual Boolean values.

Data Outputs

- **OUT**: Type `logiBUS::utils::conversion::types::ST08X`. This is a structure containing eight BOOL values (named X_00 to X_07). Each of these fields represents one bit of the input byte.

Adapters

This function block does not use adapters.

Functionality

The `BYTE_TO_ST08X` function block converts a single 8-bit byte into a predefined structure `ST08X`, which contains eight separate BOOL variables.

On a `REQ` event, the value of the `IN` byte is read. Then, each bit of the `IN` byte is assigned to the corresponding BOOL field in the `OUT` structure:

- `OUT.X_00` is assigned bit 0 of `IN`.
- `OUT.X_01` is assigned bit 1 of `IN`.
- ...
- `OUT.X_07` is assigned bit 7 of `IN`.
- After the assignment, a `CNF` event is triggered to signal the completion of the operation.

Technical Features

- **Direct Bit Extraction:** The conversion is performed by directly assigning the individual bits of the byte (e.g., `IN.0`) to the BOOL fields of the target structure (e.g., `OUT.X_00`).
- **Use of `ST08X`:** The function block uses the specific data type structure `logiBUS::utils::conversion::types::ST08X`, which is explicitly designed to hold eight Boolean values. This structure must be known to the system.
- **Event-driven:** The operation is triggered by an input event `REQ` and signals its completion with an output event `CNF`. This ensures controlled data flow in the 4diac system.

State Overview

This function block is a pure data converter without internal states. Its function is deterministic and depends solely on the input values and the triggering event.

Application Scenarios

- **Hardware Interfacing:** If a byte representing the state of eight discrete digital inputs or outputs is received from external devices (e.g., via fieldbuses such as Modbus or CANopen), this function block can be used to isolate the individual states for further processing in the control program.
- **Protocol Parsing:** Decomposition of status bytes in communication protocols, where each bit indicates a specific flag or state.
- **Logical Operations:** Preparing data for logical operations that require individual Boolean values.
- **Visualization:** Displaying individual bits of a byte value on a user interface.

⚖️ Comparison with Similar Blocks

Standard function blocks in 4diac often provide general type conversions (e.g., `BYTE_TO_INT`). However, this block specializes in decomposing a byte into a structured group of Boolean values (`ST08X`), which distinguishes it from generic converters. There is no direct equivalent in the standard library for this specific structure conversion. Other approaches could involve using bitmasks and logical operations (AND, SHIFT) with multiple individual conversion blocks, but this would result in a more complex and less user-friendly implementation. This block provides a direct and elegant solution to the task at hand.

Conclusion

The `BYTE_TO_ST08X` function block is a useful tool for efficiently and clearly decomposing a byte value into eight individual Boolean states, organized in a `ST08X` structure. It simplifies the handling of bitwise information, especially in I/O processing and protocol analysis, by providing a clear and event-driven interface.

ST01X

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `ST01X` is a simple structured data type that encapsulates a single Boolean value (BOOL). It serves to provide a clearly defined structure for a single binary state, which can improve standardization and readability in more complex applications.

Interface Structure

The "interface structure" of a data type refers to its internal members, which form the definition of the data type. The data type `ST01X` has the following internal structure:

- **`X_00`**: A variable of type `BOOL`. This member serves as "BIT 00" within the structure, as indicated in the comment.

Event Inputs

Not applicable to a data type.

Event Outputs

Not applicable to this data type.

Data Inputs

Not applicable to this data type in the sense of function block inputs. This data type merely defines the structure for data.

Data Outputs

Not applicable to this data type in the sense of function block outputs. This data type merely defines the structure for data.

Adapters

Not applicable to this data type.

Functionality

The data type `ST01X` has no active functionality in the sense of an algorithm or execution. Its function is solely to serve as a defined container for a single Boolean value. It allows developers to clearly and type-safely reference a specific Boolean state within a structured environment, thereby increasing the modularity and readability of data structures.

Technical Features

- **Minimal Structure:** `ST01X` is one of the simplest structured data types, containing only a single `BOOL` element.
- **Encapsulation:** It encapsulates a single Boolean value, typically representing a status, flag, or state.
- **Standardization:** This data type can be used to standardize the use of single Boolean values in larger data structures or when defining communication protocols to ensure consistency.

State Overview

A data type does not have its own "state overview" in the sense of a state machine within a function block. The "state" of an object of type `ST01X` is determined solely by the value of its single member, `X_00`. This can be either `TRUE` (true) or `FALSE` (false).

Application Scenarios

- **Status Flags:** Represents a simple on/off status, e.g., to indicate whether a device is active, a process is running, or a condition is met.
- **Communication Protocols:** As a standardized block within data packets or telegrams to transmit a single bit state between systems.
- **Structured Data Storage:** When a Boolean value is needed in a higher-level structure with a specific name and comment to improve readability and maintainability, especially when many individual Boolean values are to be grouped together in a logical group.

- **Type Safety:** Enforces the use of an explicitly defined type for certain Boolean information to prevent errors due to accidental type inconsistencies.

⚖️ Comparison with Similar Building Blocks

- **Comparison with the primitive type `BOOL`:** Unlike the simple `BOOL` type, which only represents the raw value, `ST01X` offers named encapsulation (`X_00`). This improves the self-description and semantics of the value within a larger structure. While `BOOL` is an elementary data type, `ST01X` is a composite (structured) data type.
- **Comparison with larger structures (e.g., `ST08X`, `ST16X`):** `ST01X` is the most basic form of this type of structure, specializing in just one bit. Larger structures like `ST08X` or `ST16X` would contain 8 or 16 Boolean values, respectively, and are used to group multiple flags.

Conclusion

The `ST01X` data type is a fundamental yet useful building block in the 4diac IDE for structuring data. It allows the explicit definition and encapsulation of a single Boolean value, which contributes to improved code readability, maintainability, and standardization in complex automation projects. It serves as the basis for standardized data structures, especially when a bit flag has a specific meaning within a broader data landscape.

]

ST02X

(No image available for this data type.)

• – ◦ • – ◦ • – ◦ •

Introduction

The **ST02X** data type is a structured data type designed to encapsulate two Boolean values. It serves as a simple data structure for organizing and transporting two individual bits, or Boolean states, in a single unit. The name “ST02X” suggests a “structure with 2 [Boolean values]”.

Interface Structure

Because ST02X is a data type and not a function block, it does not have external event or data inputs/outputs in the usual sense of a function block. Its “structure” refers to the definition of its internal components, which represent the actual data.

Event Inputs

Not applicable, as ST02X is a data type and not a function block, and therefore does not process events.

Event Outputs

Not applicable, as ST02X is a data type and not a function block, and therefore does not generate events.

Data Inputs

The internal components of this data type can be considered its “data,” which can be set or read when a variable of this type is used.

- **X_00** (Type: BOOL, Comment: BIT 00)
- The first Boolean value within the structure.
- **X_01** (Type: BOOL, Comment: BIT 01)
- The second Boolean value within the structure.

Data Outputs

The internal components can also be considered “data outputs,” as their values can be read by external function blocks or program sections when a variable of type ST02X is used.

Adapters

Not applicable, as ST02X is a data type and not a function block, and therefore does not have adapter interfaces.

Functionality

The ST02X data type is a passive container for data. It does not perform any operations or logic itself. Its function is limited to logically grouping the two Boolean values `X_00` and `X_01`. When a variable of type ST02X is declared, its components can be accessed using the dot operator (e.g., `meineVariable.X_00`) to read or write its values.

Technical Features

- **Compact Structure:** The data type is very simple and consists of only two Boolean variables.
- **Typical Application:** It is particularly suitable for grouping two related status bits, flags, or switch states that need to be handled together.
- **Packaging:** The internal structure can help keep data compact and improve code readability by grouping logically related information.

State Overview

Since ST02X itself has no active logic, it does not have a "state" in the sense of a state machine. The "state" of a variable of type ST02X is determined by the combination of the values of its two Boolean components (`X_00` and `X_01`). There are four possible states for an instance of ST02X:

- `X_00 = FALSE, X_01 = FALSE`
- `X_00 = TRUE, X_01 = FALSE`
- `X_00 = FALSE, X_01 = TRUE`
- `X_00 = TRUE, X_01 = TRUE`

Application Scenarios

- **Status Display:** Grouping of two status flags (e.g., "Alarm Active" and "Warning Pending").
- **Configuration Parameters:** Bundling of two binary configuration settings.
- **Sensor Data:** Summary of the states of two simple sensors (e.g., two limit switches).
- **Interfaces:** As parameters for function blocks that need to process or return two Boolean pieces of information at once, which simplifies interface definition.

⚖️ Comparison with Similar Building Blocks

- **Single BOOL Variables:** Instead of using ST02X, two separate BOOL variables could be declared. The advantage of ST02X lies in its logical grouping and potentially clearer passing as a single parameter to function blocks.
- **ARRAY OF BOOL:** An array like `ARRAY[0..1] OF BOOL` could also hold two Boolean values. However, ST02X offers the advantage of named accesses (`.X_00`, `.X_01`), which can improve readability compared to indexed accesses (`[0]`, `[1]`).

ARRAY OF BOOL: An array like `ARRAY[0..1] OF BOOL` could also hold two Boolean values. However, ST02X offers the advantage of named accesses (`.X_00`, `.X_01`), which can improve readability compared to indexed accesses (`[0]`, `[1]`).

- – **Other Structured Types:** Depending on the application, more complex structured data types with more Boolean values (e.g., ST04X, ST08X) or mixed data types might be more suitable if more or different information needs to be grouped. ST02X is specifically optimized for the case of exactly two Boolean values.

Conclusion

ST02X is a simple yet useful structured data type that enables the logical grouping of two Boolean values. It improves code organization and readability, especially when dealing with two related binary pieces of information. Its strength lies in its simplicity and clear definition, making it a good choice for specific use cases where exactly two Boolean states need to be grouped.

ST04X

• – ◦ • – ◦ • – ◦ •

Introduction

ST04X is a structured data type that groups four Boolean values. It serves to organize and manage a collection of four individual bits in a single structure.

Interface Structure

Since ST04X is a data type and not a function block, it does not have event or data inputs/outputs in the sense of a function block or adapter. Instead, it defines an internal structure of data fields.

Event Inputs

Not applicable to a data type.

Event Outputs

Not applicable to a data type.

Data Inputs

Not applicable to a data type.

Data Outputs

Not applicable to a data type.

Adapters

Not applicable to a data type.

Structure Elements:

The ST04X structure consists of the following four Boolean fields:

- **X_00** (Type: BOOL, Comment: BIT 00)
- **X_01** (Type: BOOL, Comment: BIT 01)
- **X_02** (Type: BOOL, Comment: BIT 02)
- **X_03** (Type: BOOL, Comment: BIT 03)

Functionality

As a data type, ST04X does not have an active "function" in the sense of a function block. Its function is passive: It merely defines how four Boolean variables can be logically grouped and referenced as a single unit. This allows for better organization and readability of the code by grouping related bits in a structure.

Technical Features

- **Compactness**: Groups four individual BOOL values, which can enable more efficient data storage or transmission in some systems.
- **Structuring**: Improves code structure and readability by grouping related bits under a common name.
- **Use in Function Blocks**: This data type can be used as an input or output parameter for function blocks or as an internal variable within a function block to manage groupings of four bits.

State Overview

Not applicable to a data type. A data type represents a data structure, not a state machine.

Application Scenarios

- **Status Register**: Mapping of a small status register or group of flags where each bit indicates a specific state or property.
- **Binary Inputs/Outputs**: Grouping of four digital inputs or outputs of a hardware interface.
- **Bit Fields**: When a compact representation of four independent binary pieces of information is required, for example, when processing serial data protocols or device configurations.

⚖️ Comparison with Similar Components

ST04X is a data type and therefore cannot be directly compared to function blocks (components).

A comparison would be more feasible with other data types, for example:

- **BOOL**: A single Boolean value. ST04X groups four of them.
- **BYTE**: An 8-bit integer. ST04X provides a structured view of 4 bits, while a BYTE is typically treated as an unstructured 8-bit number. The individual bits of a BYTE would have to be accessed via bitmasks or bitwise operations, whereas with ST04X, each bit is directly accessible by its name (e.g., `myST04X.X_00`).

- **BYTE**: An 8-bit integer. * **Array of BOOL**: An array of BOOLs (`ARRAY[0..3] OF BOOL`) also provides grouping, but access is via indices (`myArray[0]`), whereas ST04X allows access via named fields (`myST04X.X_00`), which can improve readability.

Conclusion

ST04X is a useful structured data type in 4diac that simplifies the management and organization of four Boolean values. Although it does not offer any active functionality itself, it is an important tool for improving code structure and readability in more complex control programs by logically grouping related bits and enabling direct, named access to each bit.

ST08X

• – ◦ • – ◦ • – ◦ •

The **ST08X** data type is a structured data component designed for managing and grouping eight individual Boolean values. Its primary purpose is to provide a compact representation for a collection of eight independent bits, often used as status flags, control signals, or similar binary states. Because **ST08X** is a data type and not a function block, it does not have event, data inputs, or outputs in the sense of a 4diac function block. Instead, it defines an internal structure of member variables. Not applicable to a data type.

Not applicable to a data type. The data type consists of the following internal variables:

- `X_00`: Type `BOOL`, Comment: “BIT 00”
- `X_01`: Type `BOOL`, Comment: “BIT 01”
- `X_02`: Type `BOOL`, Comment: “BIT 02”
- `X_03`: Type `BOOL`, Comment: “BIT 03”
- `X_04`: Type `BOOL`, Comment: “BIT 04”
- `X_05`: Type `BOOL`, Comment: “BIT 05”
- `X_06`: Type `BOOL`, Comment: “BIT 06”
- `X_07`: Type `BOOL`, Comment: “BIT 07”

Not applicable for a data type.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Not applicable for a data type.

Functionality

The **ST08X** data type does not have its own inherent “function” in the sense of an algorithm or processing. It merely serves as a container to organize eight Boolean values under a common name. The individual bits can be read and written in other function blocks or program logic using their names (e.g., `ST08X_Variable.X_00`).

Not applicable for a data type.

The **ST08X** data type does not have an independent “function” in the sense of an algorithm or processing. It merely serves as a container to organize eight Boolean values under a common name. The individual bits can be read and written via their names (e.g., `ST08X_Variable.X_00`).

- **Compact Structure**: Combines eight `BOOL` variables into a single logical unit.

- **Explicit Naming**: Each bit is explicitly named from `X_00` to `X_07`, improving readability and addressing.
- **No Implicit Conversion**: As a structured data type, it offers type-safe encapsulation of the bits.

As a pure data type, **ST08X** has no states in the sense of a state machine or lifecycle. Its "state" is determined by the current values of its eight Boolean members.

- **Status Register**: Mapping of status bits of an external device or an internal component.
- **Configuration Parameters**: Grouping of eight binary configuration options.
- **Error Messages**: Collection of up to 8 different error message flags.
- **Binary Inputs/Outputs**: Representation of 8 digital inputs or outputs.
- **Data Bus Representation**: In cases where a group of 8 bits should be treated as a unit without interpreting it as a complete byte value, ST08X allows direct access to individual bits.

The **ST08X** data type offers an alternative to:

- **Single BOOL Variables**: Reduces the number of declarations and simplifies parameter passing when many Boolean values belong together.
- **BYTE Data Type**: While a `BYTE` also stores 8 bits, these are treated as a numeric value. **ST08X** retains the separate, named addressability of each individual bit, which improves semantics and direct access to logical flags without the need for bit masking or bit shift operations. The explicit naming, `X_00` through `X_07`, makes the code more self-explanatory.

The **ST08X** data type is a useful construct for grouping eight independent Boolean values in a structured and well-named manner. It promotes code readability and maintainability by providing clear semantic encapsulation for collections of binary flags that go beyond simple bitwise operations on a byte.

ST16X

• – ◦ • – ◦ • – ◦ •

Introduction

ST16X is a user-defined data type that defines a structure of 16 individual BOOL values. It serves to encapsulate a collection of binary states or flags in a single, organized unit. Although it is a data type and not a function block, its structure and usage are described here. The data type was created to provide a clear and type-safe way to manage 16 logical states.

Interface Structure

Because ST16X is a data type and not a function block, it does not have classic interfaces in the sense of event or data inputs/outputs. Instead, its 'structure' defines the internal members, which are detailed below.

Event Inputs

Not applicable to a data type.

Event Outputs

Not applicable to a data type.

Data Inputs

Not applicable to a data type.

Data Outputs

Not applicable for a data type.

Adapters

Not applicable for a data type.

The structure of the ST16X data type is defined as follows:

Name	Type	Comment
X_00	BOOL	BIT 00
X_01	BOOL	BIT 01
X_02	BOOL	BIT 02
X_03	BOOL	BIT 03
X_04	BOOL	BIT 04
X_05	BOOL	BIT 05
X_06	BOOL	BIT 06
X_07	BOOL	BIT 07
X_08	BOOL	BIT 08
X_09	BOOL	BIT 9
B_10	BOOL	BIT 10
B_11	BOOL	BIT 11
B_12	BOOL	BIT 12
B_13	BOOL	BIT 13
B_14	BOOL	BIT 14
B_15	BOOL	BIT 15

Functionality

A data type like ST16X does not have an active ‘function’ in the sense of an algorithm that is executed. It merely defines a template for data. The ‘function’ arises from how this data type is used in function blocks or other program logic to store and manage 16 individual Boolean states. A variable of type ST16X can be created, and its individual BOOL elements can be read and written (e.g., `meineST16XVariable.X_00 := TRUE;`).

Technical Features

- **Structured Arrangement:** This data type groups 16 independent BOOL values into a single logical unit.
- **Unique Naming:** Each bit is addressed by an individual name (`X_00` to `B_15`) instead of an index, which improves code readability.
- **Comment:** Each variable is assigned a comment (“BIT xx”) that clarifies the bit position.
- **Modularity:** Promotes code modularity and reusability by bundling complex status information.

Application Scenarios

- **Status Registers:** Represents the state of up to 16 different components, sensors, or functions (e.g., “Motor ON,” “Fault Active,” “Limit Reached”).
- **Bit Flags:** Stores configuration flags or fault indicators in control applications.
- **Digital Input/Output Signals:** Groups the digital inputs or outputs of a module to transmit them as a single data structure.
- **Data Packaging:** Simplified transfer of multiple binary pieces of information between function blocks or via communication interfaces.

⚖️ Comparison with Similar Building Blocks

Since ST16X is a data type, it cannot be directly compared to a 'building block' in the sense of a function block. However, it can be compared to other methods for storing binary data:

- **Single BOOL Variables:** ST16X offers the advantage of treating 16 BOOLs as a single unit, which simplifies data structuring and transfer and reduces the number of declared variables.
- **Array of BOOL:** A `ARRAY [0..15] OF BOOL` offers similar functionality. ST16X has the advantage that individual bits can be addressed using descriptive names (e.g., `meineST16XVariable.X_00`), which improves readability, instead of using indices (`meinARRAY[0]`).
- **WORD/INT types:** These can also be used to store bits. ST16X offers a type-safe and self-documenting way to manage bits without manual bit masking operations or typical conversion errors.

Conclusion

The ST16X data type provides an efficient and clear method for structuring a group of 16 Boolean values. It improves code readability, simplifies the handling of complex binary states, and promotes type safety in 4diac applications, especially in scenarios where many individual pieces of binary information need to be managed as a coherent unit.

ST32X

(No image available, as this is a data type and not a function block.)

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `ST32X` is a user-defined structure data type consisting of 32 individual BOOL variables. It serves to bundle a collection of Boolean states or flags into a single, coherent data structure, which can simplify the handling and passing of status information. The name `ST32X` is derived from "Structure (ST) with 32 X/B (Boolean) bits".

Interface Structure

Since `ST32X` is a data type and not a function block, it does not have event- or data-related inputs and outputs in the sense of a function block. Its "structure" merely defines its internal elements.

Event Inputs

Not applicable, as `ST32X` is a user-defined data type and not a function block.

Data Inputs

The structure consists of the following 32 BOOL elements, which can be considered "inputs" internally, as they receive the values from which the structure is formed:

- `X_00` (Type: BOOL, Comment: BIT 00)
- `X_01` (Type: BOOL, Comment: BIT 01)
- `X_02` (Type: BOOL, Comment: BIT 02)
- `X_03` (Type: BOOL, Comment: BIT 03)
- `X_04` (Type: BOOL, Comment: BIT 04)
- `X_05` (Type: BOOL, Comment: BIT 05)
- `X_06` (Type: BOOL, Comment: BIT 06)
- `X_07` (Type: BOOL, Comment: BIT 07)
- `X_08` (Type: BOOL, Comment: BIT 08)
- `X_09` (Type: BOOL, Comment: BIT 09)
- `B_10` (Type: BOOL, Comment: BIT 10)
- `B_11` (Type: BOOL, Comment: BIT 11)
- `B_12` (Type: BOOL, Comment: BIT 12)
- `B_13` (Type: BOOL, Comment: BIT 13)
- `B_14` (Type: BOOL, Comment: BIT 14)
- `B_15` (Type: BOOL, Comment: BIT 15)

- `B_16` (Type: BOOL, Comment: BIT 16)
- `B_17` (Type: BOOL, Comment: BIT 17)
- `B_18` (Type: BOOL, Comment: BIT 18)
- `B_19` (Type: BOOL, Comment: BIT 19)
- `B_20` (Type: BOOL, Comment: BIT 20)
- `B_21` (Type: BOOL, Comment: BIT 21)
- `B_22` (Type: BOOL, Comment: BIT 22)
- `B_23` (Type: BOOL, Comment: BIT 23)
- `B_24` (Type: BOOL, Comment: BIT 24)
- `B_25` (Type: BOOL, Comment: BIT 25)
- `B_26` (Type: BOOL, Comment: BIT 26)
- `B_27` (Type: BOOL, Comment: BIT 27)
- `B_28` (Type: BOOL, Comment: BIT 28)
- `B_29` (Type: BOOL, Comment: BIT 29)
- `B_30` (Type: BOOL, Comment: BIT 30)
- `B_31` (Type: BOOL, Comment: BIT 31)

Data Outputs

Not applicable. The structure `ST32X` itself is the "output" because it represents the bundled Boolean values. Individual elements can be accessed using the dot operator (`.`) (e.g., `myST32X.X_00`).

Adapters

Not applicable because `ST32X` is a user-defined data type and not a function block.

Functionality

ST32X` has no active "function" in the sense of logic or algorithms. It merely serves as a passive data container. Its function is to organize a group of 32 individual BOOL values into a single variable, which simplifies program structuring and the transfer of data between function blocks or program sections. The individual bits of the structure can be accessed, and their values can be set or read.

Technical Specifications

- **Number of Bits:** The structure comprises 32 independent BOOL variables.
- **Naming:** The elements are named `X_00` to `X_09` and then `B_10` to `B_31`. The comments indicate the bit number in each case. This could indicate an original intention to represent the bits in a word (e.g., DINT), even though they are declared here as separate BOOLs.
- **Memory Efficiency:** The exact memory allocation depends on the compiler implementation. Typically, such a structure would occupy at least 32 bytes (one byte per BOOL) or possibly more, depending on padding and alignment.

State Overview

As a passive data type, `ST32X` does not have its own state machine. Its "state" is defined solely by the values of the 32 contained BOOL variables. Each bit can be either `TRUE` or `FALSE`.

Application Scenarios

- **Status Flag Bundling:** When a system needs to manage a large amount of binary status information (e.g., error codes, component operating states, sensor flags), `ST32X` can be used to pass or store it in a single variable.
- **Interface Optimization:** Instead of passing 32 separate BOOL signals to a function block, an instance of `ST32X` can be transmitted over a single data connection.
- **Bit Mapping:** Although the elements are defined as `BOOL`, this structure could be used in conjunction with conversion function blocks (e.g., to convert to `DINT`) to access or manipulate the bits of a 32-bit word.
- – **PLC-like I/O mappings:** In environments similar to PLC programming, such a structure can be used to map digital inputs or outputs.

⚖️ Comparison with similar function blocks

- **Standard data types (e.g., `DINT`):** A `DINT` (Double Integer) is also 32 bits wide, but stores the bits as a single numeric value. `ST32X`, on the other hand, treats each bit as a separate Boolean variable, allowing direct access by name without bit masking or bitwise operations.
- **Other structured data types:** Other user-defined structures may exist that bundle a smaller or larger number of BOOLs or mix different data types. `ST32X` is specifically designed to hold 32 Boolean values.
- **Array of Boolean Values:** A `ARRAY[0..31] OF BOOL` would also store 32 Boolean values. The difference to `ST32X` lies in the access method: `ST32X` accesses named elements (e.g., `myST32X.X_00`), while an array accesses its index (e.g., `myArray[0]`). Named elements are often more readable and more robust against changes in order.

Conclusion

The `ST32X` data typeIt offers a practical method for combining 32 individual Boolean variables into a coherent whole. It promotes code organization and simplifies the passing of extensive status information or flags. Although it does not implement any active logic itself, it is a useful tool in the architecture of complex control programs based on the 4diac IDE.

ST64X

(No image available because this is a data type and not a function block.)

• – ◦ • – ◦ • – ◦ •

Introduction

The provided XML definition describes a **DataType** named `ST64X`, not a function block (FB). This structured data type serves as a container for a collection of 64 individual binary values (BOOL variables). It allows 64 independent switches, flags, or status bits to be grouped under a single name and addressed individually via named fields. Although the internal XML comment states “A Structure with 16 BOOLs,” the actual definition contains 64 BOOL variables.

Interface Structure

Since `ST64X` is a data type and not a function block, it does not have direct event or data inputs and outputs in the sense of an FB. Instead, it defines an internal structure of components that can be used as a unified variable within a function block (e.g., as an input or output parameter).

Event Inputs

Not applicable for a data type.

Event Outputs

Not applicable for a data type.

Data Inputs

Not applicable for a data type. The elements listed here are the **internal components** of the `ST64X` structure that hold data. When `ST64X` is used as a data input for a function block, these are the available fields:

Name	Type	Comment
`X_00`	`BOOL`	`BIT 00`
`X_01`	`BOOL`	`BIT 01`
`X_02`	`BOOL`	`BIT 02`
`X_03`	`BOOL`	`BIT 03`
`X_04`	`BOOL`	`BIT 04`

X_05	BOOL	BIT 05
X_06	BOOL	BIT 06
X_07	BOOL	BIT 07
X_08	BOOL	BIT 08
X_09	BOOL	BIT 09
B_10	BOOL	BIT 10
B_11	BOOL	BIT 11
B_12	BOOL	BIT 12
B_13	BOOL	BIT 13
B_14	BOOL	BIT 14
B_15	BOOL	BIT 15
B_16	BOOL	BIT 16
B_17	BOOL	BIT 17
B_18	BOOL	BIT 18
B_19	BOOL	BIT 19
B_20	BOOL	BIT 20
B_21	BOOL	BIT 21
B_22	BOOL	BIT 22
B_23	BOOL	BIT 23
B_24	BOOL	BIT 24
B_25	BOOL	BIT 25
B_26	BOOL	BIT 26
B_27	BOOL	BIT 27
B_28	BOOL	BIT 28
B_29	BOOL	BIT 29
B_30	BOOL	BIT 30
B_31	BOOL	BIT 31
B_32	BOOL	BIT 32
B_33	BOOL	BIT 33
B_34	BOOL	BIT 34
B_35	BOOL	BIT 35
B_36	BOOL	BIT 36
B_37	BOOL	BIT 37
B_38	BOOL	BIT 38
B_39	BOOL	BIT 39
B_40	BOOL	BIT 40
B_41	BOOL	BIT 41

B_42	BOOL	BIT 42
B_43	BOOL	BIT 43
B_44	BOOL	BIT 44
B_45	BOOL	BIT 45
B_46	BOOL	BIT 46
B_47	BOOL	BIT 47
B_48	BOOL	BIT 48
B_49	BOOL	BIT 49
B_50	BOOL	BIT 50
B_51	BOOL	BIT 51
B_52	BOOL	BIT 52
B_53	BOOL	BIT 53
B_54	BOOL	BIT 54
B_55	BOOL	BIT 55
B_56	BOOL	BIT 56
B_57	BOOL	BIT 57
B_58	BOOL	BIT 58
B_59	BOOL	BIT 59
B_60	BOOL	BIT 60
B_61	BOOL	BIT 61
B_62	BOOL	BIT 62
B_63	BOOL	BIT 63

Data Outputs

Not applicable for a data type. The elements listed above are the **internal components** of the `ST64X` structure that hold data. When `ST64X` is used as a data output of a function block, these are the available fields.

Adapters

Not applicable for a data type.

Functionality

ST64Xitself has no "function" in the sense of an active component that performs calculations or changes states. Its "function" is to provide a defined structure that serves as a template for data objects. Once instantiated, a variable of typeST64Xholds 64 individual BOOL values that can be read or written directly via their names (e.g.,MyVariable.X_00, MyVariable.B_63`). It is a passive data container.

Technical Features

- **Structured Data:** Defines a fixed arrangement of 64 BOOL variables.
- **Named Fields:** Each bit has a unique name (`X_00` to `X_09` and `B_10` to `B_63`), which improves code readability compared to purely numeric indices.
- **Size:** Represents 64 bits, which typically occupies 8 bytes of memory (depending on the compiler implementation and padding).
- **Package Information:** The data type is located in the package `logiBUS::utils::conversion::types`, indicating its role in utilities or conversions.

State Overview

Not applicable for a data type, as it has no internal logic or state machine. The “state” of a `ST64X`The variable is simply the current value of the 64 contained BOOL variables.

Application Scenarios

- **Bit Fields and Flags:** Ideal for representing a large number of binary status flags, switch positions, or configuration options that need to be organized in a single, coherent block.
- **Hardware Interfaces:** Can be used to map registers or I/O ports where individual bits represent specific functions or states.
- **Compact Data Transmission:** When a large number of BOOL values need to be transmitted efficiently, this type can provide a compact representation.
- **Abstract States:** Represents complex states resulting from the combination of 64 binary features.
-

⚖️ Comparison with Similar Building Blocks

Since `ST64X` is a data type, it is not directly compared to function blocks, but rather to other ways of structuring BOOL values:

- **`ARRAY OF BOOL`:** A `ARRAY[0..63] OF BOOL` would also store 64 BOOL values. The main difference lies in the access method: `ST64X` uses named arrays (e.g., `MyVar.X_00`), which is often more readable if each bit has a specific meaning. Arrays use indices (e.g., `MyArray[0]`), which is more flexible for loops and dynamic access, but less informative if the meaning of the individual indices is not obvious.
- **`ARRAY OF BOOL`:** A `ARRAY[0..63] OF BOOL` would also store 64 BOOL values. * **Individual `BOOL` variables:** You could also declare 64 separate `BOOL` variables. However, this would result in a cluttered list of variables and obscure the relationship between the bits. `ST64X` groups them logically.
- **Integer data types (e.g., `LWORD`):** A `LWORD` (64-bit integer) could also store 64 bits. However, accessing individual bits would require bitwise operations (AND, OR, SHIFT), which can be more complex and error-prone than direct array access to a structure. `ST64X` provides direct, symbolic bit access.

Conclusion

The data type `ST64X` is a useful construct in 4diac-ide for defining a structured variable containing 64 individual BOOL values. It provides a clear, named interface to each individual bit, improving code readability and maintainability, especially in applications requiring fine-grained control or status indication with many binary flags. It is a good alternative to `ARRAY OF BOOL` or bit manipulations on integer types when the individual meaning of each bit is paramount.

`ST64X`` or bit manipulations on integer types when the individual meaning of each bit is crucial.

`ST64X`` is a useful construct in 4diac-ide for defining a structured variable containing 64 individual BOOL values.

ST01B

• – ◦ • – ◦ • – ◦ •

Introduction

The provided XML file describes the 4diac **data type** `ST01B` (Structure with 1 BYTE), not a function block (FB). This data type defines a simple data structure containing a single byte field. The following documentation attempts to apply the requested structure for a function block as closely as possible, although many sections are not applicable to a pure data type.

Interface Structure

Since `ST01B` is a data type and not a function block, it does not have event or data interfaces in the sense of a function block. Instead, it defines an internal structure for data.

Event Inputs

Not applicable, as `ST01B` is a data type and not a function block.

Event Outputs

Data Inputs

Not applicable, as `ST01B` is a data type and not a function block. It defines a structure that can be used as a type for data variables in function blocks.

Data Outputs

Adapters

Functionality

ST01B` itself has no functionality in the sense of an executable function block. This is a static definition of a data structure that comprises a single byte. This structure can be instantiated by function blocks and used to store or exchange byte values.

The structure contains the following variable:

- **B_00**: A `BYTE` field annotated as “BYTE 00”.

Technical Features

- **Simple Structure**: Defines a minimal structure for encapsulating a single byte.
- **Use in 4diac**: This data type can be used in 4diac applications to declare typed data variables or as part of more complex data types.
- **Package**: The data type is contained in the `logiBUS::utils::conversion::types` package.

State Overview

Not applicable, as `ST01B` is a data type and not an executable function block with states.

Application Scenarios

This data type can be useful in various scenarios where a single byte with a specific semantic name needs to be handled in a structured way, for example:

- As a unified type for certain register values.
- To standardize interfaces that pass single byte values.
- As a building block for more complex structures consisting of a series of bytes.

⚖️ Comparison with Similar Building Blocks

- **Direct Use of `BYTE`**: `ST01B` differs from the direct use of the primitive `BYTE` type in that it provides a specific name and encapsulation. This can improve code readability and maintainability, especially when the byte has a specific meaning beyond the generic `BYTE` type.
- **Other Structured Data Types**: Compared to more complex structured data types, `ST01B` is very simple and serves as a basic building block.

Conclusion

`ST01B`` is a simple yet useful structured data type in 4diac that allows for the encapsulation of a single byte. Although not a function block, it can improve the clarity and structure of 4diac applications by defining specifically named byte variables. The provided XML definition facilitates easy integration into 4diac projects.

ST02B

• – ◦ • – ◦ • – ◦ •

Introduction

ST02B` is a user-defined, structured data type within the 4diac IDE. It defines a data structure that combines two individual bytes into a logical unit. This simplifies the handling of byte pairs.

Structure Definition

Since `ST02B` is a data type and not a function block, it has no interfaces in the sense of event inputs/outputs, data inputs/outputs, or adapters. Instead, the internal components of the data type are described here.

Components of the Structure

The structure `ST02B` consists of the following two byte variables:

- **B_00** (Type: `BYTE`): The first byte of the structure (BYTE 00).
- **B_01** (Type: `BYTE`): The second byte of the structure (BYTE 01).

Functionality

As a passive data type, `ST02B` has no inherent "function." Its function is to provide a defined template for data. Instances of this data type can be used to store, organize, and exchange data as a unit between different functional blocks.

Technical Details

ST02B`is defined as`StructuredType`and consists of two consecutive`BYTE` variables. Therefore, the total size of an instance of this data type is 2 bytes.

Application Scenarios

- **Data Transfer**: Bundling 2 bytes that should be treated as a single unit.
- **Register Mapping**: Representation of a 2-byte register (similar to a WORD, but with explicit byte access).
- **Small Data Packets**: Simplified handling of small, predefined data packets.

⚖️ Comparison with Similar Building Blocks

- **Array of Bytes (ARRAY OF BYTE [2])**: An array of 2 bytes serves the same purpose. However, `ST02B` offers the advantage of named fields (B_00, B_01).
- **`WORD`**: Also represents 2 bytes. `ST02B` is more flexible if the individual bytes need to be manipulated independently.

Conclusion

ST02B` is a simple, useful structured data type for managing two bytes as a coherent unit.

ST04B

• – ◦ • – ◦ • – ◦ •

Introduction

ST04B` is a user-defined, structured data type within the 4diac IDE. Unlike a function block (FB), which implements specific functionality, a data type defines a data structure that can be used by function blocks or other data types. This data type groups four individual bytes into a logical unit to simplify their interaction.

Structure Definition

Since `ST04B` is a data type and not a function block, it does not have interfaces in the sense of event inputs/outputs, data inputs/outputs, or adapters. The following sections adapt the original requirement of an interface structure to represent the internal components of the data type.

Components of the Structure

The structure `ST04B` consists of the following four byte variables:

- **B_00** (Type: `BYTE`): The first byte of the structure (BYTE 00).
- **B_01** (Type: `BYTE`): The second byte of the structure (BYTE 01).
- **B_02** (Type: `BYTE`): The third byte of the structure (BYTE 02).
- **B_03** (Type: `BYTE`): The fourth byte of the structure (BYTE 03).

Functionality

As a passive data type, `ST04B` has no inherent "function" in the sense of logic or algorithm. Its function is to provide a defined template for data. Instances of this data type can be declared and used in function blocks to store, organize, and exchange data as a coherent unit between different function blocks. The internal components (B_00 to B_03) are directly addressable.

Technical Details

ST04Bis defined asStructuredTypeand consists of four consecutiveBYTEvariables. The total size of an instance of this data type is therefore 4 bytes. In the context of the 4diac runtime environment, this data type is stored in memory according to its definition. The internal structure allows direct access to each individual byte via its name (e.g.,myST04B.B_00`).

The 4diac compiler assigns this data type to the package `logiBUS::utils::conversion::types`.

State Overview

As a passive data type that merely defines a data structure, `ST04B` has no internal logic or state machine in the sense of a function block. Its "state" is determined solely by the values of its four component bytes. Therefore, a state overview in the sense of behavioral states is not applicable.

Application Scenarios

- **Data Transmission**: Bundling of 4 bytes that are received or sent via a communication interface (e.g., serial, Modbus, CAN) and are to be treated as a unit.
- **Register Mapping**: Representation of a 4-byte register or group of registers in a programmable logic controller (PLC) or other control system.
- **Small Data Packets**: Simplified handling of small, predefined data packets in industrial automation.
- **Type Conversion Utility**: Internally used in conversion function blocks to process specific byte sequences and convert them to other data types.

⚖️ Comparison with Similar Building Blocks

- **Array of Bytes (ARRAY OF BYTE [4])**: An array of 4 bytes serves the same purpose for storage. However, `ST04B` offers the advantage that individual bytes can be addressed via named fields (`B_00`, `B_01`, etc.) instead of indices (e.g., `myArray[0]`, `myArray[1]`), which can improve code readability and self-description.
- **Other structured types**: If the bytes had a specific meaning (e.g., status flag, counter value), more complex structured types with more descriptive variable names or even bit fields might be more appropriate. `ST04B` is intentionally generic to allow for flexible byte grouping.
- – **`WORD`, `DWORD`**: These standard data types also represent a specific number of bytes (2 and 4, respectively). However, `ST04B` is more flexible when individual bytes need to be manipulated independently or when byte order (endianness) is important and needs to be explicitly controlled.

Conclusion

ST04B` is a basic yet useful structured data type in 4diac that simplifies the management of four bytes as a coherent unit. It improves code readability and modularity, especially in applications that require the exchange or processing of byte-sequenced data. Its simple definition makes it a flexible building block for a wide range of data management tasks in automation technology.

ST08B

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `ST08B` is a structured data structure that sequentially groups exactly eight bytes (BYTE). It primarily serves as a container for the efficient grouping and transport of eight individual byte values within an IEC 61499-based control system. This data type is particularly useful for handling raw data, protocol frames, or for the structured transfer of parameterized data blocks between function blocks.

Interface Structure

ST08B` is a data type and, as such, does not have event-driven inputs or outputs in the sense of a function block. Its structure is defined exclusively by its data members.

Data Inputs

Not applicable. This section is intended for function blocks.

Data Outputs

Event Inputs

Not applicable. This section is for function blocks.

Event Outputs

Adapters

How it Works

As a structured data type (STRUCT), `ST08B` acts as a composite container. It groups eight independent variables of type `BYTE` under a common name. Each byte within the structure is directly addressable via its unique member name (`B_00` to `B_07`). Function blocks can declare variables of type `ST08B` to pass, store, or process all eight bytes as a single unit. Individual bytes are accessed using dot notation (e.g., `MyST08BInstance.B_04`).

Technical Features

- **Fixed Size:** The structure has a fixed and predictable size of exactly 8 bytes, which is advantageous for memory allocation and communication protocols.
- **Sequential Arrangement:** The bytes are arranged in the order `B_00` to `B_07`. This order is crucial for interpreting the data, for example, when converting it to larger data types such as `WORD`, `DWORD`, or `LWORD`.
- **TypeHash Attribute:** The data type contains the attribute `eclipse4diac::core::TypeHash` with an empty value (`''`). This indicates that type-safe validation via hash value has not (yet) been configured for this user-defined type.

State Overview

Since this is a passive data type and not an active function block, there is no state machine. The “state” of an instance of `ST08B` is simply the current value of each of its eight byte members.

Application Scenarios

1. **Data Packaging:** Grouping eight configurable parameters or status values together to be sent from one function block to another.
2. **Protocol Handling:** Representing a fixed data frame header or segment in serial or network communication.
3. **Raw Data Buffer:** Temporary storage of an 8-byte block from a sensor or communication interface before further processing or interpretation.
4. **Conversion Base:** Used as a source or target for conversion function blocks that convert `ST08B` to or generate other data types, such as `LWORD` (64-bit).

⚖️ Comparison with Similar Building Blocks

- **Simple Byte Array:** An array of 8 `BYTE` (`ARRAY[0..7] OF BYTE`) could perform a similar function. However, `ST08B` offers the advantage of named access paths (`B_01`), which, unlike index-based access (`Array[1]`), improve code readability and maintainability.
- **LWORD:** The data type `LWORD` also represents 8 bytes (64 bits), but as a single, undivided numeric value. `ST08B` allows targeted access to each individual byte within these 64 bits.
- **Other STRUCT Types:** Similar structured types such as `ST04B` (4 bytes) or `ST16B` (16 bytes) serve the same purpose, but for different amounts of data. `ST08B` fills the gap for 8-byte structured data.

Conclusion

The `ST08B` is a simple yet extremely useful structured data type for IEC 61499 programming. It provides a clear and structured method for grouping eight bytes of data, thereby promoting readability, maintainability, and type safety in applications that work with fixed data blocks or parameterized datasets. Its fixed size and sequential arrangement make it a reliable building block for data communication and conversion.

]

ST16B

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `ST16B` is a structured data component defined in the 4diac framework. Unlike a function block (FB), `ST16B` has no inherent logic or executable functions. Instead, it serves as a fixed container for 16 individual byte values. Its primary purpose is to provide a clearly defined structure for handling fixed-size raw data packets, which is particularly important in communication protocols or when interacting with low-level hardware interfaces.

Interface Structure

Since `ST16B` is a data type and not a function block, it does not have event or data interfaces in the conventional sense. Its “structure” refers to the definition of its internal components, i.e., the individual bytes that comprise it.

Event Inputs

Not applicable, as `ST16B` is a data type and not a function block, and therefore does not process events.

Event Outputs

Not applicable, as `ST16B` is a data type and not a function block, and therefore does not generate events.

Data Inputs

Not applicable, as `ST16B` is a data type and not a function block, and therefore does not have direct data inputs in the context of function block connections.

Data Outputs

Not applicable, as `ST16B` is a data type and not a function block, and therefore does not have direct data outputs in the context of function block connections.

Adapter

Not applicable, as `ST16B` is a data type and not a function block, and therefore does not implement any adapter interfaces.

Component Data Structure

ST16B`consists of 16 individual variables of type`BYTE`, arranged sequentially:

Name	Type	Description
B_00	BYTE	BYTE 00

B_01	BYTE	BYTE 01
B_02	BYTE	BYTE 02
B_03	BYTE	BYTE 03
B_04	BYTE	BYTE 04
B_05	BYTE	BYTE 05
B_06	BYTE	BYTE 06
B_07	BYTE	BYTE 07
B_08	BYTE	BYTE 08
B_09	BYTE	BYTE 09
B_10	BYTE	BYTE 10
B_11	BYTE	BYTE 11
B_12	BYTE	BYTE 12
B_13	BYTE	BYTE 13
B_14	BYTE	BYTE 14
B_15	BYTE	BYTE 15

Functionality

ST16B `itself has no active functionality. It is a passive data container. Its function is to provide a defined memory template for 16 bytes. Each byte (B_00toB_15`) can be read and written individually. This structured access to individual bytes enables granular data manipulation and easy assignment to communication fields or memory areas.

Technical Features

- **Fixed Size:** The data type `ST16B` has a fixed size of exactly 16 bytes. This is advantageous for predictable memory usage and compatibility with protocols that expect fixed lengths.
- **Direct Byte Access:** Each of the 16 bytes is directly accessible via its specific name (e.g., `MyVariable.B_00`).
- **Raw Data Container:** Ideal for storing and transporting raw data whose content will be interpreted later.
- **Architecture Independence:** As a collection of bytes, the basic structure is relatively platform-independent, although the interpretation of the bytes can vary across different systems (e.g., endianness for larger values spread across multiple bytes).

State Overview

Not applicable, as `ST16B` is a data type and does not have internal states in the sense of a function block (e.g., initialization, execution, error). The "states" of `ST16B` are simply the current values stored in its 16-byte components.

Application Scenarios

- **Communication Protocols:** Ideal for packaging or unpacking messages for protocols such as Modbus, CAN bus, or proprietary serial protocols where data packets have a fixed size of 16 bytes.
- **Hardware Interfaces:** Mapping of registers or data blocks in low-level interfaces that operate in fixed byte patterns.
- **Binary Data Buffer:** Used as a buffer for binary data read from or sent to external sources.
- **Hashe or ID Caching:** For applications that need to store 128-bit hashes (e.g., MD5) or long IDs that are exactly 16 bytes long.

⚖️ Comparison with Similar Building Blocks

- **`ARRAY[0..15] OF BYTE`:** `ST16B` is similar to a 16-byte array. The main difference lies in the access method: `ST16B` uses named components (`B_00`, `B_01`, etc.), while an array allows access via indices (`MyArray[0]`, `MyArray[1]`). Named components can improve readability if each byte has a specific semantic meaning within the 16 bytes.
- **Other structured data types:** Compared to user-defined structures that mix different data types (INT, REAL, BOOL), `ST16B` specializes in pure byte collections. It offers a flat, uniform structure.

Conclusion

The data type `ST16B` is a simple yet effective structure for handling fixed-size 16-byte data blocks. It provides a clear and readable way to access individual bytes within such a block. Although it is not a function block and does not implement its own logic, it is a valuable tool in 4diac for applications that require precise control at the byte level, especially in communication and hardware interaction.

ST32B

• – ◦ • – ◦ • – ◦ •

The data type `ST32B` is a structured data type within the 4diac IDE, designed for the aggregation of 32 individual bytes. It serves as a template for data structures that require a fixed length of 32 bytes and allow direct access to individual bytes. This type is registered in the 4diac IDE under the package `logiBUS::utils::conversion::types`. Since `ST32B` is a structured data type and not a function block, it does not have external event or data interfaces in the conventional sense. Instead, it defines an internal structure of elements that can be accessed in a program. Not applicable to structured data types. `ST32B` has no event inputs.

Not applicable to structured data types. `ST32B` has no event outputs.

Not applicable to structured data types. `ST32B` has no data inputs; its elements are directly accessible via the type name.

Not applicable to structured data types. `ST32B` has no data outputs; its elements are directly accessible via the type name.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Not applicable to structured data types. `ST32B` has no adapters.

Functionality

ST32B` is a passive data type and does not implement any active functionality or logic. It serves merely as a blueprint (schema) for organizing and storing 32-byte values under a single logical name. Instances of this data type can be declared and used in other function blocks or data types to store or transfer data in a structured manner.

The individual bytes are named as follows and can be accessed directly:

- `B_00`: Byte 00
- `B_01`: Byte 01
- ...
- `B_30`: Byte 30

- `B_31`: Byte 31
- **Fixed Size:** The data type `ST32B` is fixed to an exact size of 32 bytes.
- **Direct Byte Access:** Each of the 32 bytes can be addressed individually by its name (`B_00` to `B_31`).
- **Basic Type:** It consists exclusively of the primitive data type `BYTE`, making it ideal for low-level data operations or the representation of raw data.
- **Simplicity:** The structure is deliberately kept simple to ensure efficient use and clear data organization.

As a passive data type, `ST32B` has no internal states in the sense of a state machine. The "state" of an instance of this type is defined solely by the current values of the 32 bytes it contains.

- **Raw Data Transport:** Ideal for transmitting fixed-length raw data packets, for example, from sensors or via communication interfaces such as SPI, I2C, UART, or Ethernet, when the payload has a fixed length of 32 bytes.
- **Message Structures:** Can serve as the basis for simple message formats where a portion of the message frame occupies a defined length of 32 bytes.
- **Memory Image:** For mapping a small, fixed memory area or register set in a controller.
- **Configuration Data:** Storage of 32-byte configuration parameters.

A comparable approach would be the use of an array of type `ARRAY[0..31] OF BYTE`.
The main difference lies in the access method and semantics:

- **`ST32B` (structure):** Allows access to bytes via symbolic names (`B_00`, `B_01`, ...), which can improve code readability and maintainability, especially when individual bytes have a specific meaning.
- **`ARRAY[0..31] OF BYTE` (array):** Allows access via a numeric index (`[0]`, `[1]`, ...), which is advantageous for loops and generic operations.
- While an array can offer more flexibility in sizing, `ST32B` provides a clearly defined, named structure that makes the purpose behind each byte more explicit, even though the names are generic.

The `ST32B` data type is a fundamental structured data type in 4diac that offers a simple and efficient way to treat 32 bytes as a single unit. Its strength lies in providing a fixed, well-defined structure for raw data, making it a useful tool in applications that require precise control over byte sequences. Although it has no active functionality itself, it is an important foundation for data-driven architectures within 4diac applications.

ST64B

• – ◦ • – ◦ • – ◦ •

Introduction

The `ST64B` data type is a structured data type used to encapsulate 64 individual byte values. It was developed to provide a fixed 64-byte data structure that can be used for various use cases where a precisely defined size and direct access to individual bytes are required. The original XML definition contained a comment that incorrectly stated 16 bytes; the correct value is 64 bytes.

Structure Definition

The `ST64B` data type is a composite structure consisting exclusively of individual byte variables. It has no event- or adapter-based interfaces, as it is a pure data structure.

Event Inputs

Not applicable, as `ST64B` is a data type and not a function block.

Event Outputs

Data Components

The structure `ST64B` consists of the following 64 byte variables:

Name	Type	Description
B_00	BYTE	BYTE 00
B_01	BYTE	BYTE 01
B_02	BYTE	BYTE 02
B_03	BYTE	BYTE 03
B_04	BYTE	BYTE 04
B_05	BYTE	BYTE 05
B_06	BYTE	BYTE 06
B_07	BYTE	BYTE 07
B_08	BYTE	BYTE 08
B_09	BYTE	BYTE 09
B_10	BYTE	BYTE 10
B_11	BYTE	BYTE 11
B_12	BYTE	BYTE 12
B_13	BYTE	BYTE 13
B_14	BYTE	BYTE 14
B_15	BYTE	BYTE 15
B_16	BYTE	BYTE 16
B_17	BYTE	BYTE 17
B_18	BYTE	BYTE 18
B_19	BYTE	BYTE 19
B_20	BYTE	BYTE 20
B_21	BYTE	BYTE 21
B_22	BYTE	BYTE 22
B_23	BYTE	BYTE 23
B_24	BYTE	BYTE 24
B_25	BYTE	BYTE 25
B_26	BYTE	BYTE 26
B_27	BYTE	BYTE 27
B_28	BYTE	BYTE 28
B_29	BYTE	BYTE 29
B_30	BYTE	BYTE 30

B_31	BYTE	BYTE 31
B_32	BYTE	BYTE 32
B_33	BYTE	BYTE 33
B_34	BYTE	BYTE 34
B_35	BYTE	BYTE 35
B_36	BYTE	BYTE 36
B_37	BYTE	BYTE 37
B_38	BYTE	BYTE 38
B_39	BYTE	BYTE 39
B_40	BYTE	BYTE 40
B_41	BYTE	BYTE 41
B_42	BYTE	BYTE 42
B_43	BYTE	BYTE 43
B_44	BYTE	BYTE 44
B_45	BYTE	BYTE 45
B_46	BYTE	BYTE 46
B_47	BYTE	BYTE 47
B_48	BYTE	BYTE 48
B_49	BYTE	BYTE 49
B_50	BYTE	BYTE 50
B_51	BYTE	BYTE 51
B_52	BYTE	BYTE 52
B_53	BYTE	BYTE 53
B_54	BYTE	BYTE 54
B_55	BYTE	BYTE 55
B_56	BYTE	BYTE 56
B_57	BYTE	BYTE 57
B_58	BYTE	BYTE 58
B_59	BYTE	BYTE 59
B_60	BYTE	BYTE 60
B_61	BYTE	BYTE 61
B_62	BYTE	BYTE 62
B_63	BYTE	BYTE 63

Data Outputs

Not applicable, as `ST64B` is a data type and its components do not function as “outputs” in the sense of a function block.

Adapters

Functionality

As a structured data type, `ST64B` does not have its own "function" in the sense of active behavior or logic. Its primary function is to define a memory area of 64 bytes and make it accessible in an organized form. This allows addressing individual bytes within the structure via their named variables (e.g., `ST64B.B_00`, `ST64B.B_15`). It serves as a passive data container.

Technical Features

The main feature of `ST64B` is its fixed size of exactly 64 bytes. Each byte is individually addressable via a unique variable name. This makes it ideal for situations requiring a strict data size and byte-by-byte manipulation of the content, such as when processing communication protocols or hardware registers. The sequential naming of the variables simplifies their allocation to a continuous memory area.

State Overview

As a pure data type, `ST64B` has no states in the sense of a state machine or a function block. The "state" of a `ST64B` instance is defined solely by the current values of the 64 contained byte variables. Each combination of these values represents a valid data state of the structure.

Application Scenarios

ST64B` is ideally suited for the following application scenarios:

- **Communication Buffer:** As a standard buffer for messages or packets with a fixed size of 64 bytes, e.g., in CAN bus messages (when multiple frames are needed), serial communication, or other protocols.
- **Hardware Register Map:** Mapping of a 64-byte range of hardware registers, where each byte variable corresponds to a specific register.
- **Data Serialization:** Storing raw data before serialization or after deserialization, especially when data is transmitted without explicit type information.
- **Generic Data Blocks:** Handling generic, fixed-size data blocks that can be interpreted flexibly, e.g., as part of larger protocols or data structures.

⚖️ Comparison with Similar Building Blocks

ST64B` is a basic data type and cannot be directly compared to function blocks. Within the data types, it is comparable to:

- **Other structured data types:** `ST64B` is a specific instance of `StructuredType`. There are similar structures with different numbers or types of elements (e.g., structures with 8, 16, or 32 bytes, or those containing integers, booleans, etc.). `ST64B` is characterized by its purely byte-wise division.
- **Arrays of BYTE:** An array of type `ARRAY[0..63] OF BYTE` would also store 64 bytes. The difference lies in the access method: `ST64B` uses named members (e.g., `myST64B.B_10`), while an array uses an index (e.g., `myArray[10]`). Named members can be advantageous in certain contexts for improved code readability or for directly addressing specific byte positions.

Conclusion

ST64B` is a simple yet powerful structured data type that provides a fixed data set of 64 bytes. Its strength lies in the clear definition and direct accessibility of each individual byte, making it an excellent choice for applications requiring precise control and interpretation of raw data blocks, particularly in communication and hardware interaction.

Numeric Index (utils)

...# Numeric Index (utils){index} single: Numerischer Index (utils) Here you will find all exercises from the `utils` workspace, listed in ascending order. ...

ARR_MAX

ARR_MAX

• – ○ • – ○ • – ○ •

Introduction

The function block `ARR_MAX` calculates the maximum value of a one-dimensional array of type `INT`. The implementation is in Structured Text (ST) according to IEC 61131-3 and is from the package `logiBUS::utils::dyn_arr`. The block is suitable for dynamic arrays of any size, with the lower and upper bounds determined at runtime.

Interface Structure

Event Inputs

Name	Type	With Var	Description
`REQ`	Event	`A`	Starts the calculation of the maximum. The array `A` must be valid and contain values at the time of the event.

Event Outputs

Name	Type	With Var	Description
`CNF`	Event	(empty), `A`	Confirms the end of the calculation. The event is triggered as soon as the maximum value has been determined. The array `A` remains valid during the event.

Data Inputs

Name	Type	Initial Value	Description
`A` (IN/OUT)	`ARRAY[*] OF INT`	–	One-dimensional integer array whose maximum is to be calculated. The size is determined dynamically at runtime.

Data Outputs

Name	Type	Initial Value	Description
`MAX`	`INT`	–	The determined maximum value of the array `A`. (The name `MAX` is derived from the function – in the XML definition, the output is unnamed but is treated as a function return value.)

Adapter

Omitted.

Functionality

1. **Start**: A signal at the event input `REQ` triggers the processing. The provided array `A` must be valid at this point.
2. **Initialization**: The variable `i` is set to the index of the first element (`LOWER_BOUND(A,1)`). `currentMax` receives the value of this first element.
3. **Iteration**: A loop called `FOR` iterates through all remaining elements of `A` (from index `LOWER_BOUND(A,1)+1` to `UPPER_BOUND(A,1)`). The current maximum value is updated using the standard function `MAX()`.
4. **Closure**: After the loop, `currentMax` is set as the return value of the function `ARR_MAX`. The event output `CNF` is sent, and the output signal `MAX` (interpreted here as a return value) is available.

Technical Features

- **Dynamic Array Boundaries**: The function uses `LOWER_BOUND` and `UPPER_BOUND` to determine the actual size of the array at runtime. This allows the function block to work with arrays of any length without requiring a fixed size to be specified.
- **No State Memory**: The function block is a pure function without internal state. Each call calculates the maximum value, independent of the previous call.
- **Typing**: The function block is specialized for the data type `INT`. A separate version would need to be created for other data types (e.g., `REAL`, `LINT`).
- **Error Handling**: If the array is empty (e.g., lower bound > upper bound), access to `A[i]` would be undefined. The user must ensure that the array contains at least one element.

State Overview

Since `ARR_MAX` is implemented as a **pure function** without a state machine (ECA algorithm), there are no explicit states. The process is strictly sequential within a single event cycle:

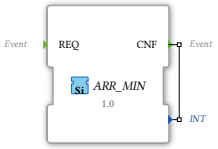
- **Waiting for REQ**
- **Calculation in progress** (no separate state signal, as the process is completed within one cycle)
- **CNF is being sent** (output of the maximum)

Therefore, an explicit state graph is not required.

Application Scenarios

- **Data Analysis**: Determining the peak value in measurement series (e.g., temperature, pressure, speed).
- **Monitoring**: Detecting threshold violations by comparing them to the maximum of an array.
- **Signal Processing**: Determining the maximum level in audio or communication signals.
- **Control Engineering**: Selecting the highest value from multiple sensor data points (e.g., for priority decisions).

Comparison with Similar Function Blocks



Function Block	Function	Difference from ARR_MAX
`ARR_MIN`	Minimum of an Array	Analogous, but minimum instead of maximum.
`ARR_SUM`	Sum of Array Elements	Different mathematical operation; no comparison between elements.
`ARR_MEAN`	Arithmetic Mean	Requires additional division by the number of elements; not just comparison.
`MAX` (IEC 61131-3)	Maximum of two values	Works only with scalars, not arrays. `ARR_MAX` extends this to entire arrays.

ARR_MAX` combines array traversal capability with simple maximum determination and is therefore a specialized, yet reusable function block for dynamic arrays.

Conclusion

The function block `ARR_MAX` offers a compact and efficient way to determine the maximum value of a dynamic integer array. Using `LOWER_BOUND` and `UPPER_BOUND` makes it flexible and robust against different array sizes. Due to its purely functional design without state storage, it is ideally suited for use in data flow-oriented automation applications.

ARR_MIN

• – ○ • – ○ • – ○ •

Introduction

The function block **ARR_MIN** determines the minimum of all elements in a one-dimensional array of type `INT`. The block expects a dynamic array (`ARRAY[*]`) as an input/output parameter and outputs the smallest element found via a separate data output. The calculation is triggered by the event `REQ`; the result is acknowledged upon completion with the event `CNF`.

Interface Structure

Event Inputs

Event	With Data
`REQ`	`A`

Event Outputs

Event	With Data
`CNF`	`A` (and empty data output)

Data Inputs

Name	Type	Comment
`A`	`ARRAY[*] OF INT`	Input Array (Input/Output)

Data Outputs

Name	Type	Comment
(Unnamed)	`INT`	Minimum value of the array

Adapter

No adapters available.

Functionality

1. The algorithm initializes a temporary variable `currentMin` with the value of the first array element (determined via `LOWER_BOUND(A,1)`).
2. The array is then traversed from index `LOWER_BOUND(A,1)+1` to `UPPER_BOUND(A,1)`.
3. In each iteration, the current value is compared to `currentMin`, and the minimum is updated using the function `MIN()`.
4. After the loop completes, the final minimum value is output via the unnamed data output, and the event `CNF` is sent.

The calculation is performed sequentially within a single execution step; the runtime increases linearly with the array size.

Technical Features

- **Dynamic Array**: The function block uses `ARRAY[*] OF INT`, meaning the actual array size is determined at runtime using the system's built-in functions `LOWER_BOUND` and `UPPER_BOUND`.
- **Package Assignment**: The function block belongs to the package `logiBUS::utils::dyn_arr` and is intended for use in environments that support dynamic arrays.
- **Input/Output Parameters**: The parameter `A` is declared as `VAR_IN_OUT` – the array is both read and (here without modification) passed on via the event output `CNF`.
- **No State Machine**: The function block operates purely functionally; there are no internal states or delays.

State Overview

The function block only has two implicit states:

- **Idle**: Waiting for a `REQ` event.
- **Processing**: After `REQ` arrives, the calculation is executed, immediately followed by `CNF`, and the function block returns to the idle state.

There are no multiple states, wait loops, or time-controlled processes.

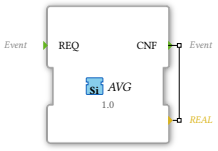
Application Scenarios

- **Sensor Field Analysis**: Determining the lowest temperature in a series of measurements.
- **Quality Control**: Searching for the minimum reject rate in a production batch.
- **Optimization**: Determining the most favorable price from a list of offers.
- **Comparison Operations**: As a basic building block for further statistical evaluations (e.g., together with maximum and sum).

Comparison with Similar Blocks

- **MIN (IEC 61131-3)**: The classic MIN block compares two scalar values. `ARR_MIN` extends this concept to an entire array, thus eliminating the need for iterative chaining.
- **ARR_MAX**: A logical counterpart to the maximum; The algorithm differs only in the comparison function (`MIN` vs. `MAX`).
- **Statistical Building Blocks**: `ARR_MIN` is a special case of general aggregation functions (e.g., SUM, MEAN). Its focus is on finding the minimum, enabling simple and fast implementation.

Conclusion



ARR_MINoffers a compact and efficient solution for determining the minimum in dynamic integer arrays. Thanks to its simple request/confirm protocol and clean package structure, it can be easily integrated into existing 4diac industrial applications. UsingLOWER_BOUND/UPPER_BOUND` makes it independent of the actual array size and allows for flexible adjustments at runtime.

AVG

• – ◦ • – ◦ • – ◦ •

Introduction

The **AVG** (Array Average) function block calculates the arithmetic mean (average) of all elements in an integer array. It is designed for use in control engineering and enables rapid statistical analysis of measured values or process data.

Interface Structure

Event Inputs

Event	With Data
`REQ`	`A`

Event Outputs

Event	With Data
`CNF`	*(Result Output)*, `A`

Data Inputs

Name	Type	Initial Value	Comment
A	ARRAY[*] OF INT	–	Array of integers whose average is calculated (InOut variable)

Data Outputs

Name	Type	Initial Value	Comment
(no name)	REAL	–	Result of the average value

Adapters

None.

Functionality

1. The function block is activated by the event REQ. The data array A is then used.
2. Internally, a loop is executed from LOWER_BOUND(A,1) to UPPER_BOUND(A,1) to sum all elements.
3. The number of elements is determined from UPPER_BOUND(A,1) - LOWER_BOUND(A,1) + 1.
4. The sum is accumulated as DINT and then divided by the number of elements. The result is converted into a value REAL and made available at the output.
5. After the calculation is complete, the event CNF is triggered. The output value is then available.

Technical Features

- **Dynamic Array Size**: The function block accepts arrays of arbitrary length (indicated by ARRAY[*]), allowing for flexible adaptation to different data volumes.
- **Type Conversions**: The sum is represented as DINT (double word) to prevent overflows with large arrays. Division is performed after conversion to REAL, resulting in a floating-point value.
- **No State Machine**: The function block is purely functional – REQ is immediately followed by CNF. There are no internal states or delays.

State Overview

Since this is a **combinatorial function block**, there are no explicit states. The process is as follows:

- Initial: Wait for REQ
- After REQ: Calculation and immediate output of CNF

Application Scenarios

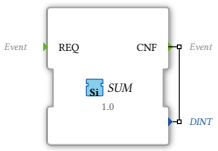
- **Averaging of Sensor Data**: Smoothing of measured values (e.g., temperature, pressure) over a defined measurement cycle.
- **Average Calculation in Batch Processes**: Determination of the average fill level, weight, or other process parameters.
- **Statistical Evaluation in Quality Control**: For example, calculating the diameter of multiple test specimens as a floating-point value for accuracy analysis.

Comparison with Similar Function Blocks

Feature	**AVG**	Typical IEC 61131-3 AVG Function Block
Parameterization	Dynamic via array (no limit)	Often static array size or lists
Event-driven	Yes (REQ/CNF)	No (pure function)
Output type	REAL	Usually REAL or LREAL
Overflow protection	Sum as DINT	Dependent on implementation

This function block combines IEC 61499 event control with the compact logic of an IEC 61131-3 average function block, making it particularly suitable for distributed automation systems.

Conclusion



The **AVG** function block offers a simple and efficient way to calculate the average of an integer array in real time. Its dynamic array support and clear event interface make it a universal tool for averaging in industrial control applications. The seamless integration into the 4diac IDE and the transparent calculation logic ensure high reusability and ease of understanding.

]

SUM

• – ◦ • – ◦ • – ◦ •

Introduction

The **SUM** function block allows you to calculate the sum of all elements in a dynamic array. It is triggered by an event at the REQ input and, after successful calculation, outputs the result via the data output and a confirmation event via CNF.

Interface Structure

Event Inputs

Name	Description
REQ	Starts the sum calculation of array A.

Event Outputs

Name	Description
CNF	Signals the completion of the calculation and the validity of the result.

Data Inputs

There are no pure data inputs. The required array is provided via the **InOut** port `A`.

Data Outputs

Name	Type	Description
(empty)	DINT	Resultant sum of all array elements (type DINT).

Adapters

None.

Functionality

The FB `SUM` accepts a one-dimensional array `A` of type `INT` with arbitrary length (declared as `ARRAY[*]`). When the event `REQ` is triggered, the array's contents are summed element by element. The sum is accumulated in a temporary variable of type `DINT` to prevent overflow. After iterating completely over all valid indices (from `LOWER_BOUND(A,1)` to `UPPER_BOUND(A,1)`), the result is passed to the output (data type `DINT`), and the event `CNF` is triggered.

Important Note: Although `A` is declared as an **InOut** variable, its value is not modified during the calculation. It functions solely as an input in this function block.

Important Note:

Technical Features

- **Dynamic Array Size:** The function block supports variable-length arrays by using the functions `LOWER_BOUND` and `UPPER_BOUND`, as specified by IEC 61131-3.
- **Type Extension:** The sum is returned as a `DINT` value (32-bit), allowing even larger sums of `INT` values (16-bit) to be represented without overflow.
- **Event-Driven Execution:** Computation is performed only when needed, enabling efficient resource utilization.

State Overview

The function block does not have an explicit state machine. Its behavior can be described as follows:

1. **Waiting:** No event is active – initial state.
2. **Calculation:** Entry after receiving `REQ`; summation of the array.
3. **Acknowledgement:** After completion of the calculation, `CNF` is sent; return to the wait state.

Application Scenarios

- Summing sensor readings over a specific period.
- Calculating totals in a production plant (e.g., quantities, fill levels).
- Preprocessing data arrays before further logical or arithmetic processing.

Comparison with Similar Function Blocks

- **SUM in IEC 61131-1:** This function block is closely based on the function of the same name from IEC 61131-3, but additionally enables event-driven execution and direct integration into the 4diac event model.
- **ADD / MULT:** While `ADD` or `MULT` process individual number pairs, `SUM` allows the processing of an entire array in one step, simplifying the application logic.

Conclusion

The function block `SUM` offers a simple and efficient way to calculate the sum of all elements in a dynamic array. Its event-driven execution and robust handling of different array sizes make it particularly suitable for industrial control tasks where large amounts of data need to be aggregated.

logging

LOG_16

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `LOG_16` is a ring logger designed for the cyclic recording of data of any type (`ANY`). It serves to hold incoming values in a buffer with 16 memory locations, overwriting older entries on new calls (ring buffer principle). This block is particularly suitable for logging process data or states in real-time controllers.

Interface Structure

Event Inputs

- **REQ (Service Request)**: Triggers a logging operation. When this event occurs, the current value at data input `IN` is written to the ring buffer.

Event Outputs

- **CNF (Confirmation of Requested Service)**: Triggered after successful processing of the `REQ` event. This event confirms the logging operation and simultaneously makes all 16 stored values available at the data outputs.

Data Inputs

- **IN (ANY)**: The data value to be written to the ring buffer upon a `REQ` event. The data type is arbitrary (`ANY`).

Data Outputs

- **OUT1 to OUT16 (ANY)**: The 16 outputs that represent the entire current contents of the ring buffer. `OUT1` contains the most recent entry (the last logged entry, `IN`), and `OUT16` contains the oldest. With each new log operation (`REQ`), all values in the buffer are shifted by one position.

Adapter

This function block has no adapter interfaces.

Functionality

LOG_16implements a fixed-size, first-in-first-out (FIFO) ring buffer with 16 elements. Upon each incomingREQ` event, the following algorithm is executed:

1. The current value at input `IN` is stored as the newest entry.
2. All previously stored values are shifted one position backward (toward `OUT16`).
3. The value that was previously at position 16 (`OUT16`) is discarded.
4. The confirmation event `CNF` is triggered.
5. The new 16 buffer contents are output at outputs `OUT1` (newest) to `OUT16` (oldest).

Technical Features

- **Generic Data Type**: The use of the `ANY` data type for inputs and outputs makes the function block extremely flexible. It can be instantiated and used with any data type (e.g., `BOOL`, `INT`, `REAL`, `STRING`, or even structured types).
- **Fixed Buffer Size**: The buffer size is fixed at 16 entries and is not configurable.
- **Immediate Output**: During each logging operation, the entire buffer content is updated at the outputs and confirmed with the `CNF` event.
-

State Overview

The function block does not possess a persistent internal state in the sense of a state machine, apart from the ring buffer itself. Its behavior is purely reactive: A `REQ` event is always followed by a buffer update and the output of `CNF` with the current data.

Application Scenarios

- **Process Value Logging**: Short-term recording of sensor data (e.g., temperature profile of the last 16 cycles).
- **Error History**: Storage of the last 16 error codes or alarm messages.
- **Data Preprocessing**: Provision of a sliding window of the last 16 values for subsequent calculations (e.g., in another function block).
- **Debugging**: Easy monitoring of variable behavior during development and commissioning.
-

⚖️ Comparison with similar modules

- **`E_DELAY` / Delay Modules**: These modules output an input value only after a defined delay. The `LOG_16`, on the other hand, stores a history of multiple values and outputs them immediately, but in order of recency.
- **`FIFO` Modules**: Classic FIFO (First-In-First-Out) storage devices often have variable lengths and a separate read/write interface. The `LOG_16` is a special fixed-length FIFO (16) that automatically outputs and overwrites its entire contents with each write operation.
- **Simple `LOG` Modules**: Simple loggers without a buffer typically write only a single value. The strength of `LOG_16` lies in its circular history.

🛠️ Related Exercises

- Exercise_122
- Exercise_122b

Conclusion

LOG_16` is a useful and generic function block for basic logging and buffering tasks in 4diac FORTE applications. Its strengths lie in its simplicity, generic type support, and deterministic behavior. The fixed buffer size of 16 is sufficient for many monitoring tasks; however, applications requiring a different buffer depth or selective reading will need adapted or extended blocks.

math

INTEGRAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `INTEGRAL` approximates the time integral of an input signal. The integration is performed by summing partial areas that result from the product of the input value and the time elapsed since the last call. This block is useful for applications where cumulative values such as energy consumed, quantities conveyed, or distances traveled need to be determined.

Interface Structure

Event Inputs

- **REQ**: Starts the normal execution of the integration. The data associated with this event, `IN` and `TM`, are processed.
- **RESET**: Resets the integrator. The output `OUT` is set to zero, and the overflow flag `OVERFLOW` is set to `FALSE`.

Event Outputs

- **CNF**: Signals confirmation of execution. This event is triggered after both `REQ` and `RESET` and returns the current values of `OUT` and `OVERFLOW`.

Data Inputs

- **IN** (`REAL`, initial value: `0.0`): The input value to be integrated.
- **TM** (`DINT`, initial value: `0`): The time elapsed since the last call in milliseconds (ms). This value must be positive for integration to occur.

Data Outputs

- **OUT** (`REAL`, initial value: `0.0`): The current value of the integral. It is calculated by summing all partial integrals (`IN * TM`). The unit is `[IN] * Sekunden` because the time value `TM` is internally converted from milliseconds to seconds.
- – **OVERFLOW** (`BOOL`, initial value: `FALSE`): Indicates an overflow. If this output is `TRUE`, the value of `OUT` has exceeded the representable range of the `REAL` data type. The integration function is blocked until it is reinitialized by a `RESET` event.

Adapters

This function block does not use adapters.

Functionality

The `INTEGRAL` function block has two primary operating states, which are controlled by incoming events:

1. **Integration (`REQ`)**: Upon a `REQ` event, the algorithm `REQ` is executed. First, it checks whether a previous overflow (`OVERFLOW = FALSE`) has occurred. An overflow check is then performed: If adding the next partial integral (`IN * TM`) to the current `OUT` value would exceed the limits of the `REAL` data type (approximately ±1.0E38), `OVERFLOW` is set to `TRUE`. Otherwise, and only if the time difference `TM` is greater than 0, the partial integral is calculated, converted to seconds (`/ 1000.0`), and added to the overall integral `OUT`.

If the value of the partial integral would exceed the limits of the `REAL` data type (approximately ±1.0E38), then `OVERFLOW` is set to `TRUE`. Otherwise, and only if the time difference `TM` is greater than 0, the partial integral is calculated, converted to seconds (`/ 1000.0`), and added to the total integral `OUT`.

1. **Reset (`RESET`)**: Upon a `RESET` event, the algorithm `RESET` is executed. This resets the integral value `OUT` to `0.0` and the overflow flag `OVERFLOW` to `FALSE`.

After the execution of each algorithm, an output event `CNF` containing the current values is always generated.

Technical Features

- **Overflow Handling**: The function block has integrated overflow detection. If a potential overflow is detected, the integration is stopped (`OVERFLOW = TRUE`) to prevent undefined behavior. A manual reset is required to resume operation.
- **Time Basis**: The integration is based on the user-specified time difference `TM` in milliseconds. The function block itself does not have an internal timer. This allows for flexible adaptation to different cycle times of the surrounding control program.

- **Initialization**: During the first initialization of the function block, `OUT = 0.0` and `OVERFLOW = FALSE` are present.

State Overview

The function block is a Simple FB and has explicitly defined execution states (ECStates) for the two possible events:

- **State REQ**: Activated upon arrival of the `REQ` event. Executes the integration algorithm.
- **RESET State**: Activated upon arrival of the `RESET` event. Executes the reset algorithm.

Both states result in the output of the `CNF` event after their execution.

Application Scenarios

- **Energy Measurement**: Calculation of total energy consumption from a momentary power measurement (`IN` = power in kW, `OUT` = energy in kWh).
- **Flow Measurement**: Determination of the total volume of liquid or gas delivered from a flow sensor (`IN` = flow rate in l/min, `OUT` = volume in l).
- **Velocity Integration**: Determining the distance traveled from a velocity signal (`IN` = velocity in m/s, `OUT` = distance in m).
- **Charge Calculation**: Integrating a current signal to determine the charge flow (`IN` = current in A, `OUT` = charge in Ah).

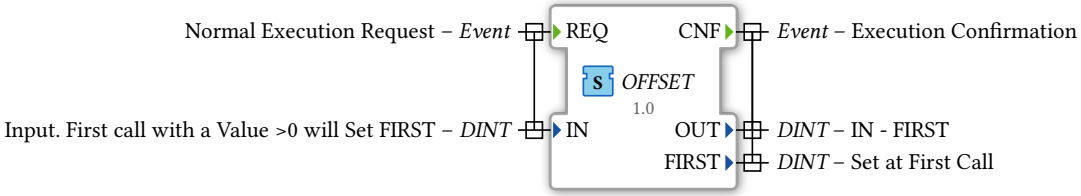
⚖️ Comparison with Similar Modules

Compared to simpler summation modules (e.g., `ADD`), `INTEGRAL` is distinguished by its explicit consideration of time as an integration variable. Unlike more complex control blocks with integrated timers (such as certain PID implementations), `INTEGRAL` is a pure, discrete-time integrator that expects the time difference as an input variable and is therefore clocked externally. This makes it more flexible in systems with variable or non-periodic cycle times.

🛠️ Related Exercises

- Exercise_072c

Conclusion



The `INTEGRAL` function block is a fundamental and robust tool for the time-integrated processing of signals in IEC 61499 controllers. Its clear interface, integrated overflow protection, and flexible handling of the time difference make it a reliable component for a wide variety of measurement and control tasks. The need to determine and provide the elapsed time externally offers maximum flexibility, but also requires correct implementation in the surrounding application program.

OFFSET

• – ◦ • – ◦ • – ◦ •

Introduction

The OFFSET function block is used to determine and apply an offset value. When an event with a non-zero input value is first processed, this value is stored as a reference point (`FIRST`). On each subsequent call, the block calculates the difference between the current input value and this stored reference value. This block is useful for measuring relative changes compared to an initial starting value.

Interface Structure

Event Inputs

- **REQ**: Starts the normal execution of the block. Linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the calculation. Linked to the data outputs `OUT` and `FIRST`.

Data Inputs

- **IN** (DINT): The input value. On the first call where this value is greater than 0, it is stored as the reference value (`FIRST`). Initial value is 0.

Data Outputs

- **OUT** (DINT): The result of the calculation `IN - FIRST`. Initial value is 0.
- **FIRST** (DINT): The reference value stored on the first relevant call. Initial value is 0.

Adapters

This function block does not use any adapters.

Functionality

The OFFSET block is a simple function block with a single state (`REQ`) and an algorithm of the same name. Upon each occurrence of a `REQ` event, the algorithm `REQ` is executed:

1. **Checking and Setting the Reference Value:** The algorithm checks whether the output `FIRST` still has its initial value of 0. If so, **and** the current input value `IN` is greater than 0, `FIRST` is set to the value of `IN`. This condition (`IN > 0`) is implicitly included in the algorithm's logic, since `FIRST` is only changed from 0 to another value during the first processing of a `IN > 0` event.
2. **Offset Calculation:** Regardless of the previous step, the output `OUT` is calculated as the difference between the current input `IN` and the stored reference value `FIRST` (`OUT := IN - FIRST`).
3. **Confirmation:** After the calculation, the `CNF` event is triggered, including the current values of `OUT` and `FIRST`.

Technical Features

- The reference value `FIRST` is set exactly once, specifically during the first `REQ` event where the data input `IN` has a value greater than 0. As long as `IN` is 0 or less during the initial calls, `FIRST` remains 0.
- Once `FIRST` has been set, it remains unchanged for the entire duration of the function block's runtime.
- The calculation `OUT = IN - FIRST` occurs with *every* call, even if `FIRST` is still 0. This means that `OUT` remains identical to `IN` until the reference value is set.

State Overview

The function block has a single, eponymous state:

- **REQ:** This state is always active. Every incoming `REQ` event triggers the execution of the associated algorithm and immediately triggers the `CNF` event. There are no internal state transitions.

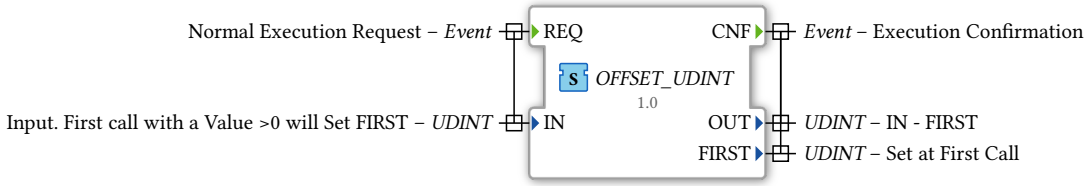
Application Scenarios

- **Incremental Path or Position Measurement:** Setting a zero point (`FIRST`) after a reference run and subsequent measurement of the relative movement (`OUT`).
- **Compensation for Base Loads or Zero Deviations:** Capture an initial base value (e.g., sensor base load) and calculate the pure change relative to this base value.
- **Relative Time Measurement:** Store a start time and calculate the elapsed time since that start.

⚖️ Comparison with Similar Function Blocks

- **SUB / DINT_SUB:** A simple subtractor always calculates the difference between two current input values. OFFSET, on the other hand, stores one of the values internally as a constant reference point.
- **DELAY / TON:** Time delay functions operate on the time axis. OFFSET works with data values and has no time-based behavior.
- **SR / RS:** Memory functions (Set/Reset) hold a binary state. OFFSET stores an integer value (`DINT`) and uses it for an arithmetic operation.

Conclusion



The OFFSET function block is a specialized and simple function block for determining a relative offset. Its strength lies in the one-time, automatic acquisition of a starting or reference value and the continuous calculation of the deviation from it. It is particularly suitable for applications where a system must be initially "zeroed" and only subsequent changes are relevant.

OFFSET_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OFFSET_UDINT` is used to calculate an offset value. On the first execution with an input value greater than zero, the block stores this value as a reference (`FIRST`). On each subsequent call, the difference between the current input value and this stored reference value is calculated as the output (`OUT`). This is particularly useful for determining relative changes compared to an initial starting value.

Interface Structure

Event Inputs

- **REQ**: Starts the normal execution of the algorithm. Linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the calculation. Linked to the data outputs `OUT` and `FIRST`.

Data Inputs

- **IN** (UDINT): The input value. On the first call with a value > 0, this value is stored in `FIRST`. The initial value is `0`.

Data Outputs

- **OUT** (UDINT): The result of the calculation `IN - FIRST`. The initial value is `0`.
- **FIRST** (UDINT): The reference value stored on the first call (with `IN` > 0). The initial value is `0`.

Adapters

This function block does not use any adapters.

Functionality

The `OFFSET_UDINT` is a simple function block (Simple FB) with a single state (`REQ`). Whenever the `REQ` event occurs, the associated algorithm `REQ` is executed.

The algorithm first checks whether the output `FIRST` still has the initial value `0`. If so, the current value of `IN` is stored in `FIRST`. The difference `OUT = IN - FIRST` is then calculated. After the calculation is complete, the `CNF` event is triggered, outputting the updated values of `OUT` and `FIRST`.

Important: The check `FIRST = 0` ensures that the value is only set on the *first* call where `IN` has a value greater than 0. A subsequent `IN` call from `0` will no longer change `FIRST`.

Technical Features

- **Data Type:** The block works exclusively with unsigned 32-bit integers (`UDINT`).
- **Initialization:** Both `FIRST` and `OUT` are initialized with `0`. The block is ready for operation immediately after startup.
- **One-Time Setting:** The variable `FIRST` is set exactly once (on the first `REQ` with `IN` > 0) and then remains constant for the lifetime of the function block instance, unless the function block is reinitialized.
-

State Overview

The function block has a single, stable state:

- **REQ:** Waits for the incoming `REQ` event. Upon receipt, the algorithm is executed, and immediately afterward, the `CNF` event is triggered. The function block remains in the `REQ` state.

Application Scenarios

- **Reference Point Establishment in Measurement Chains:** In a system that provides absolute position values (e.g., from an encoder), this block can store the first valid measurement as the zero point (offset). All subsequent values are output relative to this starting point.
- **Initial Value Compensation:** To eliminate a system-related default offset (e.g., a bias) during the first valid measurement.
- **Counter Start Normalization:** If a counter does not start at 0, the first value can be stored and subtracted from all subsequent values to simulate counting from 0.

⚖️ Comparison with Similar Blocks

- **SUB / DIF Blocks:** Standard subtraction blocks always calculate the difference between two variable inputs. `OFFSET_UDINT`, however, freezes one of the operands (`FIRST`) after the first operation and uses it as a fixed subtrahend thereafter.
- **Shift Registers (FIFO) or Delay Blocks:** These store a history of values. `OFFSET_UDINT`, on the other hand, only permanently stores a single, initial value.
- **Blocks with Markers (SR, RS):** These store a binary state. `OFFSET_UDINT` stores a specific numeric (`UDINT`) starting value.

🛠️ Related Exercises

- Exercise_072c

Conclusion

The `OFFSET_UDINT` function block is a specialized and efficient function block for applications where a single measured starting value serves as the basis for all subsequent relative calculations. Its strength lies in its simplicity and the reliable, one-time setting of the reference value, eliminating the need for manual logic to detect the "first cycle." It is ideal for initialization and normalization tasks in control applications.

- QUARTER

• – ◦ • – ◦ • – ◦ •

The function block `BOOLS_TO_QUARTERS` is a composite function block (FB) that converts 16 individual Boolean input signals into a special 2-bit format called “Quarter Byte.” It serves as a bundle and serial execution point for several basic conversion functions and is intended for applications where many binary states need to be converted into a compact, multi-valued control format.

- **REQ (Normal Execution Request):** Starts the processing chain. Upon receiving a REQ event, all associated data inputs (`I_00` to `I_15`) are read and the conversion is initiated.
- **CNF (Execution Confirmation):** This event is output after all 16 internal conversions are complete. It confirms the completion of the operation and provides the calculated quarter-byte values (`QB_00` to `QB_15`) to the downstream application.
- **I_00 to I_15 (BOOL Input):** 16 independent Boolean inputs (`BOOL`). Each represents a binary switching state (TRUE/FALSE). The initial value of all inputs is `FALSE`.
- **QB_00 to QB_15 (2-bit (quarter byte) output):** 16 outputs of type `BYTE`. Each output encodes the result of converting the corresponding Boolean input into a quarter byte. A quarter byte uses only the lower two bits of a byte and can theoretically represent four states. In this implementation, two states are primarily used, defined by the constants `quarter::COMMAND_DISABLE` and its counterpart. The initial value of all outputs is `quarter::COMMAND_DISABLE`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapter interfaces.

BOOLS_TO_QUARTERSis a composite function block (FB) internally composed of 16 instances of a basic function blockBOOL_TO_QUARTER`. Each instance is responsible for converting a single Boolean value.

The functionality follows a serial chain principle:

1. The incoming `REQ` event triggers the first internal instance, `BOOL_TO_QUARTER_00`.

2. This instance reads its assigned data input, `I_00`, performs the conversion, and sets its output, `QB_00`.
3. After completing its operation, `BOOL_TO_QUARTER_00` generates a `CNF` event, which is directly passed on as a `REQ` event to the next instance (`BOOL_TO_QUARTER_01`).
4. This process cascades through all 16 instances.
5. The last instance (`BOOL_TO_QUARTER_15`) passes its final `CNF` event to the `CNF` output of the enclosing `BOOLS_TO_QUARTERS` block. At this point, all 16 quarter-byte outputs (`QB_00` to `QB_15`) are available with their new values.

The data paths are organized in parallel: Each Boolean input `I_xx` is directly connected to the corresponding `I` input of the internal instance, and each `QB` output of an instance is directly connected to the corresponding `QB_xx` output of the composite FB.

- **Serial Execution:** The 16 conversions are executed sequentially, not in parallel. This results in a defined, but not simultaneous, update of the outputs. The total cycle time is the sum of the execution times of all 16 internal blocks.
- **Composite Structure:** This block primarily serves to consolidate and simplify the wiring in higher-level applications. The actual logic resides in the embedded `BOOL_TO_QUARTER` function blocks.

As a composite function block without its own explicit state machine, `BOOLS_TO_QUARTERS` does not possess an internal state in the strict sense. Its behavior is entirely determined by the cascade of its subordinate blocks and their states. The block can be in one of two macroscopic states:

1. **Idle:** Waiting for a `REQ` event. All outputs retain their last value.
2. **Processing:** A `REQ` event passes through the cascade of the 16 internal blocks. During this phase, the outputs are updated sequentially.

- **Control of compact value-added actuators:** For actuators or drivers that expect control commands not as simple on/off signals, but as 2-bit commands (e.g., on/off/error reset/emergency stop).
- **Data compression for bus communication:** Before transmission via fieldbuses, where many binary signals must be packed into a space-saving byte- or word-oriented protocol.
- **Interface to legacy systems:** As an adapter between modern IEC 61499 controllers and older systems that expect or deliver data in a special quarter-byte format.
-
- **Compared to `BOOL_TO_QUARTER`:** `BOOLS_TO_QUARTERS` is essentially an array of 16 `BOOL_TO_QUARTER` blocks with a hard-wired serial event chain. While `BOOL_TO_QUARTER` performs a single conversion, `BOOLS_TO_QUARTERS` aggregates many such conversions into a reusable building block.
- **Compared to Generic Pack Blocks (e.g., `BOOLx_TO_BYTE`):** Blocks like `BOOL8_TO_BYTE` pack multiple BOOL values into the bits of a single byte. In contrast, `BOOLS_TO_QUARTERS` generates a separate (albeit only partially used) byte for each input. There is no bit packing into a shared byte, but rather a one-to-one mapping to a special encoding format.
- Exercise_060

The `BOOLS_TO_QUARTERS`The function block offers a convenient and pre-configured solution for serially converting a large number of Boolean signals to the quarter-byte format. Its composite nature makes it easy to understand and use, as it abstracts the wiring of 16 individual blocks and their event logic. Serial processing is a crucial feature that must be considered for real-time applications. The block is ideal for specific applications requiring the quarter-byte format, but less suitable for general bit packing or unpacking operations.

BOOL_TO_QUARTER

🎧 Podcast

- QUARTER

• – ○ • – ○ • – ○ •

The function block `BOOL_TO_QUARTER` converts a binary BOOL signal into a special, predefined quarter byte. It translates the logical states `TRUE` and `FALSE` into corresponding, semantically meaningful byte constants, typically used for control commands (e.g., ENABLE/DISABLE). This block is part of the `logiBUS::utils::quarter` library.

- **REQ**: This event triggers the conversion function. Upon its arrival, the current value at the data input `I` is read and processed.
- **CNF**: This event signals the completion of the conversion. It is output along with the calculated output value `QB`.
- **I** (BOOL, Initial value: `FALSE`): The binary input value to be converted.
- **QB** (BYTE, Initial value: `quarter::COMMAND_DISABLE`): The output value as a byte. The block uses a so-called “quarter byte” (2 bits), which can represent four states, of which only two are used in this implementation. The specific value is derived from the constants of the imported library.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

This function block has no adapter interfaces.

Functionality

When triggered by the `REQ` event, the block evaluates the value at the input `I`. The processing is performed via a `CASE` instruction:

- If `I` has the value `BOOL#TRUE`, the output `QB` is set to the constant `quarter::COMMAND_ENABLE`.

- In all other cases (i.e., by default with `FALSE`), the output `QB` is set to the constant `quarter::COMMAND_DISABLE`.

Immediately after the assignment, the `CNF` event is output along with the new value of `QB`.

- **Library Dependency**: The block imports and uses constants (`quarter::COMMAND_ENABLE`, `quarter::COMMAND_DISABLE`) from the `logiBUS::utils::quarter::const::quarter` package. The actual byte values are therefore defined there and can be changed centrally.
- **Quarter Byte Concept**: The output is declared as `BYTE`, but conceptually only uses the lower two bits (a "quarter byte"). This allows for later expansion to include additional states without having to change the interface.
- **Initial Values**: Both the input `I` and the output `QB` have defined initial values (`FALSE` and `COMMAND_DISABLE`, respectively), which ensures deterministic startup behavior.

The block does not have an internal state in the sense of a memory. It behaves purely combinatorially with respect to the input data when the `REQ` event occurs. The output `QB` retains its last assigned value until the next execution cycle.

- **Actuator Control**: Conversion of a simple enable signal (`BOOL`) into a device-specific enable/disable command, which is sent as a byte via a fieldbus protocol.
- **Interface Adaptation**: Connection of logic blocks that work with BOOL values to control components that expect commands in quarter-byte format.
- **Code Standardization**: Ensuring that the same centrally defined constants for enable/disable commands are always used in a project.
-
- **`BOOL_TO_BYTE`**: A generic converter that typically maps `TRUE` to `1` and `FALSE` to `0`. `BOOL_TO_QUARTER` is more specialized and uses project-specific, semantic constants instead of numeric values.
- **Direct assignment**: The functionality could also be replicated by direct assignment in ST code (`QB := I`), but this would eliminate the advantages of centralized constant definition and a clear interface (events).
- Exercise_055
- Exercise_056

The `BOOL_TO_QUARTER` function block is a specialized but useful converter for control applications. It offers a clean interface with event-driven control, uses centrally managed constants for consistent semantics, and is potentially extensible thanks to the quarter-byte concept. Its strength lies in combining simple binary logic with device-specific control protocols.

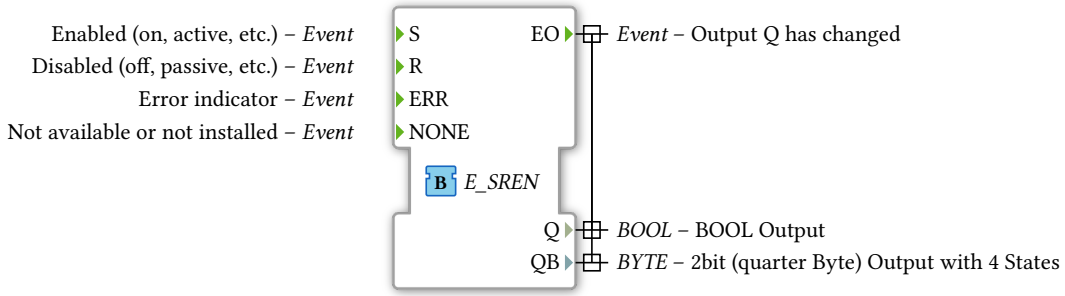
Conclusion



E_SREN

• – ○ • – ○ • – ○ •

Introduction

The E_SREN (Event-driven quad-state) is an event-driven function block that controls an output with four defined states. It reacts to various input events and sets its output accordingly to one of the four states: Enabled (`SET`), Disabled (`RESET`), Error (`ERROR`), or No Action (`NONE`). This function block is particularly suitable for applications where a signal must represent multiple operating states, such as in monitoring or control systems.

Interface Structure

Event Inputs

- **S (Set):** Sets the output `Q` to `TRUE` and `QB` to the state `COMMAND_ENABLE`.
- **R (Reset):** Sets the output `Q` to `FALSE` and `QB` to the state `COMMAND_DISABLE`.
- **ERR (Error):** Sets the output `Q` to `FALSE` and `QB` to the state `STATUS_ERROR`.
- **NONE:** Sets the output `QB` to the state `COMMAND_NO_ACTION`. The output `Q` remains unchanged.

Event Outputs

- **EO (Event Output):** Triggered when one of the output values (`Q` or `QB`) has changed. This event is always sent along with the current values of the data outputs `Q` and `QB`.

Data Inputs

- This function block has no data inputs.

Data Outputs

- **Q (BOOL):** Simple Boolean output. It is only `TRUE` when the `S` event occurs. It is `FALSE` for the `R` and `ERR` events and remains unchanged for `NONE`.
- **QB (BYTE):** A byte output specifically used to encode four states (2 bits). The specific values (e.g., `COMMAND_ENABLE`) are obtained from the imported library `quarter::const::quarter`.

Adapters

- This function block does not use any adapters.

Functionality

The E_SREN function block is implemented as a Basic function block and has an internal state machine (ECC). The output state is `START`. Upon receiving an input event (`S`, `R`, `ERR`, `NONE`), the automaton transitions to the corresponding state (`SET`, `RESET`, `Error`, `none`). In these states, the associated algorithm is executed, which calculates the values for `Q` and `QB`.

... A condition then checks whether the new value of `Q` or `QB` has changed compared to the last stored value (`old_Q`, `old_QB`). If so, the automaton transitions to state `FireEvent`. Here, the algorithm `HOLD` is executed, which stores the current output values in the internal variables and simultaneously triggers the output event `EO`. Afterward, the automaton always returns to state `START`. If the initial values have not changed, a direct transition occurs from states `SET`, `RESET`, `Error`, or `none` back to state `START`, without triggering `EO`.

Technical Features

- **State Detection:** The function block stores the previous initial state in the internal variables `old_Q` and `old_QB`. The output event `EO` is only generated when an actual state change occurs, thus preventing redundant event outputs.
- **State Detection:** The function block stores the previous initial state in the internal variables `old_Q` and `old_QB`. The output event `EO` is only generated when an actual state change occurs, preventing redundant event outputs.
- **Library Dependency:** The specific byte values for the `QB` output are imported from the constant library `logiBUS::utils::quarter::const::quarter`. Correct functionality requires the availability of this library.
- **Four-State Logic:** The logic of the `NONE` event is special: While `QB` is set to `COMMAND_NO_ACTION`, the Boolean output `Q` remains explicitly unchanged.

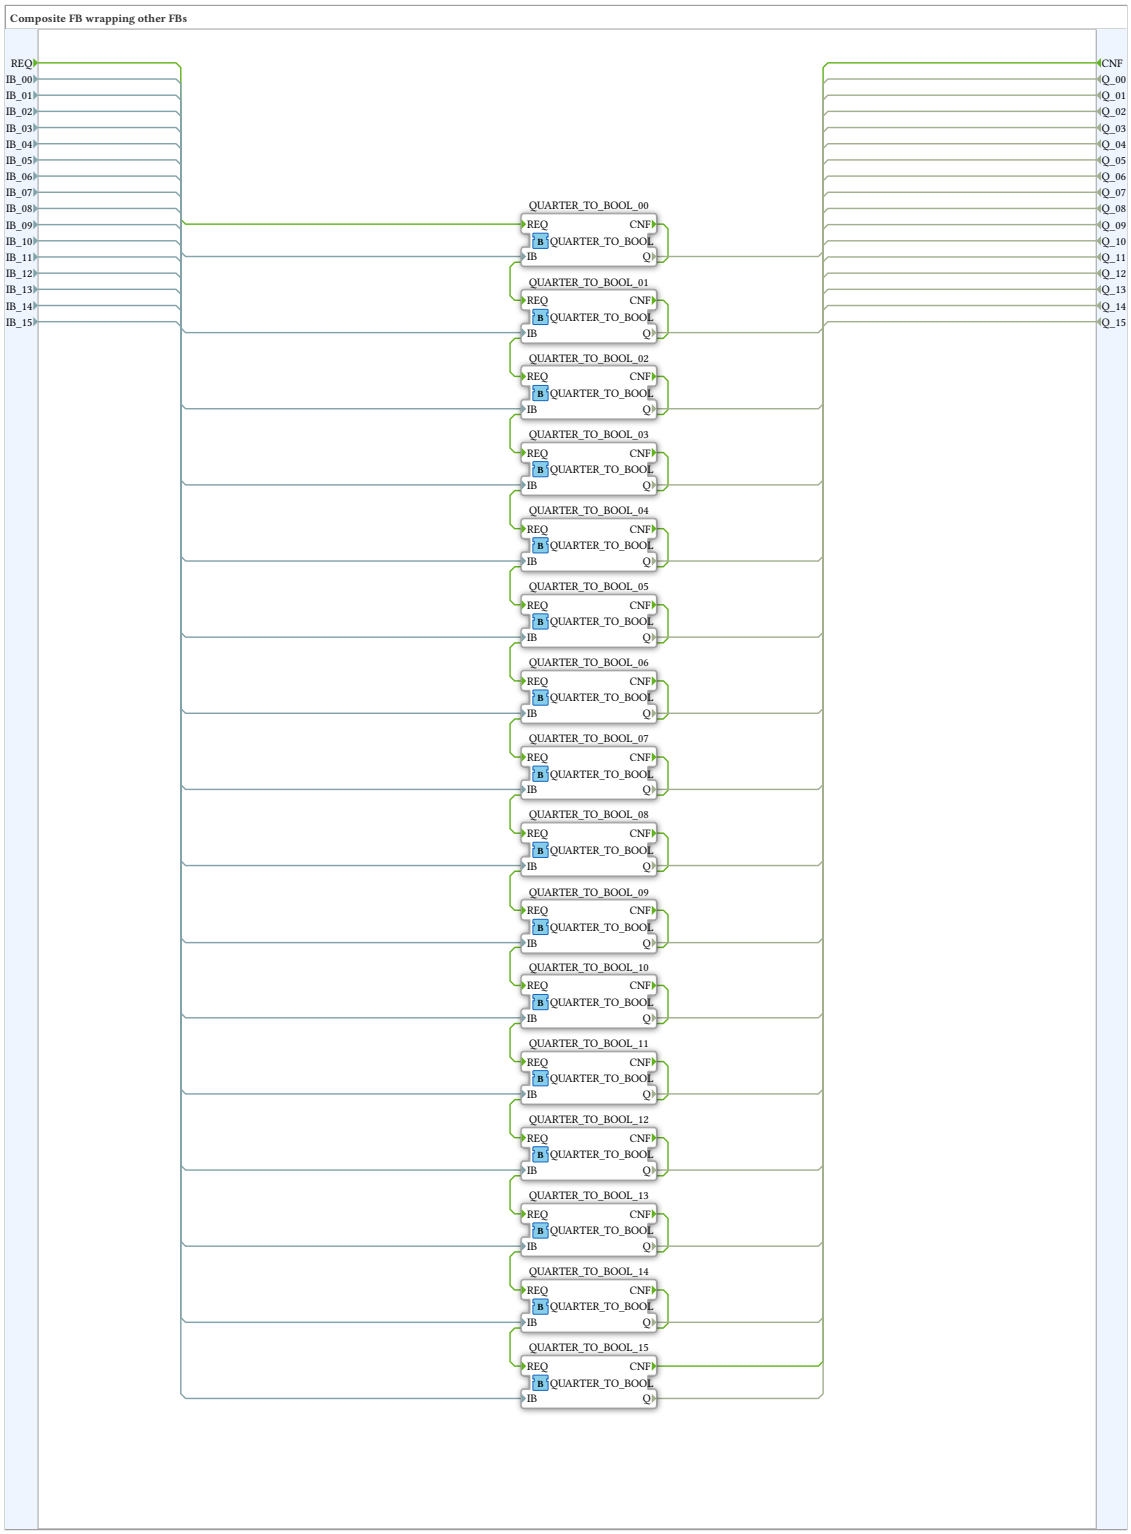
State Overview

The ECC (Execution Control Chart) consists of six states:

1. **START:** Initial and idle state.
2. **SET:** Activated by the `S` event. 3. **RESET:** Activated on event `Q=TRUE`, `QB=COMMAND_ENABLE`.
3. **Error:** Activated on event `R`. Sets `Q=FALSE`, `QB=COMMAND_DISABLE`.
4. **none:** Activated on event `ERR`. Sets `Q=FALSE`, `QB=STATUS_ERROR`.
5. **none:** Activated on event `NONE`. Sets `QB=COMMAND_NO_ACTION`. `Q` remains unchanged.
6. **FireEvent:** This event is only triggered if `Q` or `QB` has changed. It saves the new values and triggers `EO`.

Application Scenarios

- **Actuator Control:** Controlling a drive using the commands “On” (`S`), “Off” (`R`), “Fault” (`ERR`), and “Manually/Externally Controlled” (`NONE`).
- **Message Systems:** Displaying the status of a machine: “In Operation,” “Stopped,” “Error,” “Maintenance.”
- **Safety-Related Controllers:** Clear separation of normal operating (`S`/`R`), fault (`ERR`), and maintenance/override (`NONE`) states.



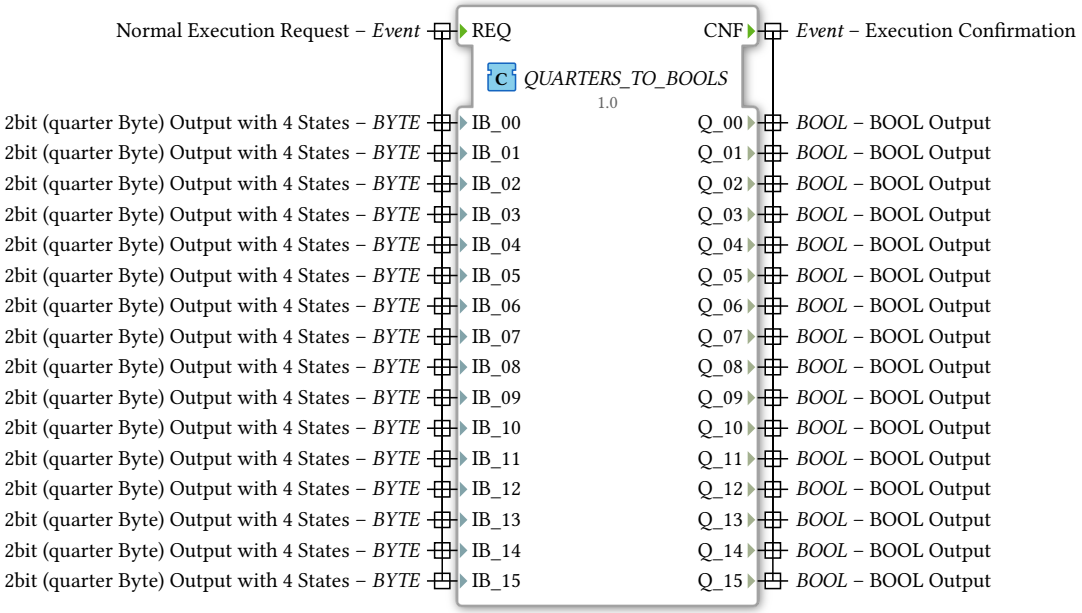
⚖️ Comparison with Similar Function Blocks

- **E_SR (Bistable Function):** The classic set-reset flip-flop only has two stable states (`TRUE`/`FALSE`). The E_SREN extends this concept to include two additional states (`ERROR`, `NO_ACTION`), which are encoded via a dedicated byte (`QB`).
- **E_D_FF (D-Flip-Flop):** Assumes a data value on a clock event. The E_SREN is event-driven (four different events) and has no separate data input. The “data” is implicitly contained in the triggering events.

Conclusion

The E_SREN is a specialized, event-driven function block for applications requiring more than two discrete states. By combining a simple Boolean signal (`Q`) with a multi-valued byte signal (`QB`) and intelligent, change-based event output (`EO`), it offers an efficient and clear solution for complex state control. Its strength lies in the clear semantics of the four input events and the reliable avoidance of redundant output events.

QUARTERS_TO_BOOLS



🎧 Podcast

- QUARTER

• – ○ • – ○ • – ○ •

Introduction

The function block `QUARTERS_TO_BOOLS` is a composite function block that converts 16 separate 2-bit input values (so-called “quarter bytes”) in parallel into corresponding Boolean output signals. It acts as a wrapper and simplifies handling by combining a multitude of individual conversion blocks into a single, easily manageable block. This block is particularly useful in control systems where compact data formats (such as 2-bit states in a byte) need to be converted into simple binary control signals for actuators or status indicators.

Interface Structure

Event Inputs

- **REQ**: Starts processing. Upon arrival of this event, all 16 input values (`IB_00` to `IB_15`) are read and processed.

Event Outputs

- **CNF**: Signals successful completion of processing. This event is output after all 16 internal conversions are complete and the output data (`Q_00` to `Q_15`) has been updated.

Data Inputs

- **IB_00** to **IB_15** (Type: `BYTE`): 16 inputs for 2-bit data (quarter bytes). Each input can represent one of four defined states (e.g., `quarter::COMMAND_DISABLE`). The default initial value for all inputs is `quarter::COMMAND_DISABLE`.

Data Outputs

- **Q_00** to **Q_15** (Type: `BOOL`): 16 Boolean outputs that reflect the converted state of the respective quarter-byte input. The initial value for all outputs is `FALSE`.

Adapters

This function block does not use any adapter interfaces.

Functionality

QUARTERS_TO_BOOLSis a composite function block that internally consists of 16 instances of the base function blockQUARTER_TO_BOOL. Each of these instances is responsible for converting a specific input (IB_xx`).

1. **Triggering**: The arrival of the event `REQ` triggers the processing chain.
2. **Parallel Data Distribution**: The byte values present at inputs `IB_00` to `IB_15` are forwarded in parallel to the corresponding inputs (`IB`) of the 16 internal `QUARTER_TO_BOOL` blocks.

3. **Serial Event Processing**: The REQ event is propagated serially through the chain of internal blocks. It starts at QUARTER_TO_BOOL_00 and is passed sequentially from one block to the next (CNF -> REQ) until the last block (QUARTER_TO_BOOL_15) completes its processing.
4. **Conversion**: Each internal QUARTER_TO_BOOL block interprets its byte input value according to a defined logic (presumably based on the two least significant bits) and converts it to a Boolean value (TRUE or FALSE).
5. **Result Output**: The Boolean results (Q) of the internal blocks are routed to the corresponding outputs Q_00 to Q_15 of the composite block.
6. **Completion**: Once the last internal block is complete, the composite block triggers its CNF event to signal the completion of the entire conversion cycle for all 16 channels.

Technical Features

- **Initialization**: All inputs are preset with the specific value quarter::COMMAND_DISABLE, and all outputs start with FALSE. This ensures a defined, inactive output state.
- **Processing Order**: While data inputs are distributed in parallel, event processing occurs strictly sequentially from index 00 to 15. This results in a deterministic, though not simultaneous, update of the outputs.
- **Composite Design**: The block encapsulates the complexity of 16 individual conversions and offers a clean, unified interface, which increases reusability and readability in higher-level applications.

State Overview

As a Composite Function Block, QUARTERS_TO_BOOLS does not have its own complex state machine in the conventional sense. Its behavior is defined by the network of internal blocks. In simplified terms, the overall state can be viewed as **Idle** (waiting for REQ) and **Processing** (event passing through the internal chain). The CNF output marks the transition back to the Idle state.

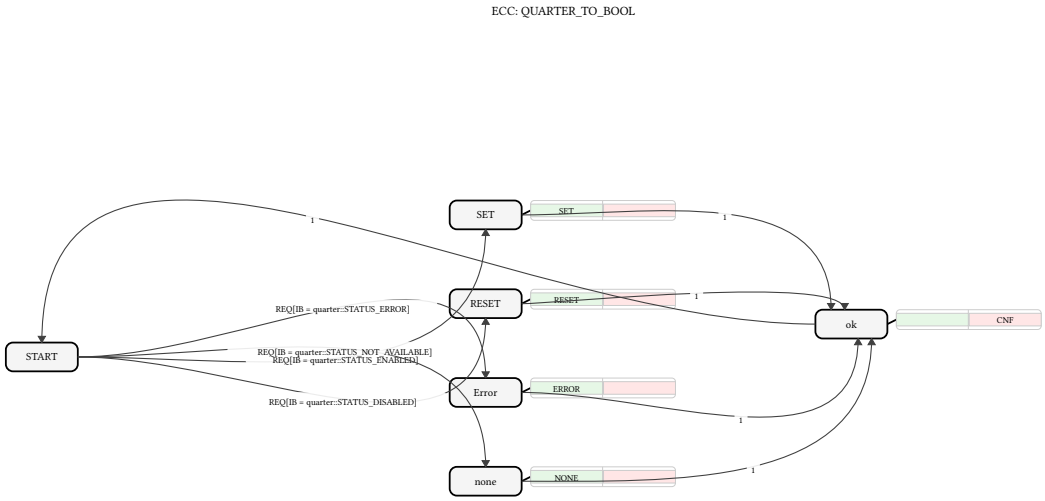
Application Scenarios

- **Compact PLC Connection**: Conversion of compact 32-bit data words (containing 16 2-bit states) into 16 individual binary control signals for valves, lamps, or relays.
- **Status Decoding**: Decoding of device status information transmitted in a “quarter byte” format into individual, easily processed error or operating state bits.
- **Simplifying Function Plans**: Replaces 16 separate QUARTER_TO_BOOL blocks and their wiring in a function plan with a single, clear block, simplifying project maintenance.

⚖️ Comparison with Similar Blocks

- **QUARTER_TO_BOOL**: This is the basic block that converts a single 2-bit input. QUARTERS_TO_BOOLS combines 16 instances of this block into a single unit. Using the composite block is more efficient for handling multiple channels, while the single block offers maximum flexibility in individual placement and wiring.
- **BYTE_TO_BOOL blocks**: Conventional blocks that split an entire byte into 8 individual bits. QUARTERS_TO_BOOLS is more specialized, as it assumes that each byte is already divided into four independent 2-bit units that must be interpreted separately.
-

🛠️ Related Exercises



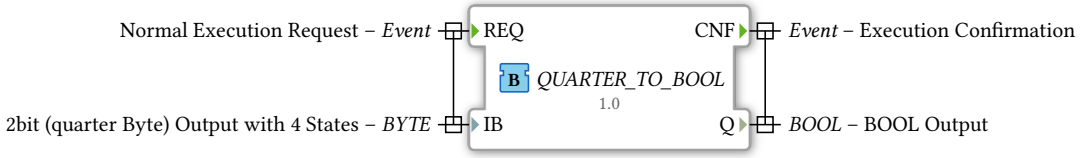
- Exercise_060

Conclusion

The QUARTERS_TO_BOOLS function block is a practical and time-saving tool for IEC 61499 programming when multiple 2-bit data channels frequently need to be converted into Boolean signals. By encapsulating 16 conversions in a single block, it significantly reduces wiring effort in higher-level applications and improves clarity. Its deterministic, serial event processing ensures reliable behavior that is well-suited for control tasks.

QUARTER_TO_BOOL

🎧 Podcast



- QUARTER

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `QUARTER_TO_BOOL` converts a quad-state signal, encoded in the lower two bits of a byte value, into a simple BOOL signal. It is particularly useful for connecting to systems that provide status information with more than two states, which should be further processed using simple binary logic.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event evaluates the incoming input value `IB`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event is always output after processing a `REQ` event.

Data Inputs

- **IB** (BYTE): Contains the 4-state value to be converted in its lower two bits. The initial value is `quarter::COMMAND_DISABLE`. The expected values are specific constants from the `quarter` namespace.

Data Outputs

- **Q** (BOOL): The result of the conversion. The initial value is `FALSE`.

Adapters

This function block does not use adapters.

Functionality

When triggered by a `REQ` event, the function block reads the value at the data input `IB`. This value is then compared with predefined constants to determine the corresponding internal state. Depending on the state, a specific algorithm is executed, which either sets the BOOL output `Q` or leaves it unchanged. After the algorithm has finished executing, the `CNF` event is triggered, and the function block returns to its initial state.

The specific mapping of the input values to the output logic is as follows:

- `quarter::STATUS_ENABLED` ⟶ Algorithm `SET` ⟶ `Q := TRUE`
- `quarter::STATUS_DISABLED` ⟶ Algorithm `RESET` ⟶ `Q := FALSE`
- `quarter::STATUS_ERROR` ⟶ Algorithm `ERROR` ⟶ `Q := FALSE`
- `quarter::STATUS_NOT_AVAILABLE` ⟶ Algorithm `NONE` ⟶ `Q` remains unchanged

Technical Features

- **State Handling**: The function block is implemented as a Basic Function Block and It has an explicit state machine (ECC). The states `SET`, `RESET`, `ERROR`, and `none` are pure algorithm states, while the state `ok` is responsible for outputting the acknowledgment event.
- **Value Preservation**: In the case of state `STATUS_NOT_AVAILABLE`, the algorithm `NONE` is executed, which explicitly does not modify the current value of the output `Q`. This enables "don't care" or "hold" behavior.
- – **Initialization**: The data output `Q` is initialized to `FALSE` at startup.

State Overview

The ECC (Execution Control Chart) consists of six states:

1. **START**: Initial and wait state. Upon receiving `REQ`, a transition to `SET`, `RESET`, `Error`, or `none` occurs, depending on the value of `IB`.
2. **SET**: Executes the algorithm `SET` (sets `Q` to TRUE).
3. **RESET**: Executes the algorithm `RESET` (sets `Q` to FALSE).
4. **Error**: Executes the algorithm `ERROR` (sets `Q` to FALSE).
5. **none**: Executes the algorithm `NONE` (leaves `Q` unchanged).
6. **OK**: Triggers the `CNF` output event and then switches back to the `START` state.

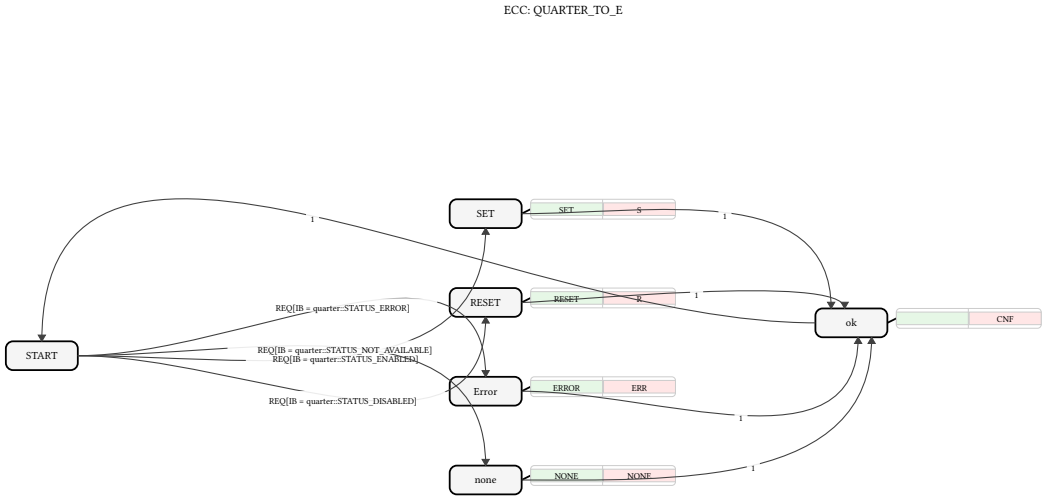
Application Scenarios

- **Connecting Field Devices**: Many sensors or actuators report statuses such as "Ready," "Faulty," "Maintenance," or "Not Connected." This function block can convert such messages into a simple "On/Off" or "OK/Not OK" signal for higher-level control logic.
- **Simplifying Logic**: In controllers that only require binary decisions (e.g., "Release Process" yes/no), this function block can reduce more complex status messages to the essential binary information.
- **Error Handling**: Consistent handling of error states (`STATUS_ERROR`) by setting the output to `FALSE`.

⚖️ Comparison with Similar Building Blocks

- **Standard Converters (e.g., `BYTE_TO_BOOL`)**: A simple `BYTE_TO_BOOL` converter would typically use a threshold (e.g., anything >0 becomes TRUE). `QUARTER_TO_BOOL`, on the other hand, interprets specific, named states and provides defined behavior for each one, including the option to leave the output unchanged for a given state.
- **`E_SELECT` or `E_DEMUX` Building Blocks**: These could be used to activate different event paths based on an input value. `QUARTER_TO_BOOL` encapsulates this logic specifically for converting 4-state signals and directly returns the Boolean result.
-

🛠️ Related Exercises



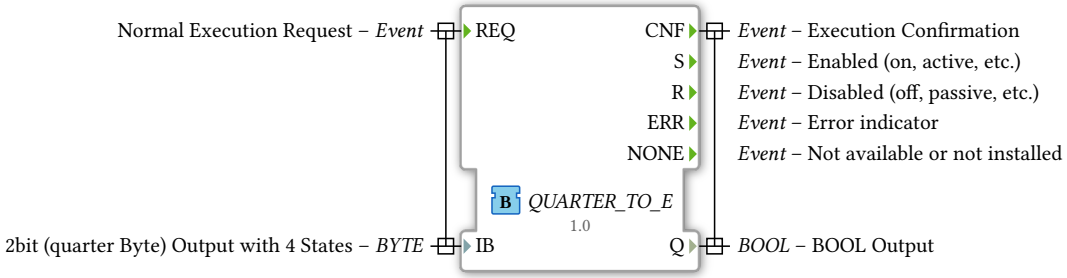
- Exercise_055
- Exercise_056

Conclusion

The `QUARTER_TO_BOOL` function block is a specialized and useful converter for applications where compact status information with four discrete states needs to be integrated into simple binary logic. Its clear definition of the behavior for each state, especially the retention of the output value in the "Not Available" case, makes it robust and highly predictable. It is ideally suited for the interface between more complex fieldbus systems and basic binary control logic.

QUARTER_TO_E

🎧 Podcast



- QUARTER

• – ○ • – ○ • – ○ •

Introduction

The function block `QUARTER_TO_E` is used to translate a 2-bit state value (a so-called "quarter byte") into four different, unique events. It is an auxiliary block frequently used in conjunction with blocks that report more than the usual two states (ON/OFF), such as status messages from devices that can also indicate error or unavailability states.

Interface Structure

Event Inputs

- **REQ**: Starts processing. This event evaluates the current value at data input `IB`.

Event Outputs

- **CNF**: Signals successful completion of processing, regardless of the detected state. It is always generated after the output of one of the specific events.
- **S** (Enabled): Triggered when the "enabled" or "switched on" state is detected.
- **R** (Disabled): Triggered when the "disabled" or "switched off" state is detected.
- **ERR** (Error): Triggered when an error state is detected.
- **NONE** (Not available): Triggered when the "not available" or "not installed" state is detected.

Data Inputs

- **IB** (BYTE): Contains the 2-bit state value to be interpreted. The initial value is set to `quarter::COMMAND_DISABLE`. The actual interpretation is performed using the defined constants from the `quarter` package.

Data Outputs

- **Q** (BOOL): A Boolean output whose value is set depending on the detected state. It serves as a simple, binary representation of the main state (enabled/disabled).

Adapters

This function block does not use adapters.

Functionality

The `QUARTER_TO_E` is a Basic Function Block with an internal state machine (ECC). Upon the arrival of the `REQ` event, the value at input `IB` is compared with predefined constants. Depending on the comparison, the automaton jumps to one of four states: `SET`, `RESET`, `Error`, or `none`. In each of these states, a corresponding algorithm is executed, which sets (or leaves unchanged) the Boolean output `Q` and triggers the associated specific event (`S`, `R`, `ERR`, `NONE`). The automaton then transitions to state `ok`, from where the confirmation event `CNF` is issued, before returning to the initial state `START` and waiting for the next `REQ`.

Technical Details

- This block uses constants from the package `logiBUS::utils::quarter::const::quarter` (`STATUS_ENABLED`, `STATUS_DISABLED`, `STATUS_ERROR`, `STATUS_NOT_AVAILABLE`). These must be available in the project.
- The output `Q` is only modified in the states `SET` (TRUE), `RESET` (FALSE), and `ERROR` (FALSE). In the state `NONE`, `Q` is explicitly not modified ("Don't care").
- The output of the `CNF` event always occurs, regardless of which specific state was detected. This enables consistent process control within the application.

State Overview

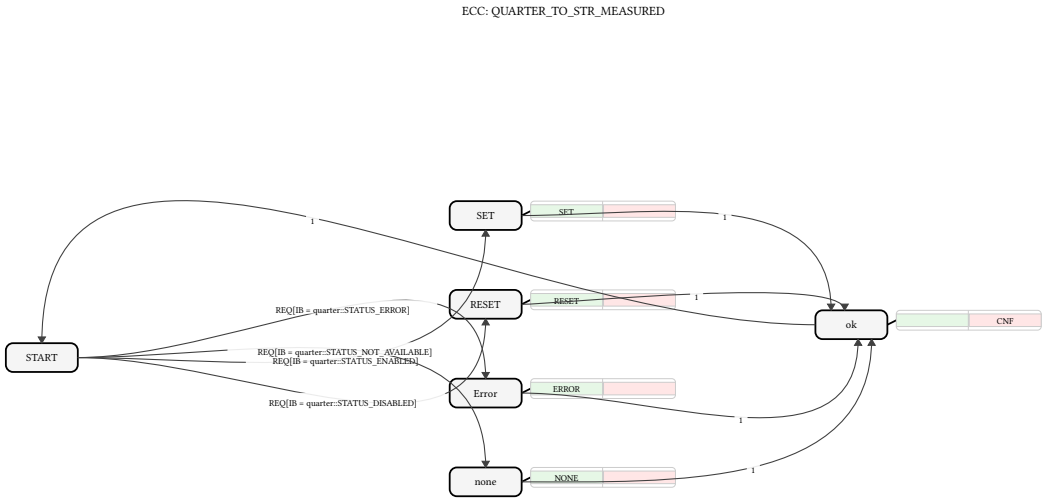
1. **START**: Waiting state. At `REQ`, `IB` is evaluated, and the process transitions to a processing state.
2. **SET**: Reached at `IB = STATUS_ENABLED`. Sets `Q:=TRUE` and triggers `S`.
3. **RESET**: Reached at `IB = STATUS_DISABLED`. Sets `Q:=FALSE` and triggers `R`.
4. **Error**: Reached at `IB = STATUS_ERROR`. Sets `Q:=FALSE` and triggers `ERR`.
5. **none**: Reached at `IB = STATUS_NOT_AVAILABLE`. Triggers `NONE` (Q remains unchanged). 6. **ok**: Intermediate state that triggers the `CNF` event and returns to the `START` state.

Application Scenarios

- **Interpretation of Device Status**: A drive reports its status not only as ON/OFF, but also as "Error" or "Not Ready". This block converts the device status into separate, easily processed events.
- **Simplification of Logic**: Instead of constantly having to query the byte value in subsequent blocks, you can react directly to the specific events (`S`, `R`, `ERR`).
- **Abstraction**: Serves as an adapter between blocks that provide a quarter-byte status and logic that works with classic event/boolean signals.

⚖️ Comparison with similar blocks

- **E_DEMUX / E_SELECT**: These blocks forward an input event based on a control value to one of several outputs. `QUARTER_TO_E` is more specialized: It not only translates a specific data value (`IB`) into a selection, but also triggers different *content-related* events and additionally calculates a boolean value (`Q`).



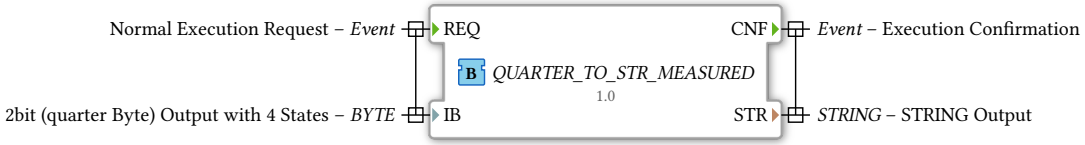
- **BYTE_TO_E**: A generic block that could convert each bit of a byte into a separate event. `QUARTER_TO_E` is semantically richer because it recognizes and outputs specific, predefined states (Enabled, Disabled, Error, None) and their meanings.

Conclusion

The `QUARTER_TO_E` is a useful and specialized component for the structured processing of four-state signals. It relieves the application logic by handling raw data interpretation and providing clear, semantic events as well as a simplified Boolean status. Its strength lies in the combination of data processing and event-based output according to IEC 61499.

QUARTER_TO_STR_MEASURED

🎧 Podcast



- QUARTER

• – ○ • – ○ • – ○ •

Introduction

The function block `QUARTER_TO_STR_MEASURED` converts a 4-state signal (encoded in the lower two bits of a BYTE value) into a human-readable text string (STRING). It is particularly suitable for displaying or logging status information in control systems, where discrete states such as “On,” “Off,” “Error,” or “Not Available” need to be converted into textual form.

Interface Structure

Event Inputs

- **REQ**: Starts the normal execution of the function block. Upon this event, the value at data input `IB` is evaluated, and the corresponding conversion is performed.

Event Outputs

- **CNF**: Signals the completion of the conversion and the availability of the result at data output `STR`.

Data Inputs

- **IB** (BYTE): The input for the quad-state value to be converted. Only the lower two bits (LSB) are evaluated. The block expects specific, predefined constant values (e.g., `quarter::STATUS_ENABLED`). The initial value is `quarter::STATUS_DISABLED`.

Data Outputs

- **STR** (STRING): The output where the converted text string is provided. The initial value is the text constant for the "Disabled" status (`quarter::STATUS_DISABLED_msg`).

Adapters

This function block has no adapter interfaces.

Operation

The `QUARTER_TO_STR_MEASURED` is a Basic Function Block (BFB) with an internal Execution Control Graph (ECC). Upon the arrival of the `REQ` event, the value at the input `IB` is compared with predefined constants from the library `logiBUS::utils::quarter::const::quarter`. Depending on the matching value, the controller branches to one of four states (`SET`, `RESET`, `Error`, `none`). In each of these states, a specific algorithm is executed, assigning the corresponding text constant (e.g., `quarter::STATUS_ENABLED_msg`) to the output `STR`. The block then transitions to state `ok`, from which the output event `CNF` is triggered, before the block returns to its initial state `START` and waits for the next `REQ`.

...

Technical Features

- **Typed Constants:** The block uses strongly typed constants for both the input values (`quarter::STATUS_...`) and the output strings (`quarter::STATUS_..._msg`). This increases the type safety and maintainability of the code.
- **Basic FB:** The implementation as a Basic FB with ECC enables clear and comprehensible state logic.
- **Initial Values:** Both the data input `IB` and the data output `STR` are pre-populated with meaningful initial values (disabled state).

State Overview

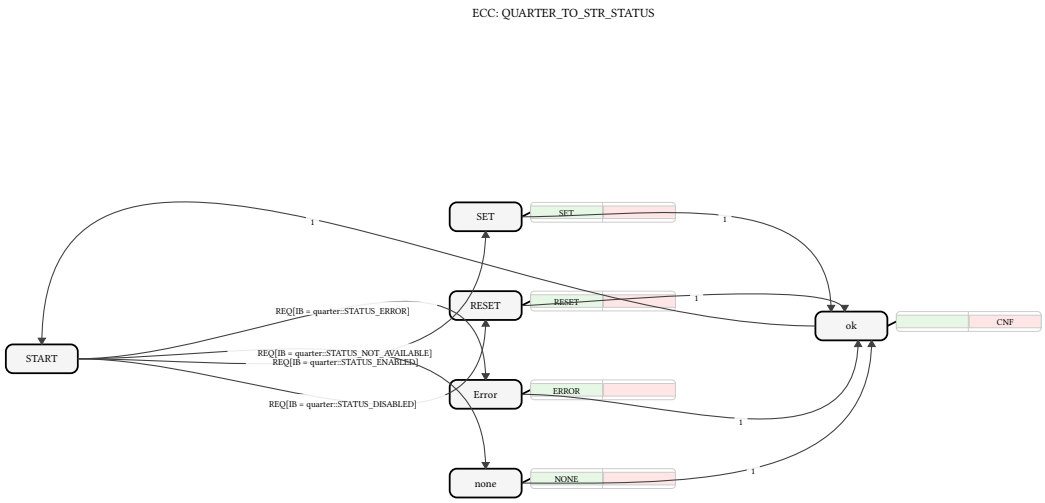
The ECC of the function block consists of six states:

1. **START:** The initial wait state. At `REQ`, a branch is triggered based on the value of `IB`.
2. **SET:** Activated at `IB = quarter::STATUS_ENABLED`. Executes the algorithm `SET`.
3. **RESET:** Activated at `IB = quarter::STATUS_DISABLED`. Executes the algorithm `RESET`.
4. **Error:** Activated at `IB = quarter::STATUS_ERROR`. Executes the algorithm `ERROR`.
5. **none:** Activated at `IB = quarter::STATUS_NOT_AVAILABLE`. Executes the algorithm `NONE`.
6. **ok:** Common state that is traversed after each successful conversion. Triggers the `CNF` event and returns to the `START` state.

Application Scenarios

- **HMI/SCADA Integration:** Conversion of internal control status values into readable text for display on operator panels or in visualization systems.
- **Logging and Diagnostics:** Generation of plain-text log entries for error or status messages, which are easier to analyze than numeric codes.
- **Interface to Higher-Level Systems:** Preparation of status information for transmission to MES or ERP systems that expect string data.

⚖️ Comparison with Similar Building Blocks



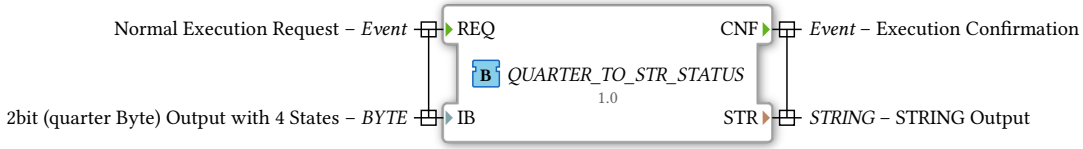
- **`BYTE_TO_STRING`:** A general-purpose converter that transforms any byte value into its decimal string representation. `QUARTER_TO_STR_MEASURED` is more specialized and converts specific, semantically meaningful values into predefined, meaningful texts, not numeric strings.
- **`E_SR` or `E_RS` (Flip-Flops):** These blocks represent binary states (SET/RESET) using Boolean signals. `QUARTER_TO_STR_MEASURED` extends this concept to four states and additionally offers textual representation.

Conclusion

The `QUARTER_TO_STR_MEASURED` is a specialized and robust function block for the semantic conversion of 4-state signals. By using library constants for inputs and outputs, it ensures high code quality and simplifies maintenance. It is the ideal choice when discrete status information from the control plane needs to be converted into textual form for display, logging, or interface purposes.

QUARTER_TO_STR_STATUS

🎧 Podcast



- QUARTER

• – ○ • – ○ • – ○ •

Introduction

The function block `QUARTER_TO_STR_STATUS` converts a 2-bit status value (also known as a “quarter byte”) into a human-readable text string. It is part of the `logiBUS::utils::quarter` library and is typically used to convert compact status information from controllers or devices into an understandable text format for display, logging, or diagnostic purposes.

Interface Structure

Event Inputs

- **REQ**: Starts processing. Upon arrival of this event, the value at data input `IB` is read and the corresponding conversion is performed.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event, along with the converted string, is output at data output `STR`.

Data Inputs

- **IB** (BYTE): The input for the 2-bit status value. Only the least significant two bits (bits 0 and 1) are evaluated. This block expects specific, predefined constants from the `quarter` library. The initial value is `quarter::COMMAND_DISABLE`.

Data Outputs

- **STR** (STRING): The output that provides the text string corresponding to the status value. The initial value is `quarter::COMMAND_DISABLE_msg`.

Adapters

This function block has no adapter interfaces.

Functionality

The `QUARTER_TO_STR_STATUS` is a Basic Function Block (BFB) with a defined Execution Control Chart (ECC). Upon an incoming `REQ` event, the value at `IB` is compared to predefined constants. Depending on this comparison, the controller branches to one of four possible states (`SET`, `RESET`, `Error`, `none`). In each of these states, a specific algorithm is executed that sets the initial `STR` to a corresponding text string. After the algorithm has finished executing, the block transitions to state `ok`, from which the `CNF` event is triggered. The block then returns to the initial `START` state and is ready for the next request.

In each of these states, a specific algorithm is executed that sets the initial `STR` to a corresponding text string. The specific string values are loaded from the `quarter` constant library (`logiBUS::utils::quarter::const::quarter`). The expected input values and their corresponding output strings are:

- `quarter::STATUS_ENABLED` ⟶ `quarter::COMMAND_ENABLE_msg`
- `quarter::STATUS_DISABLED` ⟶ `quarter::COMMAND_DISABLE_msg`
- `quarter::STATUS_ERROR` ⟶ `quarter::COMMAND_RESERVED_msg`
- `quarter::STATUS_NOT_AVAILABLE` ⟶ `quarter::COMMAND_NO_ACTION_msg`

Technical Features

- **Type Safety:** The block uses strongly typed constants from a dedicated library, which reduces the susceptibility to errors compared to the direct use of raw values (e.g., 0, 1, 2, 3).
- **2-Bit Processing:** Although the input is declared as `BYTE`, only one quarter (2 bits) of this byte is effectively used. The semantics of the four possible states are defined by the constant library used.

Deterministic Behavior: The state transitions depend solely on the input value at `REQ`. There is no internal memory or hysteresis effects.

State Overview

The ECC consists of six states:

1. **START:** Initial, waiting state. It waits for the `REQ` event.
2. **SET:** Activated at `IB = quarter::STATUS_ENABLED`. Executes algorithm `SET`.
3. **RESET:** Activated at `IB = quarter::STATUS_DISABLED`. Executes algorithm `RESET`.
4. **Error:** Activated at `IB = quarter::STATUS_ERROR`. Executes algorithm `ERROR`.
5. **none:** Activated at `IB = quarter::STATUS_NOT_AVAILABLE`. Executes algorithm `NONE`.
6. **ok:** Common state after every successful conversion. Triggers the `CNF` exit event and returns to the `START` state.

Application Scenarios

- **HMI/SCADA Integration:** Conversion of internal device states (e.g., “enabled,” “faulty”) into strings for display on operator panels or in visualization software.
- **Logging and Diagnostics:** Conversion of status codes into readable text for log files or diagnostic tools to facilitate fault analysis.
- **Interface to Text-Based Systems:** Preparation of status information for further processing in systems that work with string messages (e.g., MQTT topics, CSV export).

⚖️ Comparison with Similar Function Blocks

- **`E_SR` or `E_RS` (Flip-Flops):** These blocks store a binary state (SET/RESET). `QUARTER_TO_STR_STATUS`, on the other hand, only converts an existing 4-state value into a string; it has no dedicated memory.

- **`E_SELECT` or `E_MUX`:** These can also choose between different paths/values, but are more generic and not specifically designed for converting to strings with predefined quarter-state values.
- **Simple `STRING` assignment:** A direct assignment in ST code could achieve something similar, but the `QUARTER_TO_STR_STATUS` block encapsulates the logic, promotes reusability, and enforces the use of standardized constants, thus increasing consistency across the entire project.

`STRING` assignment: A direct assignment in ST code could accomplish something similar, but the `QUARTER_TO_STR_STATUS` block encapsulates the logic, promotes reusability, and enforces the use of standardized constants, increasing consistency throughout the project.

🛠️ Related Exercises

- Exercise_055
- Exercise_056

Conclusion

The `QUARTER_TO_STR_STATUS` is a specialized and useful function block for applications that work with the specific 4-state status model (Quarter Byte). By using a constant library and clearly separating logic and interface, it contributes to the robustness and maintainability of IEC 61499 applications. It is the ideal choice when compact status information needs to be reliably and consistently translated into a human-readable format.

const

quarter

🎧 Podcast

- The Secret of the 2-Bit Quarter: Efficiency in CAN Bus for Commercial Vehicles
- QUARTER

• – ◦ • – ◦ • – ◦

The `quarter` library is a collection of global constants designed for working with SAE J1939-compliant status and command values in logiBUS applications. It defines standardized 2-bit values (represented as `BYTE`) and associated plaintext descriptions (`STRING`) for states and control commands. These constants serve to standardize and improve the readability of code that works with binary status information and control commands.

quarter `is a collection of global constants` (GLOBALCONSTANTS`). Therefore, it is not a function block (FB) in the traditional sense with event or data interfaces. The interface consists solely of the defined constants, which can be referenced directly in the code.

Not present (constant collection).

Not present (constant collection). The constants themselves represent symbolic names for fixed values.

Not present (constant collection).

Event Outputs

Event Inputs

Data Outputs

Data Inputs

Interface Structure

Introduction

Adapters

Not present (constant collection).

Functionality

The library provides only named constants. When used in code, the symbolic name (e.g., `STATUS_ENABLED`) is replaced by the assigned value (e.g., `2#01`). The `_msg` variants contain descriptive text that can be used for debugging, logging, or user output.

- **Data Types:** All status and command constants are of type `BYTE`, even though they only use the lower two bits (values 0-3). The corresponding text constants are of type `STRING`.
- **Values:** The values are defined as binary literals (`2#00`, `2#01`, etc.), which clearly indicates their interpretation as 2-bit fields.
- **Package:** The constants are organized in the package `logiBUS::utils::quarter::const`.

Not applicable, as this is a static collection of values.

- **SAE J1939 Communication:** Used in function blocks that send or receive parameters according to SAE J1939, especially for status and control information transmitted as 2-bit fields.
- **Status Management:** Assigning and querying device or function states (e.g., on/off, faulty, unavailable) within a control application.
- **Logging and Diagnostics:** Use of the `_msg` strings to generate readable log entries or displays in the control panel.
- **`logiBUS::utils::bit::const`:** Contains constants for single bits (e.g., `BIT_FALSE`, `BIT_TRUE`). `quarter` extends this concept to 2-bit fields with application-specific semantics.
- **Manual Definition:** Instead of using this library, the values could be written directly in the code as numbers or binary literals. However, using `quarter` increases maintainability, readability, and consistency across the entire project.

SAE J1939-Specific Libraries: `quarter` is a basic utility library. More comprehensive J1939 libraries would likely rely on these constants to define more specific messages (PGNs) or parameters (SPNs).

The `quarter` constant library is a useful tool for developing control software in the SAE J1939 environment and other systems that use 2-bit status and control fields. It promotes standardized, self-explanatory programming and reduces the potential for errors through the use of "magic numbers." Its integration into the `logiBUS::utils` package makes it a fundamental component for structured logiBUS applications.

sequence_B_08_AX_AX

ECC: sequence_B_08_AX_AX

• – ○ • – ○ • – ○ •

Introduction

The function block **sequence_B_08_AX_AX** implements a sequential control system with eight outputs. State transitions are level-controlled via BOOL signals provided by an AX adapter. The block is designed for fail-safe applications and allows for the restoration of the current state after a power failure. It is particularly suitable for sequence control systems in automation technology where multiple switching operations must be executed sequentially.

Interface Structure

Event Inputs

Name	Description
S8_START	Event that triggers a jump from state 8 back to the start state.

RESET	Event that triggers an immediate reset from any active state.

Event Outputs

Name	Description
CNF	Acknowledge event that outputs the current state number after each state change. (With STATE_NR)

Data Inputs

The FB has no direct data inputs. The transition conditions are read exclusively via the socket adapters.

Data Outputs

Name	Type	Description
STATE_NR	SINT	Current state number: 0 = Start, 1…8 = State_01…State_08, 9 = State_00 (End).

Adapter

Plugs (Outputs – Type `adapter::types::unidirectional::AX`)

Name	Description
DO_S1	Output active when state 1 is active.
DO_S2	Output active when state 2 is active.
DO_S3	Output active when state 3 is active.
DO_S4	Output active when state 4 is active.
DO_S5`	Output active when state 5 is active.
DO_S6`	Output active when state 6 is active.
DO_S7`	Output active when state 7 is active.
DO_S8`	Output active when state 8 is active.

Sockets (Inputs – Type `adapter::types::unidirectional::AX`)

Name	Description
DI_S1`	Signal for transition from start state to state 1.
DI_S2`	Signal for transition from state 1 to state 2.
DI_S3	Signal for transition from state 2 to state 3.
DI_S4`	Signal for transition from state 3 to state 4.
DI_S5`	Signal for transition from state 4 to state 5.
DI_S6`	Signal for transition from state 5 to state 6.
DI_S7`	Signal for transition from state 6 to state 7.
DI_S8`	Signal for transition from state 7 to state 8.

Functionality

The function block operates on the basis of an event-driven state machine (ECM). At startup, it is in state xSTART. From there, the input signals DI_S1 to DI_S8 (each corresponding to the adapter's attribute .D1) are checked for their BOOL value. If a signal matches (TRUE), the machine transitions to the corresponding state (sState_01 … sState_08). If no signal is present, the state sState_00 is reached (end of sequence).

Each state performs the following actions upon entry:

1. **Deactivate the previous output**: The output adapter of the previous state is set to FALSE (algorithm State_n_X).
2. **Update the state number**: STATE_NR is set to the constant of the current state (e.g., sequence::State_01).
3. **Activate the new output**: The value of the corresponding input (DI_Sn.D1) is transferred to the output (DO_Sn.D1) (algorithm State_n_E).
4. **Output the confirmation event**: CNF is triggered.

From state 8, the event S8_START returns to the start state (xSTART). The event RESET can force an immediate return from any active state (1…8) to state sState_00 – setting all outputs to FALSE.

After a reset (RESET), the machine briefly enters state sRESET, which deactivates all outputs, and then immediately jumps to state sState_00.

Technical Features

- **Level-Controlled Transitions**: The transitions are triggered by the applied BOOL value of the respective input (not edge-triggered). This allows for easy recovery after a power failure, as the state can be directly detected and resumed upon power-up.
- **Use of AX Adapters**: The interfaces are implemented as unidirectional AX adapters, allowing for loose coupling and easy reuse of the inputs/outputs.
- **Configurable Constants**: The state numbers are derived from the constant sequence::State_nn in the package logiBUS::utils::sequence::const::sequence – this allows them to be defined and modified centrally.
- **Type Safety**: All outputs are explicitly set to FALSE when a state is exited and receive the value of the corresponding input when entering a new state. This prevents logic errors caused by hanging values.

State Overview

State (ECC)	State Number	Output Active	Transition Condition (to the Next State)
xSTART	0	–	DI_S1.D1 ⟶ sState_01DI_S2.D1 ⟶ sState_02… DI_S8.D1 ⟶ sState_08 otherwise ⟶ sState_00
sState_01	1	DO_S1	DI_S2.D1 ⟶ sState_02RESET ⟶ sState_00
sState_02	2	DO_S2	DI_S3.D1 ⟶ sState_03RESET ⟶ sState_00
sState_03	3	DO_S3	DI_S4.D1 ⟶ sState_04RESET ⟶ sState_00
sState_04	4	DO_S4	DI_S5.D1 ⟶ sState_05RESET ⟶ sState_00
sState_05	5	DO_S5	DI_S6.D1 ⟶ sState_06RESET ⟶ sState_00
sState_06	6	DO_S6	DI_S7.D1 ⟶ sState_07RESET ⟶ sState_00
sState_07	7	DO_S7	DI_S8.D1 ⟶ sState_08RESET ⟶ sState_00
sState_08	8	DO_S8	S8_START ⟶ xSTARTRESET ⟶ sState_00
sState_00	9	–	DI_S1.D1 ⟶ sState_01 (Sequence restart)

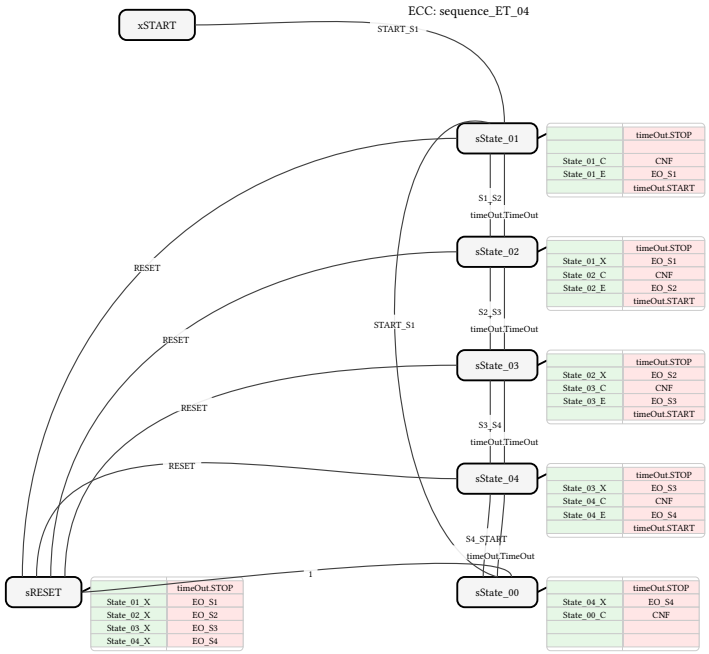
Note: The state sRESETThis function is used solely for clearing all outputs and exits automatically.

Application Scenarios

- **Sequence Control in Agricultural Machinery**: For example, the sequential switching on and off of eight hydraulic valves or lighting units.
- **Conveyor Belt Control**: Activation of belt sections sequentially, with transitions triggered by level sensors (BOOL).
- **Laboratory Automation**: Stepwise release of reagent dosing units, controlled by level signals from flow sensors.
- **End-of-Life Processes**: Since the state can be restored after a power failure using the input signals, this function block is suitable for safety-critical processes.

Comparison with Similar Function Blocks

- **Timer-Based Sequencers**: Transitions are triggered by time sequences rather than levels. In contrast, sequence_B_08_AX_AX reacts directly to external signals and is suitable for event-driven processes.

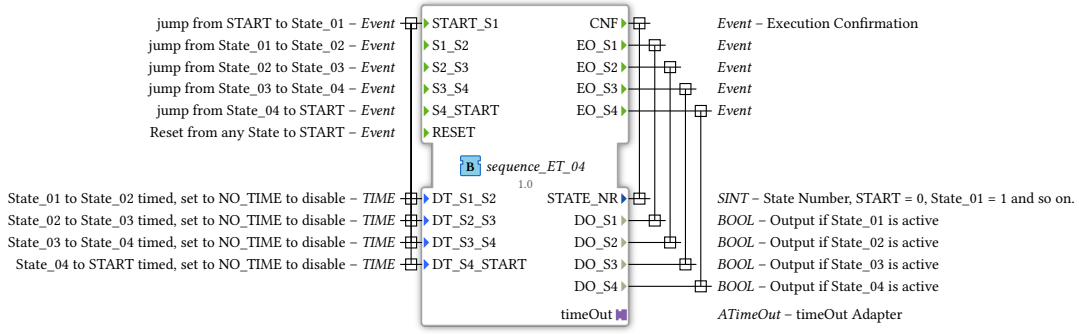


- **Edge-triggered sequencers**: These would only react to rising edges. In contrast, the function block presented here recognizes sustained levels, which improves its restart capability.
- **Adapterless blocks**: Many standard function blocks use simple BOOL inputs. The use of AX adapters achieves greater modularity and interchangeability of signal sources/sinks.

Conclusion

The `sequence_B_08_AX_AX` function block offers a robust and flexible way to implement an eight-stage sequence control with level-controlled transitions. The use of unidirectional AX adapters simplifies integration into complex automation systems, while explicit state management and reset behavior ensure high operational reliability. Thanks to its ability to recover after power outages, it is particularly suitable for applications in agricultural technology and industrial manufacturing.

combi



sequence_ET_04

• – ○ • – ○ • – ○ •

Introduction

The function block `sequence_ET_04` is a sequencer with four output states. It enables the control of a cyclic sequence of four steps (State_01 to State_04), where the transition between states can occur either through an external event or after an adjustable time. This function block is designed for applications where process steps must be executed sequentially with time-based or event-driven flexibility.

Interface Structure

Event Inputs

- **START_S1**: Transitions from START or State_00 to the first state, State_01. Transmits the time parameters for all state transitions (DT_S1_S2, DT_S2_S3, DT_S3_S4, DT_S4_START).
- **S1_S2**: Manual transition from State_01 to State_02.

S1_S2: Manual transition from State_01 to State_02. * **S2_S3**: Manual transition from State_02 to State_03.

- **S3_S4**: Manual transition from State_03 to State_04.
- **S4_START**: Manual transition from State_04 back to the START state (via State_00).
- **RESET**: Instantly resets the block from any state to the START state.

Event Outputs

- **CNF**: Execution confirmation. Triggered on every state change and returns the new state number (STATE_NR).
- **EO_S1**: Triggered upon entering State_01 and returns the output value DO_S1.
- **EO_S2**: Triggered upon entering State_02 and returns the output value DO_S2.
- **EO_S3**: Triggered upon entering State_03 and returns the output value DO_S3. * **EO_S4**: Triggered upon entering State_04 and returns the output value DO_S4.

Data Inputs

- **DT_S1_S2** (Type: TIME): Time for the automatic transition from State_01 to State_02. The value NO_TIME disables the time transition for this step.
- **DT_S2_S3** (Type: TIME): Time for the automatic transition from State_02 to State_03. The value NO_TIME disables the time transition for this step.
- **DT_S3_S4** (Type: TIME): Time for the automatic transition from State_03 to State_04. The value NO_TIME disables the time transition for this step.
- **DT_S4_START** (Type: TIME): Time for the automatic transition from State_04 back to the START state. The value NO_TIME disables the time transition for this step.

Data Outputs

- **STATE_NR** (Type: SINT): Current state number according to the constant sequence::State_XX (START = 0, State_01 = 1, State_02 = 2, State_03 = 3, State_04 = 4).

Data Outputs * DO_S1 (Type: BOOL): Is TRUE when State_01 is active

- **DO_S2** (Type: BOOL): Is TRUE when State_02 is active.
- **DO_S3** (Type: BOOL): Is TRUE when State_03 is active.
- **DO_S4** (Type: BOOL): Is TRUE when State_04 is active.

Adapter

- **timeOut** (Type: ATimeOut): A connector (Plug) for a timeout adapter. This adapter is used internally to implement timed state transitions.

Functionality

The module implements a finite state automaton (ECC) with the states START, State_01 to State_04, State_00, and RESET. The cycle begins in state START. An event START_S1 starts the sequence and transitions to State_01.

In each active state (State_01 to State_04), the following actions are executed:

1. The internal timer (timeOut) is stopped.
2. The output of the previous state is deactivated (Exit algorithm State_XX_X).
3. Confirmation CNF with the new state number is sent, and the time for the next possible automatic transition is passed to the timer (Confirmation algorithm State_XX_C).
4. The output of the current state is activated (Entry algorithm State_XX_E).
5. The internal timer is started with the time configured for this state (DT_...).

A state change can occur in two ways:

- **Event-driven**: Through the corresponding input event (e.g., S1_S2).
- **Time-controlled**: By a TimeOut event of the adapter, provided the time DT_... is not set to NO_TIME.

After State_04, the block switches to the State_00 state (from where the sequence can be restarted with START_S1) or directly back to the START state via RESET. A RESET event immediately deactivates all active outputs and returns the block to its initial state. ...

Technical Features

- **Hybrid Transitions**: Each state transition can be individually configured as purely event-driven, purely time-driven, or a combination of both. A time-driven transition takes precedence unless the time is NO_TIME.
- **Initial Values**: All time inputs (DT_...) are pre-set to NO_TIME by default, meaning that the sequence initially runs purely event-driven after startup.
- **Adapter Usage**: Time control is handled entirely via the coupled ATimeOut adapter, enabling a clear separation of functionality and potential reusability.
- **State Feedback**: The output STATE_NR provides a simple way to monitor or visualize the current step externally.

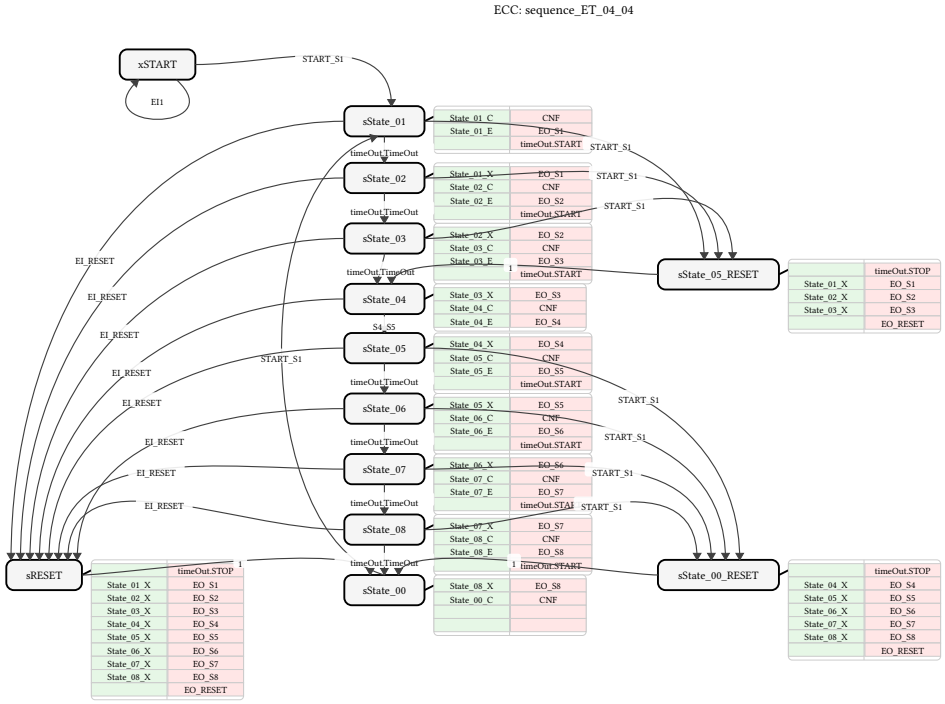
State Overview

1. **START**: Initial, inactive state. All outputs are FALSE.
2. **State_01**: First sequence step. DO_S1 is TRUE. Transition to State_02 via the S1_S2 event or after a certain time, DT_S1_S2.
3. **State_02**: Second sequence step. DO_S2 is TRUE. Transition to State_03 via the S2_S3 event or after a certain time, DT_S2_S3.
4. **State_03**: Third sequence step. DO_S3 becomes TRUE. Transition to State_04 via the S3_S4 event or after a certain time, DT_S3_S4.
5. **State_04**: Fourth sequence step. DO_S4 becomes TRUE. Transition to State_00 viaS4_START event or after a certain time, DT_S4_START.
6. **State_00**: Waiting state after sequence completion. All outputs are FALSE. A new sequence can be started from here with START_S1.
7. **sRESET**: Transition state for reset. Deactivates all outputs and automatically switches to State_00.

Application Scenarios

- **Batch Process Control**: Sequential activation of valves, pumps, or heaters in a chemical or process engineering process.
- **Automated Handling Devices**: Control of the individual steps of a pick-and-place robot (gripping, moving, positioning, and placing).
- **Packaging Machines**: Coordination of processes such as product feeding, packaging, labeling, and ejection.
- **Test Stands**: Automated sequence of testing and measurement steps on a component.

**Automated sequence of testing and measurement steps on a component.## ⚖️ Comparison with similar building blocks Unlike simple timer blocks (TON) or pure state machines (E_SR), sequence_ET_04 combines both in a single, specialized block. It offers a predefined, four-stage structure with dedicated outputs for each step, simplifying and improving the clarity of programming compared to manually linking multiple individual blocks. Blocks like E_CYCLE offer cyclic event triggering but lack individual, state-dependent data outputs or hybrid triggers.

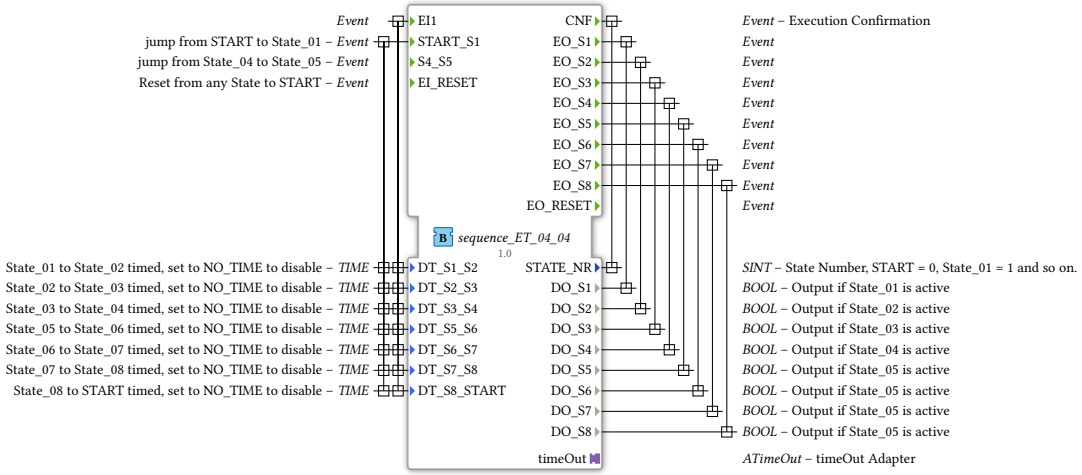


🛠️ Related Exercises

- Exercise_035
- Exercise_035b
- Exercise_035c
- Exercise_036

Conclusion

The sequence_ET_04 is a practical and flexible function block for all applications requiring a clear, cyclic sequence of steps. The combination of event-driven and time-controlled transitions, along with the clear interface featuring separate outputs for each state, makes it particularly easy to maintain and integrate into higher-level controllers. The use of a standard adapter for the timer function keeps the block lean and compatible.



sequence_ET_04_04

• — ○ • — ○ • — ○ •

Introduction

The `sequence_ET_04_04` function block is an 8-output sequencer used to control processes in automation technology. It implements a fixed sequence of states, with transitions between states triggered either by an external event or by an adjustable time interval. This block is particularly suitable for applications requiring cyclic or step-by-step activation of outputs.

Interface Structure

Event Inputs

- **`EI1`**: General input event. In the start state (`xSTART`), this triggers a self-transition (no state change).
- **`START_S1`**: Starts the sequence or jumps from states 1-3 back to state 4, or from states 5-8 back to the final state (`sState_00`). Triggers the transition from the start state (`xSTART`) or from the final state (`sState_00`) to the first active state (`sState_01`).

- **S4_S5**: Triggers the transition from state 4 (sState_04) to state 5 (sState_05). This is the only manual transition in the sequence.
- **EI_RESET**: Resets the sequence from any active state to the reset state (sRESET) and then to the final state (sState_00).

Event Outputs

- **CNF**: Execution Confirmation. Triggered on every state change, it returns the new state number (STATE_NR).
- **EO_S1 to EO_S8**: State events. These are triggered upon entering the corresponding state (State_01 to State_08) and provide the associated Boolean data output (DO_Sx).
- **EO_RESET**: Triggered upon passing through the reset state (sRESET).

Data Inputs

- **DT_S1_S2** (TIME): Time for the automatic transition from State_01 to State_02. Initial value: NO_TIME (disabled).
- **DT_S2_S3** (TIME): Time for the automatic transition from State_02 to State_03. Initial value: NO_TIME (disabled).
- **DT_S3_S4** (TIME): Time for the automatic transition from State_03 to State_04. Initial value: NO_TIME (disabled).
- **DT_S5_S6** (TIME): Time for the automatic transition from State_05 to State_06. Initial value: NO_TIME (disabled).
- **DT_S6_S7** (TIME): Time for the automatic transition from State_06 to State_07. Initial value: NO_TIME (disabled).
- **DT_S7_S8** (TIME): Time for the automatic transition from State_07 to State_08. Initial value: NO_TIME (disabled). * **DT_S8_START** (TIME): Time for the automatic transition from State_08 back to the final state (sState_00). Initial value: NO_TIME (disabled).

Data Outputs

- **STATE_NR** (SINT): Current state number. 0 = START/State_00, 1 = State_01, ..., 8 = State_08.
- **DO_S1 to DO_S8** (BOOL): Logical outputs indicating whether the corresponding state is active. The values are set to TRUE upon entering the state and to FALSE upon exiting.

Adapter

- **timeOut** (Plug, Type: iec61499::events::ATimeOut): Used to implement timed state transitions. The function block starts (START) and stops (STOP) the timer and sets the delay time (DT).

Functionality

The function block operates as a Basic Function Block (BFB) with an extended finite state machine (ECM). The sequence typically iterates through states 1 to 8 in a fixed order. The transition from state 4 to state 5 occurs exclusively via the external event S4_S5. All other transitions (1⟶2, 2⟶3, 3⟶4, 5⟶6, 6⟶7, 7⟶8, 8⟶End) can be time-controlled, provided the corresponding time (DT_...) is not set to NO_TIME.

Each active state (1-8) sets its associated Boolean output (DO_Sx) to TRUE and, if necessary, starts the timer for the next transition. Upon exiting the state, the output is reset to FALSE. With each state change, the confirmation event CNF is triggered with the new event STATE_NR.

The event START_S1 serves not only for the initial start but also for "jumping back" within the sequence: From states 1-3, it jumps back to state 4, and from states 5-8, back to the final state (sState_00). A EI_RESET terminates the sequence from any point, deactivates all outputs, and brings the function block to the consistent final state sState_00.

Technical Features

- **Hybrid Triggering**: Combination of event-driven and time-driven state transitions.
- **Flexible Time Control**: Each timed transition can be individually configured by setting the DT_... inputs or deactivated by setting the value NO_TIME.
- **Safe Reset**: The reset operation (EI_RESET) safely stops all running timers and resets all internal outputs.
- **State Return**: The START_S1 event enables specific returns to the sequence, supporting complex control patterns.

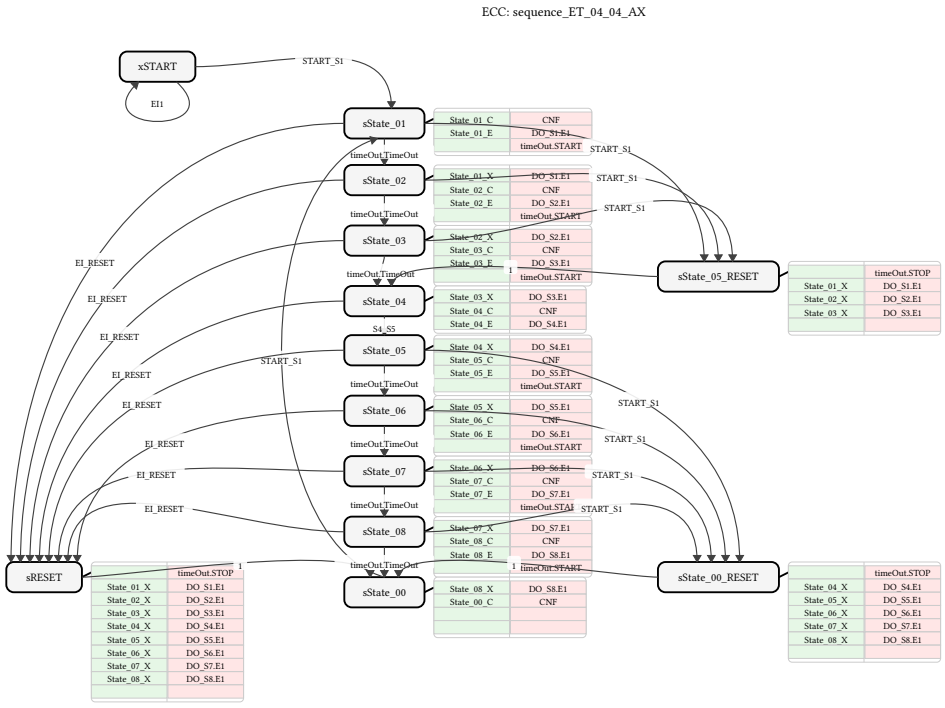
State Overview

The ECC includes the following states:

- **`xSTART`**: Initial, inactive state.
- **`sState_01` to `sState_08`**: Active operating states of the sequence.
- **`sState_00`**: Inactive end state after completion of the sequence.
- **`sRESET`**: Reset state that can be accessed from any active state.
- **`sState_05_RESET` / `sState_00_RESET`**: Intermediate states for the special return actions via `START_S1`.

Application Scenarios

- **Batch Process Control**: Step-by-step activation of valves, pumps, or heaters in a chemical process.
- **Linked Machine Sequences**: Control of individual steps in an assembly or packaging line.
- **Test Stands**: Automated, cyclical test sequences with configurable waiting times between test steps.
- **Safety Sequences**: Ordered start-up and shutdown of a system.

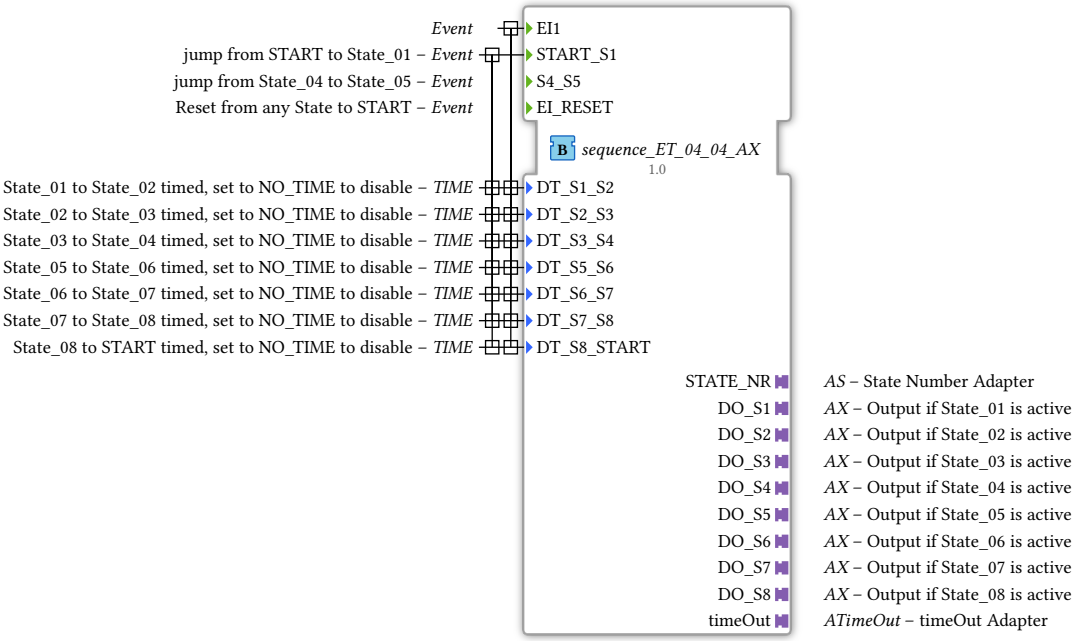


⚖️ Comparison with Similar Function Blocks

Compared to simple timers (e.g., `TON`) or counters (e.g., `CTU`), this function block offers predefined, complex state logic with multiple outputs. Compared to generic step sequence function blocks (SFCs), it is less flexible but more specific, easier to configure, and offers integrated reset and jump functions. It represents a specialized solution for 8-step processes.

Conclusion

The `sequence_ET_04_04`This is a robust and practical sequencer for standard automation tasks with up to eight steps. The combination of time and event control, along with integrated safety and reset functions, makes it a reliable component for repetitive control processes. Its strength lies in its clear structure and simple parameterization of state transitions.



sequence_ET_04_04_AX

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_ET_04_04_AX` is the adapter-based version of `sequence_ET_04_04`. It implements an 8-stage sequence control, where the outputs are controlled via `AX` adapters (event + data) instead of simple BOOL variables. Transitions can be event-driven or time-controlled.

Interface Structure

Event Inputs

- **`EI1`**: General input event.
- **`START_S1`**: Starts the sequence or jumps back within the phases.
- **`S4_S5`**: Manual transition from state 4 to 5.
- **`EI_RESET`**: Global reset of the sequence.

Event Outputs

- **`CNF`**: Execution confirmation with current `STATE_NR`.
- *(Note: The state-specific events EO_Sx are omitted here, as they are included in the adapters)*

Data Inputs

- **`DT_S1_S2`** to **`DT_S8_START`** (TIME): Time delays for automatic transitions.

Data Outputs

- **`STATE_NR`** (SINT): Current state number (0-8).

Adapters

- **`DO_S1` to `DO_S8`** (Plug, Type: `adapter::types::unidirectional::AX`): Adapter outputs for states 1 to 8. Each entry into or exit from a state triggers the event `E1` on the corresponding adapter and sets `D1` to `TRUE` or `FALSE`, respectively.
- **`timeOut`** (Plug, Type: `iec61499::events::ATimeOut`): Interface to the external timer.

Functionality

The logic is exactly the same as `sequence_ET_04_04`. The crucial difference lies in the physical encapsulation of the outputs. While the standard version uses separate event and data lines, the `_AX` version combines these into adapter connections. This reduces complexity in the graphical editor for extensive circuits.

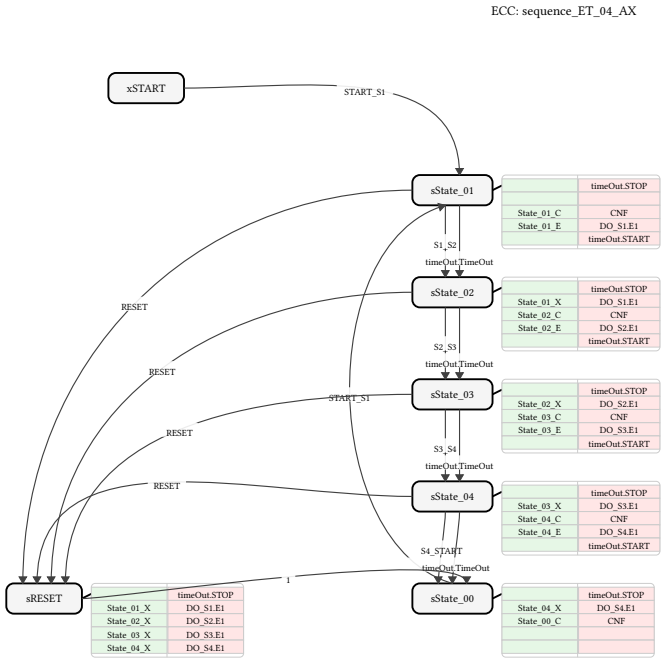
Technical Features

✓ **Adapter Outputs**: Uses the `AX` adapter for all 8 states.

✓ **Combined Triggers**: Events and time sequences control the chain.
✓ **State Feedback**: Continuous output of the `STATE_NR`.

State Overview

See `sequence_ET_04_04`.

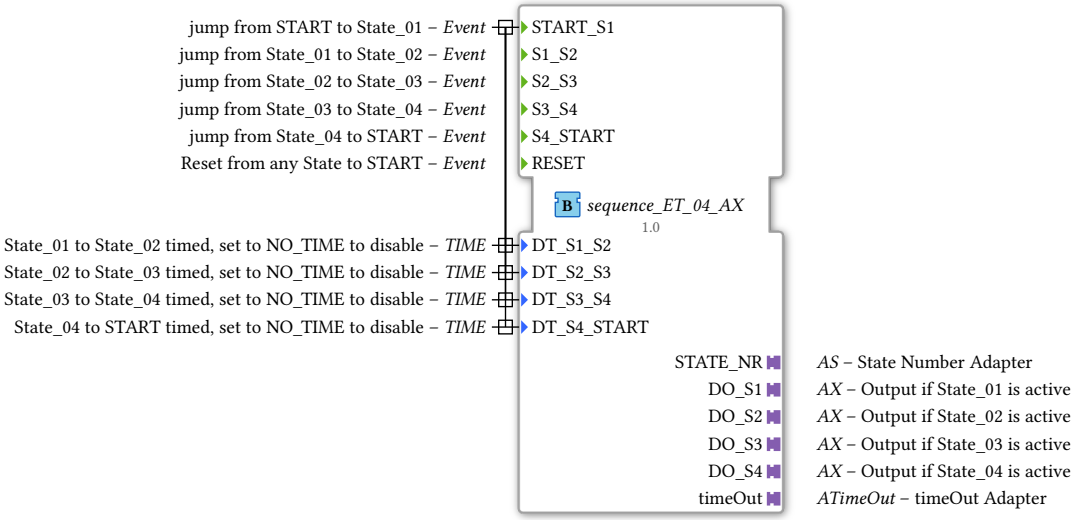


⚖️ Comparison with Similar Function Blocks

- **sequence_ET_04_04**: The version with classic BOOL outputs and EO events.

Conclusion

sequence_ET_04_04_AX` is the ideal choice for complex 8-step controls in systems that consistently rely on adapter-based communication.



sequence_ET_04_AX

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_ET_04_AX` is a variant of `sequence_ET_04`, which additionally uses adapters (`AX`) for the outputs. It controls a sequence with 4 output states, where transitions can be event-driven or time-controlled.

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence at State_01.
- **S1_S2**: Manual transition State_01 -> State_02.
- **S2_S3**: Manual transition State_02 -> State_03.
- **S3_S4**: Manual transition State_03 -> State_04.
- **S4_START**: Manual transition State_04 -> START.
- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Confirmation of execution with current state number.

Data Inputs

- **DT_S1_S2**: Time for transition State_01 -> State_02.
- **DT_S2_S3**: Time for transition State_02 -> State_03.
- **DT_S3_S4**: Time for transition State_03 -> State_04.
- **DT_S4_START**: Time for transition State_04 -> START.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** (adapter::types::unidirectional::AX): Output adapter for State_01.
- **DO_S2** (adapter::types::unidirectional::AX): Output adapter for State_02.
- **DO_S3** (adapter::types::unidirectional::AX): Output adapter for State_03.
- **DO_S4** (adapter::types::unidirectional::AX): Output adapter for State_04.
- **timeOut** (iec61499::events::ATimeOut): Timer adapter.

Functionality

The functionality is essentially the same as `sequence_ET_04`, however, the outputs `DO_S1` to `DO_S4` are not set as simple BOOL variables, but via adapters. This allows for more flexible integration in more complex systems.

Technical Features

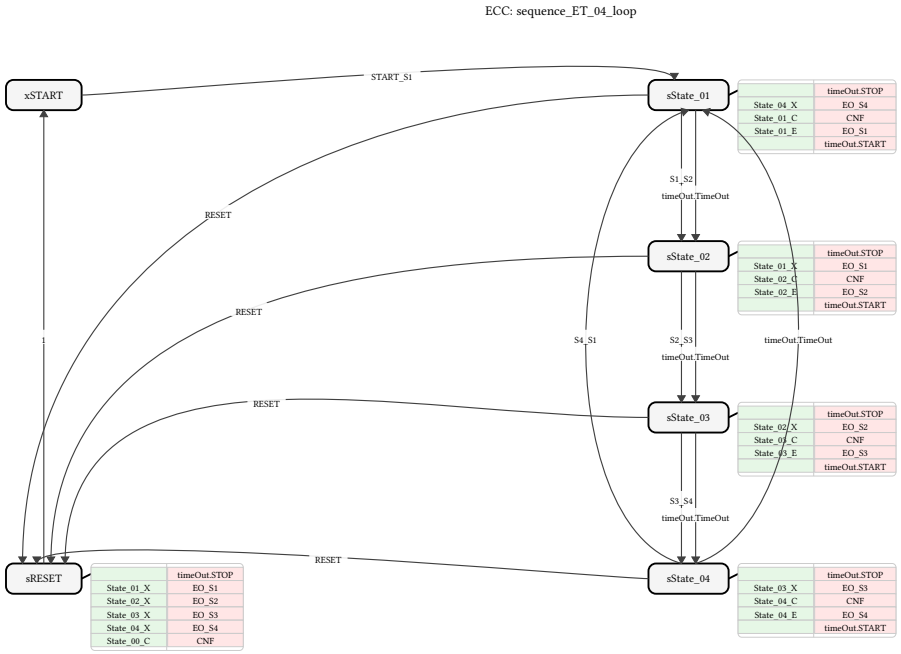
- Uses `adapter::types::unidirectional::AX` for the outputs.

Status Overview

See `sequence_ET_04`.

Application Scenarios

Similar to `sequence_ET_04`, but preferred when adapter connections are to be used.

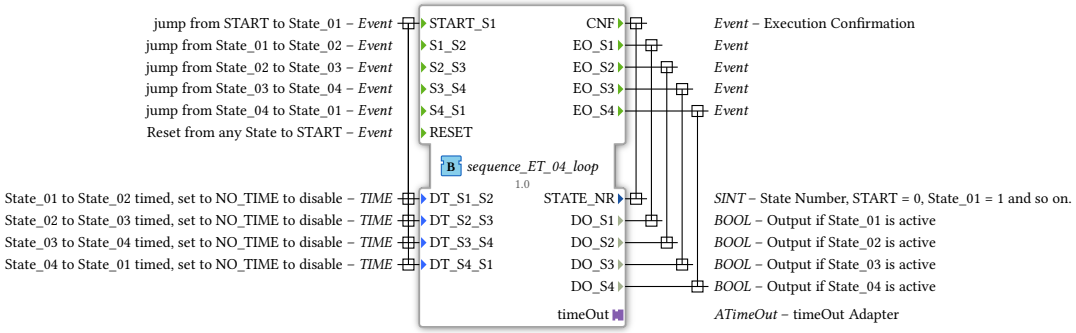


⚖️ Comparison with Similar Function Blocks

- **sequence_ET_04**: The standard version with simple BOOL outputs.

Conclusion

sequence_ET_04_AXoffers the functionality ofsequence_ET_04` with a more modern adapter interface.



sequence_ET_04_loop

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_ET_04_loop` implements a cyclic sequence with four states. The transition between states can occur either through an external event or after a configurable time has elapsed. The block is designed to implement recurring processes in control applications where actions must be executed sequentially in a loop.

Interface Structure

Event Inputs

- `START_S1`: Starts the sequence and transitions from state `START` to state `State_01`. Transmits the four time parameters `DT_S1_S2`, `DT_S2_S3`, `DT_S3_S4`, and `DT_S4_S1`.
- `S1_S2`: Triggers the transition from `State_01` to `State_02`.
- `S2_S3`: Triggers the transition from `State_02` to `State_03`.
- `S3_S4`: Triggers the transition from `State_03` to `State_04`.
- `S4_S1`: Triggers the transition from `State_04` back to `State_01` (loop).
- `RESET`: Resets the sequence from any state back to the `START` state.

Event Outputs

- `CNF`: Acknowledge event that is triggered on every state change (including reset). Transmits the current state number `STATE_NR`.
- `EO_S1`: Triggered upon entering `State_01`. Transmits the output value `DO_S1`.
- `EO_S2`: Triggered upon entering `State_02`. Transmits the output value `DO_S2`.
- `EO_S3`: Triggered upon entering `State_03`. Transmits the output value `DO_S3`.
- `EO_S4`: Triggered upon entering `State_04`. Transmits the output value `DO_S4`.
- – ...

Data Inputs

- `DT_S1_S2` (TIME): Time for the automatic transition from `State_01` to `State_02`. A value of `NO_TIME` disables the time transition.
- `DT_S2_S3` (TIME): Time for the automatic transition from `State_02` to `State_03`. A value of `NO_TIME` disables the time transition.
- `DT_S3_S4` (TIME): Time for the automatic transition from `State_03` to `State_04`. The value `NO_TIME` disables the time transition.
- `DT_S4_S1` (TIME): Time for the automatic transition from `State_04` back to `State_01`. The value `NO_TIME` disables the time transition.

Data Outputs

- `STATE_NR` (SINT): Current state number (`0`=START, `1`=State_01, `2`=State_02, `3`=State_03, `4`=State_04).
- `DO_S1` (BOOL): Is `TRUE` when `State_01` is active. ... * `DO_S2` (BOOL): Is `TRUE` when `State_02` is active.
- `DO_S3` (BOOL): Is `TRUE` when `State_03` is active.
- `DO_S4` (BOOL): Is `TRUE` when `State_04` is active.

Adapter

- `timeOut` (Plug, Type: `iec61499::events::ATimeOut`): Used internally for implementing timed state transitions.

Functionality

The function block (FB) operates as a BASIC FB with a finite state machine (ECC). The sequence iterates through the states `State_01` -> `State_02` -> `State_03` -> `State_04` and then jumps back to `State_01`. Each state has three main actions:

1. **Exit Action (X)**: Sets the corresponding Boolean output (`DO_Sx`) to `FALSE`.
2. **Confirmation Action (C)**: Sets the state number (`STATE_NR`) and configures the `timeOut` adapter with the time scheduled for the next transition (`DT_...`). Triggers the `CNF` event.
3. **Entry Action (E)**: Sets the associated Boolean output (`DO_Sx`) to `TRUE` and triggers the corresponding output event (`EO_Sx`).

A state transition can occur in two ways:

1. **By Event**: Through the corresponding input event (e.g., `S1_S2`).
2. **By Time**: After the time set in the current state in the `timeOut` adapter has elapsed, unless this is `NO_TIME`.

The `RESET` input always leads to the special `sRESET` state, which switches off all active outputs, sets the state number to 0, and then returns to the `START` state.

Technical Features

- **Hybrid Triggering**: Each state transition can be individually configured to be either event-driven or time-driven. This allows for maximum flexibility within a sequence.
- **Initial Values**: The time parameters are initialized to `NO_TIME` by default, meaning that all time-driven transitions are initially disabled and await an external event.
- **Adapter Usage**: Time control is consistently handled via the standardized `ATimeOut` adapter, increasing reusability and clarity.
- **Status Feedback**: The current position in the sequence is always visible externally via the `STATE_NR` output.

State Overview

The ECC consists of six states:

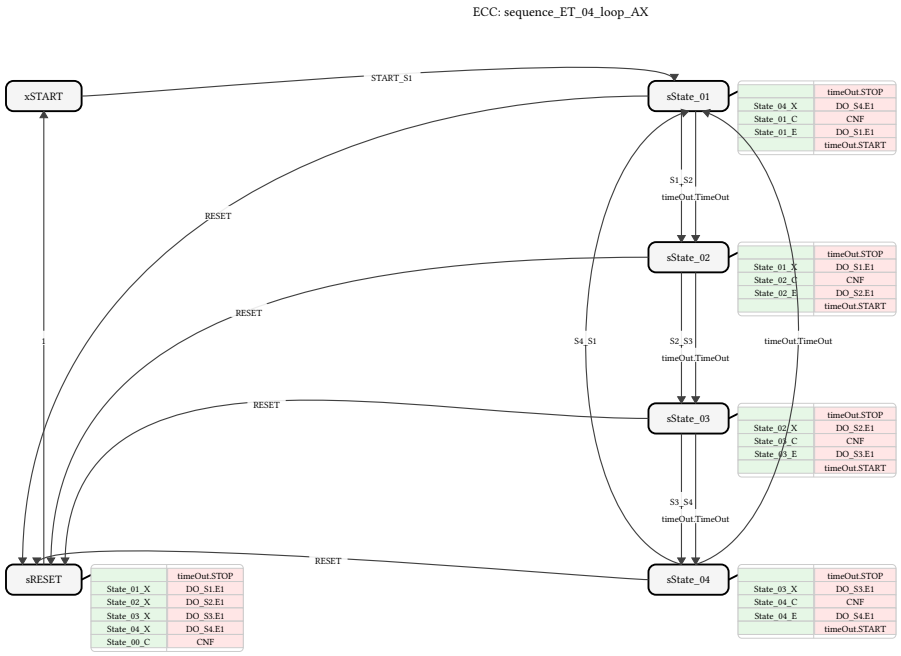
1. **xSTART**: Initial, inactive state. Waits for `START_S1`.
2. **sState_01**: Active state
3. Sets `DO_S1`. Can switch to `sState_02` via a `S1_S2` event or timeout.
4. **sState_02**: Active State
5. Sets `DO_S2`. Can transition to `sState_03` via the `S2_S3` event or timeout.
6. **sState_03**: Active State
7. Sets `DO_S3`. Can transition to `sState_04` via the `S3_S4` event or timeout.
8. **sState_04**: Active State
9. Sets `DO_S4`. Can transition back to `sState_01` via the `S4_S1` event or timeout (loop).
10. **sRESET**: Reset state. Switches off all outputs, sets `STATE_NR` to 0, and automatically switches back to `xSTART`.

Application Scenarios

- **Cyclical Process Control**: Control of machines that perform a repeating work cycle with multiple steps (e.g., filling, heating, mixing, emptying).
- **Traffic Light Circuits**: Modeling a simple, multi-phase traffic light system where each phase can last a fixed time or be terminated prematurely.
- **Batch Processes**: Processing batch processes where individual steps are terminated either by sensors (events) or after a minimum time.

⚖️ Comparison with Similar Function Blocks

Unlike simple timer blocks or flip-flops, this function block orchestrates a complete, state-based sequence. Compared to a `E_CYCLE`The `sequence_ET_04_loop` block offers explicit state logic with clear transition conditions and the ability to trigger each step individually. It is more specialized and structured than a custom-programmed sequence of `E_SR` and `E_DELAY` blocks.

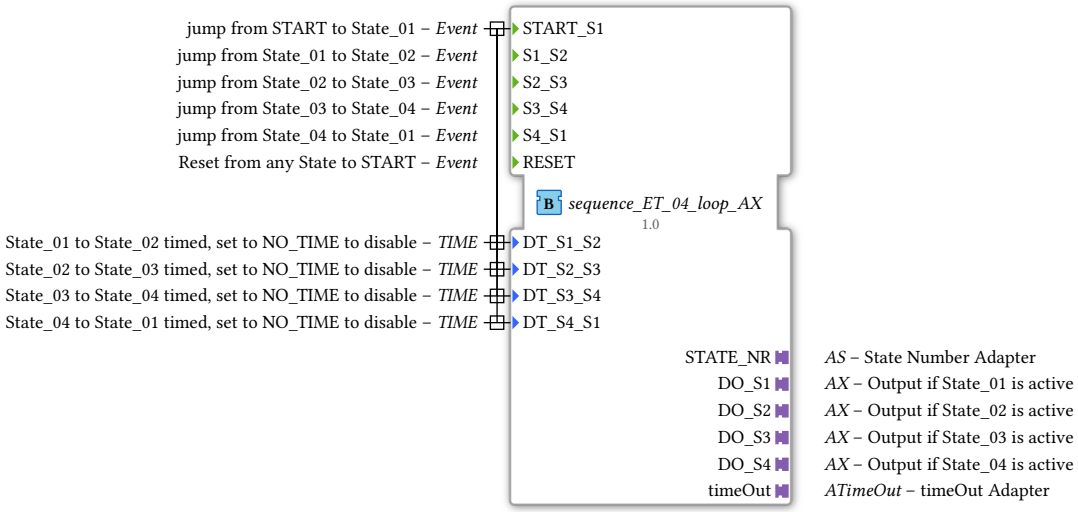


🛠️ Related Exercises

- Exercise_037

Conclusion

The `sequence_ET_04_loop` block is a robust and flexible building block for implementing cyclic 4-step sequences. Its strength lies in its hybrid triggering, which allows you to choose between event-driven and time-based triggering for each step. The clear state machine, the feedback of the current state, and the integrated reset make it a reliable component for recurring control tasks in automation technology.



sequence_ET_04_loop_AX

• — ○ • — ○ • — ○ •

Introduction

sequence_ET_04_loop_AXis a variant ofsequence_ET_04_loop that additionally uses adapters (AX`) for the outputs. It controls a cyclic sequence with 4 output states.

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence at State_01.
- **S1_S2**: Manual transition State_01 -> State_02.
- **S2_S3**: Manual transition State_02 -> State_03.
- **S3_S4**: Manual transition State_03 -> State_04.
- **S4_S1**: Manual transition State_04 -> State_01 (Loop).
- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Confirmation of execution.

Data Inputs

- **DT_S1_S2**: Time for transition State_01 -> State_02.
- **DT_S2_S3**: Time for transition State_02 -> State_03.
- **DT_S3_S4**: Time for transition State_03 -> State_04.
- **DT_S4_S1**: Time for transition State_04 -> State_01.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** (adapter::types::unidirectional::AX): Output adapter for State_01.
- **DO_S2** (adapter::types::unidirectional::AX): Output adapter for State_02.
- **DO_S3** (adapter::types::unidirectional::AX): Output adapter for State_03.
- **DO_S4** (adapter::types::unidirectional::AX): Output adapter for State_04.
- **timeOut** (iec61499::events::ATimeOut): Timer adapter.

Functionality

Corresponds to `sequence_ET_04_loop`, but uses adapters for the outputs.

Technical Features

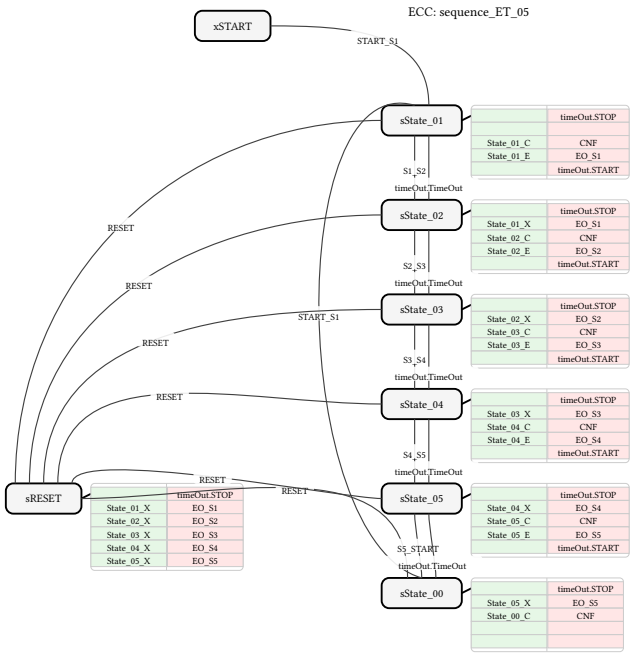
- Uses `adapter::types::unidirectional::AX`.

Status Overview

See `sequence_ET_04_loop`.

Application Scenarios

For cyclic processes that are to be controlled via adapters.

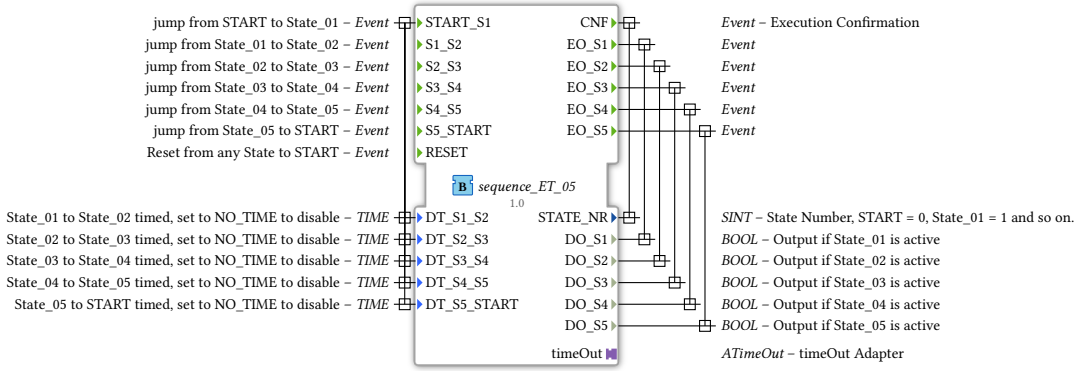


⚖️ Comparison with Similar Function Blocks

- **sequence_ET_04_loop**: Standard version without adapters.

Conclusion

Adapter version of the 4-step loop sequencer.



sequence_ET_05

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_ET_05` implements sequential control with five defined states (State_01 to State_05) and a start state (START). The transition between states can occur either through an external event or after an adjustable time. The block is designed for applications that require a step-by-step sequence of actions with flexible transition conditions.

Interface Structure

Event Inputs

- **`START_S1`**: Switches from the START state or State_00 to the State_01 state. Transmits the time parameters for all state transitions.
- **`S1_S2`**: Manual transition from State_01 to State_02.
- **`S2_S3`**: Manual transition from State_02 to State_03.
- **`S3_S4`**: Manual transition from State_03 to State_04.
- **`S4_S5`**: Manual transition from State_04 to State_05.
- **`S5_START`**: Manual transition from State_05 back to State_00 (representing START).
- **`RESET`**: Instantly returns to State_00 (START) from any state and disables all outputs.

Event Outputs

- **CNF**: Execution confirmation. Triggered on every state change and returns the new state number (STATE_NR).
- **EO_S1**: Triggered upon entering State_01 and returns the active output DO_S1.
- **EO_S2**: Triggered upon entering State_02 and returns the active output DO_S2.
- **EO_S3**: Triggered upon entering State_03 and returns the active output DO_S3.
- **EO_S4**: Triggered upon entering State_04 and provides the active output DO_S4.
- **EO_S5**: Triggered upon entering State_05 and provides the active output DO_S5.

Data Inputs

- **DT_S1_S2** (TIME): Dwell time in State_01 before automatic transition to State_02. Initial value: NO_TIME (disabled).
- **DT_S2_S3** (TIME): Dwell time in State_02 before automatic transition to State_03. Initial value: NO_TIME (disabled).
- **DT_S3_S4** (TIME): Time spent in State_03 before automatic transition to State_04. Initial value: NO_TIME (disabled).
- **DT_S4_S5** (TIME): Time spent in State_04 before automatic transition to State_05. Initial value: NO_TIME (disabled).
- **DT_S5_START** (TIME): Time spent in State_05 before automatic transition back to State_00 (START). Initial value: NO_TIME (disabled).

Data Outputs

- **STATE_NR** (SINT): Current state number (START = 0, State_01 = 1, ..., State_05 = 5).
- **DO_S1** (BOOL): Is TRUE when State_01 is active.
- **DO_S2** (BOOL): Is TRUE when State_02 is active.
- **DO_S3** (BOOL): Is TRUE when State_03 is active.
- – **DO_S4** (BOOL): Is TRUE when State_04 is active.
- **DO_S5** (BOOL): Is TRUE when State_05 is active.

Adapter

- **timeOut** (Plug, Type: iec61499::events::ATimeOut): Used internally for timed state transitions. The function block starts and stops the timer and sets its runtime (DT).

Functionality

The function block operates as a Basic function block with an Execution Control Chart (ECC). The initial state is xSTART. Upon a START_S1 event, the function block (FB) transitions to state sState_01. In each active state (sState_01 to sState_05), the following actions are performed:

1. The timeOut adapter is stopped.
2. The output of the previous state is deactivated (exit algorithm X).
3. The state number STATE_NR is updated, and the dwell time for the *next* transition is passed to the timer (confirmation algorithm C). The CNF event is then triggered.
4. The output of the previous state is deactivated (exit algorithm X). 4. The output of the current state is activated (entry algorithm E). The corresponding EO_Sx event is triggered.
5. The timeOut adapter with the previously set time is started.

A state change can now occur in two ways:

1. **Event-driven:** Through the corresponding manual event (e.g., S1_S2).
2. **Time-driven:** Through the adapter's timeOut.TimeOut event, provided the time (DT_Sx_Sy) is not set to NO_TIME.

The RESET event always leads to the special state sRESET, in which all outputs are deactivated, and from there immediately to the state sState_00 (representing the logical START state with STATE_NR = 0).

Technical Features

- **Flexible Transitions:** Each state transition can be configured independently as event-driven or time-driven. Time-driven control is deactivated by setting the corresponding DT_ input to the constant NO_TIME.

- **Immediate Reset:** The `RESET` input always has priority and immediately interrupts the current sequence.
- **Clearly Defined Interface:** The status number and active outputs are always available as data outputs and are confirmed by an event at each step.
- **Adapter-Based Time Control:** The use of a standardized TimeOut adapter makes the internal time management robust and reusable.

State Overview

The ECC includes the following states:

- **xSTART:** Initial idle state.
- **sState_01 ... sState_05:** The five sequential operating states.
- **sState_00:** Represents the logical START state after completion of the sequence or after a reset. No output is active in this state.
- **sRESET:** Intermediate state for deactivating all outputs during a reset operation.

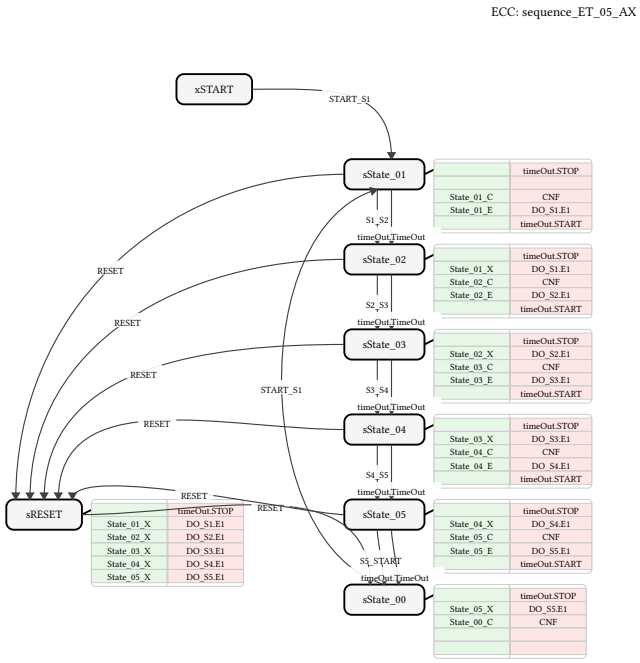
Application Scenarios

- **Batch Process Control:** Step-by-step processing of recipes in mixing or filling systems, where each step is manually acknowledged or automatically advances after a defined time.
- **Linked Machine Sequences:** Control of a machine whose cycle consists of several sequentially performed actions (e.g., loading, processing, inspection, ejection).
- **Test Sequences:** Automated test benches that perform a series of tests sequentially, where each test has a fixed duration or can be manually confirmed.

⚖️ Comparison with Similar Components

Compared to simple timer chains or counters, `sequence_ET_05` offers a fully encapsulated state machine with clear input/output events and the flexible combination of time and event control. Compared to a genericThe `E_SR` or `E_CTUD` function block, when used in an ad-hoc configuration, provides a predefined, tested, and easily configurable solution for a common control task.

🛠️ Related Exercises



- Exercise_039
- Exercise_039a

The `sequence_ET_05` is a well-structured and flexible function block for implementing 5-step sequences. The clear separation of control flow (events) and parameters (times), as well as the option to configure each transition either manually or automatically, makes it suitable for a wide variety of control tasks in automation technology. The use of standardized adapters and comprehensive interface documentation facilitate integration into larger applications.

- **DO_S4** (adapter::types::unidirectional::AX): Output adapter for State_04.
- **DO_S5** (adapter::types::unidirectional::AX): Output adapter for State_05.
- **timeOut** (iec61499::events::ATimeOut): Timer adapter.

Functionality

Corresponds to `sequence_ET_05`, but uses adapters for the outputs.

Technical Features

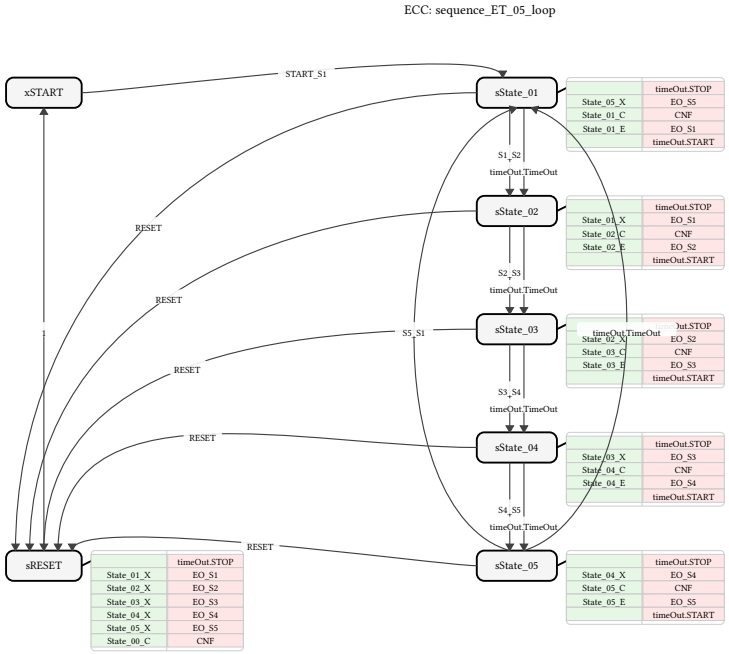
- Uses `adapter::types::unidirectional::AX`.

Status Overview

See `sequence_ET_05`.

Application Scenarios

For 5-step sequences with adapter connection.

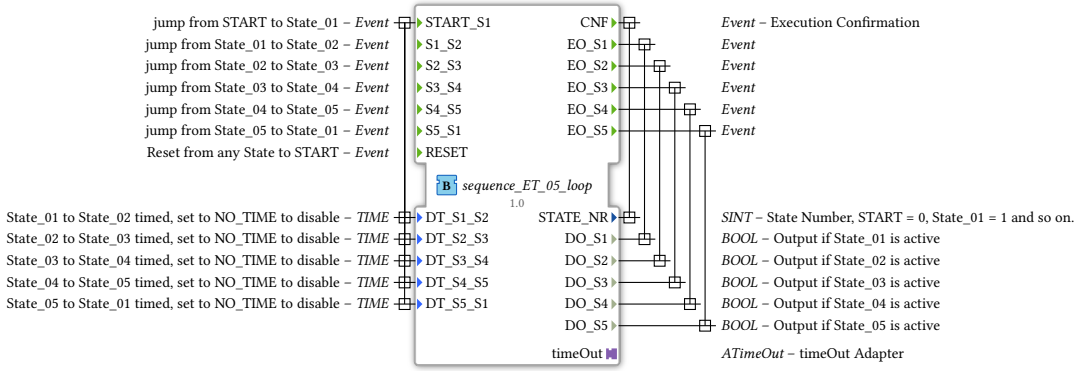


⚖️ Comparison with Similar Function Blocks

- **sequence_ET_05**: Standard version without adapter.

Conclusion

Adapter version of the 5-step sequencer.



sequence_ET_05_loop

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_ET_05_loop` implements a cyclic sequence with five states. The transition between the individual states can occur either through an external event or after a configurable time has elapsed. This block is designed for applications where a process must be executed step by step, triggering various actions in a fixed sequence, such as in packaging machines, assembly processes, or washing programs.

Interface Structure

Event Inputs

- **`START_S1`**: Starts the sequence and executes the transition from the start state (`START`) to the first state (`State_01`). Transmits the time values for all time-controlled transitions.
- **`S1_S2`**: Triggers the transition from `State_01` to `State_02`.
- **`S2_S3`**: Triggers the transition from `State_02` to `State_03`.
- **`S3_S4`**: Triggers the transition from `State_03` to `State_04`.
- **`S4_S5`**: Triggers the transition from `State_04` to `State_05`.
- **`S5_S1`**: Triggers the transition from `State_05` back to `State_01` (cycle).
- **`RESET`**: Resets the sequence from any state back to the start state (`START`).

Event Outputs

- **CNF**: Acknowledge event triggered on every state change. Transmits the current state number (STATE_NR).
- **EO_S1**: Triggered upon entering State_01. Transmits the output value DO_S1.
- **EO_S2**: Triggered upon entering State_02. Transmits the output value DO_S2.
- **EO_S3**: Triggered upon entering State_03. Transmits the output value DO_S3.
- **EO_S4**: Triggered upon entering State_04. Transmits the output value DO_S4.
- **EO_S5**: Triggered upon entering State_05. Transmits the output value DO_S5.

Data Inputs

- **DT_S1_S2** (Type: TIME, Initial value: NO_TIME): Time for the automatic transition from State_01 to State_02. The timed transition is disabled at NO_TIME.
- **DT_S2_S3** (Type: TIME, Initial value: NO_TIME): Time for the automatic transition from State_02 to State_03.
- **DT_S3_S4** (Type: TIME, Initial value: NO_TIME): Time for the automatic transition from State_03 to State_04.
- **DT_S4_S5** (Type: TIME, Initial value: NO_TIME): Time for the automatic transition from State_04 to State_05.
- **DT_S5_S1** (Type: TIME, Initial value: NO_TIME): Time for the automatic transition from State_05 to State_01.

Data Outputs

- **STATE_NR** (Type: SINT): Outputs the number of the current state (START = 0, State_01 = 1, ..., State_05 = 5).
- **DO_S1** (Type: BOOL): Is TRUE when State_01 is active.
- **DO_S2** (Type: BOOL): Is TRUE when State_02 is active.
- **DO_S3** (Type: BOOL): Is TRUE when State_03 is active.
- **DO_S4** (Type: BOOL): Is TRUE when State_04 is active.
- **DO_S5** (Type: BOOL): Is TRUE when State_05 is active.

Adapter

- **timeOut** (Type: ATimeOut): A plug-in adapter for implementing timed state transitions. The function block (FB) uses the interfaces START, STOP, and DT (time value), as well as the event TimeOut.

Functionality

The FB is implemented as a Basic FB with an Execution Control Chart (ECC). The sequence begins in state xSTART. The event START_S1 activates the first state, sState_01. The following actions are executed upon each state entry:

1. The timer adapter is stopped (timeOut.STOP).
2. The output of the previous state is reset (e.g., State_05_X for DO_S5).
3. The state number STATE_NR is updated, and the timer for the next transition is configured (e.g., State_01_C).
4. The output of the new state is set (e.g., State_01_E for DO_S1).
5. The timer adapter is started with the time configured for this transition (timeOut.START).

A state change can now occur in two ways:

- **Event-driven:** Through the corresponding input event (e.g., S1_S2).
- **Time-Controlled:** Triggered by the adapter's TimeOut event, provided the time (DT_...) is not set to NO_TIME.

The sequence cycles through states 1 to 5 and then jumps from State_05 back to State_01, creating an endless cycle. The RESET event triggers the reset state sRESET, regardless of the current state, from where the sequence automatically returns to the xSTART state.

Technical Features

- **Hybrid Triggering:** Each state transition can be individually configured to be either event-driven or time-controlled. This allows for maximum flexibility within a fixed sequence.
- **Safe State Outputs:** The Boolean outputs (DO_Sx) are explicitly reset via an exit algorithm (State_XX_X) when a state is exited. This prevents the unintentional persistence of the TRUE signal.

- **Explicit Timer Control:** The timer is restarted and stopped with each state change, ensuring precise and deterministic timing.
- **Constants:** The function block uses defined constants (`sequence::State_XX`, `NO_TIME`) from imported libraries, which improves the maintainability and readability of the code.
-

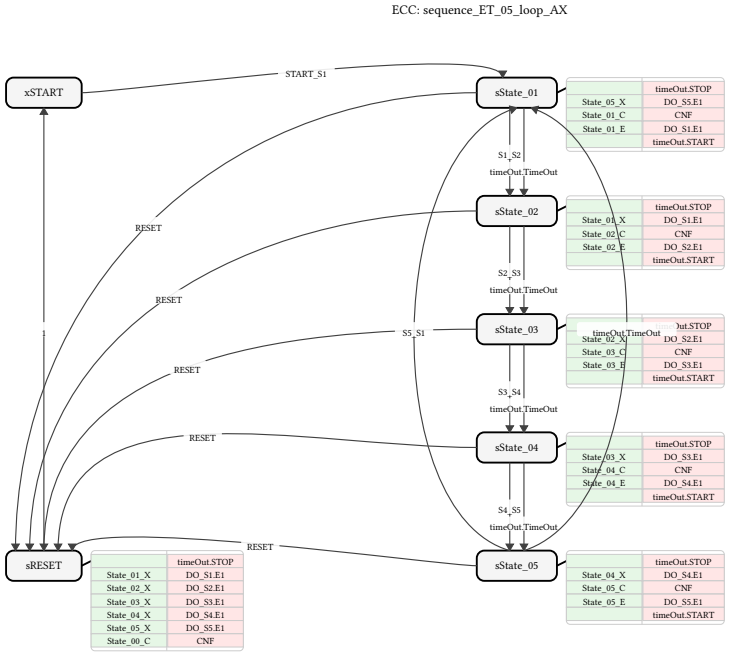
State Overview

The ECC consists of seven states:

1. **`xSTART`**: Inactive initial state.
2. **`sState_01`** to **`sState_05`**: The five active sequence states.
3. **`sRESET`**: Intermediate state that resets all outputs on reset and confirms the `xSTART`-State sends.

Application Scenarios

- **Control of Cyclic Processes:** Automated machining centers (e.g., multi-tool lathes) where each step takes a specific amount of time or is completed by a sensor event.
- **Batch Processes:** Batch processing in the food or pharmaceutical industries, where mixing, heating, and filling occur sequentially.
- **Safety Sequences:** Monitored start or stop procedures where each step is manually enabled (`EVENT`) or continues automatically after a waiting period (`TIME`).
- **Test Stands:** Automated testing sequences where various measurements or functional tests are performed sequentially.

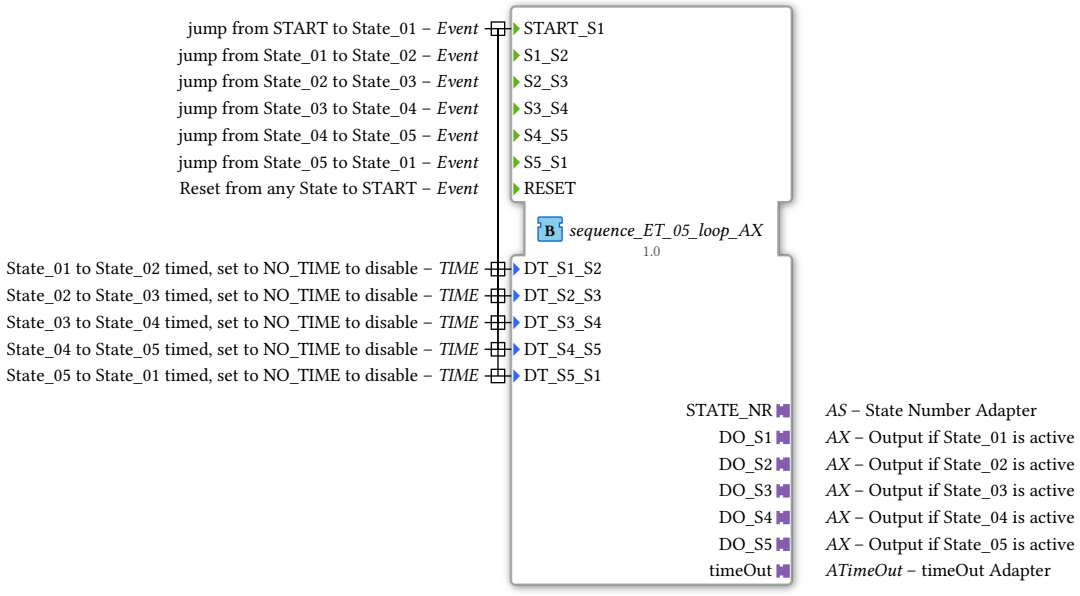


⚖️ Comparison with Similar Function Blocks

Compared to simple timer function blocks or self-holding relay cascades, `sequence_ET_05_loop` offers a predefined, cyclic structure with integrated time and event control. Compared to programming with individual blocks (e.g., `E_SR`, `E_DELAY`), it reduces wiring effort and improves clarity. Other sequencer function blocks may have a variable number of steps or different transition logic (time only OR event only). This function block is distinguished by its combined `EVENT`/`TIME` triggering per step.

Conclusion

The `sequence_ET_05_loop` is a robust and clearly structured function block for implementing cyclic 5-step sequences. The combination of event-driven and time-controlled transitions makes it extremely flexible for a wide variety of automation tasks. Explicit control of the outputs and the timer ensures deterministic and reliable behavior. It is ideally suited for efficiently and clearly mapping recurring process flows with a fixed number of steps in an IEC 61499-based controller.



sequence_ET_05_loop_AX

• — ○ • — ○ • — ○ •

Introduction

sequence_ET_05_loop_AXis a variant ofsequence_ET_05_loop that additionally uses adapters (AX`) for the outputs. It controls a cyclic sequence with 5 output states.

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence at State_01.
- **S1_S2**: Manual transition State_01 -> State_02.
- **S2_S3**: Manual transition State_02 -> State_03.
- **S3_S4**: Manual transition State_03 -> State_04.

- **S4_S5**: Manual transition State_04 -> State_05.
- **S5_S1**: Manual transition State_05 -> State_01 (loop).
- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Acknowledges execution.

Data Inputs

- **DT_S1_S2**: Time for transition State_01 -> State_02.
- **DT_S2_S3**: Time for transition State_02 -> State_03.
- **DT_S3_S4**: Time for transition State_03 -> State_04.
- **DT_S4_S5**: Time for transition State_04 -> State_05.
- **DT_S5_S1**: Transition time from State_05 to State_01.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** (adapter::types::unidirectional::AX): Output adapter for State_01.
- **DO_S2** (adapter::types::unidirectional::AX): Output adapter for State_02.
- **DO_S3** (adapter::types::unidirectional::AX): Output adapter for State_03.
- **DO_S4** (adapter::types::unidirectional::AX): Output adapter for State_04.
- **DO_S5** (adapter::types::unidirectional::AX): Output adapter for State_05.
- **timeOut** (iec61499::events::ATimeOut): Timer adapter.

Functionality

Corresponds to `sequence_ET_05_loop`, but uses adapters for the outputs.

Technical Features

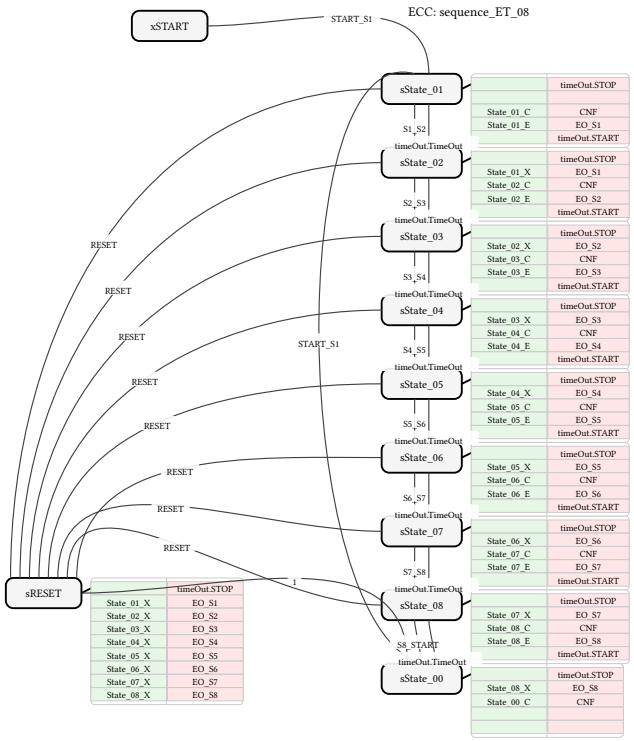
- Uses `adapter::types::unidirectional::AX`.

State Overview

See `sequence_ET_05_loop`.

Application Scenarios

For cyclic 5-step processes that are to be controlled via adapters.

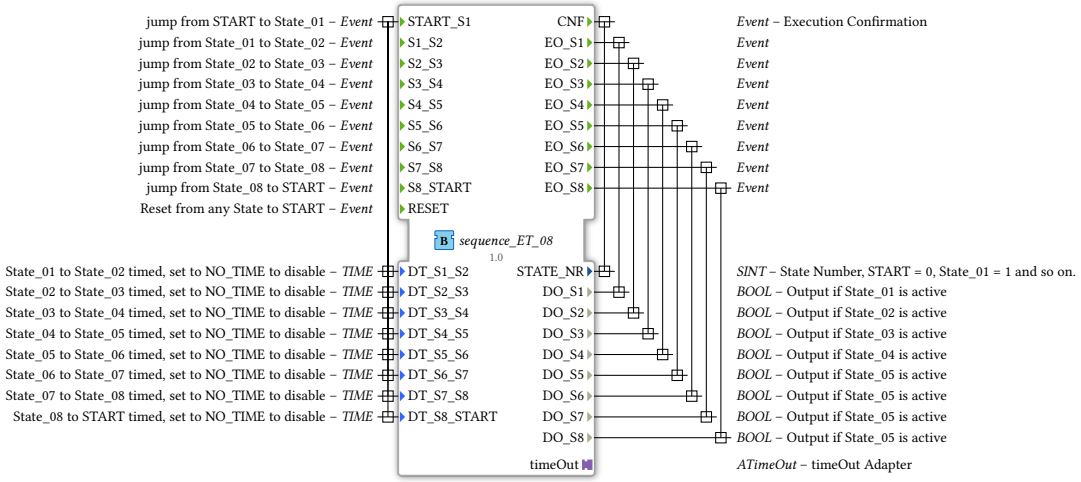


⚖️ Comparison with Similar Function Blocks

- **sequence_ET_05_loop**: Standard version without adapters.

Conclusion

Adapter version of the 5-step loop sequencer.



sequence_ET_08

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_ET_08` is a sequencer with eight outputs. It allows the execution of a fixed sequence of steps, where the transition from one step to the next can be triggered either by an external event or by an adjustable time interval. This block is particularly suitable for control tasks requiring a cyclic or time-controlled sequence of actions.

Interface Structure

Event Inputs

- `START_S1`: Jumps from state `START` to state `State_01`. Transfers all timestamps (`DT_S1_S2` to `DT_S8_START`).
- `S1_S2`: Jumps from `State_01` to `State_02`.
- `S2_S3`: Jumps from `State_02` to `State_03`.
- `S3_S4`: Jumps from `State_03` to `State_04`.

- S4_S5: Jumps from State_04 to State_05.
- S5_S6: Jumps from State_05 to State_06.
- S6_S7: Jumps from State_06 to State_07.
- S7_S8: Jumps from State_07 to State_08.
- S8_START: Jumps from State_08 back to START.
- RESET: Resets the function block from any state back to START.

Event Outputs

- CNF: Execution confirmation. Set with every state change and transmits the current state number (STATE_NR).
- EO_S1 to EO_S8: State-specific event outputs. These inputs are triggered upon entering the corresponding state (State_01 to State_08) and transmit the respective Boolean data output (DO_S1 to DO_S8).

Data Inputs

- DT_S1_S2 to DT_S8_START (Type TIME): Define the duration for the automatic transition from the current to the next state. If the value is set to NO_TIME, the timed transition for this step is disabled, and an event is required.
-

Data Outputs

- STATE_NR (Type SINT): Outputs the current state number (START = 0, State_01 = 1, ..., State_08 = 8).
- DO_S1 to DO_S8 (Type BOOL): Logical outputs that are TRUE as long as the function block is in the corresponding state (State_01 to State_08).

Adapter

- timeOut (Type iec61499::events::ATimeOut): A timer adapter used to implement timed state transitions.

Functionality

The function block is implemented as a BASIC FB with an Execution Control Chart (ECC). It starts in the initial state xSTART. An event START_S1 leads to the first active state sState_01. Each active state (sState_01 to sState_08) performs the following actions upon entry:

1. Stops the running timer.
2. Executes the exit algorithm of the previous state (switches off the previous output).
3. Executes the Confirmation algorithm (*_C), which sets the time for the next possible automatic transition in the adapter (STATE_NR).
4. Executes the Entry algorithm (*_E), which activates the associated Boolean output (DO_Sx) and triggers the corresponding event (EO_Sx).
5. Starts the timer with the duration set for this state (DT_*).

The transition to the next state can occur in two ways:

1. **Event-driven:** Through the corresponding jump event (e.g., S1_S2).
2. **Time-driven:** Through the adapter's TimeOut event, provided the duration (DT_*) is not NO_TIME.

The RESET event leads to a dedicated reset state (sRESET), which switches off all active outputs before transitioning to the inactive START state (sState_00).

Technical Features

- **Hybrid Transitions:** Each step offers two parallel transition conditions (event OR time), providing maximum flexibility.
- **Safe State Handling:** The timer is always stopped during a state change, and the outputs are cleanly deactivated by defined exit algorithms.
- **Configurable Times:** The time for each step can be set individually or deactivated using NO_TIME.
- **Explicit State Feedback:** The output STATE_NR allows for easy external monitoring of the current step position.

State Overview

1. **xSTART:** Initial, inactive state (at the start of the function block).
2. **sState_00:** Inactive START state (after reset or cycle end). STATE_NR = 0.

3. **sState_01 to sState_08:** Active states of the sequence. `STATE_NR = 1` to `8`. The corresponding outputs `DO_S1` to `DO_S8` are active.
4. **sRESET:** Temporary state that switches off all active outputs upon a `RESET` event.

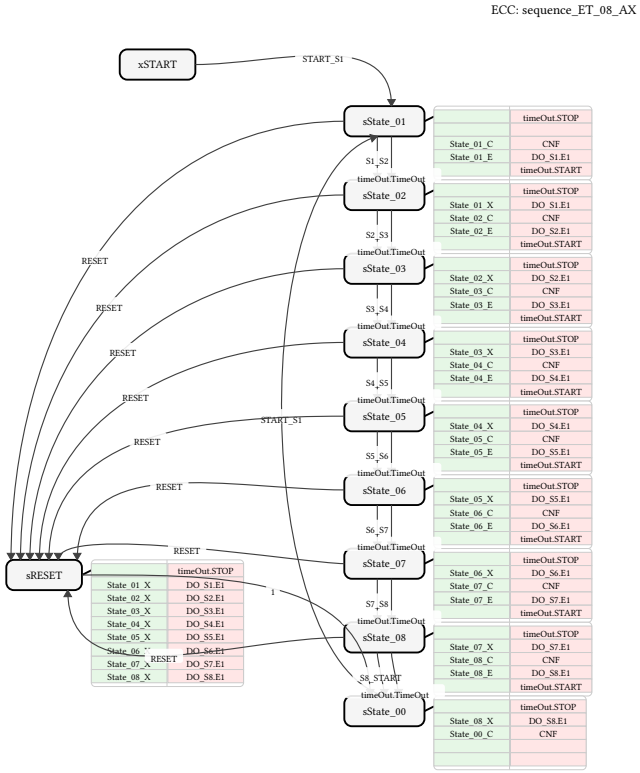
Application Scenarios

- Control of cyclic processes in packaging or manufacturing machines.
- Step sequence for an automated test or calibration process.
- Control of an exposure or rinsing sequence in semiconductor manufacturing.
- General state machines where steps can be triggered by both sensor input (events) and fixed time intervals.

⚖️ Comparison with similar components

Compared to simpler sequencers (e.g., `E_SR` or `E_CTU` in series), `sequence_ET_08` offers a fully predefined step sequence with integrated timing and dedicated outputs for each step. Unlike a custom-programmed SFC (Sequential Function Chart), the logic is hard-coded, making it easier to use but also less flexible. Components like `E_DELAY` would need to be added externally, whereas here the timing functionality is integrated.

Compared to simpler sequencers (e.g., `E_DELAY`), `sequence_ET_08` offers a fully predefined step sequence with integrated timing and dedicated outputs for each step.



Conclusion

The `sequence_ET_08` is a robust and easy-to-configure sequencer block for IEC 61499. Its strength lies in its combined event and time control, as well as its clear, step-defined interface. It is ideally suited for standardized control sequences with up to eight steps where a high degree of predictability and simple parameterization are desired. For processes with a variable number of steps or more complex branching, more flexible solutions such as composite function blocks or custom SFCs are preferable.

- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Confirmation of execution.

Data Inputs

- **DT_S1_S2** ... **DT_S8_START**: Times for automatic transitions between states.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** ... **DO_S8** (adapter::types::unidirectional::AX): Output adapter for State_01 to State_08.
- **timeOut** (iec61499::events::ATimeOut): Timer adapter.

Functionality

Corresponds to `sequence_ET_08`, but uses adapters for the outputs.

Technical Features

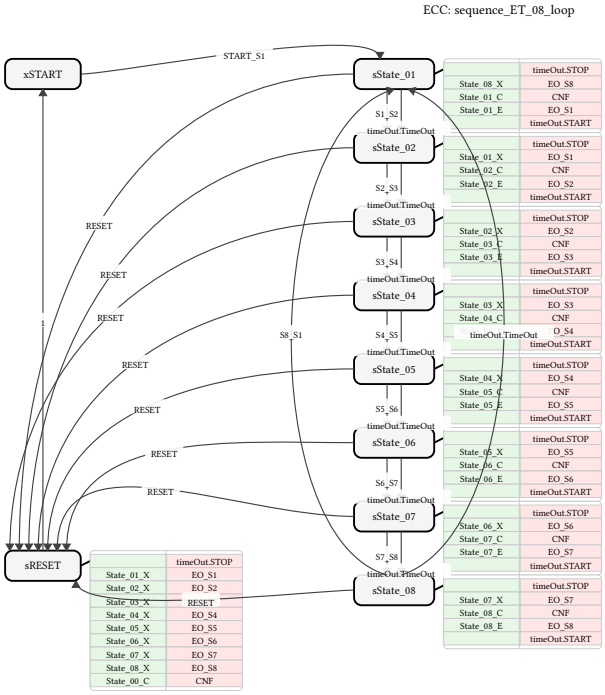
- Uses `adapter::types::unidirectional::AX`.

Status Overview

See `sequence_ET_08`.

Application Scenarios

For 8-step sequences with adapter connection.

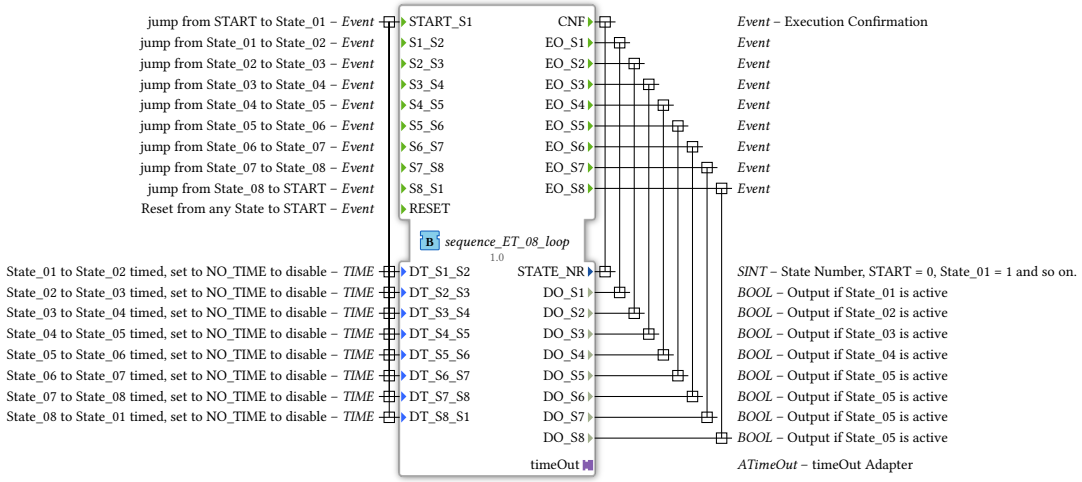


⚖️ Comparison with Similar Components

- **sequence_ET_08**: Standard version without adapter.

Conclusion

Adapter version of the 8-step sequencer.



sequence_ET_08_loop

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_ET_08_loop` is a sequencer with eight output states that operates in a loop. It allows transitions between states either triggered by an external event or timed after an adjustable time interval. This block is designed for control tasks where a defined sequence of actions (represented by outputs `DO_S1` to `DO_S8`) must be executed. A key feature is the ability to individually configure each state transition as either event-driven or time-controlled.

Interface Structure

Event Inputs

- **`START_S1`**: Starts the sequence and transitions from state `START` to state `State_01`. Transfers all time data (`DT_S1_S2` to `DT_S8_S1`).
- **`S1_S2 to S8_S1`**: Performs the transition from the corresponding source state to the next target state (e.g., `S1_S2` from `State_01` to `State_02`). These transitions are only effective if timing is disabled for this step.
- **`RESET`**: Resets the sequence from any state back to the initial state `START`.

Event Outputs

- **`CNF`**: General execution confirmation event that is triggered on every state transition. Transmits the current state number `STATE_NR`.
- **`EO_S1 to EO_S8`**: State-specific output events that are triggered upon entering the corresponding state (`State_01` to `State_08`). Each event transmits the corresponding Boolean data output (`DO_Sx`).

Data Inputs

- **`DT_S1_S2 to DT_S8_S1`** (Type: `TIME`): Define the duration for which the respective state remains active before an automatic, time-controlled transition to the next state occurs. To disable the time control for a specific transition and switch to purely event-driven transitions, the value must be set to the constant `NO_TIME`. Initially, all time inputs are preset to `NO_TIME`.

Data Outputs

- **`STATE_NR`** (Type: `SINT`): Outputs the number of the currently active state (START = 0, State_01 = 1, ..., State_08 = 8).
- **`DO_S1 to DO_S8`** (Type: `BOOL`): The physical outputs of the sequence. Each output is set to `TRUE` if the function block is in the corresponding state (`DO_S1` to `State_01`, etc.), otherwise it is `FALSE`.

Adapter

- **`timeOut`** (Type: `ATimeOut`): A plug-in timeout adapter used to implement timed state transitions. The function block (FB) starts and stops the timer and passes it the respective time setting (`DT_Sx_Sy`).

Functionality

The FB is implemented as a Basic Function Block (BFB) with an Execution Control Chart (ECC). The ECC consists of the states `xSTART` (initial state), `sState_01` to `sState_08` (active sequence states), and `sRESET` (reset state).

Upon entering an active state (e.g., `sState_01`), the following actions are executed sequentially:

1. The `timeOut` timer is stopped.
2. The exit algorithm (`X`) of the previous state is executed (setting the previous output `DO_Sx` to `FALSE`).
3. The confirmation algorithm (`C`) of the new state is executed (setting `STATE_NR` and configuring the `timeOut` adapter with the time set for this state, `DT`).

4. The entry algorithm (E) for the new state is executed (setting the corresponding output DO_Sx to TRUE and triggering the event EO_Sx).
5. The timer timeOut is started with the set time.

A state change can be triggered in two ways:

1. **Event-driven:** By the corresponding event Sx_Sy, provided the timer for this transition is disabled (DT = NO_TIME).
2. **Time-Controlled:** By the adapter's TimeOut event, provided a valid time (DT != NO_TIME) is set.

The RESET event leads to the sRESET state, disables all outputs, and confirms the 0 (START) state before the function block (FB) switches back to xSTART.

Technical Features

- **Hybrid Triggering:** Each state transition can be individually configured. This offers maximum flexibility for sequences that are partly sensor-driven and partly time-controlled.
- **Initial Configuration:** By default, all transitions are event-driven (NO_TIME), which requires explicit configuration of the time values to utilize timing.
- **State Confirmation:** The CNF event with STATE_NR enables easy monitoring and visualization of the current sequence position.
- **Closed Loop:** The sequence automatically loops back from State_08 to State_01, allowing for the implementation of cyclic processes.

State Overview

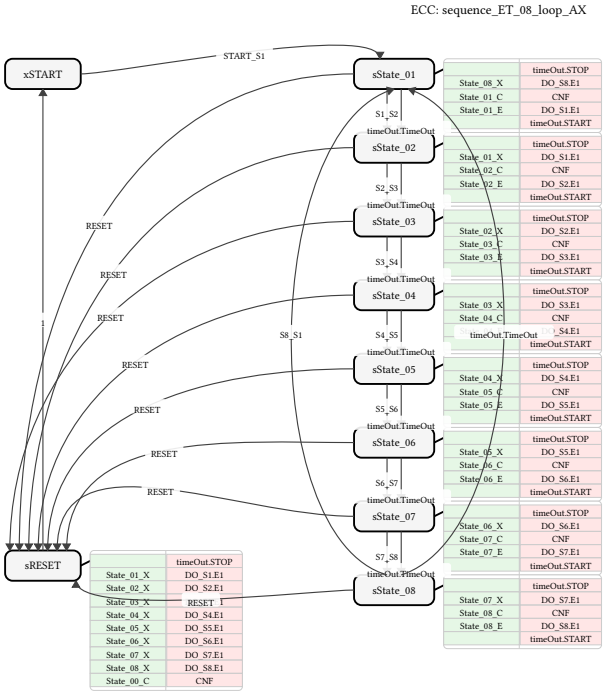
The FB passes through the following states in the ECC:

- **xSTART:** Inactive initial state. Waiting for START_S1.
- **sState_01 to sState_08:** Active operating states. Each state activates its specific output (DO_Sx) and waits for a trigger to transition to the next state.
- **sRESET:** Reset state. Exited from any state upon the RESET event, this state deactivates all outputs and returns to xSTART.

The transition conditions are defined in the ECC and combine the events Sx_Sy, timeOut.TimeOut, and RESET..

Application Scenarios

- **Batch Process Control:** Sequence control for mixing, heating, or filling processes where individual steps have varying durations.
- **Linked Machine Sequences:** Control of a machine whose work cycle consists of several sequentially connected positions or functions (e.g., turning, drilling, milling).
- **Test Stands:** Automated execution of test sequences that combine tests (event-driven) with waiting times (time-driven).
- **Packaging Machines:** Control of the cycle "feed product - close packaging - label - discharge".

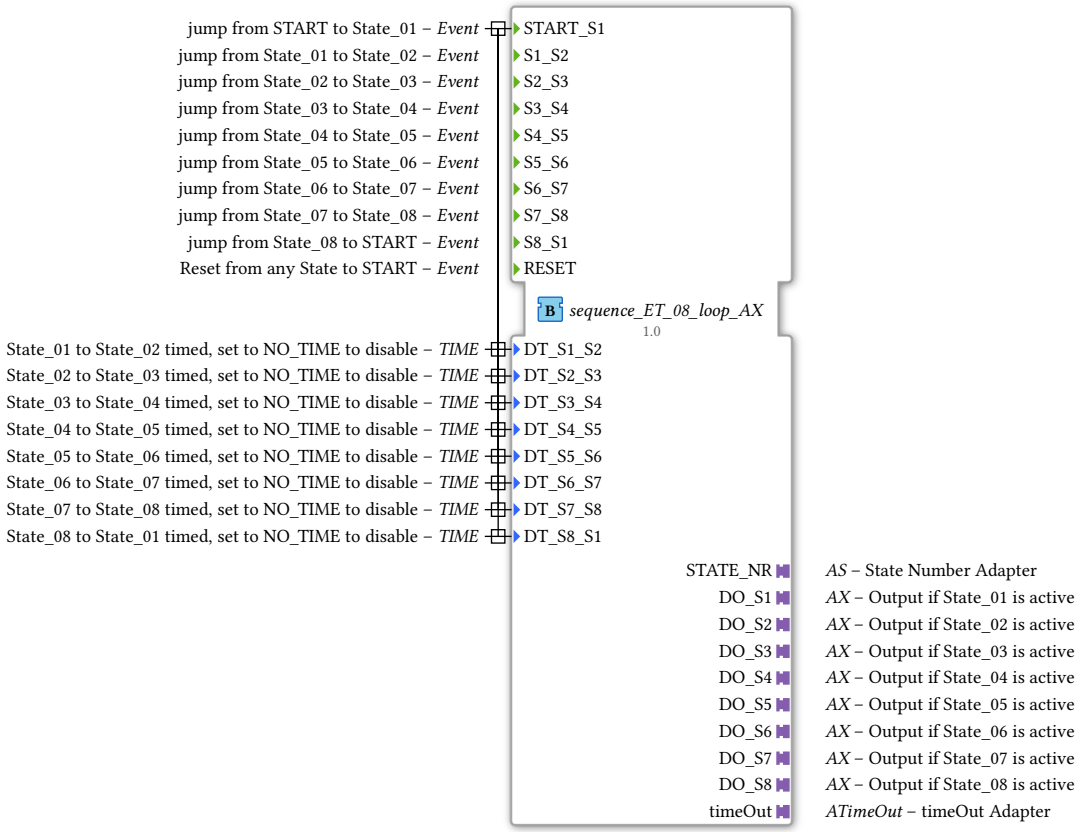


⚖️ Comparison with Similar Function Blocks

Compared to simpler timers or flip-flops, this function block offers a predefined, robust state machine for 8-step sequences. Compared to an individually programmed SFC (Sequential Function Chart) in a service or composite function block, sequence_ET_08_loop is a ready-to-use, tested, and reusable component that accelerates development and reduces the potential for errors. Function blocks with a fixed number of states are often more performant and easier to configure than fully programmable sequencers.

Conclusion

The sequence_ET_08_loop is a powerful and flexible function block for controlling cyclic 8-step sequences. Its strength lies in its hybrid triggering, which is freely selectable for each step, and its clear, event-based interface according to IEC 61499. Thanks to its integrated timing and direct Boolean outputs, it is ideally suited for directly controlling actuators in a higher-level control network.



sequence_ET_08_loop_AX

• — ○ • — ○ • — ○ •

Introduction

sequence_ET_08_loop_AXis a variant ofsequence_ET_08_loop that additionally uses adapters (AX`) for the outputs. It controls a cyclic sequence with 8 output states.

Adapter version of the 8-step loop sequencer.

const

anlagenSequenz

• – ◦ • – ◦ • – ◦ •

Introduction

This document describes the global constants defined for the “AnlagenSequenz” (plant sequence) control logic. These constants provide fixed numeric codes for the operating states, fault states, and transition types used in a motor sequence control system, particularly for a plant with six motors.

Interface Structure

Since this is a set of global constants, there are no event inputs, event outputs, data inputs, data outputs, or adapters in the traditional sense. The constants are directly accessible as global constants in the IEC 61499 environment.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The following constants are available as global constants:

Constant	Type	Value	Description
STATUS_BETRIEB_AUS	SINT	SINT#0	Anlage steht (Plant stopped)
STATUS_BETRIEB_HOCHFAHREN	SINT	SINT#1	Vorlauf-Kette aktiv (Start-up chain active)
STATUS_BETRIEB_LAEUFT	SINT	SINT#2	alle 6 Motoren laufen (All 6 motors running)
STATUS_BETRIEB_HERUNTERFAHREN	SINT	SINT#3	Nachlauf-Kette aktiv (Shutdown chain active)
STATUS_STOERUNG_KEINE	SINT	SINT#0	keine aktive Störung (No active fault)
STATUS_STOERUNG_AKTIV	SINT	SINT#4	Störung aktiv, verriegelt bis EIN (Fault active, interlocked until ENABLE)
TRANSIT_ART_KEINE	SINT	SINT#0	kein Motor aktuell im Vor-/Nachlauf (No motor currently in start-up/shut-down)
TRANSIT_ART_VORLAUF	SINT	SINT#1	TRANSIT_MOTOR startet nach Ablauf der aktuellen Zeit (motor starts after current time expires)

TRANSIT_ART_NACHLAUF	SINT	SINT#2	TRANSIT_MOTOR stoppt nach Ablauf der aktuellen Zeit (motor stops after current time expires)

Adapters

None.

Functionality

The global constants define a standardized set of status codes and transition types used within the sequence control logic. They ensure consistent representation of the plant's operational states and fault conditions across all function blocks and devices in the system. The constants separate the operational status (STATUS_BETRIEB_*) and the fault status (STATUS_STOERUNG_*), allowing clear state handling.

Technical Features

- Constants are defined as SINT (short integer) values.
- All constants are declared as `VAR_GLOBAL CONSTANT`, meaning they are read-only and globally accessible.
- The package name is `logiBUS::utils::sequence::const`.
- The values are chosen to avoid collisions between operational and fault status codes (fault status uses value 4, which is distinct from operational values 0-3).
- The transition types (TRANSIT_ART_*) allow identifying whether a motor is currently in a start-up (Vorlauf) or shutdown (Nachlauf) sequence.

State Overview

While this block does not implement a state machine itself, the constants are designed to be used in state-based control. The operational states progress from `STATUS_BETRIEB_AUS` (0) through `STATUS_BETRIEB_HOCHFAHREN` (1) to `STATUS_BETRIEB_LAEUFT` (2) and then to `STATUS_BETRIEB_HERUNTERFAHREN` (3) when shutting down. A fault is represented by `STATUS_STOERUNG_AKTIV` (4), which acts as an additional state that interlocks the sequence until a new start command (EIN) is given.

Application Scenarios

- **Plant Startup:** When the plant is commanded to start, the sequence moves from `STATUS_BETRIEB_AUS` to `STATUS_BETRIEB_HOCHFAHREN`, activating the start-up chain. The `TRANSIT_ART_VORLAUF` constant indicates that a motor is in its start-up delay.
- **Normal Operation:** After all six motors have started, the status becomes `STATUS_BETRIEB_LAEUFT`.
- **Fault Handling:** If a fault occurs, `STATUS_STOERUNG_AKTIV` is set, and the sequence is interlocked until a reset/start signal.
- **Shutdown:** During shutdown, the sequence passes through `STATUS_BETRIEB_HERUNTERFAHREN` with `TRANSIT_ART_NACHLAUF` for each motor's stop delay.

Comparison with Similar Blocks

Since this is a global constants collection, there is no direct equivalent function block. However, compared to hard-coded values or per-block constants, this approach ensures:

- Consistency across all function blocks using the sequence logic.
- Easy maintenance if status codes need to be changed.
- Clear documentation of the meaning of each numeric value.

Conclusion

The `anlagenSequenz` global constants provide a well-defined set of numeric codes for operating states, fault states, and transition types in a motor sequence control system. By centralizing these definitions, the system becomes more maintainable and less error-prone, ensuring that all components interpret the state information consistently.

motorNummer

• – ◦ • – ◦ • – ◦ •

Introduction

The `motorNummer` global constant container provides a set of predefined constants that represent motor identities in an automation system. It is part of the `logiBUS::utils::sequence::const` package and is used in sequences such as `AnlagenSequenz_06.TRANSIT_MOTOR` to unambiguously identify which motor (or no motor) is currently selected. The constants are defined as 8-bit signed integers (`SINT`) and cover the range from "no motor" to six distinct motors.

Interface Structure

Since `motorNummer` is a global constant container rather than a function block, it does not expose event or data interfaces in the traditional sense. Instead, it defines a fixed set of named constants that can be referenced globally throughout the project. The following sections describe the applicable interface elements.

Event Inputs

Not applicable. The `motorNummer` container defines no event inputs.

Event Outputs

Not applicable. The `motorNummer` container defines no event outputs.

Data Inputs

Not applicable. The `motorNummer` container defines no modifiable data inputs; all values are read-only constants.

Data Outputs

The container defines the following constant data values, each accessible by its symbolic name:

Constant Name	Type	Value	Comment
`MOTOR_KEINER`	`SINT`	0	No motor selected
`MOTOR_M1`	`SINT`	1	Motor 1
`MOTOR_M2`	`SINT`	2	Motor 2
`MOTOR_M3`	`SINT`	3	Motor 3
`MOTOR_M4`	`SINT`	4	Motor 4
`MOTOR_M5`	`SINT`	5	Motor 5
`MOTOR_M6`	`SINT`	6	Motor 6

Adapters

Not applicable. The `motorNummer` container defines no adapters.

Functionality

The primary purpose of `motorNummer` is to provide a centralized, human-readable naming scheme for motor identifiers. By using symbolic constants such as `MOTOR_M3` instead of raw numeric values, the application code becomes more readable, maintainable, and less error-prone. The constants are intended to be used in sequence logic, state machines, or any other part of the control application where a motor identity must be referenced. The special value `MOTOR_KEINER` (0) indicates that no motor is currently involved, enabling explicit handling of "no motor" states in sequences.

Technical Features

- **Data Type**: All constants are of type `SINT` (8-bit signed integer), ensuring compact storage and compatibility with typical PLC data handling.
- **Fixed Values**: The constants are immutable and defined at compile time, preventing accidental modification during runtime.
- **Global Scope**: As global constants, they are accessible from any function block, subapplication, or adapter within the same project without requiring explicit data connections.
- **Package Organization**: The constants reside in the package `logiBUS::utils::sequence::const`, promoting a structured organization of project-wide constants.

- **Documentation Support**: Each constant includes a descriptive comment (e.g., “Motor 1”, “no motor”) to clarify its intended use.

State Overview

Not applicable. `motorNummer` defines static constants and does not maintain any internal state or runtime behavior.

Application Scenarios

The following scenarios are typical use cases for the `motorNummer` constants:

- **Motor Selection in Sequences**: In a production sequence (e.g., `AnlagenSequenz_06.TRANSIT_MOTOR`), the constants determine which motor is to be transported or activated. For example, checking `IF currentMotor = MOTOR_M2 THEN ...`.
- **Initialization**: Setting the motor reference to `MOTOR_KEINER` during system startup to indicate that no motor has been selected yet.
- **Switch/Case Logic**: Using the constants in case or switch statements to dispatch distinct behaviors for each motor.
- **Parameter Passing**: Passing a motor identifier to function blocks or subapplications as a clear, self-documenting argument.

Comparison with Similar Blocks

Unlike function blocks or subapplications, `motorNummer` is a global constants container. It does not execute logic, maintain states, or process events. It is comparable to a named enum or define in traditional programming languages. A block like a motor control FB would use these constants as input parameters, while a subapplication might read them to configure its internal sequencing. The main advantage over hard-coded numeric values is the improved code readability and centralized definition, which simplifies maintenance when motor numbering changes.

Conclusion

The `motorNummer` global constant container is a simple yet essential utility for standardizing motor identification in the automation project. By providing named, typed constants for all motor slots (and the “no motor” case), it enhances code clarity, reduces the risk of numeric errors, and supports consistent behavior across sequences and applications. It is a best-practice example of structuring project-wide constants for reuse.

sequence

• – ◦ • – ◦ • – ◦ •

Introduction

The global constants file `sequence` defines a set of predefined constants that can be used in conjunction with sequence function blocks. It provides symbolic names for states and a special time value to improve the readability and maintainability of IEC 61499 applications. The constants are organized in the package `logiBUS::utils::sequence::const`.

Interface Structure

Global constants do not have event or data interfaces in the conventional sense of a function block. Instead, they are exposed as named values throughout the project. Their structure is a collection of variable declarations with fixed initial values.

Data Inputs

Not applicable. Global constants are not inputs, but rather fixed values.

Data Outputs

Not applicable. Global constants are not outputs, but rather fixed, predefined values.

Adapters

Not applicable.

Functionality

This file defines constants that are replaced by their values at compile time. They can be referenced in any function block within the project, provided the corresponding namespace (`logiBUS::utils::sequence::const`) is imported or the fully qualified name is used. Using these constants instead of direct numeric values ("magic numbers") in the code makes the logic clearer and more resistant to changes.

Technical Specifications

- **Data Types:** The constants use the basic IEC 61131-3 data types `TIME` and `SINT` (short integers).
- **Special Value `NO_TIME`:** The constant `NO_TIME` is initialized with the very large value `TIME#49d17h2m47s295ms`. This value typically serves as a placeholder or initial value to indicate an "undefined" or "unset" time, as it lies far outside the range of normal control timings.
- **State Constants:** The constants `State_00` to `State_08` represent integer states (0-8) and are of type `SINT`. They are intended for use in state machines or step sequences.

State Overview

Not applicable. This is a collection of constants and does not contain a state machine.

Application Scenarios

1. **State Machines / Sequencers:** The `State_XX` constants can be used as return values or for comparisons in step sequence function blocks (e.g., `E_SR`, `E_CTU` in conjunction with logic) to clearly identify the current step.
2. **Timer Initialization:** The constant `NO_TIME` can be used to assign an initial "invalid" value to timer function blocks before a real duration is set.
3. **Code Readability:** Replacing numbers like `SINT#5` in the code with `State_05` improves readability and indicates the semantic meaning of the value.

⚖️ Comparison with Similar Building Blocks

- **ENUM Data Type:** A user-defined enumeration type (ENUM) could fulfill a similar role to the `State_XX` constants and often offers stricter type checking. However, global constants are easier to define and use in 4diac.
- **Direct Value Input:** The main advantage over directly entering values (e.g., `3`) is the centralized definition. A change to the value only needs to be made in one place (here, in the constant file) and will affect all uses.

Conclusion

The global constant file `sequence` is a useful tool for structuring control applications. By providing descriptive names for states and a specific time value, it significantly contributes to the creation of clear, maintainable, and robust code. Their use is particularly recommended for implementing sequenced logic and state-based control systems.

zaehlstand

• – ◦ • – ◦ • – ◦ •

Introduction

The `zaehlstand` global constants block defines a set of named constants representing the current number of running motors in an industrial plant sequence. The constants are of type `SINT` (signed 8-bit integer) and cover the range from 0 to 6 motors. The constant names are used for readability and maintainability, replacing hard-coded numeric values in application logic. The block is part of the `logiBUS::utils::sequence::const` package and is intended for use within the 4diac IDE environment.

Interface Structure

The `zaehlstand` block does not contain any executable function block logic – it is a pure constant definition. Therefore, it exposes no event inputs, event outputs, or adapters. The provided values are accessible as global constants within the application.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The following constants are defined as global data outputs. They hold fixed values and cannot be modified at runtime.

Constant Name	Type	Initial Value	Description
`ZAEHLSTAND_0`	SINT	`SINT#0`	0 motors running (state S_AUS)
`ZAEHLSTAND_1`	SINT	`SINT#1`	1 motor running
`ZAEHLSTAND_2`	SINT	`SINT#2`	2 motors running
`ZAEHLSTAND_3`	SINT	`SINT#3`	3 motors running
`ZAEHLSTAND_4`	SINT	`SINT#4`	4 motors running
`ZAEHLSTAND_5`	SINT	`SINT#5`	5 motors running
`ZAEHLSTAND_6`	SINT	`SINT#6`	6 motors running (state S_LAEUFT, all)

Adapters

None.

Functionality

The block provides a set of symbolic constants that represent the exact number of motors currently active in a plant sequence. By referencing these constants in the application code, the developer can easily compare the current motor count (e.g., from a counter output) with a specific scenario. The constants are defined in a single location, simplifying changes and avoiding magic numbers scattered throughout the project.

Technical Features

- **Type:** All constants are of type `SINT` (signed 8-bit integer).
- **Initial Values:** Each constant is pre-initialised with the corresponding numeric value (`SINT#0` to `SINT#6`).
- **Scope:** Defined as `VAR_GLOBAL CONSTANT` – they are globally accessible and immutable.
- **Package:** Belongs to the `logiBUS::utils::sequence::const` package, which groups related sequence constants.
- **Licensing:** Distributed under Eclipse Public License 2.0.

State Overview

The constants represent discrete states of the motor count:

- `ZAEHLSTAND_0` – all motors off (S_AUS)
- `ZAEHLSTAND_6` – all motors running (S_LAEUFT)
- Intermediate values represent partially active motor sets.

These constants are typically used in sequence control logic to trigger actions or transitions when a certain motor count is reached.

Application Scenarios

- **Sequence Control:** Determine when to start or stop additional motors based on the current count.
- **Monitoring:** Compare the actual motor count (e.g., from a sensor or counter) with the expected count.
- **Interlocking:** Enable or disable processes when the number of running motors reaches a critical threshold.
- **Testing:** Use the constants as test inputs for simulation or validation of motor-counting logic.

Comparison with Similar Blocks

Unlike function blocks (FBs) or adapters, `zaehlstand` is a **constant definition** – it does not perform any computation or communication. It serves a similar purpose as an enumeration, but with explicit numeric values. Compared to using raw integer literals, the constants improve code readability and reduce the risk of typographical errors. Other possible implementations might use an enumerated type or a structured variable, but the use of simple SINT constants keeps the approach lightweight and directly compatible with IEC 61499 arithmetic operations.

Conclusion

`zaehlstand` is a compact and well-defined set of global constants for representing the number of running motors in a plant sequence. It provides clear, mnemonic names for the values 0 through 6, promoting maintainable and error-free application code. The block is an essential building block for sequence logic within the 4diac environment.

sequence_E_04

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_E_04` is a sequencer that implements a linear sequence of four states (State_01 to State_04) with a defined start state (START) and an end state (State_00). The transition between the individual states occurs exclusively through external events. The block is designed for control tasks where step-by-step, event-driven execution is required, such as in simple process or assembly sequences.

Interface Structure

Event Inputs

- **START_S1**: Switches from the START state or State_00 to the State_01 state.
- **S1_S2**: Changes from state State_01 to state State_02.
- **S2_S3**: Changes from state State_02 to state State_03.
- **S3_S4**: Changes from state State_03 to state State_04.
- **S4_START**: Changes from state State_04 to state State_00.
- **RESET**: Resets the function block from any state (State_01 to State_04) to state State_00.

Event Outputs

- **CNF**: Acknowledge event triggered on every state change. It returns the current state number via `STATE_NR`.
- **EO_S1**: Triggered upon entering state State_01 and returns the value of `DO_S1` (TRUE). * **EO_S2**: Triggered upon entering state_02 and returns the value `DO_S2` (TRUE).
- **EO_S3**: Triggered upon entering state_03 and returns the value `DO_S3` (TRUE).
- **EO_S4**: Triggered upon entering state_04 and returns the value `DO_S4` (TRUE).

Data Inputs

- None available.

Data Outputs

- **STATE_NR** (SINT): Outputs the number of the current state. The encoding is: START = 0, State_01 = 1, State_02 = 2, State_03 = 3, State_04 = 4.
- **DO_S1** (BOOL): Is TRUE when state State_01 is active.
- **DO_S2** (BOOL): Is TRUE when state State_02 is active.
- **DO_S3** (BOOL): Is TRUE when state State_03 is active.
- **DO_S4** (BOOL): Is TRUE when state State_04 is active.

Adapter

- None present.

Functionality

The `sequence_E_04` is implemented as a Basic Function Block (BFB) and has an Execution Control Chart (ECC). The ECC defines the states and the event-driven transitions between them. Specific algorithms are executed during each state transition:

1. **Exit Algorithm (X)**: Executed when exiting a state to set the corresponding data output (`DO_Sx`) to FALSE.

2. **Entry Algorithm (E)**: Executed when entering a state to set the corresponding data output (`DO_Sx`) to TRUE and trigger the corresponding event (`EO_Sx`).
3. **Confirmation Algorithm (C)**: Executed in every state (except RESET) to update the state number (`STATE_NR`) and trigger the confirmation event (`CNF`).

An event `RESET` executes all necessary exit algorithms for the active states and transitions via an intermediate state (`sRESET`) to the final state `State_00`.

Technical Features

- **Event-based Transition**: State changes are only possible through external events. There are no time- or data-driven transitions.
- **Explicit State Encoding**: The state numbers are defined as constants from the library `sequence`, which improves code reusability and readability.
- **Clean Reset**: The reset process deactivates all active outputs before the final state is reached to ensure clear and defined system behavior.
- **Initial State**: The function block starts in state `xSTART`. The first transition to the operational sequence occurs with the event `START_S1`.

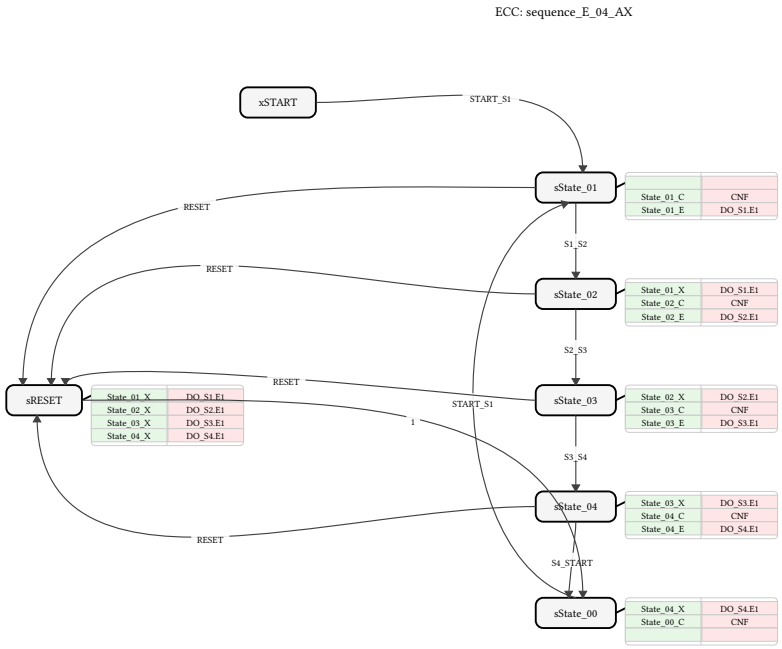
State Overview

1. **xSTART**: Initial resting state.
2. **sState_01**: First active step. `DO_S1` = TRUE.
3. **sState_02**: Second active step. `DO_S2` = TRUE.
4. **sState_03**: Third active step. `DO_S3` = TRUE.
5. **sState_04**: Fourth active step. `DO_S4` = TRUE.
6. **sState_00**: Final resting state after completion of the sequence. All `DO_Sx` = FALSE.
7. **sRESET**: Intermediate state during a reset operation. Deactivates all outputs.

Application Scenarios

- **Step-by-Step Controls**: Control of machines or systems with a fixed, step-by-step workflow (e.g., pick-and-place, filling systems).
- **Process Timing**: Synchronization of subprocesses where each step is triggered manually or by a sensor signal.
- **Manual Operating Sequences**: Implementation of guided operating sequences where the operator must confirm each step.
-

⚖️ Comparison with Similar Function Blocks



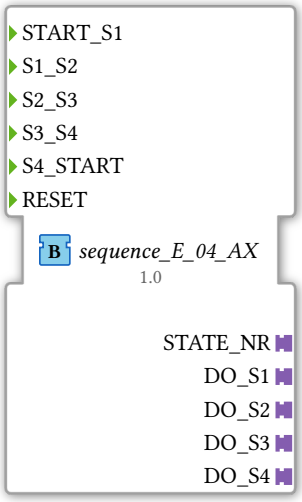
Unlike a `E_CYCLE` or `E_DELAY` function block, `sequence_E_04` offers purely event-driven transitions, not time-controlled ones. Compared to a generic `E_SR` (flip-flop) or a combination of `E_D_FF` (D flip-flop), this function block implements a predefined state machine with multiple steps and clear reset logic. It is more specialized and structured than an ad-hoc implementation using multiple individual function blocks.

...

Conclusion

The `sequence_E_04` is a robust and easy-to-use sequencer for IEC 61499. Its clear, event-driven interface and explicit state management make it ideal for applications requiring deterministic, step-by-step execution. The integrated reset functionality and state feedback via `CNF` and `STATE_NR` support secure and well-monitored integration into higher-level controllers.

sequence_E_04_AX



• – ○ • – ○ • – ○ •

Introduction

The `sequence_E_04_AX` is a variant of the `sequence_E_04`, which additionally uses adapters (`AX`) for the outputs. It controls a purely event-driven sequence with 4 output states.

jump from START to State_01 – *Event*
jump from State_01 to State_02 – *Event*
jump from State_02 to State_03 – *Event*
jump from State_03 to State_04 – *Event*
jump from State_04 to START – *Event*
Reset from any State to START – *Event*

AS – State Number Adapter
AX – Output if State_01 is active
AX – Output if State_02 is active
AX – Output if State_03 is active
AX – Output if State_04 is active

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence at State_01.
- **S1_S2**: Transition State_01 -> State_02.
- **S2_S3**: Transition State_02 -> State_03.
- **S3_S4**: Transition State_03 -> State_04.
- **S4_START**: Transition State_04 -> START.
- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Confirmation of execution.

Data Inputs

- None.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** (adapter::types::unidirectional::AX): Output adapter for State_01.
- **DO_S2** (adapter::types::unidirectional::AX): Output adapter for State_02.
- **DO_S3** (adapter::types::unidirectional::AX): Output adapter for State_03.
- **DO_S4** (adapter::types::unidirectional::AX): Output adapter for State_04.

Functionality

Corresponds to `sequence_E_04`, but uses adapters for the outputs.

Technical Features

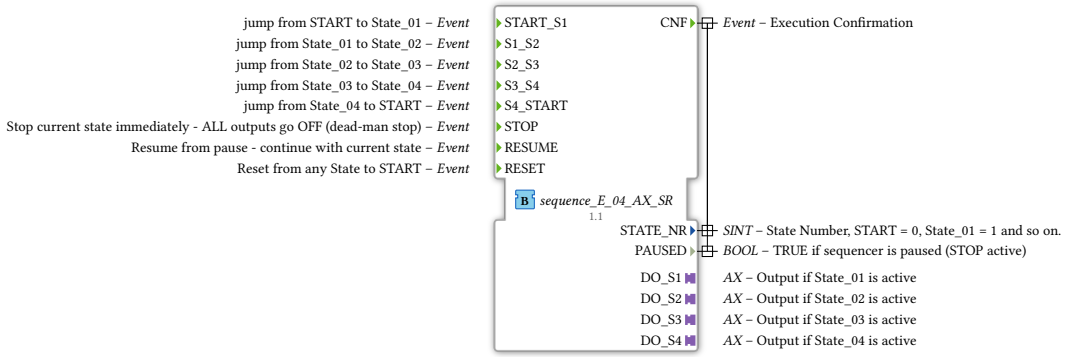
- Uses `adapter::types::unidirectional::AX`.

State Overview

See `sequence_E_04`.

Application Scenarios

For event-driven sequences controlled via adapters.



⚖️ Comparison with Similar Function Blocks

- **sequence_E_04**: Standard version without adapters.

Conclusion

Adapter version of the 4-step event sequencer.

sequence_E_04_AX_SR

• – ○ • – ○ • – ○ •

Introduction

The function block `sequence_E_04_AX_SR` implements an event-driven sequencer with four outputs via an AX adapter. It also offers a safety stop (STOP), a resume (RESUME), and a reset (RESET). The sequence cycles through the states State_00, State_01, State_02, State_03, and State_04 and can be operated cyclically.

Interface Structure

Event Inputs

Event	Description
`START_S1`	Transition from START/State_00 to State_01
`S1_S2`	Transition from State_01 to State_02
S2_S3`	Transition from State_02 to State_03
S3_S4`	Transition from State_03 to State_04
S4_START`	Transition from State_04 back to State_00
STOP`	Immediately interrupts the current state – all outputs are switched off (dead man stop)
RESUME`	Resumes the sequence from the paused state (outputs are reactivated)
RESET`	Resets the sequence from any state back to the START state (State_00)

Event Outputs

Event	Description
`CNF`	Execution confirmation. Included output data: `STATE_NR`, `PAUSED`

Data Inputs

No external data inputs.

Data Outputs

Variable	Type	Description
STATE_NR	SINT	Current state number: START = 0, State_01 = 1, ..., State_04 = 4
PAUSED	BOOL	TRUE, when the sequencer is paused (STOP active)

Adapter

Adapter	Type	Description
DO_S1	adapter::types::unidirectional::AX	Output active in State_01 (D1 = TRUE)
DO_S2	adapter::types::unidirectional::AX	Output active in State_02
DO_S3	adapter::types::unidirectional::AX	Output active in State_03
DO_S4`	adapter::types::unidirectional::AX	Output active in State_04

Functionality

The sequencer operates according to a finite state machine (ECM). The five sequential states are:

- State_00 (START)
- State_01
- State_02
- State_03
- State_04

The normal process begins with START_S1 (either from xSTART or from State_00), which then transitions to State_01. At each step, the FB activates the corresponding adapter output (e.g., DO_S1.D1 = TRUE in State_01), and the current values of STATE_NR and PAUSED are transmitted via the event output CNF. The transition to the next state occurs via the corresponding events (S1_S2, S2_S3, S3_S4), and the transition from State_04 back to State_00 with S4_START.

The transition to the next state is triggered by the corresponding events (S1_S2, S2_S3, S3_S4), and from State_04 back to State_00 with S4_START.

... Upon receiving STOP, the function block immediately deactivates the current output (exit step) and stores the current state in the internal variable savedState. The state then transitions to one of the paused states (sPAUSED_S1 to sPAUSED_S4 or sPAUSED_S0). The output PAUSED is set to TRUE. A RESUME event restores the stored state and reactivates the corresponding output.

The state then changes to one of the paused states (sPAUSED_S1 to sPAUSED_S4 or sPAUSED_S0). The RESET command puts the sequencer into a reset state, regardless of its current state. In this state, all four outputs are explicitly switched off, and then it immediately switches to State_00.

Technical Features

- **AX Adapters**: The four outputs are implemented using unidirectional AX adapters, each with a Boolean value, D1. The outputs are only set in active states and are immediately reset upon exiting or stopping.
- **Pause/Resume Mechanism**: The internal variable savedState stores the state at the time of the stop, so that the exact same state can be resumed after RESUME.
- **Safety Stop**: The STOP event causes all outputs to be switched off immediately (even without entering a paused state), which is designed as a dead-man stop.
- **Use of constants from the sequence package**: The state numbers (State_00, State_01, ...) are defined as named constants in the logiBUS::utils::sequence::const::sequence package.
- **Reset Behavior**: The RESET event switches off all four outputs before returning to State_00, thus ensuring a defined output state.

State Overview

State	Active Output	STATE_NR	PAUSED
xSTART	none	0	FALSE
sState_00	none	0	FALSE

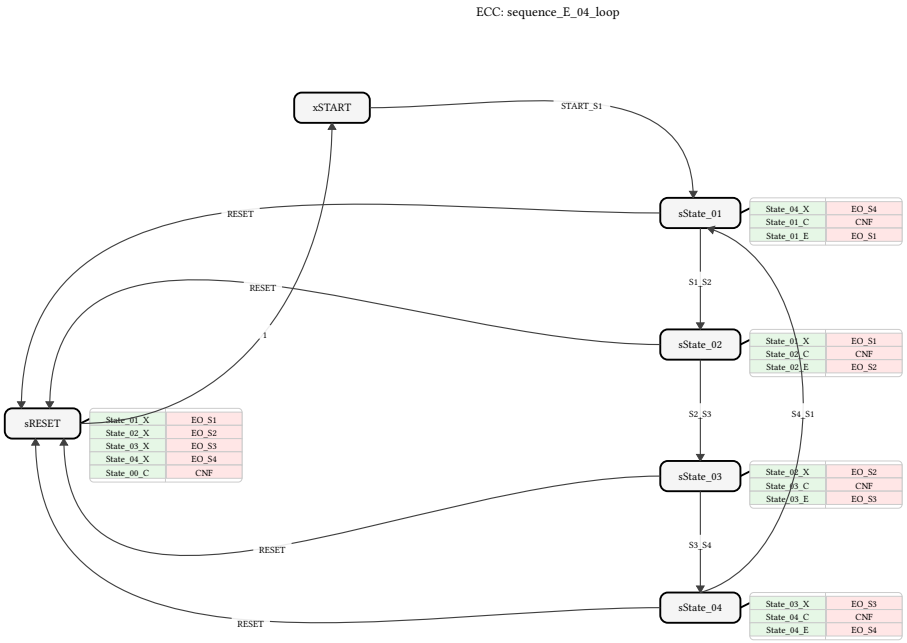
sState_01	DO_S1	1	FALSE
sState_02	DO_S2	2	FALSE
sState_03	DO_S3	3	FALSE
sState_04	DO_S4	4	FALSE
sPAUSED_S0	none	saved	TRUE
sPAUSED_S1	none	saved	TRUE
sPAUSED_S2	none	saved	TRUE
sPAUSED_S3	none	saved	TRUE
sPAUSED_S4	none	saved	TRUE
sRESET	none	–	–

Application Scenarios

- **Control of Sequential Processes**: e.g., a machine that performs four work steps in succession, with each step controlling its own actuator.
- **Safety-Critical Applications**: When a `STOP` signal must immediately shut down all actuators (e.g., emergency stop), and the exact state is restored after release.
- **Cyclic Processes**: from step 1 to 4 and back to step 0 (e.g., in packaging machines).
- **Manual Intervention**: the process can be reset to the beginning at any time using `RESET`.

Comparison with Similar Function Blocks

Unlike simpler sequencers (e.g., without STOP/RESUME), `sequence_E_04_AX_SR` offers:

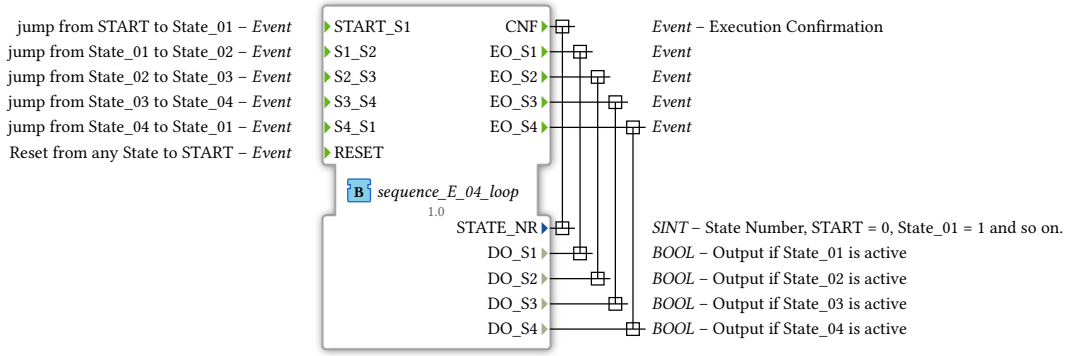


- **Safety interrupt with defined shutdown of all outputs**.
- **Pause and resume function** that saves the current state.
- **Cyclic return capability** from step 4 to step 0.
- **Output of the current state** as a number and pause status.

Other function blocks with the same number of outputs, but without STOP/RESUME, are easier to use but do not offer a safety function.

Conclusion

The `sequence_E_04_AX_SR` function blockis a versatile, safety-conscious four-step sequencer. It is particularly suitable for controllers where an interruptible sequence with defined output states and a resume option is required. The interface is clearly structured, the implementation robust, and it integrates well into automation environments through the use of AX adapters.



sequence_E_04_loop

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_E_04_loop` implements a cyclic sequence with four states. State transitions are triggered exclusively by external events. This block is designed for control tasks where a fixed sequence of actions (represented by outputs `DO_S1` to `DO_S4`) must be executed and a reset from any state is required.

Interface Structure

Event Inputs

- **`START_S1`**: Changes from the initial state `START` to the first active state `State_01`.
- **`S1_S2`**: Changes from `State_01` to `State_02`.
- **`S2_S3`**: Changes from `State_02` to `State_03`.
- **`S3_S4`**: Switches from `State_03` to `State_04`.
- **`S4_S1`**: Switches from `State_04` back to `State_01`, thus closing the cycle.
- **`RESET`**: Resets the function block from any active state (`State_01` to `State_04`) to the initial state `START`.

Event Outputs

- **CNF**: Triggered on every state change and confirms execution. Transports the current status code for STATE_NR.
- **EO_S1**: Triggered upon entering State_01. Transports the value TRUE for DO_S1.
- **EO_S2**: Triggered upon entering State_02. Transports the value TRUE for DO_S2.
- **EO_S3**: Triggered upon entering State_03. Transports the value TRUE for DO_S3.
- **EO_S4**: Triggered upon entering State_04. Transports the value TRUE for DO_S4.

Data Inputs

- This function block has no data inputs.

Data Outputs

- **STATE_NR** (SINT): Outputs the number of the current state. The encoding is: START = 0, State_01 = 1, State_02 = 2, State_03 = 3, State_04 = 4.
- **DO_S1** (BOOL): Is TRUE when state State_01 is active.
- **DO_S2** (BOOL): Is TRUE when state State_02 is active.
- **DO_S3** (BOOL): Is TRUE when state State_03 is active.
- **DO_S4** (BOOL): Is TRUE when state State_04 is active.

Adapters

- This function block does not use any adapters.

Functionality

The block is implemented as a Basic Function Block (BFB) with an Execution Control Chart (ECC). The internal logic is based on six states: an initial state (xSTART), four active operating states (sState_01 to sState_04), and a special reset state (sRESET).

During a state transition, three actions are executed sequentially:

1. **Exit Algorithm (X)**: The output of the previous state is set to FALSE.
2. **Confirmation Algorithm (C)**: The state number STATE_NR is updated, and the CNF event is triggered.
3. **Entry Algorithm (E)**: The output of the new state is set to TRUE, and the corresponding event (EO_Sx) is triggered.

A RESET event always leads to the sRESET state, where all outputs (DO_S1 to DO_S4) are deactivated, the state number is set to 0 (START), and a CNF is sent. The function block then automatically returns to the initial xSTART state.

Technical Features

- **Event-driven transitions**: Unlike time- or condition-driven sequencers, all state transitions occur only upon the occurrence of the specific event. There are no automatic or time-controlled advances.
- **Explicit Reset Logic**: The reset process is modeled as a separate state (sRESET) that cleanly resets all outputs before the initial state is reached again.
- **State Encoding**: Using the constants from sequence::State_xx for assignment to STATE_NR improves the maintainability and readability of the code.

State Overview

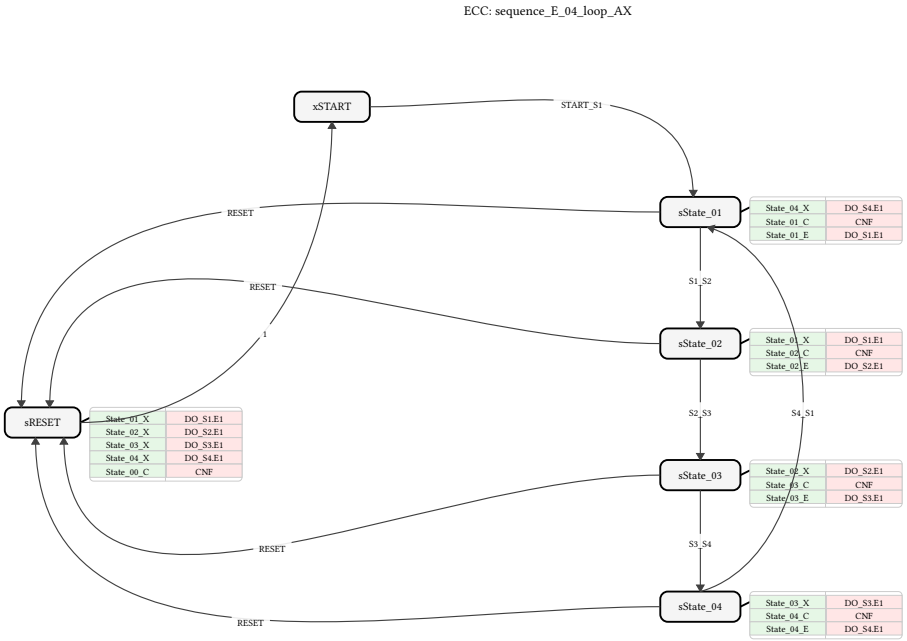
1. **xSTART**: Initial, inactive state. All outputs are FALSE, STATE_NR is 0.
2. **sState_01**: First active state. DO_S1 = TRUE, STATE_NR = 1.
3. **sState_02**: Second active state. DO_S2 = TRUE, STATE_NR = 2.
4. **sState_03**: Third active state. DO_S3 = TRUE, STATE_NR = 3.
5. **sState_04**: Fourth active state. DO_S4 = TRUE, STATE_NR = 4.
6. **sRESET**: Temporary reset state. Sets all actuator outputs (DO_Sx) to FALSE and STATE_NR to 0.

The permitted transitions are: START -> S1 -> S2 -> S3 -> S4 -> (S1) and from any state S1-S4 via RESET back to START.

Application Scenarios

- **Step-by-Step Controls**: Control of machine processes where each step must be enabled manually or by a sensor signal (e.g., manual assembly stations).
- **Clock-Controlled Processes**: In production lines where a central clock signal (Sx_Sy events) signals the progress of the assembly from station to station.

- **Test and commissioning sequences**: A structured sequence of tests that must be confirmed by the operator.

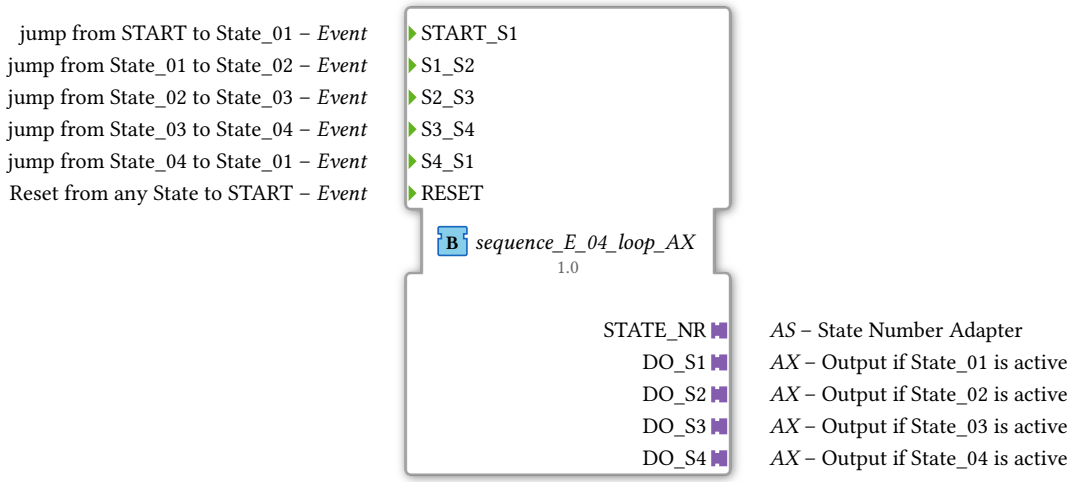


⚖️ Comparison with similar modules

Compared to a **Cyclic sequencer with timer** (e.g., `E_CYCLE`), this module lacks integrated timing; transitions are purely event-driven. Compared to a **Binary shift register** or counter, this module offers an explicit, easily understandable state machine with clear entry/exit actions and a dedicated reset path, simplifying troubleshooting.

Conclusion

The `sequence_E_04_loop` is a robust and clearly structured function block for implementing an event-driven 4-state sequence. Its strengths lie in the explicit modeling of each state transition, the clean reset logic, and the clear separation of entry, exit, and confirmation actions. It is ideally suited for applications where the sequence control is to be carried out by external signals (buttons, sensors, higher-level controllers).



sequence_E_04_loop_AX

• — ○ • — ○ • — ○ •

Introduction

sequence_E_04_loop_AXis a variant ofsequence_E_04_loop that additionally uses adapters (AX`) for the outputs. It controls a purely event-driven, cyclic sequence with 4 output states.

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence at State_01.
- **S1_S2**: Transition State_01 -> State_02.
- **S2_S3**: Transition State_02 -> State_03.
- **S3_S4**: Transition State_03 -> State_04.
- **S4_S1**: Transition State_04 -> State_01 (Loop).
- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Acknowledges execution.

Data Inputs

- None.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** (adapter::types::unidirectional::AX): Output adapter for State_01.
- **DO_S2** (adapter::types::unidirectional::AX): Output adapter for State_02.
- **DO_S3** (adapter::types::unidirectional::AX): Output adapter for State_03.
- **DO_S4** (adapter::types::unidirectional::AX): Output adapter for State_04.

Functionality

Corresponds to `sequence_E_04_loop`, but uses adapters for the outputs.

Technical Features

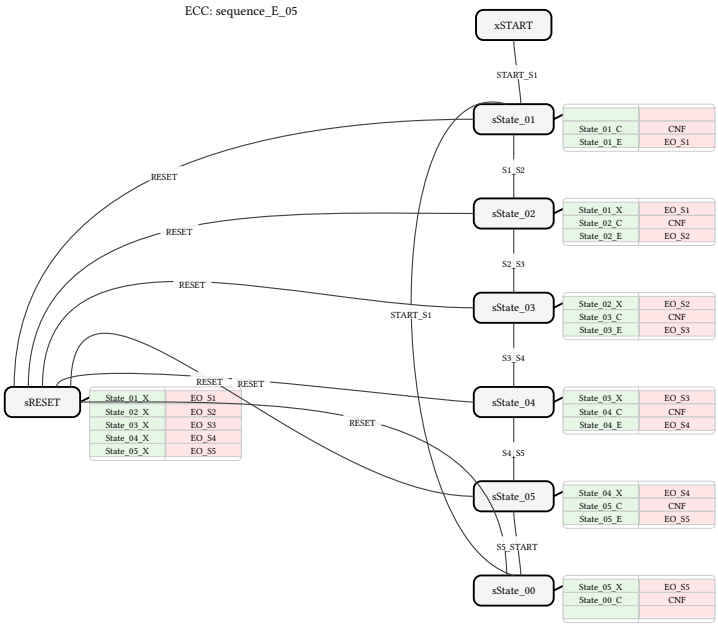
- Uses `adapter::types::unidirectional::AX`.

State Overview

See `sequence_E_04_loop`.

Application Scenarios

For cyclic event-driven sequences with adapter connectivity.

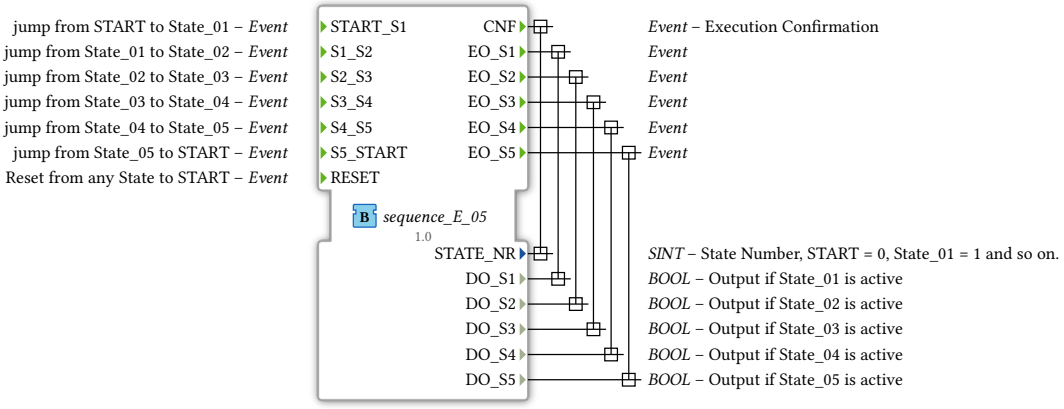


⚖️ Comparison with Similar Function Blocks

- **sequence_E_04_loop**: Standard version without adapters.

Conclusion

Adapter version of the 4-step loop event sequencer.



sequence_E_05

• – ○ • – ○ • – ○ •

Introduction

The function block `sequence_E_05` is a sequential state machine that cycles through a fixed sequence of five states. The transition between individual states occurs exclusively through external events. This block is designed for control tasks requiring the step-by-step execution of a process sequence, such as in handling or packaging systems. Each active state sets its own binary output and confirms execution.

Interface Structure

The function block has a pure event-based interface. State transitions are triggered by input events, and the active state is signaled via output events and data outputs.

Event Inputs

- `START_S1`: Changes from the initial START state or from state `sState_00` to the first state `State_01`.
- `S1_S2`: Changes from `State_01` to `State_02`.
- `S2_S3`: Changes from `State_02` to `State_03`.

- S3_S4: Changes from State_03 to State_04.
- S4_S5: Changes from State_04 to State_05.
- S5_START: Changes from State_05 back to the inactive state sState_00.
- RESET: Immediately resets the automaton from any state to the inactive state sState_00.

Event Outputs

- CNF: General confirmation event. Triggered on every state change and returns the current state number STATE_NR.
- EO_S1: Triggered upon entry into State_01 and returns the value DO_S1.
- EO_S2: Triggered upon entry into State_02 and returns the value DO_S2.
- EO_S3: Triggered upon entry into State_03 and returns the value DO_S3.
- EO_S4: Triggered upon entry into State_04 and returns the value DO_S4.
- EO_S5: Triggered upon entering State_05 and returns the value DO_S5.

Data Inputs

There are no data inputs.

Data Outputs

- STATE_NR (SINT): Numeric identifier of the current state. START = 0, State_01 = 1, State_02 = 2, ..., State_05 = 5.
- DO_S1 (BOOL): Is TRUE when state State_01 is active.
- STATE_NR (SINT): Numeric identifier of the current state. START = 0, State_01 = 1, State_02 = 2, ..., State_05 = 5.
- DO_S1 (BOOL): Is TRUE when state State_01 is active. * DO_S2 (BOOL): Is TRUE when state State_02 is active.
- DO_S3 (BOOL): Is TRUE when state State_03 is active.
- DO_S4 (BOOL): Is TRUE when state State_04 is active.
- DO_S5 (BOOL): Is TRUE when state State_05 is active.

Adapter

No adapter interfaces are available.

Functionality

The FB is implemented as a Basic Function Block (BFB) with an Execution Control Chart (ECC). The ECC consists of seven states: an initial state (xSTART), five active states (sState_01 to sState_05), an inactive end state (sState_00), and a special reset state (sRESET).

... Upon entering an active state (e.g., sState_01), two algorithms are executed sequentially:

1. A Confirmation Step (e.g., State_01_C) that sets STATE_NR to the corresponding constant and triggers the CNF event.
2. An Entry Step (e.g., State_01_E) that sets the associated binary output (e.g., DO_S1) to TRUE and triggers the corresponding event (e.g., EO_S1).

When exiting an active state, an *Exit Step* (e.g., State_01_X) is executed, which resets the corresponding binary output to FALSE. State transitions are strictly controlled by the incoming event inputs. An event RESET leads, via the intermediate state sRESET, to the deactivation of all active outputs (DO_S1 to DO_S5) before the automaton transitions to the inactive state sState_00.

Technical Features

- **Event-driven Transitions:** Unlike time- or condition-driven sequencers, state changes here occur exclusively through external events. This enables close coupling to other process steps or operator actions.
- **Explicit Reset Logic:** The reset process is modeled as a separate ECC state (sRESET), ensuring that all five outputs (DO_S1 to DO_S5) are properly deactivated during a reset, regardless of their current state.
- **Separate Entry/Exit Actions:** The logic for setting and resetting the outputs is divided into separate algorithms (E for Entry, X for Exit). This promotes a clear and maintainable structure.
- **Constants for State Numbers:** The values for STATE_NR are retrieved from an imported library (sequence::State_01, etc.), facilitating reusability and centralized maintenance.
-

State Overview

1. **xSTART:** Initial state after startup. Waiting for `START_S1`.
2. **sState_01:** First active step. Sets `DO_S1=TRUE` and `STATE_NR=1`. Waits for `S1_S2` or `RESET`.
3. **sState_02:** Second active step. Sets `DO_S2=TRUE` and `STATE_NR=2`. Waits for `S2_S3` or `RESET`.
4. **sState_03:** Third active step. Sets `DO_S3=TRUE` and `STATE_NR=3`. Waits for `S3_S4` or `RESET`.
5. **sState_04:** Fourth active step. Sets `DO_S4=TRUE` and `STATE_NR=4`. Waits for `S4_S5` or `RESET`.
6. **sState_05:** Fifth active step. Sets `DO_S5=TRUE` and `STATE_NR=5`. Waiting for `S5_START` or `RESET`.
7. **sState_00:** Inactive end state. All outputs are `FALSE` or `STATE_NR=0`. Waiting for `START_S1` for a new cycle.
8. **sRESET:** Temporary reset state. Disables all active outputs and then switches to `sState_00`..

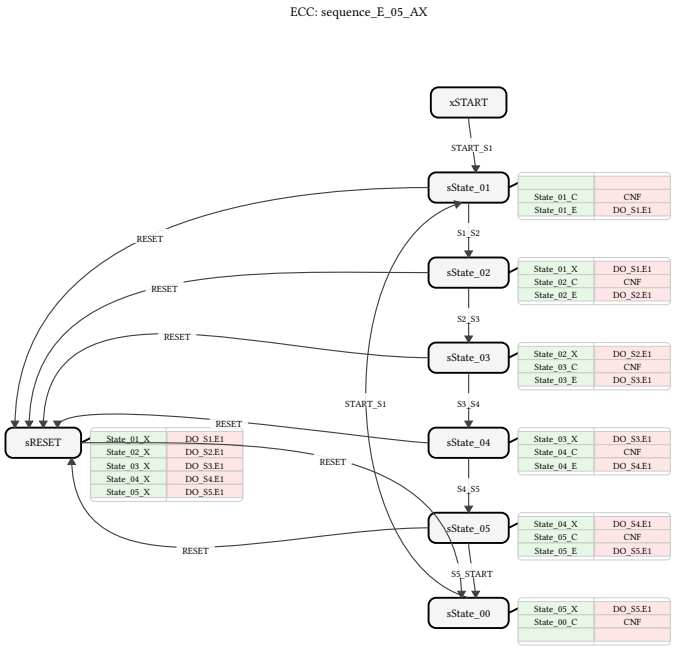
Application Scenarios

- **Step Sequence in Handling Devices:** Control of a pick-and-place robot (grasping → lifting → moving → lowering → releasing), where each step is triggered by a sensor event (e.g., "part detected," "position reached").
- **Manual Operating Sequences:** Execution of a sequence specified by the operator, e.g., in a machine setup ("Release step 1" → "Release step 2").
- **Synchronization with Higher-Level Controllers:** The sequence serves as a subroutine of a main controller, which dictates the progress via the events.

⚖️ Comparison with Similar Function Blocks

Unlike a cyclically running sequencer (e.g., `CYCLE_5`), which automatically advances after a fixed time, `sequence_E_05` remains in each state until the corresponding next event occurs. This makes it more deterministic with respect to external conditions, but requires reliable event generation by the peripherals or higher-level logic. It is simpler and more transparent than a complete sequential function block (SFC) for fixed, linear sequences.

Conclusion



The `sequence_E_05` is a robust and easy-to-configure function block for event-driven, fixed-length sequences. Its clear separation of state logic and output actions, as well as the integrated reset mechanism, make it a reliable component for sequential control tasks in 4diac-based automation systems. The lack of flexibility in the number of steps or transition conditions is an advantage for defined, linear processes in terms of clarity and predictability.

sequence_E_05_AX

• – ○ • – ○ • – ○ •

Introduction

sequence_E_05_AXis a variant ofsequence_E_05 that additionally uses adapters (AX`) for the outputs. It controls a purely event-driven sequence with 5 output states.

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence at State_01.
- **S1_S2**: Transition State_01 -> State_02.
- **S2_S3**: Transition State_02 -> State_03.
- **S3_S4**: Transition State_03 -> State_04.

- **S4_S5**: Transition State_04 -> State_05.
- **S5_START**: Transition State_05 -> START.
- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Confirmation of execution.

Data Inputs

- None.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** (adapter::types::unidirectional::AX): Output adapter for State_01.
- **DO_S2** (adapter::types::unidirectional::AX): Output adapter for State_02.
- **DO_S3** (adapter::types::unidirectional::AX): Output adapter for State_03.
- **DO_S4** (adapter::types::unidirectional::AX): Output adapter for State_04.
- **DO_S5** (adapter::types::unidirectional::AX): Output adapter for State_05.

Functionality

Corresponds to `sequence_E_05`, but uses adapters for the outputs.

Technical Features

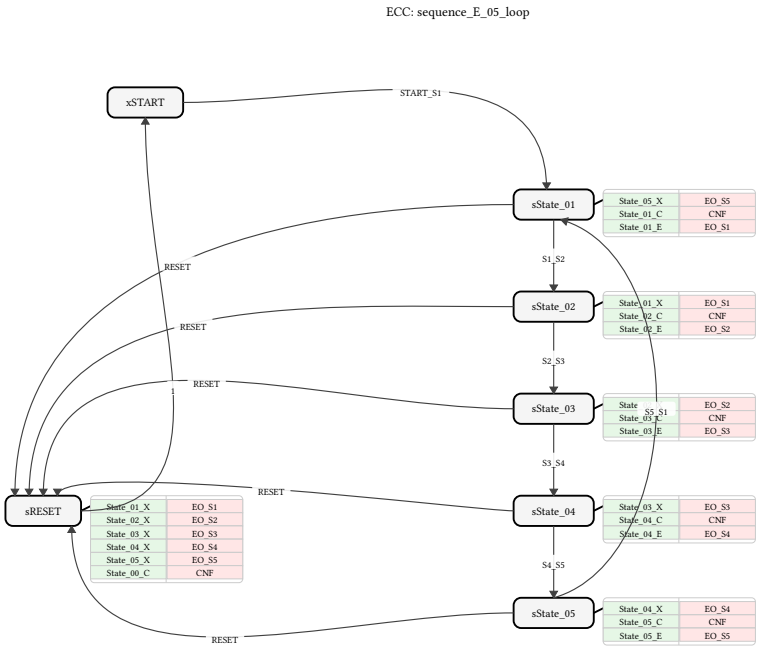
- Uses `adapter::types::unidirectional::AX`.

State Overview

See `sequence_E_05`.

Application Scenarios

For event-driven 5-step sequences with adapter connectivity.

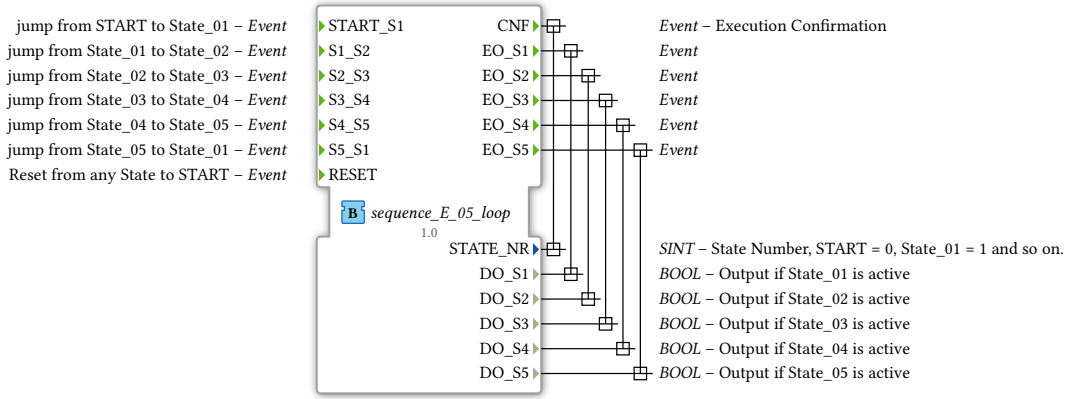


⚖️ Comparison with Similar Function Blocks

- **sequence_E_05**: Standard version without adapters.

Conclusion

Adapter version of the 5-step event sequencer.



sequence_E_05_loop

• – ○ • – ○ • – ○ •

Introduction

The function block `sequence_E_05_loop` implements a cyclic sequence with five states. The transition between the individual states occurs exclusively via external events. The block is designed for applications in which a process step may only begin after the completion of a previous step and the arrival of a specific enable signal. The sequence can be reset to the initial start state from any state.

Interface Structure

Event Inputs

- `START_S1`: Switches from the start state (`START`) to the first active state (`State_01`).
- `S1_S2`: Changes from `State_01` to `State_02`.
- `S2_S3`: Changes from `State_02` to `State_03`.
- `S3_S4`: Changes from `State_03` to `State_04`.
- `S4_S5`: Changes from `State_04` to `State_05`.
- `S5_S1`: Switches from `State_05` back to `State_01` (cycle).
- `RESET`: Resets the sequence from any state to the initial start state (`START`).

Event Outputs

- CNF: General acknowledgment event that is triggered on every state change. It returns the current state number (STATE_NR).
- EO_S1: Triggered upon entering State_01 and returns the corresponding data output DO_S1. ...* EO_S1: Triggered upon entering State_01 and returns the corresponding data output DO_S1. * EO_S2: Triggered upon entry into State_02 and outputs the corresponding data output DO_S2.
- EO_S3: Triggered upon entry into State_03 and outputs the corresponding data output DO_S3.
- EO_S4: Triggered upon entry into State_04 and outputs the corresponding data output DO_S4.
- State_04: Triggered upon entry into State_04 and outputs the corresponding data output DO_S4.
- EO_S3: Triggered upon entry into State_04.
- qzmsdocs000036 ... * EO_S5: Triggered upon entering State_05 and outputs the corresponding data output DO_S5.

Data Inputs

- This function block has no data inputs.

Data Outputs

- STATE_NR (SINT): Outputs the number of the currently active state. The encoding is: START = 0, State_01 = 1, State_02 = 2, ..., State_05 = 5.
- DO_S1 (BOOL): Is TRUE when State_01 is active.
- DO_S2 (BOOL): Is TRUE when State_02 is active.
- DO_S3 (BOOL): Is TRUE when State_03 is active.
- DO_S4 (BOOL): Is TRUE when State_04 is active.
- DO_S5 (BOOL): Is TRUE when State_05 is active.

Adapters

- This function block does not use adapters.

Functionality

The FB is implemented as a Basic Function Block (BFB) with an Execution Control Chart (ECC). The internal logic is based on seven states: an initial start state (xSTART), five active states (sState_01 to sState_05), and a separate reset state (sRESET).

Upon entering an active state, three actions are executed sequentially:

1. **Exit action of the previous state:** The corresponding algorithm (State_XX_X) sets the associated data output (DO_Sx) to FALSE.
2. **Confirmation Action:** The State_XX_C algorithm sets the state number STATE_NR and triggers the CNF event.
3. **Entry Action of the New State:** The State_XX_E algorithm sets the corresponding data output (DO_Sx) to TRUE and triggers the corresponding event EO_Sx.

A RESET event leads to the sRESET state. Here, all potentially active outputs (DO_S1 to DO_S5) are deactivated via their respective exit algorithms, the state number is set to 0 (START), and a CNF event is triggered. The function block then automatically switches back to the initial xSTART state (condition = 1, i.e., always true).

Technical Features

- **Event-driven transitions:** Every state transition must be explicitly triggered by the corresponding input event. There are no time- or data-driven automatic transitions.
- **Decoupled Signals:** The Boolean state outputs (DO_Sx) and the associated event outputs (EO_Sx) are set and triggered synchronously. This allows for flexible integration with subsequent logic.
- **Explicit Reset Logic:** The reset process systematically deactivates all outputs before restoring the initial state, ensuring clean and defined behavior.
- **Constants for State Numbers:** State numbers are assigned via the imported namespace sequence:: (e.g., sequence::State_01), which improves maintainability and code readability.

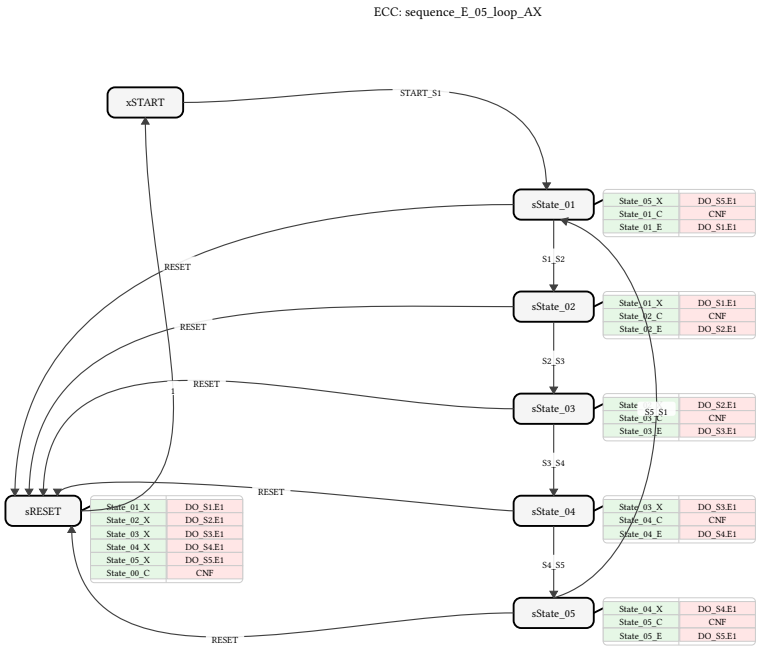
State Overview

The ECC consists of the following states and possible transitions:

- **xSTART:** Initial, inactive state. Transition to `sState_01` via `START_S1`.
- **sState_01:** First active state. Transitions to `sState_02` via `S1_S2` or to `sRESET` via `RESET`.
- **sState_02:** Second active state. Transitions to `sState_03` via `S2_S3` or to `sRESET` via `RESET`.
- **sState_03:** Third active state. Transitions to `sState_04` via `S3_S4` or to `sRESET` via `RESET`.
- **sState_04:** Fourth active state. Transitions to `sState_05` via `S4_S5` or to `sRESET` via `RESET`.
- **sState_05:** Fifth active state. Transitions to `sState_01` via `S5_S1` (cycle) or to `sRESET` via `RESET`.
- – **sRESET:** Reset state. Executes reset actions and then unconditionally reverts to `xSTART`.

Application Scenarios

- **Sequence-Step Controls:** Control of machine processes where each step must be enabled manually or by a sensor signal (e.g., manual workstation with enable button).
- **Batch Processes:** Execution of recipe steps where the operator or a higher-level system must confirm the next step.
- **Safety-Critical Sequences:** Processes where uncontrolled automatic switching must be avoided.
- **Test and Commissioning Sequences:** Manually cycling through individual functions of a system.

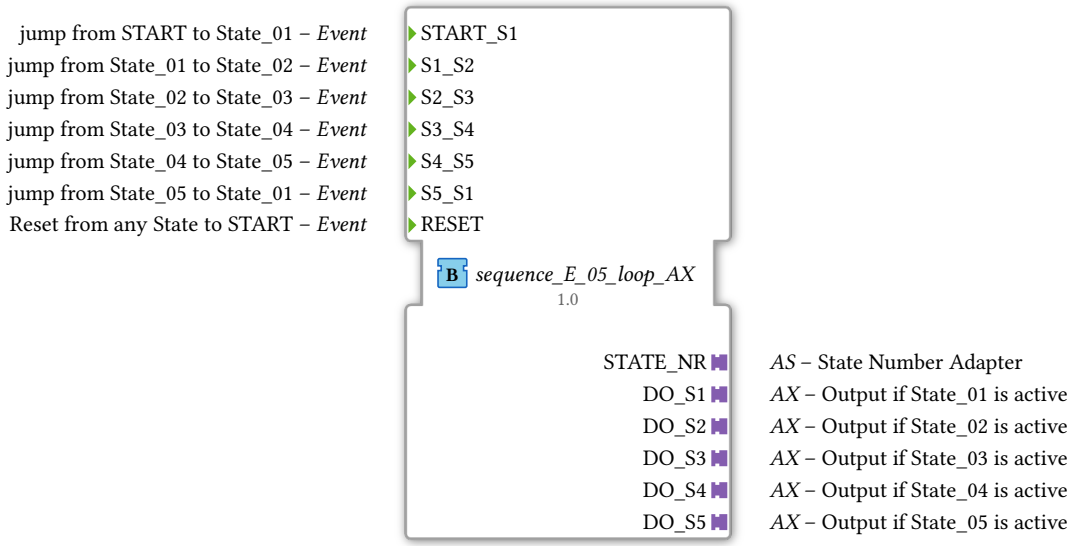


⚖️ Comparison with similar building blocks

In contrast to **cyclically running sequencers** (e.g., `E_CYCLE`) or **time-controlled sequencers** (with `DELAY`)(In blocks) this function block remains in each state until the specific change event occurs. It thus offers maximum external control. Compared to a generic **counter** (`CTU`) with downstream decoding logic, this function block provides a fully encapsulated, state-based solution with clear entry/exit actions and an integrated reset mechanism.

Conclusion

The `sequence_E_05_loop` is a robust and easy-to-configure function block for event-driven sequences with five states. Its clear interface, clean separation of entry/exit logic, and reliable reset mechanism make it ideal for applications where each process step must be explicitly enabled. The included data outputs and acknowledgment events allow for easy integration into higher-level control and visualization systems.



sequence_E_05_loop_AX

• – ○ • – ○ • – ○ •

Introduction

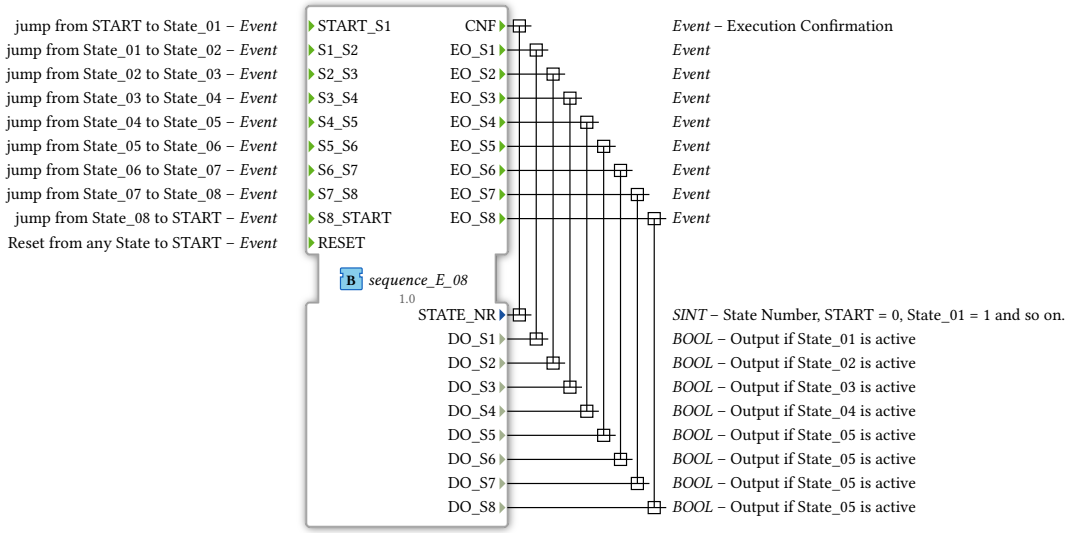
⚖️ Comparison with similar components

- **sequence_E_05_loop**: Standard version without adapter.

Conclusion

Adapter version of the 5-step loop event sequencer.



sequence_E_08

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_E_08` is an eight-output sequencer controlled by events. It implements a linear state machine with a defined start state and eight active states. The transition from one state to the next occurs exclusively upon the occurrence of a specific event. This block is suitable for control tasks where process steps must be executed sequentially and in response to events, such as in handling or assembly processes.

Interface Structure

Event Inputs

- **START_S1**: Changes from the start state (`START`) to the state `State_01`.
- **S1_S2**: Changes from `State_01` to `State_02`.
- **S2_S3**: Changes from `State_02` to `State_03`.

- **S3_S4**: Changes from State_03 to State_04.
- **S4_S5**: Changes from State_04 to State_05.
- **S5_S6**: Changes from State_05 to State_06.
- **S6_S7**: Changes from State_06 to State_07.
- **S7_S8**: Changes from State_07 to State_08.
- **S8_START**: Switches from State_08 back to the START state (represented by sState_00).
- **RESET**: Immediately resets the function block from *any state* to the START state.

Event Outputs

- **CNF**: Execution Confirmation. Triggered on every state change and returns the new state number (STATE_NR).
- **EO_S1**: Triggered upon entering State_01 and returns the value of DO_S1 (TRUE).
- **EO_S2**: Triggered upon entry into State_02 and returns the value of DO_S2 (TRUE).
- **EO_S3**: Triggered upon entry into State_03 and returns the value of DO_S3 (TRUE).
- **EO_S4**: Triggered upon entry into State_04 and returns the value of DO_S4 (TRUE).
- **EO_S5**: Triggered upon entry into State_05 and returns the value of DO_S5 (TRUE).
- **EO_S6**: Triggered upon entry into State_06 and returns the value of DO_S6 (TRUE).
- **EO_S7**: Triggered upon entry into State_07 and returns the value of DO_S7 (TRUE).
- **EO_S8**: Triggered upon entry into State_08 and returns the value of DO_S8 (TRUE).

Data Inputs

- This function block has no data inputs.

Data Outputs

- **STATE_NR** (SINT): Current state number. START = 0, State_01 = 1, State_02 = 2, ..., State_08 = 8. The values are loaded from the constant library sequence.
- **DO_S1** (BOOL): Is TRUE when state State_01 is active.
- **DO_S2** (BOOL): Is TRUE when state State_02 is active.
- **DO_S3** (BOOL): Is TRUE when state State_03 is active.
- **DO_S4** (BOOL): Is TRUE when state State_04 is active.
- **DO_S5** (BOOL): Is TRUE when state State_05 is active.
- **DO_S6** (BOOL): Is TRUE when state State_06 is active.
- **DO_S7** (BOOL): Is TRUE when state State_07 is active.
- **DO_S8** (BOOL): Is TRUE when state State_08 is active.

Adapters

- This function block does not use any adapters.

Functionality

The sequence_E_08 function block is implemented as a BASIC function block with a detailed Execution Control Chart (ECC). The logic follows a linear sequence of states (sState_01 to sState_08), a start/idle state (sState_00), and an explicit reset state (sRESET).

Three actions are performed on each state transition:

1. **Exit action of the previous state**: An algorithm (State_XX_X) sets the corresponding data output (DO_Sx) to FALSE.
2. **Confirmation Action of the New State**: A State_XX_C algorithm sets the STATE_NR and triggers the CNF event.
3. **Entry Action of the New State**: A State_XX_E algorithm sets the corresponding data output (DO_Sx) to TRUE and triggers the corresponding EO_Sx event.

A RESET event leads directly to the sRESET state. There, exit algorithms set *all* potentially active outputs (DO_S1 to DO_S8) to FALSE. An automatic transition then occurs (Condition=1, i.e., always true) to sState_00 (START).

Technical Features

- **Event-Based Transitions**: State transitions are strictly tied to the occurrence of defined events. There are no time- or data-triggered transitions.

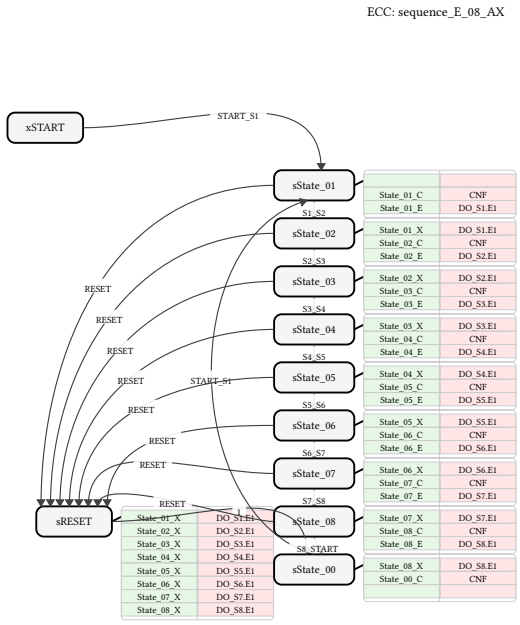
- **Explicit Reset Path**: The reset process runs through a dedicated state (`sRESET`), which ensures that all outputs are deactivated before the start state (`sState_00`) is reached. This ensures a clean and defined restart.
- **Consistent Interface**: The naming convention for events (e.g., `S1_S2`) makes the expected transition intuitively understandable.
- **Use of Constants**: The state numbers (`STATE_NR`) are retrieved from a central constant library (`sequence`), which improves maintainability and consistency.

State Overview

- **sState_00**: Start or idle state. `STATE_NR` = 0. All outputs are `FALSE`.
- **sState_01** to **sState_08**: Active process states 1 to 8. The respective output `DO_Sx` corresponds to `TRUE`, and `STATE_NR` corresponds to the state number.
- **sRESET**: Intermediate state during a reset operation. Resets all outputs.
- **xSTART**: Initial ECC state (only executed once at application startup).

Application Scenarios

- **Sequential Control Systems**: Control of machines with clearly sequential workflows, such as presses, welding systems, or packaging machines.
- **Handling Devices**: Control of a robot arm that picks up, transports, and places parts sequentially.
- **Test Stands**: Automated sequence of test and inspection steps on a component.
- **Batch Processes**: Control of reactors or mixing vessels in which different ingredients must be added or process parameters changed sequentially.



⚖️ Comparison with similar building blocks

- **VS. `E_R_TRIG` / `E_F_TRIG`**: These building blocks detect edges. `sequence_E_08`It typically uses such edge detectors as a source for its transition events, but is itself a complex state machine.
- **VS. `E_DELAY`**: A pure delay component. `sequence_E_08` can implement time-controlled processes through external timers and appropriate linking, but does not offer integrated timing by default.
- **VS. `E_SR` (Flip-Flop)**: An elementary memory component with set/reset functionality. `sequence_E_08` can be understood as a chain of such memories, where setting a state implies resetting the previous one.
- **VS. SFC (Sequential Function Chart)**: Its operation is essentially the same as a simple SFC sequence. `sequence_E_08` encapsulates this SFC-like logic in a reusable function block.

Conclusion

The `sequence_E_08` is a robust and well-structured tool for implementing event-driven sequences in IEC 61499. Its clear interface and explicit reset mechanism make it reliable and easy to integrate into higher-level controllers. It is ideally suited for applications where a fixed, linear sequence of actions is driven by external signals (e.g., limit switches, user commands). For cyclical or complex branched sequences, the function block would need to be extended or a different approach chosen.

sequence_E_08_AX

sequence_E_08_AX_AX

• – ○ • – ○ • – ○ •

Introduction

The function block **sequence_E_08_AX_AX** implements a sequential control loop with eight output stages. It enables the step-by-step switching of states, with each state being exited by an event via an AX adapter input. An AX adapter provides a unidirectional interface with a data value (`D1`) that is transferred from the input adapter to the corresponding output adapter upon entering a state. The block is designed for use in automation systems that require a clear, event-driven sequence of steps.

Interface Structure

Event Inputs

Name	Type	Comment
`S8_START`	Event	Jumps from `State_08` back to the initial state `START`
`RESET`	Event	Resets from any state back to the initial state `START`

Event Outputs

Name	Type	Comment
`CNF`	Event	Confirmation of execution (coupled with `STATE_NR`)

Data Inputs

None (state transitions are controlled exclusively via events).

Data Outputs

Name	Type	Comment
`STATE_NR`	SINT	Current state number: `START` = 0, `State_01` = 1, ..., `State_08` = 8

Adapter

Plugs (Outputs – Unidirectional AX Adapter)

Name	Type	Comment
DO_S1	adapter::types::unidirectional::AX	Output active when State_01 is active
DO_S2	adapter::types::unidirectional::AX	Output active when State_02 is active
DO_S3`	adapter::types::unidirectional::AX	Output active when State_03 is active
DO_S4`	adapter::types::unidirectional::AX	Output active when State_04 is active
DO_S5`	adapter::types::unidirectional::AX	Output active when State_05 is active
DO_S6`	adapter::types::unidirectional::AX	Output active when State_06 is active
DO_S7	adapter::types::unidirectional::AX	Output active when State_07 is active
DO_S8	adapter::types::unidirectional::AX	Output active when State_08 is active

Sockets (Inputs – Unidirectional AX Adapter)

Name	Type	Comment
DI_S1	adapter::types::unidirectional::AX	Jumps from START to State_01
DI_S2	adapter::types::unidirectional::AX	Jumps from State_01 to State_02
DI_S3	adapter::types::unidirectional::AX	Jumps from State_02 to State_03
DI_S4	adapter::types::unidirectional::AX	Jumps from State_03 to State_04
DI_S5	adapter::types::unidirectional::AX	Jumps from State_04 to State_05
DI_S6	adapter::types::unidirectional::AX	Jumps from State_05 to State_06
DI_S7	adapter::types::unidirectional::AX	Jumps from State_06 to State_07
DI_S8	adapter::types::unidirectional::AX	Jumps from State_07 to State_08

Functionality

The function block operates on the principle of an event-driven step sequence. After starting, it is in state xSTART. As soon as an event arrives at socket DI_S1, it switches to state sState_01. Upon entering a state, the current data value of the associated input adapter (DI_Sx.D1) is transferred to the corresponding output adapter (DO_Sx.D1), and simultaneously, the event CNF with the current state number (STATE_NR) is triggered. When the component exits a state (e.g., due to an event at the next DI_Sx), the corresponding output adapter is set to FALSE (exit algorithm). The transition occurs stepwise: State_01 → State_02 → ... → State_08. After State_08, the event S8_START returns the component to the idle state sState_00. From there, a new sequence can be started with DI_S1. The event RESET interrupts the sequence at any time, sets all output adapters to FALSE, and returns to the idle state sState_00.

Technical Features

- **Use of AX Adapters**: All inputs and outputs are implemented as unidirectional AX adapters, which transmit a data value (D1) in addition to the event channel. This allows not only the event but also an associated value (e.g., a setpoint for an actuator) to be transmitted during a state change.
- **Entry/Exit Logic**: Deterministic state changes are ensured by the strict separation of entry (State_xx_E) and exit (State_xx_X) actions. The output of a state is always deactivated upon exiting to prevent looping.
- **Configurable Start Condition**: The input DI_S1 serves as the start condition both on the initial startup and after each sequence iteration. The separate event input S8_START allows for a manual or externally triggered return from the last state.
- **State Numbering**: The output STATE_NR always outputs the current state number, with 0 corresponding to the idle state.

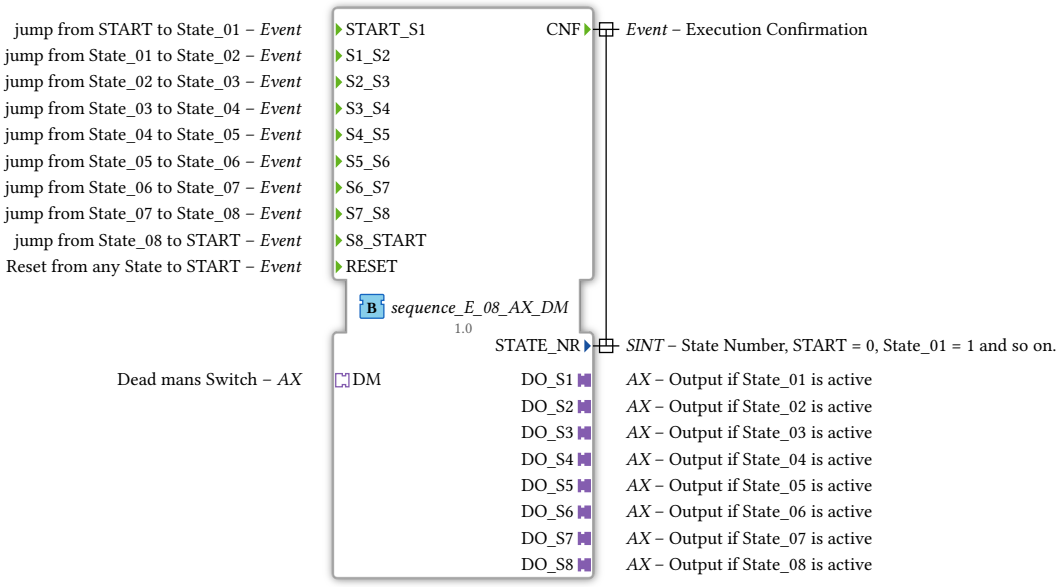
State Overview

State (ECC)	Meaning	Actions
xSTART	Initial sleep state after activation	No output, expects DI_S1
sState_01	First step of the sequence	Sets DO_S1.D1 to DI_S1.D1; output STATE_NR=1
sState_02	Second step	Sets DO_S2.D1 to DI_S2.D1; STATE_NR=2
sState_03	Third step	Sets DO_S3.D1 to DI_S3.D1; STATE_NR=3
sState_04	Fourth Step	Sets DO_S4.D1 to DI_S4.D1; STATE_NR=4
sState_05	Fifth Step	Sets DO_S5.D1 to DI_S5.D1; STATE_NR=5
sState_06	Sixth Step	Sets DO_S6.D1 to DI_S6.D1; STATE_NR=6
sState_07`	Seventh Step	Sets DO_S7.D1 to DI_S7.D1; STATE_NR=7
sState_08	Eighth Step	Sets DO_S8.D1 to DI_S8.D1; STATE_NR=8
sState_00	Idle State After Sequence Iteration or Reset	No Output; STATE_NR=0
sRESET	Intermediate State on Reset	Sets **all** DO_Sx.D1 toFALSE; then transition to sState_00

Application Scenarios

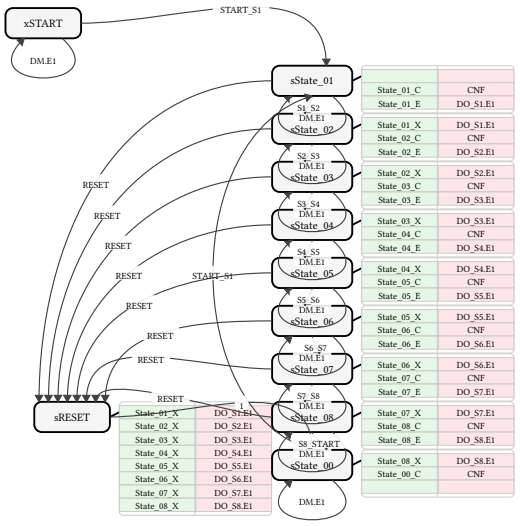
- **Multi-stage Conveyor Control**: Each step activates a different conveyor section or a different diverter. The data value D1 can contain the speed or the direction of travel.
- **Program Flow in Machine Tools**: E.g., sequential approach to tools or stations, where each step receives a configurable parameter (e.g., pressure, temperature) via the AX adapter.
- **Lighting Control with Scenes**: Eight steps can activate different lighting scenes, where the data value of a scene (e.g., brightness values) is transferred from the input adapter to the output.
- **Test and Inspection Sequences**: Automated test sequences with eight consecutive test steps, where the measured values of the previous step serve as the target value for the next.

Comparison with Similar Function Blocks



- **sequence_E_08 (without AX)**: A simple sequential function block that only controls Boolean signals. The function block described here extends this functionality with AX adapters, enabling the additional transfer of data values.
- **sequence_E_08_AX (with fewer adapters)**: Versions with fewer than eight stages offer a smaller number of steps, which may be sufficient or too restrictive depending on the application.
- **SFC Function Blocks (Step Function Chart)**: High-level language function blocks such as SFC allow parallel branching, which this simple sequencer does not support. However, it is significantly more resource-efficient and deterministic in its execution.

The function block presented here represents an optimized compromise between flexibility (through AX adapters) and clarity – ideal for standard step sequences with data transfer.



Conclusion

The sequence_E_08_AX_AX function block is a modular, event-driven sequencer with eight stages. Using AX adapters, it enables compact data transfer between steps. Its clear entry/exit logic, separate reset behavior, and state numbering make it a reliable tool for simple to medium-complexity sequence control applications in automation technology. It is particularly advantageous when each step needs to transmit not only a signal but also a configurable value to the actuator.

sequence_E_08_AX_DM

ECC: sequence_E_08_AX_DM

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_E_08_AX_DM` implements an event-driven sequence control with eight sequentially switchable outputs. It is based on a finite state machine with nine states and allows switching between states via explicit events. An integrated deadman switch (DM) allows monitoring and controlled reset of the outputs. The function block is specifically designed for use in safety-critical or monitored control sequences in agricultural technology.

Interface Structure

Event Inputs

Event	Description
START_S1	Transition from start state to state 1 (State_01)

Plug	DO_S1	unidirectional::AX	Output for state 1 (State_01 active)
Plug	DO_S2	unidirectional::AX	Output for State 2 (State_02 active)
Plug	DO_S3	unidirectional::AX	Output for State 3 (State_03 active)
Plug	DO_S4	unidirectional::AX	Output for State 4 (State_04 active)
Plug	DO_S5	unidirectional::AX	Output for State 5 (State_05 active)
Plug	DO_S6	unidirectional::AX	Output for State 6 (State_06 active)
Plug	DO_S7	unidirectional::AX	Output for State 7 (State_07 active)
Plug	DO_S8	unidirectional::AX	Output for state 8 (State_08 active)
Socket	DM	unidirectional::AX	Deadman switch; returns the event DM.E1 and the data value DM.D1

Functionality

The function block operates as a finite automaton with the following states: `xSTART` (initial), `sState_01` to `sState_08` (active sequence states), `sState_00` (start/wait state after sequence completion), and `sRESET` (intermediate state for reset).

Start and Process: After starting, the automaton is in state `xSTART`. The event `START_S1` transitions it to state `sState_01`. From there, the events `S1_S2`, `S2_S3`, ... up to `S7_S8` sequentially cycle through the eight states. The last state, `sState_08`, is transitioned to state `sState_00` by `S8_START`. This state serves as the rest point after the sequence and can be restarted via `START_S1`.

... - **Outputs**: Each state activates the corresponding plug adapter (`DO_Sx`). Upon entering a state, the data value of the deadman adapter (`DM.D1`) is passed to the output adapter (`DO_Sx.D1 := DM.D1`). Upon exiting a state, the output is deactivated (`DO_Sx.D1 := FALSE`).

- **Deadman Switch**: The event `DM.E1` triggers a self-transition in the current state (e.g., `sState_01 → sState_01`). This results in the exit and entry actions being re-executed, so that the current value from `DM.D1` is updated and passed to the output adapter. As long as the Deadman event is active (i.e., `DM.E1` occurs repeatedly), the output value remains at the current `DM.D1` state. If the Deadman event is no longer triggered, the state remains until a normal sequence event or `RESET` occurs.
- **Reset**: The event `RESET` transitions from every state (except `xSTART` and `sRESET`) to the intermediate state `sRESET`. There, all eight outputs are deactivated by calling the exit algorithms. The system then automatically transitions (with `1`) to the state `sState_00`. From there, the sequence can be restarted with `START_S1`.
- **Confirmation**: With each state change (except within `sRESET`), the event `CNF` is output with the current state number `STATE_NR`. The state number is set via the constants `sequence::State_00` to `sequence::State_08`.

Technical Features

- **Adapter-Based Outputs**: All eight outputs and the dead man's switch are implemented as unidirectional AX adapters. This allows for flexible connection to external hardware (e.g., analog or digital actuators) via the adapter frame.
- **Reusable Sequence Constants**: The state numbers are retrieved from a separate library (`logiBUS::utils::sequence::const::sequence`), allowing for consistent numbering across different sequence blocks.
- **Deadman Integration**: The deadman switch does not act as a block, but rather as a dynamic value generator for the outputs. Each state inherits the current value from `DM.D1` upon entry and can be updated by a repeated `DM.E1` event.
- **Explicit Reset**: The `RESET` event immediately deactivates all outputs and returns to a defined initial state – an important safety feature.

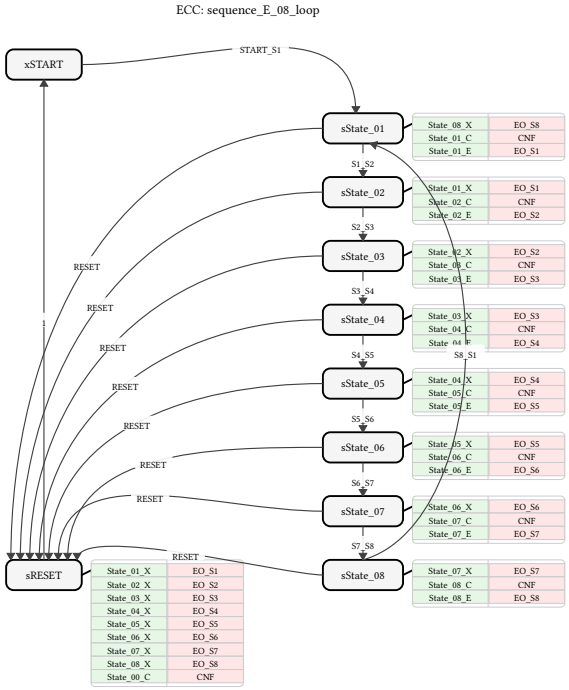
State Overview

State	Label	Output Active	Transitions
`xSTART`	Initial state	none	⟶ `sState_01` at `START_S1`; Self-transition at `DM.E1`
`sState_01`	Sequence step 1	`DO_S1`	⟶ `sState_02` at `S1_S2`; Self-transition at `DM.E1`; ⟶ `sRESET` at `RESET`
`sState_02`	Sequence step 2	`DO_S2`	⟶ `sState_03` at `S2_S3`; Self-translation at `DM.E1`; ⟶ `sRESET` at `RESET`
`sState_03`	Sequence step 3	`DO_S3`	⟶ `sState_04` at `S3_S4`; Self-translation at `DM.E1`; ⟶`sRESET` at `RESET`
`sState_04`	Sequence step 4	`DO_S4`	⟶ `sState_05` at `S4_S5`; Self-translation at `DM.E1`; ⟶ `sRESET` at `RESET`
`sState_05`	Sequence step 5	`DO_S5`	⟶ `sState_06` at `S5_S6`; Self-translation at `DM.E1`; ⟶ `sRESET` at `RESET`
`sState_06`	Sequence step 6	`DO_S6`	⟶ `sState_07` at `S6_S7`; Self-translation at `DM.E1`; ⟶ `sRESET` at `RESET`

sState_07	Sequence step 7	DO_S7	→ sState_08 at S7_S8; Self-translation at DM.E1; → sRESET at RESET
sState_08	Sequence step 8	DO_S8	→ sState_00 at S8_START; Self-translation at DM.E1; → sRESET at RESET
sState_00	Sleep state (after sequence)	None	→ sState_01 at START_S1; Self-transaction at DM.E1
sRESET	Reset state	All disabled	Automatic → sState_00

Application Scenarios

- **Agricultural Control Systems**: Step-by-step control of eight valves, actuators, or lighting units, e.g., for irrigation sequences or harvesting machines.
- **Safety-Monitored Processes**: Use in systems requiring a deadman's switch – the operator must keep the outputs active by repeatedly pressing the deadman switch.
- **Test and Inspection Stations**: Sequential activation of test steps with manual release by the operator (via events).
- **Modular Sequence Control**: Combination of multiple `sequence_E_08_AX_DM` blocks for more complex sequences with more than eight steps.

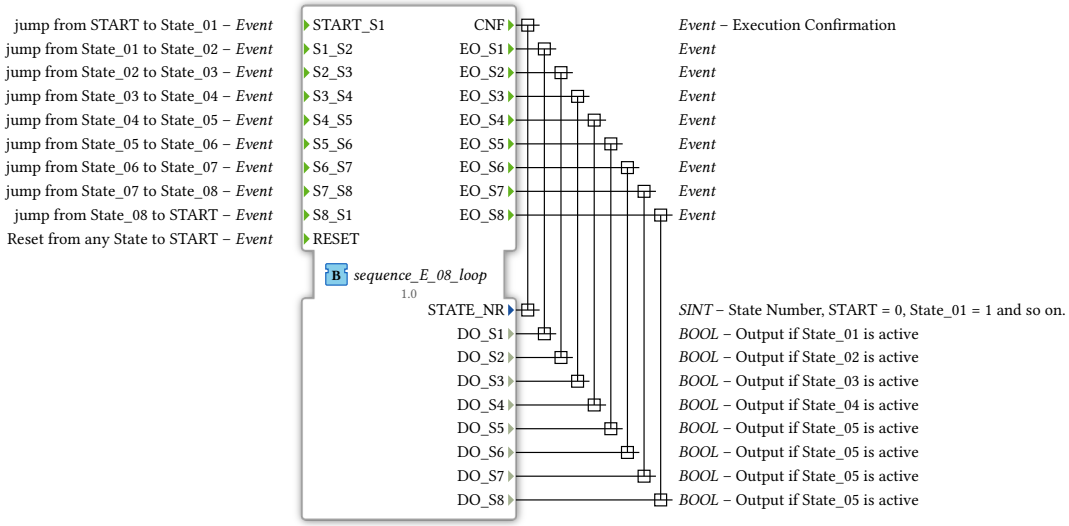


Comparison with Similar Blocks

- **`sequence_E_08_AX` (without deadman)**: Does not have a deadman switch – the outputs are permanently activated upon entry (e.g., with `TRUE`) and only deactivated upon exit. Suitable for non-critical control systems.
- **`sequence_E_04_AX_DM`**: Four-stage variant with correspondingly fewer outputs and events. Offers identical deadman functionality.
- **`sequence_T_08_AX_DM`**: Time-controlled variant – state transitions occur via timers instead of external events. Comparable deadman integration.

Conclusion

The `sequence_E_08_AX_DM` function block is a powerful and safe component for event-driven processes with up to eight steps. The integration of a deadman switch increases operational safety by requiring operator interaction. The adapter-based output interface allows for easy connection to various actuators. Thanks to its clearly structured state machine and explicit reset capability, this module is particularly suitable for safety-critical control tasks in agricultural technology and beyond.



sequence_E_08_loop

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_E_08_loop` is a sequencer with eight output states that operates in a loop. It is used to control sequential processes where each step is triggered by an external event. The block is implemented as a Basic Function Block (BasicFB) according to IEC 61499 and is suitable for applications that require a clear, event-driven state machine.

Interface Structure

Event Inputs

- `START_S1`: Changes from the start state (`START`) to the state `State_01`.
- `S1_S2`: Changes from `State_01` to `State_02`.
- `S2_S3`: Changes from `State_02` to `State_03`.
- `S3_S4`: Changes from `State_03` to `State_04`.

- S4_S5: Changes from State_04 to State_05.
- S5_S6: Changes from State_05 to State_06.
- S6_S7: Changes from State_06 to State_07.
- S7_S8: Switches from State_07 to State_08.
- S8_S1: Switches from State_08 back to state State_01 (loop).
- RESET: Resets from any state back to the initial state (START).

Event Outputs

- CNF (Execution Confirmation): Triggered on every state change and returns the current state number (STATE_NR).
- EO_S1 ... EO_S8: These are triggered upon entering the respective state (State_01 to State_08) and provide the corresponding Boolean data output (DO_S1 ... DO_S8).

Data Inputs

- None present.

Data Outputs

- STATE_NR (SINT): The number of the active state. START = 0, State_01 = 1, State_02 = 2, etc.
- DO_S1 ... DO_S8 (BOOL): Logical outputs that are TRUE when the corresponding state is active.

Adapter

- No adapter interfaces are available.

Functionality

The function block operates as an event-driven state machine (ECC). The initial state is xSTART. An incoming event at one of the named event inputs (e.g., START_S1) triggers a transition to the next state (e.g., sState_01).

Three actions are performed during each state transition:

1. **Exit action (X) of the previous state**: Sets the corresponding data output (DO_Sx) to FALSE.
2. **Confirmation action (C) of the new state**: Sets the state number STATE_NR and triggers the CNF event.
3. **Entry Action (E) of the new state**: Sets the associated data output (DO_Sx) to TRUE and triggers the corresponding event EO_Sx.

The sequence traverses states 1 through 8 linearly. From State_08, the event S8_S1 returns to State_01, creating an infinite loop. The RESET event always returns to the initial state xSTART via a dedicated reset state (sRESET), resetting all active outputs in the process.

Technical Features

- **Pure Event Trigger**: State transitions occur exclusively through external events, not through conditions or timers.
- **Explicit Reset Logic**: The reset process uses a dedicated state (sRESET) in which all possible exit actions are invoked to ensure that all outputs are disabled before the initial state is reached.
- **State Confirmation**: The CNF event and the STATE_NR output provide clear feedback on the current system status.
- **Consistent Naming Scheme**: The names of events, states, and algorithms follow a consistent scheme (e.g., S1_S2, sState_01, State_01_C), which facilitates readability and maintenance.

State Overview

The ECC (Execution Control Chart) comprises the following states:

- xSTART: Initial, inactive wait state (state number 0).
- sState_01 to sState_08: The eight active sequence states (state numbers 1-8). Each activates its specific output.
- sRESET: Dedicated reset state. Upon entering this state, all potentially active outputs (DO_S1 to DO_S8) are deactivated, the state number is set to 0, and a transition to xSTART is executed.

Application Scenarios

- Control of cyclical manufacturing or assembly processes with manual or sensor-based release for the next step.

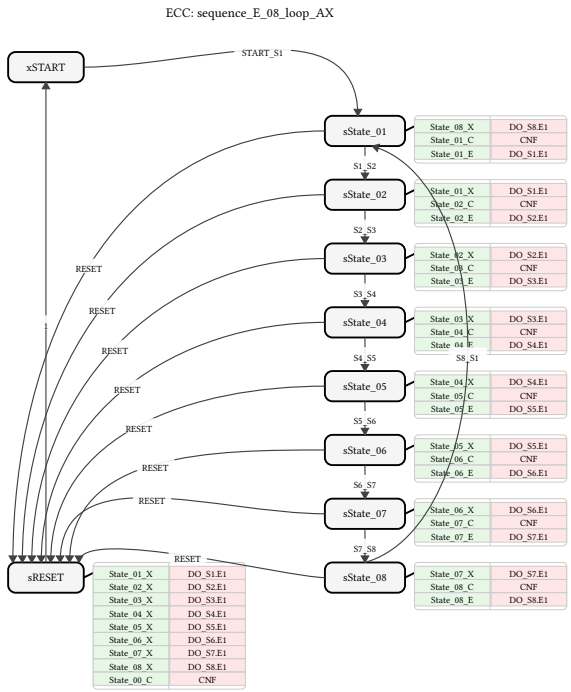
- Control of test sequences where each test step is started manually.
- Monitoring and control of batch processes where an operator initiates the next phase.
- As a central control module in machines with a clearly defined, step-by-step workflow.

⚖️ Comparison with Similar Modules

Compared to sequencers with time-controlled transitions (e.g., `sequence_T_08_loop`), this function block offers maximum flexibility because the dwell time in each state is externally defined. It has a simpler structure than building blocks with integrated error handling or complex branching, but provides a robust foundation for event-driven processes. Alternative implementations using `E_SR` or `E_CTUD` blocks would be significantly more complex and less user-friendly.

🛠️ Related Exercises

- Exercise_040
- Exercise_040_2
- Exercise_041



Conclusion

The `sequence_E_08_loop` is a specialized, reliable, and easy-to-configure function block for event-driven sequence flows. Its clear structure, consistent interface, and integrated reset functionality make it particularly suitable for applications where a step-by-step process needs to be driven by external signals (e.g., buttons, sensors, higher-level controllers). The output of the status number and the confirming events enable easy integration with visualization and monitoring systems.

sequence_E_08_loop_AX

• — ○ • — ○ • — ○ •

Introduction

sequence_E_08_loop_AXis a variant ofsequence_E_08_loop that additionally uses adapters (AX`) for the outputs. It controls a purely event-driven, cyclic sequence with 8 output states.

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence at State_01.
- **S1_S2** ... **S7_S8**: Manual transitions between states.
- **S8_S1**: Transition State_08 -> State_01 (Loop).
- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Confirmation of execution.

Data Inputs

- None.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** ... **DO_S8** (adapter::types::unidirectional::AX): Output adapters for State_01 to State_08.

Functionality

Corresponds to `sequence_E_08_loop`, but uses adapters for the outputs.

Technical Features

- Uses `adapter::types::unidirectional::AX`.

State Overview

See `sequence_E_08_loop`.

Application Scenarios

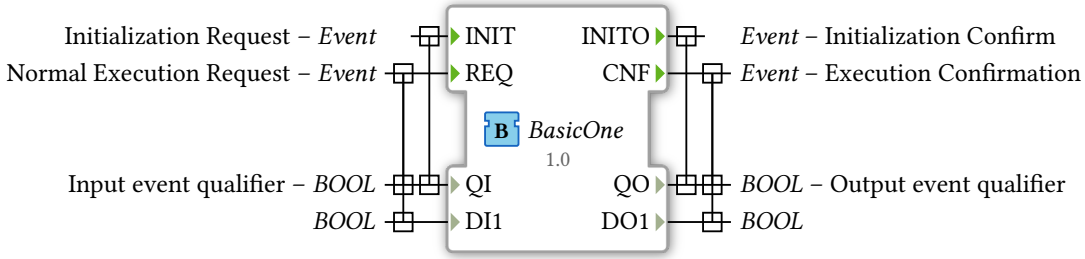
For cyclic, event-driven 8-step sequences with adapter connectivity.

⚖️ Comparison with similar modules

- **sequence_E_08_loop**: Standard version without adapter.

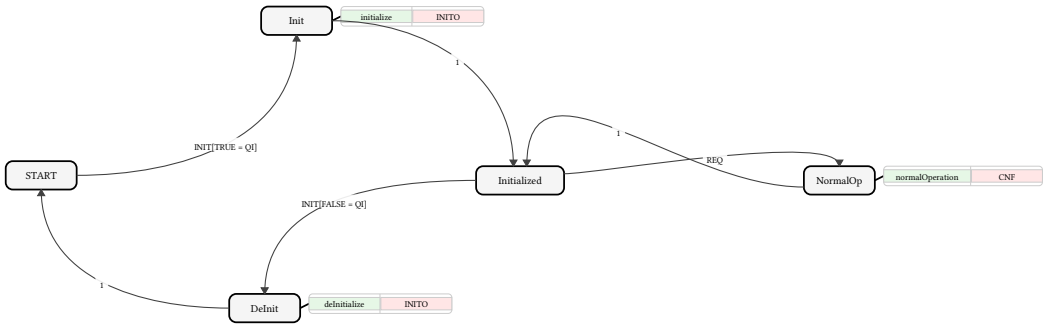
🛠️ Related Exercises

- Exercise_040_AX



Conclusion

Adapter version of the 8-step loop event sequencer.



Numeric Index (sequence)

Here you will find all exercises from the `sequence` workspace, listed in ascending order. ...

BasicOne

ECC: BasicOne

• — ○ • — ○ • — ○ •

Introduction

The **BasicOne** function block is a basic, event-driven block according to IEC 61499. It serves as a simple sequence element for initialization, execution of a main operation, and proper deinitialization. The block is particularly suitable for control sequences where a resource state (e.g., device ready) needs to be monitored and reset. The block is included in the package `logiBUS::utils::sequence::one`.

Interface Structure

Event Inputs

Event	Type	Accompanying Data	Description
INIT	EInit	QI	Initialization request; the transition depends on the value of the qualifier QI.
REQ	Event	QI, DI1	Normal execution request; starts the main operation.

Event Outputs

Event	Type	Accompanying Data	Description
INITO	Initialization	QO	Confirmation of successful initialization or deinitialization.
CNF	Event	QO, DO1	Confirmation of normal execution; outputs the current state.

Data Inputs

Name	Type	Description
QI	BOOL	Input qualifier – controls whether initialization is active (TRUE) or deinitializing (FALSE). Also affects the execution of the main operation.
DI1	BOOL	First data input; The output is only transferred to DO1 during normal operation if initialization (QI = TRUE) is active.

Data Outputs

Name	Type	Description
QO	BOOL	Output qualifier – reflects the value of QI after an action (except after deinitialization: then FALSE).
DO1	BOOL	First data output; During a normal operation, the value is DI1 if QI = TRUE is present, otherwise FALSE.

Adapter

None.

Functionality

The function block goes through a clearly defined lifecycle:

1. **Start State (START)**: After startup, the function block waits for a INIT event.
2. **Initialization (Init)**: If INIT is received with QI = TRUE, the function block executes the *initialize* algorithm. This sets QO := QI (i.e., TRUE). Then, INITO is sent, and the function block transitions to the **Initialized** state.
3. **Normal Operation (NormalOp)**: In the **Initialized** state, a REQ event can initiate normal operation. The *normalOperation* algorithm sets QO := QI (still TRUE) and, if QI = TRUE is present, transfers the value from DI1 to DO1. Afterward, CNF is sent, and the function block automatically returns to **Initialized**.

The normalOperation* algorithm sets QO := QI (still TRUE) and transfers the value from DI1 to DO1. 4. **DeInitialization**: If a INIT event with QI = FALSE is received in the **Initialized** state, the function block executes the *deInitialize* algorithm. This sets QO := FALSE and DO1 := FALSE. Subsequently, INITO is sent, and the function block returns to the **START** start state.

Important: The normal operation is only executed if QI = TRUE is present. In the REQ event, the algorithm is executed, but DO1 remains unchanged (it is not set to DI1; instead, the last value or the default value FALSE remains as defined by the algorithm – in QI = FALSE, the IF condition is not met, therefore DO1 does not change).

`QI = FALSE``

Technical Features

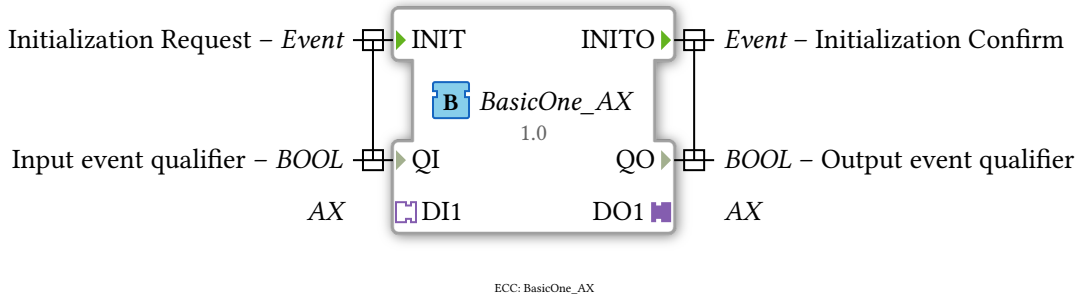
- **Event Dependency of QI**: The transitions `INIT[TRUE = QI]` and `INIT[FALSE = QI]` demonstrate that the same event, `INIT`, triggers different state transitions depending on the value of `QI`. This enables compact control of initialization and deinitialization via a single event.
- **Automatic Fallback**: After a `REQ` event, the function block returns to the **Initialized** state without an external event (transition with condition `1`). This simplifies integration into cyclic processes.
- **No Self-Locking**: The function block does not block; after each successful execution, it is ready for the next event.

State Overview

State	Description	Possible Actions
`START`	Initial idle state after system startup or deinitialization.	Waits for `INIT` with `QI = TRUE`.
`Init`	Initialization phase; sets `QO = QI`.	Executes the *initialize* algorithm, sends `INITO`.
`Initialized`	Waiting state after successful initialization.	Can respond to `REQ` (starts NormalOp) or to `INIT` with `QI = FALSE` (starts DeInit).
`NormalOp`	Executes the main operation; transfers `DI1` to `DO1` (only if `QI = TRUE`).	Executes the *normalOperation* algorithm, sends `CNF`.
`DeInit`	Deinitialization phase; sets `QO = FALSE` and `DO1 = FALSE`.	Executes the *deInitialize* algorithm, sending `INITO`.

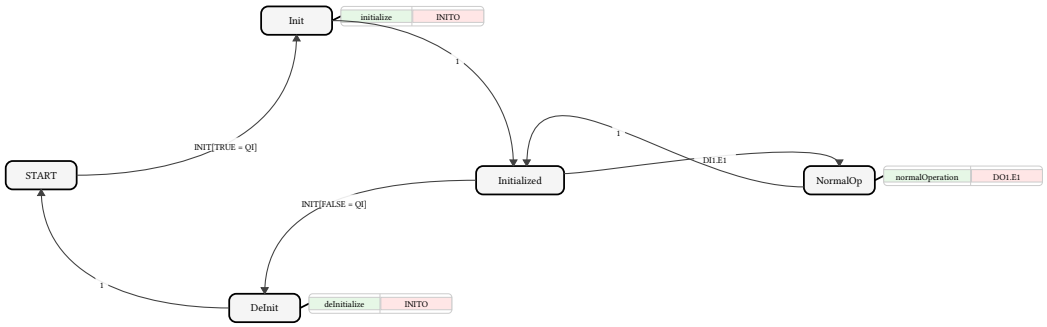
Application Scenarios

- **Initializing a Component**: A device must be configured upon power-up. Using `INIT` (QI=TRUE), the device state is set to "ready." `REQ` then executes the actual logic cyclically.
- **Resource Management**: The function block can be used as a simple sequencer for one-time initialization and subsequent deinitialization (e.g., for a database connection).
- **Safety-Oriented Control**: The qualifier `QI` ensures that the output `DO1` can only accept the input value if the function block is initialized. Deinitialization resets all outputs (`FALSE`).



Comparison with similar building blocks

- **BasicBOOLEAN**: A simple Boolean building block without a state machine that only reacts to an event and passes a value. `BasicOne`, on the other hand, offers an explicit initialization and deinitialization sequence.
- **SR Flip-Flop**: A memory building block with set and reset capabilities. `BasicOne` is more of a state machine that implements a single start and stop operation, but does not have a hold function.
- **SimpleCycle**: A cyclic building block that repeatedly performs the same operation. `BasicOne`It distinguishes between initialization and cyclic execution, allowing for a clean separation.



Conclusion

The function block `BasicOne` is an excellent basic element for control projects that require controlled initialization, reliable operation, and defined deinitialization. Its simple state machine and dependency on the qualifier `QI` make it flexible and easy to use without unnecessary complexity. It is suitable for both newcomers to the IEC 61499 world and experienced developers who need clear, reusable function blocks.

BasicOne_AX

ECC: BasicOne_AX

• – ○ • – ○ • – ○ •

Introduction

The function block `BasicOne_AX` is a basic IEC 61499 block of type *Basic Function Block*, serving as a template for simple control tasks. It implements an initializable switching of a Boolean signal using unidirectional adapter interfaces of type `AX`. The block is suitable for scenarios in which an input signal needs to be copied to an output and the initialization state needs to be monitored.

Interface Structure

Event Inputs

Event	Type	With Variables	Comment
`INIT`	`EInit`	`QI`	Initialization Request

Event Outputs

Event	Type	With Variables	Comment
`INITO`	`EInit`	`QO`	Initialization Confirmation

Data Inputs

Variable	Type	Comment

QI	BOOL	Input Qualifier (Turns initialization on/off)

Data Outputs

Variable	Type	Comment
QO	BOOL	Output Qualifier (Reflects the initialization state)

Adapter

Direction	Name	Type	Comment
Plug (Output)	DO1	adapter::types::unidirectional::AX	Unidirectional adapter for data transmission (AX interface)
Socket (input)	DI1	adapter::types::unidirectional::AX	Unidirectional adapter for receiving data (AX interface)

Functionality

The function block iterates through a finite state machine (ECC) with the states START, Init, Initialized, NormalOp, and DeInit.

- **START → Init**: Upon the occurrence of the event INIT, the process is executed with QI = TRUE. The algorithm initialize sets QO to the value of QI (i.e., TRUE). The output INITO signals successful initialization.
- **Init → Initialized**: After initialization, the automaton immediately transitions to the state Initialized (transition with condition 1). The module remains in this state until either an event arrives at socket DI1.E1 or a subsequent event, INIT, triggers deinitialization with QI = FALSE.
- **Initialized → NormalOp**: Upon arrival of the adapter event DI1.E1, the module transitions to state NormalOp. The algorithm normalOperation then performs the actual switching: If QI = TRUE is present, the value of the adapter input DI1.D1 is copied to the adapter output DO1.D1. Additionally, QO is set to the current value of QI (remaining TRUE until QI is set to FALSE).
- **NormalOp → Initialized**: After execution, the function block immediately returns to the state Initialized (transition 1), ready for the next DI1.E1 event.
- **Initialized → DeInit**: When the event INIT with QI = FALSE is received, deinitialization occurs. The algorithm deInitialize sets QO to FALSE and the adapter output DO1.D1 to FALSE. Then, INITO is output.
- **DeInit → START**: After deinitialization, the automaton returns to its initial state and awaits re-initialization.

In summary, the function block operates as a *triggered passthrough*: The adapter input is copied to the adapter output with each event at the socket, but only if the function block was previously initialized correctly (QI=TRUE for INIT).

Technical Features

- **Adapter-Based Interface**: Input/output data is not exchanged via direct variables, but rather via the unidirectional adapters DI1 and DO1 (type AX). This enables flexible coupling with other function blocks of the same adapter type.
- **Initialization Logic**: The function block distinguishes between an initialized (QI=TRUE) and a deinitialized (QI=FALSE) state. Incoming adapter events are only processed after successful initialization.
- **Package Name**: The function block is organized in the package logiBUS::utils::sequence::one, indicating its use in a logiBUS environment.
- **Automatic State Transitions**: The transitions of Init→Initialized, NormalOp→Initialized, and DeInit→START occur without any further condition (transition 1), meaning the execution of the algorithms is complete.

State Overview

The ECC (Execution Control Chart) of the module comprises five states:

State	Description
START	Waiting for the first INIT event with QI=TRUE.

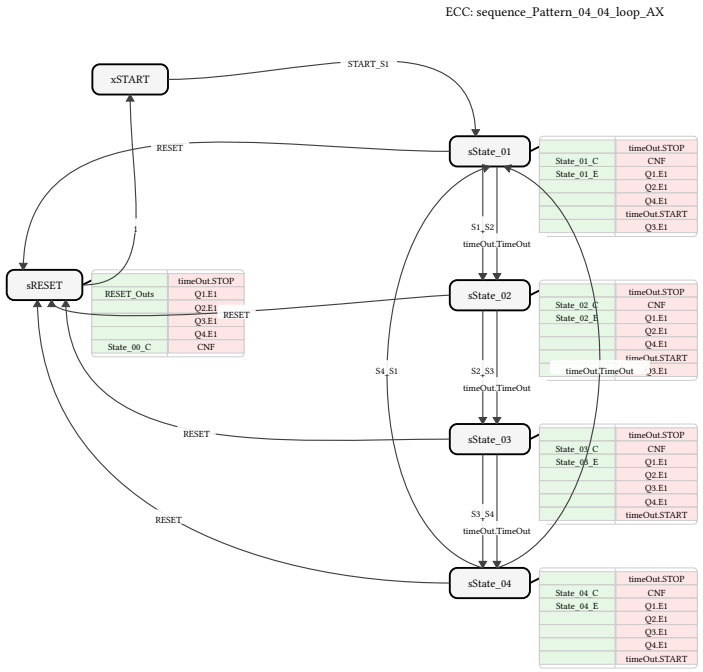
Init	Executes initialization algorithm, sets QO=QI, and sends INITO.
Initialized	Idle state after successful initialization; waits for DI1.E1 or another INIT (with QI=FALSE).
NormalOp	Performs passthrough (copies DI1.D1 to DO1.D1 if QI=TRUE is present).
DeInit	Performs deinitialization (sets QO and DO1.D1 to FALSE), sends INITO.

Application Scenarios

- **Signal Passthrough with Fuse**: A Boolean signal (e.g., enabling a process) should only be passed from a source to a sink if the function block has been initialized beforehand. Sending INIT followed by QI=FALSE again interrupts the passthrough.
- **Initialization Sequence in Manufacturing Plants**: Before production starts, the function block is initialized (e.g., checking safety conditions). Only then may actuators be controlled via DO1.
- **Data Transfer in Modular Systems**: The unidirectional adapter AX allows loose coupling between modules – the component serves as a simple "pass-through" in a data chain.

Comparison with Similar Components

- **BasicOne (without adapter)**: A typical BasicOne component uses direct input/output variables. BasicOne_AX extends this with an adapter-based interface, improving reusability and structuring in larger systems.
- **Standard E_SR (Set/Reset)**: A set/reset flip-flop stores a state, while BasicOne_AXIt has no memory function – the output follows the input only during active initialization and upon each event.
- **Move Function Block**: A MOVE block continuously copies values. In contrast, BasicOne_AX only copies upon an event (triggered) and only after successful initialization.

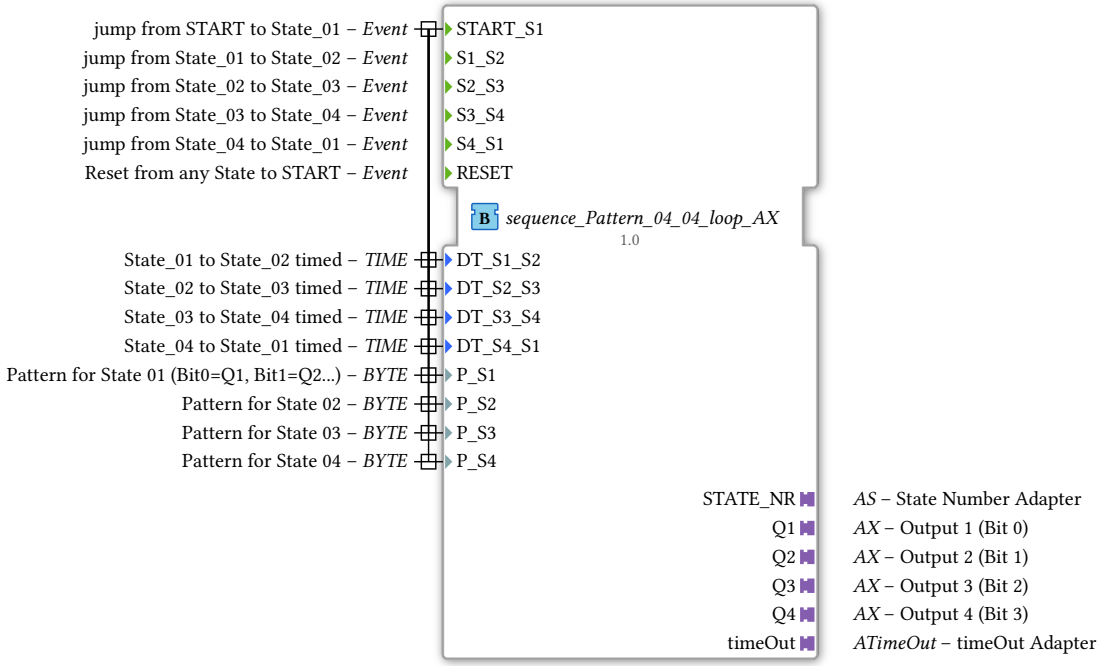


Conclusion

The BasicOne_AX is a minimalist yet robust IEC 61499 block for initialization-controlled signal switching with an adapter interface. Its clear state logic and the separation of initialization and operation make it particularly suitable for safety-critical or sequential applications where a defined start state is required before data transmission. The use of unidirectional adapters increases modularity and facilitates integration into complex automation systems.

Numerical Index (sequence)

Here you will find all exercises from the sequence workspace in ascending order. ...



sequence_Pattern_04_04_loop_AX

• — ○ • — ○ • — ○ •

Introduction

The function block **sequence_Pattern_04_04_loop_AX** is a sequencer (step switch) that controls a sequence of four states in an endless loop. It functions similarly to an electronic cam switch. A specific output pattern can be defined for each of the four steps, controlling four outputs (Q1 to Q4). The block uses **AX adapters** for the outputs and supports both timed transitions (timeouts) and event-driven manual advancement. After the fourth step, the sequence automatically or manually returns to the first step (loop behavior).

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence and jumps directly to state 1 (`State_01`). The configuration data (times and patterns) is read in.
- **S1_S2**: Manual trigger for the transition from step 1 to step 2.
- **S2_S3**: Manual trigger for the transition from step 2 to step 3.
- **S3_S4**: Manual trigger for the transition from step 3 to step 4.
- **S4_S1**: Manual trigger for the transition from step 4 back to step 1 (loop closure).
- **RESET**: Resets the function block from any state to its initial state (`START`). All outputs are deactivated.

Event Outputs

- **CNF**: Execution Confirmation Event. Fires when the state changes or the function block is initialized.

Data Inputs

- **DT_S1_S2** (TIME): Dwell time in step 1 before automatically switching to step 2. Default value: `NO_TIME` (no automatic switch).
- **DT_S2_S3** (TIME): Dwell time in step 2.
- **DT_S3_S4** (TIME): Dwell time in step 3.
- **DT_S4_S1** (TIME): Dwell time in step 4 before automatically switching back to step 1.
- **P_S1** (BYTE): Output pattern for step 1.
- Bit 0 controls Q1
- Bit 1 controls Q2
- Bit 2 controls Q3
- Bit 3 controls Q4
- **P_S2** (BYTE): Output pattern for step 2.
- **P_S3** (BYTE): Output pattern for step 3.
- **P_S4** (BYTE): Output pattern for step 4.

Data Outputs

- **STATE_NR** (SINT): Current state number (0 = START, 1 = State_01, ..., 4 = State_04).

Adapter

- **Q1** (`adapter::types::unidirectional::AX`): Output 1 (controlled by bit 0 of the pattern).
- **Q2** (`adapter::types::unidirectional::AX`): Output 2 (controlled by bit 1 of the pattern).
- **Q3** (`adapter::types::unidirectional::AX`): Output 3 (controlled by bit 2 of the pattern).
- **Q4** (`adapter::types::unidirectional::AX`): Output 4 (controlled by bit 3 of the pattern).
- **timeOut** (`iec61499::events::ATimeOut`): Internal adapter for managing time delays (timers).

Functionality

The function block implements a state machine (ECC) that cycles through four active states.

1. **Initialization**: The function block starts in state `xSTART`. Upon the event `START_S1`, it transitions to state `sState_01`.
2. **State Processing**: In each state (`sState_01` to `sState_04`):

- The timer (`timeOut`) is stopped and restarted with the corresponding time (`DT_xx`).
- The current state number (`STATE_NR`) is updated and sent (`CNF`).
- The outputs (`Q1` to `Q4`) are set based on the corresponding input byte (`P_Sx`). The mapping is bitwise (bit 0 -> Q1, bit 1 -> Q2, etc.).
- The outputs (`Q1` to `Q4`) are set based on the corresponding input byte (`P_Sx`). * Events are fired at the adapters `Qx` (`Qx.E1`) to signal the data change.

1. **Transitions**: A transition to the next step occurs either:

- **Automatic**: When the configured time (`DT_...`) has expired (`timeOut.TimeOut`).
- **Manual**: When the explicit transition event (e.g., `S1_S2`) arrives.

1. **Loop**: After `sState_04`, the transition back to `sState_01` (loop) occurs, unless a reset is triggered.
2. **Reset**: The `RESET` event causes all outputs to be set to `FALSE`, `STATE_NR` to be reset to 0, and the function block to wait for a new start command in the `xSTART` state.

Technical Features

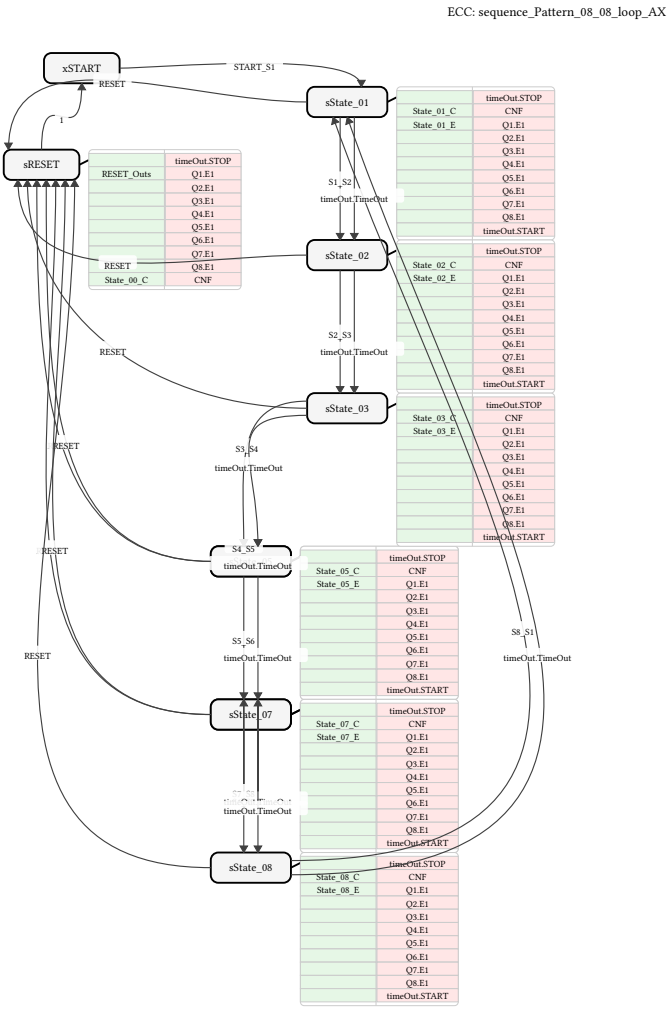
- **Bit Mapping**: Output control is efficiently achieved via byte patterns. This allows any combination of the four outputs per step to be defined with a single parameter.
- Example: `P_S1 = 5` (binary `0000 0101`) activates Q1 and Q3.
- **AX Adapter**: The use of AX adapters indicates that this function block is designed for modular systems where actuators are connected via standardized interfaces.
- **Time & Event Duality**: The flexibility to exit steps based on both time and event allows for mixed operating modes (e.g., Step 1 exits after a time delay, Step 2 waits for manual confirmation).

State Overview

State	Description	Exit Logic (Q1-Q4)	Next State (Auto/Manual)
xSTART	Idle State	Inactive	sState_01 (via `START_S1`)
sState_01	Step 1	P_S1	sState_02
sState_02	Step 2	P_S2	sState_03
sState_03	Step 3	P_S3	sState_04
sState_04	Step 4	P_S4	sState_01 (Loop)
sRESET	Reset Logic	All FALSE	xSTART

Application Scenarios

- **Running Light / Flashing Light**: Simple cyclical light control.
- **Cam Switch Simulation**: Control of recurring machine cycles (e.g., gripping, lifting, moving, lowering).
- **Traffic Light Control**: Simple traffic light phases can be implemented by adjusting the `DT` times (where 4 steps are usually sufficient, e.g., red, red-yellow, green, yellow).
- **Test Pattern Generator**: Generation of defined signal sequences for testing purposes.



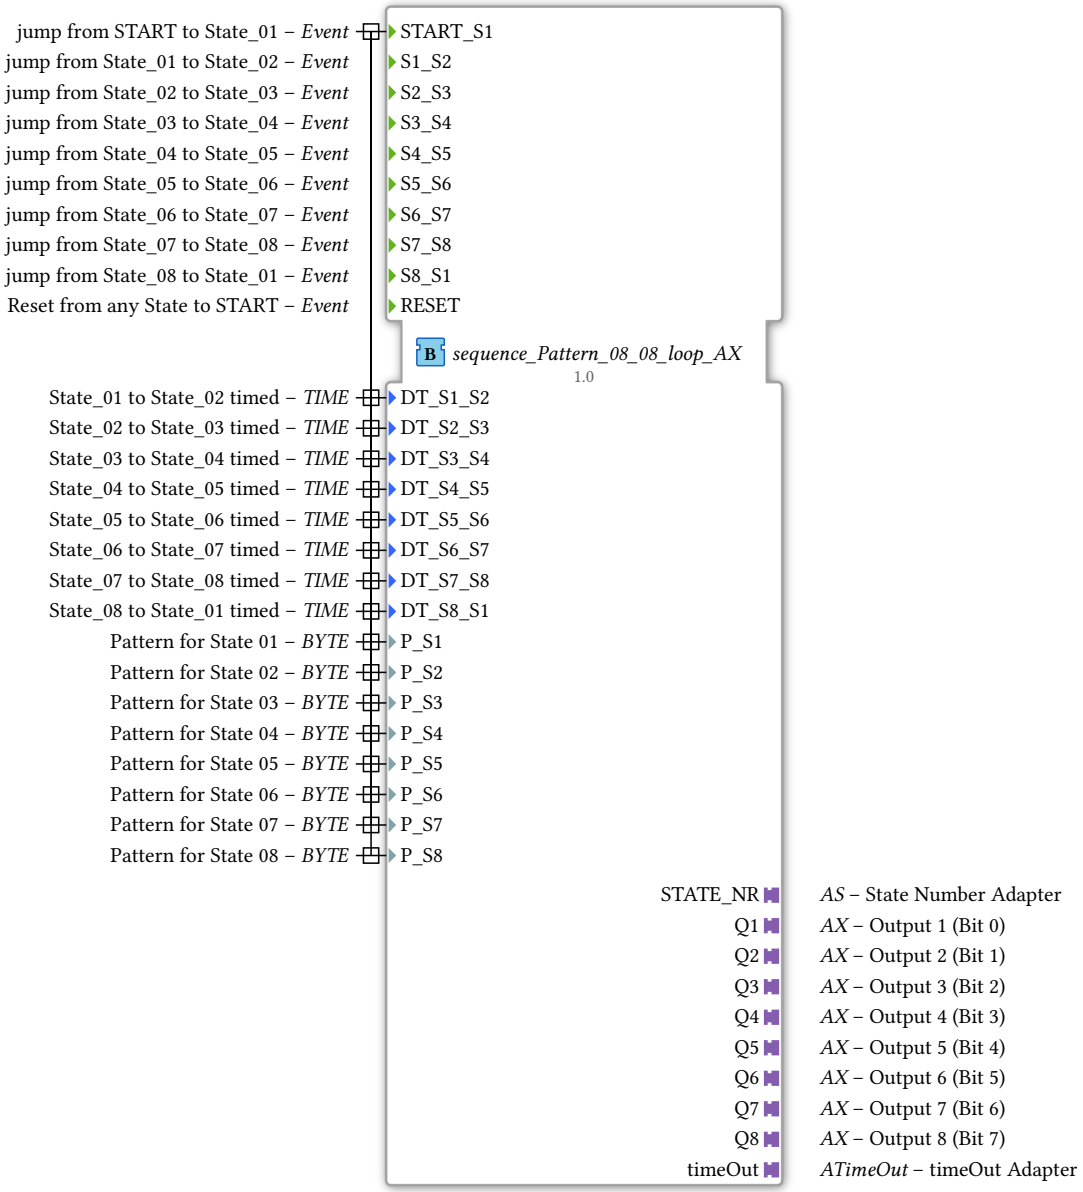
⚖️ Comparison with Similar Function Blocks

Unlike simple counters, this function block offers integrated timers per step and direct pattern assignment. Compared to more complex sequencers (e.g., SFC / Sequential Function Chart), it is more compact but limited to exactly 4 steps and 4 outputs. The “loop” variant differs from “single-shot” sequencers in that it does not stop at the end but repeats indefinitely.

Conclusion

The `sequence_Pattern_04_04_loop_AX` is a robust and flexible function block for small, cyclic control tasks in IEC 61499 applications. Its combination of time and event control, along with direct bit-to-adapter assignment, makes it ideally suited for repetitive automation sequences.

sequence_Pattern_08_08_loop_AX



• – ○ • – ○ • – ○ •

Introduction

The function block **sequence_Pattern_08_08_loop_AX** is a sequencer (step chain) that implements a configurable cam switch with 8 states (steps) and 8 outputs. It is designed to operate cyclically (loop behavior), transitioning from step 8 back to step 1.

This block allows the definition of bit patterns for each of the 8 steps, which are output via special adapters (AX interface). Transitions between states can be either event-driven or time-controlled.

Interface Structure

Event Inputs

- **START_S1**: Initializes the sequence and jumps directly to state 1 (`State_01`). This event also inherits the parameterized time values (`DT_...`) and bit patterns (`P_...`).
- **S1_S2** to **S8_S1**: Manual trigger events to immediately switch from the current state to the next (e.g., `S1_S2` jumps from state 1 to 2).
- **RESET**: Resets the function block from any state to the initial state (`START`) and disables all outputs.
- **S1_S2** to **S8_S1**: Manual trigger events to immediately switch from the current state to the next (e.g., `S1_S2` jumps from state 1 to 2).

Event Outputs

- **CNF**: Execution Confirmation event. It fires as soon as a new state is reached and the outputs are updated.

Data Inputs

- **DT_S1_S2** to **DT_S8_S1** (Type: `TIME`): Define the dwell time in the respective state before automatically switching to the next one. The default value is `NO_TIME` (no automatic switching based on time).
- **P_S1** to **P_S8** (Type: `BYTE`): Define the output pattern for the respective state.

- Bit 0 controls adapter Q1
- Bit 1 controls adapter Q2
- ...
- Bit 7 controls adapter Q8

Data Outputs

- **STATE_NR** (Type: `SINT`): Outputs the current state number (0 = START, 1 = State_01, ..., 8 = State_08).

Adapters

- **Q1** to **Q8** (Type: `adapter::types::unidirectional::AX`): The 8 physical or logical outputs. Each adapter receives a data signal (`D1`) and an event signal (`E1`).
- **timeOut** (Type: `iec61499::events::ATimeOut`): An internal adapter for handling timed transitions between steps.

Functionality

The component operates as a finite state machine with a cyclic structure:

1. **Initialization**: The sequence is started by the event `START_S1`. The configured time values and bit patterns are read in. The state machine transitions to **State_01**.
2. **State Logic**: In each state (`State_01` to `State_08`), the corresponding byte pattern (`P_Sn`) is parsed.

- If bit 0 of `P_S1` is set, `Q1.D1` is set to TRUE.
- If bit 1 of `P_S1` is set, `Q2.D1` is set to TRUE, and so on.
- Simultaneously, the event `E1` is triggered on all adapters `Q1` through `Q8` to signal the change.

1. **Transitions**: The transition to the next state occurs when:

- The explicit event is received (e.g., `S1_S2`).
- OR the configured time (`DT_S1_S2`) has expired (via the `timeOut` adapter).
- 1. **Cycle**: After **State_08**, the process transitions back to **State_01** (`S8_S1` or timeout), creating an infinite loop.

1. **Reset**: The event `RESET` immediately interrupts the process, sets all outputs (`Q1` to `Q8`) to `FALSE`, and sets the state number to 0.

Technical Features

- **AX Adapter Usage**: Instead of classic `BOOL` outputs, this function block uses adapters of type `AX`. This allows for more flexible integration, e.g., with hardware abstraction layers or complex actuators that require an event signal for data transfer.
- **Bit Mapping**: The 8 outputs are efficiently controlled via `BYTE` variables. This drastically reduces the number of required input pins on the function block compared to individual Boolean inputs per step and output.
- **Hybrid Control**: The function block supports both time-controlled (timer) and event-controlled (external trigger) sequences, making it highly flexible.

State Overview

State ID	Name	Description	Output Logic	Transition to
0	xSTART	Waiting State / Reset	None	State_01 (at START_S1)
1	sState_01	Step 1	Q1-Q8 according to P_S1	State_02
2	sState_02	Step 2	Q1-Q8 according to P_S2	State_03
3	sState_03	Step 3	Q1-Q8 according to P_S3	State_04
4	sState_04	Step 4	Q1-Q8 according to P_S4	State_05
5	sState_05	Step 5	Q1-Q8 according to P_S5	State_06
6	sState_06	Step 6	Q1-Q8 according to P_S6	State_07

7	sState_07	Step 7	Q1-Q8 according to P_S7	State_08
8	sState_08	Step 8	Q1-Q8 according to P_S8	State_01 (Loop)
-	sRESET	Reset State	Q1-Q8 = FALSE	xSTART

Application Scenarios

- **Running Light Controls**: A simple running light effect can be implemented by setting `P_S1=1`, `P_S2=2`, `P_S3=4`, etc.
- **Cam Switches**: Control of mechanical processes where multiple actuators (cylinders, valves) must be activated in a fixed sequence.
- **Traffic Light Controls**: Cyclic sequence of red-yellow-green phases.
- **Cleaning Cycles**: Rinsing, washing, and drying at recurring intervals.
-

⚖️ Comparison with Similar Function Blocks

Unlike linear sequencers (without a loop), this function block is explicitly designed for recurring processes. It differs from simple counters in that an individual output pattern and time can be defined for each step. The use of AX adapters distinguishes it from standard IEC 61499 function blocks, which mostly use direct Boolean outputs, and makes it ideal for structured, object-oriented control designs.

Conclusion

The **sequence_Pattern_08_08_loop_AX** is a powerful and compact function block for implementing complex, cyclic sequences. Parameterization via byte patterns and time values allows for the implementation of diverse control tasks without modifying the internal logic. The integrated reset functionality and adapter interface ensure seamless integration into modern 4diac applications.

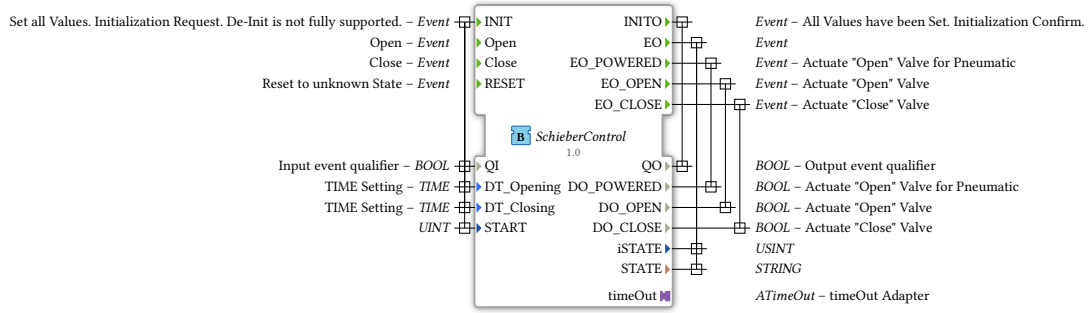
slider



Slide Control

• – ○ • – ○ • – ○ •

Introduction

The function block `SchieberControl` is a basic function block (FB) according to IEC 61499 for controlling a slide actuator (e.g., pneumatic). It implements a complete state control (ECC) that manages the movement (open/close), holding states, and fault states of a slide. The block offers an interface for parameterization, operation via the `Open`, `Close`, and `RESET` events, as well as for outputting the state and control signals to the actuators.

Interface Structure

Event Inputs

- **`INIT`**: Initialization request. Sets all values. A complete de-initialization is not fully supported. Associated with the data `QI`, `DT_Opening`, `DT_Closing`, and `START`.
- **`Open`**: Starts the opening process of the slide.
- **`Close`**: Starts the closing process of the slide.
- **`RESET`**: Resets the internal state to “Unknown”.

Event Outputs

- **`INITO`**: Initialization confirmation. Linked to the data output `QO`.

- **EO**: General output event that provides the current system state and the configured output values. Linked to iSTATE and STATE.
- **EO_POWERED**: Control signal for actuating the "open" valve for the pneumatic system. Linked to DO_POWERED.
- **EO_OPEN**: Control signal for actuating the "open" valve. Linked to DO_OPEN.
- **EO_CLOSE**: Control signal for actuating the "close" valve. Linked to DO_CLOSE.

Data Inputs

- **QI (BOOL)**: Qualifier for the INIT event.
- **DT_Opening (TIME)**: Time duration for the opening process.
- **DT_Closing (TIME)**: Duration of the closing process.
- **START (UINT)**: Defines the desired start state after initialization (e.g., START::STARTClosed, START::STARTOpened, START::STARTUnknown).

Data Outputs

- **QO (BOOL)**: Qualifier for the INITO event.
- **DO_POWERED (BOOL)**: Binary signal to actuate the "open" valve for the pneumatics.
- **DO_OPEN (BOOL)**: Binary signal to actuate the "open" valve.
- **DO_CLOSE (BOOL)**: Binary signal to actuate the "close" valve.
- **iSTATE (USINT)**: Numeric value of the current internal state of the function block (output with EO).
- **STATE (STRING)**: String describing the current internal state of the function block (e.g., "Closed", "Opening").

Adapter

- **timeOut (ATimeOut)**: A plug adapter of type ATimeOut. Used to implement time-controlled state transitions (open/close). The function block (FB) starts (START) and stops (STOP) the timer and reacts to its TimeOut event.

Functionality

The SchieberControl FB operates as a state-controlled sequence. The internal control flow graph (ECC) defines the states Closed (Closed), Opened (Open), Opening (Opening), Closing (Closing), various STOP states, and Unknown (Unknown). Each state change triggers a corresponding algorithm that sets the data outputs (such as DO_OPEN, iSTATE, STATE) and, if necessary, starts the timer adapter. The movement between Closed and Opened is time-controlled via the states Opening and Closing. During a movement, a stop can be initiated by the opposite event (Open during Closing or Close during Opening), which transitions to the corresponding STOP state. From any state, a RESET event can move the function block to the Unknown state.

Technical Features

- **State Initialization**: The desired initial state (State_01, State_02, or State_03) can be specified via the START input after INIT.- **Adapter Usage**: The timing control is completely outsourced to the timeOut adapter, enabling a clear separation of functionality and potential reusability.
- **State Output**: The current state is output both numerically (iSTATE, USINT) and as text (STATE, STRING) with the EO event, so it can be evaluated by user interfaces.
- **Power Signal**: The signal DO_POWERED is only activated in states Opening and Opened, indicating a specific pneumatic control logic (e.g., maintaining compressed air in the open state).

State Overview

The ECC comprises the following main states:

1. **START**: Inactive initial state.
2. **Init/INIT3**: Initialization sequence.
3. **Closed**: Final state "closed". Activates DO_CLOSE.
4. **Opened**: Final state "open". Activates DO_OPEN and DO_POWERED.
5. **Opening/Closing**: Motion states. Start the timer with DT_Opening/DT_Closing and activate the corresponding actuator signals as well as DO_POWERED (only with Opening).
6. **Opening_STOP/Closing_STOP**: Stop states during movement, triggered by the opposite command. Deactivate DO_OPEN/DO_CLOSE and stop the timer.
7. **Opening_STOP_R/Closing_STOP_R**: Stop states during movement, triggered by RESET. This leads to the Unknown state.

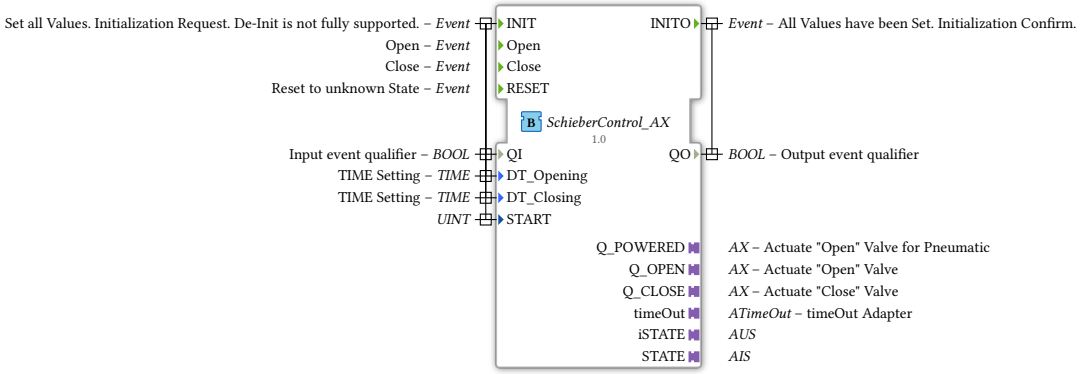
8. **`Unknown`**: Error or unknown state. Resets all actuator signals.

Application Scenarios

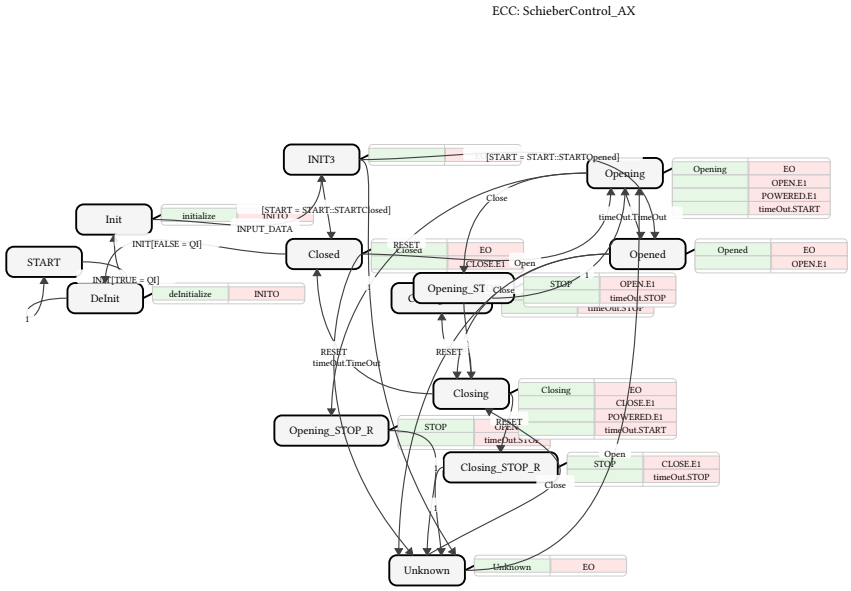
- **Control of pneumatic slides** in packaging, conveying, or sorting systems.
- **Integration into higher-level sequencers** for material flow control.
- **Connection to operator panels (HMI)**, as the state is provided as a number (`iSTATE`) and text (`STATE`) for displays.
- **Logging and visualization** of the slide state via the `STATE` string output.

⚖️ Comparison with similar function blocks

Compared to simpler binary actuator function blocks (e.g., a simple cylinder function block), `SchieberControl` offers significantly higher functionality:



- **Complete state machine** with motion, end, and stop states.
- **Integrated timing control** for motion.
- **Extensive HMI interface** for configuring operating elements.
- **Explicit handling of an "unknown" state** (`RESET` functionality).



It is more specialized and complex than a generic `E_SR` (flip-flop) or a simple timer block, as it combines these functionalities and tailors them to the control of a slide valve actuator.

Conclusion

The `SchieberControl` is a robustly designed and functionally comprehensive control block for slide valve actuators. Its strengths lie in its clear state logic, the flexible configurability of the user interface, and the clean separation of control logic and timing functionality through adapters. It is well suited for use in medium to complex control applications where reliable and monitorable control of a slide valve is required.

SlideControl_AX

• – ○ • – ○ • – ○ •

Introduction

The function block **SlideControl_AX** is used to control a slide valve (valve, flap, or similar actuator) within a 61499-based control system. It implements a state machine that not only manages the logical states (Open, Closed, Opening, Closing) but also handles the timing of the movements and provides the current state via the adapters `STATE` and `iSTATE`.

This version of the block (“AX Adapter Version”) uses special adapters (`adapter::types::unidirectional::AX`) to control the physical valves.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Initialization request (with QI, DT_Opening, DT_Closing, START). Sets all values and parameters.
Open	Event	Command to open the slider.
Close	Event	Command to close the slider.
RESET	Event	Resets the function block to an unknown state (“Unknown”).

Event Outputs

Event	Type	Comment
INITO	EInit	Confirmation of initialization (with QO).

Data Inputs

Variable	Data Type	Comment
QI	BOOL	Input Event Qualifier (True = Normal operation, False = De-Init).

DT_Opening	TIME	Duration of the opening process.
DT_Closing	TIME	Duration of the closing process.
START	UINT	Start configuration (Defines the state in which the function block starts). Default: `STARTUnknown`.

Data Outputs

Variable	Data Type	Comment
QO	BOOL	Output Event Qualifier.

Adapter

Name	Type	Comment
Q_POWERED	AX	Adapter for controlling the "open" valve (pneumatic/main supply). Active during opening and in the open state.
Q_OPEN	AX	Adapter for controlling the "open" signal.
Q_CLOSE	AX	Adapter for controlling the "close" signal.
timeOut	ATimeOut	Adapter for timer functionality (monitors opening/closing times).
iSTATE	AUS	Adapter (`adapter::types::unidirectional::AUS`), outputs the current state as an `iSTATES` constant via `iSTATE.D1`.
STATE	AIS	Adapter (`adapter::types::unidirectional::AIS`), outputs the current state as a `STATES` constant via `STATE.D1`.

Functionality

This module operates as an event-controlled logic controller (ECC) that controls transitions based on the events `Open` and `Close`, as well as the timer adapter `timeOut`.

1. **Initialization:**

Upon startup (`INIT`), the initial state of the slider is checked (defined by `START`). Possible states include "Closed," "Opened," or "Unknown."

1. **Movement Sequence:**

- When the command `Open` is executed, the function block switches to the **Opening** state. This activates the adapters `Q_POWERED` and `Q_OPEN`, and starts the timer with `DT_Opening`.
- After the specified time (`timeOut.TimeOut`), the state automatically switches to **Opened**.
- – If the command `Close` is issued, the function block switches to **Closing**. The adapter `Q_CLOSE` is activated (while `Q_POWERED` and `Q_OPEN` are deactivated), and the timer is started with `DT_Closing`.
- After the specified time has elapsed, the state changes to **Closed**.

1. **Interruption:**

If the command `Close` (or vice versa) is issued during the opening process, the process is stopped (`STOP` states), the outputs are reset, and the reverse process is initiated.

1. **Visualization:**

In each state (Closed, Opening, Opened, Closing, Unknown), the adapters `STATE` (constant from `STATES`) and `iSTATE` (constant from `iSTATES`) are written with the current state. This enables dynamic adaptation of the user interface by downstream blocks.

Technical Features

- **AX Adapter Integration:** The direct use of `adapter::types::unidirectional::AX` indicates a standardized interface for hardware abstraction, making the function block reusable for various valve types, provided the adapter is compatible.

- **State Output:** The function block outputs the current state as constants (`STATES`, `iSTATES`) via the adapters `STATE` (AIS) and `iSTATE` (AUS). This reduces the logic in the HMI.
- **Stop Logic:** Explicit `STOP` states are implemented to ensure that, when changing direction, the outputs are briefly and precisely switched off (`timeOut.STOP`, Valves Off) before the new direction is initiated.

State Overview

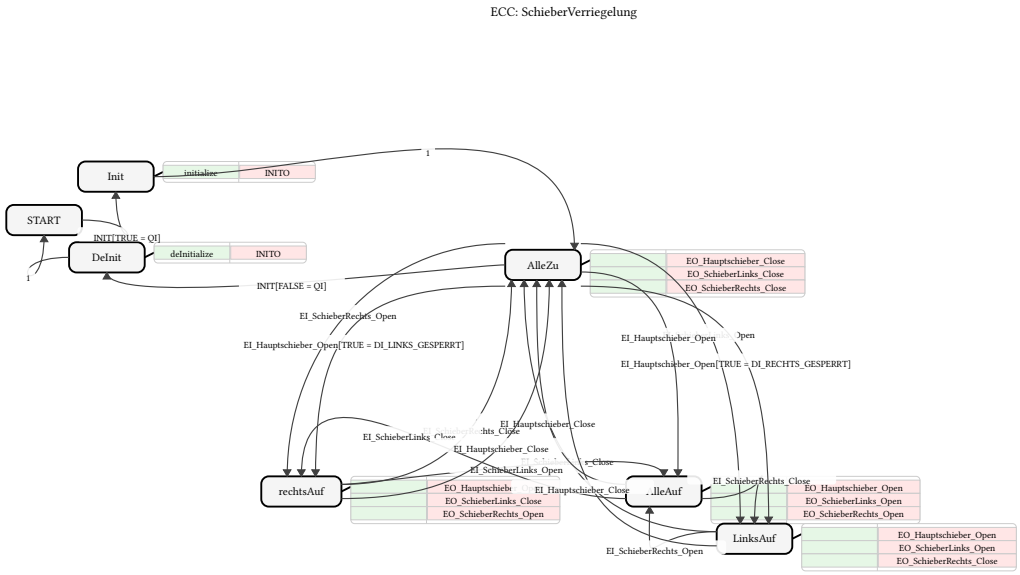
The most important states in the ECC (Execution Control Chart) are:

- **START / Init / DeInit:** Management states for the block's lifecycle.
- **Unknown:** Error or initial state when the position is unknown.
- **Closed:** The valve is fully closed. (`Q_CLOSE`=False, `Q_OPEN`=False).
- **Opening:** The slider is currently opening. (`Q_POWERED`=True, `Q_OPEN`=True, timer running).
- **Opened:** The slider is fully open. (`Q_POWERED`=True, `Q_OPEN`=False).
- **Closing:** The slider is currently closing. (`Q_CLOSE`=True, `Q_POWERED`=False, timer running).
- **..._STOP:** Intermediate states for cleanly stopping movements.

Application Scenarios

- **Agricultural Machinery:** Control of slurry scrapers, metering flaps, or hydraulic booms.
- **Process Automation:** Simple valve controls that do not have end-position sensors but operate based on time (`DT_Opening`/`DT_Closing`).
- **HMI Integration:** Systems where the symbol or button color on the display must change depending on whether the valve is moving, open, or closed.

Comparison with Similar Modules

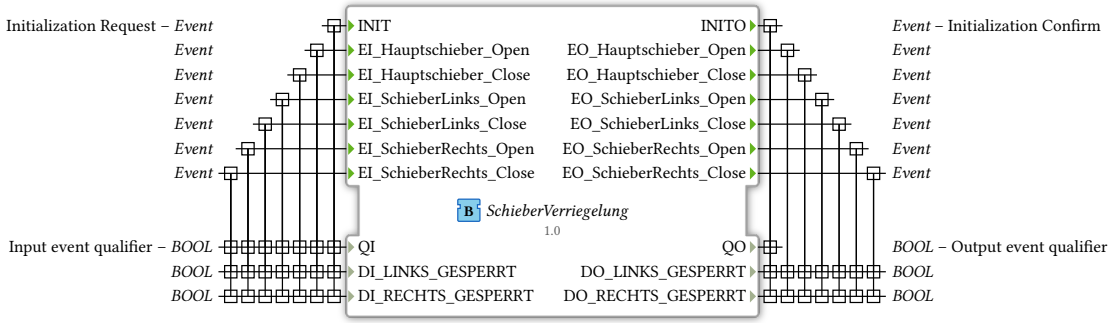


In contrast to a simple `SR`The **SchieberControl_AX** offers the following flip-flop functionality for valve control:

1. **Time Monitoring:** Integrated timers simulate the runtime.
2. **State Output:** Built-in output of the current state for UI information.
3. **Hardware Abstraction:** Uses adapters instead of direct Boolean outputs for the valves.
4. **Intermediate States:** Explicit representation of "Opens" and "Closes," not just "On" and "Off."

Conclusion

The `SchieberControl_AX` is a specialized, robust function block for time-controlled actuators. It encapsulates the complexity of state transitions, timer handling, and UI status management in a single component, thus significantly simplifying the development of control software for machines with hydraulic or pneumatic valves.



Slide Lock

• – ○ • – ○ • – ○ •

Introduction

The function block `SchieberVerriegelung` is used for the coordinated control and locking of three slides: a main slide, a left slide, and a right side slide. Its primary purpose is to ensure valid and collision-free slide combinations based on external requests (events) and locking states. This block is particularly suitable for applications where the movement of one slide must prevent or force the movement of another.

Interface Structure

Event Inputs

- **`INIT`**: Initialization request. Triggers the transition to the initialized state. Linked to the data `QI`, `DI_LINKS_GESPERRT`, and `DI_RECHTS_GESPERRT`.
- **`EI_Hauptschieber_Open`**: Requests the main slider to open.
- **`EI_Hauptschieber_Close`**: Requests the main slider to close.
- **`EI_SchieberLinks_Open`**: Requests the left side slider to open.
- **`EI_SchieberLinks_Close`**: Requests the left side slider to close.
- **`EI_SchieberRechts_Open`**: Requests the right side slider to open.
- **`EI_SchieberRechts_Close`**: Requests the right side slider to close.

Event Outputs

- **`INITO`**: Initialization confirmation. Triggered after completion of initialization (`INIT`) or deinitialization. Associated with the data `QO`, `DO_LINKS_GESPERRT`, and `DO_RECHTS_GESPERRT`.
- **`EO_Hauptschieber_Open`**: Signals the command to open the main slide.
- **`EO_Hauptschieber_Close`**: Signals the command to close the main slide.
- **`EO_SchieberLinks_Open`**: Signals the command to open the left side slide.
- **`EO_SchieberLinks_Close`**: Signals the command to close the left side slide.
- **`EO_SchieberRechts_Open`**: Signals the command to open the right side slider.
- **`EO_SchieberRechts_Close`**: Signals the command to close the right side slider.

Data Inputs

- **`QI` (BOOL)**: Qualifies the INIT event. `TRUE` starts initialization, `FALSE` starts deinitialization.
- **`DI_LINKS_GESPERRT` (BOOL)**: Signals the locked state of the left side slider (`TRUE` = locked).
- **`DI_RECHTS_GESPERRT` (BOOL)**: Signals the locked state of the right side slider (`TRUE` = locked).

Data Outputs

- **`QO` (BOOL)**: Status output reflecting the success of initialization/deinitialization.
- **`DO_LINKS_GESPERRT` (BOOL)**: Outputs the internally processed or forwarded locked state for the left slider.
- **`DO_RECHTS_GESPERRT` (BOOL)**: Outputs the internally processed or forwarded locked state for the right slider.

Adapters

This function block does not use any adapter interfaces.

Functionality

The `SchieberVerriegelung` function block is implemented as a Basic Function Block and follows a defined state machine (ECC). After initialization, the block starts in state `AlleZu` (all sliders closed). From here, transitions to other states can occur depending on the incoming event and the current lock states (`DI_LINKS_GESPERRT`, `DI_RECHTS_GESPERRT`).

The `SchieberVerriegelung` function block is implemented as a Basic Function Block and follows a defined state machine (ECC). After initialization, the block starts in state `AlleZu` (all sliders closed). The central logic lies in the interpretation of the `EI_Hauptschieber_Open` event in state `AlleZu`:

1. If **no** side slider is locked (`DI_LINKS_GESPERRT = FALSE` and `DI_RECHTS_GESPERRT = FALSE`), the function block transitions to state `AlleAuf` (all sliders open).
2. If **only the right slider** is locked (`DI_RECHTS_GESPERRT = TRUE`), the function block transitions to state `LinksAuf` (main and left sliders open, right slider remains closed).
3. If **only the left** slider is locked (`DI_LINKS_GESPERRT = TRUE`), the function block (FB) transitions to state `rechtsAuf` (main and right sliders open, left one remains closed).

States `LinksAuf` and `rechtsAuf` represent the locked operating states. From these states, the system can transition to state `AlleAuf` by selectively opening/closing the side sliders, or return to state `AlleZu` by closing the main slider.

The algorithm `normalOperation` copies the blocking states from the inputs (`DI_*_GESPERRT`) to the outputs (`DO_*_GESPERRT`) when operation is enabled (`QI=TRUE`).

Technical Features

- **State-Controlled Output**: Each operational state (`AlleZu`, `AlleAuf`, `LinksAuf`, `rechtsAuf`) immediately triggers a fixed combination of output events (`EO_*`) that define the desired slider position. ... * **Conditional Transitions**: The transition from `AlleZu` to `LinksAuf`/`rechtsAuf` is linked to the `EI_Hauptschieber_Open` event **and** the corresponding lock state (`DI_*_GESPERRT`). This represents low-level locking logic.
- **Explicit Deinitialization**: A `INIT` event with `QI=FALSE` transitions from any state to the `DeInit` state and sets the output `QO` to `FALSE`.

State Overview

1. **START**: Inactive initial state before initialization.
2. **Init**: Triggered at `INIT` with `QI=TRUE`. Executes the `initialize` algorithm and confirms with `INITO`.
3. **AllClosed** (Default operating state): All three sliders are closed. Sends `Close` commands for all sliders.

4. **AllOpen**: All three sliders are open. Sends `Open` commands for all sliders.
5. **LeftOpen**: Main slider and left side slider are open; the right side slider is closed (locked). Sends corresponding `Open`/`Close` commands.
6. **RightOpen**: The main slide and right side slide are open, the left one is closed (locked). Sends corresponding `Open`/`Close` commands.
7. **DeInit**: Deinitialization state. Sets `QO` to `FALSE` and then reverts to `START`.

Application Scenarios

Typical applications can be found in distribution and conveying systems, for example, in agricultural technology or material logistics:

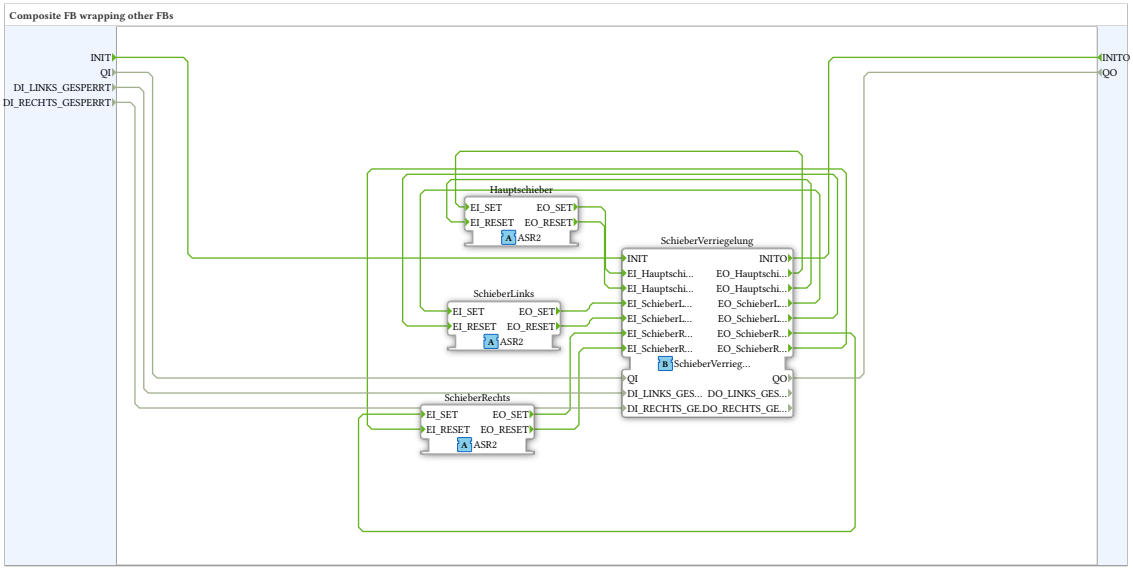
- **Grain or bulk material conveyors**: The main slide conducts the flow. The side gates can be opened as needed, for example, to distribute material into different silos. The interlock prevents both sides from being open simultaneously if this is mechanically or process-related impermissible.
- **Switch control**: Analogous to a mechanical switch, where the position of one switch shoe blocks the other position.

⚖️ Comparison with similar components

Compared to simple gate control components (e.g., individual `E_SR` flip-flops per gate), the `SchieberVerriegelung`-FB:

- **Integrated Collision Avoidance**: The interlock logic is hard-coded within the state machine and does not require external wiring.

** **State-Based Coordination**: The output commands are always consistent sets (`Open`/`Close` combinations for all three slides).



- **Explicit Lock Inputs**: The consideration of external lock signals (`DI_*_GESPERRT`) is an integral part of the control logic.

A disadvantage is the reduced flexibility. The logic is specific to exactly three slides with this particular locking relationship. For other numbers or dependencies, a new function block must be created.

Conclusion

The `SchieberVerriegelung` function block is a specialized control block for the coordinated control of three mechanically or process-coupled slides. Its strength lies in the robust, state-based implementation of the locking logic, which guarantees secure and consistent slide positions. It is ideally suited for clearly defined plant sections with clear dependencies between the actuators and relieves the higher-level control design of the wiring of this safety logic.

SlideLockComposite

• – ○ • – ○ • – ○ •

Introduction

The function block `SchieberVerriegelungComposite` is a composite function block that serves as a wrapper for other function blocks. Its main purpose is to manage and coordinate the locking logic for multiple slides (main slide, left slide, right slide). It encapsulates the internal logic and provides a unified interface for initialization and data exchange with the connected actuators and sensors.

Interface Structure

Event Inputs

- **`INIT`**: Initialization request. Triggers the initialization process of the internal `SchieberVerriegelung` function block and thus of the entire composite block. Linked to the data `QI`, `DI_LINKS_GESPERRT`, and `DI_RECHTS_GESPERRT`.

Event Outputs

- **`INITO`**: Initialization confirmation. Triggered by the internal `SchieberVerriegelung` function block, it signals successful completion of the initialization. Linked to the data output `QO`.

Data Inputs

- **`QI` (BOOL)**: Qualifier for the INIT event. Controls the initialization.
- **`DI_LINKS_GESPERRT` (BOOL)**: Status input indicating whether the left slider is locked.
- **`DI_RECHTS_GESPERRT` (BOOL)**: Status input indicating whether the right slide is locked.

Data Outputs

- **`QO` (BOOL)**: Qualifier for the INITO event. Returns the initialization status.

Adapters

The composite FB provides three bidirectional adapter interfaces for communicating with the physical or logical slide actuators. Each adapter follows the type `adapter::types::bidirectional::ASR2`, which typically supports SET and RESET commands and corresponding feedback.

1. **`Hauptschieber`**: Adapter for controlling and providing status feedback to the main slide.
2. **`SchieberLinks`**: Adapter for controlling and providing status feedback to the left slide.
3. **`SchieberRechts`**: Adapter for controlling and providing status feedback to the right slide.

Functionality

The `SchieberVerriegelungComposite` primarily acts as an intermediary. It forwards all external events and data to the internal, encapsulated function block `SchieberVerriegelung`. Likewise, the output events and data of this internal function block are passed through to the composite interfaces.

The central logic for controlling and locking the slides resides entirely within the internal function block `SchieberVerriegelung`. The composite block translates the generic adapter events (`EI_SET`/`EI_RESET`, `EO_SET`/`EO_RESET`) into the specific, named events of the internal function block (e.g., `EI_Hauptschieber_Open`, `EO_SchieberLinks_Close`) and vice versa. This enables a clean separation between application-specific control logic and generic adapter communication.

Technical Features

- **Encapsulation**: The complex interlock logic is implemented in a separate function block (`SchieberVerriegelung`), which promotes reusability and testability.

- **Adapter-based communication**: Connection to the actuators is exclusively via standardized adapter interfaces (`ASR2`). This abstracts the specific actuators and increases flexibility.
- **Pass-through design**: Except for translating the adapter event names, this composite FB has no logic of its own. It serves to structure the FBNetwork.

State overview

As a composite FB, `SchieberVerriegelungComposite` does not have an explicit state machine itself. The system state is managed entirely by the internal `SchieberVerriegelung` FB. The composite block can be in one of the following two macro states:

- **Not initialized**: Before the arrival of a valid `INIT` event.
- **Initialized and ready for operation**: After the internal function block acknowledges the initialization via `INITO`. In this state, all adapter events are passed through.

Application Scenarios

This function block is designed for control applications where multiple mechanically or logically linked slides or closures need to be coordinated, e.g.:

- Interlocking systems in conveyor systems or silos.
- Safety controls for gates or flaps that may only be opened under certain conditions.
- Process controls where the sequence of switching operations must be maintained (e.g., main slides may only open if side closures are closed).

⚖️ Comparison with similar function blocks

Unlike a simple, monolithic function block that mixes logic and interfaces, this composite block offers a clear separation of concerns. A direct comparison would be a `SchieberVerriegelung` function block, which would have integrated the adapter interfaces directly. The composite approach is more modular and allows the core logic (`SchieberVerriegelung`) to be reused unchanged in different network environments by simply adapting the enclosing composite block.

Conclusion

The `SchieberVerriegelungComposite` is a well-structured wrapper block that simplifies the integration of complex slider locking logic into a larger 4diac control system. By using standardized adapters and encapsulating the core functionality, it promotes reusability, maintainability, and clear interface definitions. It is ideal for applications requiring reliable and transparent coordination of multiple actuators.

START

🎧 Podcast

- Events and IEC 61499: The Starting Signal for Intelligent Systems

Introduction

The `START` constant declaration defines a set of integer constants (of type `UINT`) for use in control programs. These constants represent specific states typically used in sequence controls, such as for sliders. They improve code readability and maintainability by replacing numeric values with meaningful names.

Interface Structure

START` is a **GlobalConstants** declaration and not a function block. Therefore, it does not have event- or data-flow-based interfaces such as inputs or outputs. Instead, it defines global, constant values that can be referenced within other function blocks or programs.

Event Inputs

Not applicable. This declaration does not contain any event inputs.

Event Outputs

Not applicable. This declaration does not contain any event outputs.

Data Inputs

Not applicable. This declaration does not contain any data inputs.

Data Outputs

Not applicable. This declaration does not contain any data outputs.

Adapters

Not applicable. This declaration does not use adapters.

Functionality

The `START` constant declaration assigns fixed, unchanging numerical values to the symbolic names `STARTClosed`, `STARTOpened`, and `STARTUnknown`. Once this declaration is included in a project, the defined names can be used throughout the application code instead of the raw numbers (5, 6, 7). During compilation, the compiler replaces any reference to, for example, `STARTClosed` with the value `UINT#5`.

Technical Details

- **Type:** All constants are of type `UINT` (unsigned integer).
- **Scope of Validity:** The constants are defined globally (`VAR_GLOBAL CONSTANT`) and available within the declared package (`logiBUS::utils::sequence::schieber::const`).
- **Immutability:** As constants (`CONSTANT`), their values cannot be changed at runtime.
- **Package Structure:** The constants are organized in a specific package hierarchy that reflects their application domain (auxiliary functions for sequence control of sliders).

State Overview

The constants themselves represent abstract states:

- `STARTClosed` (value 5): Represents the state “closed” or “in starting position”.
- `STARTOpened` (value 6): Represents the state “open” or “in end position”.
- `STARTUnknown` (value 7): Represents an undefined, unknown, or error state.

Application Scenarios

Primarily, these constants are used in state machines or sequencer function blocks to uniquely and readably encode the current position or status of an actuator (such as a linear slider). For example, a function block could set its internal state or an output value to `STARTOpened` to indicate that the slider is fully open.

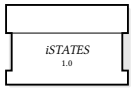
⚖️ Comparison with Similar Function Blocks

Unlike function blocks such as `E_SR` (flip-flop) or `E_CYCLE` (cycle encoder), `START` has no algorithm or behavioral logic. It is a pure data declaration. Similar constructs would be other `GlobalConstants` or `Type` declarations, which also provide symbolic names for values (e.g., for error codes or operating modes).

Conclusion

The `START` constant declaration is a simple yet essential tool for structuring and professionalizing IEC 61499-based control applications. By using meaningful names instead of “magic numbers,” the code becomes significantly more understandable, less error-prone, and easier to maintain. Its integration is particularly recommended in larger projects or reusable library components.

STATES



States (Closed, Opened, Transitions)

Global Constants

Name	Type	Initial Value
Closed	STRING	‘Closed’
Opening	STRING	‘Opening’
Opened	STRING	‘Opened’
Closing	STRING	‘Closing’
Unknown	STRING	‘Unknown’

iSTATES

• – ◦ • – ◦ • – ◦ •

Introduction

The **iSTATES** block is a special GlobalConstants block in the 4diac IDE. It defines a set of named constants that represent the possible states of a (slider) actuator. The constants are stored as `USINT` values and enable a uniform, human-readable reference to the states in the control logic.

Interface Structure

Event Inputs

None. The block has no event inputs.

Event Outputs

None. The block has no event outputs.

Data Inputs

None. The block has no data inputs.

Data Outputs

None. The function block has no data outputs. The defined constants are available as globally accessible symbols within the project context.

Adapter

None.

Functionality

The **iSTATES** function block provides five symbolic constants that can be used throughout the application. Each constant represents a discrete state of a slider or similar actuator. The values are defined as `USINT` (unsigned short integer) and are assigned as follows:

Constant	Value (USINT)	Meaning
Unknown	0	Unknown state

Closed	1	Closed
Opening	2	Opens
Opened	3	Opened
Closing	4	Closes

These values can be used directly in FB networks for initializing variables or for comparison with status feedback.

Technical Features

- **Type: GlobalConstants** – The function block is not instantiated but integrated into the project as a global constant definition.
- **Value Range**: All states are declared as `USINT`, which guarantees low memory usage and compatibility with many fieldbus protocols.
- **Extensibility**: The scheme can easily be extended with additional states if the application requires it.
- **Package**: The function block is organized in the package `logiBUS::utils::sequence::schieber::const`, which allows for clear structuring within the project.

State Overview

The five states cover a complete lifecycle of a slider:

1. **Unknown** (0) – Initial state or error state if the current position is unknown.
2. **Closed** (1) – Slide is closed (end position closed).
3. **Opening** (2) – Slide is in the opening phase.
4. **Opened** (3) – Slide is fully open (end position open).
5. **Closing** (4) – Slide is in the closing phase.

Application Scenarios

- **State Function Blocks for Slides, Valves, or Gates** – This function block provides the basis for state management in sequential controllers.
- **Visualization** – The symbolic names can be used in HMI or SCADA systems to display the current state.
- **Fault Detection** – The `Unknown` state allows for the unambiguous identification of invalid or initial states.

Comparison with Similar Blocks

Similar GlobalConstants blocks often exist in other packages (e.g., for motor controllers, conveyor systems). The difference lies in the specific definition of the states – while other blocks use `Idle`, `Running`, `Error`, etc., **iSTATES** is specifically tailored to the five typical slider states. Using `USINT` instead of `BOOL` or `INT` is platform-efficient and standards-compliant.

Conclusion

The **iSTATES** block is a simple yet useful tool for the consistent definition of slider states. Using global constants makes the code more readable, fault-resistant, and maintainable. It is ideally suited for all applications where an actuator cycles through the state sequence “Closed → Opens → Open → Closes → Closed”.

SliderAuxInStruct

• – ◦ • – ◦ • – ◦ •

Introduction

The structured data type `SchieberAuxInStruct` is used to bundle information for the visual representation of an auxiliary element (AUX) in a slider control. It combines the specification of an image with a background color to define the graphical representation of an auxiliary input or element.

Interface Structure

This function block is a structured data type (struct) and therefore has no event or adapter interfaces. Its structure consists of the following two data elements:

Data Inputs

Since it is a data type, there are no direct inputs. The structure is used as a whole at the data inputs of other function blocks.

Data Outputs

Since it is a data type, there are no direct outputs. The structure is used as a whole at the data outputs of other function blocks.

Structured Elements

- **`Picture`** (`logiBUS::utils::sequence::schieber::SchieberStruct`):
- **Comment:** `u16ObjId for Picture`
- **Description:** Contains the identifier (Object ID) for the image to be displayed in the helper element. The underlying type `SchieberStruct` likely provides the necessary information for referencing and handling the image object.
- **`u8Colour`** (`logiBUS::utils::sequence::schieber::SchieberColorStruct`):
- **Comment:** `Background Color of the AUX`
- **Description:** Defines the background color of the helper element. The type `SchieberColorStruct` specifies the color used, likely in a format suitable for the target system (e.g., an HMI).

Functionality

The data type `SchieberAuxInStruct` is a passive data structure. Its sole function is to logically combine the two properties `Picture` (image) and `u8Colour` (background color) into a single, reusable data record. It is used to transport these visual attributes consistently between different functional blocks within an application.

Technical Details

- **Namespaces:** The data type and its components are defined in the package `logiBUS::utils::sequence::schieber`, indicating a specific application in agricultural machinery control technology.
- **Typing:** Using specific, user-defined types (`SchieberStruct`, `SchieberColorStruct`) for members promotes type safety and reusability throughout the project.

State Overview

As a pure data type, `SchieberAuxInStruct` has no internal state or state machine.

Application Scenarios

This data type is typically used in PLC (Programmable Logic Controller) controllers for mobile machinery, particularly in:

- **HMI Configuration:** To define the appearance of operating or display elements (e.g., sliders, buttons, status lights) on an operator panel.
- **Sequence Controls:** Within sequential control systems where the display of an element (color, image) should change depending on the process state.
- **Data Encapsulation:** Simplifies the parameterization of function blocks that control the appearance of an "AUX" element by allowing all visual parameters to be passed in a single variable.

⚖️ Comparison with Similar Building Blocks

Unlike function blocks (FBs), this building block has no algorithm or behavioral logic. It is comparable to a `STRUCT` in IEC 61131-3 or a `class`/`struct` in higher-level programming languages. Other similar elements would be simple data types (e.g., `ARRAY` of single values), but these do not offer the semantic grouping and type safety of this structured type.

Conclusion

The `SchieberAuxInStruct` is a fundamental, reusable data type for modeling the visual properties of a helper element in a specific control environment. By encapsulating image and color information, it contributes to better structuring, readability, and maintainability of the application code. Its use is particularly advantageous in projects with complex user interfaces or state-dependent visualizations.

SliderColorStruct

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `SchieberColorStruct` is a structured data structure used to manage color values for different states of a slider (e.g., a valve, flap, or closure). It defines a consistent color coding for the visual representation of the states `Unbekannt`, `Geschlossen`, `Öffnend`, `Geöffnet`, and `Schließend` in a user interface or display.

Interface Structure

The data type is a structure (`STRUCT`) and does not contain any events or adapters. Its interface consists exclusively of data elements.

Data Inputs

This structure does not have event inputs in the conventional sense, as it is a data type. The following elements are the structure's member variables, which can be written to or assigned values during instantiation.

Data Outputs

This structure does not have event outputs. The member variables represent the stored data.

Data Elements (Structure Members)

Name	Data Type	Comment	Initial Value
`Unknown`	`USINT`	u8Colour for Unknown State	`COLOR_WHITE`
`Closed`	`USINT`	u8Colour for Closed State	`COLOR_WHITE`
`Opening`	`USINT`	u8Colour for Opening State	`COLOR_WHITE`
`Opened`	`USINT`	u8Colour for Opened State	`COLOR_WHITE`
`Closing`	`USINT`	u8Colour for Closing State	`COLOR_WHITE`

Adapters

This data structure does not use adapters.

Functionality

The `SchieberColorStruct` is a pure data type. It serves as a container to group five different color values (each as an 8-bit unsigned integer, `USINT`) for the five defined slider states. By using this structure, a function block or application can pass or store a single, consistent variable containing all the colors

required for display. The initial values of all members are set to the constant `COLOR_WHITE`, which comes from the imported package `isobus::UT::Q::const::colours`.

Technical Details

- **Imported Constant:** The structure depends on the externally defined constant `COLOR_WHITE`, which is provided via the compiler import `isobus::UT::Q::const::colours::COLOR_WHITE`. This ensures that a consistent, project-wide shade of white is used.
- **Type Safety:** Using a structured type instead of five individual variables improves code readability and maintainability and reduces the likelihood of errors.
- **Hash Attribute:** The structure contains the attribute `eclipse4diac::core::TypeHash` with an empty value. This is used by the 4diac system for type identification and management.

State Overview

Because it is a static data type, `SchieberColorStruct` itself does not have a state machine. Instead, it encodes the display attributes for the states of another, parent element (e.g., a `Schieber` function block).

Application Scenarios

- **Visualization in HMIs:** Passing the color configuration to visualization components to correctly display the state of a slider using color (e.g., red for "Closed," green for "Open").
- **Function Block Configuration:** A function block that controls a physical slider can have an instance of this type as a configurable input to enable user-defined colors for state feedback.
- **Data Encapsulation:** Bundling all state-related color information into a single parameter that can be exchanged between different software modules (e.g., controller and visualization).
-

⚖️ **Comparison with Similar Building Blocks**

Unlike function blocks (FBs) such as `E_SR` or `E_D_FF`, which implement logic, `SchieberColorStruct` is a pure **data type** (STRUCT). Similar structured types could be, for example, `MotorConfigStruct` (for configuration data) or `AxisPositionStruct` (for multidimensional positions). Its specific function is to define a color scheme for a predefined set of states.

Conclusion

The `SchieberColorStruct` is a simple yet useful structured data type that standardizes the management and exchange of color values for representing the state of a slider. It promotes clean interfaces, facilitates reuse, and contributes to consistency within a project through the use of initial default values and imported constants.

SlideStruct

• – ◦ • – ◦ • – ◦ •

Introduction

The `SchieberStruct` is a structured data type used to represent all possible states of a slide (e.g., a valve, flap, or closure) within a control system. It serves as a central container for the object identifiers (IDs) assigned to the various states of the slide. This data type is typically used in conjunction with function blocks that implement state machines or sequences for slide control.

Interface Structure

The `SchieberStruct` is a data type and therefore does not have event or adapter interfaces in the conventional sense. Its structure consists exclusively of data fields.

Data Inputs

Not applicable. The structure defines a data type, not function block interfaces.

Data Outputs

Adapter

Not applicable.

Functionality

The `SchieberStruct` is a data structure containing five fields of type `UINT` (16-bit unsigned integer). Each field represents a specific state of a slider and stores the corresponding object ID (`u16ObjId`). These IDs are used to access the graphical or logical representations of the states in a higher-level system (e.g., a visualization or logic module).

The initial values of all fields are set to the constant `ID_NULL`, indicating an undefined or unassigned state. These must be populated with valid object IDs before using the structure.

Technical Features

- **Initialization:** All member variables are initialized with the default value `ID_NULL`. This ensures that the structure starts in a defined, neutral state before specific IDs are assigned.
- **Type Safety:** Using a structured data type instead of individual, loosely coupled variables improves code maintainability and readability.
- **Compilation Note:** The data type is defined in the package `logiBUS::utils::sequence::schieber` and imports the constant `ID_NULL` from the `isobus::UT::Q::const::IDs` namespace.

State Overview

The structure explicitly maps the following five states of a slider:

1. **`Unknown`:** The slider's state is unknown or could not be determined.
2. **`Closed`:** The slide is in the closed end position.
3. **`Opening`:** The slide is in the process of opening (movement state).
4. **`Opened`:** The slide is in the open end position.
5. **`Closing`:** The slide is in the process of closing (movement state).

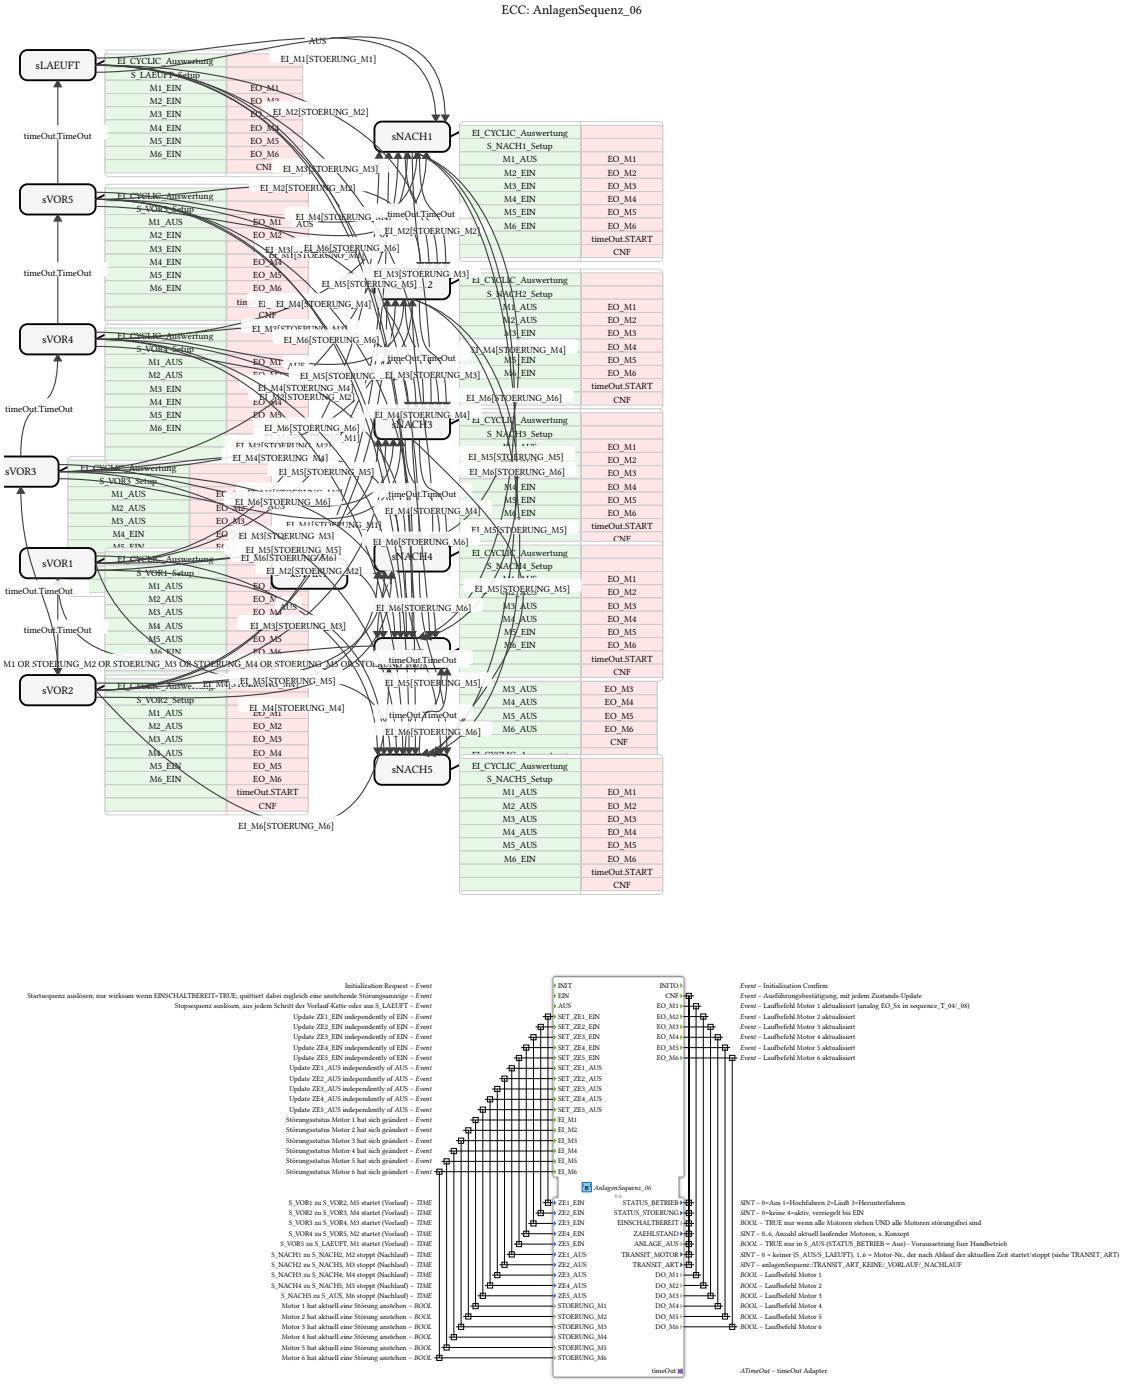
Application Scenarios

- **State Management:** A higher-level control block can maintain an instance of this structure to centrally manage the currently valid object IDs for all slide states.
- **Parameterization:** The structure can be passed as a configurable parameter to a function block, which then selects the corresponding ID from the structure based on its internal state and forwards it, for example, to a visualization system. * **Visualization:** An HMI or SCADA system can use the IDs stored in the structure to update the slider's graphical symbol according to its current state (e.g., color, symbol).

⚖️ Comparison with similar blocks

Unlike function blocks such as `E_SR` (memory element) or `E_CTUD` (counter), which implement active logic, `SchieberStruct` is a passive data type. Similar structured data types could be defined for other devices with state machines (e.g., `PumpeStruct`, `MotorStruct`). The unique feature lies in the specific mapping of the states characteristic of a linear slider: `Opening`, `Closing`, `Opened`, and `Closed`, including a `Unknown` state.

Conclusion



The `SchieberStruct` data type is a useful construct for the structured and type-safe handling of state information for slider actuators. By encapsulating the relevant object IDs in a single structure, the configuration and maintenance of applications that control and visualize such actuators is simplified. Its use promotes a clear and consistent programming style.

timed

AnlagenSequenz_06

• — ○ • — ○ • — ○ •

Introduction

The `AnlagenSequenz_06` function block is a time-controlled ring sequencer for the ordered start-up and shutdown sequence of six motors (M1..M6), as needed e.g. for a grain-intake conveyor chain. Unlike the generic sequence_T_04/ sequence_T_08 blocks, it is not a general-purpose sequencer but hard-wired to this one application pattern: start-up (motors switch on one by one, back to front) and shutdown (motors switch off one by one, front to back) are two separate, purely linear chains, joined into a closed ring by the two ring poles `sAUS` (bottom, all motors off) and `sLAEUFT` (top, all motors on). The block additionally implements a complete fault cascade: if any of the six motors reports a fault during start-up, shutdown, or

continuous operation, the FB jumps in a single step (no re-evaluation over multiple cycles) to the matching shutdown state, taking into account exactly the upstream motors that are still running at that moment.

Interface Structure

Event Inputs

- **INIT**: Initialization request (type EInit).
- **EIN**: Starts the start-up chain (transition sAUS → sVOR1). Only effective when EINSCHALTBEREIT = TRUE (condition EIN[NOT (STOERUNG_M1 OR ... OR STOERUNG_M6)]); also acknowledges a pending, latched STATUS_STOERUNG indication.
- **AUS**: Triggers the shutdown sequence from any start-up step (sVOR1..sVOR5) or from sLAEUFT. Jumps to the mirror point of the shutdown chain (sVOR_k → sNACH_(6-k)), since this is an operator request, not a motor fault.
- **SET_ZE1_EIN, SET_ZE2_EIN, SET_ZE3_EIN, SET_ZE4_EIN, SET_ZE5_EIN**: Update ZE1_EIN .. ZE5_EIN independently of EIN; each event carries (With) the identically named time variable (SET_ZEk_EIN → ZEk_EIN).
- **SET_ZE1_AUS, SET_ZE2_AUS, SET_ZE3_AUS, SET_ZE4_AUS, SET_ZE5_AUS**: Update ZE1_AUS .. ZE5_AUS independently of AUS; each event carries (With) the identically named time variable (SET_ZEk_AUS → ZEk_AUS).
- **EI_M1**: Motor 1 fault status has changed. Leads (With STOERUNG_M1) directly to sNACH1 from every state that precedes it.
- **EI_M2**: Motor 2 fault status has changed. Leads (With STOERUNG_M2) directly to sNACH2.
- **EI_M3**: Motor 3 fault status has changed. Leads (With STOERUNG_M3) directly to sNACH3.
- **EI_M4**: Motor 4 fault status has changed. Leads (With STOERUNG_M4) directly to sNACH4.
- **EI_M5**: Motor 5 fault status has changed. Leads (With STOERUNG_M5) directly to sNACH5.
- **EI_M6**: Motor 6 fault status has changed. Leads (With STOERUNG_M6) directly to sAUS (M6 is the last/outermost motor in the chain, so there is no shorter shutdown step).

Event Outputs

- **INITO**: Initialization confirmation (type EInit).
- **CNF**: Execution confirmation, triggered on every state change; carries STATUS_BETRIEB, STATUS_STOERUNG, ZAEHLSTAND, EINSCHALTBEREIT, ANLAGE_AUS, TRANSIT_MOTOR, and TRANSIT_ART.
- **EO_M1**: Motor 1 run command updated; carries DO_M1 (analogous to EO_Sx in sequence_T_04/_08).
- **EO_M2**: Motor 2 run command updated; carries DO_M2.
- **EO_M3**: Motor 3 run command updated; carries DO_M3.
- **EO_M4**: Motor 4 run command updated; carries DO_M4.
- **EO_M5**: Motor 5 run command updated; carries DO_M5.
- **EO_M6**: Motor 6 run command updated; carries DO_M6.

Data Inputs

- **ZE1_EIN .. ZE5_EIN** (TIME; individually ZE1_EIN, ZE2_EIN, ZE3_EIN, ZE4_EIN, ZE5_EIN): Dwell time per start-up step (sVOR1→sVOR2 through sVOR5→sLAEUFT) before the next motor is automatically added. Default: NO_TIME.
- **ZE1_AUS .. ZE5_AUS** (TIME; individually ZE1_AUS, ZE2_AUS, ZE3_AUS, ZE4_AUS, ZE5_AUS): Dwell time per shutdown step (sNACH1→sNACH2 through sNACH5→sAUS) before the next motor is automatically switched off. Default: NO_TIME.
- **STOERUNG_M1 .. STOERUNG_M6** (BOOL): Live, continuous fault signal per motor (not a pulse). Default: FALSE.

Data Outputs

- **STATUS_BETRIEB** (SINT): 0=Off, 1=Starting up, 2=Running, 3=Shutting down.
- **STATUS_STOERUNG** (SINT): 0=none, 4=active — stays latched until the next successful EIN acknowledgement (see Technical Details).
- **EINSCHALTBEREIT** (BOOL): TRUE only when ZAEHLSTAND = 0 (all motors stopped) AND all six STOERUNG_Mx are currently FALSE.
- **ZAEHLSTAND** (SINT): 0..6, number of motors currently running.
- **ANLAGE_AUS** (BOOL): TRUE only in sAUS (STATUS_BETRIEB = Off) — prerequisite for manual operation.
- **TRANSIT_MOTOR** (SINT): 0 = none (sAUS/sLAEUFT), 1..6 = number of the motor that starts/stops after the current time elapses (see TRANSIT_ART).

- **TRANSIT_ART** (SINT): Kind of transition: anlagenSequenz::TRANSIT_ART_KEINE, _VORLAUF or _NACHLAUF.
- **DO_M1 .. DO_M6** (BOOL): Run command per motor.

Adapters

- **timeOut** (Plug, type: iec61499::events::ATimeOut): Standardized TimeOut adapter used for the start-up and shutdown step timing, the same mechanism used by sequence_T_04.

Functionality

The FB is a Basic Function Block (BFB) with 12 real states plus a start state, arranged as a ring made of two linear chains:

1. **Start-up chain** (sVOR1 → sVOR2 → sVOR3 → sVOR4 → sVOR5 → sLAEUFT): Each step adds exactly one more motor, in the order M6, M5, M4, M3, M2, M1 (the highest-numbered motors start first). The transition to the next step happens automatically once the corresponding ZEk_EIN time elapses (timeOut.TimeOut).
2. **Shutdown chain** (sNACH1 → sNACH2 → sNACH3 → sNACH4 → sNACH5 → sAUS): Mirror image of the start-up chain — each step switches off exactly one motor, in the order M1, M2, M3, M4, M5, M6.
3. **Start**: EIN (only from sAUS, only when EINSCHALTBEREIT) acknowledges a pending STATUS_STOERUNG indication and activates sVOR1.
4. **Planned stop**: AUS from any start-up step or from sLAEUFT jumps to the mirror point of the shutdown chain (sVOR_k → sNACH_(6-k), sLAEUFT → sNACH1) — only the motors that are actually running at that moment are shut down in order; motors already stopped are left untouched.
5. **Fault cascade**: Every EI_Mx event (With STOERUNG_Mx) has a direct, single-step transition from every state preceding its target step to the matching sNACH_x (or to sAUS for x=6). This makes the FB react to any fault immediately, regardless of whether the ring is currently in start-up, shutdown, or continuous operation (sLAEUFT) — with no detour through a mirror point and no multi-cycle re-evaluation.
6. **Continuous operation**: sLAEUFT is the upper ring pole — all six motors are running, no timing is active, and the FB stays here until AUS or a fault report.
7. **End of cycle**: After sNACH5 (or directly from a fault), the ring reaches sAUS again — the idle state from which a new EIN cycle can begin.

Technical Details

- **EINSCHALTBEREIT is deliberately NOT coupled to STATUS_STOERUNG.** STATUS_STOERUNG stays latched after a fault until the next successful EIN acknowledgement (it exists for the Visu indicator). If EINSCHALTBEREIT depended on it, the EIN button could never be released again after the very first fault ever recorded — a genuine deadlock. EINSCHALTBEREIT instead checks the *live* STOERUNG_Mx signals directly ((ZAEHLSTAND = 0) AND NOT (STOERUNG_M1 OR ... OR STOERUNG_M6)).
- **The sAUS → sVOR1 transition also carries the full interlock condition inside the event bracket** (EIN[NOT (STOERUNG_M1 OR ... OR STOERUNG_M6)]), not just a check against the computed status. A plain status flag like EINSCHALTBEREIT enforces nothing by itself — only an actual ECTransition Condition prevents a start while a fault is pending.
- **Events are polar and are never combined with AND/OR.** Every condition that combines an event with a data condition uses exclusively the bracket syntax EventName[boolean_expression] (e.g. EI_M3[STOERUNG_M3]) — the only valid form for this in IEC 61499.
- **No self-loops left in the ECC.** An earlier revision used a cyclic EI_CYCLIC event to re-evaluate faults over multiple cycles; that has been removed. EI_CYCLIC_Auswertung now runs as an entry algorithm in every active state instead, re-evaluating STOERUNG_M1..M6 on every state change.
- **Direct single-step fault dispatch instead of a mirror-point detour.** Every state preceding an sNACH_x has its own direct EI_Mx transition to it (51 edges in total for the fault cascade) — no intermediate step via a mirror point as used for the planned AUS.
- **MaxBetriebRest/shutdown remaining-time tracking (demo-server scheme) is not yet implemented** — a deliberate, documented simplification of the current revision (see the comment in the FB header).

State Overview

State	Description	Active motors	Transition condition to the next state

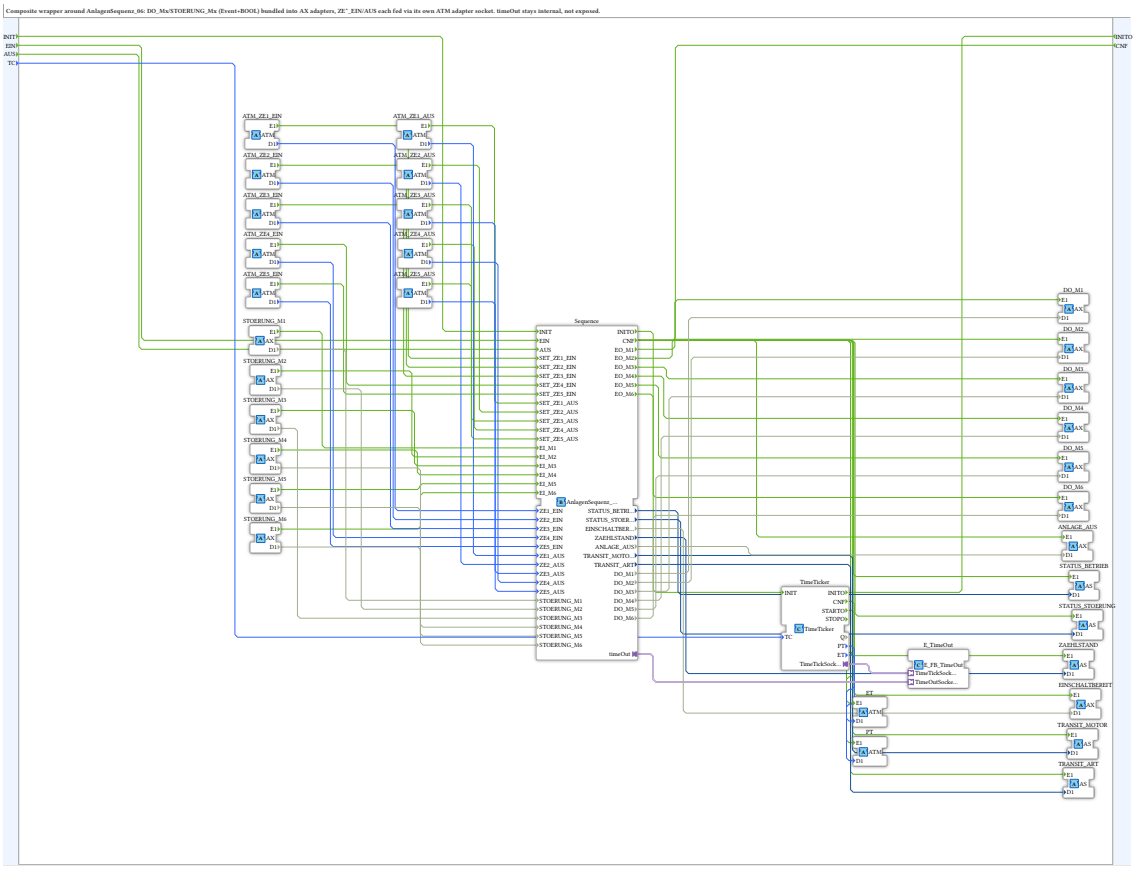
xSTART	Initial idle state.	—	1 (immediately to sAUS)
sAUS	Ring base state, bottom.	none	EIN[NOT (STOERUNG_M1..M6)] → sVOR1
sVOR1	Start-up step 1.	M6	timeOut.TimeOut → sVOR2; AUS → sNACH5; EI_Mx → matching sNACHx/sAUS
sVOR2	Start-up step 2.	M5, M6	timeOut.TimeOut → sVOR3; AUS → sNACH4; EI_Mx → matching sNACHx/sAUS
sVOR3	Start-up step 3.	M4, M5, M6	timeOut.TimeOut → sVOR4; AUS → sNACH3; EI_Mx → matching sNACHx/sAUS
sVOR4	Start-up step 4.	M3, M4, M5, M6	timeOut.TimeOut → sVOR5; AUS → sNACH2; EI_Mx → matching sNACHx/sAUS
sVOR5	Start-up step 5.	M2, M3, M4, M5, M6	timeOut.TimeOut → sLAEUFT; AUS → sNACH1; EI_Mx → matching sNACHx/sAUS
sLAEUFT	Ring pole, top — continuous operation.	M1..M6 (all)	AUS → sNACH1; EI_Mx → matching sNACHx/sAUS
sNACH1	Shutdown step 1 (M1 stopped).	M2..M6	timeOut.TimeOut → sNACH2; EI_Mx → matching sNACHx/sAUS
sNACH2	Shutdown step 2 (M1, M2 stopped).	M3..M6	timeOut.TimeOut → sNACH3; EI_Mx → matching sNACHx/sAUS
sNACH3	Shutdown step 3 (M1..M3 stopped).	M4, M5, M6	timeOut.TimeOut → sNACH4; EI_Mx → matching sNACHx/sAUS
sNACH4	Shutdown step 4 (M1..M4 stopped).	M5, M6	timeOut.TimeOut → sNACH5; EI_Mx → matching sNACHx/sAUS
sNACH5	Shutdown step 5 (M1..M5 stopped).	M6	timeOut.TimeOut → sAUS; EI_M6 → sAUS

Global fault cascade: from every state preceding an sNACH_x, EI_Mx[STOERUNG_Mx] leads directly, with no detour, straight into that state (or to sAUS for x=6) — 51 such direct edges in total, see the network diagram.

Application Scenarios

- **Grain-intake conveyor chain**: Six conveyor elements in series (e.g. bucket elevator, cross conveyor, trough or screw conveyor) that must only be switched on and off in a fixed order so that no element ever conveys against a stopped downstream element.
- **Multi-stage conveying systems in general**: Any system with a fixed cascade of motors where a fault at one stage requires a controlled but immediate retreat of the upstream stages.
- **Safety-critical sequence chains**: Processes where a plain timed sequencer is not enough because a latched fault indication and a restart interlock (EINSCHALTBEREIT) are also required.

⚖️ Comparison with Similar Blocks

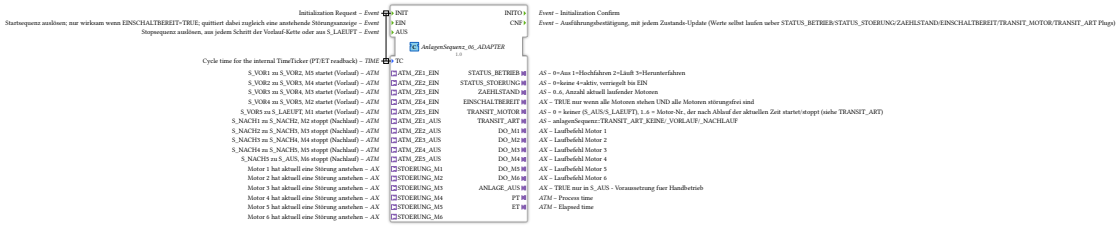


- **sequence_T_04** / **sequence_T_08**: Generic, linear timed sequencers with 4 or 8 steps and a single reset path. AnlagenSequenz_06 reuses the same ATimeOut adapter mechanism, but is not a generic block —

the ring topology (two coupled linear chains), the fixed six-motor pattern per step, and the direct single-step fault cascade are all hard-coded, not configurable.
- **Plain timer chains (TON chaining)**: Would need to reimplement state logic, the per-step motor pattern, and fault handling by hand. `AnlagenSequenz_06` encapsulates all of that, including the interlock logic.
- **Counter-/event-based sequencers**: Advance on external triggers rather than time. `AnlagenSequenz_06` is specifically designed for the case where the dwell time per step is fixed (motor start-up time), with faults as the only asynchronous interruption path.

Conclusion

`AnlagenSequenz_06` bundles a complete, safety-relevant start/stop logic for six motors operating in series into a single block: an ordered start-up and shutdown sequence via two coupled linear chains, a latched fault status with an explicit restart interlock, and a direct, delay-free fault cascade from every operating state. The clear separation of ring topology (ECC), motor switching logic (algorithms), and timing (`timeOut` adapter) keeps the block maintainable despite its complexity and significantly reduces the programming effort in the parent application network.



AnlagenSequenz_06_ADAPTER

• – ○ • – ○ • – ○ •

Introduction

`AnlagenSequenz_06_ADAPTER` is a composite wrapper around AnlagenSequenz_06: the same ring-sequencer logic for six motors, but with every data-carrying input/output moved onto adapter connections, so the block can be wired into an application entirely through adapters (`AX`, `AS`, `ATM`) without pulling individual Event/BOOL/TIME lines. The timing (`timeOut`) stays internal and is not exposed.

Function Blocks Used (FBs)

Sub-modules: AnlagenSequenz_06_ADAPTER

- **Type**: Composite (FBNetwork)
- **Internal FBs used**:
  - **Sequence**: `logiBUS::utils::sequence::timed::AnlagenSequenz_06` - the actual ring sequencer, see AnlagenSequenz_06 for the full state overview.
  - **TimeTicker**: `adapter::events::TimeOut::TimeTicker` - generates the cyclic time tick (`TC`, default `T#200ms`) for the internal timing.
  - **E_TimeOut**: `adapter::events::TimeOut::E_FB_TimeOut` - couples `Sequence.timeOut` to `TimeTicker`, so the lead/lag times run without a dedicated timer FB in the application.
- **Functionality**: Bundles the six `DO_Mx` run commands and six `STOERUNG_Mx` fault inputs, plus every status value (`STATUS_BETRIEB`, `STATUS_STOERUNG`, `ZAEHLSTAND`, `EINSCHALTBEREIT`, `TRANSIT_MOTOR`, `TRANSIT_ART`, `ANLAGE_AUS`), into `AX`/`AS` adapters, and feeds each of the ten dwell times (`ZE1..5_EIN`/`_AUS`) through its own `ATM` adapter socket instead of exposing them as individual `TIME` data inputs. `PT`/`ET` (process/elapsed time) are exposed as `ATM` plugs for a readback of the internal timing.
- **Dwell-time sockets (`ATM`)**: The ten sockets `ATM_ZE1_EIN`..`ATM_ZE5_EIN` and `ATM_ZE1_AUS`..`ATM_ZE5_AUS` (each of type `adapter::types::unidirectional::ATM`) deliver the dwell times of the transitions:
  - `ATM_ZE1_EIN`: S_VOR1 to S_VOR2, M5 starts (lead)
  - `ATM_ZE2_EIN`: S_VOR2 to S_VOR3, M4 starts (lead)
  - `ATM_ZE3_EIN`: S_VOR3 to S_VOR4, M3 starts (lead)
  - `ATM_ZE4_EIN`: S_VOR4 to S_VOR5, M2 starts (lead)
  - `ATM_ZE5_EIN`: S_VOR5 to S_LAEUFT, M1 starts (lead)
  - `ATM_ZE1_AUS`: S_NACH1 to S_NACH2, M2 stops (lag)
  - `ATM_ZE2_AUS`: S_NACH2 to S_NACH3, M3 stops (lag)
  - `ATM_ZE3_AUS`: S_NACH3 to S_NACH4, M4 stops (lag)
  - `ATM_ZE4_AUS`: S_NACH4 to S_NACH5, M5 stops (lag)
  - `ATM_ZE5_AUS`: S_NACH5 to S_AUS, M6 stops (lag)

Program Flow and Connections

1. `EIN`/`AUS` pass through unchanged to `Sequence.EIN`/`Sequence.AUS`.
2. Each `ATM_ZEk_EIN`/`ATM_ZEk_AUS` adapter delivers its time (`.D1`) to `Sequence.ZEk_EIN`/`Sequence.ZEk_AUS` and simultaneously (`.E1`) triggers the matching `Sequence.SET_ZEk_EIN`/`SET_ZEk_AUS` set event.
3. Each `STOERUNG_Mx` adapter delivers its fault signal (`.D1`) to `Sequence.STOERUNG_Mx` and (`.E1`) triggers `Sequence.EI_Mx`.
4. `Sequence.CNF` simultaneously triggers all status adapters (`STATUS_BETRIEB`, `STATUS_STOERUNG`, `ZAEHLSTAND`, `EINSCHALTBEREIT`, `TRANSIT_MOTOR`, `TRANSIT_ART`, `ANLAGE_AUS`); the associated data values run in parallel via their `.D1`.
5. Each `Sequence.EO_Mx` triggers `DO_Mx.E1`, with the run command carried via `DO_Mx.D1`.
6. `Sequence.INITO` starts the `TimeTicker`; its `CNF`/`STARTO` feed `ET`/`PT` for a pure time readback to the outside.
7. `Sequence.timeOut` (adapter socket) is connected internally to `E_TimeOut.TimeOutSocket`, `TimeTicker.TimeTickSocket` to `E_TimeOut.TimeTickSocket` - the entire timing stays encapsulated inside the composite.

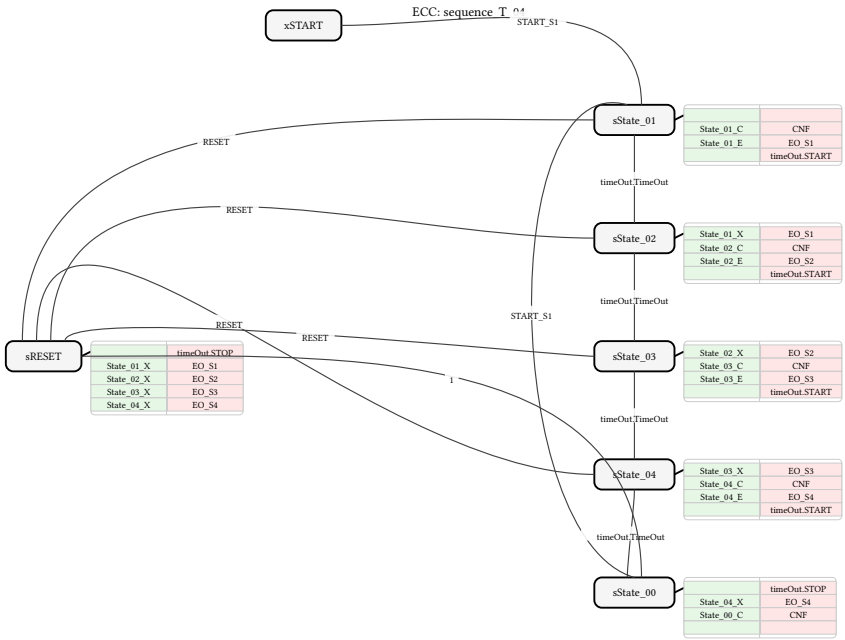
Application Scenarios

- Applications that consistently rely on adapter connections (e.g. for VT integration or OPC-UA exposure via existing adapter conversion chains) and don't want to pull individual event/data lines to the motor sequence.

- Reusing the same ring-sequencer logic across multiple plant sections while keeping the wiring uniform through standardized adapter types (`AX`, `AS`, `ATM`).

⚖️ Comparison with Similar Function Blocks

- **AnlagenSequenz_06**: The underlying basic-FB logic with classic event/data connections. `AnlagenSequenz_06_ADAPTER` only changes the interface, not the state behavior.
- **sequence_T_08_ADAPTER**: Same adapter-wrapper pattern, applied to the generic 8-step sequencer instead of the fixed 6-motor ring topology.



Conclusion

`AnlagenSequenz_06_ADAPTER` makes the complete ring-sequencer logic for six motors usable through pure adapter connections, without changing the underlying state logic - the timing stays fully encapsulated internally.

sequence_T_04

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_T_04` is a time-controlled sequencer with four defined states (State_01 to State_04) and a start state (START). It enables the cyclical or one-time execution of a fixed sequence, with the dwell time in each state controlled by configurable time values. The transition between states occurs automatically after the set time has elapsed. This function block is ideally suited for time-controlled sequences, such as those found in conveyor systems, packaging machines, or washing processes.

Interface Structure

Event Inputs

- **`START_S1`**: Starts the sequence. An event at this input causes the transition from the START state or sState_00 to the first active state, State_01. The time data `DT_S1_S2`, `DT_S2_S3`, `DT_S3_S4`, and `DT_S4_START` are read.
- **`RESET`**: Immediately resets the sequence from any state to the idle state (sState_00). All outputs (`DO_S1` to `DO_S4`) are deactivated.

Event Outputs

- **`CNF`**: Execution Confirmation event. Triggered on every state change and returns the current state number `STATE_NR`.
- **`EO_S1`**: Triggered upon entering state State_01 and returns the corresponding data output `DO_S1`.
- **`EO_S2`**: Triggered upon entering state State_02 and returns the corresponding data output `DO_S2`.
- **`EO_S3`**: Triggered upon entering state State_03 and returns the corresponding data output `DO_S3`.
- **`EO_S4`**: Triggered upon entering state_04 and outputs the corresponding data output `DO_S4`.

Data Inputs

- **`DT_S1_S2`** (TIME): Time spent in state_01 before the automatic transition to state_02. Initial value: `NO_TIME`.
- **`DT_S2_S3`** (TIME): Time spent in state_02 before the automatic transition to state_03. Initial value: `NO_TIME`.
- **`DT_S3_S4`** (TIME): Time spent in state_03 before the automatic transition to state_04. Initial value: `NO_TIME`.
- **`DT_S4_START`** (TIME): Duration in state State_04 before the automatic transition to idle state sState_00 occurs. Initial value: `NO_TIME`.

Data Outputs

- **`STATE_NR`** (SINT): Outputs the number of the currently active state. START = 0, State_01 = 1, State_02 = 2, State_03 = 3, State_04 = 4.
- **`DO_S1`** (BOOL): Logical output that is TRUE as long as the function block is in state State_01.
- **`DO_S2`** (BOOL): Logical output that is TRUE while the FB is in state State_02.
- **`DO_S3`** (BOOL): Logical output that is TRUE while the FB is in state State_03.
- **`DO_S4`** (BOOL): Logical output that is TRUE while the FB is in state State_04.

Adapter

- **`timeOut`** (Plug, Type: `iec61499::events::ATimeOut`): A standardized TimeOut adapter used for timed state transitions. The function block (FB) starts the timer (`timeOut.START`) upon entering an active state and reacts to its `TimeOut` event.

Functionality

The FB operates as a Basic Function Block (BFB) with a defined Execution Control Chart (ECC). The sequence iterates through the states in the fixed order: START -> State_01 -> State_02 -> State_03 -> State_04 -> sState_00.

1. **Start**: A `START_S1` event (from states `xSTART` or `sState_00`) activates State_01.
2. **State Activation**: Upon entering a state (State_01-04), the following actions are performed:

- The corresponding data output (`DO_Sx`) is set to TRUE (Entry Algorithm `State_x_E`).
- The associated event (`EO_Sx`) is triggered.
- The state number (`STATE_NR`) is updated (Confirmation Algorithm `State_x_C`).
- The time configured for the next transition (`DT_...`) is passed to the `timeOut` adapter, and the timer is started.
- The general confirmation event (`CNF`) is triggered.

1. **Time-Controlled Transition**: After the time set in the timer has elapsed, the adapter triggers the `TimeOut` event. This is the condition for transitioning to the next state in the sequence.
2. **State Exit**: When exiting a state, the corresponding data output (`DO_Sx`) is reset to FALSE by the exit algorithm (`State_x_X`).
3. **Cycle End and Reset**: After State_04, the function block switches to the state `sState_00` (idle state). From here, the sequence can be restarted by another `START_S1` event. A `RESET` event from any state immediately leads to state `sRESET`, disables all outputs, and then transitions to `sState_00`.

Technical Features

- **Initial Values**: The time data inputs are pre-assigned the constant `NO_TIME` by default. A value of `NO_TIME` causes the function block to wait indefinitely after entering the state until a `RESET` event occurs.
- **State sState_00**: This state is the stable idle state after the completion of a cycle. Unlike the initial `xSTART`, it is part of the ECC and can execute algorithms (set the state number to 0 here).
- **Adapter Usage**: The timing control is completely outsourced to the standardized `ATimeOut` adapter, increasing reusability and clarity.

State Overview

State Name	Description	Active Outputs	Transition Condition to Next State
xSTART	Initial Idle State.	None	`START_S1`
sState_01	First Active Step.	`DO_S1=1`, `STATE_NR=1`	`timeOut.TimeOut` (after DT_S1_S2)
sState_02	Second Active Step.	`DO_S2=1`, `STATE_NR=2`	`timeOut.TimeOut` (after DT_S2_S3)
sState_03	Third active step.	`DO_S3=1`, `STATE_NR=3`	`timeOut.TimeOut` (after DT_S3_S4)
sState_04	Fourth active step.	`DO_S4=1`, `STATE_NR=4`	`timeOut.TimeOut` (after DT_S4_START)
sState_00	Idle state after sequence completion.	`STATE_NR=0`	`START_S1` (for new cycle)
sRESET	Intermediate state for reset operation.	None	Always (`Condition=1`)

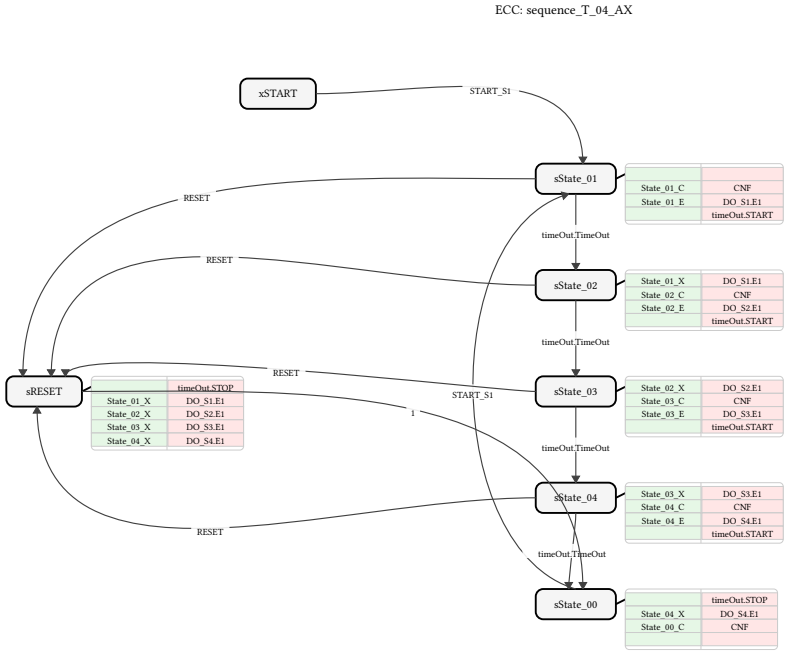
Global transition condition: From states sState_01 to sState_04, a `RESET`-Event always returns to the sRESET state.

Application Scenarios

- **Control of Cycle Machines**: Automatic sequencing of machining steps such as drilling, milling, and deburring with adjustable processing times.
- **Packaging Systems**: Control of the timing sequence: product feeding -> packaging closure -> label application -> palletizing.

``* **Cleaning Processes**: Control of a spray booth: Pre-rinse (State_01) -> Main cleaning (State_02) -> Rinse (State_03) -> Dry (State_04).

- **Test Stands**: Automated test sequence where each test step has a fixed duration.

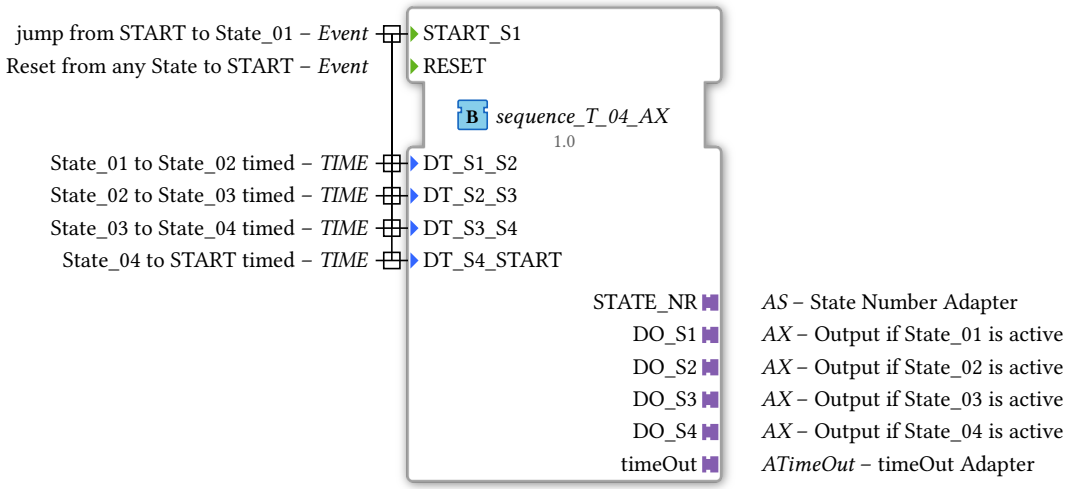


⚖️ Comparison with similar modules

- **Simple Timers (TON)**: Individual timer modules would have to be chained together for a sequence, and the logic for the state transitions and outputs would have to be programmed separately. `sequence_T_04` encapsulates this complete logic.
- **Counter-based Sequencers**: Sequencers that advance based on events (not time) offer a different type of control. `sequence_T_04` is specifically designed for time-critical processes without external triggers.
- **PLC-specific Sequence Flow Languages (S7-GRAFCET)**: This function block implements a similar principle to a Grafcet step chain, but within the portable IEC 61499 standard.

Conclusion

The `sequence_T_04` is a robust and easy-to-configure tool for time-controlled sequence functions with up to four steps. The clear separation of state logic (ECC) and time control (adapter), as well as the complete encapsulation of its behavior, makes it easy to maintain and significantly reduces programming effort in the higher-level application network. The ability to instantly reset from any state also ensures high operational reliability.



sequence_T_04_AX

• — ○ • — ○ • — ○ •

Introduction

sequence_T_04_AXis a variant ofsequence_T_04 that additionally uses adapters (AX`) for the outputs. It controls a purely time-based sequence with 4 output states.

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence at State_01.
- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Confirms execution.

Data Inputs

- **DT_S1_S2**: Transition time from State_01 to State_02.
- **DT_S2_S3**: Transition time from State_02 to State_03.
- **DT_S3_S4**: Transition time from State_03 to State_04.
- **DT_S4_START**: Transition time from State_04 to START.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** (adapter::types::unidirectional::AX): Output adapter for State_01.
- **DO_S2** (adapter::types::unidirectional::AX): Output adapter for State_02.
- **DO_S3** (adapter::types::unidirectional::AX): Output adapter for State_03.
- **DO_S4** (adapter::types::unidirectional::AX): Output adapter for State_04.
- **timeOut** (iec61499::events::ATimeOut): Timer adapter.

Functionality

Corresponds to `sequence_T_04`, but uses adapters for the outputs.

Technical Features

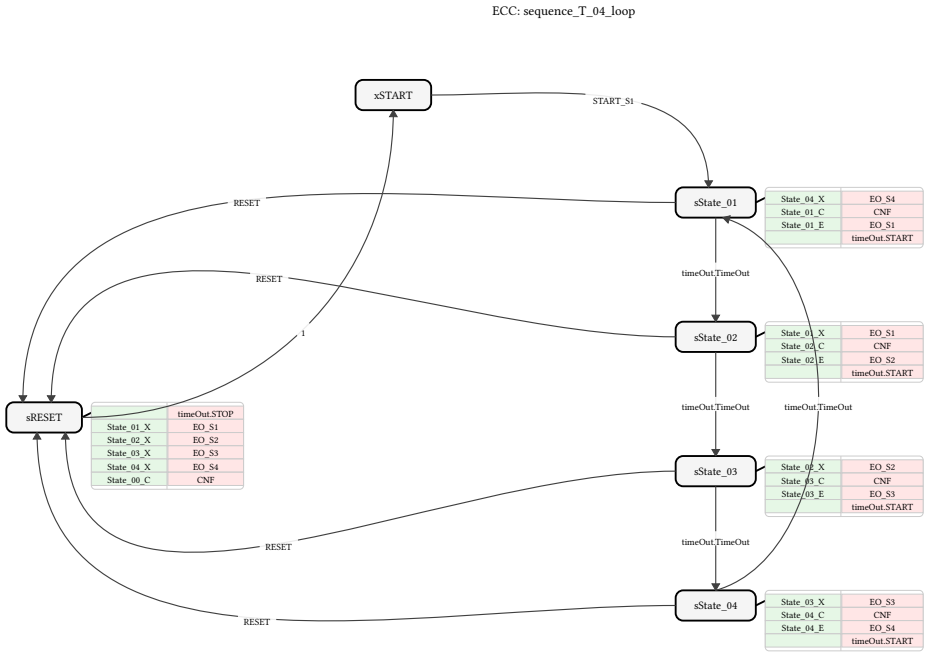
- Uses `adapter::types::unidirectional::AX`.

State Overview

See `sequence_T_04`.

Application Scenarios

For time-controlled 4-step sequences with adapter connection.

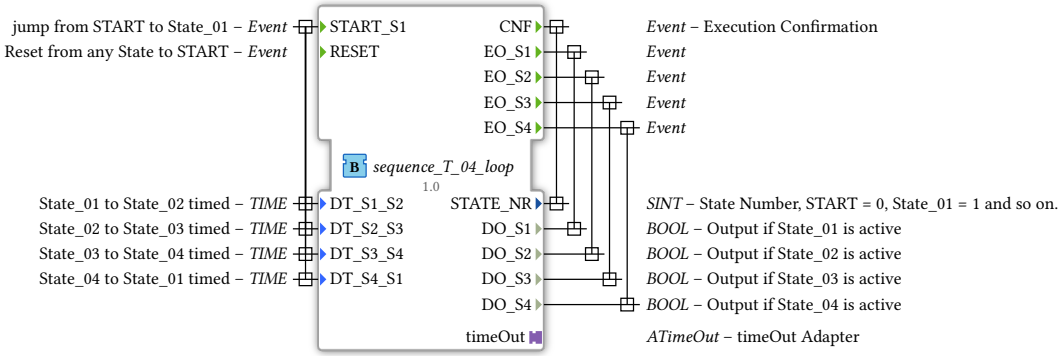


⚖️ Comparison with Similar Function Blocks

- **sequence_T_04**: Standard version without adapter.

Conclusion

Adapter version of the 4-step time sequencer.



sequence_T_04_loop

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_T_04_loop` is a time-controlled sequencer with four outputs that operates in a loop. It cycles through four states (State_01 to State_04) sequentially. The transition from one state to the next occurs automatically after an adjustable time delay. The block can be reset from any state and then restarts the sequence.

Interface Structure

Event Inputs

- **`START_S1`**: Starts the sequence. The transition occurs from the initial state `START` to `State_01`. This event is linked to the four time data inputs.
- **`RESET`**: Resets the sequence from any active state back to the initial state `START`.

Event Outputs

- **`CNF`**: Confirmation. Triggered on every state change, it returns the current state number.

- **EO_S1**: Triggered upon entering State_01 and returns the corresponding data output DO_S1.
- **EO_S2**: Triggered upon entry into State_02 and returns the corresponding data output DO_S2.
- **EO_S3**: Triggered upon entry into State_03 and returns the corresponding data output DO_S3.
- **EO_S4**: Triggered upon entry into State_04 and returns the corresponding data output DO_S4.

Data Inputs

- **DT_S1_S2** (TIME): Time delay for the transition from State_01 to State_02. Initial value: NO_TIME.
- **DT_S2_S3** (TIME): Time delay for the transition from State_02 to State_03. Initial value: qzmsdocs000031 ... * **DT_S3_S4** (TIME): Time delay for the transition from State_03 to State_04. Initial value: NO_TIME.
- **DT_S4_S1** (TIME): Time delay for the transition from State_04 back to State_01 (loop). Initial value: NO_TIME.

Data Outputs

- **STATE_NR** (SINT): Current status number. 0 = START, 1 = State_01, 2 = State_02, 3 = State_03, 4 = State_04.
- **DO_S1** (BOOL): Is TRUE when State_01 is active.
- **DO_S2** (BOOL): Is TRUE when State_02 is active.
- **DO_S3** (BOOL): Is TRUE when State_03 is active.
- **DO_S4** (BOOL): Is TRUE when State_04 is active.

Adapter

- **timeOut** (Plug, Type: iec61499::events::ATimeOut): A timer adapter used for timed state transitions. The function block starts the timer when a state is entered and reacts to its TimeOut event.

Functionality

The function block (FB) is implemented as a BasicFB with an Execution Control Chart (ECC). The sequence begins in the initial state xSTART. An event START_S1 leads to the first active state sState_01.

In each active state (sState_01 to sState_04), the following actions are executed sequentially:

1. **Exit step of the previous state**: The corresponding data output (DO_Sx) is set to FALSE (except on the first entry of xSTART).
2. **Confirmation Step**: The state number STATE_NR is updated, and the delay time for the *next* transition is passed to the timeOut adapter (timeOut.DT).
3. **Entry Step of the New State**: The corresponding data output (DO_Sx) is set to TRUE, and the corresponding event (EO_Sx) is triggered.
4. **Timer Start**: The timeOut adapter is started (timeOut.START).

The transition to the next state occurs exclusively via the TimeOut event of the adapter. After State_04, the sequence jumps back to State_01 according to the loop logic.

An event RESET from any state leads to state sRESET. There, all outputs (DO_S1 to DO_S4) are deactivated, the timer is stopped, the state number is set to 0 (START), and an acknowledgment (CNF) is issued. The function block then automatically returns to state xSTART.

Technical Features

- **Time Control**: The transitions are purely time-controlled. There are no event-driven transitions between the main states. * **Initial Values**: The time data inputs are pre-assigned to NO_TIME by default. This must be adjusted for proper operation.
- **Constants**: The function block uses constants from the library logiBUS::utils::sequence::const::sequence (e.g., for state numbers) and logiBUS::utils::sequence::const::sequence::NO_TIME.

State Overview

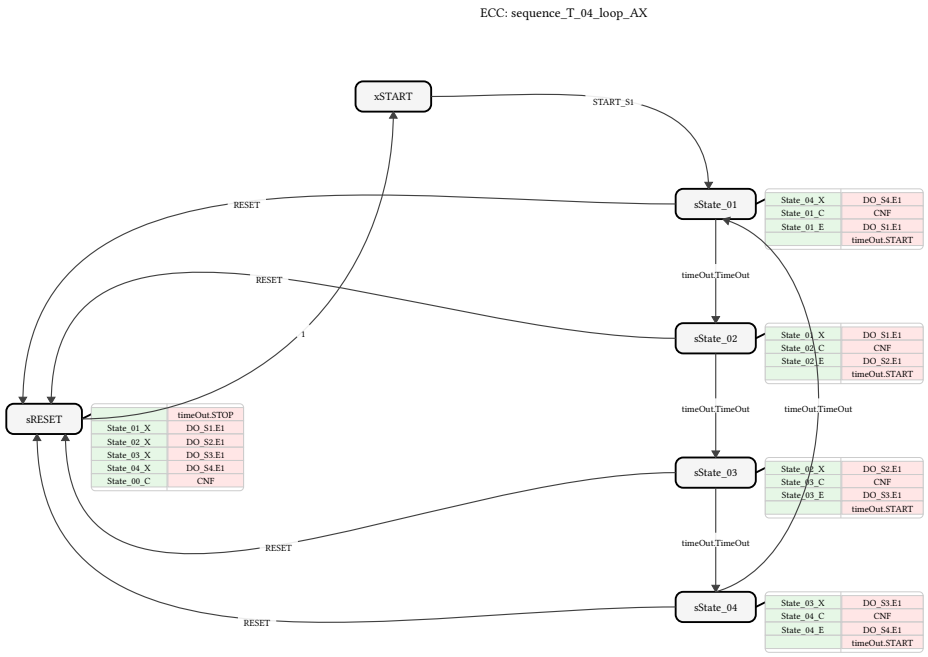
1. **xSTART**: Initial, inactive state. Waiting for START_S1.
2. **sState_01**: First active state. DO_S1 = TRUE. Timer for transition to State_02 is running.
3. **sState_02**: Second active state. DO_S2 = TRUE. Timer for transition to State_03 is running.
4. **sState_03**: Third active state. DO_S3 = TRUE. Timer for transition to State_04 is running.
5. **sState_04**: Fourth active state. DO_S4 = TRUE. Timer for transition (back) to State_01 is running.
6. **sRESET**: Reset state. Disables all outputs, stops the timer, and confirms the reset.

Application Scenarios

- Control of cyclic processes with fixed time steps, e.g., in packaging machines, washing systems, or automated assembly lines.
- Control of actuators in a fixed, time-based sequence.
- As a central clock for higher-level control processes.

⚖️ Comparison with Similar Components

- **Simple Timers (TON)**: Individual timers do not offer integrated sequence logic. `sequence_T_04_loop` encapsulates the complete state machine with four steps.
- **Event-Driven Sequencers**: In contrast to event-driven sequencers (e.g., `sequence_E_04_loop`), transitions here occur exclusively based on time, not through external events.
- **PLC Cycle**: Time-controlled sequence monitoring is more precise and independent of the PLC cycle because it is based on the `ATimeOut` adapter.

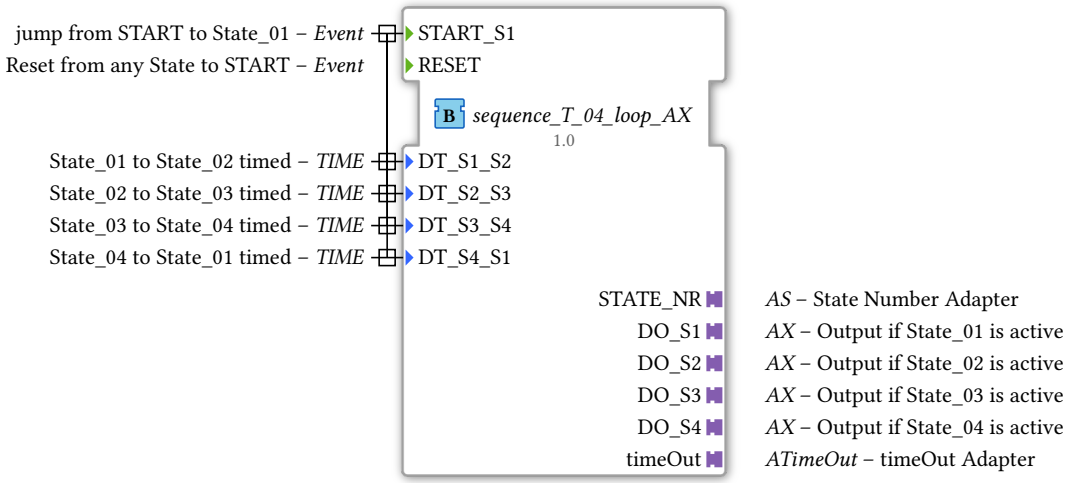


🛠️ Related Exercises

- Exercise_035a

Conclusion

The `sequence_T_04_loop`This is a robust and easy-to-configure function block for time-controlled, four-step sequences. Its clear separation of state logic and time parameters, along with its integrated reset functionality, makes it well-suited for standardized cyclic processes in automation technology. The use of a standard timing adapter ensures portability and reliability.



sequence_T_04_loop_AX

• – ○ • – ○ • – ○ •

Introduction

sequence_T_04_loop_AXis a variant ofsequence_T_04_loop that additionally uses adapters (AX`) for the outputs. It controls a purely time-controlled, cyclic sequence with 4 output states.

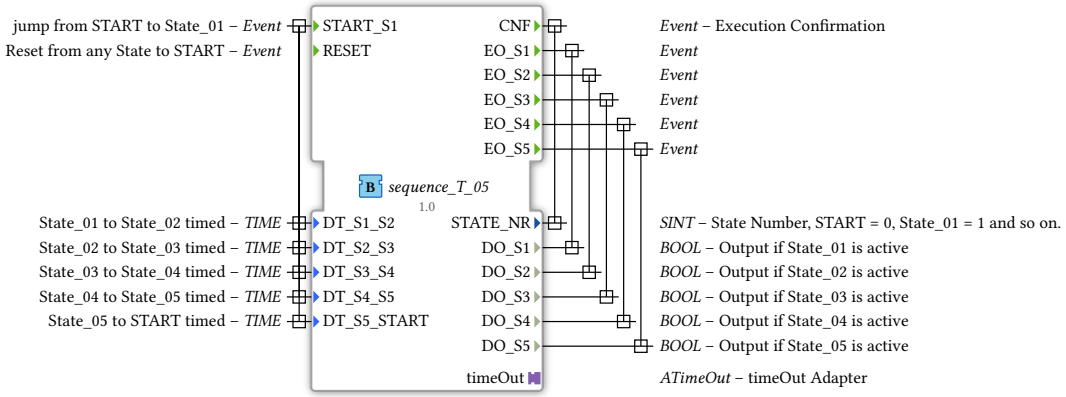
⚖️ Comparison with Similar Blocks
- **sequence_T_04_loop**: Standard version without adapter.

Conclusion

Adapter version of the 4-step loop time sequencer.



sequence_T_05

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_T_05` is a time-controlled sequencer with five output states. It cycles through a fixed sequence of states (State_01 to State_05), with the transition between each state controlled by adjustable time delays. The block is designed for applications where process steps or actions need to be activated sequentially for a defined duration.

Interface Structure

Event Inputs

- **`START_S1`**: Starts the sequence. The block transitions from the start state (`START` or `State_00`) to the first active state, `State_01`. This event is linked to the five time data inputs.
- **`RESET`**: Resets the sequence from any state back to the inactive start state (`State_00`). All outputs are disabled.

Event Outputs

- **CNF**: Confirmation. Triggered on every state transition, it returns the new state number (STATE_NR).
- **EO_S1**: Triggered upon entering state State_01 and outputs the corresponding data output DO_S1.
- **EO_S2**: Triggered upon entering state State_02 and outputs the corresponding data output DO_S2.
- **EO_S3**: Triggered upon entering state State_03 and outputs the corresponding data output DO_S3.
- **EO_S4**: Triggered upon entering state State_04, this output provides the corresponding data output DO_S4.
- **EO_S5**: Triggered upon entering state State_05, this output provides the corresponding data output DO_S5.

Data Inputs

All time data inputs are of type TIME and have the initial value NO_TIME. They define the dwell time in the respective state before the automatic transition to the next state occurs.

** ... * **DT_S1_S2**: Retention time in State_01 before the transition to State_02.

- **DT_S2_S3**: Retention time in State_02 before the transition to State_03.
- **DT_S3_S4**: Retention time in State_03 before the transition to State_04.
- **DT_S4_S5**: Retention time in State_04 before the transition to State_05.
- **DT_S5_START**: Dwell time in State_05 before transitioning back to the start state State_00.

Data Outputs

- **STATE_NR** (SINT): Outputs the current state number. 0 = START/State_00, 1 = State_01, ..., 5 = State_05.
- **DO_S1** (BOOL): Is TRUE when state State_01 is active.
- **DO_S2** (BOOL): Is TRUE when state State_02 is active.
- **DO_S3** (BOOL): Is TRUE when state State_03 is active.
- **DO_S4** (BOOL): Is TRUE when state State_04 is active.
- **DO_S5** (BOOL): Is TRUE when state State_05 is active.

Adapter

- **timeOut** (Plug, Type: iec61499::events::ATimeOut): A timeout adapter used for timed state transitions. The block starts (START) the timer when entering an active state and stops (STOP) it when leaving.

Functionality

The block operates as a Basic Function Block with a defined Execution Control Chart (ECC). The sequence is initiated by the event START_S1. The block then cycles through the states State_01 to State_05. In each active state, the corresponding data output (DO_Sx) is set to TRUE, and a timer with the duration configured for that state (DT_Sx_Sy) is started. Once the timer expires (timeOut.TimeOut), the block automatically transitions to the next state. During the state change, the previous output is deactivated, and the new one is activated. After State_05, the block returns to the inactive state State_00. An event in RESET immediately interrupts the sequence, disables all outputs, and brings the block to state State_00.

Technical Features

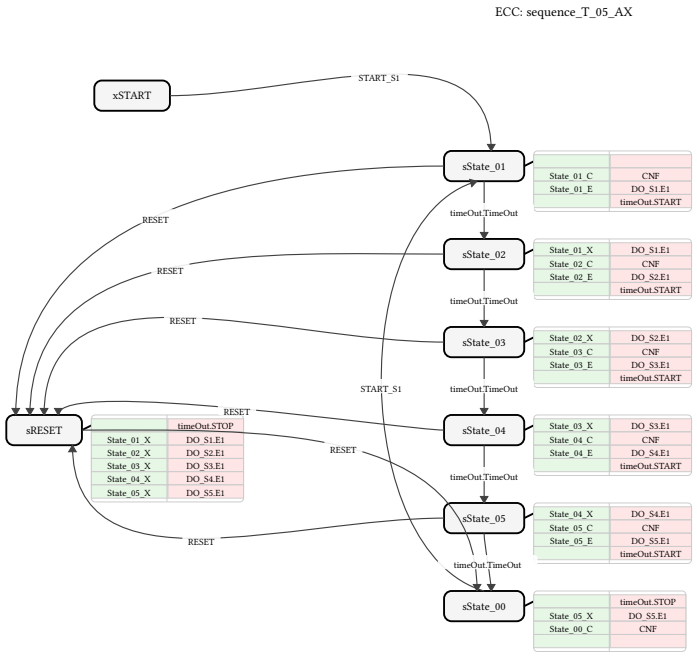
- **State Handling**: Each active state (State_01 to State_05) has separate algorithms for entry (_E), acknowledgment (_C), and exit (_X). This allows for a clear separation of logic.
- **Timer Integration**: The timing control is completely outsourced to the adapter ATimeOut, which increases reusability and maintainability.
- **Constants**: The block imports constants from logiBUS::utils::sequence::const::sequence (for state numbers) and ::NO_TIME for the initial duration values.
- **Initial State**: The actual inactive sleep state after a reset or sequence completion is sState_00. xSTART is the initial ECC state during the first boot.

State Overview

1. **xSTART**: Initial ECC state at system startup.
2. **sState_00**: Inactive sleep state. All outputs are FALSE. The sequence can be started from here with START_S1. 3. **sState_01 to sState_05**: Active sequence states. The respective output DO_Sx is TRUE. The transition to the next state is time-controlled.
3. **sRESET**: Intermediate state that is accessed from any active state upon a RESET event. It deactivates all outputs and then switches to sState_00.

Application Scenarios

- **Batch Process Control**: Sequentially activated steps such as filling, heating, stirring, cooling, and emptying with adjustable step times.
- **Sequence Controls in Machines**: Time-controlled sequence of cylinder movements or tool changes in an automated system.
- **Test Sequences**: Automated test sequences in which various signals are applied sequentially for a specific duration, and the results are evaluated.
- **Lighting Control**: Time-controlled choreographies for advertising or decorative lighting.

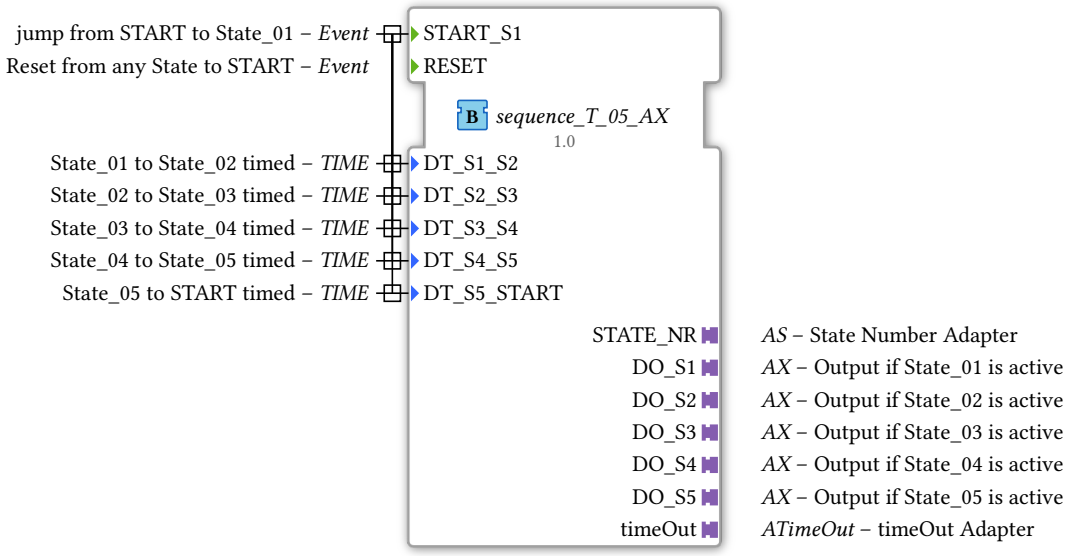


⚖️ Comparison with Similar Function Blocks

Compared to a simple `E_DELAY` or `E_SR` function block, `sequence_T_05` offersA predefined, multi-stage sequence logic in a single, configurable block. Compared to a custom-programmed sequence with multiple interconnected blocks, it significantly simplifies the application and reduces the potential for errors. Other sequencer blocks might react to events (instead of time) for transitions or allow a variable number of steps.

Conclusion

The `sequence_T_05` is a robust and easy-to-configure tool for time-controlled sequences with a fixed number of steps. Due to the clear separation of state logic and timing, as well as the comprehensive confirmation and reset mechanisms, it is ideally suited for reliable automation tasks in industrial environments. Parameterization of step times at runtime enables a high degree of flexibility.



sequence_T_05_AX

• — ○ • — ○ • — ○ •

Introduction

sequence_T_05_AXis a variant ofsequence_T_05 that additionally uses adapters (AX`) for the outputs. It controls a purely time-based sequence with 5 output states.

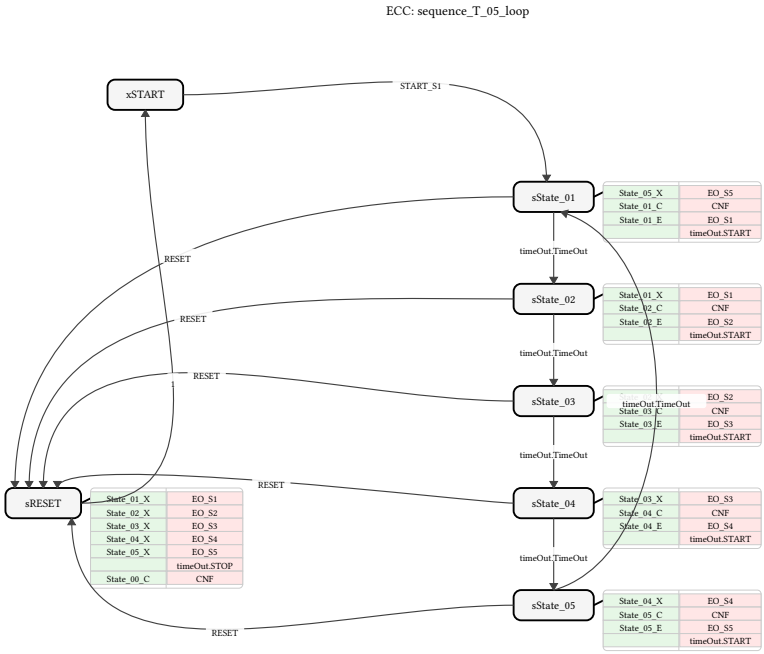
State Overview

See `sequence_T_05`.

Application Scenarios

For time-controlled 5-step sequences with adapter connection.

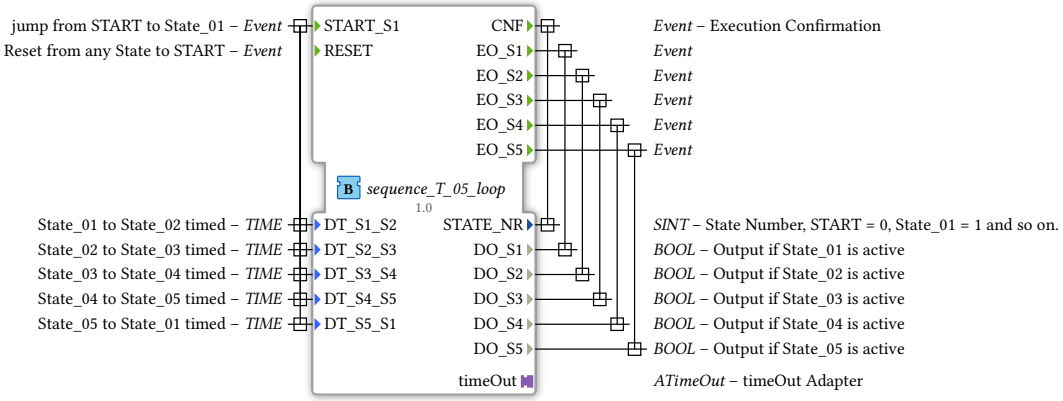


⚖️ Comparison with similar components

- **sequence_T_05**: Standard version without adapter.

Conclusion

Adapter version of the 5-step time sequencer.



sequence_T_05_loop

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_T_05_loop` is a time-controlled sequencer that implements a cyclical sequence of five states (State_01 to State_05). The transition from one state to the next occurs after an adjustable time delay. This function block is designed for applications where actions or process steps need to be activated sequentially for a defined duration, for example, in automated handling or manufacturing processes.

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence and performs a transition from the initial state (START) to the first active state (State_01). The event is linked to the five time data inputs.
- **RESET**: Aborts the current sequence and enters the reset state (sRESET), from where it automatically returns to the initial state (xSTART). Resets all outputs.

Event Outputs

- **CNF**: Confirmation event. Triggered on every state change, this output returns the current state number (STATE_NR).
- **EO_S1** to **EO_S5**: State events. Triggered upon entering the respective state (State_01 to State_05), these outputs return the corresponding Boolean data output (DO_S1 to DO_S5).

Data Inputs

- **DT_S1_S2** (Type: TIME, Initial value: NO_TIME): Duration of the transition from State_01 to State_02.
- **DT_S2_S3** (Type: TIME, Initial value: NO_TIME): Time for the transition from State_02 to State_03.
- **DT_S3_S4** (Type: TIME, Initial value: NO_TIME): Time for the transition from State_03 to State_04.
- **DT_S4_S5** (Type: TIME, Initial value: NO_TIME): Time for the transition from State_04 to State_05.
- **DT_S5_S1** (Type: TIME, Initial value: NO_TIME): Time for the transition from State_05 back to State_01, which closes the loop.

Data Outputs

- **STATE_NR** (Type: SINT): Outputs the number of the currently active state. 0 = START, 1 = State_01, ..., 5 = State_05.
- **DO_S1** to **DO_S5** (Type: BOOL): Logical outputs that are TRUE while the FB is in the corresponding state (State_01 to State_05).

Adapter

- **timeOut** (Type: iec61499::events::ATimeOut, Plug): A timer adapter used for timed state transitions. The FB starts the timer upon entering a state and transitions to the next state upon receiving the TimeOut event.

Functionality

The FB is implemented as a Basic Function Block (BFB) with an Execution Control Chart (ECC). After starting (START_S1), it cycles through states State_01 to State_05 in a fixed sequence. In each active state, the following actions are performed:

1. **Exit action of the previous state**: Sets the corresponding Boolean output (DO_Sx) to FALSE.
2. **Confirmation action**: Sets the current state STATE_NR and configures the dwell time for the *current* state in the timeOut adapter (e.g., the value from DT_S1_S2 is loaded in State_01).
3. **Entry Action of the New State**: Sets the corresponding Boolean output (DO_Sx) to TRUE.
4. **Timer Start**: Starts the timeOut adapter with the time loaded in step 2.

The transition to the next state occurs only if the timeOut adapter returns the TimeOut event. After State_05, the function block jumps back to State_01 according to DT_S5_S1, creating an infinite loop. A RESET event from any state disables all outputs, stops the timer, and returns the function block to its initial state, xSTART.

Technical Features

- **Initial Values**: The time data inputs are initialized with the constant NO_TIME by default. A value of NO_TIME or T#0s results in an immediate state transition.
- **State Confirmation**: The CNF event is triggered in every state (including reset), enabling reliable external monitoring of the function block's activity.
- **Adapter Usage**: The time control is completely outsourced to the standardized ATimeOut adapter, which promotes reusability and clear interfaces.
- **Constants**: The function block imports constants from logiBUS::utils::sequence::const::sequence, e.g., for the state numbers (State_00, State_01, ...).

State Overview

The ECC comprises seven states:

- **`xSTART`**: Inactive initial state. Waiting for `START_S1`.
- **`sState_01`** to **`sState_05`**: Active operating states. Each one activates its specific output (`DO_Sx`) and starts the timer for its own duration.
- **`sRESET`**: Reset state. Deactivates all outputs, stops the timer, and sends an acknowledgment (`CNF`) with `STATE_NR=0`. Automatically reverts to condition `1` (always true) and then back to `xSTART`.

Application Scenarios

- **Cycle Control**: Automated sequences in packaging machines where various actuators (grippers, punches, conveyors) must be activated sequentially for specific durations.
- **Process Control**: Step-by-step execution of chemical or thermal processes where each step has a defined dwell time.
- **Display or Flashing Sequences**: Control of visual or audible signals in a defined, timed sequence.

⚖️ Comparison with Similar Function Blocks

Unlike a simple TON timer (delay-on delay), this function block implements a complete state machine with multiple steps. Compared to generic sequencer function blocks, which often use step detection (e.g., via slope edges), this block is purely time-controlled. It resembles a chain of TON blocks but is encapsulated in a single, state-based function block, simplifying its arrangement and parameterization.

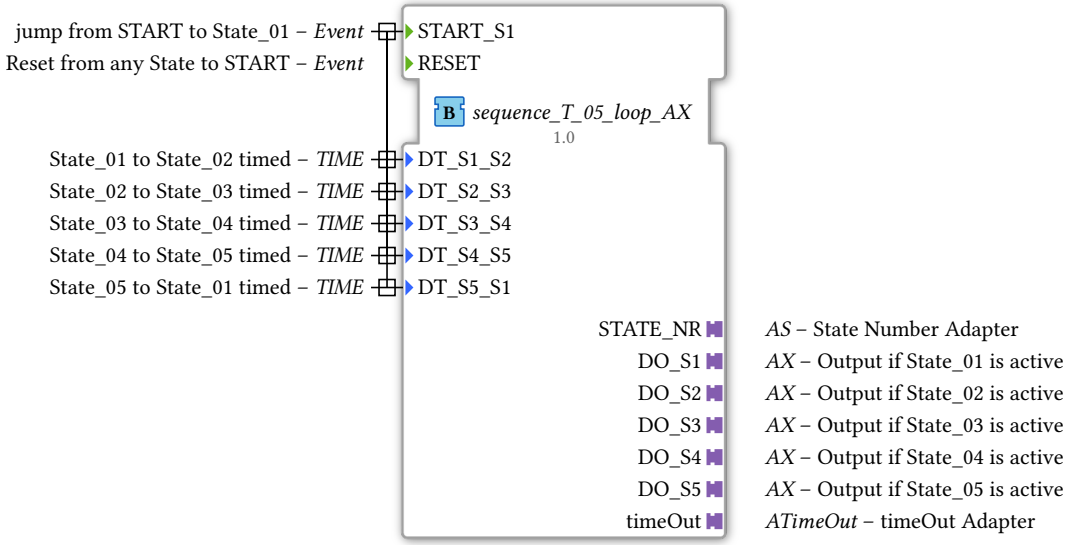
Conclusion

The `sequence_T_05_loop`This is a specialized, robust, and easy-to-configure sequencer for cyclic, time-controlled, five-step processes. Its clear structure, use of standardized adapters, and comprehensive confirmation of all state changes make it a reliable component for time-critical automation tasks. The loop function and central reset are particularly well-suited for continuous operation applications.



sequence_T_05_loop_AX

• — ○ • — ○ • — ○ •

Introduction

sequence_T_05_loop_AXis a variant ofsequence_T_05_loop that additionally uses adapters (AX`) for the outputs. It controls a purely time-controlled, cyclic sequence with 5 output states.

Interface Structure

Event Inputs

- **START_S1**: Starts the sequence at State_01.
- **RESET**: Resets the sequence.

Event Outputs

- **CNF**: Confirmation of execution.

Data Inputs

- **DT_S1_S2**: Transition time for State_01 -> State_02.
- **DT_S2_S3**: Transition time for State_02 -> State_03.
- **DT_S3_S4**: Transition time for State_03 -> State_04.
- **DT_S4_S5**: Transition time for State_04 -> State_05.
- **DT_S5_S1**: Transition time for State_05 -> State_01.

Data Outputs

- **STATE_NR** (SINT): Current state number.

Adapters

- **DO_S1** (adapter::types::unidirectional::AX): Output adapter for State_01.
- **DO_S2** (adapter::types::unidirectional::AX): Output adapter for State_02.
- **DO_S3** (adapter::types::unidirectional::AX): Output adapter for State_03.
- **DO_S4** (adapter::types::unidirectional::AX): Output adapter for State_04.
- **DO_S5** (adapter::types::unidirectional::AX): Output adapter for State_05.
- **timeOut** (iec61499::events::ATimeOut): Timer adapter.

Functionality

Corresponds to `sequence_T_05_loop`, but uses adapters for the outputs.

Technical Features

- Uses `adapter::types::unidirectional::AX`.

State Overview

See `sequence_T_05_loop`.

Application Scenarios

For time-controlled, cyclical 5-step sequences with adapter connectivity.

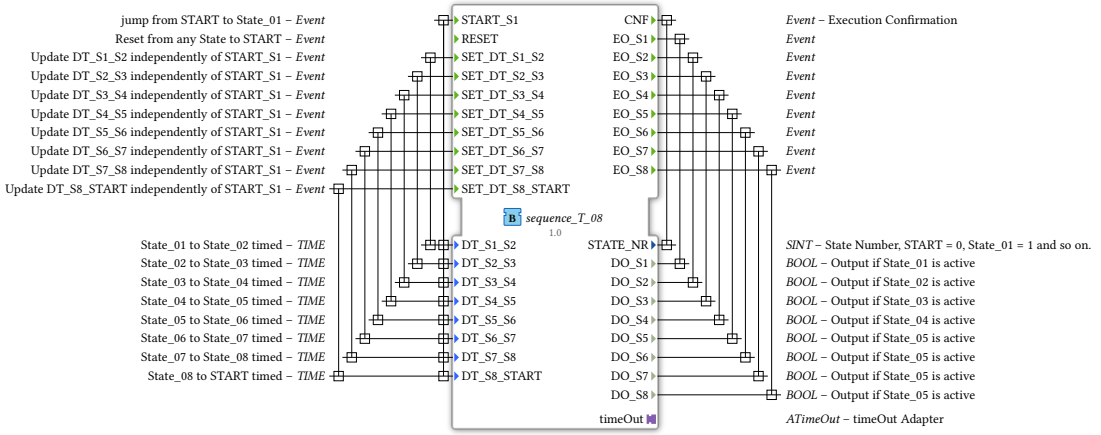
Conclusion

Adapter version of the 5-step loop time sequencer.



sequence_T_08

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_T_08` is a time-controlled sequencer with eight outputs. It implements a fixed sequence of states, with the transition between individual states controlled by adjustable time delays. This block is designed for applications where process steps or machine states need to be activated sequentially for a defined duration, such as in packaging machines, conveyor systems, or washing systems.

Interface Structure

Event Inputs

- `START_S1`: Starts the sequence. An event at this input causes the transition from state `START` to the first active state, `State_01`. All eight time data inputs are read.
- `RESET`: Immediately resets the sequence. An event at this input leads from any state to state `START` and disables all outputs.
- `SET_DT_S1_S2`, `SET_DT_S2_S3`, `SET_DT_S3_S4`, `SET_DT_S4_S5`, `SET_DT_S5_S6`, `SET_DT_S6_S7`, `SET_DT_S7_S8`, `SET_DT_S8_START`: Update the time of the same name (`DT_S1_S2` to `DT_S8_START`) independently of `START_S1`. If the FB is currently in the corresponding state, that state's time setting is executed again (live update of the running timer).

Event Outputs

- `CNF`: Execution Confirmation event. Triggered on every state change, it returns the new state number, `STATE_NR`.
- `EO_S1` to `EO_S8`: State events. Each of these events is triggered upon entering the corresponding state (`State_01` to `State_08`) and returns the associated Boolean data output value (`DO_S1` to `DO_S8`).

Data Inputs

- `DT_S1_S2` to `DT_S8_START` (Type `TIME`): Define the dwell time for each state. This value determines how long the function block remains in the respective state before the automatic transition to the next state occurs. The default value, `NO_TIME`, disables the timed transition, so the function block remains in the state until `RESET` occurs.
- `DT_S1_S2` to `DT_S8_START` (Type `TIME`): Define the dwell time for each state.

Data Outputs

- `STATE_NR` (Type `SINT`): Outputs the current state number. `0` corresponds to state `START`, `1` to `8` correspond to the active states `State_01` to `State_08`.
- `DO_S1` to `DO_S8` (Type `BOOL`): The physical output signals of the sequence. Each output is set to `TRUE` when the corresponding state is active; otherwise, it is `FALSE`.

Adapter Ports

- `timeOut` (Type `iec61499::events::ATimeOut`): A plug-in adapter that provides the timer. The function block (FB) uses the interface to start a timer (`timeOut.START`) and wait for its expiration (`timeOut.TimeOut`). The respective time duration is transmitted via `timeOut.DT`.

Functionality

The FB operates as a Basic Function Block (BFB) with a defined Execution Control Chart (ECC). The sequence cycles through states `State_01` to `State_08` in a fixed order. Each active state performs three essential actions:

1. **Exit action of the previous state**: Disables the corresponding output (algorithm `State_XX_X`).
2. **Confirmation action**: Sets the state number `STATE_NR` and passes the time duration configured for this state to the timer adapter (algorithm `State_XX_C`). Triggers the `CNF` event.

3. **Entry action**: Enables the corresponding output (algorithm `State_XX_E`). Triggers the corresponding `EO_Sx` event. Starts the timer.

The transition to the next state occurs only when the timer has expired (`timeOut.TimeOut`). After `State_08`, the function block jumps to the inactive `State_00` (also represented as `START`), where the timer is stopped. From here, the sequence can only be restarted by a new `START_S1` event. A `RESET` event from any state leads back to `State_00` via a dedicated reset state (`sRESET`), deactivating all active outputs.

Technical Features

- **Flexible Time Control**: Each state transition can be individually configured at runtime via the `DT_` inputs. The value `NO_TIME` allows the sequence to be paused at a specific point.
- **Immediate Reset**: The `RESET` input always has priority and immediately interrupts the running time control.
- **State Feedback**: The current position in the sequence is always traceable via the `STATE_NR` output.
- **Event-Driven Outputs**: In addition to the continuous data outputs (`DO_Sx`), the function block provides a separate event (`EO_Sx`) for each state, which simplifies the control of downstream, event-driven function blocks.

State Overview

The ECC comprises the following states:

- **xSTART / sState_00**: Inactive start and end state. `STATE_NR = 0`, all outputs are `FALSE`.
- **sState_01 to sState_08**: The eight active sequence states. `STATE_NR = 1` to `8`. The corresponding output `DO_Sx` is `TRUE`.
- **sRESET**: Internal reset state. Deactivates all outputs and returns to `sState_00`.

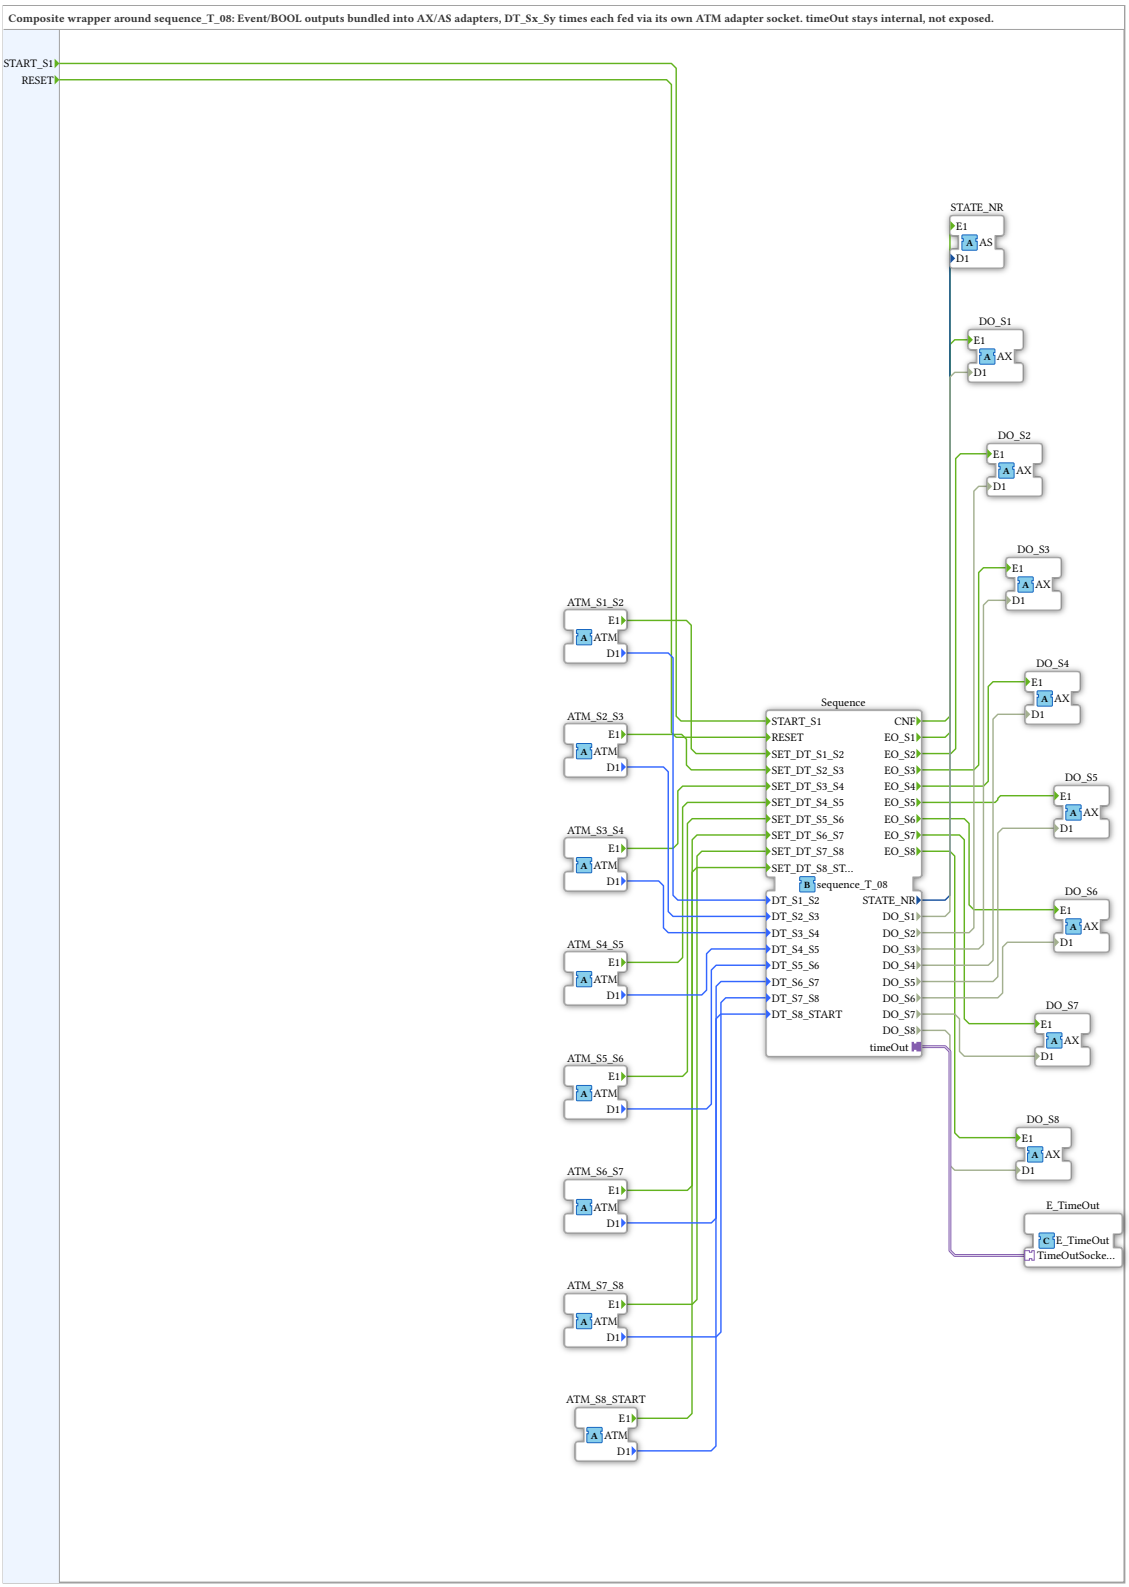
Application Scenarios

- **Cycle Control**: In machines where various actuators (valves, motors, heaters) need to be switched on and off sequentially for a specific period of time.
- **Batch Processes**: For the sequential control of process steps in the food or chemical industries, e.g., filling, heating, stirring, cooling.
- **Test Stands**: Automated sequence of testing and measurement steps on a component.
- **Safety Sequences**: Orderly start-up and shutdown of a system, where steps may only be triggered after a waiting period.

⚖️ Comparison with Similar Components

Unlike a simple TON (Timer On-Delay) or TOF (Timer Off-Delay), which only control a single time-delayed switching operation, `sequence_T_08` orchestrates a complete chain of time-controlled actions. Compared to a Control Unit Transducer (CTU), it offers predefined, state-based logic with dedicated outputs and is therefore easier to configure and secure. It is a specialized form of Sequential Function Chart (SFC) with a fixed number of steps and pure timing control.

Conclusion



The `sequence_T_08`is a robust and easy-to-configure function block for all applications requiring a fixed, time-controlled sequence of steps. Its clear separation of state logic, time parameters, and output signals, along with its immediate reset functionality, makes it particularly suitable for well-organized and easily maintainable control programs. The integration of a standard timer adapter also makes it portable and reusable in various 4diac projects.

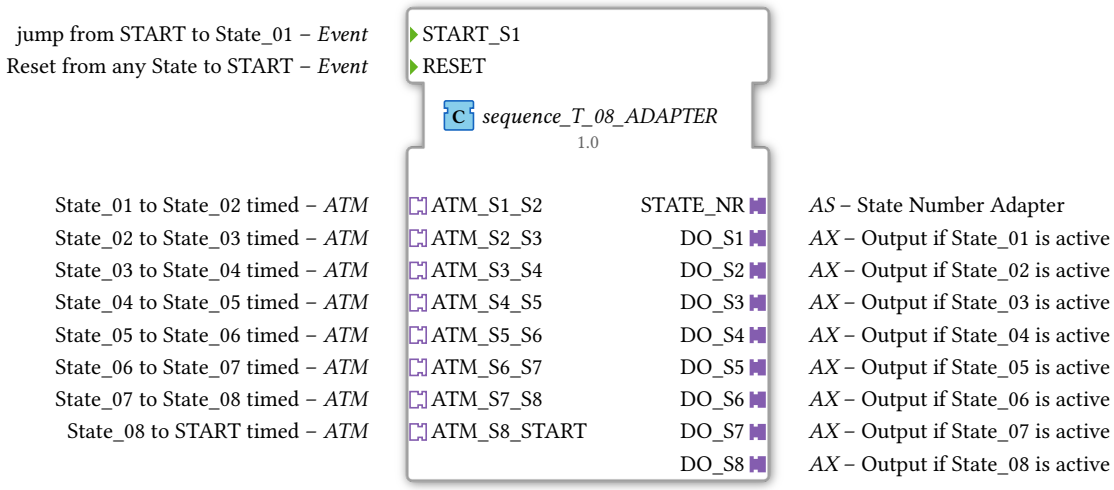
sequence_T_08_ADAPTER



• — ○ • — ○ • — ○ •

Introduction

`sequence_T_08_ADAPTER` is a composite wrapper around sequence_T_08: the same generic time-controlled 8-step sequencer, but with every output and transition time moved onto adapter connections. Unlike sequence_T_08_AX, which only moves the eight outputs onto `AX` adapters, `sequence_T_08_ADAPTER`

additionally bundles the state number (AS) and feeds each of the eight transition times through its own ATM adapter socket.

Function Blocks Used (FBs)

Sub-modules: sequence_T_08_ADAPTER

- **Type**: Composite (FBNetwork)
- **Internal FBs used**:
  - **Sequence**: `logiBUS::utils::sequence::timed::sequence_T_08` - the generic 8-step time sequencer, see sequence_T_08.
  - **E_TimeOut**: `iec61499::events::E_TimeOut` - standard TimeOut adapter for the internal timing; unlike `AnlagenSequenz_06_ADAPTER`, a single standard FB is enough here, no separate `TimeTicker` needed.
- **Functionality**: `DO_S1`..`DO_S8` (per-state outputs) and `STATE_NR` (current state number) run through `AX`/`AS` adapters respectively; each of the eight transition times `DT_S1_S2`..`DT_S8_START` is fed through its own `ATM` adapter socket (`ATM_S1_S2`..`ATM_S8_START`) instead of an individual `TIME` data input.

Program Flow and Connections

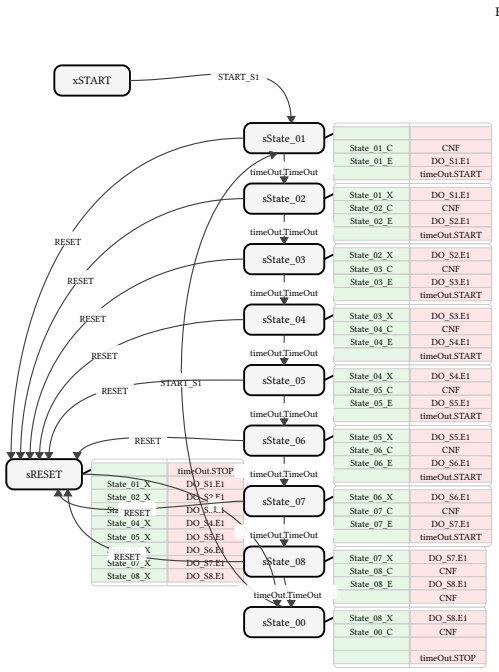
1. `START_S1`/`RESET` pass through unchanged to `Sequence.START_S1`/`Sequence.RESET`.
2. Each `ATM_Sx_Sy` adapter delivers its time (`.D1`) to `Sequence.DT_Sx_Sy` and simultaneously (`.E1`) triggers the matching `Sequence.SET_DT_Sx_Sy` set event.
3. `Sequence.CNF` triggers `STATE_NR.E1`, with the current state number carried via `STATE_NR.D1`.
4. Each `Sequence.EO_Sx` triggers `DO_Sx.E1`, with the output value carried via `DO_Sx.D1`.
5. `Sequence.timeOut` (adapter socket) is connected internally to `E_TimeOut.TimeOutSocket` - the timing stays fully encapsulated inside the composite, unlike `sequence_T_08`/`sequence_T_08_AX`, which expose their own `timeOut` adapter.

Application Scenarios

- Applications that consistently rely on adapter connections and don't want to pull individual `TIME` lines for the transition times or a separate `timeOut` adapter connection in the application.
- Reusing the generic 8-step sequencer across multiple plant sections with uniform, adapter-based wiring.

⚖️ Comparison with Similar Function Blocks

- **sequence_T_08**: The base variant with classic event/data/adapter connections (only `timeOut` as an adapter).
- **sequence_T_08_AX**: Only moves the eight outputs onto `AX` adapters, but keeps `TIME` data inputs for the transition times and still exposes `timeOut` itself.
- **AnlagenSequenz_06_ADAPTER**: Same adapter-wrapper pattern, applied to the fixed 6-motor ring topology instead of the generic 8-step sequencer.



Conclusion

`sequence_T_08_ADAPTER` makes the generic 8-step time sequencer fully usable through adapter connections - outputs, state number, transition times, and timing all run exclusively through adapters, no individual event/data line leaves the block.

- **timeOut** (iec61499::events::ATimeOut): Timer adapter.

Functionality

Corresponds to `sequence_T_08`, but uses adapters for the outputs.

Technical Features

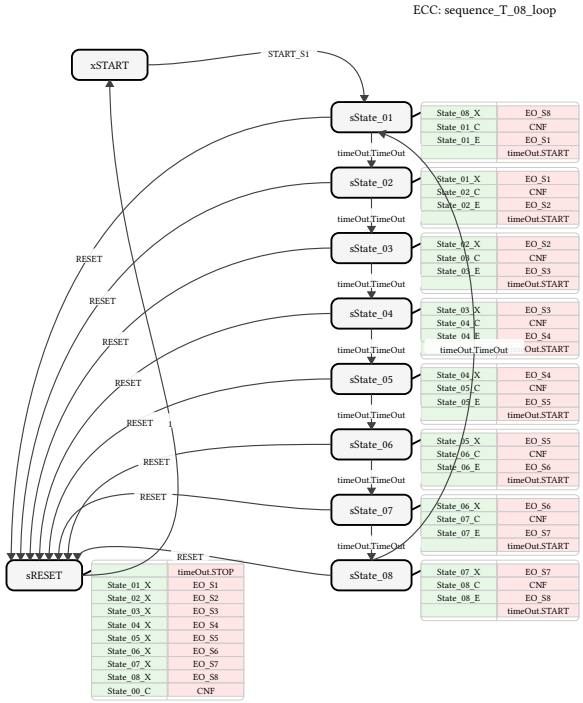
- Uses `adapter::types::unidirectional::AX`.

State Overview

See `sequence_T_08`.

Application Scenarios

For time-controlled 8-step sequences with adapter connection.

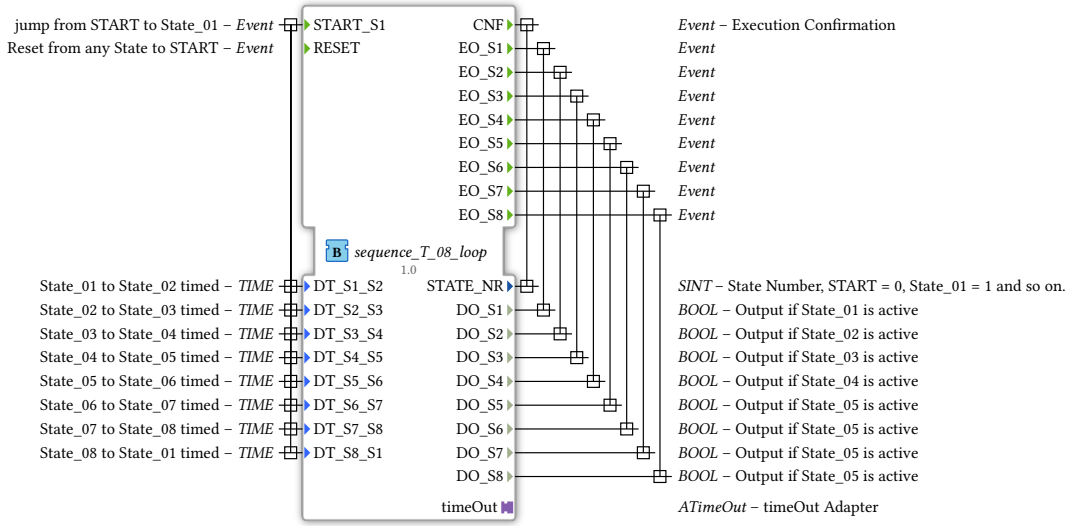


⚖️ Comparison with Similar Function Blocks

- **sequence_T_08**: Standard variant without adapters.

Conclusion

Adapter variant of the 8-step time sequencer.



sequence_T_08_loop

• — ○ • — ○ • — ○ •

Introduction

The function block `sequence_T_08_loop` is a time-controlled sequencer with eight output states. It implements a cyclic sequence of states, with the transition between individual states controlled by adjustable time delays. This block is designed for applications where process steps or machine states need to be activated sequentially for a defined duration, for example, in conveyor systems, packaging machines, or automated assembly processes.

Interface Structure

Event Inputs

- **`START_S1`**: Starts the sequence by jumping from the initial state `START` to the first active state `State_01`. Triggers the execution of the associated algorithms.
- **`RESET`**: Immediately resets the sequence to the initial state `START`, regardless of the current state. All active outputs are deactivated.

Event Outputs

- **`CNF`** (Execution Confirmation): Triggered on every state change and confirms execution. Transmits the current state number `STATE_NR`.
- **`EO_S1` to `EO_S8`**: Event outputs triggered upon entering the respective state `State_01` to `State_08`. They transmit the corresponding Boolean data value (`DO_S1` to `DO_S8`), which is set to `TRUE`.

Data Inputs

Eight time-based data inputs of type `TIME`, defining the duration in each state. The default value is `NO_TIME` (no time, immediate transition).

* `DT_S1_S2`: Retention time in `State_01` before transition to `State_02`

- `DT_S2_S3`: Retention time in `State_02` before transition to `State_03`.
- `DT_S3_S4`: Retention time in `State_03` before transition to `State_04`.
- `DT_S4_S5`: Retention time in `State_04` before transition to `State_05`.
- `DT_S5_S6`: Retention time in `State_05` before transition to `State_06`.
- `DT_S6_S7`: Retention time in `State_06` before transition to `State_07`.
- `DT_S7_S8`: Retention time in `State_07` before transition to `State_08`.
- `DT_S8_S1`: Retention time in `State_08` before the cyclical transition back to `State_01`.

Data Outputs

- **`STATE_NR`** (SINT): Outputs the number of the currently active state. `START` = 0, `State_01` = 1, ..., `State_08` = 8.
- **`DO_S1` to `DO_S8`** (BOOL): The physical output signals of the sequence. Each output is set to `TRUE` when the corresponding state is active; otherwise, it is `FALSE`.

Adapter

- **`timeOut`** (Plug, Type: `iec61499::events::ATimeOut`): A timer adapter used to implement timed state transitions. The function block starts the timer upon entering a state and transitions to the next state upon receiving the `TimeOut` event.

Functionality

The function block operates as a Basic Function Block with an internal Execution Control Chart (ECC). The sequence begins in the initial state `xSTART`. A `START_S1` event leads to the state `sState_01`. Upon entering a state (e.g., `sState_01`), three actions are performed:

1. The exit algorithm of the previous state (e.g., `State_08_X`) disables its output.
2. The confirmation algorithm (e.g., `State_01_C`) sets the `STATE_NR` and loads the time configured for this state (`DT_S1_S2`) into the `timeOut` adapter.
3. The entry algorithm (e.g., `State_01_E`) sets the corresponding data output (`DO_S1`) to `TRUE` and triggers the corresponding event (`EO_S1`).
4. The timer adapter is started with `timeOut.START`.

After the set time has elapsed, the adapter triggers the `timeOut.TimeOut` event, which causes the transition to the next state in the ECC (e.g., from `sState_01` to `sState_02`). After the last state (`sState_08`), the system transitions back to the first state (`sState_01`), creating an infinite loop.

A `RESET` event from any state leads to state `sRESET`. Here, all outputs are deactivated, the timer is stopped, and an acknowledgment is sent with `STATE_NR=0` before the system automatically returns to state `xSTART`.

Technical Features

- **Non-Stop Cycle**: After starting, the sequence runs indefinitely in a loop until a `RESET` signal is received. There is no built-in stop command.
- **Immediate State Transitions**: By setting the time values to `NO_TIME` (default), the function block can be configured to immediately transition to the next state as soon as the entry algorithm of the current state has been executed.
- **Deterministic Execution**: The algorithms for Exit, Confirmation, and Entry are executed atomically in exactly this order upon state entry.
- **Constants for State Numbers**: The state number `STATE_NR` is set via constants from the imported state `sequence` (e.g., `sequence::State_01`), which improves maintainability and readability.

State Overview

The ECC consists of 10 states:

- **`xSTART`**: Initial, inactive state. Waiting for `START_S1`.
- **`sState_01` to `sState_08`**: The eight active sequence states. Each manages its own output and the time until the next state.
- **`sRESET`**: Reset state. Upon the `RESET` event, it jumps from any state, disables all outputs, and then returns to `xSTART`.

The transition conditions are:

- `START_S1`: From `xSTART` to `sState_01`.
- `timeOut.TimeOut`: From each state `sState_XX` to the next `sState_YY` (cyclically from `sState_08` to `sState_01`).
- `RESET`: From each active state (`sState_01` to `sState_08`) to `sRESET`.
- `1` (always true): From `sRESET` back to `xSTART`.

Application Scenarios

- **Control of Rotary Transfer Machines**: Activation of various tools or stations in a rotating machine for a precisely defined duration.
- **Batch Processes in Chemical Engineering**: Step-by-step control of valves, pumps, and heaters in a chemical process with fixed cycle times.
- **Automated Test Sequences**: Sequential execution of various measurements or tests on a component.
- **Light or Signaling Systems**: Generation of fixed flashing or running light patterns.

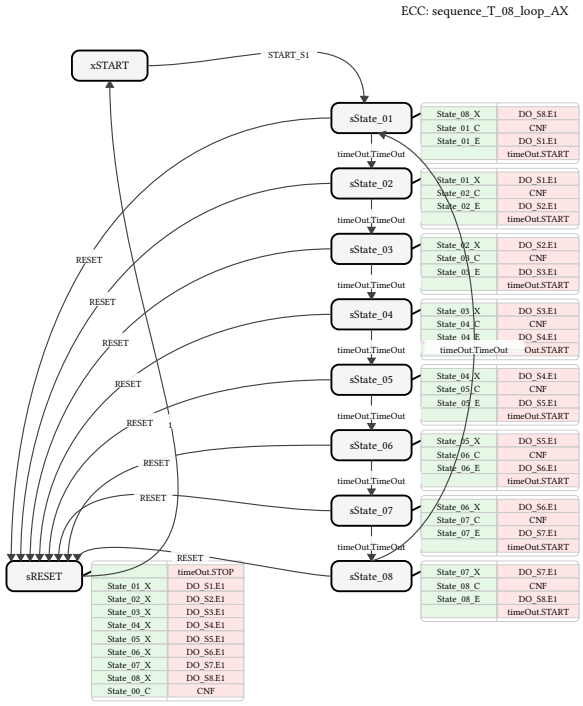
⚖️ Comparison with Similar Components

In contrast to aIn contrast to the `E_CYCLE` or `E_DELAY` function blocks, which generate simple periodic or delayed events, the `sequence_T_08_loop` function block offers a structured state machine with multiple independent outputs. Compared to a freely programmable `E_CTU` (counter) in combination with `SEL` blocks, this function block is preconfigured and therefore easier and faster to use for standard sequences

with up to eight steps. For more complex or state-dependent sequences, a Service Sequence Function Block (SFC) or custom Basic Function Block programming would be required.

This function block is preconfigured and therefore easier and faster to use for standard sequences with up to eight steps.## 🛠️ Related Exercises

- Exercise_038



Conclusion

The `sequence_T_08_loop` is a robust and easy-to-configure function block for time-controlled sequences with a fixed number of steps. Its clear structure of states, configurable dwell times, and dedicated outputs makes it particularly suitable for standardized control tasks in automation technology where reliability and ease of parameterization are paramount. The integration of a timer adapter decouples the timing from the function block logic and promotes reusability.

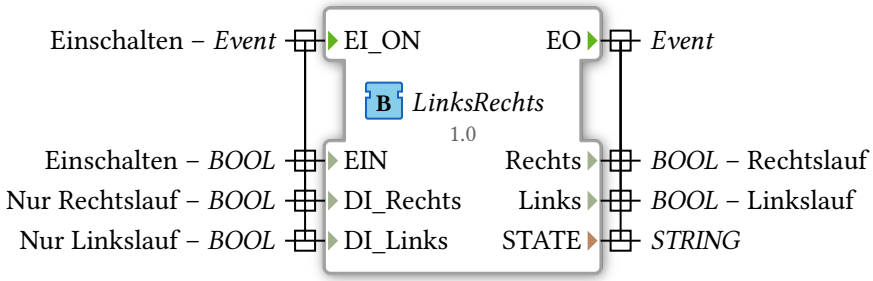
Conclusion

Adapter version of the 8-step loop time sequencer.

distribution list

...



Left/Right

• – ○ • – ○ • – ○ •

Introduction

The function block `LinksRechts` is a fundamental building block for controlling bidirectional motion, such as a drive that can operate in both clockwise and counterclockwise directions. It implements a simple prioritization logic where clockwise rotation takes precedence over counterclockwise rotation unless a specific counterclockwise command is active. The block also allows pausing the motion.

Interface Structure

Event Inputs

- **`EI_ON`**: The central control event. Upon arrival, it triggers an evaluation of the current input data and a potential state transition.

Event Outputs

- **EO**: This event is triggered on every state change. It provides the updated output data Rechts, Links, and STATE.

Data Inputs

- **EIN** (BOOL): General enable/enable command. TRUE allows operation, while FALSE puts the block into a pause state.
- **DI_Rechts** (BOOL): Command for "Right-Hand Rotation Only". Enforces right-hand rotation if EIN is active.
- **DI_Links** (BOOL): Command for "Left Rotation Only". Enforces left rotation if EIN is active and no DI_Rechts command is present.

Data Outputs

- **Rechts** (BOOL): Control signal for right rotation. Is TRUE when the block is in state Rechtslauf.
- **Links** (BOOL): Control signal for left rotation. Is TRUE when the block is in state Linkslauf.
- **STATE** (STRING): Displays the current internal state of the function block as readable text (e.g., "Right Rotation", "Left Rotation_Pause").

Adapters

This function block does not use any adapters.

Functionality

The LinksRechts block is implemented as a Basic Function Block with Event Control (ECC). The arrival of the event EI_ON triggers an evaluation of the accompanying data EIN, DI_Rechts, and DI_Links. Based on the current combination of these values and the current state, a transition to a new state occurs.

In each state, a specific algorithm is executed that sets the output signals Rechts and Links and writes the state name to STATE. The output event EO is then generated to inform downstream blocks of the change.

The priority logic is defined as follows: If EIN is active (TRUE), DI_Rechts is checked first. If this is TRUE, forward rotation is activated. If DI_Rechts or FALSE, DI_Links is checked. If TRUE is present, forward scrolling is activated. If EIN or FALSE is present, the block enters a pause state, regardless of the scrolling commands.

Technical Features

- **Priority**: The specification emphasizes that "Forward scrolling only" (DI_Rechts) takes precedence over "Left scrolling only" (DI_Links). This is implemented in the ECC transition from START to Rechtslauf, which only requires EIN, while the transition to Linkslauf additionally requires DI_Links.
- **Status Output**: The output STATE is of type STRING and is fed from an imported enumeration STATES, which facilitates diagnosis and visualization.
- **Pause States**: There are two separate pause states (Rechtslauf_Pause and Linkslauf_Pause). These remember the last active direction. Upon reactivation (EIN=TRUE), the last active direction is resumed, unless a specific run command (DI_Rechts/DI_Links) is pending.

Pause States: Two separate pause states exist (Rechtslauf_Pause and Linkslauf_Pause). These remember the last active direction.

State Overview

The ECC (Execution Control Chart) of the function block comprises five states:

1. **START**: Initial state. This state is exited with the first EI_ON event.
2. **Rechtslauf**: Active state, in which the output signal Rechts is set to TRUE.
3. **Linkslauf**: Active state, in which the output signal Links is set to TRUE.
4. **Rechtslauf_Pause**: Pause state reached from Rechtslauf when EIN becomes FALSE. Both outputs are FALSE.
5. **Linkslauf_Pause**: Pause state reached from Linkslauf when EIN becomes FALSE. Both outputs are FALSE.

The transitions between states are triggered exclusively by the event EI_ON in combination with the data conditions.

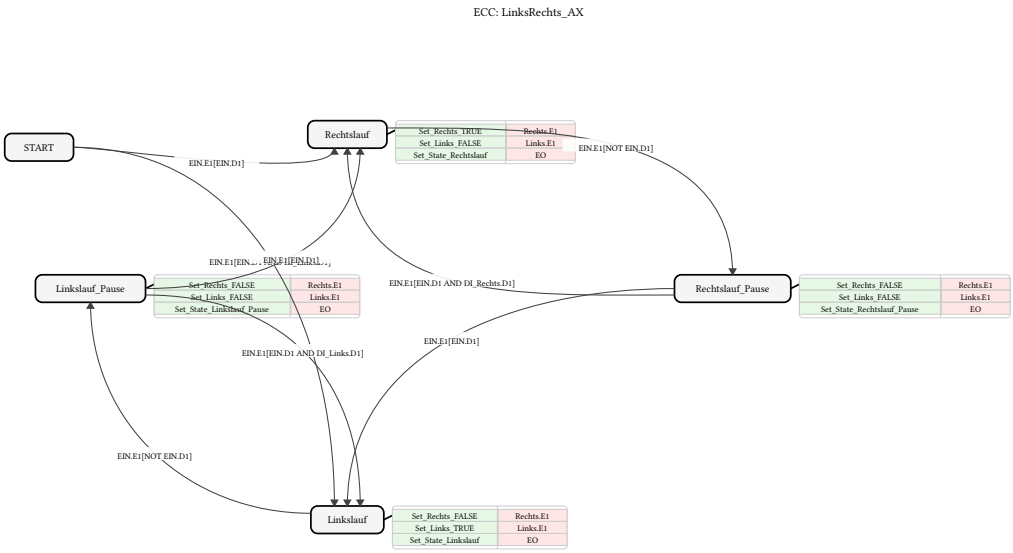
Application Scenarios

Typical applications include:

- Controlling a dual-direction AC motor.
- Controlling a horizontally moving unit (e.g., a carriage, a gate).
- Any application where forward/reverse movement needs to be controlled with a general enable and individual direction commands.

⚖️ Comparison with Similar Function Blocks

Compared to a simple `SR` or `RS` flip-flop, `LinksRechts` offers a higher level of abstraction because it already encapsulates the prioritization logic and pause functionality. In contrast to a simple `E_SWITCH` block, which only switches between two outputs, `LinksRechts` additionally manages internal states (pause) and offers defined input prioritization.



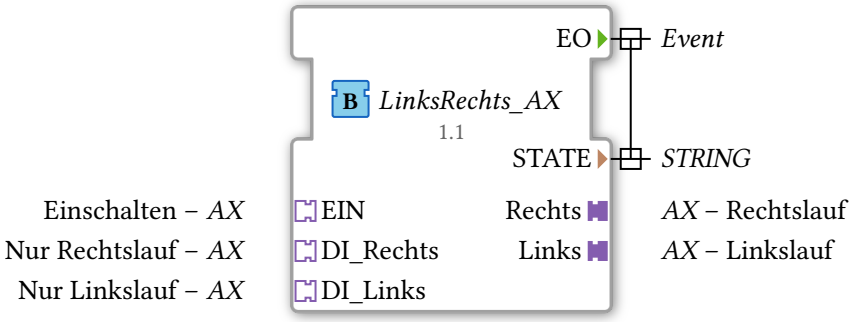
🛠️ Related Exercises

- Exercise_006a4

Conclusion

The `LinksRechts` function block is a useful and robust basic building block for controlling bidirectional movements. Its integrated prioritization logic (clockwise before counterclockwise) and state-based pause function simplify application programming and improve the clarity of control programs. Its clear interface and output status support commissioning and troubleshooting.

LeftRight_AX



Note: An image of the function block is not available here.

• – ○ • – ○ • – ○ •

Introduction

The function block **LeftRight_AX** (from the package `logiBUS::utils::sequence::verteiler`) controls an alternating process with two directions (clockwise and counterclockwise rotation). It is designed to switch back and forth between two outputs, taking pause states into account.

Of particular note is the ability to prevent automatic switching via digital inputs (`DI_Rechts`, `DI_Links`) to force operation in only one direction. The block uses the `AX` adapter interface for this purpose.

Interface Structure

This function block primarily uses adapters for communication but also provides a status string as a direct output.

Event Inputs

There are no direct event inputs. Control is achieved via the events of the adapter sockets.

Event Outputs

Name	Type	Description
EO	Event	Event triggered when the internal state (`STATE`) changes.

Data Inputs

There are no direct data inputs. Data is read via the adapter sockets.

Data Outputs

Name	Type	Description
STATE	STRING	Current state of the function block (e.g., “Right Rotation”, “Left Rotation_Pause”).

Adapter

Sockets (Input Interfaces):

Name	Type	Comment
ON	adapter::types::unidirectional::AX	**Turn On**: The main signal to start and stop the movement.
DI_Right	adapter::types::unidirectional::AX	**Right Rotation Only**: When active, a change to left rotation is prevented, and right rotation is enforced.
DI_Left	adapter::types::unidirectional::AX	**Left Rotation Only**: When active, a change to right rotation is prevented, and left rotation is enforced.

Plugs (Output Interfaces):

Name	Type	Comment
Right	adapter::types::unidirectional::AX	**Right Rotation**: Output signal for rightward movement.
Left	adapter::types::unidirectional::AX	**Left Rotation**: Output signal for leftward movement.

Functionality

The **LeftRight_AX** function block implements a state machine that alternates between rightward and leftward movement, separated by pause phases.

1. **Start:** Starting from the `START` state, the function block decides, based on the inputs `EIN` and `DI_Links`, whether to switch to leftward or rightward rotation first.

2. **Activation (Run):** As long as the signal `EIN.D1` (data) is present together with an event `EIN.E1` as `TRUE`, the function block enters an active state (`Rechtslauf` or `Linkslauf`). The corresponding output adapter (`Rechts` or `Links`) is then set to `TRUE`.
3. **Deactivation (Pause):** When `EIN.D1` changes to `FALSE` (switch off), the function block switches to the corresponding pause state (`Rechtslauf_Pause` or `Linkslauf_Pause`). The outputs are deactivated (`FALSE`).
4. **Alternating Logic:**

- If the function block is in `Rechtslauf_Pause` and is switched on again (`EIN` = TRUE), it switches to **counterclockwise** by default.
- If the function block is in `Linkslauf_Pause` and is switched on again, it switches to **clockwise** by default.
- If the function block is in `Linkslauf_Pause` and is switched on again, it switches to **clockwise** by default. 5. **Override Logic (Forcing):**
- If input `DI_Rechts` is active in state `Rechtslauf_Pause`, the switch to counterclockwise rotation is prevented, and counterclockwise rotation is restarted.
- If input `DI_Links` is active in state `Linkslauf_Pause`, the switch to clockwise rotation is prevented, and counterclockwise rotation is restarted.

Technical Features

- **AX Adapter:** This function block uses the generic `unidirectional::AX` type. This typically combines a Boolean data signal (`D1`) with an event (`E1`).
- – **Prioritization:** According to the internal description, "clockwise rotation only takes precedence over counterclockwise rotation only," which is reflected in the start conditions. However, the sequence logic is primarily determined by the previous state (history).
- **Status Reporting:** Each state change updates the `STATE` variable and fires the `EO` event. The state names are obtained via an external enumeration (`STATES::...`).

State Overview

The ECC (Execution Control Chart) defines the following states:

State Name	Action	Description
START	-	Initial state. Waiting for the `EIN` signal.
clockwise rotation	`Set_Rechts_TRUE`, `Set_Links_FALSE`, Status update	Enables adapter `Rechts`, disables `Links`.
Right Rotation_Pause	`Set_Rechts_FALSE`, `Set_Links_FALSE`, Status update	Both outputs off. The system remembers that it was last in right rotation.
Left Rotation	`Set_Rechts_FALSE`, `Set_Links_TRUE`, Status update	Enables adapter `Links`, disables `Rechts`.
Left Rotation_Pause	`Set_Rechts_FALSE`, `Set_Links_FALSE`, Status update	Both outputs off. The system remembers that it was last on the left.

Application Scenarios

- **Pendulum Operation:** Automatic control of mechanisms that need to move back and forth (e.g., a windshield wiper mode or a cleaning head), controlled by a single button (`EIN`).
- **Irrigation Systems:** Sequential control of two sectors (Sector Right -> Pause -> Sector Left -> Pause), whereby a sector can be activated multiple times in succession if required (using `DI_Rechts`/`DI_Links`).
- **Reversing Motor:** Control of a motor that should change its direction of rotation every time it restarts, unless otherwise specified.

⚖️ Comparison with Similar Function Blocks

- **Simple Toggle (Flip-Flop):** A standard toggle switch simply turns one output on/off. `LinksRechts_AX` toggles between *two* outputs.

- **RS Gate:** An RS gate stores only one state based on set/reset. This function block incorporates sequence logic (history memory) because it remembers which state was active *before* the pause.
- **E_SELECT:** Similar to a selector, but `LinksRechts_AX` includes the timing component of the "pause" and automatic switching at the next start signal.

Conclusion

The **LeftRight_AX** function block is a specialized component for sequence control systems that require alternating operation between two outputs. Through the integration of the adapter technology (`AX`) and the ability to control the sequence through digital inputs (To influence `DI`), it offers a flexible solution for sequential control tasks with direction prioritization.

STATES

• – ◦ • – ◦ • – ◦ •

Introduction

The global constant declaration `STATES` defines a collection of predefined state labels as strings (STRING). These constants are typically used to name operating states in a control sequence, especially for processes with alternating direction (clockwise/counterclockwise) and integrated pauses. It serves as a central and consistent source for these state names within a project.

Interface Structure

Global constants are not function blocks with event or data interfaces. Instead, they declare constant values that are available project-wide.

Data Declarations

The following constants are defined:

- `Rechtslauf`: String with the value `'Rechtslauf'`
- `Linkslauf`: String with the value `'Linkslauf'`
- `Linkslauf_Pause`: String with the value `'Linkslauf_Pause'`
- `Rechtslauf_Pause`: String with the value `'Rechtslauf_Pause'`

Functionality

The constants themselves have no active functionality. They merely provide named values. Their main purpose is to avoid "magic numbers" or hard-coded strings in the program code. Using these constants makes the code more readable, maintainable, and less error-prone, as changes to the state names only need to be made in one central location.

Technical Details

- **Type:** All declared constants are of the data type `STRING`.
- **Scope:** As global constants, they are available within the entire namespace `logiBUS::utils::sequence::verteiler::LinksRechts` and in components that depend on it.
- **Initialization:** The values are set directly during declaration using the `InitialValue` attribute.

State Overview

Not applicable, as this is a static data declaration and not a stateful component.

Application Scenarios

Typical applications for these constants include:

- **State Machines:** These constants can serve as unique identifiers for the different states of a state machine that controls a process with changes of direction and pauses (e.g., a distribution table).
- **Documentation and Logging:** They can be used to display the current operating state in messages, log files, or on operator panels.

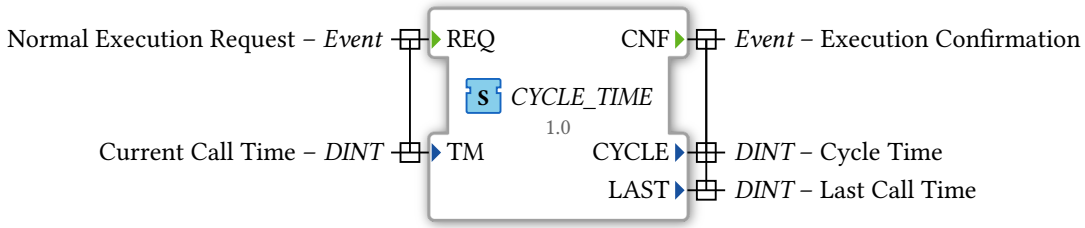
- **Comparisons and Switching Logic:** In program logic, variables or outputs can be compared with these constants to make decisions based on the current state.

⚖️ Comparison with Similar Function Blocks

- **Global Variables (VAR_GLOBAL):** Unlike global variables, the values of constants (`CONSTANT`) cannot be changed at runtime.
- **Enumerations (ENUM):** While ENUM data types serve similar purposes in some programming languages, the IEC 61499 standard library does not provide a built-in ENUM type. Using STRING constants is a common method for defining semantically named values in this environment.
- **Function Block-Internal Constants:** Constants can also be defined within function blocks. However, global constants are visible across block boundaries, thus promoting reusability and consistency throughout an entire project.

Conclusion

The global constant declaration `STATES` is a simple yet useful construct for structuring control software. It improves code quality by providing central and immutable state labels specifically tailored for sequences with forward/reverse and pause states. Its use makes programs more understandable and facilitates future modifications.



timing

CYCLE_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `CYCLE_TIME` is used to calculate the elapsed time between two consecutive calls. It is a useful tool for monitoring and diagnosing cycle times in real-time applications, for example, for performance analysis or for detecting unexpected delays in a control system.

Interface Structure

Event Inputs

- **REQ**: Starts the cycle time calculation. The algorithm is executed upon this event.

Event Outputs

- **CNF**: Triggered as soon as the calculation is complete. This event confirms execution and delivers the calculated values to the data outputs.

Data Inputs

- **TM** (DINT): Provides the current timestamp at the time of the call. This value is typically supplied by a system clock or a timer block. The initial value is `0`.

Data Outputs

- **CYCLE** (DINT): Contains the calculated cycle time, i.e., the difference between the current (`TM`) and the previous timestamp (`LAST`). The initial value is `0`.
- **LAST** (DINT): Stores the timestamp of the last call (`TM`). This value is used for the next calculation. The initial value is `0`.

Adapters

This function block does not have any adapter interfaces.

Functionality

Whenever the REQ event occurs, the corresponding algorithm REQ is executed. This algorithm performs two essential operations:

1. **Calculation of the cycle time**: The difference between the newly received time value TM and the stored value LAST (from the previous call) is calculated and output to CYCLE.
2. **Update of the timestamp**: The current input value TM is saved in the internal memory LAST for the next calculation cycle.

Immediately after the algorithm executes, the CNF event is triggered with the updated values at CYCLE and LAST.

Technical Features

- The function block is a **Simple Function Block (Basic FB)** according to IEC 61499.
- The data types used (DINT) are signed 32-bit integers suitable for representing large time values (e.g., in milliseconds or microseconds).
- The initial values of TM, CYCLE, and LAST are set to 0. The first valid CYCLE value after startup is therefore the difference TM - 0. This should be taken into account in the application's initialization logic.

State Overview

The function block has a single Execution Control State (EC State) named REQ. Upon entering this state, the algorithm REQ is always executed, followed by the CNF event.

Application Scenarios

- **Cycle Time Monitoring**: Continuous measurement of the execution time of a program or a specific program segment.
- **Performance Monitoring**: Identification of bottlenecks or unusually long cycle times in a control application.
- **Diagnostics**: Logging cycle times for analysis or to generate system runtime statistics.
- **Adaptive Control**: Providing the current cycle time for algorithms whose behavior depends on the available processing time.

⚖️ **Comparison with similar modules**

Compared to generic timing modules (such as E_DELAY or E_CYCLE), CYCLE_TIME specializes in **calculating the difference between consecutive time points**. It does not use its own timer but evaluates externally provided timestamps. Modules such as E_SR or E_R_TRIG serve fundamentally different purposes (storage, edge detection) and do not offer time difference calculation.

🛠️ **Related Exercises**

- Exercise_072c

Conclusion

The CYCLE_TIME function block is a simple yet effective tool for runtime measurement in IEC 61499-based control systems. Its clear interface and straightforward operation make it a robust component for diagnostic and monitoring tasks where the accuracy and reliability of cycle time measurement are paramount.

- Understanding VT Versions: Your path to becoming a master of agricultural and construction machinery mechatronics](https://podcasters.spotify.com/pod/show/isobus-vt-objects/episodes/VT-Versionen-verstehen-Dein-Weg-zum-Meister-der-Land–und-Baumaschinenmechatronik-e36a8e8) The function block `version` facilitates the simple transmission of version information. It receives a string as input and outputs it unchanged. This block is useful for transporting version numbers or other identifiers within an application chain or for diagnostic purposes.
- **REQ**: This event triggers the processing of the function block. Upon its arrival, the value of the corresponding data input `VERSION` is copied to the data output `VERSIONO`.
- **CNF**: This event signals the successful completion of the operation. It is generated simultaneously with the data output `VERSIONO`.
- **VERSION** (STRING): This input expects the string to be passed on (e.g., a version number such as “1.2.3”).
- **VERSIONO** (STRING): This output outputs the received value from `VERSION` unchanged.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not have any adapter interfaces.

Functionality

The `version` block operates in an extremely simple and deterministic manner. Upon each occurrence of the `REQ` event, the current value of the input variable `VERSION` is copied to the output variable `VERSIONO`. Immediately following this assignment, the acknowledgment event `CNF` is generated along with the new output value. No formatting checks, manipulation, or storage of the value takes place.

- **Simple Pass-Through**: The block performs no transformations or logic on the data.
- **Direct Coupling**: The `REQ` and `CNF` events are directly coupled; the execution time is negligible.
- **No Internal State**: The block has no internal memory. Every execution depends solely on the current inputs.

The function block `version` is stateless. It remains in a single, passive state until a `REQ` event occurs. The response to this event (copying the data and triggering `CNF`) is instantaneous and does not result in a different state.

1. **Version Propagation**: In an application chain, a higher-level function block (e.g., a master or management function block) can pass its own version to this block to be sent to downstream diagnostic or logging functions.
2. **Data Consolidation**: In conjunction with other function blocks, it can be used to provide version information from various sources in a central location (e.g., an HMI or a network service).

- **`E_SR` or `E_RS` (Flip-Flops)**: These blocks have an internal state (set/reset) that is changed by events. The `version` block does not have such a state.
- **`E_MERGE`**: This block merges events from multiple inputs. The `version` block has only a single event input and does not process any event streams.
- **Simple data blocks (e.g., `E_R_TRIG`)**: These react to signal edges or perform timing operations. The `version` block performs only data copying.
- **Generic blocks like `COPY`**: A `COPY` block would perform a similar function (copying data from A to B) but is typically a pure data block without event control. The `version` block follows the standard IEC 61499 event/data flow paradigm.
-

The `version` function block is a minimalist and specialized tool for passing string information within an event-driven control system. Its strength lies in the simplicity and clarity of its purpose. For simple data copying without event logic, alternative implementations might be suitable; however, it is well-suited for integration into a standards-compliant IEC 61499 application with a clearly defined event flow.

Conclusion

2.11 Standard Libraries

2.11.1 convert

2.11.1.1 ARRAY2ARRAY_2_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`ARRAY2ARRAY_2_BYTE` is a service interface function block that copies a `BYTE` array of size 2 unchanged from `IN` to `OUT`. It belongs to the generic `GEN_ARRAY2ARRAY` family (cf. ARRAY2ARRAY_2_LREAL) and serves as a pure type/interface bridge between two `BYTE` arrays of the same size.

Interface Structure

Event Inputs

- **REQ**: Triggers the copy operation, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN** (`BYTE`, array size 2): The source array (8-bit bit pattern).

Data Outputs

- **OUT** (BYTE, array size 2): The destination array, identical values to IN.

Functionality

On REQ, the 2 elements of IN are copied unchanged to OUT, then CNF is triggered. No type conversion or value change takes place — the block exists solely to decouple two array variables of identical type and size.

Technical Features

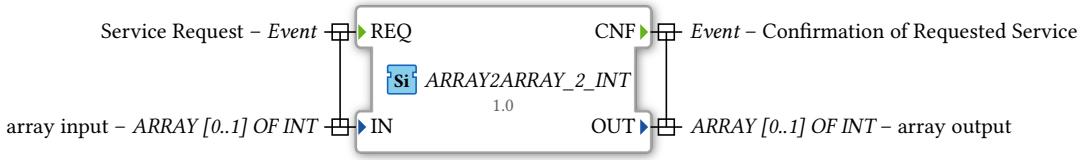
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY', the same C++ base as all other ARRAY2ARRAY_* variants (e.g. ARRAY2ARRAY_2_LREAL); only array size and data type differ per instantiation.
- **Fixed size 2**: For other array sizes of the same type see ARRAY2ARRAY_8_BYTE.

State Overview

Stateless: every REQ immediately results in a full copy and CNF.

Application Scenarios

- **Interface decoupling**: One block provides a BYTE array of size 2 as output, another expects a separate input array — ARRAY2ARRAY_2_BYTE acts as a bridge with no side effects.
- **Data routing** of fixed-size BYTE arrays between parts of a 4diac application.



Comparison with similar function blocks

- ARRAY2ARRAY_2_LREAL: the same generic implementation for data type LREAL.
- **ARRAY2ARRAY_8_BYTE**: the same implementation with array size 8 instead of 2.
- **ARRAY2VALUES_2_BYTE**: splits the array into 2 individual scalar variables instead.

Conclusion

ARRAY2ARRAY_2_BYTE provides a simple, generically implemented one-to-one copy of a BYTE array of size 2 and serves as an uncomplicated interface bridge between like-typed array variables.

2.11.1.2 ARRAY2ARRAY_2_INT

• – ◦ • – ◦ • – ◦ •

Introduction

ARRAY2ARRAY_2_INT is a service interface function block that copies a INT array of size 2 unchanged from IN to OUT. It belongs to the generic GEN_ARRAY2ARRAY family (cf. ARRAY2ARRAY_2_LREAL) and serves as a pure type/interface bridge between two INT arrays of the same size.

Interface Structure

Event Inputs

- **REQ**: Triggers the copy operation, carries IN.

Event Outputs

- **CNF**: Confirms completion, carries OUT.

Data Inputs

- **IN** (INT, array size 2): The source array (16-bit signed integer).

Data Outputs

- **OUT** (INT, array size 2): The destination array, identical values to IN.

Functionality

On REQ, the 2 elements of IN are copied unchanged to OUT, then CNF is triggered. No type conversion or value change takes place — the block exists solely to decouple two array variables of identical type and size.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as all other ARRAY2ARRAY_* variants (e.g. ARRAY2ARRAY_2_LREAL); only array size and data type differ per instantiation.
- **Fixed size 2**: For other array sizes of the same type see ARRAY2ARRAY_8_INT.

State Overview

Stateless: every REQ immediately results in a full copy and CNF.

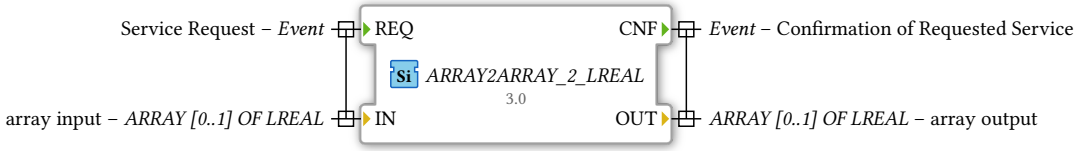
Application Scenarios

- **Interface decoupling**: One block provides a INT array of size 2 as output, another expects a separate input array — ARRAY2ARRAY_2_INT acts as a bridge with no side effects.
- **Data routing** of fixed-size INT arrays between parts of a 4diac application.

Comparison with similar function blocks

- **ARRAY2ARRAY_2_LREAL**: the same generic implementation for data type LREAL.
- **ARRAY2ARRAY_8_INT**: the same implementation with array size 8 instead of 2.
- **ARRAY2VALUES_2_INT**: splits the array into 2 individual scalar variables instead.

Conclusion



ARRAY2ARRAY_2_INT provides a simple, generically implemented one-to-one copy of a INT array of size 2 and serves as an uncomplicated interface bridge between like-typed array variables.

2.11.1.3 ARRAY2ARRAY_2_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) ARRAY2ARRAY_2_LREAL is a service interface function block designed to copy values from an input array to an output array. It serves as a simple, event-driven interface for transferring data between arrays within a 4diac application.

Interface Structure

Event Inputs

- **REQ** (Event): Triggers the copying process. This event signals the function block to start the data transfer.
- Associated with data variable: IN

Event Outputs

- **CNF** (Event): Confirms completion of the copy process. This event is triggered after successful data transfer.
- Associated with data variable: OUT

Data Inputs

- **IN** (Type: LREAL, Array Size: 2): The source array whose values are to be copied. This is a double-precision floating-point array of long real numbers.

Data Outputs

- **OUT** (Type: `LREAL`, Array Size: `2`): The target array into which the copied values are written. This is also an array of long real numbers.

Adapters

This function block does not use any adapters.

Functionality

The function block `ARRAY2ARRAY_2_LREAL` operates in an event-driven manner. As soon as the input event `REQ` is received, the function block reads the current values from the data input array `IN`. These values are then copied directly into the data output array `OUT`. After the copying process is complete, the output event `CNF` is triggered to signal the successful completion of the operation. The block thus processes a one-to-one copy of the array elements.

Technical Features

- **Service Interface:** The function block is designed as a "Service Interface Function Block Type," indicating a standard interface for specific services.
- **Generic Implementation:** Internally, this function block likely uses a generic implementation, as indicated by the attribute value `'GEN_ARRAY2ARRAY'`. This allows for the flexible creation of similar function blocks for different array sizes and data types.
- – **Fixed Array Size:** The array size for `IN` and `OUT` is fixed at `2`, limiting its use to specific scenarios with this array dimension.
- **Data Type `LREAL`:** The function block is specialized for the data type `LREAL` (Long Real Number), making it ideal for processing high-precision floating-point numbers.

State Overview

The function block typically exists in two main states:

1. **Waiting for Request:** The block waits for the `REQ` event. In this state, it is passive and performs no operations.
2. **Processing the Request:** After receiving `REQ`, the block switches to this state, executes the copy process from `IN` to `OUT`, and then emits `CNF` before returning to the "Waiting for Request" state.

Application Scenarios

- **Data Routing:** Forwarding `LREAL` data packets of size 2 between different parts of a control system.
- **Data Buffering:** Short-term storage or transmission of measured values or setpoints.
- **Interface Adaptation:** If a function block outputs a `LREAL` array of size 2 and another function block requires the same array as input, this function block can act as a bridge.
- – **Constant Data Transfer:** Transferring static or infrequently updated `LREAL` arrays from one point to another.

⚖️ Comparison with Similar Building Blocks

This building block is very specific in its function. Compared to more general data manipulation building blocks, which often allow flexible data types or array sizes via configuration parameters, `ARRAY2ARRAY_2_LREAL` is specifically designed for `LREAL` arrays of size 2. If building blocks for generic array copies existed (e.g., `ARRAY_COPY` with configurable size and type), this building block would be a specialized instance of one. It is simpler than such generic building blocks but less flexible. However, for its specific task, it offers a clear and efficient solution.

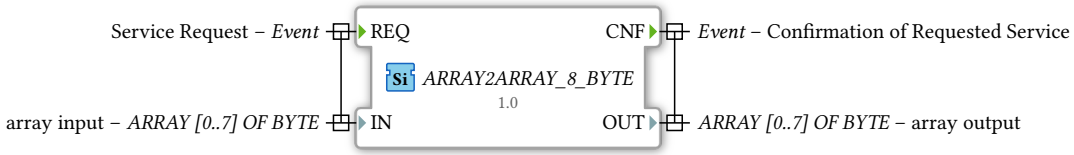
Version	3.0 (2025-04-14, Patrick Aigner), 1.0 (2014-08-05, Matthias Plasch)

4diac Package	eclipse4diac::convert

Conclusion



The `ARRAY2ARRAY_2_LREAL` function block provides a straightforward, event-driven method for copying `LREAL` arrays of size 2. Its specialization for this data type and array size makes it a useful tool for defined use cases where this precise data structure is required. It contributes to the modularity and readability of 4diac applications by providing an explicit function for this type of data transfer.

2.11.1.4 ARRAY2ARRAY_8_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`ARRAY2ARRAY_8_BYTE` is a service interface function block that copies a `BYTE` array of size 8 unchanged from `IN` to `OUT`. It belongs to the generic `GEN_ARRAY2ARRAY` family (cf. ARRAY2ARRAY_2_LREAL) and serves as a pure type/interface bridge between two `BYTE` arrays of the same size.

Interface Structure

Event Inputs

- **REQ**: Triggers the copy operation, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN** (`BYTE`, array size 8): The source array (8-bit bit pattern).

Data Outputs

- **OUT** (`BYTE`, array size 8): The destination array, identical values to `IN`.

Functionality

On `REQ`, the 8 elements of `IN` are copied unchanged to `OUT`, then `CNF` is triggered. No type conversion or value change takes place — the block exists solely to decouple two array variables of identical type and size.

Technical Features

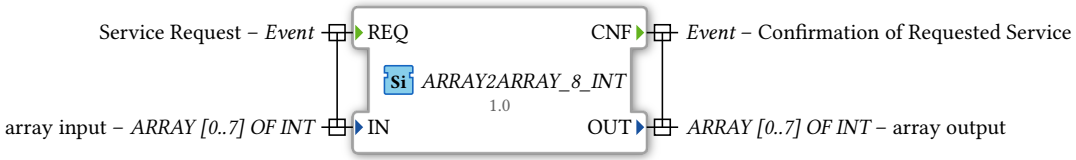
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as all other `ARRAY2ARRAY_*` variants (e.g. ARRAY2ARRAY_2_LREAL); only array size and data type differ per instantiation.
- **Fixed size 8**: For other array sizes of the same type see `ARRAY2ARRAY_2_BYTE`.

State Overview

Stateless: every `REQ` immediately results in a full copy and `CNF`.

Application Scenarios

- **Interface decoupling**: One block provides a BYTE array of size 8 as output, another expects a separate input array — ARRAY2ARRAY_8_BYTE acts as a bridge with no side effects.
- **Data routing** of fixed-size BYTE arrays between parts of a 4diac application.



Comparison with similar function blocks

- ARRAY2ARRAY_2_LREAL: the same generic implementation for data type LREAL.
- **ARRAY2ARRAY_2_BYTE**: the same implementation with array size 2 instead of 8.
- **ARRAY2VALUES_8_BYTE**: splits the array into 8 individual scalar variables instead.

Conclusion

ARRAY2ARRAY_8_BYTE provides a simple, generically implemented one-to-one copy of a BYTE array of size 8 and serves as an uncomplicated interface bridge between like-typed array variables.

2.11.1.5 ARRAY2ARRAY_8_INT

• – ◦ • – ◦ • – ◦ •

Introduction

ARRAY2ARRAY_8_INT is a service interface function block that copies a INT array of size 8 unchanged from IN to OUT. It belongs to the generic GEN_ARRAY2ARRAY family (cf. ARRAY2ARRAY_2_LREAL) and serves as a pure type/interface bridge between two INT arrays of the same size.

Interface Structure

Event Inputs

- **REQ**: Triggers the copy operation, carries IN.

Event Outputs

- **CNF**: Confirms completion, carries OUT.

Data Inputs

- **IN** (INT, array size 8): The source array (16-bit signed integer).

Data Outputs

- **OUT** (INT, array size 8): The destination array, identical values to IN.

Functionality

On REQ, the 8 elements of IN are copied unchanged to OUT, then CNF is triggered. No type conversion or value change takes place — the block exists solely to decouple two array variables of identical type and size.

Technical Features

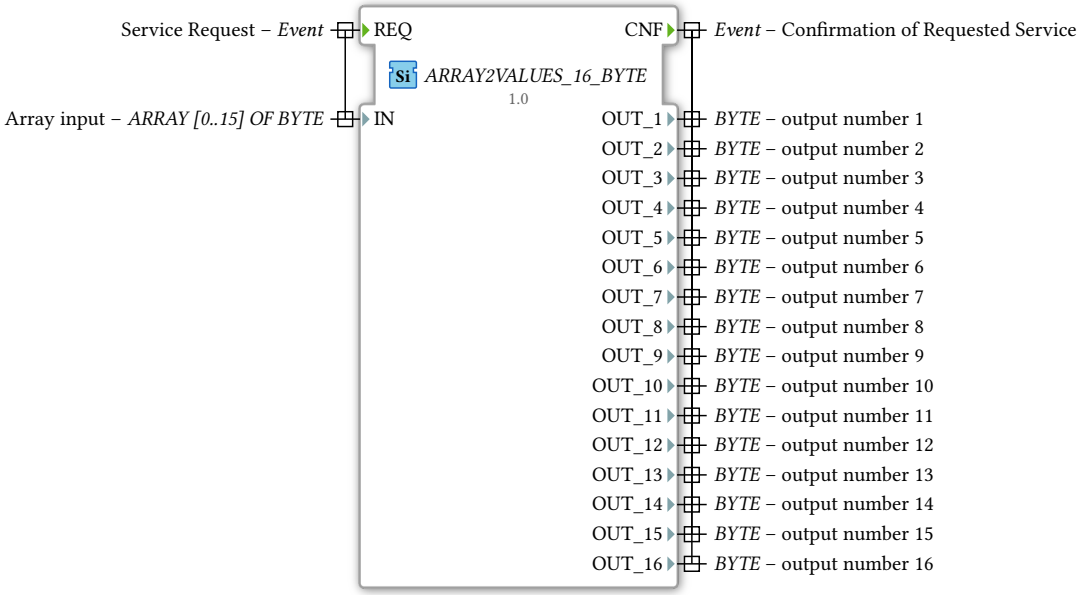
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as all other ARRAY2ARRAY_* variants (e.g. ARRAY2ARRAY_2_LREAL); only array size and data type differ per instantiation.
- **Fixed size 8**: For other array sizes of the same type see ARRAY2ARRAY_2_INT.

State Overview

Stateless: every REQ immediately results in a full copy and CNF.

Application Scenarios

- **Interface decoupling**: One block provides a `INT` array of size 8 as output, another expects a separate input array — `ARRAY2ARRAY_8_INT` acts as a bridge with no side effects.
- **Data routing** of fixed-size `INT` arrays between parts of a 4diac application.



Comparison with similar function blocks

- ARRAY2ARRAY_2_LREAL: the same generic implementation for data type `LREAL`.
- **`ARRAY2ARRAY_2_INT`**: the same implementation with array size 2 instead of 8.
- **`ARRAY2VALUES_8_INT`**: splits the array into 8 individual scalar variables instead.

Conclusion

`ARRAY2ARRAY_8_INT` provides a simple, generically implemented one-to-one copy of a `INT` array of size 8 and serves as an uncomplicated interface bridge between like-typed array variables.

2.11.1.6 ARRAY2VALUES_16_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`ARRAY2VALUES_16_BYTE` splits a `BYTE` array of size 16 into 16 individual scalar variables `OUT_1`...`OUT_16`. It belongs to the generic `GEN_ARRAY2ARRAY` family (cf. ARRAY2VALUES_2_LREAL) and converts array data into discrete individual values.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT_1`, `OUT_2`, `OUT_3`, `OUT_4`, `OUT_5`, `OUT_6`, `OUT_7`, `OUT_8`, `OUT_9`, `OUT_10`, `OUT_11`, `OUT_12`, `OUT_13`, `OUT_14`, `OUT_15`, `OUT_16`.

Data Inputs

- **IN** (`BYTE`, array size 16): The array to split (8-bit bit pattern).

Data Outputs

- `OUT_1`, `OUT_2`, `OUT_3`, `OUT_4`, `OUT_5`, `OUT_6`, `OUT_7`, `OUT_8`, `OUT_9`, `OUT_10`, `OUT_11`, `OUT_12`, `OUT_13`, `OUT_14`, `OUT_15`, `OUT_16` (`BYTE`): `OUT_i` corresponds to `IN[i-1]`, i.e. the i-th element of the array.

Functionality

On REQ, every element of IN is copied to the corresponding scalar output OUT_i (IN[0] ⟶ OUT_1, ..., IN[15] ⟶ OUT_16), then CNF is triggered.

Technical Features

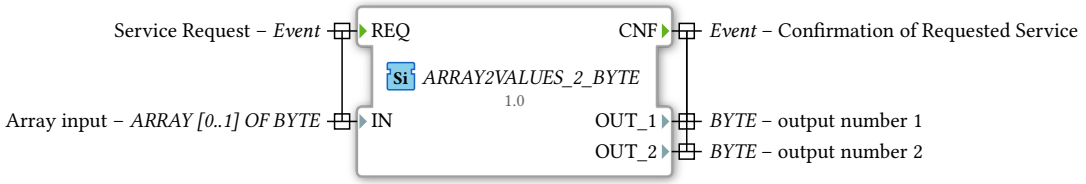
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as ARRAY2VALUES_2_LREAL and the other ARRAY2VALUES_* variants.
- **Fixed size 16**: For other array sizes of the same type see ARRAY2VALUES_2_BYTE, ARRAY2VALUES_4_BYTE, ARRAY2VALUES_8_BYTE, ARRAY2VALUES_32_BYTE.

State Overview

Stateless: every REQ immediately results in a full split and CNF.

Application Scenarios

- **Data preparation**: An upstream block delivers a BYTE array, but a downstream block needs discrete individual variables.
- **Interface adaptation** between array-based and variable-based block interfaces.



Comparison with similar function blocks

- **ARRAY2VALUES_2_LREAL**: the same generic implementation for data type LREAL.
- **VALUES2ARRAY_16_BYTE**: the reverse direction — combines 16 individual values into an array.
- **ARRAY2ARRAY_2_BYTE**: copies the array unchanged instead of splitting it.

Conclusion

ARRAY2VALUES_16_BYTE provides a simple, generically implemented split of a BYTE array of size 16 into 16 discrete individual variables and is suitable for adapting array-based to variable-based interfaces.

2.11.1.7 ARRAY2VALUES_2_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

ARRAY2VALUES_2_BYTE splits a BYTE array of size 2 into 2 individual scalar variables OUT_1...OUT_2. It belongs to the generic GEN_ARRAY2ARRAY family (cf. ARRAY2VALUES_2_LREAL) and converts array data into discrete individual values.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries IN.

Event Outputs

- **CNF**: Confirms completion, carries OUT_1, OUT_2.

Data Inputs

- **IN** (BYTE, array size 2): The array to split (8-bit bit pattern).

Data Outputs

- OUT_1, OUT_2 (BYTE): OUT_i corresponds to IN[i-1], i.e. the i-th element of the array.

Functionality

On REQ, every element of IN is copied to the corresponding scalar output OUT_i (IN[0] ⟶ OUT_1, ..., IN[1] ⟶ OUT_2), then CNF is triggered.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY', the same C++ base as ARRAY2VALUES_2_LREAL and the other ARRAY2VALUES_* variants.
- **Fixed size 2**: For other array sizes of the same type see ARRAY2VALUES_4_BYTE, ARRAY2VALUES_8_BYTE, ARRAY2VALUES_16_BYTE, ARRAY2VALUES_32_BYTE.

State Overview

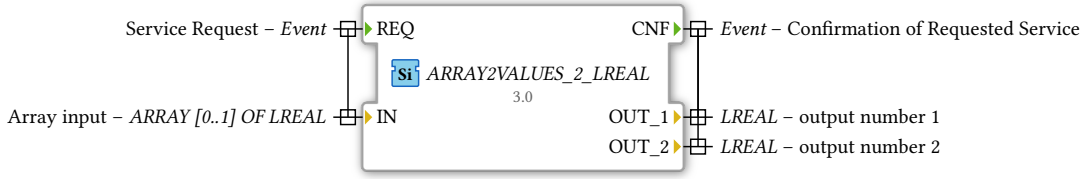
Stateless: every REQ immediately results in a full split and CNF.

Application Scenarios

- **Data preparation**: An upstream block delivers a BYTE array, but a downstream block needs discrete individual variables.
- **Interface adaptation** between array-based and variable-based block interfaces.

Comparison with similar function blocks

- **ARRAY2VALUES_2_LREAL**: the same generic implementation for data type LREAL.
- **VALUES2ARRAY_2_BYTE**: the reverse direction — combines 2 individual values into an array.
- **ARRAY2ARRAY_2_BYTE**: copies the array unchanged instead of splitting it.



Conclusion

ARRAY2VALUES_2_BYTE provides a simple, generically implemented split of a BYTE array of size 2 into 2 discrete individual variables and is suitable for adapting array-based to variable-based interfaces.

2.11.1.8 ARRAY2VALUES_2_LREAL

• – ◦ • – ◦ • – ◦ •

The function block ARRAY2VALUES_2_LREAL is a service interface module designed to split an array of two LREAL values into two separate LREAL output variables. It facilitates the simple conversion from a structured array format to individual data points.

- **REQ**: A service request event that initiates the conversion. It is associated with the data input IN.
- **CNF**: An acknowledgment event that signals the completion of the requested service. It is associated with the data outputs OUT_1 and OUT_2.
- **IN**: An array input of type LREAL with a size of 2 elements. This array contains the two values to be split.
- **OUT_1**: The first output value of type LREAL, corresponding to the first element of the IN array.
- **OUT_1**: The first output value of type LREAL, corresponding to the first element of the IN array. * **OUT_2**: The second output value of type LREAL, corresponding to the second element of the IN array.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

Not present.

Functionality

When the `REQ` event is received, the `ARRAY2VALUES_2_LREAL` function block reads the two `LREAL` values from the `IN` array. The first element of the `IN` array (`IN[0]`) is assigned to the output `OUT_1`, and the second element (`IN[1]`) is assigned to the output `OUT_2`. Upon successful assignment, the `CNF` event is triggered to signal the completion of the operation.

This function block is specifically designed to process exactly one array of two `LREAL` values and split them into two separate `LREAL` variables. Its implementation is straightforward and optimized for this specific conversion purpose.

- **Generic Implementation:** Interestingly, the attribute `eclipse4diac::core::GenericClassName` references `'GEN_ARRAY2ARRAY'`. This suggests that the function block may be derived from a generic array-to-array class, even though its function is to split the array into individual values. This could be a detail of the implementation history.

This function block is stateless. Each triggering of the `REQ` event results in direct processing of the current `IN` values and output via `OUT_1` and `OUT_2` without any internal state changes beyond the current transaction.

- **Data Preparation**: When sensors or other components deliver data as an array of two `LREAL` values (e.g., X/Y coordinates, minimum/maximum values), but subsequent components require individual variables.
- **Interface Adaptation**: Adapting interfaces where a source component sends array data, but the target component expects discrete input variables.
- **Logic Simplification**: Increasing readability and simplifying logic by converting array accesses into individual variables that can be more easily processed in subsequent steps.

Similar components could be generic array splitters that can divide a variable number of array elements into a corresponding number of outputs. However, `ARRAY2VALUES_2_LREAL` is optimized for the specific case of a `LREAL` array of size 2, making it easier to configure and potentially more efficient for this particular use case than a more flexible, but potentially more complex, generic component.

2.11.1.9 ARRAY2VALUES_32_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

ARRAY2VALUES_32_BYTE splits a BYTE array of size 32 into 32 individual scalar variables OUT_1…OUT_32. It belongs to the generic GEN_ARRAY2ARRAY family (cf. ARRAY2VALUES_2_LREAL) and converts array data into discrete individual values.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries IN.

Event Outputs

- **CNF**: Confirms completion, carries `OUT_1`, `OUT_2`, `OUT_3`, `OUT_4`, `OUT_5`, `OUT_6`, `OUT_7`, `OUT_8`, `OUT_9`, `OUT_10`, `OUT_11`, `OUT_12`, `OUT_13`, `OUT_14`, `OUT_15`, `OUT_16`, `OUT_17`, `OUT_18`, `OUT_19`, `OUT_20`, `OUT_21`, `OUT_22`, `OUT_23`, `OUT_24`, `OUT_25`, `OUT_26`, `OUT_27`, `OUT_28`, `OUT_29`, `OUT_30`, `OUT_31`, `OUT_32`.

Data Inputs

- **IN** (`BYTE`, array size 32): The array to split (8-bit bit pattern).

Data Outputs

- `OUT_1`, `OUT_2`, `OUT_3`, `OUT_4`, `OUT_5`, `OUT_6`, `OUT_7`, `OUT_8`, `OUT_9`, `OUT_10`, `OUT_11`, `OUT_12`, `OUT_13`, `OUT_14`, `OUT_15`, `OUT_16`, `OUT_17`, `OUT_18`, `OUT_19`, `OUT_20`, `OUT_21`, `OUT_22`, `OUT_23`, `OUT_24`, `OUT_25`, `OUT_26`, `OUT_27`, `OUT_28`, `OUT_29`, `OUT_30`, `OUT_31`, `OUT_32` (`BYTE`): `OUT_i` corresponds to `IN[i-1]`, i.e. the i-th element of the array.

Functionality

On `REQ`, every element of `IN` is copied to the corresponding scalar output `OUT_i` (`IN[0]` ⟶ `OUT_1`, ..., `IN[31]` ⟶ `OUT_32`), then `CNF` is triggered.

Technical Features

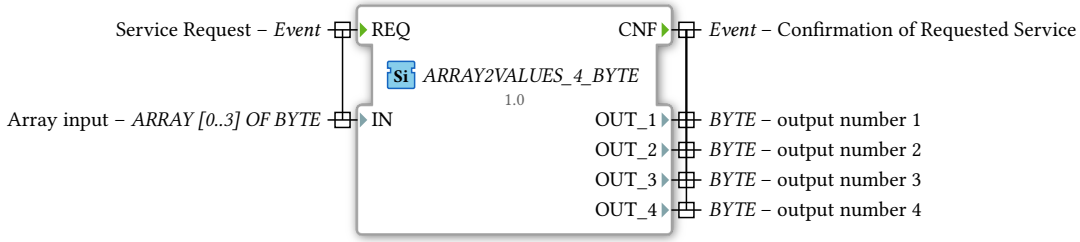
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as ARRAY2VALUES_2_LREAL and the other `ARRAY2VALUES_*` variants.
- **Fixed size 32**: For other array sizes of the same type see `ARRAY2VALUES_2_BYTE`, `ARRAY2VALUES_4_BYTE`, `ARRAY2VALUES_8_BYTE`, `ARRAY2VALUES_16_BYTE`.

State Overview

Stateless: every `REQ` immediately results in a full split and `CNF`.

Application Scenarios

- **Data preparation**: An upstream block delivers a `BYTE` array, but a downstream block needs discrete individual variables.
- **Interface adaptation** between array-based and variable-based block interfaces.



Comparison with similar function blocks

- **ARRAY2VALUES_2_LREAL**: the same generic implementation for data type `LREAL`.
- **`VALUES2ARRAY_32_BYTE`**: the reverse direction — combines 32 individual values into an array.
- **`ARRAY2ARRAY_2_BYTE`**: copies the array unchanged instead of splitting it.

Conclusion

`ARRAY2VALUES_32_BYTE` provides a simple, generically implemented split of a `BYTE` array of size 32 into 32 discrete individual variables and is suitable for adapting array-based to variable-based interfaces.

2.11.1.10 ARRAY2VALUES_4_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`ARRAY2VALUES_4_BYTE` splits a `BYTE` array of size 4 into 4 individual scalar variables `OUT_1`...`OUT_4`. It belongs to the generic `GEN_ARRAY2ARRAY` family (cf. ARRAY2VALUES_2_LREAL) and converts array data into discrete individual values.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT_1`, `OUT_2`, `OUT_3`, `OUT_4`.

Data Inputs

- **IN** (`BYTE`, array size 4): The array to split (8-bit bit pattern).

Data Outputs

- `OUT_1`, `OUT_2`, `OUT_3`, `OUT_4` (`BYTE`): `OUT_i` corresponds to `IN[i-1]`, i.e. the i-th element of the array.

Functionality

On `REQ`, every element of `IN` is copied to the corresponding scalar output `OUT_i` (`IN[0]` ⟶ `OUT_1`, ..., `IN[3]` ⟶ `OUT_4`), then `CNF` is triggered.

Technical Features

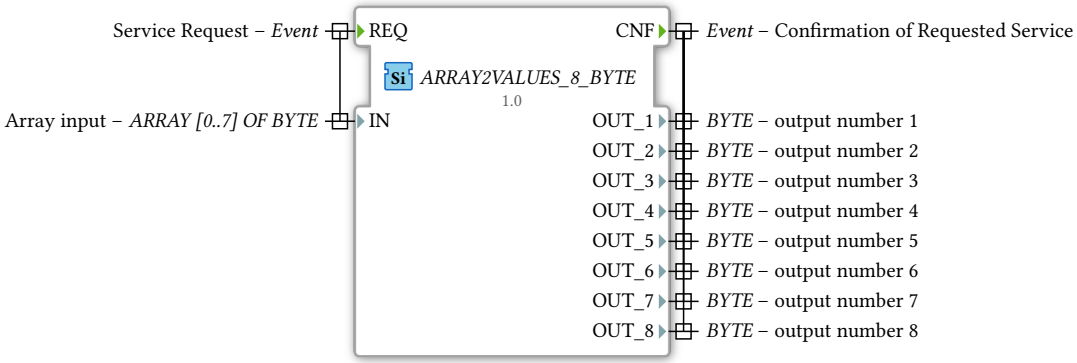
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as ARRAY2VALUES_2_LREAL and the other `ARRAY2VALUES_*` variants.
- **Fixed size 4**: For other array sizes of the same type see `ARRAY2VALUES_2_BYTE`, `ARRAY2VALUES_8_BYTE`, `ARRAY2VALUES_16_BYTE`, `ARRAY2VALUES_32_BYTE`.

State Overview

Stateless: every `REQ` immediately results in a full split and `CNF`.

Application Scenarios

- **Data preparation**: An upstream block delivers a `BYTE` array, but a downstream block needs discrete individual variables.
- **Interface adaptation** between array-based and variable-based block interfaces.



Comparison with similar function blocks

- **ARRAY2VALUES_2_LREAL**: the same generic implementation for data type `LREAL`.
- **`VALUES2ARRAY_4_BYTE`**: the reverse direction — combines 4 individual values into an array.
- **`ARRAY2ARRAY_2_BYTE`**: copies the array unchanged instead of splitting it.

Conclusion

`ARRAY2VALUES_4_BYTE` provides a simple, generically implemented split of a `BYTE` array of size 4 into 4 discrete individual variables and is suitable for adapting array-based to variable-based interfaces.

2.11.1.11 ARRAY2VALUES_8_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

ARRAY2VALUES_8_BYTE splits a BYTE array of size 8 into 8 individual scalar variables OUT_1...OUT_8. It belongs to the generic GEN_ARRAY2ARRAY family (cf. ARRAY2VALUES_2_LREAL) and converts array data into discrete individual values.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries IN.

Event Outputs

- **CNF**: Confirms completion, carries OUT_1, OUT_2, OUT_3, OUT_4, OUT_5, OUT_6, OUT_7, OUT_8.

Data Inputs

- **IN** (BYTE, array size 8): The array to split (8-bit bit pattern).

Data Outputs

- OUT_1, OUT_2, OUT_3, OUT_4, OUT_5, OUT_6, OUT_7, OUT_8 (BYTE): OUT_i corresponds to IN[i-1], i.e. the i-th element of the array.

Functionality

On REQ, every element of IN is copied to the corresponding scalar output OUT_i (IN[0] ⟶ OUT_1, ..., IN[7] ⟶ OUT_8), then CNF is triggered.

Technical Features

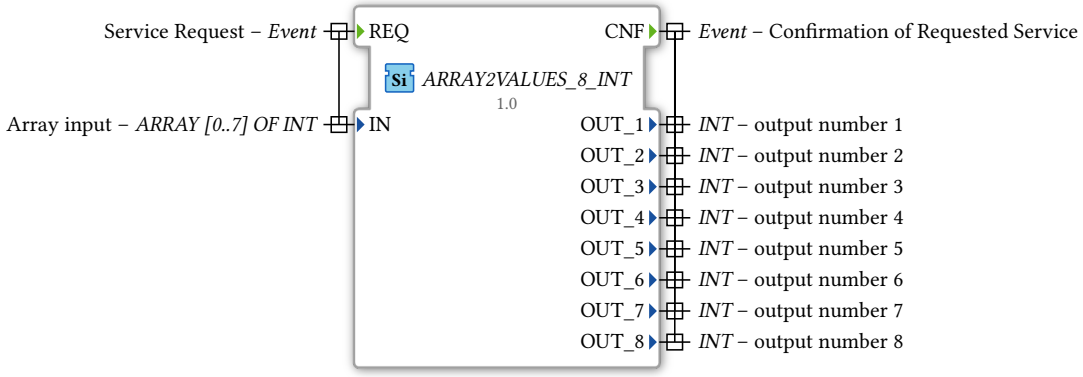
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY', the same C++ base as ARRAY2VALUES_2_LREAL and the other ARRAY2VALUES_* variants.
- **Fixed size 8**: For other array sizes of the same type see ARRAY2VALUES_2_BYTE, ARRAY2VALUES_4_BYTE, ARRAY2VALUES_16_BYTE, ARRAY2VALUES_32_BYTE.

State Overview

Stateless: every REQ immediately results in a full split and CNF.

Application Scenarios

- **Data preparation**: An upstream block delivers a BYTE array, but a downstream block needs discrete individual variables.
- **Interface adaptation** between array-based and variable-based block interfaces.



Comparison with similar function blocks

- **ARRAY2VALUES_2_LREAL**: the same generic implementation for data type LREAL.
- **VALUES2ARRAY_8_BYTE**: the reverse direction — combines 8 individual values into an array.
- **ARRAY2ARRAY_8_BYTE**: copies the array unchanged instead of splitting it.

Conclusion

ARRAY2VALUES_8_BYTE provides a simple, generically implemented split of a BYTE array of size 8 into 8 discrete individual variables and is suitable for adapting array-based to variable-based interfaces.

2.11.1.12 ARRAY2VALUES_8_INT

• – ◦ • – ◦ • – ◦ •

Introduction

`ARRAY2VALUES_8_INT` splits a `INT` array of size 8 into 8 individual scalar variables `OUT_1`...`OUT_8`. It belongs to the generic `GEN_ARRAY2ARRAY` family (cf. ARRAY2VALUES_2_LREAL) and converts array data into discrete individual values.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT_1`, `OUT_2`, `OUT_3`, `OUT_4`, `OUT_5`, `OUT_6`, `OUT_7`, `OUT_8`.

Data Inputs

- **IN** (`INT`, array size 8): The array to split (16-bit signed integer).

Data Outputs

- `OUT_1`, `OUT_2`, `OUT_3`, `OUT_4`, `OUT_5`, `OUT_6`, `OUT_7`, `OUT_8` (`INT`): `OUT_i` corresponds to `IN[i-1]`, i.e. the i-th element of the array.

Functionality

On `REQ`, every element of `IN` is copied to the corresponding scalar output `OUT_i` (`IN[0]` ⟶ `OUT_1`, ..., `IN[7]` ⟶ `OUT_8`), then `CNF` is triggered.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as ARRAY2VALUES_2_LREAL and the other `ARRAY2VALUES_*` variants.
- **Fixed size 8**: For other array sizes of the same type see .

State Overview

Stateless: every `REQ` immediately results in a full split and `CNF`.

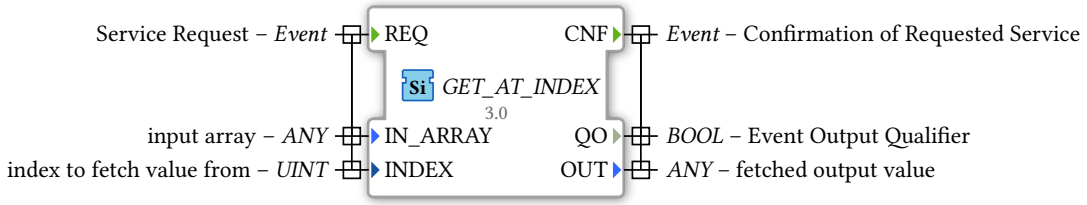
Application Scenarios

- **Data preparation**: An upstream block delivers a `INT` array, but a downstream block needs discrete individual variables.
- **Interface adaptation** between array-based and variable-based block interfaces.

Comparison with similar function blocks

- ARRAY2VALUES_2_LREAL: the same generic implementation for data type `LREAL`.
- **`VALUES2ARRAY_8_INT`**: the reverse direction — combines 8 individual values into an array.
- **`ARRAY2ARRAY_8_INT`**: copies the array unchanged instead of splitting it.

Conclusion



ARRAY2VALUES_8_INT provides a simple, generically implemented split of a INT array of size 8 into 8 discrete individual variables and is suitable for adapting array-based to variable-based interfaces.

2.11.1.13 GET_AT_INDEX

• – ◦ • – ◦ • – ◦ •

Introduction

This function block (FB) is used to retrieve a value from an array at a specific index position. An important prerequisite for correct operation is that the data type of the input array matches the data type of the output value. It is a fundamental building block for accessing array elements.

Interface Structure

The GET_AT_INDEX function block has a clearly defined interface structure with event and data inputs and outputs.

Event Inputs

- **REQ** (Type: Event)
- Service request to execute the function block.
- Is linked to the data inputs IN_ARRAY and INDEX, which are read when the event is triggered.

Event Outputs

- **CNF** (Type: Event)
- Acknowledgement of the requested service after successful processing.
- Is linked to the data outputs QO and OUT, which are provided after processing.

Data Inputs

- **IN_ARRAY** (Type: ANY)
- The input array from which a value is to be retrieved. The data type is generic (ANY) but must match the output.
- **IN_ARRAY** (Type: ANY)
- The input array from which a value is to be retrieved. The data type is generic (ANY) but must match the output.
- **INDEX** (Type: UINT)
- The index (position) within IN_ARRAY from which the value is to be retrieved.

Data Outputs

- **QO** (Type: BOOL)
- A qualifier for the event output, typically indicating the success or failure of the operation (e.g., TRUE for success, FALSE for failure).
- **OUT** (Type: ANY)
- The retrieved value from IN_ARRAY at the specified INDEX position. The data type is generic (ANY).

Adapters

This function block does not use any adapters.

Functionality

When a REQ event is received at the input of the function block, the GET_AT_INDEX function block reads the current values of the data inputs IN_ARRAY and INDEX. It then accesses IN_ARRAY and extracts the value at the position specified by INDEX. This retrieved value is then passed to the data output OUT. Simultaneously,

the output QO is set according to the result of the operation (e.g., TRUE for successful access). Finally, the CNF event is triggered to signal the termination of the service.

Technical Specifications

- **Data Type Match**: It is crucial that the data type of the input array (IN_ARRAY) is compatible with the expected data type of the retrieved value (OUT) to avoid type errors.
- **Index Range**: The value of INDEX must be within the valid limits of IN_ARRAY to prevent runtime errors or undefined behavior. Index range verification may need to be ensured by upstream or downstream logic.
- **ANY Type**: Using the ANY type for IN_ARRAY and OUT makes the function block very flexible, but requires careful typing in the application.

State Overview

The GET_AT_INDEX function block is essentially stateless with respect to data storage. Its states are limited to the execution cycle:

1. **Ready**: Waits for a REQ event.
2. **Executing**: Reads inputs, performs array access, and sets outputs.
3. **Completed**: Triggers the CNF event and returns to the "Ready" state.

Application Scenarios

- **Data Logging and Analysis**: Retrieving specific measured values from a time-series array.
- **Configuration Management**: Reading individual parameters from an array of configuration values.
- **List Processing**: Sequentially or randomly retrieving items from a list of tasks or objects.
- **Robot Control**: Accessing positions or motion parameters stored in arrays.
- **Visualization**: Retrieving data points for display on a user interface.

⚖️ Comparison with Similar Blocks

The GET_AT_INDEX block is a specialized block for array access. It differs from:

- **SET_AT_INDEX**: A complementary building block that sets values at a specific array position instead of retrieving them.
- **Array Iterators**: Building blocks that typically iterate through the entire array instead of retrieving a single element via a direct index.
- **General Data Manipulation Building Blocks**: These are not specifically designed for array access but perform more general operations (e.g., addition, comparison).

GET_AT_INDEX` thus fills a fundamental gap for direct, indexed read access to array data structures.

Metadata

Attribute	Value
Copyright	(c) 2014 Profactor GmbH
License	EPL-2.0
Version	Version 3.0 (April 14, 2025, Patrick Aigner), Version 1.0 (July 11, 2014, Matthias Plasch)
4diac package	eclipse4diac::convert

Conclusion

The GET_AT_INDEX function block is a basic and flexible building block that enables direct and indexed access to array elements. Its simplicity and support for generic data types (ANY) make it a versatile tool in numerous automation and control applications where data is stored in ordered lists or tables. Correct use requires only attention to data type compatibility and the valid index range.

2.11.1.14 GET_STRUCT_VALUE

• – ○ • – ○ • – ○ •

Introduction

The function block (FB) `GET_STRUCT_VALUE` is a service interface module designed to dynamically read specific values from a given data structure. It provides a flexible way to access structure members whose names or paths are determined at runtime.

Interface Structure

Event Inputs

Name	Type	Description	Data with
`REQ`	`Event`	Requests the retrieval of a value from the structure.	`member`, `in_struct`

Event Outputs

Name	Type	Description	Data with
`CNF`	`Event`	Confirms the completion of the `REQ` event.	`QO`, `output`

Data Inputs

Name	Type	Description
`in_struct`	`ANY`	The data structure from which a value is to be read.
`member`	`STRING`	The name of the member of the structure to be retrieved. Inner members are accessed using the dot operator (`.`).

Data Outputs

Name	Type	Description
`QO`	`BOOL`	`TRUE` if no errors occurred, otherwise `FALSE`.
`output`	`ANY`	The value of the selected member if `QO = TRUE`. Otherwise, this value remains unchanged.

Adapters

No adapters available.

Functionality

The `GET_STRUCT_VALUE` function block is activated by a `REQ` event. Upon activation, the function block attempts to extract the value of a structure member specified in `member` from the data structure present at input `in_struct`. The path to the member can also specify nested members (e.g., “config.port”) using the dot operator (`.`). After reading, a `CNF` event is triggered, which provides the status (`QO`) and the extracted value (`output`). If an error occurs (e.g., member not found or invalid path), `QO` is set to `FALSE`.

Technical Features

- **Dynamic Member Access:** This function block allows access to structure members via a `STRING` input, offering high flexibility in data processing.
- **Nested Structures:** Members in nested structures can also be efficiently addressed using the dot operator (`.`) in the string `member`.
- **Type Independence:** The inputs and outputs `in_struct` and `output` are of type `ANY`, meaning that the function block can handle any data structure and member data type.

State Overview

The `GET_STRUCT_VALUE` is a stateless service function block that implements simple request acknowledgment logic (REQ/CNF). It processes each request individually and does not maintain any complex internal states.

Application Scenarios

- **Dynamic Configuration:** Reading configuration parameters from a central structure, where the required parameters are determined at runtime.
- **Generic Data Processing:** Developing generic algorithms or logic that need to access different parts of a data structure based on external inputs or rules.
- **Logging and Diagnostics:** Extracting specific status information or measured values from a complex system state structure for monitoring or diagnostic purposes.
- **Interfaces to External Systems:** Adapting to data formats of external systems where field names are passed dynamically.

⚖️ Comparison with Similar Building Blocks

There are no directly comparable function blocks in the 4diac standard library that allow dynamic access to structure members via a `STRING` path. This building block fills a niche for use cases requiring flexible, runtime-configurable structure manipulation that goes beyond the static access of conventional function blocks.

Metadata

Attribute	Value

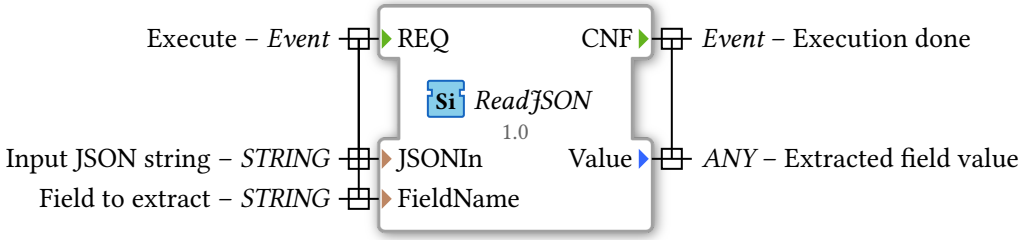
4diac Package	eclipse4diac::convert

🛠️ Related Exercises

- Exercise_052



Conclusion

The `GET_STRUCT_VALUE` function block is a valuable tool for developers who need a flexible and dynamic method for reading values from data structures in 4diac. Its ability to access members via string paths, including nested structures, makes it particularly useful in scenarios where the structure of the required data is not fully known or is variable at compile time.

2.11.1.15 ReadJSON

• – ◦ • – ◦ • – ◦ •

Introduction

The `ReadJSON` function block extracts the value of a named field from a JSON string. It serves as a simple, event-driven JSON decoder for use cases where a single field needs to be read from a JSON structure, without having to map the entire structure to dedicated IEC 61131-3 data types.

Interface Structure

Event Inputs

- **REQ**: Triggers the extraction, carries `JSONIn` and `FieldName`.

Event Outputs

- **CNF**: Confirms completion, carries `Value`.

Data Inputs

- **JSONIn** (STRING): The JSON string to search.
- **FieldName** (STRING): The name of the field to extract.

Data Outputs

- **Value** (ANY): The extracted field value, generically typed.

Functionality

On `REQ`, the block searches `JSONIn` for the field `FieldName` and outputs its value via `Value`. Since `Value` is of type `ANY`, the extracted value can be interpreted as a number, string, or boolean depending on the JSON content. `CNF` is then triggered.

Technical Features

- **ANY return type**: `Value` generically adapts to the actual JSON field type, but when wired to a concretely typed variable must be compatible with that type.
- **Single-field extraction**: The block reads exactly one named field per call; nested or multiple fields require several `ReadJSON` calls or instances.

State Overview

Stateless: every `REQ` immediately results in extraction and `CNF`.

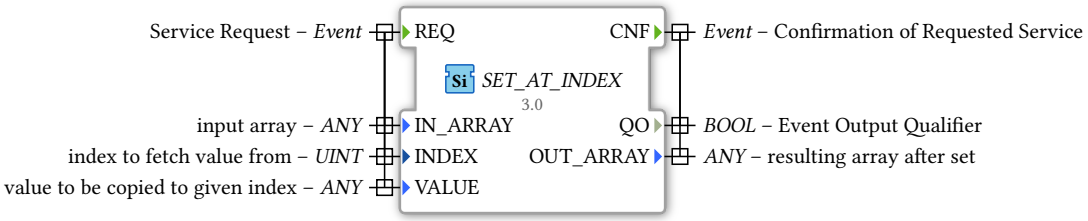
Application Scenarios

- **Reading configuration**: A JSON configuration string received over the network or from a file needs to be evaluated without defining a full STRUCT.
- **Communicating with REST/web interfaces**: Responses from HTTP APIs that return JSON can be read field by field.

Comparison with similar function blocks

- **ToJSON**: the reverse direction — adds a field to a JSON string or creates a new one.
- **`GET_STRUCT_VALUE`**: reads a field from an IEC 61131-3 STRUCT instead of a JSON string.

Conclusion



`ReadJSON` provides a simple, field-by-field JSON decoder for 4diac applications communicating with JSON-based configurations or web interfaces, without requiring a full structure type definition.

2.11.1.16 SET_AT_INDEX

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SET_AT_INDEX` is used to set the value of an element in an array at a specific index. It must be ensured that the data types of the value to be set match the data type of the array. The resulting output array will also have the same data type as the input array. This function block is useful for dynamically manipulating array data within a control program.

Interface Structure

Event Inputs

- **REQ** (Event): A request input that initiates the execution of the function block. This event processes the data inputs `IN_ARRAY`, `INDEX`, and `VALUE`.

Event Outputs

- **CNF** (Event): An acknowledgment output triggered after successful service execution. This event updates the data outputs `QO` and `OUT_ARRAY`.

Data Inputs

- **IN_ARRAY** (ANY): The input array whose value is to be modified at a specific index. The data type `ANY` allows its use with various array types.
- **INDEX** (UINT): The zero-based index of the element in the array whose value is to be set.
- **IN_ARRAY** (ANY): The input array whose value is to be modified at a specific index. * **VALUE** (ANY): The value to be set at the specified position in the array. The data type must match the data type of `IN_ARRAY`.

Data Outputs

- **QO** (BOOL): An event output qualifier that indicates the success of the operation. `TRUE` on success, `FALSE` on error (e.g., invalid index).
- **OUT_ARRAY** (ANY): The resulting array after the value has been set at the specified index.

Adapter

Not present.

Functionality

The `SET_AT_INDEX` function block waits for a `REQ` event. As soon as this event occurs, the function block checks the passed arrays `IN_ARRAY`, `INDEX`, and `VALUE`. It attempts to store `VALUE` at the address of `INDEX` within `IN_ARRAY`. If the operation is successful, a new array is created and output to `OUT_ARRAY`, setting `QO` to `TRUE`. If the specified `INDEX` is outside the valid range of `IN_ARRAY`, or if the data types of `VALUE` and the array elements do not match, the operation may fail, and `QO` could display `FALSE`.

Technical Features

- **Data Type Flexibility:** By using `ANY` for the array and value parameters, the function block is flexible with respect to the data types it can process. However, it is crucial that the data type of `VALUE` exactly matches the element data type of `IN_ARRAY` to avoid runtime errors.
- **Index Type:** The `INDEX` block is of type `UINT` (Unsigned Integer), meaning that only positive indices are allowed.
- **Zero-Based Indexing:** The index starts at 0 for the first element of the array.
- **Error Handling:** The `QO` output serves as a simple indicator of the operation's success. More advanced error handling (e.g., for index out-of-bounds errors) may need to be implemented at the application level or supplemented with additional checks.

State Overview

The `SET_AT_INDEX` block is essentially an event-driven block without complex internal state. It waits for a `REQ` event, executes the action, and outputs a `CNF` event. Its function is direct and reactive.

Application Scenarios

- **Dynamic Configuration:** Modifying configuration parameters stored in arrays at runtime.

- **Data Processing:** Updating sensor or actuator data collected in arrays.
- **Algorithmic Adjustment:** Modifying lookup tables or controller parameters in real time.
- **User Interaction:** Setting array values based on user input.

⚖️ Comparison with Similar Blocks

This block is complementary to the `GET_AT_INDEX` block, which would read values from an array at a specific index. It is a fundamental operation for array manipulation and forms the basis for more complex data structure algorithms. Unlike building blocks that copy or move entire arrays, `SET_AT_INDEX` focuses on the precise manipulation of a single element.

4diac Package	eclipse4diac::convert

Conclusion

The `SET_AT_INDEX` function block is a fundamental yet powerful tool for manipulating array data in 4diac applications. Its flexibility, thanks to the `ANY` data types and its clear event-driven interface, makes it a valuable component for many applications requiring dynamic data structures. Correct handling of data types and indices is crucial for its error-free use.

2.11.1.17 SET_STRUCT_VALUE

• – ○ • – ○ • – ○ •

Introduction

The function block `SET_STRUCT_VALUE` is a service interface function block used to set a specific value within a data structure. It enables the dynamic manipulation of structure elements by assigning a new value to a named member of the structure.

Interface Structure

The function block has event and data interfaces to enable its functionality.

Event Inputs

- **REQ**: This event requests the function block to set the value in the specified structure. It is associated with the data variables `member`, `in_struct`, and `element_value`.

Event Outputs

- **CNF**: This event is triggered when the `REQ` request is completed. It is associated with the data variable `out_struct`.

Data Inputs

- **in_struct** (Type: ANY): The input structure in which a value is to be changed. The type `ANY` allows the processing of any structure type.
- **member** (Type: STRING): The name of the structure member whose value is to be set. Inner members can be addressed using the dot operator (`.`) (e.g., "config.port").
- **element_value** (Type: ANY): The new value to be assigned to the specified structure member.

Data Outputs

- **out_struct** (Type: ANY): The modified structure after the element is set. The comment in the XML states "TRUE if no errors occurred, FALSE otherwise," which is a remnant of a `STATUS` output, but here it refers to the output, modified structure.

Adapters

No adapters are present.

Functionality

Upon receiving a `REQ` event, the function block accesses the data structure provided via `in_struct`. Based on the string passed as `member`, the corresponding element within the structure is identified. The function block then assigns the value provided via `element_value` to this element. The function block then outputs the modified structure via `out_struct` and signals the completion of the operation with the `CNF` event.

Technical Features

- **Generic Types (ANY)**: By using the data type `ANY` for `in_struct`, `element_value`, and `out_struct`, this function block offers high flexibility. It can work with any user-defined or predefined structure types and values without requiring specific types to be known at compile time.
- **Access to Nested Members**: The `member` variable supports access to deeper levels of a nested structure using dot notation (e.g., "outer.inner.value"). This simplifies the handling of complex data models.

State Overview

The function block primarily operates in a request-based (`REQ`) and confirmation-based (`CNF`) schema. It processes a request, modifies the data, and signals completion. There are no complex internal states beyond this simple request/confirm cycle.

Application Scenarios

- **Runtime Configuration Management**: Dynamically modify configuration parameters stored in structures without recompiling the function block.
- **Data Manipulation in SCADA/HMI Systems**: Updating specific values in complex data objects received from or sent to higher-level systems.
- **Interfaces to External Systems**: Adapting data structures used for communication with external APIs or databases.
- **Process Control**: Modifying process parameters organized in structures based on dynamic conditions or user input.

⚖️ Comparison with Similar Function Blocks

Compared to function blocks that support hard-coded structures or only read values, `SET_STRUCT_VALUE` offers unique flexibility through:

- **Write Access**: Allows setting values, not just reading.
- **Generic Access**: Works with any `ANY` type, making it more universal than function blocks bound to specific structure types.
- **Dynamic Member Selection**: The member name is passed as a string at runtime, allowing for more dynamic field selection than with fixed inputs/outputs.

It often complements function blocks that read values from structures (`GET_STRUCT_VALUE`) to provide complete read/write functionality for generic structures.

Version	3.0 (2025-04-14, Patrick Aigner), 1.0 (2023-03-06, Alois Zoitl)
4diac Package	eclipse4diac::convert

Conclusion

The `SET_STRUCT_VALUE` function block is a powerful tool for dynamically manipulating data structures within a 4diac application. Its generic nature and support for accessing nested members make it extremely versatile for applications that require flexible configuration or runtime data processing.

2.11.1.18 STRUCT_DEMUX

• – ◦ • – ◦ • – ◦ •

The function block (FB) `STRUCT_DEMUX` is a generic demultiplexer for structured data types. Its main task is to split an input data structure into its individual components (members). These individual members are then made available via separate data outputs, which are generated dynamically.

The interface of the `STRUCT_DEMUX` function block is defined generically. The actual data outputs are only determined during the instantiation of the block.

- **REQ**: Triggers the execution of the function block and causes the input structure to be read.
- **With Data Variable**: `IN`
- **CNF**: Confirms the completion of the operation after the structure's values have been passed to the outputs.
- **With Data Variables**: All dynamically generated data outputs.
- **IN** (Type: `ANY_STRUCT`): The input data structure to be split.

The data outputs of this function block are not predefined. Instead, they are created **dynamically** based on the data type associated with the `IN` input. For each member of the input structure, a corresponding data output with the same name and data type is created in the function block.

If a structure of type `MyStruct` with members `a` (type `INT`) and `b` (type `BOOL`) is connected to the `IN` input, the `STRUCT_DEMUX` block automatically generates two data outputs:

- `a` (type `INT`)
- `b` (type `BOOL`)

The image above illustrates this exact case.

- `a` (type `INT`)
- `b` (type `BOOL`)

...

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

As soon as a `REQ` event is received at the input of the `STRUCT_DEMUX` function block, the block reads the data structure present at the `IN` input. It extracts the values of each individual member of the structure and forwards them to the corresponding, dynamically generated data outputs. After all output values have been updated, the `CNF` event is triggered to signal the completion of the process.

- **Generic Block**: Thanks to the attribute `GEN_STRUCT_DEMUX`, the block is able to adapt to any structured data type (`ANY_STRUCT`).
- **Dynamic Interface**: The ability to generate its outputs based on the input data type makes it extremely flexible and reusable.
- **Service Interface Function Block Type**: The function block is designed as a standardized interface for this service.

The `STRUCT_DEMUX` is a stateless function block that operates according to a simple request-acknowledgment cycle:

1. **Ready**: Waits for a `REQ` event.
2. **Executing**: Reads the input structure, extracts the member values, and sets the corresponding outputs.
3. **Completed**: Triggers the `CNF` event and returns to the ready state.

- **Complex Data Splitting**: Decomposing complex data structures (e.g., sensor data, status information) into individual signals for further processing.
- **Improved Readability**: Instead of accessing structure members via `GET_STRUCT_VALUE`, the members can be used directly as separate data lines in the logic.
- **Interface Adaptation**: Adapting data arriving as a single structure from a function block to multiple function blocks that expect individual inputs.
- **`GET_STRUCT_VALUE`**: While `GET_STRUCT_VALUE` dynamically extracts a single member via a `STRING` name, `STRUCT_DEMUX` statically exposes all members as separate outputs. `STRUCT_DEMUX` is often easier to use when all members are needed, while `GET_STRUCT_VALUE` is more flexible when only specific members need to be addressed at runtime.
- **`STRUCT_MUX`**: The complementary component that combines individual data inputs into a single data structure.

2.11.1.19 STRUCT_MUX

• – ◦ • – ◦ • – ◦ •

Introduction

The function block (FB) `STRUCT_MUX` is a generic multiplexer for structured data types. It functions as the counterpart to `STRUCT_DEMUX` and is responsible for combining individual data values from multiple inputs into a single data structure at the output.

Interface Structure

The interface of the `STRUCT_MUX` function block is defined generically. The actual data inputs are only determined during the instantiation of the block.

Event Inputs

- **REQ**: Triggers the execution of the function block. This causes the values at the inputs to be read and the output structure to be assembled.
- **With Data Variables**: All dynamically generated data inputs.

Event Outputs

- **CNF**: Confirms the completion of the operation after the output structure has been successfully created.
- **With Data Variable**: `OUT`

Data Inputs

The data inputs of this function block are not predefined. Instead, they are created **dynamically** based on the data type specified for the `OUT` output. For each member of the output structure, a corresponding data input with the same name and data type is created in the function block.

Example:

If the output `OUT` is set to the data type `MyStruct` with the members `a` (type `INT`) and `b` (type `BOOL`), the `STRUCT_MUX` block automatically creates two data inputs:

- `a` (type `INT`)
- `b` (type `BOOL`)

The image above illustrates this exact case.

- `a` (type `INT`)
- `b` (type `BOOL`)

...

Data Outputs

- **OUT** (Type: `ANY_STRUCT`): The output data structure, which is assembled from the values of the inputs.

Functionality

As soon as a `REQ` event is received at the input of the `STRUCT_MUX` function block, the block reads the values from all its dynamically generated data inputs. These values are then combined into a single data structure. The resulting structure is made available at the `OUT` output. Immediately afterward, the `CNF` event is triggered to signal the completion of the process.

Technical Features

- **Generic Block**: Thanks to the attribute `GEN_STRUCT_MUX`, the block can adapt to any structured data type (`ANY_STRUCT`).
- **Dynamic Interface**: The ability to generate its inputs based on the output data type makes it extremely flexible and reusable.
- **Service Interface Function Block Type**: The block is designed as a standardized interface for this service.

State Overview

The `STRUCT_MUX` is a stateless block that operates according to a simple request-acknowledgment cycle:

1. **Ready**: Waits for a `REQ` event.
2. **Executing**: Reads the input values and assembles the output structure.
3. **Completed**: Provides the structure at the `OUT` output, triggers the `CNF` event, and returns to standby mode.

Application Scenarios

- **Data Consolidation**: Bundles individual signals (e.g., configuration parameters, control values) into a single structure for further processing or communication.
- **Improved Clarity**: Combines many individual data lines into a single structured line to reduce the complexity of graphical representations.
- **Interface Adaptation**: Adapts individual data values to a function block that expects a single data structure as an input.

⚖️ Comparison with Similar Function Blocks

- **`STRUCT_DEMUX`**: The complementary function block that splits a single data structure into its individual members.
- **`SET_STRUCT_VALUE`**: While `SET_STRUCT_VALUE` dynamically modifies a single value within an existing structure, `STRUCT_MUX` creates a completely new structure from individual values.

2.11.1.20 ToJSON

• – ◦ • – ◦ • – ◦ •

Introduction

The `ToJSON` function block adds a named field with a value to a JSON string. If `JSONIn` is empty, a new JSON object containing exactly that one field is created — by chaining several `ToJSON` calls (`JSONOut` of one as `JSONIn` of the next), a complete JSON object can be built up step by step.

Interface Structure

Event Inputs

- **REQ**: Triggers the addition, carries `JSONIn`, `Value`, and `FieldName`.

Event Outputs

- **CNF**: Confirms completion, carries `JSONOut`.

Data Inputs

- **JSONIn** (STRING): The existing JSON string a field is added to (an empty string creates a new object).
- **Value** (ANY): The value to store, generically typed.
- **FieldName** (STRING): The key (field name) under which `Value` is stored.

Data Outputs

- **JSONOut** (STRING): The updated JSON string with the newly added field.

Functionality

On `REQ`, the block checks `JSONIn`: if the string is empty, a new JSON object `{"FieldName": Value}` is created; otherwise the field `FieldName` with `Value` is inserted into the existing object (overwriting an existing field of the same name, if any). The result is output via `JSONOut`, then `CNF` is triggered.

Technical Features

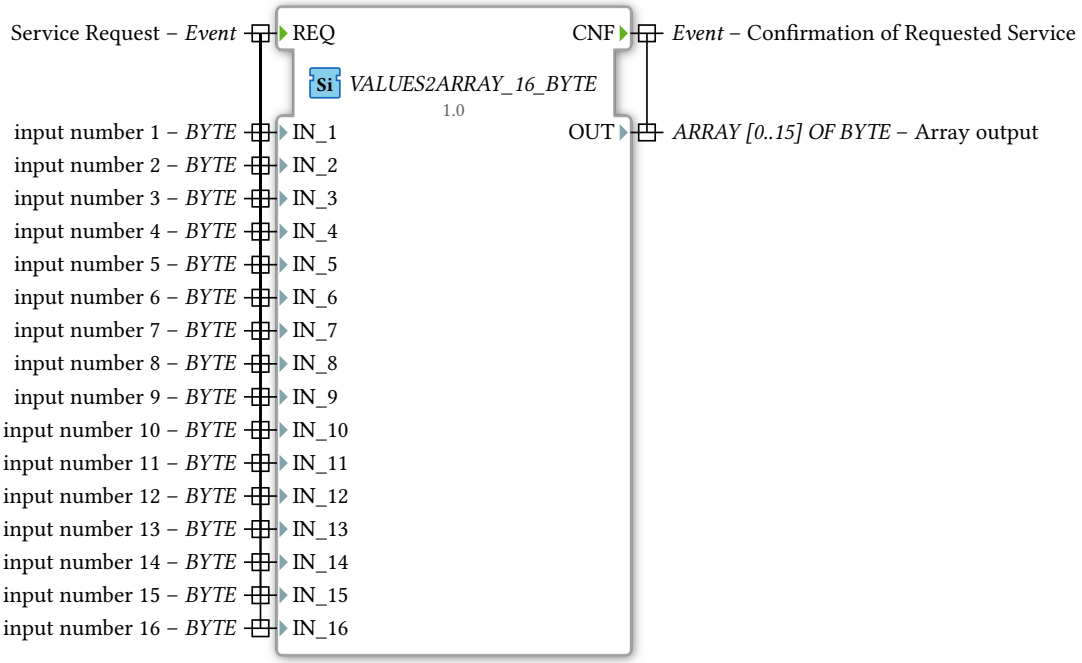
- **ANY input type**: `Value` generically accepts numbers, strings, and boolean values, which are translated to the corresponding JSON data type.
- **Chainable**: Since `JSONOut` has the same type as `JSONIn`, multiple `ToJSON` instances can be chained to build up a JSON object with several fields step by step.
- **Empty `JSONIn` creates a new object**: No separate "create" block is needed — the first call in a chain can start directly with an empty `JSONIn`.

State Overview

Stateless: every `REQ` immediately results in the field being inserted and `CNF`.

Application Scenarios

- **Building JSON payloads**: A JSON object is assembled step by step from several process values for sending to a REST API or an MQTT topic.
- **Logging**: Structured log entries in JSON format, with individual fields added from different parts of a program.



Comparison with similar function blocks

- **ReadJSON**: the reverse direction — extracts a field from a JSON string.
- **`SET_STRUCT_VALUE`**: sets a field in an IEC 61131-3 STRUCT instead of a JSON string.

Conclusion

`ToJSON` enables the step-by-step, chainable construction of JSON strings from individual field/value pairs and is suitable for building JSON payloads in 4diac applications without requiring a full structure type definition.

2.11.1.21 VALUES2ARRAY_16_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

VALUES2ARRAY_16_BYTE combines 16 individual BYTE scalar variables IN_1...IN_16 into a BYTE array of size 16. It is the reverse of ARRAY2VALUES_16_BYTE and belongs to the generic GEN_ARRAY2ARRAY family (cf. VALUES2ARRAY_2_LREAL).

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries IN_1, IN_2, IN_3, IN_4, IN_5, IN_6, IN_7, IN_8, IN_9, IN_10, IN_11, IN_12, IN_13, IN_14, IN_15, IN_16.

Event Outputs

- **CNF**: Confirms completion, carries OUT.

Data Inputs

- IN_1, IN_2, IN_3, IN_4, IN_5, IN_6, IN_7, IN_8, IN_9, IN_10, IN_11, IN_12, IN_13, IN_14, IN_15, IN_16 (BYTE): The 16 individual values (8-bit bit pattern) to be combined into the array.

Data Outputs

- **OUT** (BYTE, array size 16): OUT[i-1] corresponds to IN_i.

Functionality

On REQ, every input value IN_i is written to the corresponding element OUT[i-1] (IN_1 ⟶ OUT[0], ..., IN_16 ⟶ OUT[15]), then CNF is triggered.

Technical Features

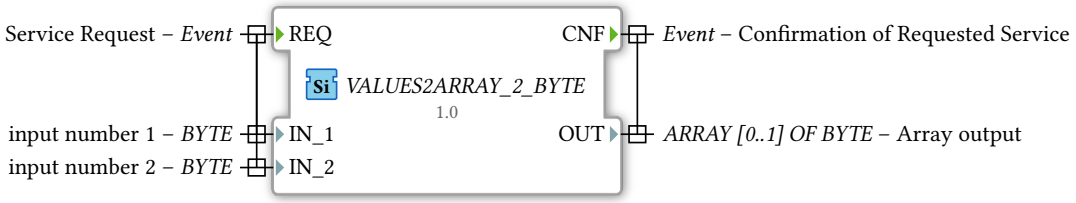
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY', the same C++ base as VALUES2ARRAY_2_LREAL and the other VALUES2ARRAY_* variants.
- **Fixed size 16**: For other array sizes of the same type see VALUES2ARRAY_2_BYTE, VALUES2ARRAY_4_BYTE, VALUES2ARRAY_8_BYTE, VALUES2ARRAY_32_BYTE.

State Overview

Stateless: every REQ immediately results in a full merge and CNF.

Application Scenarios

- **Building an array from individual values**: Several discrete BYTE variables need to be passed as an array to a downstream block that expects an array interface.
- **Interface adaptation** between variable-based and array-based block interfaces.



Comparison with similar function blocks

- **VALUES2ARRAY_2_LREAL**: the same generic implementation for data type LREAL.
- **ARRAY2VALUES_16_BYTE**: the reverse direction — splits an array into 16 individual values.

Conclusion

VALUES2ARRAY_16_BYTE provides a simple, generically implemented merge of 16 BYTE individual values into an array and is suitable for adapting variable-based to array-based interfaces.

2.11.1.22 VALUES2ARRAY_2_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

VALUES2ARRAY_2_BYTE combines 2 individual BYTE scalar variables IN_1...IN_2 into a BYTE array of size 2. It is the reverse of ARRAY2VALUES_2_BYTE and belongs to the generic GEN_ARRAY2ARRAY family (cf. VALUES2ARRAY_2_LREAL).

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries IN_1, IN_2.

Event Outputs

- **CNF**: Confirms completion, carries OUT.

Data Inputs

- IN_1, IN_2 (BYTE): The 2 individual values (8-bit bit pattern) to be combined into the array.

Data Outputs

- **OUT** (BYTE, array size 2): OUT[i-1] corresponds to IN_i.

Functionality

On REQ, every input value IN_i is written to the corresponding element OUT[i-1] (IN_1 ⟶ OUT[0], ..., IN_2 ⟶ OUT[1]), then CNF is triggered.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY', the same C++ base as VALUES2ARRAY_2_LREAL and the other VALUES2ARRAY_* variants.
- **Fixed size 2**: For other array sizes of the same type see VALUES2ARRAY_4_BYTE, VALUES2ARRAY_8_BYTE, VALUES2ARRAY_16_BYTE, VALUES2ARRAY_32_BYTE.

State Overview

Stateless: every REQ immediately results in a full merge and CNF.

Application Scenarios

- **Building an array from individual values**: Several discrete BYTE variables need to be passed as an array to a downstream block that expects an array interface.
- **Interface adaptation** between variable-based and array-based block interfaces.

Comparison with similar function blocks

- **VALUES2ARRAY_2_LREAL**: the same generic implementation for data type LREAL.
- **ARRAY2VALUES_2_BYTE**: the reverse direction — splits an array into 2 individual values.

Conclusion

VALUES2ARRAY_2_BYTE provides a simple, generically implemented merge of 2 BYTE individual values into an array and is suitable for adapting variable-based to array-based interfaces.

2.11.1.23 VALUES2ARRAY_2_LREAL

• – ◦ • – ◦ • – ◦ •

The function block VALUES2ARRAY_2_LREAL is used to convert two individual floating-point numbers of type LREAL into an array of the same type. It is designed as a service interface function block, providing a simple interface for this conversion task.

- **REQ** (Type: Event)
- Comment: Service Request
- Associated Data: IN_1, IN_2
- Description: This event triggers the conversion of the two input values IN_1 and IN_2 into the array OUT.
- **CNF** (Type: Event)
- Comment: Confirmation of Requested Service
- Associated Data: OUT
- Description: This event is triggered after the conversion is successful and the output array OUT is updated.
- **IN_1** (Type: LREAL)
- Comment: Input number 1
- Description: The first floating-point number to be added to the array.
- **IN_2** (Type: LREAL)
- Comment: Input number 2
- Description: The second floating-point number to be added to the array.
- **OUT** (Type: LREAL, Size: 2)
- Comment: Array output
- Description: An array of type LREAL containing the values of IN_1 and IN_2. IN_1 occupies the first index, and IN_2 the second index of the array.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not have any adapter interfaces.

Functionality

When a REQ event is received at the input of the function block, VALUES2ARRAY_2_LREAL reads the current values of the data inputs IN_1 and IN_2. These two values are then transferred to the output array OUT, with IN_1 being assigned to element OUT[0] and IN_2 to element OUT[1]. After successful completion of this operation, a CNF event is issued to signal the completion of the request.

- The function block is specialized for converting exactly two LREAL values.
- The output array OUT is fixed at size 2.
- Processing is event-driven, allowing for explicit requests to initiate the conversion process.

The VALUES2ARRAY_2_LREAL function block is stateless. Each REQ request is processed independently, without maintaining internal state across requests. The function depends solely on the input values at the time of the REQ event.

- **Data Bundling**: When two separate LREAL values need to be passed as a single data packet (array) to other function blocks that expect arrays as input.
- **Preprocessing for Mathematical Operations**: Preparing data pairs for array-based operations, such as vector addition or scaling.

This function block is specifically for converting two LREAL values into an LREAL array. General "value-to-array" blocks might be more flexible regarding the number and data type of inputs, but this block provides a simple, specialized solution for the specified use case. For a larger number of values or different data types, corresponding, specially adapted blocks would be required.

2.11.1.24 VALUES2ARRAY_32_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`VALUES2ARRAY_32_BYTE` combines 32 individual `BYTE` scalar variables `IN_1`…`IN_32` into a `BYTE` array of size 32. It is the reverse of `ARRAY2VALUES_32_BYTE` and belongs to the generic `GEN_ARRAY2ARRAY` family (cf. VALUES2ARRAY_2_LREAL).

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries `IN_1`, `IN_2`, `IN_3`, `IN_4`, `IN_5`, `IN_6`, `IN_7`, `IN_8`, `IN_9`, `IN_10`, `IN_11`, `IN_12`, `IN_13`, `IN_14`, `IN_15`, `IN_16`, `IN_17`, `IN_18`, `IN_19`, `IN_20`, `IN_21`, `IN_22`, `IN_23`, `IN_24`, `IN_25`, `IN_26`, `IN_27`, `IN_28`, `IN_29`, `IN_30`, `IN_31`, `IN_32`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- `IN_1`, `IN_2`, `IN_3`, `IN_4`, `IN_5`, `IN_6`, `IN_7`, `IN_8`, `IN_9`, `IN_10`, `IN_11`, `IN_12`, `IN_13`, `IN_14`, `IN_15`, `IN_16`, `IN_17`, `IN_18`, `IN_19`, `IN_20`, `IN_21`, `IN_22`, `IN_23`, `IN_24`, `IN_25`, `IN_26`, `IN_27`, `IN_28`, `IN_29`, `IN_30`, `IN_31`, `IN_32` (`BYTE`): The 32 individual values (8-bit bit pattern) to be combined into the array.

Data Outputs

- **OUT** (`BYTE`, array size 32): `OUT[i-1]` corresponds to `IN_i`.

Functionality

On `REQ`, every input value `IN_i` is written to the corresponding element `OUT[i-1]` (`IN_1` ⟶ `OUT[0]`, ..., `IN_32` ⟶ `OUT[31]`), then `CNF` is triggered.

Technical Features

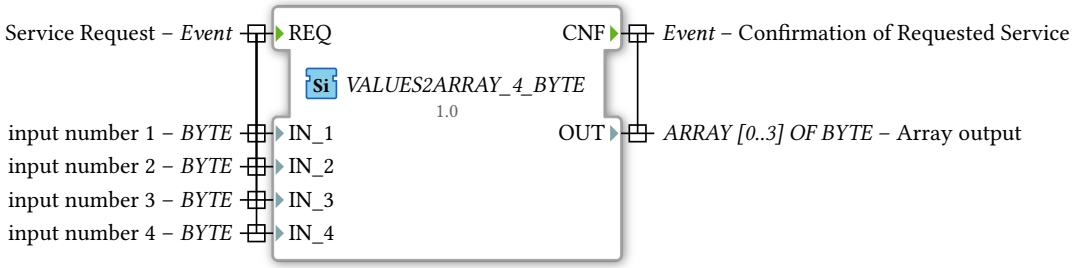
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as VALUES2ARRAY_2_LREAL and the other `VALUES2ARRAY_*` variants.
- **Fixed size 32**: For other array sizes of the same type see `VALUES2ARRAY_2_BYTE`, `VALUES2ARRAY_4_BYTE`, `VALUES2ARRAY_8_BYTE`, `VALUES2ARRAY_16_BYTE`.

State Overview

Stateless: every `REQ` immediately results in a full merge and `CNF`.

Application Scenarios

- **Building an array from individual values**: Several discrete `BYTE` variables need to be passed as an array to a downstream block that expects an array interface.
- **Interface adaptation** between variable-based and array-based block interfaces.



Comparison with similar function blocks

- **VALUES2ARRAY_2_LREAL**: the same generic implementation for data type `LREAL`.
- **`ARRAY2VALUES_32_BYTE`**: the reverse direction — splits an array into 32 individual values.

Conclusion

`VALUES2ARRAY_32_BYTE` provides a simple, generically implemented merge of 32 `BYTE` individual values into an array and is suitable for adapting variable-based to array-based interfaces.

2.11.1.25 VALUES2ARRAY_4_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`VALUES2ARRAY_4_BYTE` combines 4 individual `BYTE` scalar variables `IN_1`...`IN_4` into a `BYTE` array of size 4. It is the reverse of `ARRAY2VALUES_4_BYTE` and belongs to the generic `GEN_ARRAY2ARRAY` family (cf. VALUES2ARRAY_2_LREAL).

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries `IN_1`, `IN_2`, `IN_3`, `IN_4`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- `IN_1`, `IN_2`, `IN_3`, `IN_4` (`BYTE`): The 4 individual values (8-bit bit pattern) to be combined into the array.

Data Outputs

- **OUT** (`BYTE`, array size 4): `OUT[i-1]` corresponds to `IN_i`.

Functionality

On `REQ`, every input value `IN_i` is written to the corresponding element `OUT[i-1]` (`IN_1` ⟶ `OUT[0]`, ..., `IN_4` ⟶ `OUT[3]`), then `CNF` is triggered.

Technical Features

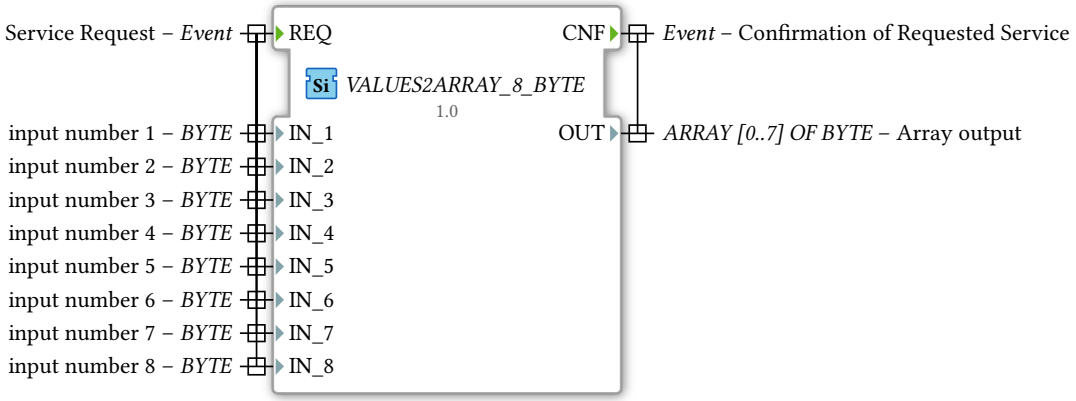
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as VALUES2ARRAY_2_LREAL and the other `VALUES2ARRAY_*` variants.
- **Fixed size 4**: For other array sizes of the same type see `VALUES2ARRAY_2_BYTE`, `VALUES2ARRAY_8_BYTE`, `VALUES2ARRAY_16_BYTE`, `VALUES2ARRAY_32_BYTE`.

State Overview

Stateless: every `REQ` immediately results in a full merge and `CNF`.

Application Scenarios

- **Building an array from individual values**: Several discrete `BYTE` variables need to be passed as an array to a downstream block that expects an array interface.
- **Interface adaptation** between variable-based and array-based block interfaces.



Comparison with similar function blocks

- VALUES2ARRAY_2_LREAL: the same generic implementation for data type `LREAL`.
- **`ARRAY2VALUES_4_BYTE`**: the reverse direction — splits an array into 4 individual values.

Conclusion

`VALUES2ARRAY_4_BYTE` provides a simple, generically implemented merge of 4 `BYTE` individual values into an array and is suitable for adapting variable-based to array-based interfaces.

2.11.1.26 VALUES2ARRAY_8_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

VALUES2ARRAY_8_BYTE combines 8 individual BYTE scalar variables IN_1...IN_8 into a BYTE array of size 8. It is the reverse of ARRAY2VALUES_8_BYTE and belongs to the generic GEN_ARRAY2ARRAY family (cf. VALUES2ARRAY_2_LREAL).

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries IN_1, IN_2, IN_3, IN_4, IN_5, IN_6, IN_7, IN_8.

Event Outputs

- **CNF**: Confirms completion, carries OUT.

Data Inputs

- IN_1, IN_2, IN_3, IN_4, IN_5, IN_6, IN_7, IN_8 (BYTE): The 8 individual values (8-bit bit pattern) to be combined into the array.

Data Outputs

- **OUT** (BYTE, array size 8): OUT[i-1] corresponds to IN_i.

Functionality

On REQ, every input value IN_i is written to the corresponding element OUT[i-1] (IN_1 ⟶ OUT[0], ..., IN_8 ⟶ OUT[7]), then CNF is triggered.

Technical Features

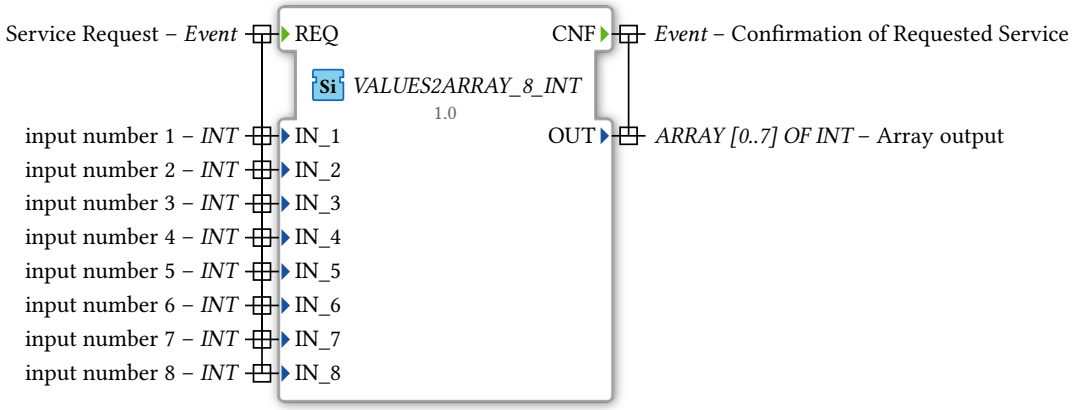
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY', the same C++ base as VALUES2ARRAY_2_LREAL and the other VALUES2ARRAY_* variants.
- **Fixed size 8**: For other array sizes of the same type see VALUES2ARRAY_2_BYTE, VALUES2ARRAY_4_BYTE, VALUES2ARRAY_16_BYTE, VALUES2ARRAY_32_BYTE.

State Overview

Stateless: every REQ immediately results in a full merge and CNF.

Application Scenarios

- **Building an array from individual values**: Several discrete BYTE variables need to be passed as an array to a downstream block that expects an array interface.
- **Interface adaptation** between variable-based and array-based block interfaces.



Comparison with similar function blocks

- **VALUES2ARRAY_2_LREAL**: the same generic implementation for data type LREAL.
- **ARRAY2VALUES_8_BYTE**: the reverse direction — splits an array into 8 individual values.

Conclusion

VALUES2ARRAY_8_BYTE provides a simple, generically implemented merge of 8 BYTE individual values into an array and is suitable for adapting variable-based to array-based interfaces.

2.11.1.27 VALUES2ARRAY_8_INT

• – ◦ • – ◦ • – ◦ •

Introduction

`VALUES2ARRAY_8_INT` combines 8 individual `INT` scalar variables `IN_1`...`IN_8` into a `INT` array of size 8. It is the reverse of `ARRAY2VALUES_8_INT` and belongs to the generic `GEN_ARRAY2ARRAY` family (cf. VALUES2ARRAY_2_LREAL).

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries `IN_1`, `IN_2`, `IN_3`, `IN_4`, `IN_5`, `IN_6`, `IN_7`, `IN_8`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- `IN_1`, `IN_2`, `IN_3`, `IN_4`, `IN_5`, `IN_6`, `IN_7`, `IN_8` (`INT`): The 8 individual values (16-bit signed integer) to be combined into the array.

Data Outputs

- **OUT** (`INT`, array size 8): `OUT[i-1]` corresponds to `IN_i`.

Functionality

On `REQ`, every input value `IN_i` is written to the corresponding element `OUT[i-1]` (`IN_1` ⟶ `OUT[0]`, ..., `IN_8` ⟶ `OUT[7]`), then `CNF` is triggered.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_ARRAY2ARRAY'`, the same C++ base as VALUES2ARRAY_2_LREAL and the other `VALUES2ARRAY_*` variants.
- **Fixed size 8**: For other array sizes of the same type see .

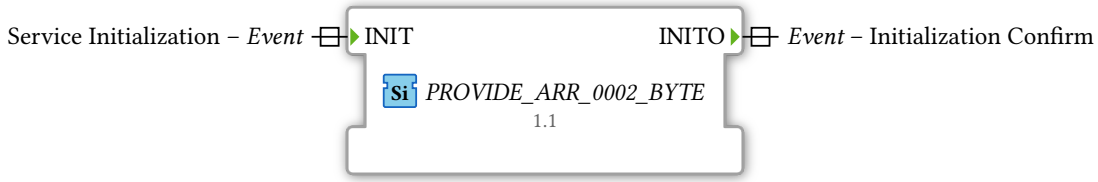
State Overview

Stateless: every `REQ` immediately results in a full merge and `CNF`.

Application Scenarios

- **Building an array from individual values**: Several discrete `INT` variables need to be passed as an array to a downstream block that expects an array interface.
- **Interface adaptation** between variable-based and array-based block interfaces.

Comparison with similar function blocks



- VALUES2ARRAY_2_LREAL: the same generic implementation for data type `LREAL`.
- **`ARRAY2VALUES_8_INT`**: the reverse direction — splits an array into 8 individual values.

Conclusion

`VALUES2ARRAY_8_INT` provides a simple, generically implemented merge of 8 `INT` individual values into an array and is suitable for adapting variable-based to array-based interfaces.

2.11.1.28 Providers

PROVIDE_ARR_0002_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0002_BYTE` provides a fixed-size `BYTE` array container of size 2 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 2, index 0…1): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

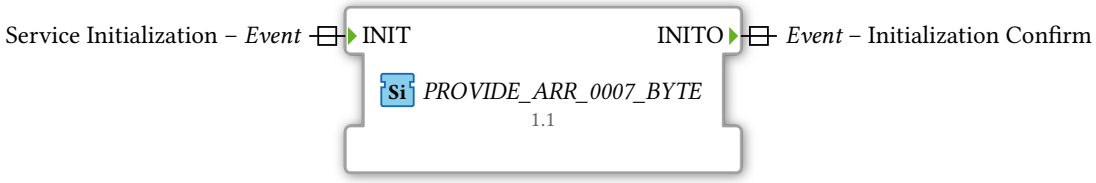
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 2**: Other sizes of the same or different data types: `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`, `PROVIDE_ARR_0016_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`, `PROVIDE_ARR_0016_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0002_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 2 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0007_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0007_BYTE` provides a fixed-size `BYTE` array container of size 7 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 7, index 0…6): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 7**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`, `PROVIDE_ARR_0016_BYTE`.

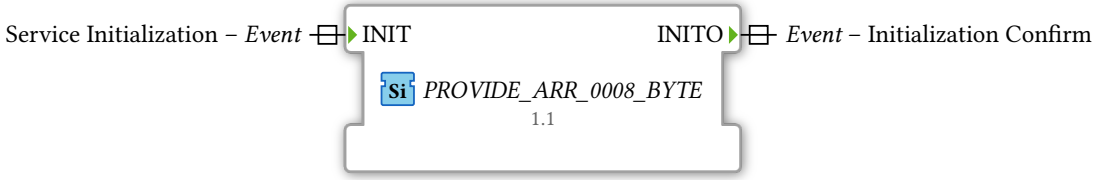
State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.

- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`, `PROVIDE_ARR_0016_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0007_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 7 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0008_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0008_BYTE` provides a fixed-size `BYTE` array container of size 8 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 8, index 0…7): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

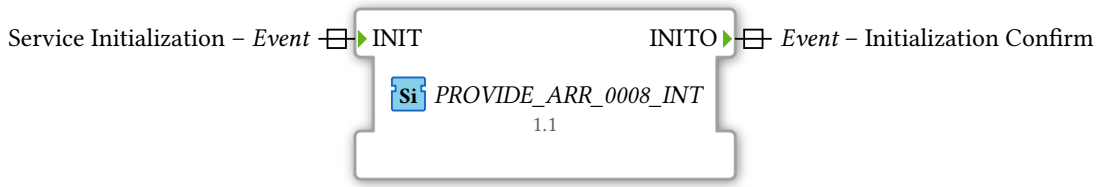
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 8**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0014_BYTE`, `PROVIDE_ARR_0016_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0014_BYTE`, `PROVIDE_ARR_0016_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_8_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0008_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 8 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0008_INT

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0008_INT` provides a fixed-size `INT` array container of size 8 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`INT`, array size 8, index 0…7): The array container (16-bit signed integer per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

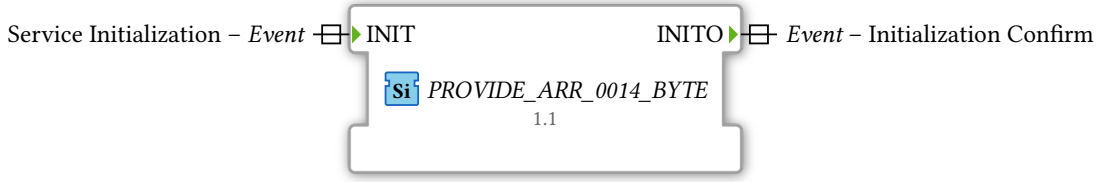
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 8**: Other sizes of the same or different data types: none.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `INT` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- none: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_8_INT`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0008_INT` provides a simple, design-time pre-fillable `INT` array container of fixed size 8 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0014_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0014_BYTE` provides a fixed-size `BYTE` array container of size 14 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 14, index 0…13): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

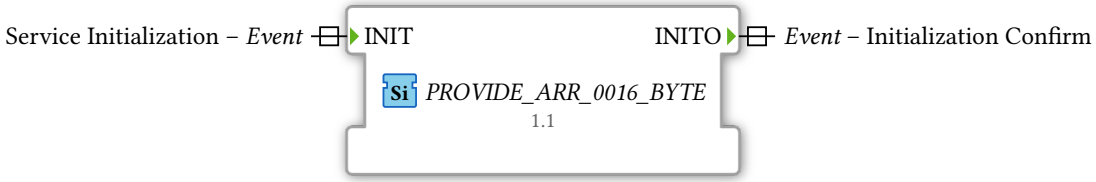
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 14**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0016_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0016_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0014_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 14 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0016_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0016_BYTE` provides a fixed-size `BYTE` array container of size 16 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 16, index 0…15): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.

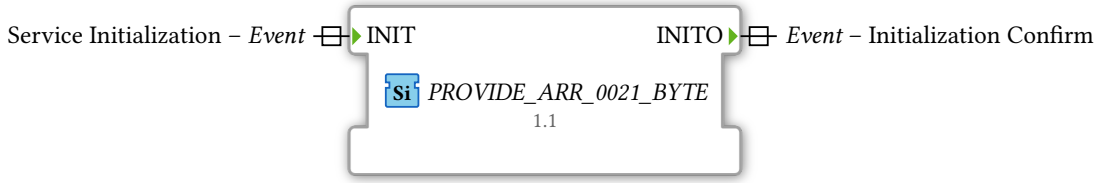
- **Fixed size 16**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0016_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 16 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0021_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0021_BYTE` provides a fixed-size `BYTE` array container of size 21 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 21, index 0…20): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.

- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 21**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.

Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0021_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 21 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0028_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0028_BYTE` provides a fixed-size `BYTE` array container of size 28 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 28, index 0…27): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 28**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.

Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0028_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 28 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0032_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0032_BYTE` provides a fixed-size `BYTE` array container of size 32 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 32, index 0...31): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs

no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 32**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.

Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0032_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 32 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0035_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0035_BYTE` provides a fixed-size `BYTE` array container of size 35 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 35, index 0…34): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

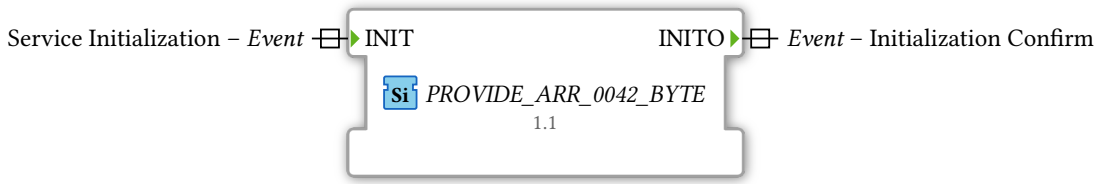
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 35**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0035_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 35 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0042_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0042_BYTE` provides a fixed-size `BYTE` array container of size 42 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (BYTE, array size 42, index 0...41): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for BYTE).

Functionality

On INIT, the block reads the InOut array D1 (which may already be pre-filled with start values at design time) and immediately confirms this via INITO, forwarding D1 unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other PROVIDE_ARR_* variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: D1 is a single InOut variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 42**: Other sizes of the same or different data types: PROVIDE_ARR_0002_BYTE, PROVIDE_ARR_0007_BYTE, PROVIDE_ARR_0008_BYTE, PROVIDE_ARR_0014_BYTE.

State Overview

Stateless: INIT reads D1 and confirms immediately via INITO, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined BYTE array for test setups without manually re-wiring the array in every application.

Comparison with similar function blocks

- PROVIDE_ARR_0002_BYTE, PROVIDE_ARR_0007_BYTE, PROVIDE_ARR_0008_BYTE, PROVIDE_ARR_0014_BYTE: the same generic implementation with a different array size or data type.
- **ARRAY2ARRAY_2_BYTE**: copies an already existing array instead of providing/pre-filling one.

Conclusion

PROVIDE_ARR_0042_BYTE provides a simple, design-time pre-fillable BYTE array container of fixed size 42 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0056_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

PROVIDE_ARR_0056_BYTE provides a fixed-size BYTE array container of size 56 as an InOut variable D1. It belongs to the generic GEN_INIT_ARR family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries D1.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 56, index 0…55): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

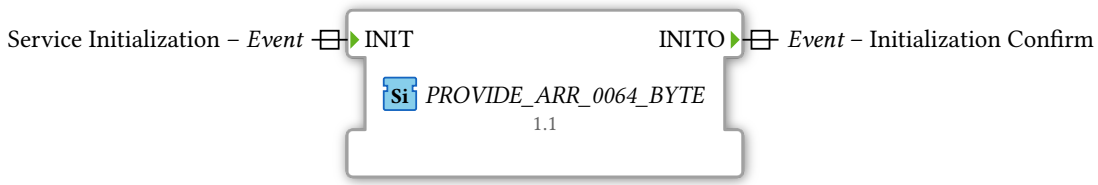
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 56**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0056_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 56 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0064_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0064_BYTE` provides a fixed-size `BYTE` array container of size 64 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 64, index 0…63): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

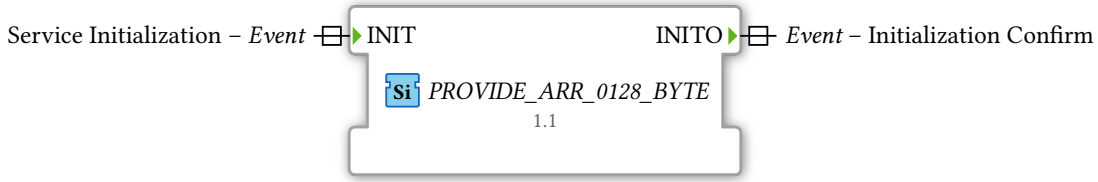
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 64**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0064_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 64 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0128_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0128_BYTE` provides a fixed-size `BYTE` array container of size 128 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ

in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 128, index 0…127): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

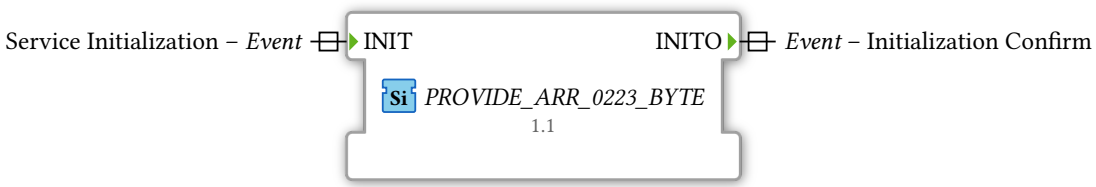
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 128**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0128_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 128 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0223_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0223_BYTE` provides a fixed-size `BYTE` array container of size 223 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 223, index 0…222): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

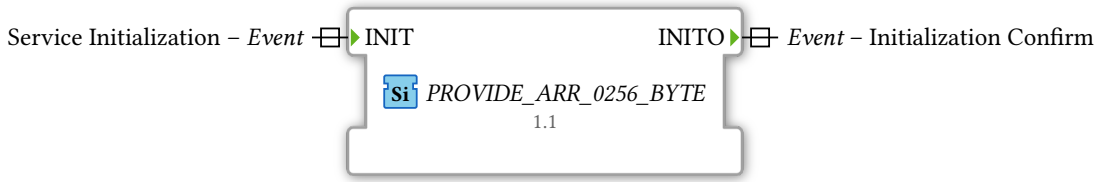
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 223**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_0223_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 223 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0256_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

PROVIDE_ARR_0256_BYTE provides a fixed-size BYTE array container of size 256 as an InOut variable D1. It belongs to the generic GEN_INIT_ARR family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries D1.

Event Outputs

- **INITO**: Confirms the initialization, carries D1.

In/Out Variables

- **D1** (BYTE, array size 256, index 0…255): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for BYTE).

Functionality

On INIT, the block reads the InOut array D1 (which may already be pre-filled with start values at design time) and immediately confirms this via INITO, forwarding D1 unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

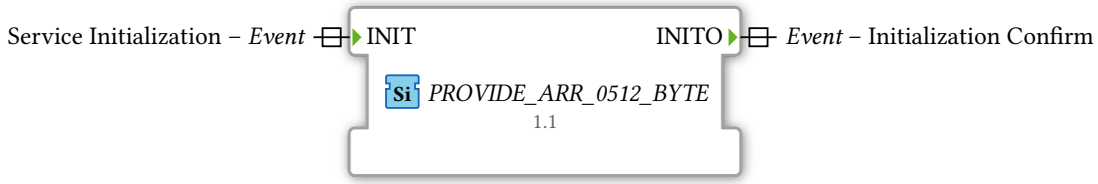
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other PROVIDE_ARR_* variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: D1 is a single InOut variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 256**: Other sizes of the same or different data types: PROVIDE_ARR_0002_BYTE, PROVIDE_ARR_0007_BYTE, PROVIDE_ARR_0008_BYTE, PROVIDE_ARR_0014_BYTE.

State Overview

Stateless: INIT reads D1 and confirms immediately via INITO, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined BYTE array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- PROVIDE_ARR_0002_BYTE, PROVIDE_ARR_0007_BYTE, PROVIDE_ARR_0008_BYTE, PROVIDE_ARR_0014_BYTE: the same generic implementation with a different array size or data type.
- **ARRAY2ARRAY_2_BYTE**: copies an already existing array instead of providing/pre-filling one.

Conclusion

PROVIDE_ARR_0256_BYTE provides a simple, design-time pre-fillable BYTE array container of fixed size 256 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_0512_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_0512_BYTE` provides a fixed-size `BYTE` array container of size 512 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 512, index 0…511): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

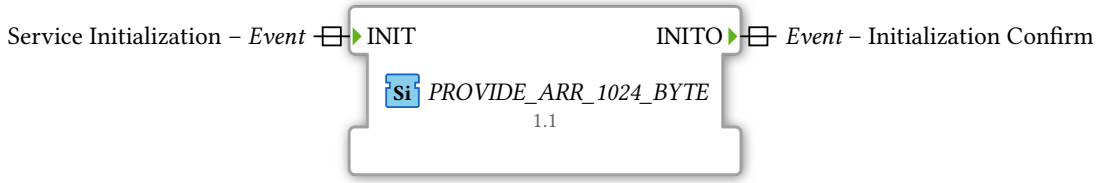
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 512**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

PROVIDE_ARR_0512_BYTE provides a simple, design-time pre-fillable BYTE array container of fixed size 512 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_1024_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

PROVIDE_ARR_1024_BYTE provides a fixed-size BYTE array container of size 1024 as an InOut variable D1. It belongs to the generic GEN_INIT_ARR family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries D1.

Event Outputs

- **INITO**: Confirms the initialization, carries D1.

In/Out Variables

- **D1** (BYTE, array size 1024, index 0…1023): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. [16#01, 16#00, ...] for BYTE).

Functionality

On INIT, the block reads the InOut array D1 (which may already be pre-filled with start values at design time) and immediately confirms this via INITO, forwarding D1 unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR', the same C++ base as all other PROVIDE_ARR_* variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: D1 is a single InOut variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 1024**: Other sizes of the same or different data types: PROVIDE_ARR_0002_BYTE, PROVIDE_ARR_0007_BYTE, PROVIDE_ARR_0008_BYTE, PROVIDE_ARR_0014_BYTE.

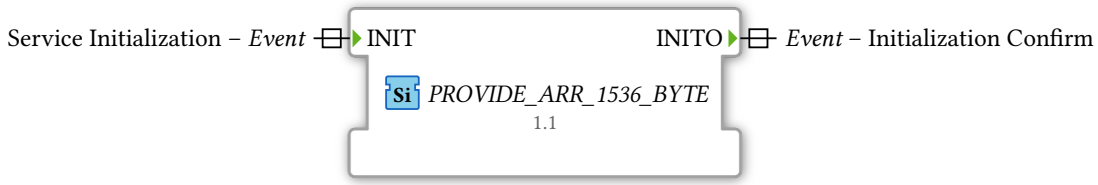
State Overview

Stateless: INIT reads D1 and confirms immediately via INITO, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined BYTE array for test setups without manually re-wiring the array in every application.

Comparison with similar function blocks



- PROVIDE_ARR_0002_BYTE, PROVIDE_ARR_0007_BYTE, PROVIDE_ARR_0008_BYTE, PROVIDE_ARR_0014_BYTE: the same generic implementation with a different array size or data type.

- **ARRAY2ARRAY_2_BYTE**: copies an already existing array instead of providing/pre-filling one.

Conclusion

PROVIDE_ARR_1024_BYTE provides a simple, design-time pre-fillable BYTE array container of fixed size 1024 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_1536_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

PROVIDE_ARR_1536_BYTE provides a fixed-size BYTE array container of size 1536 as an InOut variable D1. It belongs to the generic GEN_INIT_ARR family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries D1.

Event Outputs

- **INITO**: Confirms the initialization, carries D1.

In/Out Variables

- **D1** (BYTE, array size 1536, index 0…1535): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for BYTE).

Functionality

On INIT, the block reads the InOut array D1 (which may already be pre-filled with start values at design time) and immediately confirms this via INITO, forwarding D1 unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

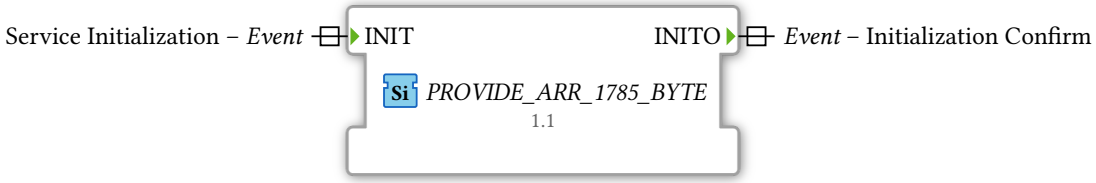
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other PROVIDE_ARR_* variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: D1 is a single InOut variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 1536**: Other sizes of the same or different data types: PROVIDE_ARR_0002_BYTE, PROVIDE_ARR_0007_BYTE, PROVIDE_ARR_0008_BYTE, PROVIDE_ARR_0014_BYTE.

State Overview

Stateless: INIT reads D1 and confirms immediately via INITO, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.
- **Test data generation**: Providing a predefined BYTE array for test setups without manually re-wiring the array in every application.



Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_1536_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 1536 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

PROVIDE_ARR_1785_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

`PROVIDE_ARR_1785_BYTE` provides a fixed-size `BYTE` array container of size 1785 as an `InOut` variable `D1`. It belongs to the generic `GEN_INIT_ARR` family: a series of identically structured blocks that only differ in array size and data type, used to make an array that can be pre-filled with start values at design time available inside a 4diac application.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `D1`.

Event Outputs

- **INITO**: Confirms the initialization, carries `D1`.

In/Out Variables

- **D1** (`BYTE`, array size 1785, index 0…1784): The array container (8-bit bit pattern per element). Can be pre-filled with start values in the FB instance editor (e.g. `[16#01, 16#00, ...]` for `BYTE`).

Functionality

On `INIT`, the block reads the `InOut` array `D1` (which may already be pre-filled with start values at design time) and immediately confirms this via `INITO`, forwarding `D1` unchanged. The block performs no computation of its own — it acts as a declarative container whose content is set via the FB instance parameterization.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_INIT_ARR'`, the same C++ base as all other `PROVIDE_ARR_*` variants; array size and data type are fixed per instantiation via the type definition.
- **InOut instead of separate input/output**: `D1` is a single `InOut` variable — pre-filling and provisioning happen through the same variable, there is no separate copy.
- **Fixed size 1785**: Other sizes of the same or different data types: `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`.

State Overview

Stateless: `INIT` reads `D1` and confirms immediately via `INITO`, without modifying the content.

Application Scenarios

- **Configuration arrays**: Providing fixed, pre-filled tables (e.g. calibration values, lookup tables, protocol header bytes) as a reusable block that can be parameterized at design time.

- **Test data generation**: Providing a predefined `BYTE` array for test setups without manually re-wiring the array in every application.

Comparison with similar function blocks

- `PROVIDE_ARR_0002_BYTE`, `PROVIDE_ARR_0007_BYTE`, `PROVIDE_ARR_0008_BYTE`, `PROVIDE_ARR_0014_BYTE`: the same generic implementation with a different array size or data type.
- **`ARRAY2ARRAY_2_BYTE`**: copies an already existing array instead of providing/pre-filling one.

Conclusion

`PROVIDE_ARR_1785_BYTE` provides a simple, design-time pre-fillable `BYTE` array container of fixed size 1785 and is suitable for configuration and test-data arrays intended for reuse across 4diac applications.

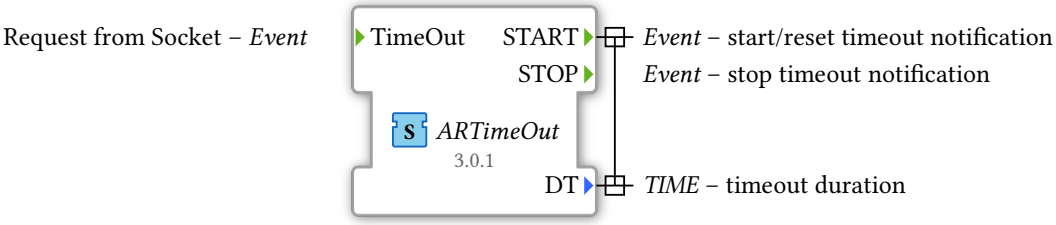
2.11.3.2 ARTimeOut

Plug (adapter output)



Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

IEC 61499 is an international standard for modeling distributed industrial control systems. Within this standard, adapter types are an important component for defining reusable interfaces between function blocks. The **ARTimeOut** adapter (Adapter for Resettable Timeout) is an example of such an adapter, providing an interface for a resettable timeout service.

Structure of the ARTimeOut Adapter

The ARTimeOut adapter is specified as **AdapterType** in IEC 61499 and defines an interface for communication between a socket and a plug.

Interface

The ARTimeOut adapter interface consists of:

- **Input Events**:
- **TimeOut**: This event is triggered by the SOCKET to indicate that the timeout has expired.
- **Output Events**:
- **START**: This event is triggered by the PLUG to start or reset the timeout. It is linked to the output variable **DT**, which defines the timeout duration.
- **STOP**: This event is triggered by the PLUG to stop the timeout.
- **Output Variable**:
- **DT (Duration Time)**: A time variable (TIME) that specifies the duration of the timeout.

Service Behavior

The ARTimeOut adapter offers two service sequences:

1. **Timeout**:

- The PLUG sends a **START** event with a duration of **DT** to start the timeout.
- When the timeout expires, the SOCKET sends a **TimeOut** event back to the PLUG.

1. **NormalOperation**:

- The PLUG sends a **START** event with a duration of **DT** to start the timeout.
- The PLUG can send a **STOP** event to end the timeout prematurely.

ARTimeOut Adapter Behavior

The ARTimeOut adapter enables the control of a timeout mechanism with the following functions:

1. **Start/Reset Timeout**:

- The **START** event starts or resets the timeout with the specified duration **DT**.

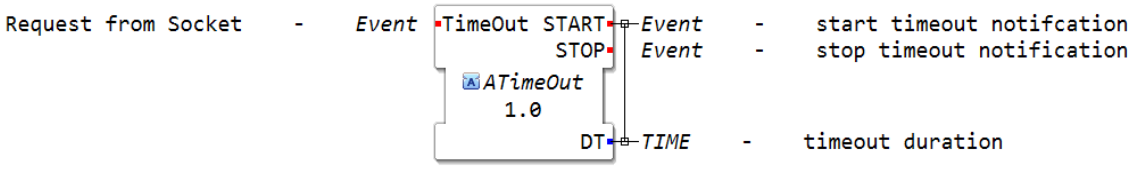
1. **Stop Timeout**:

- The **STOP** event terminates the timeout prematurely.

1. **Timeout Expiration**:

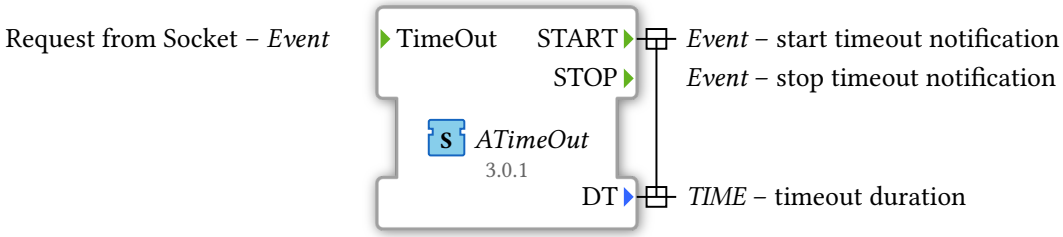
- When the timeout expires, the **TimeOut** event is triggered to notify the PLUG.

Application Examples



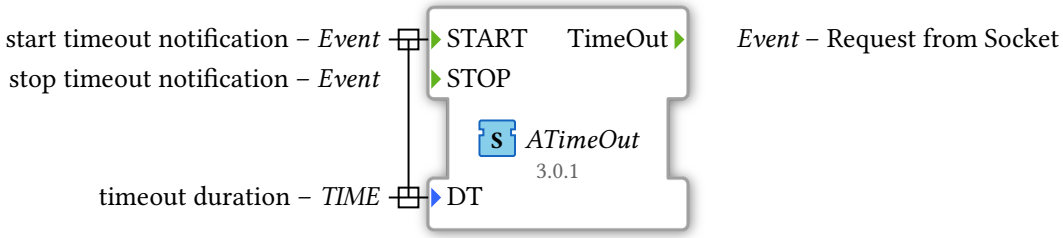
The ARTimeOut adapter can be used in various industrial control applications, particularly in scenarios requiring a reliable and resettable timeout mechanism. Examples include:

- **Network Communication**: Monitoring response timeouts in distributed systems.
- **Machine Control**: Timeouts for command execution to detect hung processes.
- **Safety Systems**: Monitoring sensors to detect malfunctions when no updates are received.



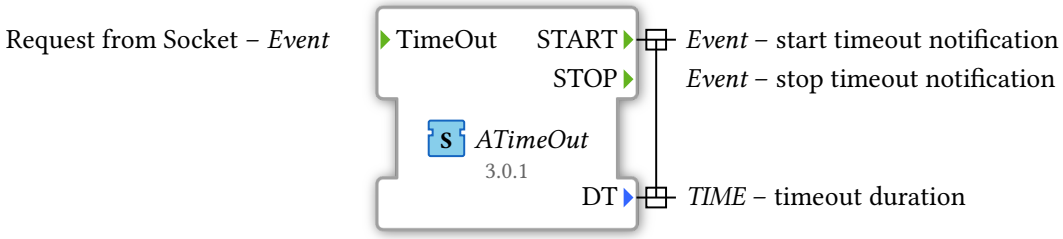
Conclusion

The ARTimeOut adapter is a useful tool within IEC 61499 to provide a standardized interface for resettable timeout services. Its clear separation between SOCKET and PLUG, along with defined service sequences, makes it ideal for integration into distributed control systems. The ability to start, stop, and notify when the timeout expires makes it a flexible solution for a wide range of industrial applications.



2.11.3.3 ATimeOut

Plug (adapter output)



Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

The **ATimeOut** adapter is a standardized interface (AdapterType) according to IEC 61499 for implementing timeout services. It defines the communication between a service user (PLUG) and a time service provider (SOCKET). Unlike `ARTimeOut`, this adapter is designed for simple, non-retriggerable timeouts.

Structure of the ATimeOut Adapter

The ATimeOut adapter defines a clear separation of responsibilities between the control logic (Plug) and the timer (Socket).

Interface

The interface is defined from the perspective of the **plug**:

- **Input Events (received from the socket)**:
- **TimeOut**: Signals that the specified time has elapsed.
- **Output Events (sent to the socket)**:
- **START**: Initiates the timeout process. This event is associated with the variable **DT**.
- **STOP**: Terminates an ongoing timeout process.
- **Output Variables (sent to the socket)**:
- **DT (Duration Time)**: Defines the duration of the timeout (data type: TIME).

Behavior and Service Sequences

The adapter supports two basic processes:

1. **Timeout Expiration**:

- The plug sends `START` with a value for `DT`.
- The socket processes the time and sends back `TimeOut` after the time expires.

1. **Premature Termination**:

- The plug sends `START`.
- Before the time expires, the plug sends `STOP`. The socket terminates the timer; no `TimeOut` event occurs.

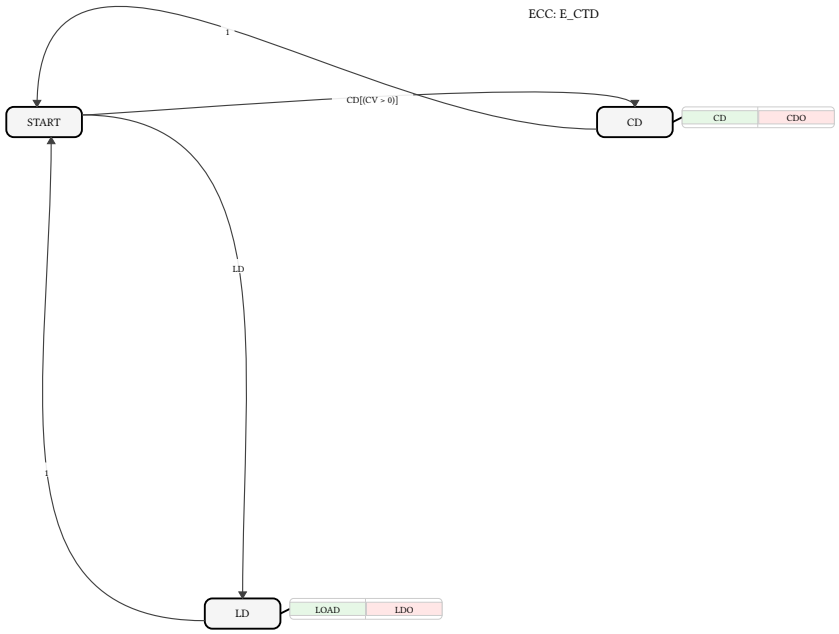
Technical Features

- **Non-retriggerable**: A repeated `START` during an ongoing timeout is ignored in the standard implementation (`E_TimeOut`).
- **Adapter Concept**: Enables clean encapsulation of the timing logic and simplifies the component network by reducing the number of connection lines.

Application Examples

- **Monitoring Response Times**: Waiting for an acknowledgment (e.g., from a communication partner) within a fixed time window.
- **Process Monitoring**: Ensuring that a mechanical process is completed within the expected time.

⚖️ Comparison with ARTimeOut

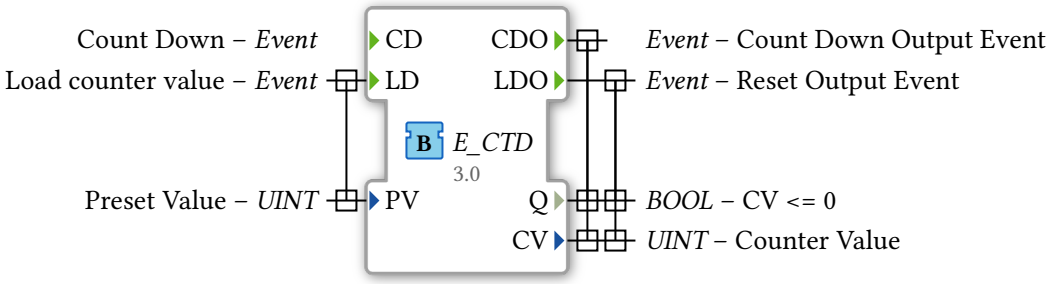


Feature	ATimeOut (this)	ARTimeOut
Type	Adapter	Adapter
Retriggerable	No	Yes
Event START	Start Timer	Start/Reset Timer

Conclusion

The ATimeOut adapter provides a robust and simple interface for time-critical monitoring tasks in distributed control systems. It forms the basis for the function block `E_TimeOut`.

2.11.3.4 E_CTD



Podcast

- E_CTD: Event-Driven Down Counter according to IEC 61499

Introduction

The **E_CTD** (Event-Driven Down Counter) is an event-driven down counter according to the IEC 61499 standard. This function block is used in industrial control systems to implement counting operations that are triggered by events.

Structure of the E_CTD Function Block

Interface

Event Inputs:

- **CD (Count Down):** Triggers a counting step that decrements the counter value.
- **LD (Load):** Loads the initial value `PV` into the counter.

Event Outputs:

- **CDO (Count Down Output):** Confirms a counting step. Triggered after each `CD` event, as long as the counter value was greater than 0.
- **Related Data:** `Q`, `CV`
- **LDO (Load Output):** Confirms the successful loading of a new counter value.
- **Related Data**: `Q`, `CV`

Input Variables:

- **PV (Preset Value):** The initial value loaded during a load event (Data Type: `UINT`).

Output Variables:

- **Q (Status):** Output flag set when the counter reaches 0 (Data Type: `TRUE`).
- **CV (Counter Value):** The current counter value (Data Type: `UINT`).

Behavior of the E_CTD Block

1. **Initialization/Loading:**

- When an **LD** event occurs, the counter value `CV` is set to the value of **PV**.
- The output flag `Q` is updated based on the condition `CV = 0`.
- The **LDO** event is triggered and outputs the new counter value `CV` and the flag `Q`.

1. **Countdown:**

- With each **CD** event, the counter value **CV** is decremented by 1 if it is greater than 0.
- The output flag `Q` is then updated based on the new condition `CV = 0`.
- The **CDO** event is triggered and outputs the current counter value `CV` and the flag `Q`.

1. **Counter Reload:**

- A subsequent **LD** event resets **CV** back to **PV** at any time and triggers **LDO**.

Technical Features

- **Event-driven:** The function block operates exclusively based on events and does not require cyclic calls.
- **Flexible Initialization:** The initial value **PV** can be changed at any time by an **LD** event.

Application Examples

- **Production Lines:** Counting units produced.
- **Packaging Machines:** Control of filling processes.
- **Energy Management:** Monitoring of consumption cycles.

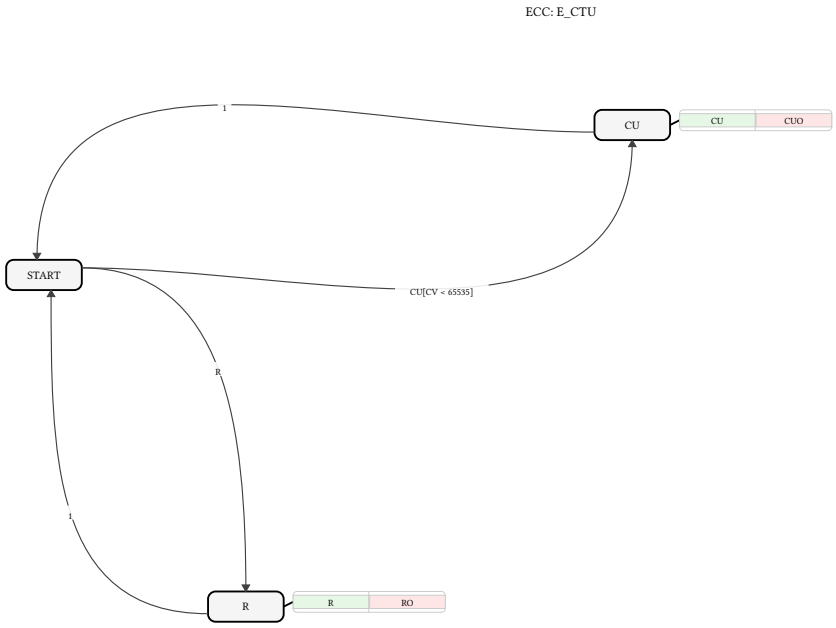
⚖️ Comparison with similar modules

Feature	E_CTD	E_CTU (Up Counter)	E_CTUD (Up/Down Counter)
Counting Direction	Down	Up	Both
Event-Driven	Yes	Yes	Yes
Reset Function	LD (Reload)	R (Reset)	R (Reset)

🛠️ Related Exercises

- Exercise_081

Conclusion



The **E_CTD** block is an essential element in IEC 61499, providing a reliable and flexible counting function for industrial controllers. Its event-driven nature makes it particularly suitable for distributed systems where cyclic polling is impractical. Its clear interface and intuitive behavior make it easy to integrate into existing control concepts.

---

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_CTU` (Event-Driven Up Counter) is an event-driven up counter according to the IEC 61499 standard. Its function is to increment an internal counter value with each incoming counting event and compare this value to a predefined limit. The block can be reset at any time.

Interface Structure

Event Inputs

- **CU (Count Up)**: Triggers a counting step that increments the counter value `CV` by 1.
- **Related Data**: `PV`
- **R (Reset)**: Resets the counter value `CV` to 0.

Event Outputs

- **CUO (Count Up Output)**: Confirms a count increment. Triggered after each `CU` event.
- **Related Data**: `Q`, `CV`
- **RO (Reset Output)**: Confirms the counter reset.
- **Related Data**: `Q`, `CV`

Data Inputs

- **PV (Preset Value)**: The threshold value (data type: `UINT`). This value is compared to the counter reading on every `CU` event.

Data Outputs

- **Q (Status)**: Output flag that is set when the counter reading reaches or exceeds the threshold value (data type: `PV`) (data type: `BOOL`).
- **CV (Counter Value)**: The current counter value (data type: `UINT`).

Functionality

The `E_CTU` block has two main functions: counting and resetting.

1. **Counting (CU)**: When a `CU` event occurs and the internal counter value `CV` has not yet reached the maximum value for `UINT` (65535), `CV` is incremented by 1. Then, `CV` is compared to the limit value at the `PV` input. If `CV >= PV` is the current value, the output `Q` is set to `TRUE`; otherwise, it is set to `FALSE`. After the counting process, the event `CUO` is triggered, which outputs the current counter value `CV` and the status flag `Q`.

If `CV >= PV` is the current value, the output `Q` is set to `TRUE`; otherwise, it is set to `FALSE`. 2. **Reset (R)**: When a `R` event occurs, the counter value `CV` is immediately reset to 0 and the status flag `Q` is set to `FALSE`. Subsequently, the `RO` event is triggered, which outputs the reset values `CV` and `Q`.

Technical Features

- **Event-driven**: This function block operates exclusively based on events (`CU`, `R`).
- **Overflow Protection**: The counter stops when the maximum value for `UINT` (65535) is reached to prevent an overflow.
- **PV at Each Count Step**: The limit value `PV` is linked to the `CU` event, meaning it can potentially be changed at each count step.

Application Examples

- **Piece Counter**: Counting produced parts on a conveyor belt. When a target quantity (`PV`) is reached, `Q` becomes `TRUE`.
- **Event Counting**: Recording the frequency of events, such as the activation of a switch.
- **Cycle Counter**: Counts cycles in a machine to signal maintenance intervals.

⚖️ Comparison with similar function blocks

Feature	E_CTU (Up Counter)	E_CTD (Down Counter)	E_CTUD (Up/Down Counter)
Counting Direction	Up	Down	Both
Event-Driven	Yes	Yes	Yes
Reset Function	R (Reset to 0)	LD (Set to PV)	R (Reset to 0)

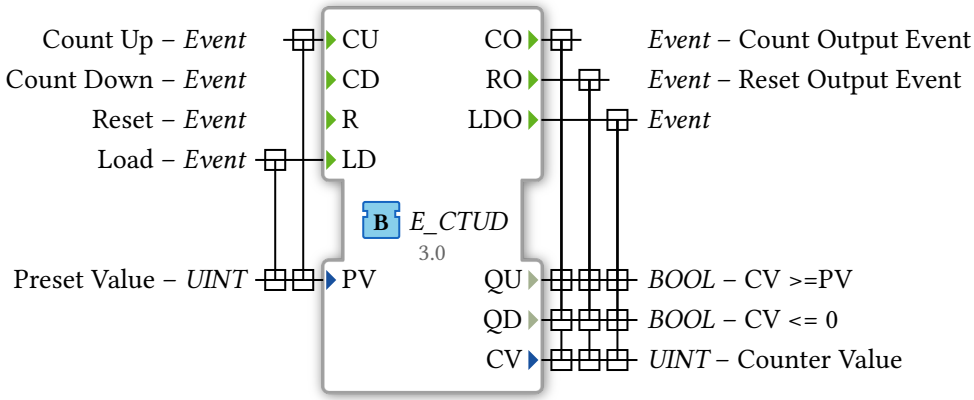
2.11.3.6 E_CTUD

🎧 Podcast



- E_CTUD: Bidirectional Counter in IEC 61499 Systems

• – ◦ • – ◦ • – ◦

The `E_CTUD` (Event-Driven Up-Down Counter) is an event-driven up- and down-counter compliant with the IEC 61499 standard. It can increment, decrement, reset, or load a counter value based on separate events. This makes it a flexible and powerful component for a wide variety of counting applications.

- **CU (Count Up)**: Triggers an up count.
- **Linked Data**: `PV`
- **CD (Count Down)**: Triggers a down count.
- **R (Reset)**: Resets the counter to 0.
- **LD (Load)**: Loads a new value into the counter.
- **Linked Data**: `PV`

- **CO (Count Output)**: Acknowledges a counting operation (`CU` or `CD`).
- **Linked Data**: `QU`, `CV`, `QD`
- **RO (Reset Output)**: Confirms that the counter has been reset.
- **Linked Data**: `QU`, `CV`, `QD`
- **LDO (Load Output)**: Confirms that a new counter value has been loaded.
- **Linked Data**: `QU`, `CV`, `QD`
- **PV (Preset Value)**: The threshold value for `QU` or the value to be loaded for `LD` (Data type: `UINT`).
- **QU (Status Up)**: Output flag that is set when `TRUE` (Data type: `CV >= PV`) is reached.
- **CV (Counter Value)**: The current counter value (data type: `UINT`).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

The `E_CTUD` counter responds to four different events:

1. **Count Up (CU)**: When a `CU` event occurs and `CV` is less than the maximum value (65535), `CV` is incremented by 1. The `CO` event is then triggered.
2. **Count Down (CD)**: If a `CD` event occurs and `CV` is greater than 0, `CV` is decremented by 1. The `CO` event is then triggered.
3. **Reset (R)**: If a `R` event occurs, `CV` is set to 0. The `RO` event is then triggered.
4. **Load (LD)**: When a `LD` event occurs, `CV` is set to the value of `PV`. Then, the `LDO` event is triggered.

After each of these actions, the status flags `QU` and `QD` are updated based on the new value of `CV` (`QU = (CV >= PV)` and `QD = (CV == 0)`). The respective output events (`CO`, `RO`, `LDO`) then output the current counter value (`CV`) and the two status flags.

- **Bidirectional Counting**: The function block supports both up and down counting in a single block.
- **Comprehensive Control**: In addition to counting, it also offers functions for explicit loading and resetting.
- **Two Status Outputs**: `QU` signals when the upper limit is reached, and `QD` signals when the lower limit (0) is reached.
- **Overflow and Underflow Protection**: Counting operations are only performed within the valid limits (0 to 65535).
- **Position Detection**: Counting incremental encoder steps in both directions.
- **Fill Level Control**: Detecting inflows and outflows in a tank.
- **Storage Location Management**: Counting incoming and outgoing pallets.

Feature	E_CTUD (Up/Down)	E_CTU (Up)	E_CTD (Down)
Counting Direction	Up & Down	Up Only	Down Only
Reset (to 0)	Yes (`R`)	Yes (`R`)	No
Load (to PV)	Yes (`LD`)	No	Yes (`LD`)
Top Status	`QU` (`CV >= PV`)	`Q` (`CV >= PV`)	No
Bottom Status	`QD` (`CV = 0`)	No	`Q` (`CV = 0`)

- Exercise_082

The `E_CTUD` is a universal counter module that combines and extends the functionality of a simple up and down counter. With its four control events (`CU`, `CD`, `R`, `LD`) and two status outputs (`QU`, `QD`), it offers maximum flexibility for complex counting and monitoring tasks in industrial automation.

2.11.3.7 E_CTUD_UDINT

• – ○ • – ○ • – ○ •

The `E_CTUD_UDINT` is a variant of the `E_CTUD` counter that uses the `UDINT` data type (Unsigned Double Integer, 32-bit). This event-driven up and down counter can cover a very large counter range. It can increment, decrement, reset, or load a counter value with a predefined value based on separate events.

- **CU (Count Up)**: Triggers an up count.
- **Related Data**: `PV`
- **CD (Count Down)**: Triggers a countdown.
- **R (Reset)**: Resets the counter to 0.
- **LD (Load)**: Loads a new value into the counter.
- **Related Data**: `PV`
- **CO (Count Output)**: Acknowledges a counting operation (`CU` or `CD`).
- **Linked Data**: `QU`, `CV`, `QD`
- **RO (Reset Output)**: Confirms that the counter has been reset.
- **Linked Data**: `QU`, `CV`, `QD`
- **LDO (Load Output)**: Confirms that a new counter value has been loaded.
- **Linked Data**: `QU`, `CV`, `QD`
- **PV (Preset Value)**: The threshold value for `QU` or the value to be loaded for `LD` (Data type: `UDINT`).
- **QU (Status Up)**: Output flag that is set when `TRUE` (Data type: `CV >= PV`) (Data type: `BOOL`) is reached.
- **CV (Counter Value)**: The current counter value (data type: `UDINT`).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

The `E_CTUD_UDINT` responds to four different events:

1. **Count Up (CU)**: When a `CU` event occurs and `CV` is less than the maximum value (4,294,967,295), `CV` is incremented by 1. The `CO` event is then triggered.
2. **Count Down (CD)**: If a `CD` event occurs and `CV` is greater than 0, `CV` is decremented by 1. The `CO` event is then triggered.
3. **Reset (R)**: If a `R` event occurs, `CV` is set to 0. The `RO` event is then triggered.
4. **Load (LD)**: When a `LD` event occurs, `CV` is set to the value of `PV`. Then, the `LDO` event is triggered.

After each of these actions, the status flags `QU` and `QD` are updated based on the new value of `CV` (`QU = (CV >= PV)` and `QD = (CV == 0)`). The respective output events (`CO`, `RO`, `LDO`) then output the current counter value (`CV`) and the two status flags.

- **Large Counting Range**: By using `UDINT`, the counter can take values from 0 to 4,294,967,295.
- **Bidirectional Counting**: The function block supports both up and down counting in a single block.
- **Comprehensive Control**: In addition to counting, it also offers functions for explicit loading and resetting.
- **Overflow and Underflow Protection**: Counting operations are only performed within the valid `UDINT` limits (0 to 4,294,967,295).
- **Total Counter**: Recording total production quantities or operating hours over the entire lifespan of a machine, where a 16-bit counter is insufficient.
- **Energy Measurement**: Counting pulses from an energy meter (e.g., Wh or kWh) over extended periods.
- **High-Resolution Position Detection**: Counting a very large number of increments from a high-resolution encoder.
- Exercise_009
- Exercise_034b
- Exercise_083

The `E_CTUD_UDINT` is the `UDINT` variant of the universal `E_CTUD` counter. It offers the same functionality, but with a significantly larger counting range (32 bits). This makes it the ideal choice for applications where the counter value can exceed the limit of a 16-bit `UINT` counter. Its robust, event-driven nature and comprehensive control and status functions are retained.

2.11.3.8 E_CYCLE

Introduction

The `E_CYCLE` is a function block according to IEC 61499 that serves as a periodic event generator. After starting, the block repeatedly fires an output event (`EO`) at a defined time interval (`DT`). It is the fundamental tool for creating clocks and cyclic sequences.

Interface Structure

Event Inputs

- **START**: Starts the periodic generation of `EO` events.
- **Related Data**: `DT`
- **STOP**: Stops the generation of `EO` events.

Event Outputs

- **EO (Event Output)**: The cyclically triggered output event.

Data Inputs

- **DT (Delay Time)**: The time interval between individual `EO` events (data type: `TIME`).

Functionality

The functionality of `E_CYCLE` is internally based on a feedback loop with a `E_DELAY` block.

1. **Starting the Cycle**:

- A `START` event at the input triggers the internal timer with the duration specified at the `DT` input.
- After this time `DT` has elapsed, the first `EO` event is triggered at the output.

1. **Cyclic Operation**:

- The triggered `EO` event is immediately fed back internally to the timer's start input.
- This immediately restarts the timer, and after another time interval `DT`, the next `EO` event is triggered.
- This process repeats continuously, generating a periodic sequence of `EO` events at intervals of `DT`.

1. **Stopping the Cycle**:

- A `STOP` event at the input breaks the internal feedback loop.
- The timer stops, and no further `EO` events are generated until another `START` event occurs.

Technical Features

- **Event Generator**: The module generates a chain of events, not a continuous state (such as a square wave). To implement blinking, the `EO` event would, for example, trigger a `E_T_FF` (toggle flip-flop).
- **Precise timing control**: Enables precise definition of the cycle time via the `TIME` data type.
- **Event-driven architecture**: All control (start/stop) is purely event-based.

Application scenarios

- **Clock generator**: Periodically triggers other function blocks at a fixed clock rate (e.g., for sampling or calculations).
- **Blinker/warning lights**: As a pulse generator for a downstream flip-flop to produce a visual signal.
- **Watchdog**: Periodically sends a "life sign." If the signal is absent, an error can be detected.
- **Test Automation**: Generation of periodic stimuli for systems under test.

⚖️ **Comparison with similar components**

Feature	E_CYCLE	E_DELAY	E_PULSE (hypothetical)
Function	Periodic Clock	Single Delay	Single Pulse of Fixed Duration
Repetition	Continuous	Once per `START` event	Once per `REQ` event
Control	START/STOP	START/STOP	REQ

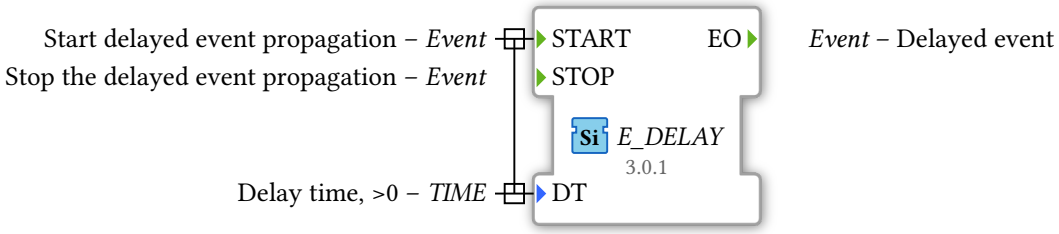
Conclusion

The `E_CYCLE` function block is an essential tool for all applications requiring periodic or cyclic logic. It easily implements a clock generator whose frequency can be precisely set via the `DT` parameter. Its purely event-based behavior makes it an efficient and fundamental component in the IEC 61499 system architecture.



2.11.3.9 E_DELAY

🎧 Podcast

- E_DELAY in IEC 61499: Precise, Cancelable Time Delay in Control Systems

Introduction

The **E_DELAY** is a key functional block in the IEC 61499 standard for industrial control systems. As an event-driven timer, it enables the delayed triggering of events with a configurable duration and the option to cancel. This block is widely used in time-controlled automation processes.

Structure of the E_DELAY Block

Interface

Event Inputs:

- `START`: Initializes the delay
- `STOP`: Terminates the active delay

Event Outputs:

- `EO` (Event Output): Triggered after the delay has elapsed

Data Inputs:

- `DT` (Delay Time): TIME value for the delay duration

Functionality

1. **Delay Start:**

- On the `START` event, the timer starts with the set time `DT`
- During runtime, further `START` events ignored

1. **Delay Termination:**

- The `STOP` event immediately terminates the active delay
- No `EO` event is generated

1. **Delay Completion:**

- The `EO` event is triggered exactly after `DT`
- If DT ≤ T#0s, immediate triggering occurs without delay

Technical Features

✓ **Precise Time Control** (millisecond-accurate delay)
✓ **Termination Function** for flexible process control
✓ **Event-driven** (no cyclical call required)
✓ **Real-time capable** for industrial applications

Application Scenarios

- **Machine Safety**: Delayed shutdown of systems
- **Process Control**: Time-controlled process steps
- **Alarm Management**: Delayed fault messages
- **Test Automation**: Time-controlled test sequences

⚖️ Comparison with similar function blocks

Feature	E_DELAY	E_CYCLE	E_PULSE
Operating principle	Single delay	Continuous cycle	Single pulse
Abort option	Yes	Yes	No

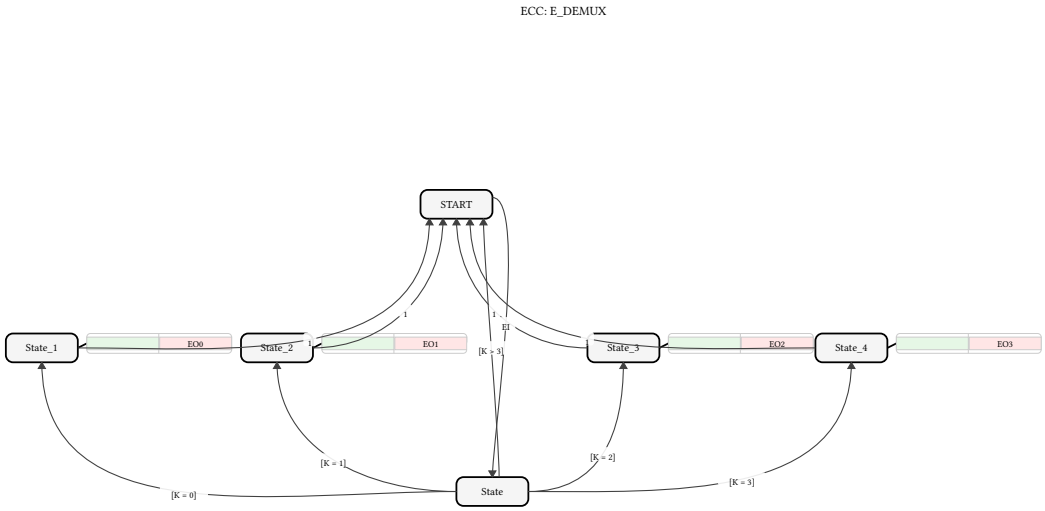
Conclusion

The E_DELAY function block is an indispensable tool for time-controlled automation processes. Its main advantages are:

- Precise and flexible timing control
- Immediate response to control events
- Robust integration into distributed control architectures

Thanks to its reliable operation and compliance with IEC 61499, it is ideally suited for safety applications and complex process control in industrial environments. Its cancel function makes it particularly valuable for flexible production scenarios.



2.11.3.10 E_DEMUX

Introduction

The `E_DEMUX` (Event Demultiplexer) is a function block according to IEC 61499 that forwards a single input event (`EI`) to one of several outputs. The selection of the specific output is determined by the value of an input variable (`K`). This version of the block is a 1-to-4 demultiplexer.

Interface Structure

Event Inputs

- **EI (Event Input)**: The input event to be distributed.
- **Related Data**: `K`

Event Outputs

- **EO0**: Triggered when `EI` and `K = 0` arrive.
- **EO1**: Triggered when `EI` and `K = 1` arrive.
- **EO2**: Triggered when `EI` and `K = 2` arrive.
- **EO3**: Triggered when `EI` and `K = 3` arrive.

Data Inputs

- **K**: The selection index that determines which output is triggered (data type: `UINT`).

Functionality

1. **Event Reception**: The function block waits for an event at input `EI`.
2. **Selection**: When the `EI` event arrives, the value of the data variable `K` is evaluated.
3. **Forwarding**:

- If `K` = 0, the event is forwarded to `EO0`.
- If `K` = 1, the event is forwarded to `EO1`.
- If `K` = 2, the event is forwarded to `EO2`.
- If `K` = 3, the event is forwarded to `EO3`.

1. **Invalid Index**: If the value of `K` is outside the valid range [0, 3], no output event is triggered, and the `EI` event is discarded.

The input event is therefore always forwarded exclusively to exactly one output, provided the index `K` is valid.

Technical Features

- **1-to-4 Distribution**: This function block distributes an event to four possible outputs.
- **Index-driven**: The logic is based on a numerical index.
- **Deterministic behavior**: The routing is clearly and unambiguously defined, ensuring reliable control.

Application scenarios

- **State machines**: Selection of the next state transition based on a calculated index.
- **Mode switching**: Activation of different plant components depending on the selected operating mode (`K` = mode number).
- **Sequencers/Step chains**: Activation of the next step in a chain.
- **Error routing**: Routing of a general error event to a specific handler based on an error code (`K` = error code).

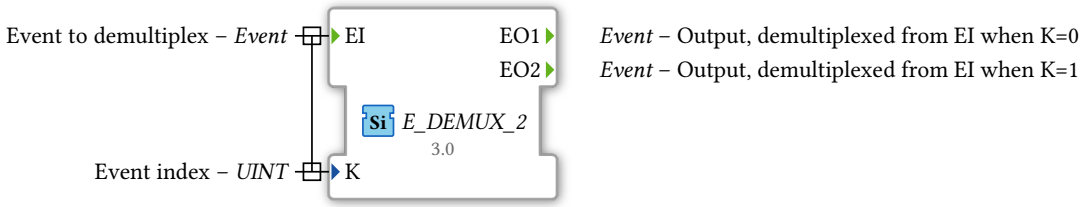
⚖️ Comparison with similar function blocks

Feature	E_DEMUX (this)	E_MUX	E_SWITCH
Operating principle	1:4 distribution	n:1 merging	1:2 distribution
Control	Index `K` [0-3]	Index `K`	`BOOL` condition `G`
Event flow	Splitting	Merging	Conditional switch

Note: Other variants exist, such as `E_DEMUX_2` and `E_DEMUX_8` for 2 and 8 outputs, respectively.

🛠️ Related Exercises

- Exercise_040
- Exercise_040_AX
- Exercise_087



Conclusion

The `E_DEMUX` is a fundamental building block for controlling event flow in IEC 61499 applications. It enables a clear, index-based division of event streams and is therefore a key tool for implementing state logic, mode switching, and sequence control.

2.11.3.11 E_DEMUX_2

• – ◦ • – ◦ • – ◦ •

The `E_DEMUX_2` (Event Demultiplexer) is a function block according to IEC 61499 that forwards a single input event (`EI`) to one of two outputs. The output selection is determined by the value of the input variable `K`.

- **EI (Event Input)**: The input event to be distributed.
- **Associated Data**: `K`
- **EO1**: Triggered when `EI` arrives and the selection index is `K = 0`.
- **EO2**: Triggered when `EI` arrives and the selection index is `K = 1`.
- **K**: The zero-based selection index that determines which output is triggered (data type: `UINT`).

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

1. **Event Reception**: The function block waits for an event at input `EI`.

2. **Forwarding**:

If `K` = 0, the event is forwarded to `EO1`.
If `K` = 1, the event is forwarded to `EO2`.

1. **Invalid Index**: If the value of `K` is outside the valid range [0, 1], no output event is triggered.

The input event is therefore always forwarded exclusively to exactly one output, provided the index `K` is valid.

- **1-to-2 Distribution**: This function block distributes an event to two possible outputs.
- **Index-Driven**: The logic is based on a numeric index (`K`).
- **Confusing Naming Convention**: Note that the outputs are named 1-based (`EO1`, `EO2`), but the selection index `K` is 0-based (`K=0` for `EO1`, `K=1` for `EO2`).
- **Generic Building Block**: The functionality is provided by the generic class `GEN_E_DEMUX`.
- **Conditional Branching**: Splitting an event flow based on a simple condition that results in either 0 or 1.
- **State Machines**: Selection between two possible next states.
- **Activation/Deactivation**: Forwarding an event to an "on" or "off" path.

The `E_DEMUX_2` is a specialized version of the demultiplexer for cases where an event needs to be split into exactly two paths. It is useful for simple binary decisions in the event flow. The inconsistent naming of the outputs relative to the index value requires special attention during implementation.

Technical Features

Application Scenarios

Conclusion

2.11.3.12 E_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_DEMUX_4` (Event Demultiplexer) is a function block according to IEC 61499 that forwards a single input event (`EI`) to one of four outputs. The output selection is determined by the value of the input variable `K`.

Interface Structure

Event Inputs

- **EI (Event Input)**: The input event to be distributed.
- **Related Data**: `K`

Event Outputs

- **EO1**: Triggered when `EI` arrives and the selection index is `K = 0`.
- **EO2**: Triggered when `EI` arrives and the selection index is `K = 1`.
- **EO3**: Triggered when `EI` arrives and the selection index is `K = 2`.
- **EO4**: Triggered when `EI` arrives and the selection index is `K = 3`.

Data Inputs

- **K**: The zero-based selection index that determines which output is triggered (data type: `UINT`).

Functionality

1. **Event Reception**: The function block waits for an event at input `EI`.
2. **Selection**: When the `EI` event arrives, the value of the data variable `K` is evaluated.
3. **Forwarding**:

- If `K` = 0, the event is forwarded to `EO1`.
- If `K` = 1, the event is forwarded to `EO2`.
- If `K` = 2, the event is forwarded to `EO3`.
- If `K` = 3, the event is forwarded to `EO4`.

1. **Invalid Index**: If the value of `K` is outside the valid range [0, 3], no output event is triggered.

Technical Features

- **1-to-4 Distribution**: This function block distributes an event across four possible outputs.
- **Index-Driven**: The logic is based on a numeric index (`K`).
- **Confusing Naming Convention**: Note that the outputs are named 1-based (`EO1` to `EO4`), but the selection index `K` is 0-based (`K=0` for `EO1`, `K=1` for `EO2`, etc.).
- **Generic Building Block**: The functionality is provided by the generic class `GEN_E_DEMUX`.

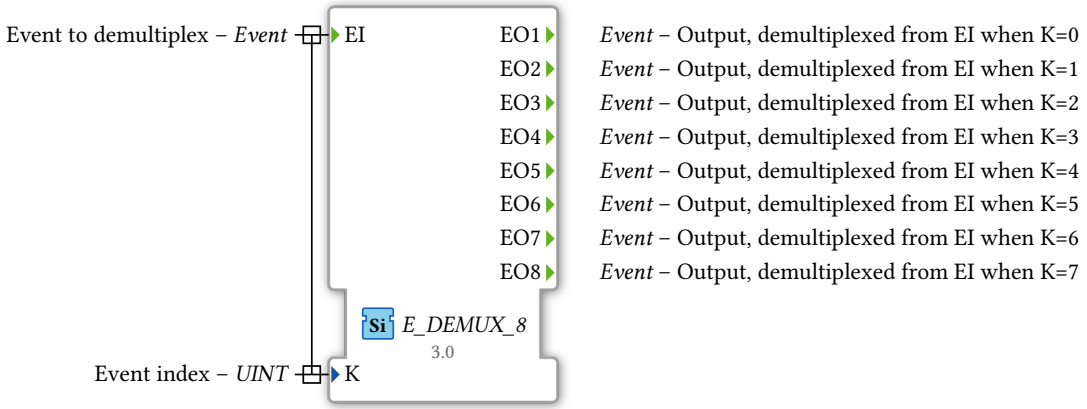
Application Scenarios

- **State Machines**: Selection of the next state transition based on a calculated index.
- **Mode Switching**: Activation of different system components depending on the selected operating mode (`K` = mode number).
- **Sequencer/Step Chains**: Activation of one of four possible next steps.

🛠️ Related Exercises

- Exercise_040_2
- Exercise_087a1
- Exercise_087a2

Conclusion



The `E_DEMUX_4` is a standard implementation of the demultiplexer principle for four outputs. It is useful for splitting an event flow into up to four paths. The inconsistent naming of the outputs in relation to the index value requires special attention during implementation.

2.11.3.13 E_DEMUX_8

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_DEMUX_8` (Event Demultiplexer) is a function block according to IEC 61499 that forwards a single input event (`EI`) to one of eight outputs. The output selection is determined by the value of the input variable `K`.

Interface Structure

Event Inputs

- **EI (Event Input)**: The input event to be distributed.
- **Related Data**: `K`

Event Outputs

- **EO1**: Triggered when `EI` arrives and `K = 0` is present.
- **EO2**: Triggered when `EI` arrives and `K = 1` is present.
- **EO3**: Triggered when `EI` arrives and `K = 2` is present.
- **EO4**: Triggered when `EI` arrives and `K = 3` is present.
- **EO5**: Triggered when `EI` arrives and is `K = 4`.
- **EO6**: Triggered when `EI` arrives and is `K = 5`.
- **EO7**: Triggered when `EI` arrives and is `K = 6`.
- **EO8**: Triggered when `EI` arrives and is `K = 7`.

Data Inputs

- **K**: The zero-based selection index that determines which output is triggered (data type: `UINT`).

Functionality

1. **Event Receipt**: The function block waits for an event at input `EI`.
2. **Selection**: When the `EI` event arrives, the value of the data variable `K` is evaluated.
3. **Forwarding**: The event is forwarded to output `EO(K+1)`. For example:

- If `K` = 0, the event is forwarded to `EO1`.
- If `K` = 7, the event is forwarded to `EO8`.

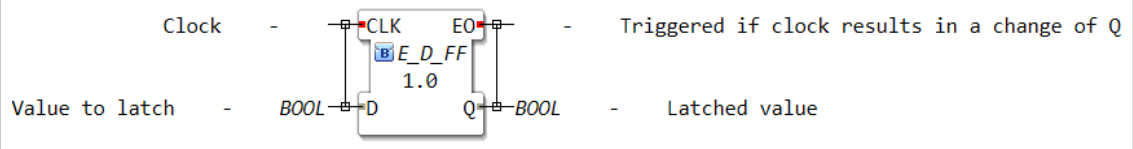
1. **Invalid Index**: If the value of `K` is outside the valid range [0, 7], no output event is triggered.

Technical Features

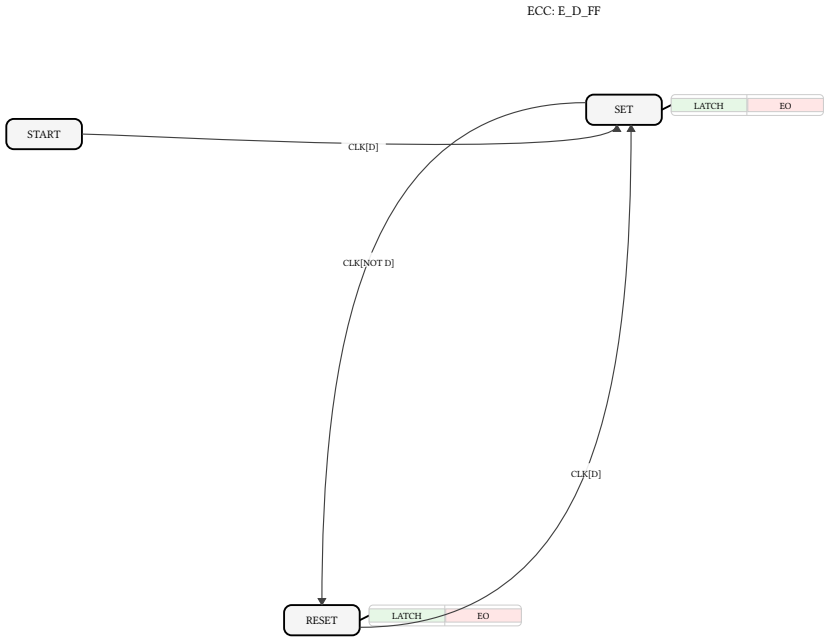
- **1-to-8 Distribution**: This function block distributes an event across eight possible outputs.
- **Index-Driven**: The logic is based on a numeric index (`K`).
- **Confusing Naming Convention**: Note that the outputs are named 1-based (`EO1` to `EO8`), but the selection index `K` is 0-based (`K=0` for `EO1`, `K=7` for `EO8`, etc.).
- **Generic Block**: The functionality is provided by the generic class `GEN_E_DEMUX`.

Application Scenarios

- **State Machines**: Selection of the next state transition from up to eight possibilities.
- **Mode Switching**: Activation of different system components depending on the selected operating mode.
- **Communication Router**: Forwards messages or commands to one of eight channels.



🛠️ Related Exercises

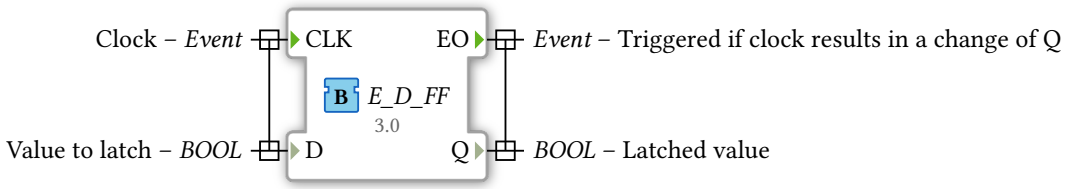


- Exercise_006c
- Exercise_041

Conclusion

The `E_DEMUX_8` is a useful implementation of the demultiplexer principle for use cases with up to eight different event paths. As with the other `E_DEMUX` blocks, the inconsistent naming of the outputs relative to the index value requires special attention during implementation.

2.11.3.14 E_D_FF



• – ○ • – ○ • – ○ •

Introduction

IEC 61499 is an international standard for modeling distributed industrial control systems. The **E_D_FF** (Data Flip-Flop) is a fundamental memory element in this standard that stores digital signals synchronously with a clock signal. This functional block plays a central role in state machines and memory applications in industrial automation solutions.

Structure of the E_D_FF Block

Interface

Event Inputs:

- `CLK` (Clock): Clock event that triggers the transfer of the data input `D`.
- **Linked Data**: `D`

Event Outputs:

- `EO` (Event Output): Triggered when the `CLK` pulse results in a change to the output `Q`.
- **Linked Data**: `Q`

Data Inputs:

- `D`: The data value to be stored (data type: `BOOL`).

Data Outputs:

- `Q`: The currently stored value (data type: `BOOL`).

Functionality

1. **Data Storage:**

- On each rising edge of the `CLK` signal, the value of `D` is transferred to `Q`.
- When the value changes, the `EO` event is triggered.

1. **Data Retention:**

- Between clock edges, the stored value `Q` remains stable.
- Changes at the `D` input have no effect without a clock edge.

Technical Features

✓ **Clock-controlled storage** for synchronous systems ✓ **Event output** for change detection ✓ **Deterministic behavior** in real-time systems ✓ **Easy integration** into IEC 61499 applications

Application Scenarios

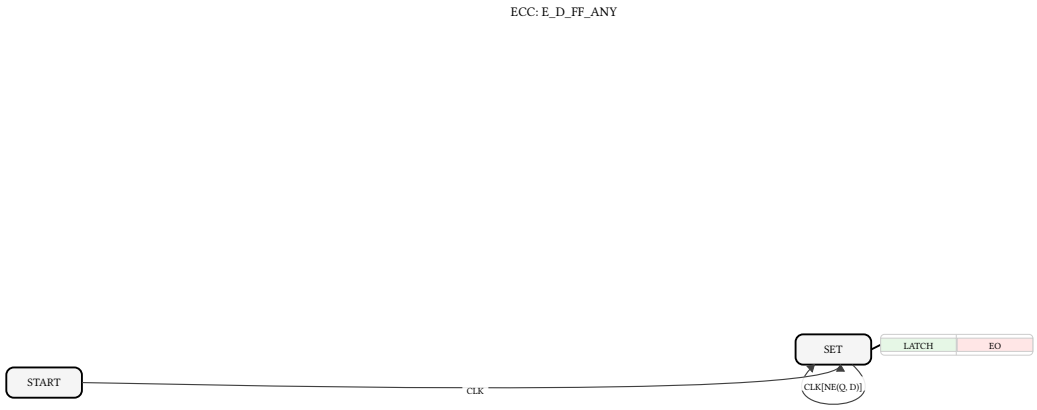
- **State Storage** in Automation Processes
- **Input Buffering** for Operator Input
- **Edge Detection** in Signal Processing Chains
- **Synchronization** between Asynchronous System Components

⚖️ Comparison with Similar Function Blocks

Feature	E_D_FF	E_SR	E_R_TRIG
Memory Type	D Flip-Flop	SR Latch	Edge Detector
Clocking	Required	None	None
Data Retention	Yes	Yes	No
Event Output	On Change	On Set/Reset	On Edge

🛠️ Related Exercises

- Exercise_071a
- Exercise_071b
- Exercise_072b
- Exercise_085

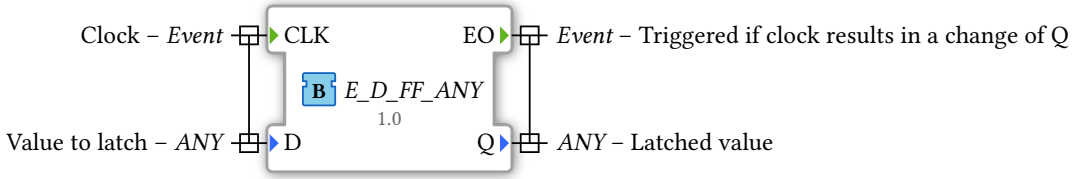


Conclusion

The E_D_FF block represents an essential memory element for IEC 61499-based control systems. Its main advantages are:

- Reliable clock-synchronous data storage
- Immediate feedback of state changes
- Robust integration into distributed control architectures

Due to its simple yet effective functionality, it forms the basis for more complex memory and state controls in industrial automation solutions. Strict adherence to the IEC 61499 standards ensures seamless interoperability with other functional modules.



2.11.3.15 E_D_FF_ANY

• – ◦ • – ◦ • – ◦ •

Introduction

`E_D_FF_ANY` is the generically-typed variant of `E_D_FF`: while `E_D_FF` only latches `BOOL` values, `E_D_FF_ANY` accepts an input `D` of data type `ANY` and can therefore be used as a clocked latch with built-in change detection for arbitrary data types (e.g. `TIME`, `DINT`, `REAL`, `STRING`).

Interface Structure

Event Inputs

- **CLK**: Clock event, latches the current value of `D`.
  - **Connected data**: `D`

Event Outputs

- **EO**: Only triggered if `Q` actually changed as a result of the `CLK` pulse.
  - **Connected data**: `Q`

Data Inputs

- **D** (ANY): The value to be latched, of arbitrary data type.

Data Outputs

- **Q** (ANY): The last latched value, of the same data type as `D`.

Functionality

On every `CLK` event, the ECC compares the new value `D` with the currently stored `Q` (`NE(Q, D)`). Only if the value has actually changed is `Q := D` executed and `EO` triggered — if the value is unchanged, the

block remains in state SET without generating an event. The initial state START always latches the value unconditionally on the first CLK, regardless of change detection.

Technical Features

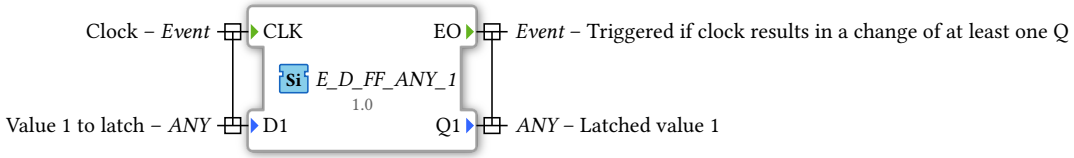
- **ANY typing**: Unlike E_D_FF (fixed to BOOL), E_D_FF_ANY can be instantiated with any IEC 61131-3 data type the target environment supports for generic ANY adaptation.
- **Built-in change detection**: Unlike a plain latch, E_D_FF_ANY only triggers EO on an actual value change — this significantly reduces event load in downstream FB networks.
- **Basis for the _TMIN variants**: E_D_FF_ANY_TMIN additionally combines this block with a minimum spacing time between two EO events.

State Overview

State	Meaning
START	Initial state, first CLK unconditionally latches D
SET	Q holds the last latched value; further CLK events only trigger EO again if NE(Q, D)

Application Scenarios

- **Change-driven downstream processing of arbitrary data types**: A TIME or REAL value should only trigger a follow-up event if it actually changed — e.g. as a building block inside composite FBs such as ATM_SUB (see the adapter library), which combines F_MOVE + E_D_FF_ANY for explicit, FBNetwork-visible change detection.
- **Generic caching**: Buffering an arbitrary value with notification only on a genuine change, independent of the concrete data type.



Comparison with similar function blocks

- **E_D_FF**: functionally identical, but fixed to BOOL.
- E_D_FF_ANY_TMIN: the same functionality, additionally with a minimum spacing time between EO events.
- E_D_FF_TMIN: the BOOL variant with a minimum spacing time.

Conclusion

E_D_FF_ANY provides a generically-typed, change-detecting latch and is a central building block wherever composite FBs for arbitrary data types need to trigger an event only on an actual value change.

2.11.3.16 E_D_FF_ANY_1

• – ◦ • – ◦ • – ◦ •

Introduction

E_D_FF_ANY_1 is the variant of E_D_FF_ANY for **one** latched value of any data type (ANY) and is part of the family E_D_FF_ANY_1 to E_D_FF_ANY_5 with numbered ports (D1/Q1). It is a clock-driven data latch (D flip-flop) with built-in change detection: the output event EO is only triggered if Q1 changes due to the clock.

Interface Structure

Event Inputs

- **CLK**: clock, takes over the current value of D1
  - **Associated data**: D1

Event Outputs

- **EO**: triggered if the clock causes a change of Q1

- **Associated data**: `Q1`

Data Inputs

- **D1** (ANY): value 1 to latch

Data Outputs

- **Q1** (ANY): latched value 1

Adapters

No adapters are used.

Functionality

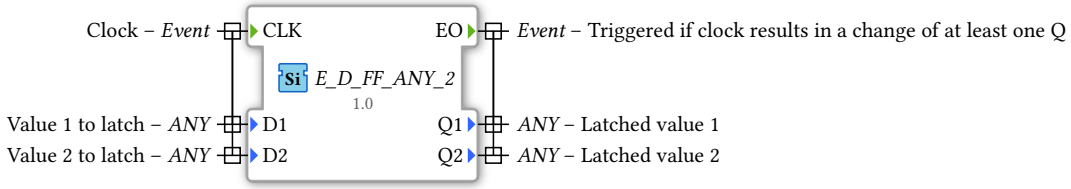
On every `CLK` event `D1` is taken over and compared with the previously stored value `Q1`. If `D1` differs from `Q1`, the value is stored and `EO` is triggered; if the value is unchanged, no output event is produced. The block is a generic FB (`eclipse4diac::core::GenericClassName = GEN_E_D_FF_ANY`); the native implementation `GEN_E_D_FF_ANY` (FORTE) is required.

Technical Details

- **Generic block**: the types of `D1` and `Q1` are `ANY` and are fixed at instantiation
- Port names `D1`/`Q1` (instead of `D`/`Q` for `E_D_FF_ANY`) correspond to the numbered family
- Version 1.0 (2026-08-26): extension of `E_D_FF_ANY` to a numbered variable

Application Scenarios

- Adapter wrappers around functions with one result, with output only on value change (e.g. `CEIL_AR`)
- Change-driven further processing of one value of any data type



⚖️ Comparison with Similar Building Blocks

`E_D_FF_ANY` also stores one value (ports `D`/`Q`), `E_D_FF_ANY_2` two, `E_D_FF_ANY_3` three, `E_D_FF_ANY_4` four and `E_D_FF_ANY_5` five values.

Conclusion

`E_D_FF_ANY_1` is a generic, change-detecting one-value latch that only outputs `EO` if the latched value changes.

2.11.3.17 E_D_FF_ANY_2

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_D_FF_ANY_2` is a data latch (D flip-flop) for **two `ANY` variables** (generic block). The output `EO` is fired only if at least one `Qi` changes due to the clock. It is the extension of `E_D_FF_ANY` to two variables.

Interface Structure

Event Inputs

- **CLK**: Clock; takes `D1` and `D2` into the latches. Associated data: `D1`, `D2`

Event Outputs

- **EO**: Triggered if the clock results in a change of at least one `Q`. Associated data: `Q1`, `Q2`

Data Inputs

- **D1** (`ANY`): Value 1 to latch

- **D2** (ANY): Value 2 to latch

Data Outputs

- **Q1** (ANY): Latched value 1
- **Q2** (ANY): Latched value 2

Adapters

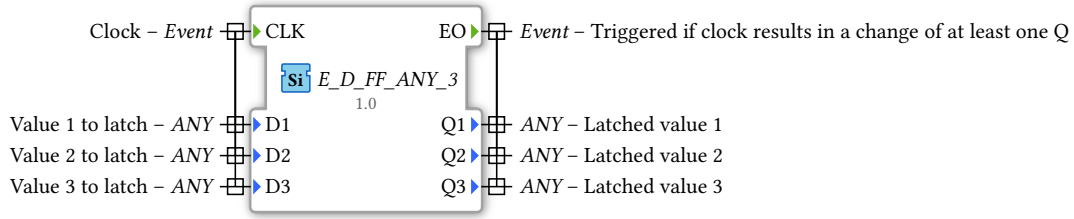
This function block uses no adapters.

How it works

On every CLK event, D1 and D2 are compared with the stored values Q1 and Q2. If at least one Di differs from the stored Qi, the values are taken over and EO is fired. If both values are unchanged, no EO is fired.

Technical Details

- Service interface FB (generic, ANY types); it requires the native implementation GEN_E_D_FF_ANY (FORTE).
- Unlike the simple D flip-flop E_D_FF, EO is fired only on an actual change.
- The variant for three variables is E_D_FF_ANY_3.



Application Scenarios

- Jointly latching related values (e.g. control output and control error) and forwarding only on change, to avoid unnecessary follow-up events

Summary

E_D_FF_ANY_2 stores two arbitrary values and signals an event only if at least one of them has changed.

2.11.3.18 E_D_FF_ANY_3

• – ◦ • – ◦ • – ◦ •

Introduction

The E_D_FF_ANY_3 is the variant of E_D_FF_ANY for **three** simultaneously latched values of arbitrary data type (ANY). It is a clock-driven data latch with built-in change detection: the output event EO is triggered only if at least one of the three outputs Q1..Q3 actually changes due to the clock.

Interface Structure

Event Inputs

- **CLK**: clock, takes over the current values of D1, D2 and D3
  - **Associated data**: D1, D2, D3

Event Outputs

- **EO**: triggered if the clock results in a change of at least one Qi
  - **Associated data**: Q1, Q2, Q3

Data Inputs

- **D1** (ANY): value 1 to latch
- **D2** (ANY): value 2 to latch
- **D3** (ANY): value 3 to latch

Data Outputs

- **Q1** (ANY): latched value 1
- **Q2** (ANY): latched value 2
- **Q3** (ANY): latched value 3

Adapters

No adapters are used.

Functionality

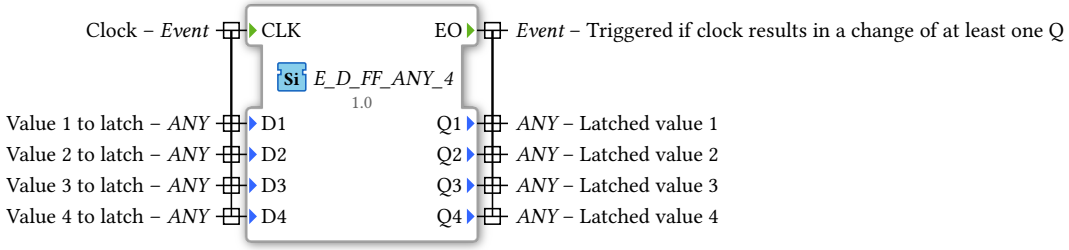
On every `CLK` event, `D1`, `D2` and `D3` are taken over and compared with the previously stored values `Q1`, `Q2` and `Q3`. If at least one `Di` differs from its `Qi`, the values are stored and `EO` is triggered; if all values are unchanged, no output event is produced. The block is a generic service interface FB whose native implementation is `GEN_E_D_FF_ANY` (FORTE).

Technical Details

- **Generic block**: the types of `D1`..`D3` and `Q1`..`Q3` are `ANY` and are fixed on instantiation
- **Common change detection**: a single `EO` reports the change of any of the three values; which one has changed cannot be seen from the event
- Serves to pass on several related values (e.g. control output, control error and limit flag of a controller) with just one event and to avoid follow-up events when the values are unchanged

Application Scenarios

- Adapter wrappers around functions delivering three results, with output only on value change (e.g. `CTRL_PI_AR`)
- Change-driven further processing of several values of arbitrary type



⚖️ Comparison with Similar Blocks

`E_D_FF_ANY` latches one value, `E_D_FF_ANY_3` three. Corresponding variants with another number of values exist as `E_D_FF_ANY_1`, `E_D_FF_ANY_2`, `E_D_FF_ANY_4` and `E_D_FF_ANY_5`.

Conclusion

`E_D_FF_ANY_3` is a generic, change-detecting three-value latch that outputs `EO` only if at least one of the three latched values changes.

2.11.3.19 E_D_FF_ANY_4

• – ◦ • – ◦ • – ◦ •

Introduction

`E_D_FF_ANY_4` is the variant of `E_D_FF_ANY` for **four** simultaneously latched values of any data type (`ANY`). It is a clock-driven data latch (D flip-flop) with built-in change detection: the output event `EO` is only triggered if at least one of the four outputs `Q1`..`Q4` changes due to the clock.

Interface Structure

Event Inputs

- **CLK**: clock, takes over the current values of `D1`..`D4`
  - **Associated data**: `D1`, `D2`, `D3`, `D4`

Event Outputs

- **EO**: triggered if the clock causes a change of at least one `Qi`
  - **Associated data**: `Q1`, `Q2`, `Q3`, `Q4`

Data Inputs

- **D1** (ANY): value 1 to latch
- **D2** (ANY): value 2 to latch
- **D3** (ANY): value 3 to latch
- **D4** (ANY): value 4 to latch

Data Outputs

- **Q1** (ANY): latched value 1
- **Q2** (ANY): latched value 2
- **Q3** (ANY): latched value 3
- **Q4** (ANY): latched value 4

Adapters

No adapters are used.

Functionality

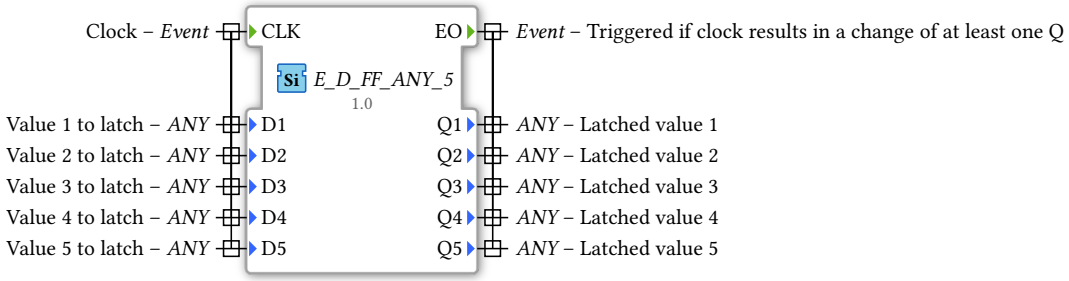
On every `CLK` event `D1`..`D4` are taken over and compared with the previously stored values `Q1`..`Q4`. If at least one `Di` differs from its `Qi`, the values are stored and `EO` is triggered; if all values are unchanged, no output event is produced. The block is a generic FB (`eclipse4diac::core::GenericClassName = GEN_E_D_FF_ANY`).

Technical Details

- **Generic block**: the types of `D1`..`D4` and `Q1`..`Q4` are `ANY` and are fixed at instantiation
- **Common change detection**: a single `EO` reports the change of any of the four values; which one changed cannot be seen from the event

Application Scenarios

- Adapter wrappers around functions that deliver four results, with output only on value change
- Change-driven further processing of several values of any data type



⚖️ Comparison with Similar Building Blocks

`E_D_FF_ANY` stores one value, `E_D_FF_ANY_2` two, `E_D_FF_ANY_3` three and `E_D_FF_ANY_4` four values.

Conclusion

`E_D_FF_ANY_4` is a generic, change-detecting four-value latch that only outputs `EO` if at least one of the four latched values changes.

2.11.3.20 E_D_FF_ANY_5

• – ◦ • – ◦ • – ◦ •

Introduction

`E_D_FF_ANY_5` is the variant of `E_D_FF_ANY` for **five** simultaneously latched values of any data type (`ANY`). It is a clock-driven data latch (D flip-flop) with built-in change detection: the output event `EO` is only triggered if at least one of the five outputs `Q1`..`Q5` changes due to the clock.

Interface Structure

Event Inputs

- **CLK**: clock, takes over the current values of `D1..D5`
  - **Associated data**: `D1`, `D2`, `D3`, `D4`, `D5`

Event Outputs

- **EO**: triggered if the clock causes a change of at least one `Qi`
  - **Associated data**: `Q1`, `Q2`, `Q3`, `Q4`, `Q5`

Data Inputs

- **D1** (ANY): value 1 to latch
- **D2** (ANY): value 2 to latch
- **D3** (ANY): value 3 to latch
- **D4** (ANY): value 4 to latch
- **D5** (ANY): value 5 to latch

Data Outputs

- **Q1** (ANY): latched value 1
- **Q2** (ANY): latched value 2
- **Q3** (ANY): latched value 3
- **Q4** (ANY): latched value 4
- **Q5** (ANY): latched value 5

Adapters

No adapters are used.

Functionality

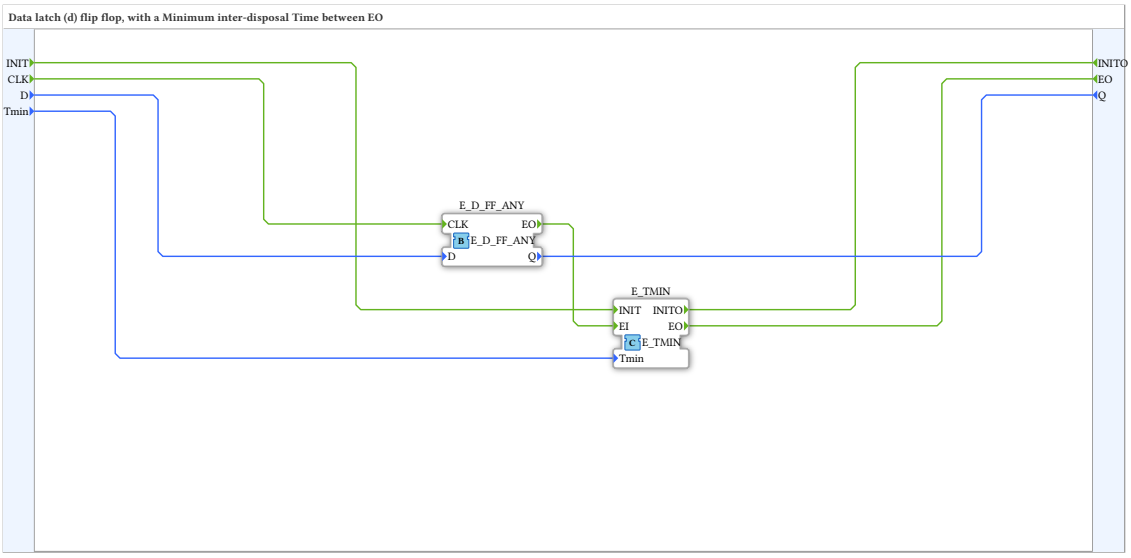
On every `CLK` event `D1..D5` are taken over and compared with the previously stored values `Q1..Q5`. If at least one `Di` differs from its `Qi`, the values are stored and `EO` is triggered; if all values are unchanged, no output event is produced. The block is a generic FB (`eclipse4diac::core::GenericClassName = GEN_E_D_FF_ANY`); the native implementation `GEN_E_D_FF_ANY` (FORTE) is required.

Technical Details

- **Generic block**: the types of `D1..D5` and `Q1..Q5` are `ANY` and are fixed at instantiation
- **Common change detection**: a single `EO` reports the change of any of the five values; which one changed cannot be seen from the event
- Version 1.0 (2026-08-26): extension of `E_D_FF_ANY` to 5 variables

Application Scenarios

- Adapter wrappers around functions that deliver five results, with output only on value change
- Change-driven further processing of several values of any data type

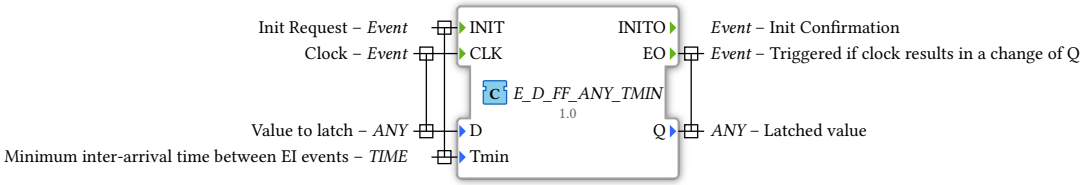


⚖️ Comparison with Similar Building Blocks

`E_D_FF_ANY` stores one value, `E_D_FF_ANY_2` two, `E_D_FF_ANY_3` three, `E_D_FF_ANY_4` four and `E_D_FF_ANY_5` five values.

Conclusion

`E_D_FF_ANY_5` is a generic, change-detecting five-value latch that only outputs `EO` if at least one of the five latched values changes.



2.11.3.21 E_D_FF_ANY_TMIN

• — ○ • — ○ • — ○ •

Introduction

`E_D_FF_ANY_TMIN` is the generically-typed variant of E_D_FF_TMIN: it combines E_D_FF_ANY (change-detecting latch for arbitrary data types) with E_TMIN (minimum spacing time), making it suitable for any data type, not just `BOOL`.

Interface Structure

Event Inputs

- **INIT**: Initialization, carries `Tmin`.
- **CLK**: Clock event, latches `D` into `Q`.
  - **Connected data**: `D`

Event Outputs

- **INITO**: Confirms the initialization.
- **EO**: Change event throttled to `Tmin`.
  - **Connected data**: `Q`

Data Inputs

- **D** (ANY): The value to be latched, of arbitrary data type.
- **Tmin** (TIME): Minimum spacing between two `EO` events.

Data Outputs

- **Q** (ANY): The last latched value.

Functionality

Identical to E_D_FF_TMIN, but with E_D_FF_ANY instead of `E_D_FF`: `CLK` triggers the internal change detection (`NE(Q, D)`), whose `EO` is forwarded to the internal E_TMIN, which throttles it to at least `Tmin` between two triggers of `EO`.

Technical Features

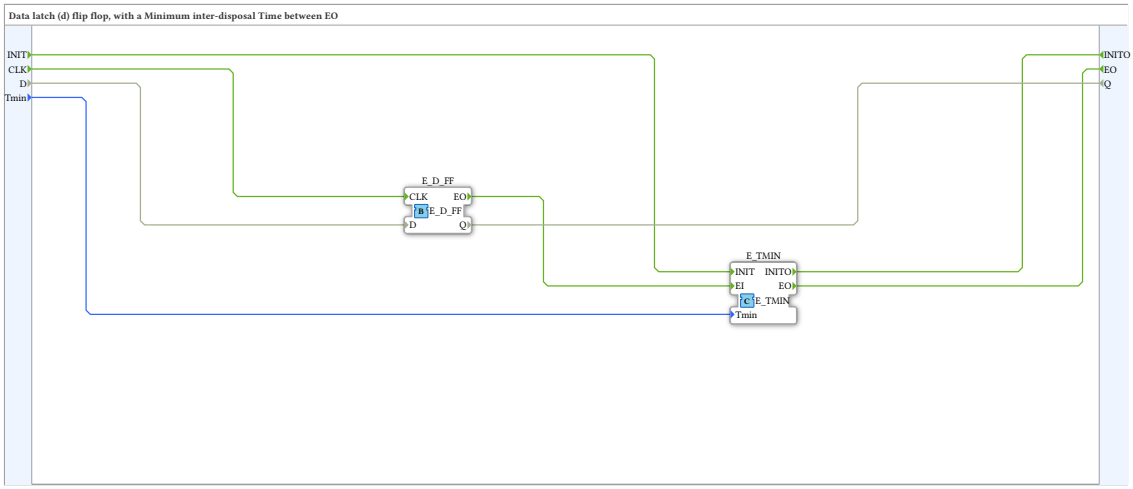
- **ANY typing**: can be instantiated with any data type supported by the target environment (e.g. `TIME`, `REAL`, `DINT`).
- **Two-stage filtering**: content-based change detection (`E_D_FF_ANY`) plus time-based throttling (`E_TMIN`); `Q` is unaffected by this and always current.

State Overview

Stateless wiring logic; see E_D_FF_ANY (change detection) and E_TMIN (time throttling).

Application Scenarios

- **Low-noise forwarding of arbitrary measurements**: A `REAL` or `TIME` value fluctuates slightly, but `EO` should only trigger at most every `Tmin` — e.g. to limit the transmission rate to an upstream system.

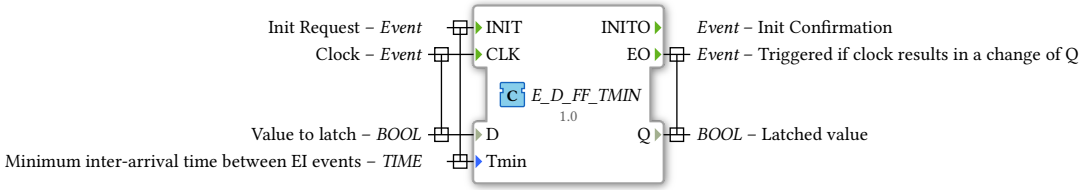


Comparison with similar function blocks

- **E_D_FF_ANY**: the same change detection, but without time throttling.
- **E_D_FF_TMIN**: the same functionality, but fixed to `BOOL`.
- **E_TMIN**: the internally used throttling logic.

Conclusion

`E_D_FF_ANY_TMIN` provides a generically-typed, change-detecting latch with a guaranteed minimum spacing between change events, for arbitrary data types.



2.11.3.22 E_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

`E_D_FF_TMIN` combines `E_D_FF` (clocked `BOOL` latch with change detection) with E_TMIN (minimum spacing time): changes to `Q` are still latched immediately, but the change event `EO` is additionally limited to at most one trigger per `Tmin` interval.

Interface Structure

Event Inputs

- **INIT**: Initialization, carries `Tmin`.
- **CLK**: Clock event, latches `D` into `Q`.

  - **Connected data**: `D`

Event Outputs

- **INITO**: Confirms the initialization.
- **EO**: Change event throttled to `Tmin`.
  - **Connected data**: `Q`

Data Inputs

- **D** (BOOL): The value to be latched.
- **Tmin** (TIME): Minimum spacing between two `EO` events.

Data Outputs

- **Q** (BOOL): The last latched value.

Functionality

`CLK` internally triggers the encapsulated `E_D_FF`, whose `D`/`Q` data connection is forwarded directly to the outer `D`/`Q` ports. Only when `E_D_FF` detects an actual value change (`Q := D`) does it trigger its own `EO` — this is forwarded to the `EI` input of the internal E_TMIN, which only passes the event through to the outer `EO` output if at least `Tmin` has passed since the last pass-through.

Technical Features

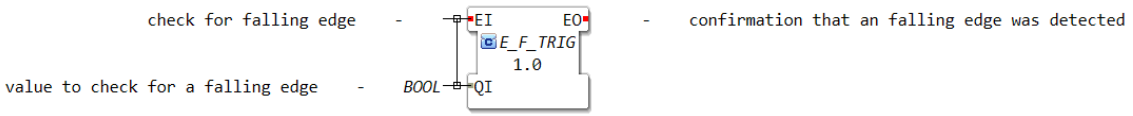
- **Two-stage filtering**: first content-based change detection (`E_D_FF`), then time-based throttling (`E_TMIN`) — `Q` itself is not affected by this and is always current, even while `EO` is being throttled.
- **Pure wiring of two standard blocks**, no ECC of its own.

State Overview

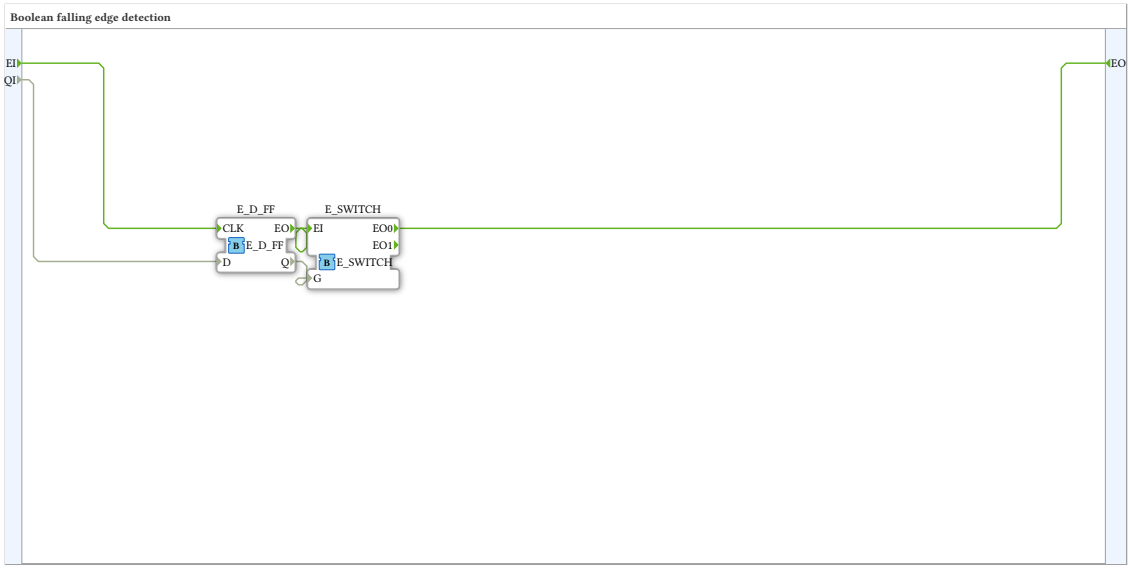
Stateless wiring logic; see `E_D_FF` (change detection) and E_TMIN (time throttling) for the respective internal states.

Application Scenarios

- **Low-noise status reporting of a `BOOL` signal**: A digital state changes frequently over short periods (bouncing, noise); `EO` should only trigger at most every `Tmin`, while `Q` always shows the current value.



Comparison with similar function blocks



- **`E_D_FF`**: the same change detection, but without time throttling.
- **E_D_FF_ANY_TMIN**: the same functionality for arbitrary data types instead of just `BOOL`.
- **E_TMIN**: the internally used throttling logic.

Conclusion

`E_D_FF_TMIN` provides a change-detecting `BOOL` latch with a guaranteed minimum spacing between change events and is suitable for low-noise event forwarding of digital signals.

2.11.3.23 E_F_TRIG

• – ○ • – ○ • – ○ •

Introduction

The **E_F_TRIG** (Falling Edge Trigger) is a fundamental function block of the IEC 61499 standard for detecting falling signal edges. This block plays an important role in event detection and signal processing in industrial control systems.

Structure of the E_F_TRIG Block

Interface

Event Inputs:

- **EI (Event Input)**: Triggers the edge detection.
- **Associated Data**: `QI`

Event Outputs:

- **EO (Event Output)**: Triggered when an edge is detected.

Data Inputs:

- **QI (Qualifier Input)**: The Boolean signal to be monitored (data type: `BOOL`).

Functionality

The `E_F_TRIG` input is designed to detect a falling edge at the `QI` input. A falling edge occurs when `QI` was `TRUE` at the last `EI` event and is `FALSE` at the current `EI` event.

Each `EI` event compares the current state of `QI` with the state from the previous cycle. If a falling edge is detected, the `EO` event should be triggered.

Caution: Incorrect Implementation The internal logic of the function block (as of `events-3.0.0`) is incorrect and actually implements a **rising edge detector (`E_R_TRIG`)** instead of a falling one. The `EO` event is triggered when `QI` transitions from `FALSE` to `TRUE`.

Caution: Incorrect Implementation The internal logic of the function block (as of `events-3.0.0`) is incorrect and actually implements a **rising edge detector (`E_R_TRIG`)** instead of a falling one.** The `EO` event is triggered when `QI` transitions from `FALSE` to `TRUE`.**

**

Technical Features

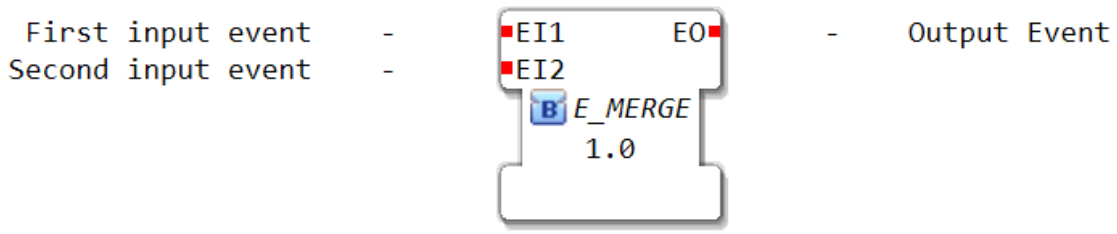
✓ **Event-driven**: The check only occurs when a `EI` event occurs.
✓ **Faulty logic**: The function block is named `E_F_TRIG`, but its internal wiring of `E_D_FF` and `E_SWITCH` causes it to react to a **rising edge**. Users who require falling edge detection must instead use the `E_R_TRIG` function block and invert its input or wait for a correction of the function block.

Application Scenarios (for a falling edge)

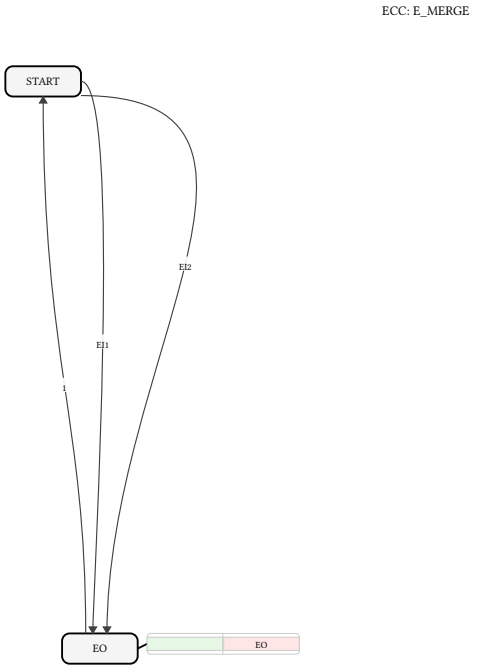
- **Sensor data evaluation**: Detect when a sensor changes from "active" to "inactive".
- **Machine Safety**: Detection when a protective contact changes from "closed" (TRUE) to "open" (FALSE).
- **Process Monitoring**: Detection of the end of a signal or process.

⚖️ **Comparison with similar function blocks**

Feature	E_F_TRIG (this)	E_R_TRIG	E_SWITCH
Detected Edge	Falling (named), Rising (implemented)	Rising	-
Event Control	Yes	Yes	Yes
Principle	Edge Detector	Edge Detector	Event Switch



🛠️ **Related Exercises**

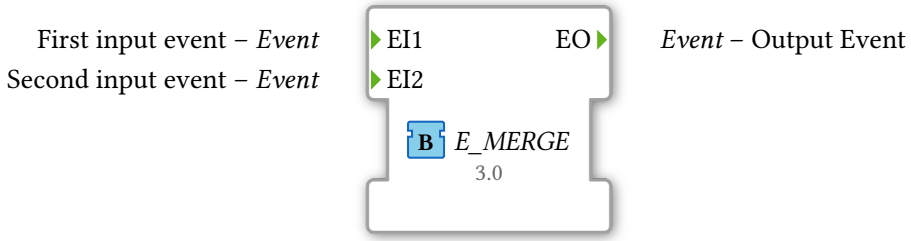


- Exercise_088

Conclusion

The E_F_TRIG function block is designed to detect falling edges, a common use case in control engineering. **However, due to an implementation error in the `events-3.0.0` library, this function block also functions as a detector for rising edges.** This discrepancy between name and function is critical and must be carefully considered during use. For reliable detection of falling edges, alternative logic should be used.

2.11.3.24 E_MERGE



• – ◦ • – ◦ • – ◦ •

Introduction

The **E_MERGE** is a fundamental function block of the IEC 61499 standard that combines multiple event streams into a single output. This logical OR operation of events is essential for control logic in industrial automation systems.

Structure of the E_MERGE Block

Interface

Event Inputs:

- `EI1` (Event Input 1): First event input
- `EI2` (Event Input 2): Second event input

Event Outputs:

- `EO` (Event Output): Merged event output

Functionality

1. **Event Merging:**

- Each event at `EI1` or `EI2` triggers an output event at `EO`
- The inputs are logically ORed

1. **Independent Processing:**

- Events at both inputs are Equal treatment

- No prioritization of specific inputs

1. **Immediate forwarding:**

- No delay between input and output events
- No memory behavior or state maintenance

Technical Features

✓ **Simple and fast** event linking ✓ **Lossless** event forwarding ✓ **Real-time capable** for industrial applications ✓ **Expandable** to multiple inputs

Application Scenarios

- **Operating concepts**: Combining control signals from multiple buttons
- **Sensor data**: Combining events from different sensors
- **Fault management**: Central location for various fault messages
- **Process control**: Linking process events

⚖️ Comparison with similar function blocks

Feature	E_MERGE	E_DEMUX	E_SWITCH
Functional principle	OR operation	Distribution	Conditional forwarding
Direction	n:1	1:n	1:1
Event flow	Combination	Splitting	Selection

Similar Building Blocks

For use cases requiring more than two event inputs, the library provides additional variants:

- **E_MERGE**: This building block (2 inputs)
- **E_MERGE_2**: Functionally identical to `E_MERGE` (2 inputs)
- **E_MERGE_3**: A variant with 3 inputs (`EI1`, `EI2`, `EI3`)
- **E_MERGE_4**: A variant with 4 inputs

These building blocks allow for the easy merging of up to four event sources into a single output.

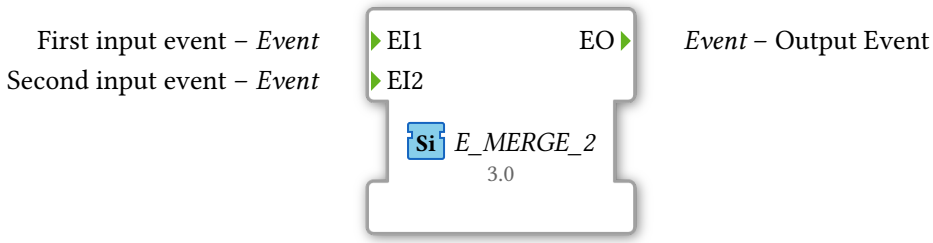
🛠️ Related Exercises

- Exercise_004a2
- Exercise_004a2_AX

Conclusion

The E_MERGE block is a fundamental building block for event processing in IEC 61499 systems. Its main advantages are:

- Simple and efficient event combination
- Immediate response to input events
- Flexible application possibilities in various control scenarios



Due to its clear functionality and standard compliance, it is ideally suited for basic logic tasks in industrial automation solutions. Its deterministic operation makes it particularly valuable for safety-critical applications.

2.11.3.25 E_MERGE_2

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_MERGE_2` is a fundamental function block according to the IEC 61499 standard. It combines two event streams (`EI1`, `EI2`) into a single output (`EO`). This logical OR operation of events is essential for control logic in industrial automation systems. This block is functionally identical to the `E_MERGE` block.

Interface Structure

Event Inputs:

- `EI1` (Event Input 1): First event input
- `EI2` (Event Input 2): Second event input

Event Outputs:

- `EO` (Event Output): Combined event output

Functionality

The function is simple and direct:

- An event at input `EI1` immediately triggers an event at output `EO`.
- An event at input `EI2` also immediately triggers an event at output `EO`.

The inputs are logically ORed and forwarded without prioritization or delay.

Technical Features

- **2-to-1 Linking**: Combines two event streams into one.
- **Stateless**: The function block has no internal memory.
- **Generic Function Block**: The functionality is provided by the generic class `GEN_E_MERGE`, enabling optimized execution by the 4diac runtime environment.

Application Scenarios

- **Operating Concepts**: Combining control signals from two pushbuttons into a single function.
- **Sensors**: Combining trigger events from two different sensors.
- **Fault Management**: Creating a collective fault message from two potential fault sources.

🛠️ Related Exercises

- Exercise_004a2_2

Conclusion

The `E_MERGE_2` is a fundamental and frequently used building block for the simplest form of event linking. Its clear functionality and efficient implementation as a generic building block make it a reliable component for basic control logic.

2.11.3.26 E_MERGE_3

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_MERGE_3` is a fundamental function block of the IEC 61499 standard that combines three event streams (`EI1`, `EI2`, `EI3`) into a single output (`EO`). This logical OR operation of events is essential for control logic in industrial automation systems.

Interface Structure

Event Inputs:

- `EI1` (Event Input 1): First event input
- `EI2` (Event Input 2): Second event input
- `EI3` (Event Input 3): Third event input

Event Outputs:

- `EO` (Event Output): Combined event output

Functionality

The function is simple and direct:

- An event at input `EI1`, `EI2`, or `EI3` immediately triggers an event at output `EO` without prioritization.

The inputs are logically ORed and forwarded without delay.

Technical Features

- **3-to-1 Linking**: Combines three event streams into one.
- **Stateless**: The function block has no internal memory.
- **Generic Function Block**: The functionality is provided by the generic class `GEN_E_MERGE`, enabling optimized execution by the 4diac runtime environment.

Application Scenarios

- **Operating Concepts**: Combining control signals from three buttons into a common function (e.g., "Manual," "Automatic," and "Service" start the same process).
- **Sensors**: Combining the trigger events from three different sensors into a single event.
- **Fault Management**: Creating a collective fault message from three potential fault sources.

🛠️ Related Exercises

- Exercise_004a2_3

Conclusion

The `E_MERGE_3` is a simple yet useful building block for linking up to three event sources. Its clear functionality and efficient implementation as a generic building block make it a reliable component for basic control logic.

2.11.3.27 E_MERGE_4

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_MERGE_4` is a fundamental function block of the IEC 61499 standard that combines four event streams (`EI1` to `EI4`) into a single output (`EO`). This logical OR operation of events is essential for control logic in industrial automation systems.

Interface Structure

Event Inputs:

- `EI1` (Event Input 1): First Event Input
- `EI2` (Event Input 2): Second Event Input
- `EI3` (Event Input 3): Third Event Input
- `EI4` (Event Input 4): Fourth Event Input

Event Outputs:

- `EO` (Event Output): Combined Event Output

Functionality

The function is simple and direct:

- An event at one of the four inputs (`EI1` to `EI4`) immediately triggers an event at the output without prioritization. `EO`.

The inputs are logically ORed and forwarded without delay.

Technical Features

- **4-to-1 Linking**: Combines four event streams into one.
- **Stateless**: The block has no internal memory.
- **Generic Block**: The functionality is provided by the generic class `GEN_E_MERGE`, enabling optimized execution by the 4diac runtime environment.

Application Scenarios

- **Collective Fault Message**: Combines four different fault events into a single alarm message.
- **Operation**: A process step can be triggered by four different buttons or sources.
- **Sensor Array**: A single “object detected” event is triggered when one of four sensors detects an object.

Conclusion

The `E_MERGE_4` is a simple yet useful building block for linking up to four event sources. Its clear functionality and efficient implementation as a generic building block make it a reliable component for basic control logic.

2.11.3.28 E_MUX_2

• – ○ • – ○ • – ○ •

Introduction

The `E_MUX_2` (Event Multiplexer) is a function block according to IEC 61499 that combines two event inputs (`EI1`, `EI2`) into a single event output (`EO`). In addition to combining the inputs, the block outputs a data output, `K`, indicating which input triggered the event. It is the counterpart to the `E_DEMUX_2`.

Interface Structure

Event Inputs:

- **EI1**: First input channel. - **EI2**: Second input channel.

Event Outputs:

- **EO (Event Output)**: The common event output.
- **Associated Data**: `K`

Data Outputs:

- **K**: The index of the triggering input channel (data type: `UINT`).
- `K = 0` if `EI1` was triggered.
- `K = 1` if `EI2` was triggered.

Functionality

1. **Event Receipt**: The function block waits for an event at one of its inputs (`EI1` or `EI2`).
2. **Forwarding and Identification**:

- When an event arrives at `EI1`, the data output `K` is set to `0`, and the `EO` event is immediately triggered.
- When an event arrives at `EI2`, the data output `K` is set to `1`, and the `EO` event is immediately triggered.

In this way, the event flow is merged while preserving information about the event's origin.

Technical Features

- **2-to-1 Multiplexer**: Merges two event streams into one.
- **Origin Index**: Indicates which input triggered the event.
- **Stateless**: The function block has no internal memory.
- **Generic Function Block**: The functionality is provided by the generic class `GEN_E_MUX`.

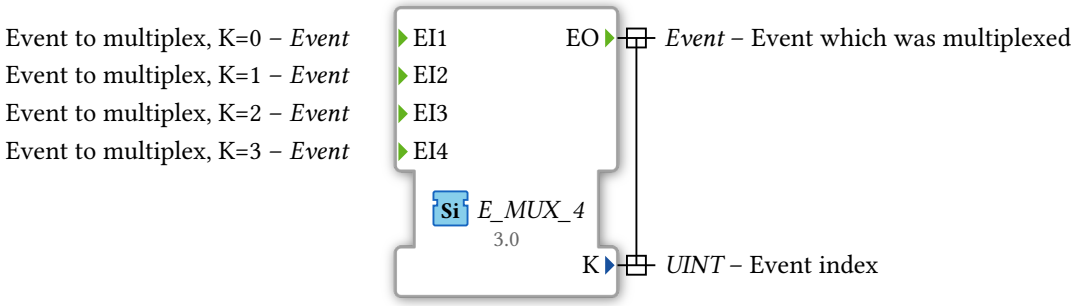
Application Scenarios

- **Command Combining**: Two different buttons (e.g., "Start Forward" and "Start Reverse") trigger the same process, but the process needs to know which button was pressed.
- **Combined Alarms**: Two different alarms are routed to a central alarm routine, which then displays the specific alarm text based on `K`.
- **Simplified Logic**: Instead of having two separate paths for similar logic, the triggering events are merged, and the index `K` is used as a parameter for subsequent logic.

🛠️ **Related Exercises**

- Exercise_172

Conclusion



The `E_MUX_2` is a useful component for bundling event streams while simultaneously identifying the event source. It is the standard counterpart to `E_DEMUX_2` and is frequently used to reduce wiring complexity and centralize logic.

2.11.3.29 E_MUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_MUX_4` (Event Multiplexer) is a function block according to IEC 61499 that combines four event inputs (`EI1` to `EI4`) into a single event output (`EO`). In addition to combining the inputs, the block outputs a data output, `K`, indicating which input triggered the event. It is the counterpart to the `E_DEMUX_4`.

Interface Structure

Event Inputs:

- **EI1**: First input channel. - **EI2**: Second input channel.
- **EI3**: Third input channel.
- **EI4**: Fourth input channel.

Event Outputs:

- **EO (Event Output)**: The common event output.
- **Associated Data**: `K`

Data Outputs:

- **K**: The index of the triggering input channel (data type: `UINT`).
- `K = 0` if `EI1` was triggered.
- `K = 1` if `EI2` was triggered.
- `K = 2` when `EI3` is triggered.
- `K = 3` when `EI4` is triggered.

Functionality

1. **Event Receipt**: The function block waits for an event at one of its four inputs.
2. **Forwarding and Identification**: When an event arrives at `EIn` (where `n` represents 1 to 4), the data output `K` is set to `n-1`, and the `EO` event is immediately triggered.

In this way, the event flow is merged while preserving information about the event's origin.

Technical Features

- **4-to-1 Multiplexer**: Merges four event streams into one.
- **Origin Index**: Indicates which input triggered the event.
- **Stateless**: The function block has no internal memory.
- **Generic Function Block**: The functionality is provided by the generic class `GEN_E_MUX`.

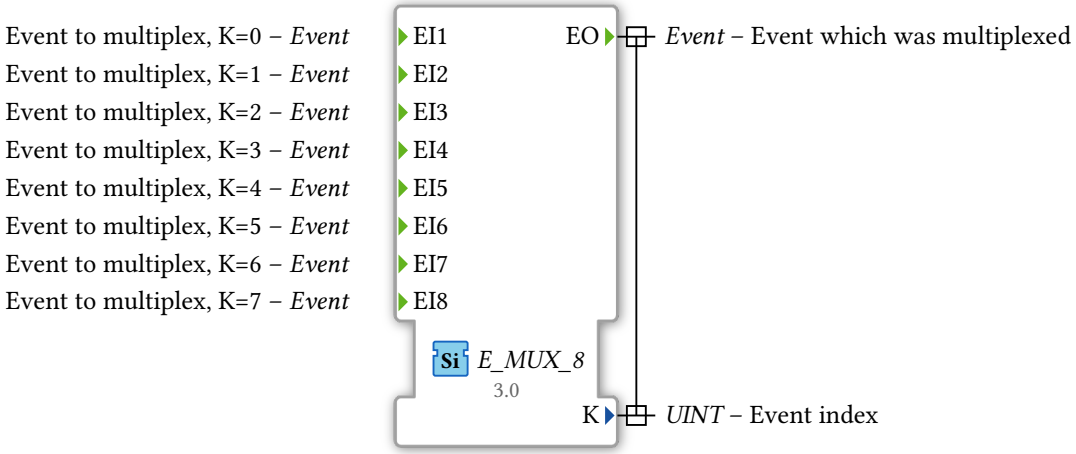
Application Scenarios

- **Command Grouping**: Four different buttons trigger the same process, but the process needs to know which of the four buttons was pressed.
- **Combined Alarms**: Four different alarms are routed to a central alarm routine, which then displays the specific alarm text based on `K`.
- **Mode Selection**: Combines the startup events from four different operating modes.

🛠️ Related Exercises

- Exercise_087a2

Conclusion



The `E_MUX_4` is a useful component for bundling event streams from up to four sources while simultaneously identifying the event's source. It is the standard counterpart to the `E_DEMUX_4` and is frequently used to reduce wiring complexity and centralize logic.

2.11.3.30 E_MUX_8

• − ◦ • − ◦ • − ◦ •

Introduction

The `E_MUX_8` (Event Multiplexer) is a function block according to IEC 61499 that combines eight event inputs (`EI1` to `EI8`) into a single event output (`EO`). In addition to combining the inputs, the block outputs a data output, `K`, indicating which input triggered the event. It is the counterpart to the `E_DEMUX_8`.

Interface Structure

Event Inputs:

- **EI1 ... EI8**: The eight separate input channels.

Event Outputs:

- **EO (Event Output)**: The common event output.
- **Associated Data**: `K`

Data Outputs:

- **K**: The index of the triggering input channel (data type: `UINT`).
- `K = 0` if `EI1` was triggered.
- `K = 1` if `EI2` was triggered.
- ...
- `K = 7` when `EI8` is triggered.

Functionality

1. **Event Reception**: The function block waits for an event at one of its eight inputs.
2. **Forwarding and Identification**: When an event arrives at `EIn` (where `n` represents 1 to 8), the data output `K` is set to `n-1`, and the `EO` event is immediately triggered.

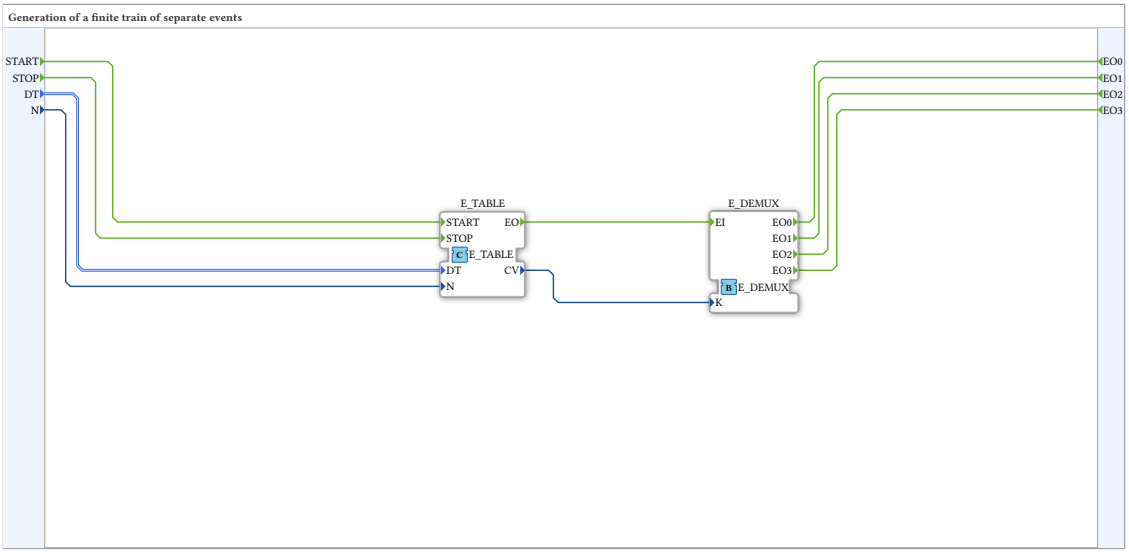
In this way, the event streams are merged while preserving information about the event's origin.

Technical Features

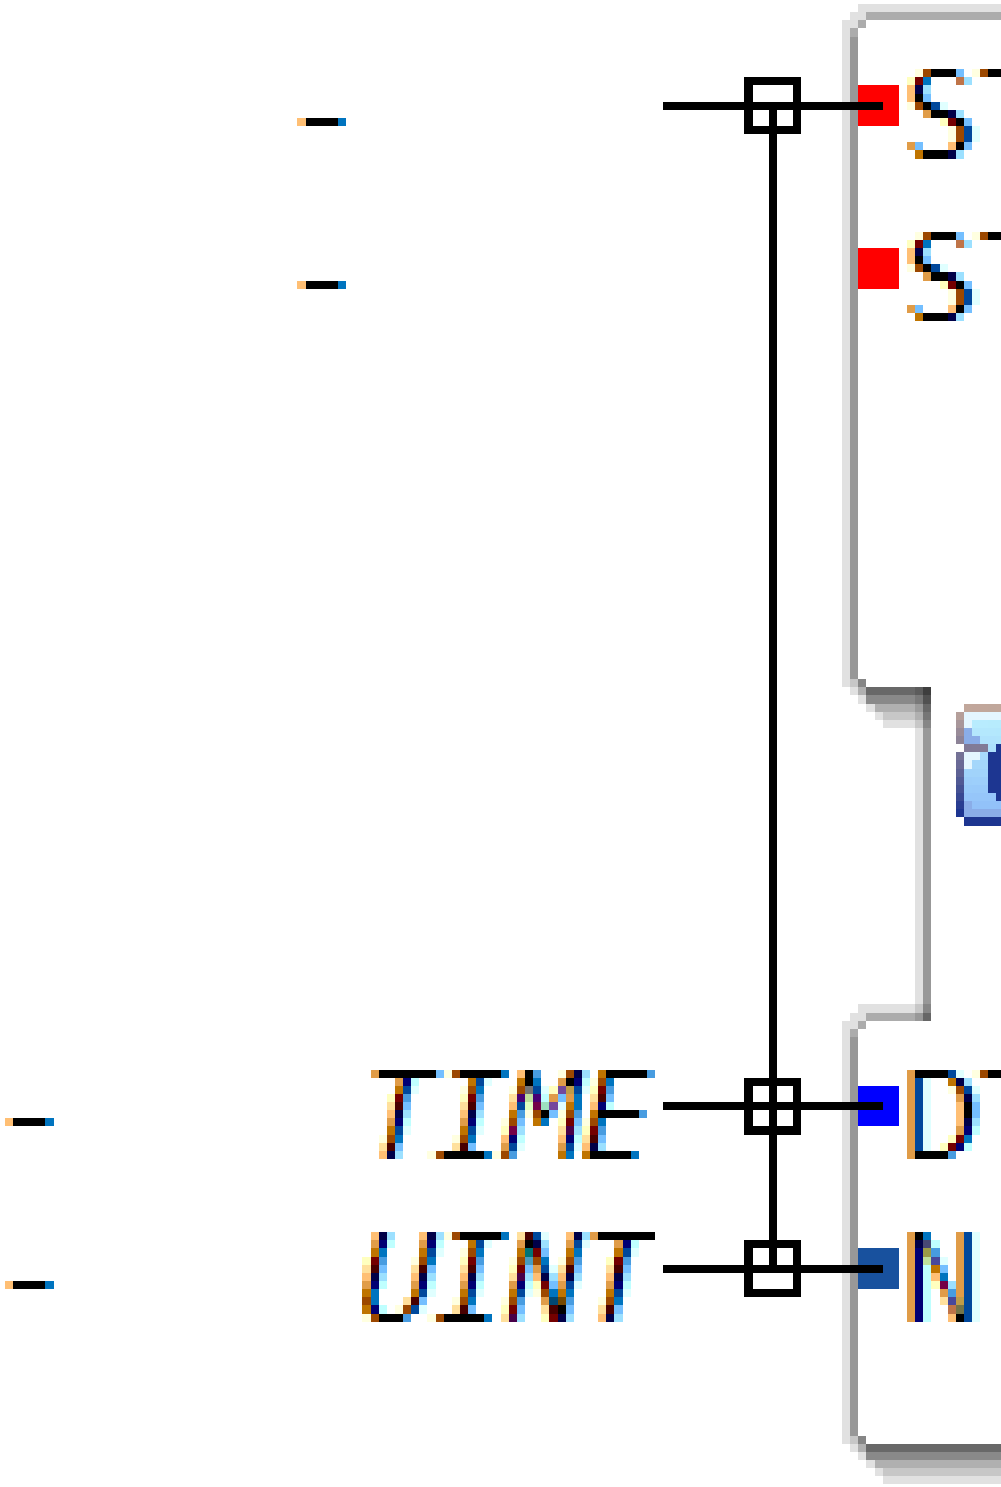
- **8-to-1 Multiplexer**: Combines eight event streams into one.
- **Origin Index**: Indicates which input triggered the event.
- **Stateless**: The function block has no internal memory.
- **Generic Function Block**: The functionality is provided by the generic class `GEN_E_MUX`.

Application Scenarios

- **Keyboard Matrix**: Groups the signals from eight keys into a central evaluation logic.
- **Comprehensive Alarming**: Groups eight different alarms into a central routine, which then processes the specific alarm message based on `K`.
- **Prioritized Command Selection**: Eight command sources are combined, and downstream logic determines the priority based on the index `K`.



🛠️ Related Exercises

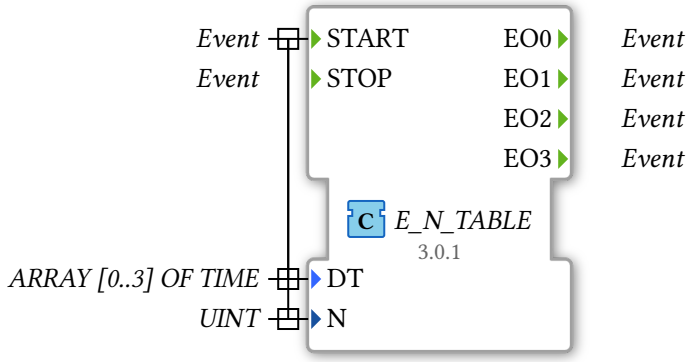


- Exercise_173

Conclusion

The `E_MUX_8` is a useful component for bundling event streams from up to eight sources while simultaneously identifying the event's source. It is the standard counterpart to the `E_DEMUX_8` and is frequently used to reduce wiring complexity and centralize logic.

2.11.3.31 E_N_TABLE



• – ◦ • – ◦ • – ◦ •

Introduction

The `E_N_TABLE` (Event N-Table) is a function block according to IEC 61499 that generates a finite sequence of time-staggered events on separate outputs. Internally, it combines a table-controlled timer (`E_TABLE`) with a demultiplexer (`E_DEMUX`) to create a chain of events, with each event output on its own channel.

Interface Structure

Event Inputs

- **START**: Starts the generation of the event sequence.
- **Related Data**: `DT`, `N`
- **STOP**: Stops the sequence prematurely.

Event Outputs

- **EO0**: Outputs the first event of the sequence (index 0).
- **EO1**: Outputs the second event of the sequence (index 1).
- **EO2**: Outputs the third event of the sequence (index 2).
- **EO3**: Outputs the fourth event of the sequence (index 3).

Data Inputs

- **DT**: An array of durations (data type: `TIME`, size: 4). `DT[i]` defines the delay time to wait *before* the `i`-th event.
- **N**: The total number of events to be generated (data type: `UINT`, max. 4 for this function block).

Functionality

1. **Start of sequence**: A `START` event triggers the internal `E_TABLE` function block. The number of events to be generated is determined by `N`.
2. **First event**: The function block waits for the time interval defined in `DT[0]`. Then, the first event is triggered at output `EO0`.
3. **Subsequent Events**: The function block waits for the time interval defined in `DT[1]` and then triggers the second event at `EO1`. This process repeats for the next events according to the durations in `DT[2]`, `DT[3]`, and so on, until `N` events have been generated.
4. **End of Sequence**: The sequence ends automatically after `N` events have been triggered.
5. **Stop**: A `STOP` event immediately terminates the sequence at any point.

Example:

- `N = 3`
- `DT = [T#2s, T#5s, T#1s]`
- After a `START` event:

1. After 2 seconds, `EO0` is triggered.
2. 5 seconds later, `EO1` is triggered.
3. 1 second later, `EO2` is triggered.
4. The sequence is complete. `EO3` is not triggered.

Technical Features

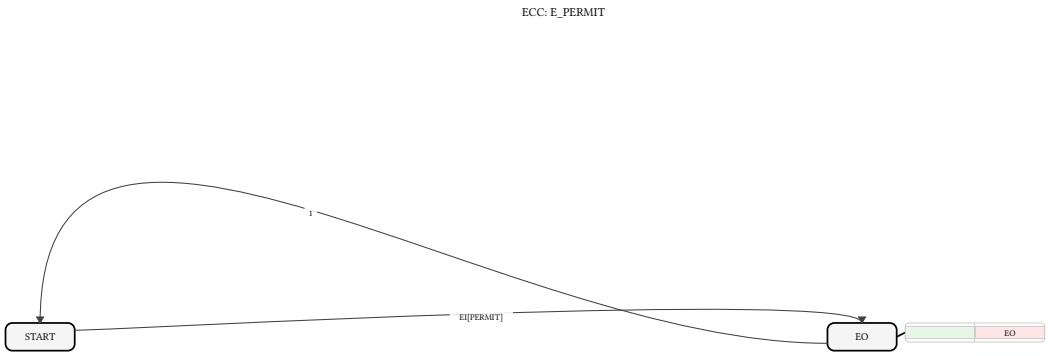
- **Sequence Generator**: Generates a chain of individual, time-staggered events.
- **Demultiplexing**: Each event in the chain is routed to its own dedicated output.
- **Table-driven**: The time intervals between events are not fixed but are read from the `DT` array.

Application Scenarios

- **Control of step sequences**: Each output (`EO0`, `EO1`, ...) can trigger a subsequent step in a process chain.

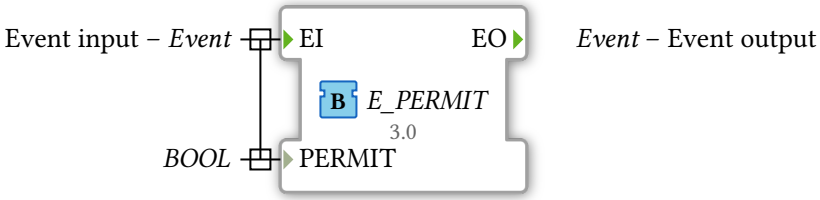
- **Complex control**: Controlling various actuators in a precisely defined temporal sequence (e.g., valves in a rinsing process).
- **Test automation**: Generating a complex, time-defined stimulus sequence for a test object.

🛠️ Related Exercises



- Exercise_093b

Conclusion



The `E_N_TABLE` is a powerful building block for generating complex, time-defined event sequences. Unlike a simple `E_CYCLE`, which only generates a periodic clock signal, `E_N_TABLE` allows the definition of variable time intervals and the distribution of individual sequence events across separate channels. This makes it ideal for controlling sequential processes.

2.11.3.32 E_PERMIT

🎧 Podcast

- The E_PERMIT block: The “gatekeeper” for events in IEC 61499 systems decoded
- Decoding E_PERMIT: The Unsung Hero of Industrial Automation’s Safety and Reliability The E_PERMIT (Event Permit) is a fundamental function block according to IEC 61499 that acts as a controllable “gate” for events. It allows an input event to pass to the output only if an explicit enable condition is met.

- **EI (Event Input)**: The input event to be checked.
- **Associated Data**: `PERMIT`
- **EO (Event Output)**: The event output, which is only triggered if permission has been granted.
- **PERMIT**: The permission condition (data type: `BOOL`).

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

1. **Event Reception**: The function block waits for an event at input `EI`.
2. **Conditional Forwarding**:

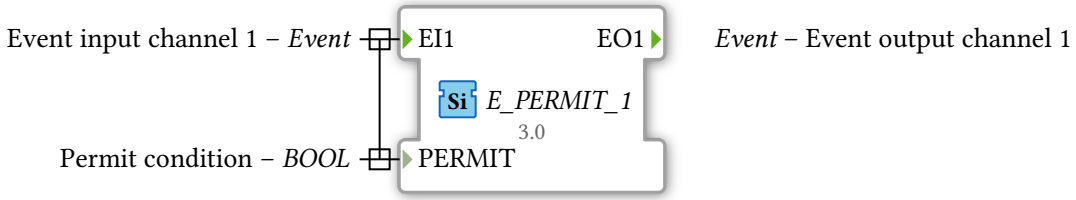
- **If `PERMIT` = `TRUE`**: The event is allowed through and output at `EO`.
- **If `PERMIT` = `FALSE`**: The event is blocked, and nothing happens. Output `EO` is not triggered.

This function block thus acts as a simple monitor for the event flow.

- **Event Gate**: Serves as a fundamental "gate" for controlling event flows.
- **Stateless**: The function block itself has no internal memory; its decision is based solely on the value of `PERMIT` at the moment of the `EI` event.
- **Allowances/Interlocks**: A process step (`EI`) may only be started if a safety allow (`PERMIT`) is present (e.g., safety door closed).
- **Operating Mode Switching**: Commands from a manual controller (`EI`) are only forwarded if the system is in "Manual" mode (`PERMIT` = true).
- **Data Validation**: An event that triggers further data processing is only triggered if a previous data validation was successful (`PERMIT` = true).
- **`E_SWITCH`**: While `E_PERMIT` either passes or blocks an event (1-to-1 or 1-to-0), `E_SWITCH` forwards an event to one of two different outputs (1-to-2). `E_PERMIT` is a gate, and `E_SWITCH` is a switch.
- Exercise_009
- Exercise_080c
- Exercise_094

The `E_PERMIT` block is a fundamental and widely used block for implementing conditions and enable statements in the event-driven logic of IEC 61499. Its simplicity and clear function make it an indispensable tool for creating safe and robust control sequences.

Technical Features



Application Scenarios

Conclusion

2.11.3.33 E_PERMIT_1

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_PERMIT_1` is a function block for the **permissive propagation of one event channel** (generic block). The event `EI1` is forwarded to `EO1` only if the permit condition `PERMIT` is fulfilled. It is the one-channel variant of the generic `E_PERMIT` family.

Interface Structure

Event Inputs

- **EI1**: Event input, channel 1. Associated data: `PERMIT`

Event Outputs

- **EO1**: Event output, channel 1

Data Inputs

- **PERMIT** (`BOOL`): Permit condition

Data Outputs

No data outputs

Adapters

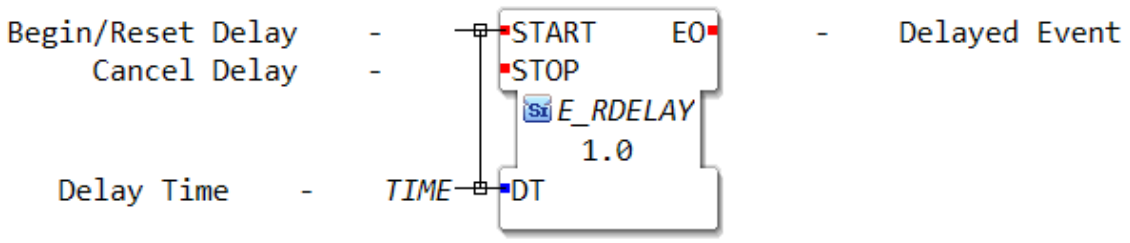
This function block uses no adapters.

How it works

On every `EI1` event, `PERMIT` is evaluated. If `PERMIT = TRUE`, `EO1` is fired; otherwise the event is suppressed.

Technical Details

- Generic block that requires the native implementation `GEN_E_PERMIT` (FORTE).
- Pure event filter: no data is stored or output.
- `PERMIT` is associated with `EI1` and is therefore read anew on every event.
- See also `E_PERMIT` (standard variant).

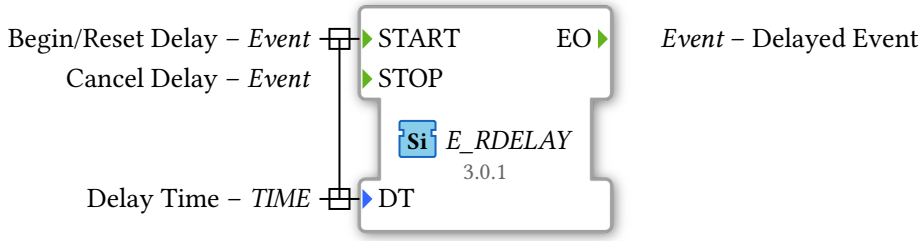


Application Scenarios

- Forwarding events only while a permit is active, e.g. key events only in automatic mode
- Blocking event paths by a status signal

Summary

`E_PERMIT_1` forwards a single event only if the `PERMIT` condition is fulfilled.



2.11.3.34 E_RDELAY

• – ◦ • – ◦ • – ◦ •

Introduction

The **E_RDELAY** (Reloadable Delay) is an extended delay function block according to IEC 61499, which, unlike the simple E_DELAY, enables a reloadable and abortable event delay. Developed under the EPL-2.0 license.

Interface Structure

Event Inputs

- `START`: Starts/Resets the delay (with DT parameter)
- `STOP`: Cancels the active delay

Event Outputs

- `EO`: Delayed output event

Data Inputs

- `DT` (Delay Time): Delay duration (TIME data type)

Operating Principle

1. **Delay Start**:

- On the `START` event, the timer starts with the configured `DT` time
- New `START` resets the timer during an active delay

1. **Delay Termination**:

- `STOP` immediately terminates the active delay
- No `EO` event is generated

1. **Delay Completion**:

- `EO` is triggered once after exactly `DT`
- Immediate triggering occurs if DT ≤ T#0s

Service Sequences (according to the XML specification)

1. **event_delay**:

- Normal delay with START ⟶ EO

1. **delay_canceled**:

- START followed by STOP (no EO)

1. **reload_delay**:

- Multiple START events reload (reset) the delay; only one EO is triggered

Technical Special Features

✓ **Reloadable Delay** (Reset Function) ✓ **Cancellable** during runtime ✓ **Deterministic Timing Behavior** ✓ **Real-Time Capable** Implementation

Application Scenarios

- **Machine Safety**: Delayed Shutdown Sequences
- **Process Control**: Time-Controlled State Transitions
- **Alarm Systems**: Fault Message Delay
- **Robot Control**: Motion Sequence Timing

⚖️ **Comparison with E_DELAY**

Feature	E_RDELAY	E_DELAY

Reset Function	✓ (via START)	❌
Multiple Triggers	Only 1 EO	Only 1 EO

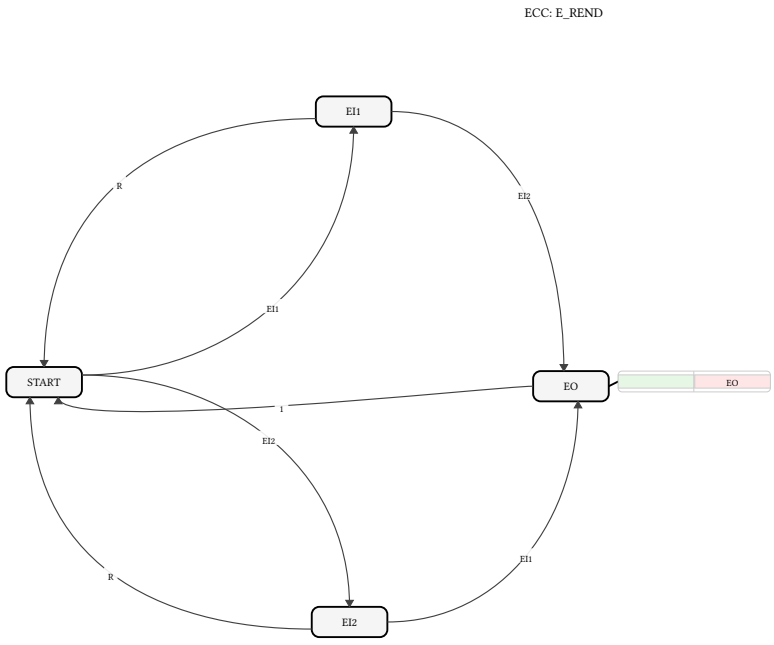
Conclusion



The E_RDELAY function block extends the classic delay function with essential, industry-ready features:

- Flexible reconfiguration during operation
- Safe termination of time sequences
- Standardized service interfaces

Thanks to its XML-based specification, the function block is particularly well-suited for use in distributed control systems. The implemented version offers reliable timing control for critical automation processes.

🎧 Podcast

- E_REND: Event Synchronization in IEC 61499
- E_REND: Event Synchronization in IEC 61499

Introduction

The `E_REND` (Event Rendezvous) is a function block according to IEC 61499 that serves as a synchronization point for two different event streams. It only fires an output event when it has received at least one event from each of its inputs. This corresponds to a logical AND operation over time.

Interface Structure

Event Inputs:

- **EI1**: The first event input.
- **EI2**: The second event input.
- **R (Reset)**: Resets the function block to its initial state.

Event Outputs:

- **EO (Event Output)**: Triggered after both `EI1` and `EI2` have been received at least once since the last reset.

Functionality

1. **Waiting for Events**: In its initial state, the function block waits for events at `EI1` and `EI2`.
2. **Store the First Event**: When an event arrives at the first input (e.g., `EI1`), the function block stores this internally and then waits for the event at the second input (`EI2`).
3. **Rendezvous and Triggering**: As soon as the second event (`EI2`) arrives, the "rendezvous" condition is met. The function block immediately triggers the output event `EO`.
4. **Automatic Reset**: Immediately after `EO` is triggered, the function block automatically resets to its initial state and waits for the next pair of events, `EI1` and `EI2`.
5. **External Reset**: An event at the `R` input resets the function block to its initial state at any time, discarding all previously recorded but incomplete event pairs.

Important: The input events `EI1` and `EI2` do **not** have to arrive simultaneously. The order in which they arrive is also irrelevant.

Technical Features

- **Static**: Unlike a `E_MERGE` (OR), `E_REND` has an internal state to remember the arrival of the first event.
- **Synchronization**: Used to synchronize two asynchronous event flows.

Application Scenarios

- **Process Synchronization**: A subsequent process step (`EO`) may only start when two independent preconditions are met (e.g., "Component clamped" (`EI1`) and "Safety door closed" (`EI2`)).
- **Acknowledgement**: An action is only executed when both a command (`EI1`) and manual acknowledgement by an operator (`EI2`) are present.
- **Material Flow**: A conveyor belt stops (`EO`) when both the front and rear sensors have detected a long component.

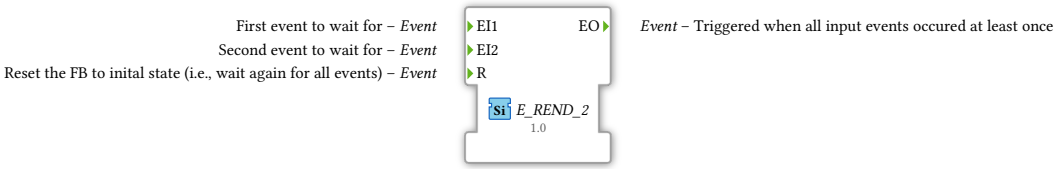
Conclusion



The `E_REND` block is a critical tool for process synchronization in IEC 61499. It provides a robust method to ensure that multiple conditions are met before a subsequent action is triggered. Its ability to "remember" the arrival of events makes it significantly more powerful than simple logical connections and is fundamental for controlling asynchronous and parallel processes.

2.11.3.36 E_REND_2

• – ◦ • – ◦ • – ◦ •

Introduction

`E_REND_2` is the generic 2-input variant of the rendezvous block `E_REND` (2 inputs). It only triggers `EO` once it has received at least one event since the last reset from **all** 2 inputs (`EI1`, `EI2`) — a logical AND across 2 asynchronous event streams.

Interface Structure

Event Inputs

- **EI1**: Event input 1.
- **EI2**: Event input 2.
- **R (Reset)**: Resets the block to its initial state, discarding all events recorded so far.

Event Outputs

- **EO**: Triggered once all 2 inputs have fired at least once since the last reset.

Functionality

`E_REND_2` is implemented as a generic function block (`eclipse4diac::core::GenericClassName = 'GEN_E_REND'`) — the same C++ implementation underlies all `E_REND_n` variants; only the number of inputs differs. Internally, the block remembers which of the `EI1`…`EI2` inputs have already received at least one event. Once all 2 inputs are marked, `EO` is triggered and the internal marker is reset. An `R` event resets the marker at any time without triggering `EO`.

Technical Features

- **Generic implementation**: Like `E_REND` (2 inputs) itself, `E_REND_2` is based on the same generic `GEN_E_REND` C++ class; the input count is fixed at compile time via the type definition.
- **Order-independent**: The inputs `EI1`, `EI2` do not need to arrive in any particular order.
- **Automatic reset after triggering**: After every `EO`, the block starts over from scratch.

State Overview

The block internally tracks a bitmask of inputs that have already arrived; once the mask is complete, `EO` is triggered and the mask is cleared.

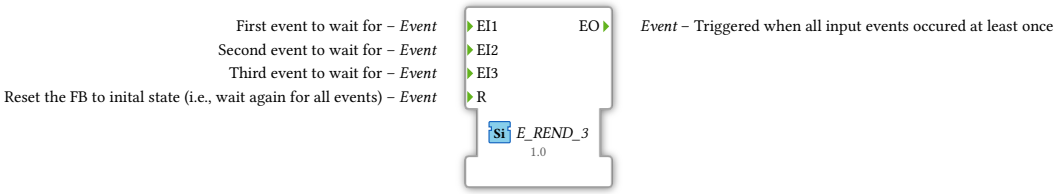
Application Scenarios

- **Synchronizing 2 independent preconditions** before a follow-up step is triggered (e.g. 2 sensors must all have fired before a machine continues).
- **Extending `E_REND`** to more than two event sources without having to cascade multiple `E_REND` blocks.

Comparison with similar function blocks

- **`E_REND`**: the 2-input base variant.
- `E_REND_3`, `E_REND_4`: the same generic implementation with a different input count.
- **`E_MERGE_2`**: the logical OR of multiple event inputs (fires on each individual event instead of only after all of them).

Conclusion



`E_REND_2` extends the rendezvous principle of `E_REND` to 2 simultaneously synchronized event streams and is the generic, 2-input-instantiated variant of the same underlying implementation.

2.11.3.37 E_REND_3

• – ◦ • – ◦ • – ◦ •

Introduction

`E_REND_3` is the generic 3-input variant of the rendezvous block `E_REND` (2 inputs). It only triggers `EO` once it has received at least one event since the last reset from **all** 3 inputs (`EI1`, `EI2`, `EI3`) — a logical AND across 3 asynchronous event streams.

Interface Structure

Event Inputs

- **EI1**: Event input 1.
- **EI2**: Event input 2.
- **EI3**: Event input 3.
- **R (Reset)**: Resets the block to its initial state, discarding all events recorded so far.

Event Outputs

- **EO**: Triggered once all 3 inputs have fired at least once since the last reset.

Functionality

`E_REND_3` is implemented as a generic function block (`eclipse4diac::core::GenericClassName = 'GEN_E_REND'`) — the same C++ implementation underlies all `E_REND_n` variants; only the number of inputs differs. Internally, the block remembers which of the `EI1`…`EI3` inputs have already received at least one event. Once all 3 inputs are marked, `EO` is triggered and the internal marker is reset. An `R` event resets the marker at any time without triggering `EO`.

Technical Features

- **Generic implementation**: Like `E_REND` (2 inputs) itself, `E_REND_3` is based on the same generic `GEN_E_REND` C++ class; the input count is fixed at compile time via the type definition.
- **Order-independent**: The inputs `EI1`, `EI2`, `EI3` do not need to arrive in any particular order.
- **Automatic reset after triggering**: After every `EO`, the block starts over from scratch.

State Overview

The block internally tracks a bitmask of inputs that have already arrived; once the mask is complete, `EO` is triggered and the mask is cleared.

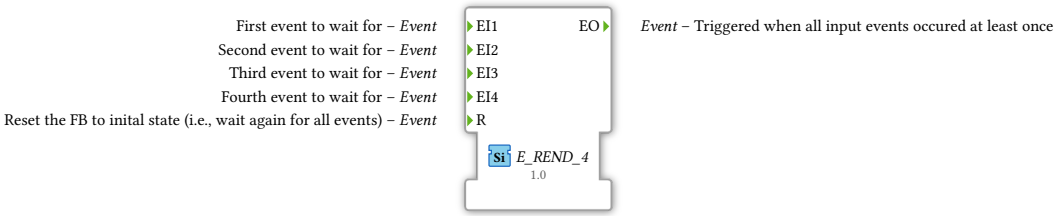
Application Scenarios

- **Synchronizing 3 independent preconditions** before a follow-up step is triggered (e.g. 3 sensors must all have fired before a machine continues).
- **Extending `E_REND`** to more than two event sources without having to cascade multiple `E_REND` blocks.

Comparison with similar function blocks

- **`E_REND`**: the 2-input base variant.
- `E_REND_2`, `E_REND_4`: the same generic implementation with a different input count.
- **`E_MERGE_3`**: the logical OR of multiple event inputs (fires on each individual event instead of only after all of them).

Conclusion



`E_REND_3` extends the rendezvous principle of `E_REND` to 3 simultaneously synchronized event streams and is the generic, 3-input-instantiated variant of the same underlying implementation.

2.11.3.38 E_REND_4

• – ◦ • – ◦ • – ◦ •

Introduction

`E_REND_4` is the generic 4-input variant of the rendezvous block `E_REND` (2 inputs). It only triggers `EO` once it has received at least one event since the last reset from **all** 4 inputs (`EI1`, `EI2`, `EI3`, `EI4`) — a logical AND across 4 asynchronous event streams.

Interface Structure

Event Inputs

- **EI1**: Event input 1.
- **EI2**: Event input 2.
- **EI3**: Event input 3.
- **EI4**: Event input 4.
- **R (Reset)**: Resets the block to its initial state, discarding all events recorded so far.

Event Outputs

- **EO**: Triggered once all 4 inputs have fired at least once since the last reset.

Functionality

`E_REND_4` is implemented as a generic function block (`eclipse4diac::core::GenericClassName = 'GEN_E_REND'`) — the same C++ implementation underlies all `E_REND_n` variants; only the number of inputs differs. Internally, the block remembers which of the `EI1`…`EI4` inputs have already received at least one event. Once all 4 inputs are marked, `EO` is triggered and the internal marker is reset. An `R` event resets the marker at any time without triggering `EO`.

Technical Features

- **Generic implementation**: Like `E_REND` (2 inputs) itself, `E_REND_4` is based on the same generic `GEN_E_REND` C++ class; the input count is fixed at compile time via the type definition.
- **Order-independent**: The inputs `EI1`, `EI2`, `EI3`, `EI4` do not need to arrive in any particular order.
- **Automatic reset after triggering**: After every `EO`, the block starts over from scratch.

State Overview

The block internally tracks a bitmask of inputs that have already arrived; once the mask is complete, `EO` is triggered and the mask is cleared.

Application Scenarios

- **Synchronizing 4 independent preconditions** before a follow-up step is triggered (e.g. 4 sensors must all have fired before a machine continues).
- **Extending `E_REND`** to more than two event sources without having to cascade multiple `E_REND` blocks.

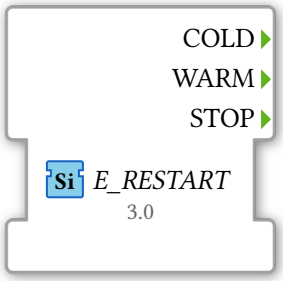
Comparison with similar function blocks

- **`E_REND`**: the 2-input base variant.
- `E_REND_2`, `E_REND_3`: the same generic implementation with a different input count.
- **`E_MERGE_4`**: the logical OR of multiple event inputs (fires on each individual event instead of only after all of them).

Conclusion

`E_REND_4` extends the rendezvous principle of `E_REND` to 4 simultaneously synchronized event streams and is the generic, 4-input-instantiated variant of the same underlying implementation.

2.11.3.39 E_RESTART



```
COLD  -  Information on cold restart
WARM  -  Information on warm restart
STOP  -  information that the resource is to be stopped
```

• – ◦ • – ◦ • – ◦ •

Introduction

The **E_RESTART** is a special service interface function block according to IEC 61499 (Annex A) for controlling restart sequences in distributed automation systems. The block serves as an interface between resources and higher-level controllers.

Event – Information on cold restart
Event – Information on warm restart
Event – information that the resource is to be stopped

Interface Structure

Event Outputs

- `COLD`: Signals a cold start (full reset)
- `WARM`: Indicates a warm start (partial reset)
- `STOP`: Indicates an upcoming stop command

Service Interfaces

- Left: E_RESTART (FB interface)
- Right: RESOURCE (Device interface)

Functionality

1. **Cold Start Sequence**:

- Upon an external `start` command to the resource
- Triggers the `COLD` event

1. **Warm Start Sequence**:

- Upon `restart` resource command
- Generation of the `WARM` event

1. **Stop Sequence**:

- Upon receiving the `stop` signal
- Output of the `STOP` event

Service Sequences (XML Specification)

1. **cold_restart**:

- `start` ⟶ `COLD` (Full reinitialization)

1. **warm_restart**:

- `restart` ⟶ `WARM` (State-preserving restart)

1. **stopping**:

- `stop` ⟶ `STOP` (Ordered Shutdown)

Technical Features

✓ **Standardized Restart Control** according to IEC 61499 Annex A ✓ **Three Operating Modes** (Cold/Warm/Stop) ✓ **Cross-Resource** Consistency ✓ **EPL 2.0 Open-Source** Implementation

Application Scenarios

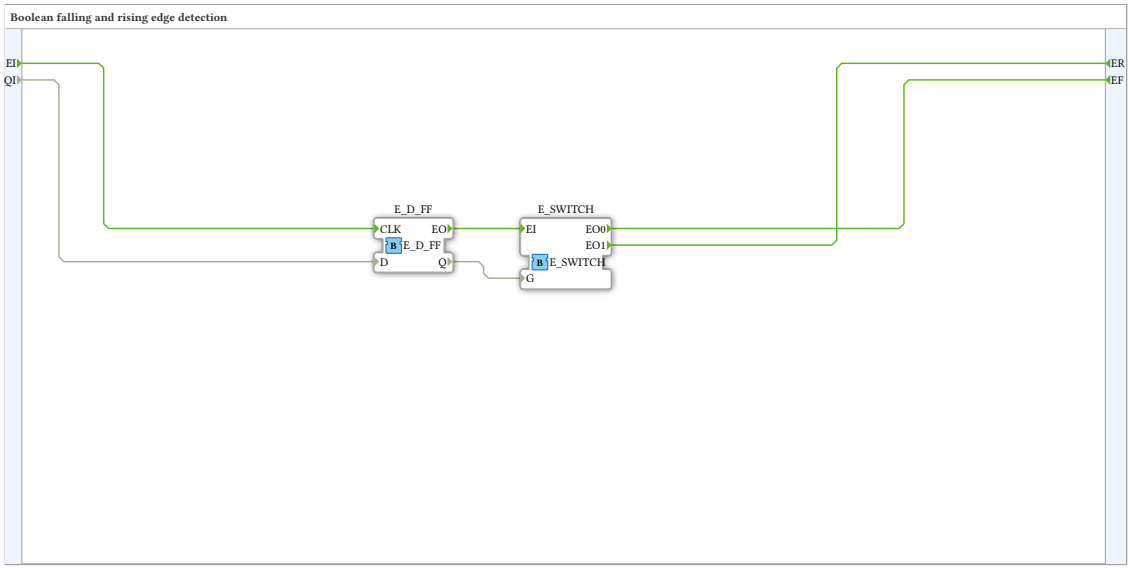
- **Field Device Control**: Ordered Reinitialization
- **System Recovery**: Automatic Restart Routines
- **Energy Management**: Scheduled Shutdown
- **Safety-Critical Systems**: State-Safe Restarts

⚖️ Comparison with Similar Function Blocks

Feature	E_RESTART	E_CYCLE	E_DELAY
Purpose	System Control	Time Control	Event Delay
Event Type	Control Commands	Periodic	One-Time
Standard	Annex A	Core	Core

🛠️ Related Exercises

- Exercise_174

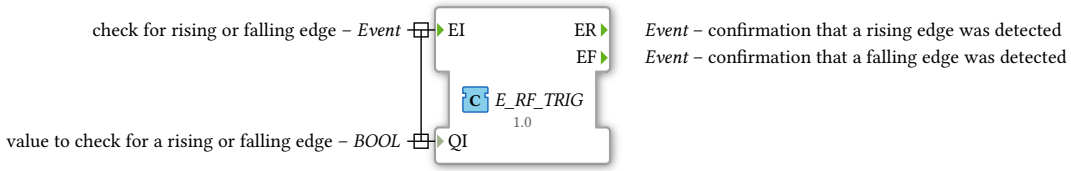


Conclusion

The E_RESTART block offers a standards-compliant solution for critical system control tasks:

- Standardized restart management
- Separation of cold/warm start logic
- Reliable signal forwarding

It particularly enables the development of robust, fault-tolerant control systems. The clear service interface according to IEC 61499 Annex A ensures interoperability across different device platforms.



2.11.3.40 E_RF_TRIG

• – ○ • – ○ • – ○ •

Introduction

E_RF_TRIG (rising/falling trigger) detects both rising and falling edges of a BOOL value and reports them via two separate output events. It combines the functionality of E_R_TRIG (rising edge) and E_F_TRIG (falling edge) in a single block.

Interface Structure

Event Inputs

- **EI**: Checks QI for a rising or falling edge.
  - **Connected data**: QI

Event Outputs

- **ER**: Confirms a detected rising edge (QI from FALSE to TRUE).
- **EF**: Confirms a detected falling edge (QI from TRUE to FALSE).

Data Inputs

- **QI** (BOOL): The value to check for edge transitions.

Functionality

Internally, an E_D_FF stores the last known value of QI and, on every EI event, delivers the new value via its EO to an E_SWITCH. Depending on the current Q value (G input), this forwards the event either to EO1 (⟶ ER, rising edge) or EO0 (⟶ EF, falling edge). Since E_D_FF only triggers EO on an actual change of Q, neither ER nor EF is triggered for an unchanged QI.

Technical Features

- **Composed of two standard blocks**: E_D_FF (change detection) + E_SWITCH (branch by value), no ECC of its own.
- **Only on actual change**: Repeated EI events with unchanged QI produce no output event, since E_D_FF already filters internally.
- **Basis for E_TLIM**: There, E_RF_TRIG is used to detect the start (ER) and end (EF) of a TRUE state.

State Overview

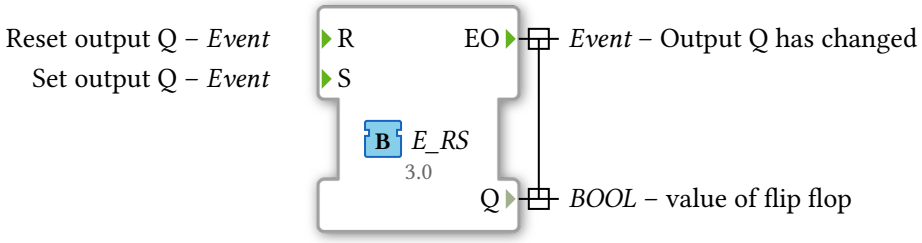
Stateless wiring logic: the only stored state is the last known QI value inside the internal E_D_FF.

Application Scenarios

- **Edge detection without two separate blocks**: Wherever both the start and the end of a TRUE state need to be detected (e.g. start and end of a signal), E_RF_TRIG saves a second block compared to using E_R_TRIG/E_F_TRIG separately.
- **Duration measurement of states**: Combined with E_DELAY/E_SR (see E_TLIM) to measure how long a BOOL signal remains in a state.

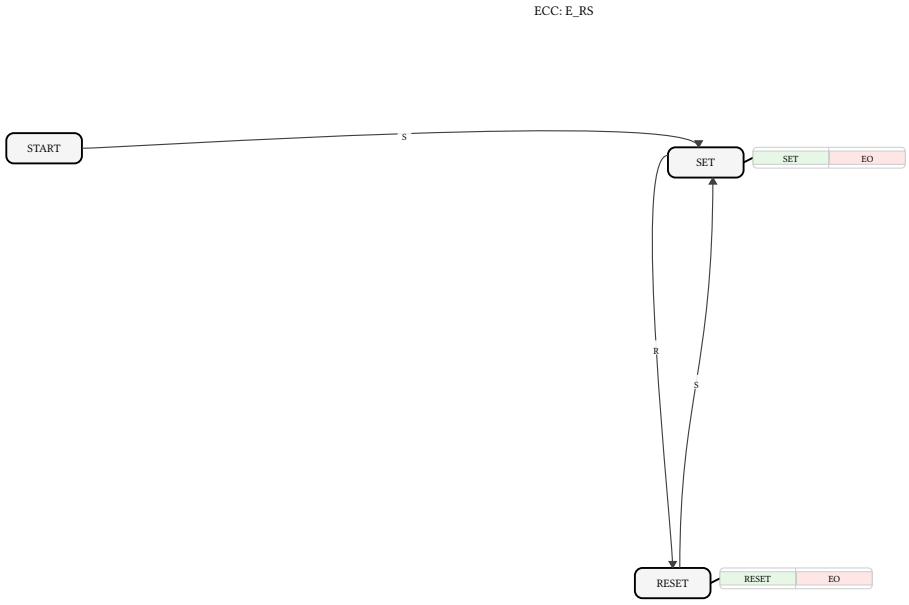
Comparison with similar function blocks

- **E_R_TRIG**: detects only rising edges.
- **E_F_TRIG**: detects only falling edges.
- E_TLIM: uses E_RF_TRIG internally to time-limit a TRUE state.



Conclusion

E_RF_TRIG provides compact, combined edge detection for rising and falling transitions of a BOOL signal and is a building block for more complex timing and state logic such as E_TLIM.



2.11.3.41 E_RS

Introduction

The `E_RS` (Event-driven RS Flip-Flop) is an event-driven, bistable function block according to IEC 61499. It serves as a basic memory element controlled by separate "Set" and "Reset" events. Its output `Q` retains its state until an opposing event occurs.

Interface Structure

Event Inputs:

- **S (Set)**: Sets the output `Q` to `TRUE`.
- **R (Reset)**: Sets the output `Q` to `FALSE`.

Event Outputs:

- **EO (Event Output)**: Triggered when the state of `Q` changes.
- **Associated Data**: `Q`

Data Outputs:

- **Q**: The current state of the flip-flop (data type: `BOOL`).

Functionality

The `E_RS` block functions as a simple latch:

1. **Set**: When an event arrives at the input `S`, the output `Q` is set to `TRUE`. If `Q` was previously `FALSE`, the `EO` event is triggered.

2. **Reset**: When an event arrives at the input R, the output Q is set to FALSE. If Q was previously TRUE, the EO event is triggered.
3. **Save**: Between events, Q retains its last set state.

Technical Features and Standards Comparison

According to **DIN EN 61499-1 (Table A.1, Note 8)**, the implementation of this function block is identical to E_SR. Both function blocks (E_RS and E_SR) exist to maintain consistency with the types in IEC 61131-3, even though IEC 61499 does not have an inherent "dominance" of events, as is the case with level-controlled inputs in classic PLC programming.

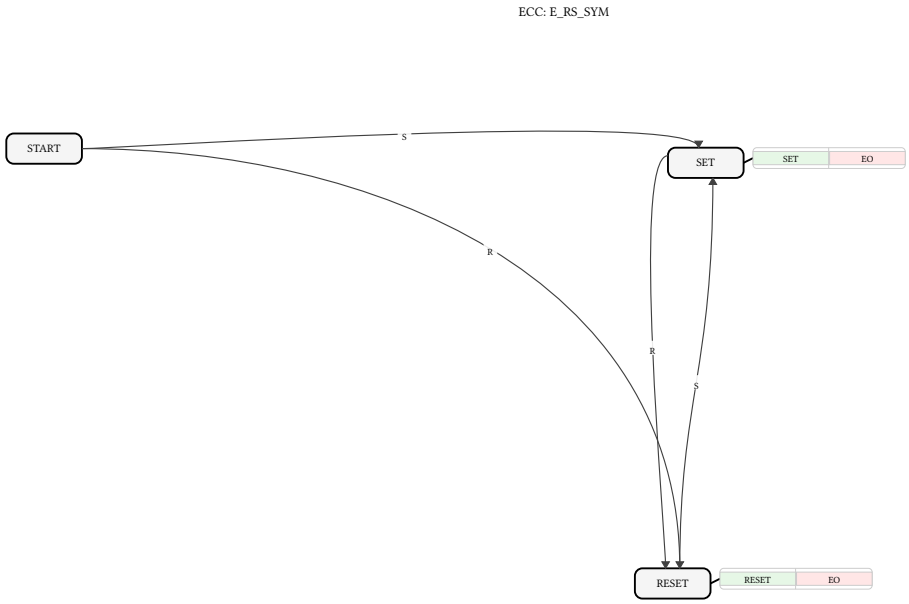
- **Comparison to IEC 61131-3**: See RS (Bistable, priority reset). While in IEC 61131-3 the RS function block has a defined "reset dominance" (if R and S are TRUE simultaneously, R wins), the behavior in IEC 61499 for closely spaced events depends on the processing order of the runtime environment (ECC). Since events are transient, there is no permanent conflict between two static signals.
- **Functional Identity**: E_RS and E_SR are technically identical. Their graphical representation and naming conventions simply follow the established naming conventions to facilitate orientation for developers.
- **Change Detection**: The EO output is only triggered by an actual state change.

Application Scenarios

- **Start/Stop Logic**: A "Start" button is connected to S, and a "Stop" button to R, to control the state of a machine.
- **Start/Stop Logic**: - **Error Storage**: An error event sets the function block (S), which stores the error state until it is explicitly acknowledged by an operator or another process (R).
- **Mode Storage**: Stores the current operating mode of a system (e.g., "Manual" vs. "Automatic").

Related Function Blocks

- **E_SR**: Functionally identical to E_RS, with the inputs in the symbol swapped.
- **E_D_FF**: Clock-based storage (Data Latch). E_D_FF takes the value at the D input on a CLK event.

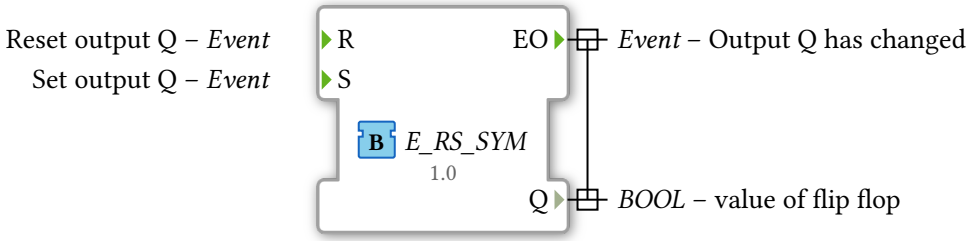


🛠️ Related Exercises

- Exercise_006b
- Exercise_020a
- Exercise_020b
- Exercise_020d

Conclusion

The E_RS block is a fundamental memory block in IEC 61499. It is ideal for simple state storage where a state is set by one event and explicitly reset by another. The lack of guaranteed set or reset dominance for simultaneous events must be considered in critical applications.



2.11.3.42 E_RS_SYM

• – ◦ • – ◦ • – ◦ •

Introduction

`E_RS_SYM` (Event-driven RS Flip-Flop, symmetric start-up behaviour) is an event-driven, bistable memory element according to IEC 61499. It behaves functionally like E_RS/E_SR, but differs in its initial state: while `E_RS`/`E_SR` only produce a defined output after the first `S` or `R` event, `E_RS_SYM` already reacts symmetrically to both events in its initial state `START` and immediately transitions into the matching `SET` or `RESET` state.

Interface Structure

Event Inputs

- **S (Set)**: Sets output `Q` to `TRUE`.
- **R (Reset)**: Sets output `Q` to `FALSE`.

Event Outputs

- **EO (Event Output)**: Triggered after every `S` or `R` event.
  - **Connected data**: `Q`

Data Outputs

- **Q**: The current state of the flip-flop (data type: `BOOL`).

Functionality

The ECC has three states: `START`, `SET`, and `RESET`. From `START`, both an `S` and an `R` event lead to a defined follow-up state (`SET` or `RESET`) — unlike `E_RS`, where `START` only reacts to one of the two events and the

other has no effect initially. From SET and RESET, the block behaves like a classic RS flip-flop: R switches from SET to RESET, S from RESET to SET. Every state change runs the SET (Q := TRUE) or RESET (Q := FALSE) algorithm and triggers EO.

Technical Features

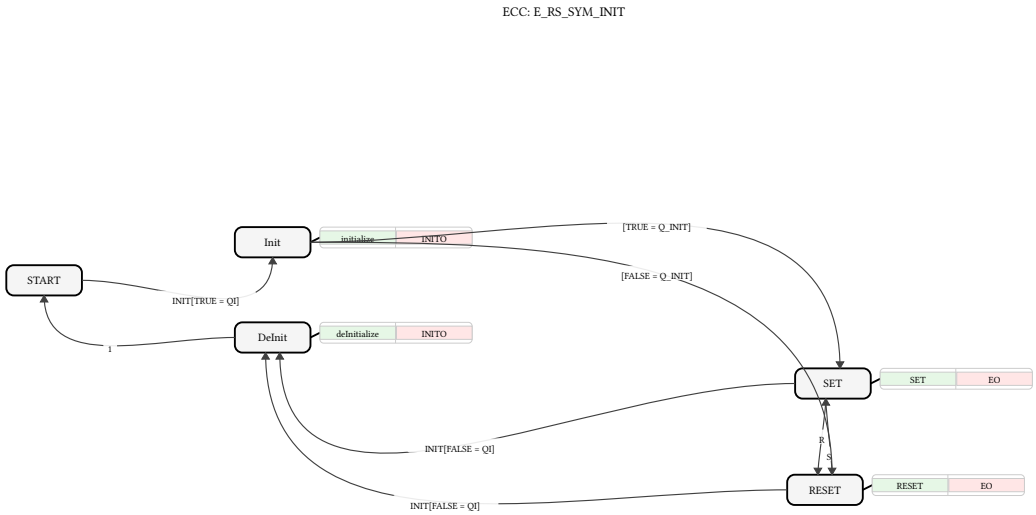
- **Symmetric start-up behaviour**: The key difference to E_RS/E_SR lies in the START state: both input events (S and R) lead to a defined transition there, so a correct Q value is set regardless of which event arrives first after startup.
- **No init mechanism**: Unlike E_RS_SYM_INIT, this block has no INIT/INITO interface; the start state results solely from the first S or R event received.

State Overview

State	Meaning
START	Initial state, waits symmetrically for S or R
SET	Q = TRUE, reachable from START (via S) or RESET (via S)
RESET	Q = FALSE, reachable from START (via R) or SET (via R)

Application Scenarios

- **Start/stop logic with a guaranteed initial state**: Wherever it is unpredictable after an application restart whether a set or a reset signal arrives first, but a correct Q value is still required immediately.
- **Fault storage**: Like E_RS, but with the additional guarantee that even a first R event (e.g., an acknowledgment before the first fault) correctly results in Q = FALSE.

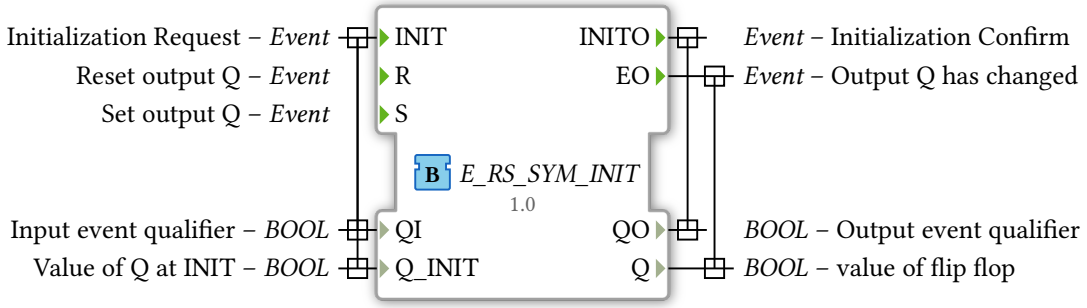


Comparison with similar function blocks

- **E_RS** / **E_SR**: functionally nearly identical, but without symmetric start-up behaviour — in the initial state only one of the two events has an effect.
- **E_RS_SYM_INIT**: the same base functionality, extended with an explicit INIT/INITO interface for setting a defined start value.
- **E_SR_SYM**: functionally identical, only the order of S/R in the interface definition is swapped (naming convention analogous to E_RS/E_SR).

Conclusion

E_RS_SYM provides a bistable memory element with guaranteed, well-defined behaviour from the very first event received, making it suitable wherever the initial-state behaviour of E_RS/E_SR is insufficient.



2.11.3.43 E_RS_SYM_INIT

• – ○ • – ○ • – ○ •

Introduction

`E_RS_SYM_INIT` extends E_RS_SYM with an explicit `INIT`/`INITO` interface: instead of the start value resulting purely from the first `S` or `R` event, it can be initialized (via `INIT`) with a defined value `Q_INIT`, or deinitialized via `QI = FALSE`.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `QI` and `Q_INIT`.
- **S (Set)**: Sets output `Q` to `TRUE`.
- **R (Reset)**: Sets output `Q` to `FALSE`.

Event Outputs

- **INITO**: Confirms (de-)initialization, carries `QO`.
- **EO**: Triggered after every `S` or `R` event, carries `Q`.

Data Inputs

- **QI** (BOOL): Input event qualifier — `TRUE` initializes, `FALSE` deinitializes.
- **Q_INIT** (BOOL): The value `Q` is set to during initialization.

Data Outputs

- **QO** (BOOL): Output event qualifier, mirrors `QI`.
- **Q** (BOOL): The current state of the flip-flop.

Functionality

From `START`, `INIT` with `QI = TRUE` leads into state `Init`, which sets `QO := QI` and triggers `INITO`; from there, depending on `Q_INIT`, it moves directly to `SET` (`Q_INIT = TRUE`) or `RESET` (`Q_INIT = FALSE`) — without triggering `EO`. From `SET`/`RESET`, the block behaves like E_RS_SYM: `S` switches to `SET`, `R` to `RESET`, each triggering `EO`. A subsequent `INIT` with `QI = FALSE` leads from `SET` or `RESET` into state `DeInit` (sets `QO := FALSE`, triggers `INITO`) and from there back to `START`.

Technical Features

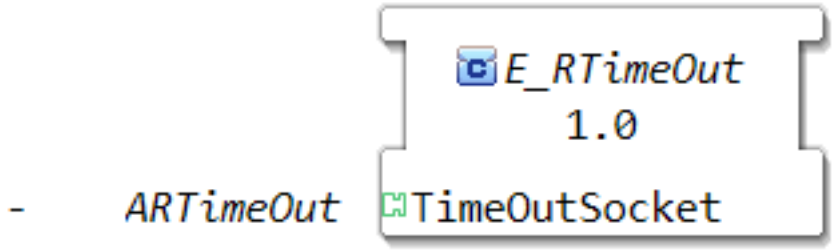
- **QI as init/deinit switch**: `QI = TRUE` initializes the block with `Q_INIT`, `QI = FALSE` deinitializes it and returns it to the unconfigured `START` state.
- **Separate event channels**: Initialization (`INIT`/`INITO`) is fully separated from the running set/reset logic (`S`/`R`/`EO`) — an initialization during runtime deliberately resets `Q`, confirmed via `INITO` rather than `EO`.

State Overview

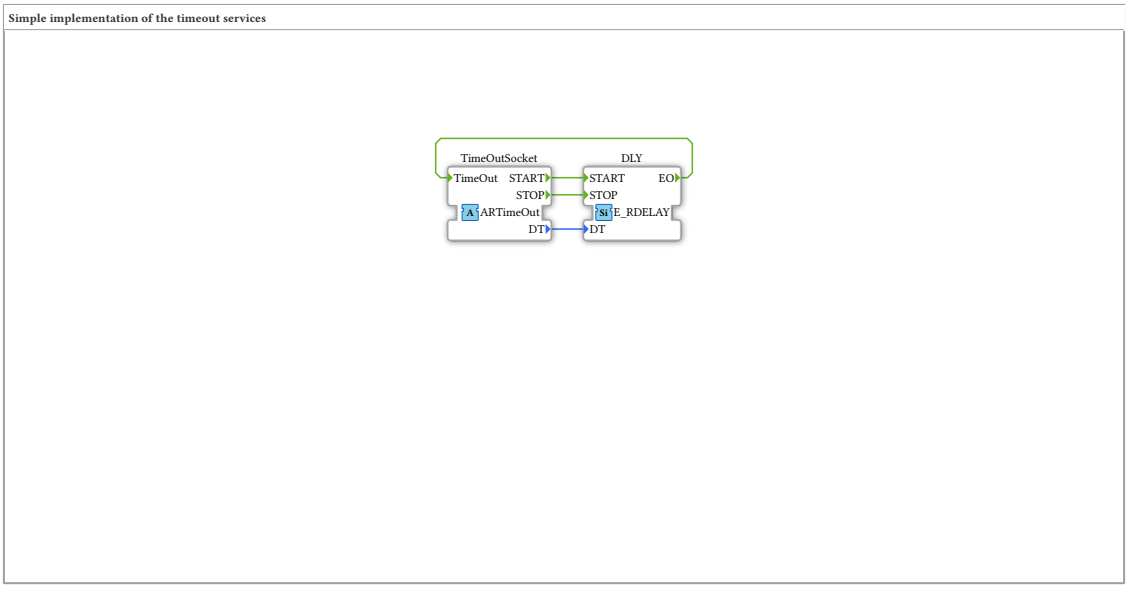
State	Meaning
START	Unconfigured initial state
Init	Initialization in progress, `QO := QI`
DeInit	Deinitialization in progress, `QO := FALSE`
SET	`Q = TRUE`
RESET	`Q = FALSE`

Application Scenarios

- **Well-defined startup with a preset value**: The start value of `Q` should come from a configuration variable (`Q_INIT`) at system start, instead of depending on which of `S`/`R` happens to arrive first.
- **Controlled reset of entire subnetworks**: `INIT`/`QI = FALSE` can be used to deliberately deinitialize the block, e.g. when disabling part of an FB network.



Comparison with similar function blocks

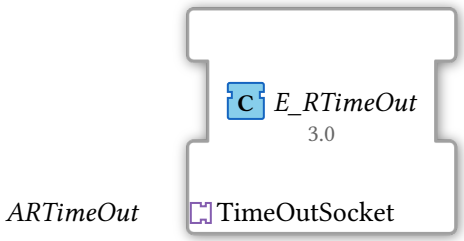


- E_RS_SYM: the same base functionality without an `INIT`/`INITO` interface.
- E_SR_SYM_INIT: functionally identical, only the order of `S`/`R` in the interface is swapped.
- E_T_FF_INIT: the same INIT/DeInit structure, but with toggle instead of set/reset behaviour during normal operation.

Conclusion

`E_RS_SYM_INIT` provides a bistable memory element with a deliberately configurable start value, making it suitable for applications where the pure chance of the first set/reset event is not sufficient.

2.11.3.44 E_RTimeOut (Resettable Timeout Service)



• – ○ • – ○ • – ○ •

Introduction

The **E_RTimeOut** is a special function block according to IEC 61499-2. It implements a resettable timeout service by internally using an E_RDELAY block.

Structure and Interfaces

Adapter Interface (Socket Perspective)

The block uses a **socket** named `TimeOutSocket` of type `ARTimeOut` (`iec61499::events::ARTimeOut`); the block has no other event or data connections. Since it is a socket, the signal directions are inverted compared to the adapter definition (plug):

- **Inputs (received from the socket)**:
- `START`: Starts or resets the internal timer.
- `STOP`: Stops the internal timer.
- `DT` (TIME): The delay time to use.
- **Output (sent to the socket)**:
- `TimeOut`: Signaled to the connected plug after the time has elapsed.

Internal Components

- `DLY` (E_RDELAY): Core component for time control

Functionality

1. **Timeout Initialization**:

- The timer starts when the `START` event occurs on the socket.
- Uses the configured `DT` value.

1. **Timeout Reset**:

- A new `START` event resets the running timer.
- Uses the new `DT` value.

1. **Timeout Termination**:

- The `STOP` event terminates the active timer.

1. **Timeout Triggering**:

- After `DT` expires, the `TimeOut` event is generated
- Signaled via the adapter socket

Technical Features

✓ **Resettable Timeout Function**
  ✓ **Adapter-Based Interface** (ARTimeOut)
  ✓ **Internal E_RDELAY Implementation**
  ✓ **IEC 61499-2 Compliant**

Application Scenarios

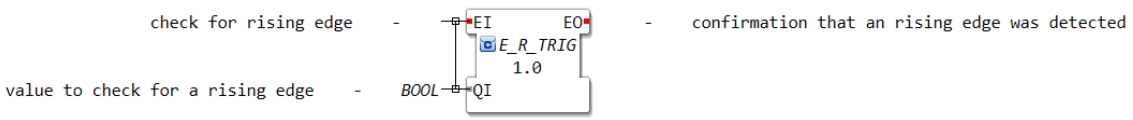
- **Network Communication**: Response Timeout Monitoring
- **Machine Safety**: Monitoring of Motion Periods
- **Process Control**: Time-Limited Operation Control
- **Device Control**: Watchdog Functionality

⚖️ **Comparison with Similar Components**

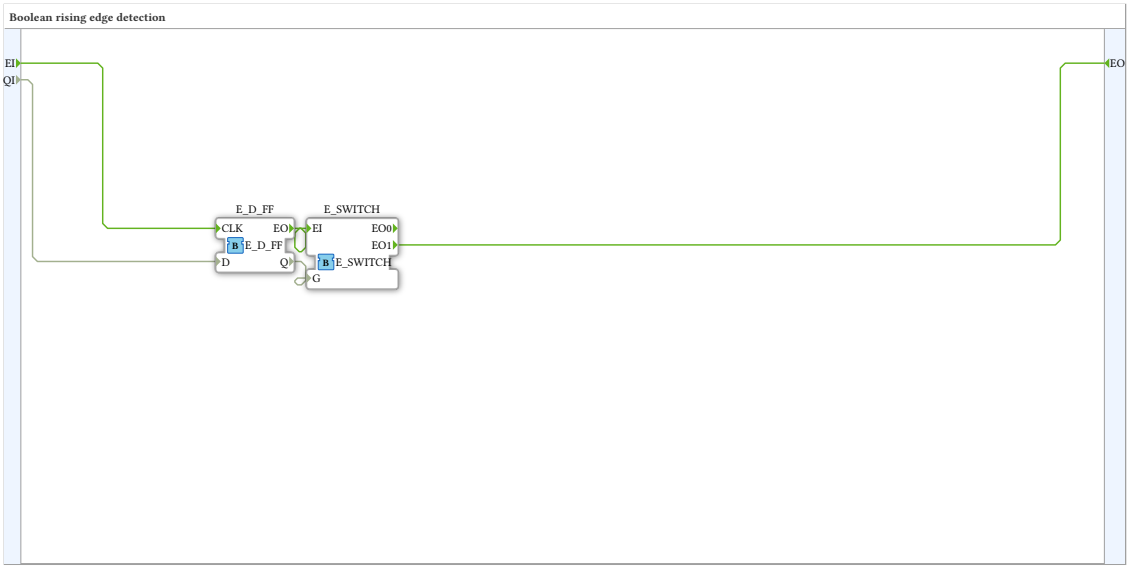
Feature	E_RTimeOut	E_DELAY	E_TABLE
Reset Function	✓	❌	❌
Interface	Adapter	Direct	Direct
Standard	61499-2	61499-1	61499-1

🛠️ **Related Exercises**

- Exercise_035b
- Exercise_170



Conclusion



The E_RTimeOut block offers an elegant solution for timeout requirements in distributed control systems:

- Reusable adapter interface
- Flexible timeout configuration
- Reliable reset functionality

By internally utilizing the E_RDELAY block, it combines precise timing control with a robust architecture. Its standardized implementation according to IEC 61499-2 makes it particularly suitable for interoperable automation solutions.

2.11.3.45 E_R_TRIG (Rising Edge Detection)

• – ◦ • – ◦ • – ◦ •

Introduction

The **E_R_TRIG** (Rising Edge Trigger) is a fundamental function block according to IEC 61499 for detecting rising edges in digital signals. Based on the XML specification, it implements reliable edge detection for industrial control systems.

Structure of the E_R_TRIG Block

Interface

Event Inputs:

- `EI` (Event Input): Enables edge detection (linked to the `QI` value)

Event Outputs:

- `EO` (Event Output): Acknowledges a detected rising edge

Data Inputs:

- `QI` (Query Input): Input signal to be monitored (BOOL)

Internal Structure

According to the XML specification, the block consists of:

1. **E_D_FF**: D flip-flop for signal state storage
2. **E_SWITCH**: Switch for conditional Event Forwarding

Functionality

1. **Edge Detection**:

- With each `EI` event, the current `QI` value is compared with the stored state from the previous cycle.
- A rising edge occurs when `QI` transitions from `FALSE` to `TRUE`.
- Upon detection of such an edge, the `EO` event should be triggered.

1. **Internal Structure and Faulty Behavior**:

- The function block is internally composed of a `E_D_FF` and a `E_SWITCH`.

- **Caution: Faulty Implementation!** The internal logic of the function block (as of `events-3.0.0`) is faulty and actually implements a **falling edge detector (`E_F_TRIG`)** instead of a rising one.
- The `EO` event is triggered when `QI` transitions from `TRUE` to `FALSE`.

Technical Features

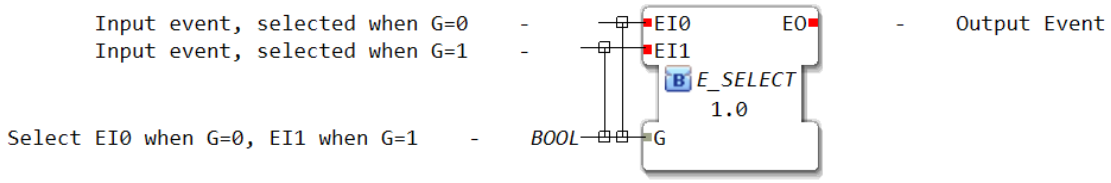
✓ **Event-driven** architecture (no polling).
✓ **State storage** via an internal D flip-flop.
✓ **Faulty Logic**: The function block is named `E_R_TRIG` (Rising), but its internal wiring causes it to react to a **falling edge**. Users who require rising edge detection must use the logic of the `E_F_TRIG` function block, which ironically correctly detects a rising edge.

Application Scenarios (for a rising edge)

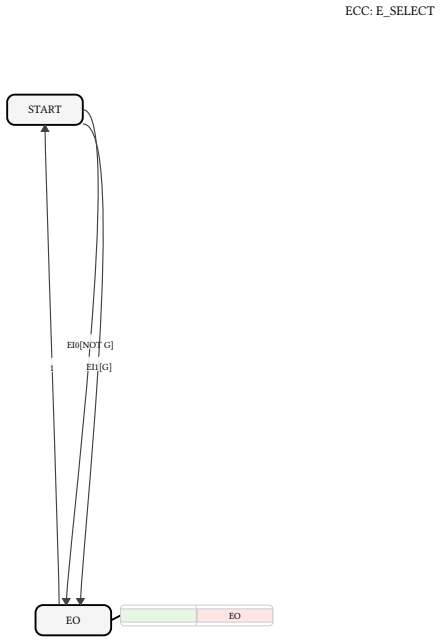
- **Sensor Data Evaluation**: Detect when a sensor changes from "inactive" to "active".
- **Machine Safety**: Detect a start or enable signal.
- **Process Control**: Start a process when a signal becomes `TRUE`.

⚖️ Comparison with Similar Function Blocks

Feature	E_R_TRIG (this one)	E_F_TRIG	E_D_FF
Detected Edge	Rising (named), Falling (implemented)	Falling (named), Rising (implemented)	Clock Edge
Event Output	Yes	Yes	Yes
Memory Behavior	Yes	Yes	Yes



🛠️ Related Exercises

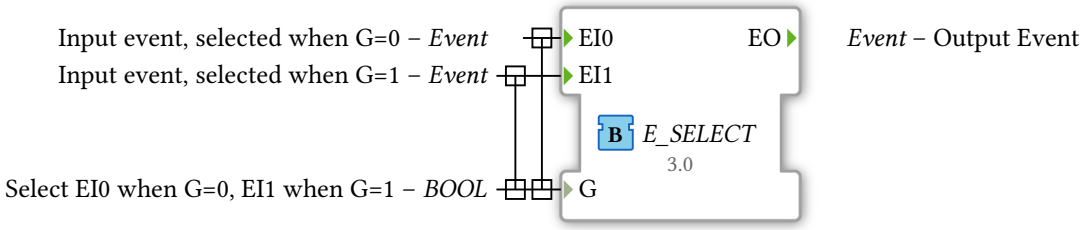


- Exercise_089

Conclusion

The E_R_TRIG block is designed to detect rising edges. **Due to an implementation error in the `events-3.0.0` library, this function block functions as a detector for falling edges.** This discrepancy between name and function is critical and must be taken into account when using it. For reliable detection of rising edges, the `E_F_TRIG` function block should be used instead, whose logic (contrary to *its* name) correctly detects a rising edge.

2.11.3.46 E_SELECT



• – ○ • – ○ • – ○ •

Introduction

The **E_SELECT** is a basic function block according to IEC 61499 (Annex A) that enables the conditional forwarding of events based on a control signal. The current version 1.0 is licensed under EPL-2.0.

Interface Structure

Event Inputs

- `EI0`: Input event (passed on if G=0)
- `EI1`: Input event (passed on if G=1)

Event Outputs

- `EO`: Output event (passed on)

Data Inputs

- `G` (BOOL): Control signal for selection:
- G=0: Pass on EI0
- G=1: Pass on EI1

Functionality

1. **Event Processing**:

- Upon input of EI0 or EI1, the G-value is evaluated.
- Only the event matching the G-value is passed on.

1. **State Machine** (ECC):

- **START**: Wait state
- **EO**: Output state (with EO action)
- Transitions:
- EI0 at G=0 ⟶ EO
- EI1 at G=1 ⟶ EO
- Always returns to START

1. **Execution Logic**:

- Deterministic event selection
- No buffering of events

Technical Features

✓ **Boolean control** of event selection ✓ **Real-time processing**
✓ **State-based implementation (BasicFB) ✓ **EPL 2.0 Open-Source** implementation

Application Scenarios

- **Branched Process Control**: Alternative execution paths
- **Mode Switching**: Operating mode change
- **Error Handling**: Alternative error routines
- **Test Automation**: Switching between test and normal operation

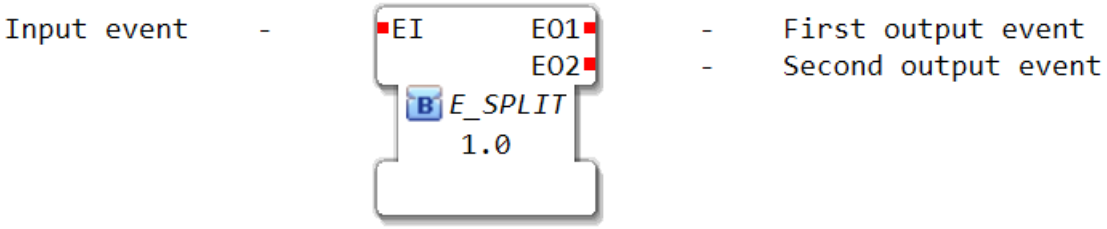
⚖️ **Comparison with similar function blocks**

Feature	E_SELECT	E_SWITCH	E_MERGE
Selection Criterion	Boolean (G)	Boolean (G)	None
Direction	2:1 (Multiplexer)	1:2 (Demultiplexer)	n:1 (OR Gate)
State Model	BasicFB	BasicFB	BasicFB/Generic

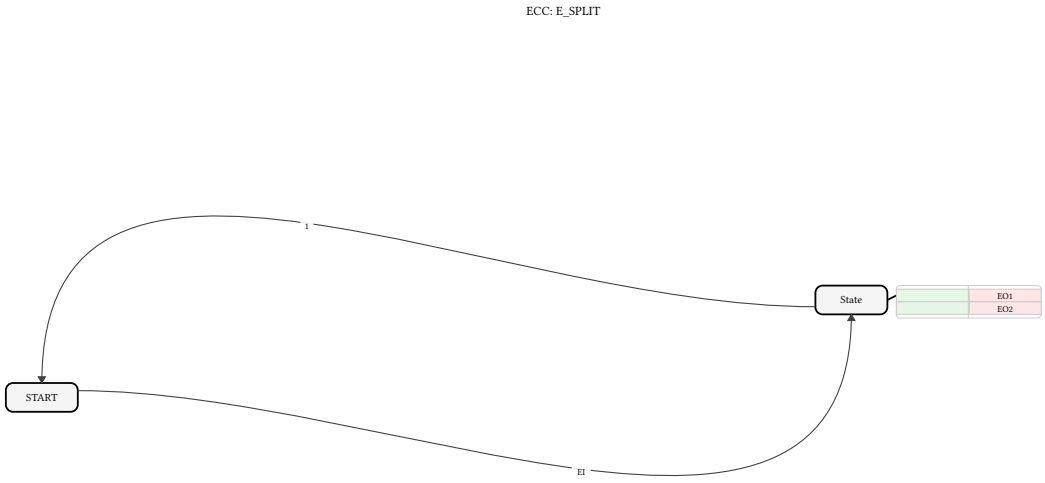
🛠️ **Related Exercises**

- Exercise_095

Conclusion



The E_SELECT function block offers a robust solution for event-based control decisions:

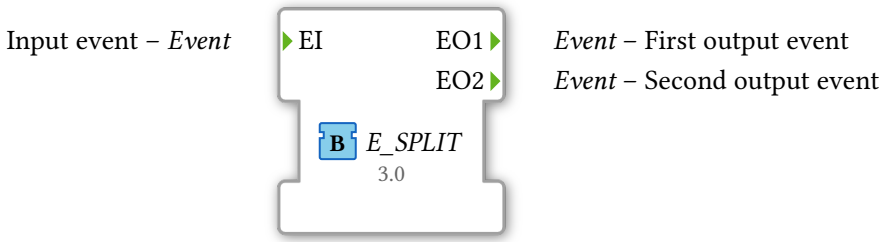


- Simple yet effective selection
- Clear state machine implementation
- Standards-compliant interface

Due to its deterministic operation, it is particularly suitable for safety-critical applications and complex control logic. Its use as a BasicFB also enables integration into all IEC 61499-compliant development environments.

See also: https://www.holobloc.com/doc/fb/rt/events/E_SELECT.htm

2.11.3.47 E_SPLIT (Event Distributor)



• – ◦ • – ◦ • – ◦ •

Introduction

The **E_SPLIT** is a standards-compliant function block (IEC 61499-1 Annex A) for event distribution, developed under the EPL 2.0 license. Version 1.0 splits an incoming event sequentially into two output events.

Interface Structure

Event Input

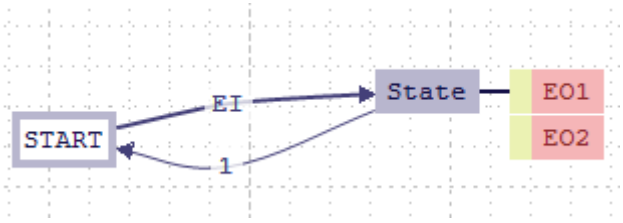
- `EI`: Input event (trigger for distribution)

Event Outputs

- `EO1`: First output event
- `EO2`: Second output event

Functionality

1. **Event Receipt**:



- Upon receipt of `EI`, the state machine is activated.

1. **Sequential Processing**:

- **START State**: Waits for input event.
- **STATE State**:
- Executes action `EO1` (immediately).
- Executes action `EO2`. (Immediately after)
- Automatic return to START

1. **Execution Order**:

- Guaranteed sequence: EI ⟶ EO1 ⟶ EO2
- Deterministic timing

Technical Features

✓ **Strict Sequencing** (EO1 before EO2)
✓ **State-based Implementation** (BasicFB) ✓ **Real-time event processing**
✓ **EPL 2.0 Open-Source** Implementation

Application Scenarios

- **Flow Control**: Clocked process steps
- **Device Control**: Activation sequences
- **Security Systems**: Delayed emergency routines
- **Test Automation**: Triggers for test sequences

⚖️ **Comparison with similar building blocks**

Feature	E_SPLIT	E_DEMUX	E_MERGE
Functional principle	1:2 sequence	1:n distribution	n:1 combination
Event sequence	Fixed	Address-dependent	Arbitrary
State model	BasicFB	Variable	None

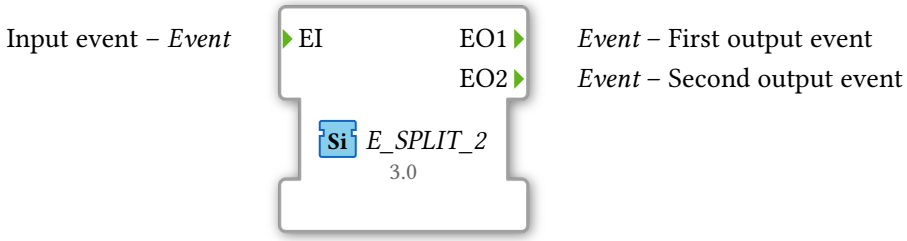
🛠️ **Related Exercises**

- Exercise_004a4
- Exercise_004a4_AX
- Exercise_080b

Conclusion

The E_SPLIT block offers a reliable solution for sequential event distribution:

- Guaranteed event sequence
- Simple yet effective functionality
- Robust state machine model



Due to its deterministic operation, it is particularly suitable for time-critical control tasks and safety-related applications. Its standards-compliant implementation enables seamless integration into IEC 61499-based systems.

2.11.3.48 E_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_SPLIT_2` is a basic function block according to IEC 61499 that splits a single input event (`EI`) into a sequence of two output events (`EO1` and `EO2`). This block is functionally identical to `E_SPLIT`.

Interface Structure

Event Input

- **EI**: The input event that triggers the sequence.

Event Outputs

- **EO1**: The first output event of the sequence.
- **EO2**: The second output event of the sequence.

Functionality

When an event arrives at input `EI`, the function block immediately triggers the two output events in succession. The sequence is guaranteed:

1. First, `EO1` is triggered.
2. Immediately afterward, `EO2` is triggered.

Technical Features

- **1-to-2 Sequence**: Splits an event into a guaranteed sequence of two events.
- **Stateless**: The function block has no internal memory beyond a single transaction.
- **Generic Function Block**: The functionality is provided by the generic class `GEN_E_SPLIT`, enabling optimized execution by the 4diac runtime environment.

Application Scenarios

- **Reset and Start**: A single `RESET` event can be used to first reset a value (`EO1`) and then restart a process (`EO2`).
- **Read and Process**: A `REQ` event can first read a sensor value (`EO1`) and then trigger a calculation using the new value (`EO2`).
- **Sequence Control**: Triggering two consecutive actions with a single trigger event.

🛠️ Related Exercises

- Exercise_004a8
- Exercise_004a8_AX

Conclusion

The `E_SPLIT_2` block is a useful tool for generating a fixed, short event sequence from a single trigger. Its simplicity and guaranteed execution order make it a robust component for sequence control in IEC 61499 applications.

2.11.3.49 E_SPLIT_3

• – ◦ • – ◦ • – ◦ •

The `E_SPLIT_3` is a basic function block according to IEC 61499 that splits a single input event (`EI`) into a sequence of three output events (`EO1`, `EO2`, `EO3`).

Input event – *Event*

Event – First output event
Event – Second output event
Event

- **EI**: The input event that triggers the sequence.
- **EO1**: The first output event of the sequence.
- **EO3**: The third output event of the sequence.

Event Outputs

Ereignis-Eingang

Interface Structure

Introduction

Functionality

When an event arrives at input `EI`, the function block immediately triggers the three output events in succession. The order is guaranteed:

1. First, `EO1` is triggered.
2. Immediately afterward, `EO2` is triggered.
3. Immediately afterward, `EO3` is triggered.

- **1-to-3 Sequence**: Splits an event into a guaranteed sequence of three events.
- **Stateless**: The function block has no internal memory beyond a single transaction.
- **Generic Building Block**: The functionality is provided by the generic class `GEN_E_SPLIT`.
- **Initialization Sequence**: A `INIT` event can be used to initialize three different system components sequentially (`EO1`, `EO2`, `EO3`).
- **Sequence Control**: Triggering three consecutive actions with a single trigger event (e.g., “Close gripper,” “Raise arm,” “Rotate arm”).
- Exercise_004a9
- Exercise_004a9_AX

The `E_SPLIT_3` block is a useful tool for generating a fixed, short event sequence of three steps from a single trigger. Its simplicity and guaranteed execution order make it a robust component for sequence control in IEC 61499 applications.

2.11.3.50 E_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_SPLIT_4` is a basic function block according to IEC 61499 that splits a single input event (`EI`) into a sequence of four output events (`EO1` to `EO4`).

Input event – *Event*

Event – First output event
Event – Second output event
Event
Event

Interface Structure

Event Input

- **EI**: The input event that triggers the sequence.

Event Outputs

- **EO1**: The first output event of the sequence.
- **EO2**: The second output event of the sequence.
- **EO3**: The third output event of the sequence.
- **EO4**: The fourth output event of the sequence.

Functionality

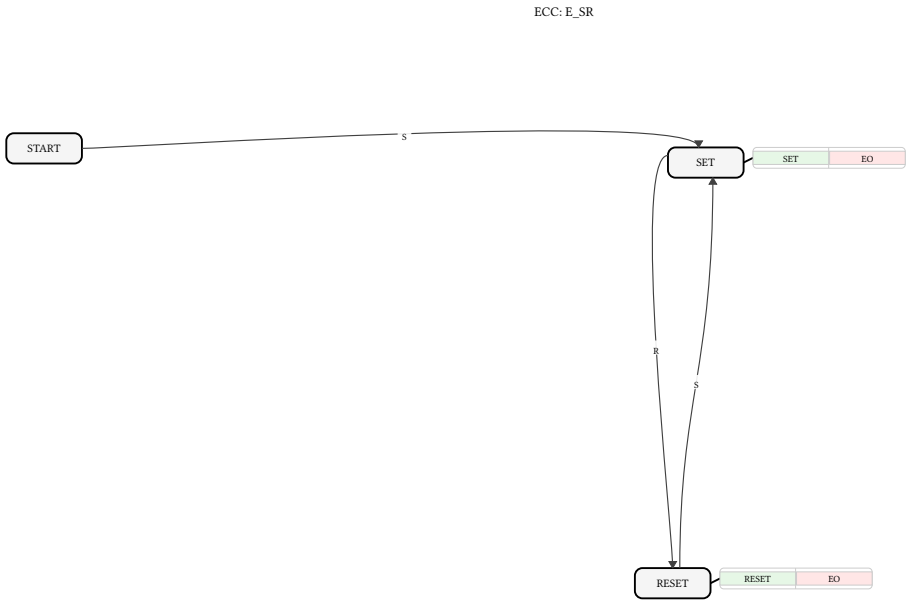
When an event arrives at input `EI`, the function block immediately triggers the four output events in succession. The order is guaranteed:

1. First, `EO1` is triggered.
2. Immediately afterward, `EO2` is triggered.
3. Immediately afterward, `EO3` is triggered.
4. Immediately afterward, `EO4` is triggered.

Technical Features

- **1-to-4 Sequence**: Splits an event into a guaranteed sequence of four events.
- **Stateless**: The function block has no internal memory beyond a single transaction.
- **Generic Block**: The functionality is provided by the generic class `GEN_E_SPLIT`.

Application Scenarios

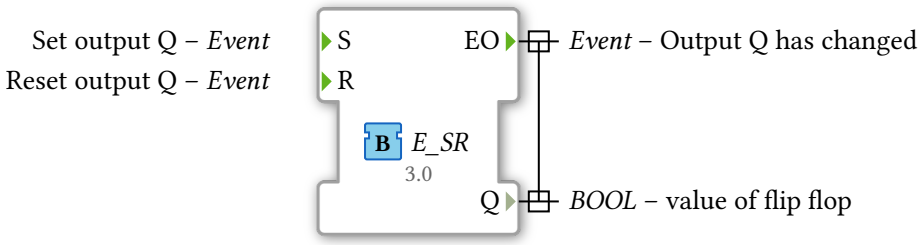


- **Complex Initialization**: A `INIT` event can be used to initialize four different system components sequentially.
- **Sequence Control**: Triggering four consecutive actions with a single trigger event.

Conclusion

The `E_SPLIT_4` block is a useful tool for generating a fixed, short event sequence of four steps from a single trigger. Its simplicity and guaranteed execution order make it a robust component for sequence control in IEC 61499 applications.

2.11.3.51 E_SR



Podcast

- IEC 61499: The E_SR Function Block Decoded – Simplicity Meets Event Control
- Decoding the E_SR Function Block: The Unsung Hero of Industrial Automation

Introduction

The `E_SR` (Event-driven SR Flip-Flop) is an event-driven, bistable function block according to IEC 61499. It serves as a basic memory element controlled by separate "Set" and "Reset" events. Its output, `Q`, retains its state until an opposing event occurs.

Interface Structure

Event Inputs:

- **S (Set)**: Sets the output `Q` to `TRUE`.
- **R (Reset)**: Sets the output `Q` to `FALSE`.

Event Outputs:

- **EO (Event Output)**: Triggered when the state of `Q` changes.
- **Associated Data**: `Q`

Data Outputs:

- **Q**: The current state of the flip-flop (data type: `BOOL`).

Functionality

The `E_SR` block functions as a simple latch:

1. **Set**: When an event arrives at the input `S`, the output `Q` is set to `TRUE`. If `Q` was previously `FALSE`, the `EO` event is triggered.
2. **Reset**: When an event arrives at the input `R`, the output `Q` is set to `FALSE`. If `Q` was previously `TRUE`, the `EO` event is triggered.
3. **Save**: Between events, `Q` retains its last set state.

Technical Features and Standards Comparison

According to **DIN EN 61499-1 (Table A.1, Note 8)**, the implementation of this function block is identical to E_RS. Both function blocks (`E_SR` and `E_RS`) exist to maintain consistency with the types in IEC 61131-3, even though IEC 61499 does not have an inherent "dominance" of events, as is the case with level-controlled inputs in classic PLC programming.

- **Comparison to IEC 61131-3**: See SR (Bistable, set first). While in IEC 61131-3 the `SR` function block has a defined "set dominance" (if S and R are TRUE simultaneously, S wins), in IEC 61499 the behavior with closely spaced events depends on the processing order of the runtime environment (ECC). Since events are transient, there is no permanent conflict between two static signals.
- **Functional Identity**: `E_SR` and `E_RS` are technically identical. Their graphical representation and naming conventions simply follow established naming conventions to aid developers.
- **Change Detection**: The `EO` output is only triggered by an actual state change.

Application Scenarios

- **Start/Stop Logic**: A "Start" button is connected to `S`, and a "Stop" button to `R`, to control the state of a machine.
- **Start/Stop Logic**: - **Error Storage**: An error event sets the function block (`S`), which stores the error state until it is explicitly acknowledged by an operator or another process (`R`).
- **Mode Storage**: Stores the current operating mode of a system (e.g., "Manual" vs. "Automatic").

Related Function Blocks

- **E_RS**: Functionally identical to `E_SR`. The only difference is the graphical arrangement of the `S` and `R` connections on the symbol.
- **`E_D_FF`**: Also stores a state, but on a clock-based basis. `E_D_FF` takes the value from the `D` input when a `CLK` event occurs.

E_D_FF`

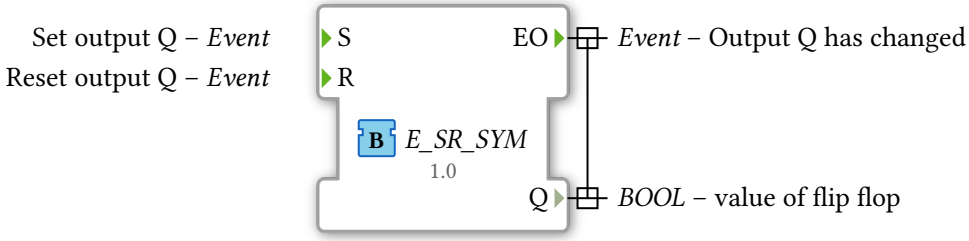
- Uebung_024
- Exercise_025
- Exercise_026_sub

- Exercise_039a_sub_Outputs
- Exercise_160b

Conclusion

The E_SR block is a fundamental memory block in IEC 61499. It is ideal for simple state storage where a state is set by one event and explicitly reset by another. The lack of guaranteed set or reset dominance for simultaneous events must be considered in critical applications.



2.11.3.52 E_SR_SYM

• – ○ • – ○ • – ○ •

Introduction

E_SR_SYM (Event-driven SR Flip-Flop, symmetric start-up behaviour) is functionally identical to E_RS_SYM — both blocks exist, analogous to E_RS/E_SR, purely to preserve the IEC 61131-3 naming convention (SR = named set-first, RS = named reset-first), even though IEC 61499 has no true dominance between events.

Interface Structure

Event Inputs

- **S (Set)**: Sets output Q to TRUE.
- **R (Reset)**: Sets output Q to FALSE.

Event Outputs

- **EO (Event Output)**: Triggered after every S or R event.

- **Connected data**: `Q`

Data Outputs

- **Q**: The current state of the flip-flop (data type: `BOOL`).

Functionality

Identical to E_RS_SYM: the ECC has the states `START`, `SET`, and `RESET`. Already in state `START`, both `S` and `R` lead to a defined follow-up state. From `SET`/`RESET`, `R` switches to `RESET`, `S` to `SET`. Every transition sets `Q` accordingly and triggers `EO`.

Technical Features

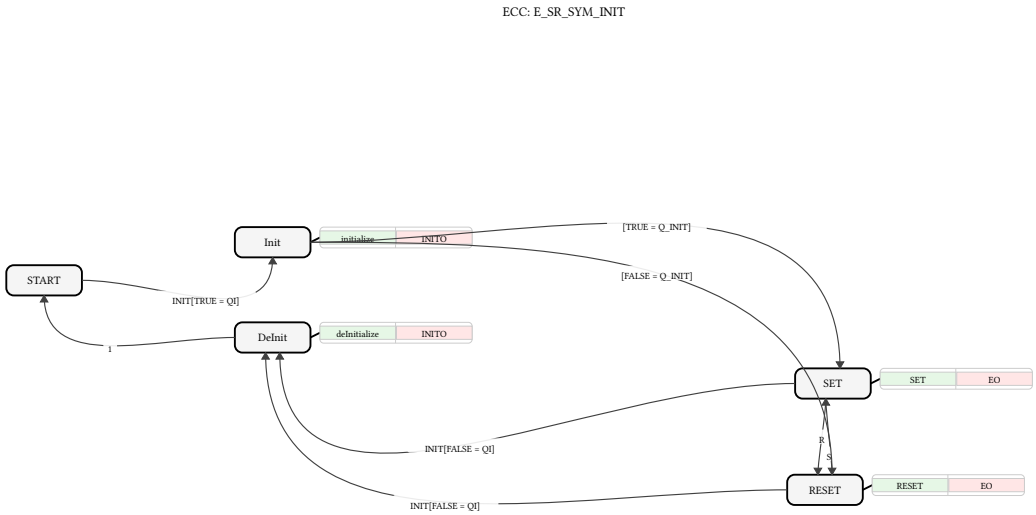
- **Functionally identical to `E_RS_SYM`**: The graphical representation and naming (`S` before `R` in the interface) follows the IEC 61131-3 convention but has no effect on actual behaviour.
- **Symmetric start-up behaviour**: As with `E_RS_SYM`, the initial state already reacts in a well-defined way to both events.

State Overview

State	Meaning
START	Initial state, waits symmetrically for `S` or `R`
SET	`Q = TRUE`
RESET	`Q = FALSE`

Application Scenarios

See E_RS_SYM — identical use cases; `E_SR_SYM` is preferred wherever a project consistently uses the `SR` naming convention (set listed first).

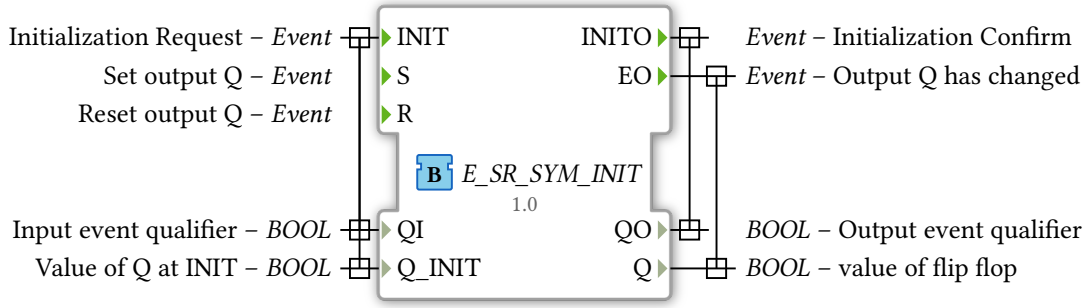


Comparison with similar function blocks

- **E_RS_SYM**: functionally identical, only the order of `S`/`R` in the symbol is swapped.
- **E_SR_SYM_INIT**: the same base functionality, extended with an `INIT`/`INITO` interface.
- **E_SR**: without symmetric start-up behaviour.

Conclusion

`E_SR_SYM` is the naming-convention counterpart of `E_RS_SYM` and functionally identical variant of the symmetric set-reset flip-flop.



2.11.3.53 E_SR_SYM_INIT

• – ○ • – ○ • – ○ •

Introduction

`E_SR_SYM_INIT` is functionally identical to E_RS_SYM_INIT — analogous to E_SR_SYM/E_RS_SYM, it exists purely to preserve the `SR` naming convention (set listed first) and extends E_SR_SYM with an `INIT`/`INIT0` interface.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `QI` and `Q_INIT`.
- **S (Set)**: Sets output `Q` to `TRUE`.
- **R (Reset)**: Sets output `Q` to `FALSE`.

Event Outputs

- **INIT0**: Confirms (de-)initialization, carries `QO`.
- **EO**: Triggered after every `S` or `R` event, carries `Q`.

Data Inputs

- **QI** (BOOL): Input event qualifier — `TRUE` initializes, `FALSE` deinitializes.
- **Q_INIT** (BOOL): The value `Q` is set to during initialization.

Data Outputs

- **QO** (BOOL): Output event qualifier, mirrors `QI`.
- **Q** (BOOL): The current state of the flip-flop.

Functionality

Identical to E_RS_SYM_INIT: `INIT` with `QI = TRUE` initializes `Q` via `Q_INIT`, `INIT` with `QI = FALSE` deinitializes the block back to state `START`. During normal operation, `S`/`R` switch between `SET` and `RESET`, each confirmed via `EO`.

Technical Features

See E_RS_SYM_INIT — identical behaviour, only the `S`/`R` order in the symbol is swapped.

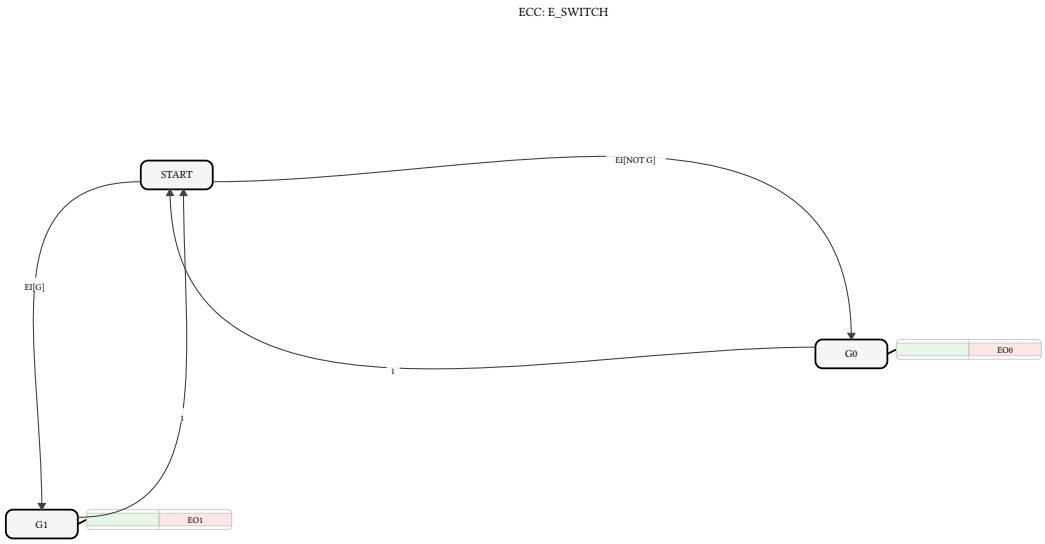
State Overview

State	Meaning
START	Unconfigured initial state
Init	Initialization in progress, `QO := QI`
DeInit	Deinitialization in progress, `QO := FALSE`
SET	`Q = TRUE`
RESET	`Q = FALSE`

Application Scenarios

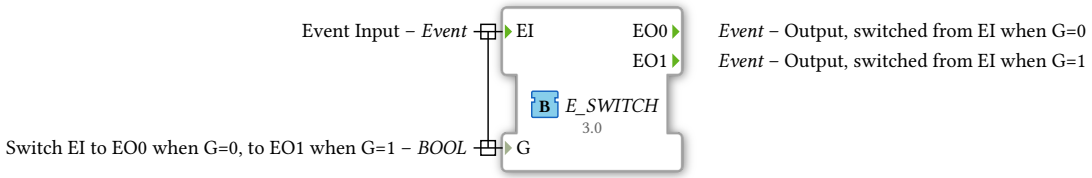
See E_RS_SYM_INIT.

Comparison with similar function blocks



- **E_RS_SYM_INIT**: functionally identical, swapped `S`/`R` order.
- **E_SR_SYM**: the same base functionality without `INIT`/`INITO`.

Conclusion



`E_SR_SYM_INIT` is the naming-convention counterpart of `E_RS_SYM_INIT` and functionally identical variant with a configurable start value.

2.11.3.54 E_SWITCH

🎧 Podcast

- E_SWITCH: The Switch of Automation – Why Simplicity Revolutionizes IEC 61499
- E_SWITCH: The Unsung Hero of Industrial Automation's Modular Design The `E_SWITCH` (Event Switch) is a basic function block according to IEC 61499 that functions as a conditional event switch or 1-to-2 demultiplexer. It forwards a single input event (`EI`) to one of two outputs based on the state of a Boolean control variable (`G`).

- **EI (Event Input)**: The input event to be forwarded.
- **Associated Data**: `G`
- **EO0**: The first event output.
- **EO1**: The second event output.
- **G (Guard)**: The Boolean condition that controls the switch (data type: `BOOL`).

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

1. **Event Reception**: The function block waits for an event at input `EI`.
2. **Conditional Forwarding**:

- **If `G` = `FALSE`**: The event is forwarded to output `EO0`.

- **If `G` = `TRUE`**: The event is forwarded to output `EO1`.

The event at input `EI` is always routed to exactly one of the two outputs, depending on the control condition `G`.

- **Event Switch**: Serves as a fundamental "switch" or "if-else" construct for the event flow.
- **Stateless**: The block itself has no internal memory; its decision is based solely on the value of `G` at the moment of the `EI` event.
- **Conditional Logic**: Execution of alternative actions based on a condition. If `G` is true, execute action A (`EO1`); otherwise, execute action B (`EO0`).
- **Mode-Dependent Processing**: Route commands to different processing paths depending on whether the system is in "Automatic" mode (`G=TRUE`) or "Manual" mode (`G=FALSE`).
- **Error Handling**: Route a sensor event either to the normal processing logic (`G=FALSE` for "no error") or to an error handling routine (`G=TRUE` for "error detected").

Feature	E_SWITCH	E_SELECT	E_DEMUX
Selection Criterion	Boolean (G)	Boolean (G)	Index (K)
Direction	1:2 (Demultiplexer)	2:1 (Multiplexer)	1:n (Demultiplexer)

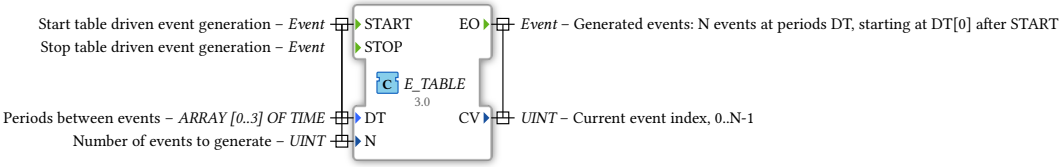
Conclusion

2.11.3.55 E_TABLE



• – ◦ • – ◦ • – ◦ •

Introduction

The `E_TABLE` (Event Table) is a function block according to IEC 61499 that generates a finite sequence of events with individually definable time intervals. It reads the time intervals from a table (an array) and fires a specified number of events sequentially.

Interface Structure

Event Inputs

- **START**: Starts the generation of the event sequence.
- **Connected Data**: `DT`, `N`
- **STOP**: Stops the sequence prematurely.

Event Outputs

- **EO (Event Output)**: The output event that is triggered N times.
- **Associated Data**: DT, N

Data Inputs

- **DT**: An array of durations (data type: `TIME`, size: 4). `DT[i]` defines the delay time *before* the ith event.
- **N**: The total number of events to be generated (data type: `UINT`, max. 4 for this function block).

Data Outputs

- **CV (Current Value)**: The index of the currently triggered event (0 to N-1) (Data type: `UINT`).

Functionality

1. **Start of the sequence**: A `START` event triggers the function block. The number of events to be generated is determined by `N`.
2. **Event generation**: The function block processes the table:

- It waits for the time interval defined in `DT[0]`. Then, the first `EO` event is triggered, and `CV` is set to `0`.
- It waits for the time interval defined in `DT[1]`. Then, the second `EO` event is triggered, and `CV` is set to `1`.
- This process repeats until `N` events have been generated.

1. **End of Sequence**: The sequence ends automatically after `N` events have been triggered.
2. **Stop**: A `STOP` event immediately terminates the sequence at any point.

Example:

- `N` = 3
- `DT` = `[T#2s, T#5s, T#1s]`
- After a `START` event:

1. After 2 seconds, `EO` is triggered with `CV=0`.
2. 5 seconds later, `EO` is triggered with `CV=1`.
3. 1 second later, `EO` is triggered with `CV=2`.
4. The sequence is complete.

Technical Features

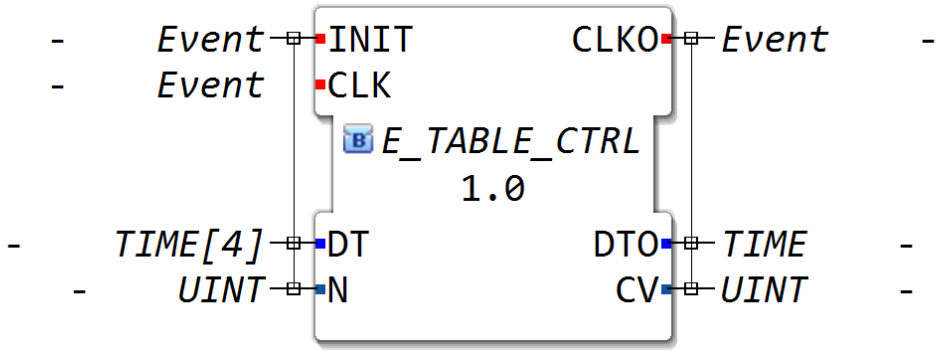
- **Table-Controlled Time Intervals**: The strength of this function block lies in its ability to define variable time intervals between events, rather than a fixed interval.
- **Sequence Counter**: The `CV` output provides valuable information about the current position in the sequence.

Application Scenarios

- **Control of Step Sequences**: Triggering steps with varying wait or processing times.
- **Complex Control**: Controlling an actuator with a series of pulses with variable pauses.
- **Test Automation**: Generating a complex, time-defined stimulus sequence for a test object, where the `CV` output can be used for synchronization with the evaluation.

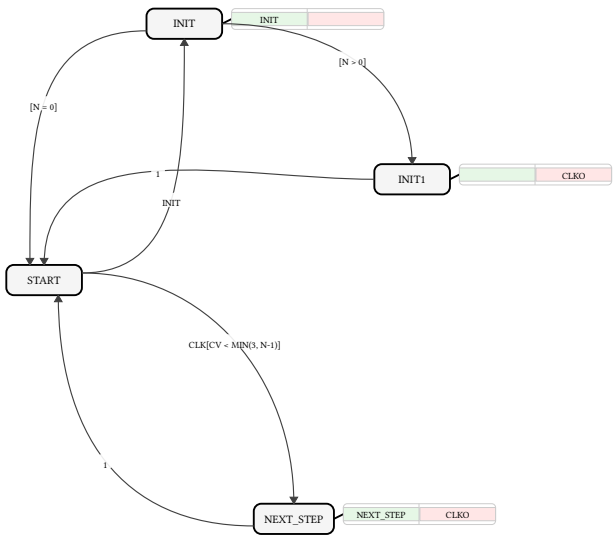
⚖️ Comparison with Similar Function Blocks

Feature	E_TABLE	E_CYCLE	E_N_TABLE
Event Interval	Variable (Array `DT`)	Fixed (`DT`)	Variable (Array `DT`)
Outputs	One `EO` channel	One `EO` channel	Multiple (`EO0..EO3`)
Counter Output (`CV`)	Yes	No	No (internal)



🛠️ Related Exercises

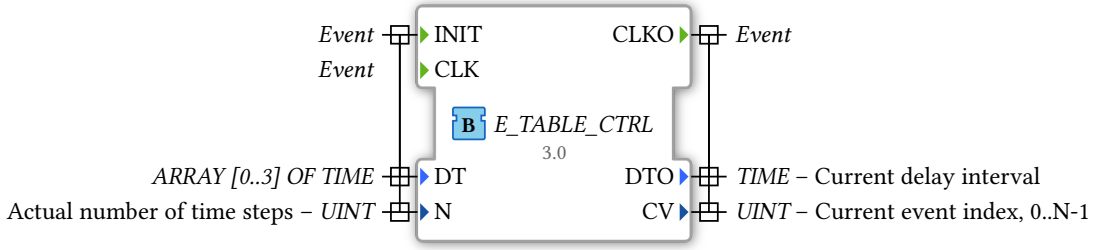
- Exercise_093



Conclusion

The `E_TABLE` function block is a highly flexible timer for generating complex, finite event sequences. Its ability to read variable time intervals from a table makes it ideal for non-periodic, sequential control tasks. It forms the basis for other function blocks such as `E_N_TABLE`, but unlike the latter, it provides the current counter value as useful output information.

2.11.3.56 E_TABLE_CTRL



ECC: E_TABLE_CTRL

• – ○ • – ○ • – ○ •

Introduction

The **E_TABLE_CTRL** is a support function block for E_TABLE according to IEC 61499-1 (Annex A), under the EPL-2.0 license. Version 1.0 enables precise control of event sequences based on a configurable time table.

Interface Structure

Event Inputs

- `INIT`: Initializes the event table (with DT and N parameters)
- `CLK`: Clock signal for table increment

Event Outputs

- `CLKO`: Generated clock event (with DTO and CV data)

Data Inputs

- `DT` (TIME array): Time intervals for event generation
- `N` (UINT): Number of active time steps

Data Outputs

- `DTO` (TIME): Current time interval
- `CV` (UINT): Current event index (0..N-1)

Functionality

1. **Initialization**:

- On the `INIT` event, the index (CV) is set to 0
- The first time interval (DTO) is taken from the DT array

1. **Table Control**:

- Each `CLK` event increments CV by 1
- The next time interval from the DT array is loaded
- `CLKO` is generated at each step

1. **State Machine** (ECC):

- **START**: Wait state
- **INIT**: Initialization phase
- **INIT1**: First event generation
- **NEXT_STEP**: Table progress

Technical Features

✓ **Table-driven** Scheduling ✓ **Array-based** configuration (up to 4 time steps) ✓ **State-based** implementation (BasicFB) ✓ **Real-time capable** event generation

Application Scenarios

- **Process control**: Complex timing sequences
- **Test automation**: Programmable test sequences
- **Machine control**: Motion sequences
- **Production lines**: Cycle-controlled processes

Relationship to E_TABLE

The `E_TABLE_CTRL` block is not intended as a standalone block for direct use, but rather as the **internal control logic** of the composite function block `E_TABLE`.

Within `E_TABLE`, `E_TABLE_CTRL` interacts with a `E_DELAY` block:

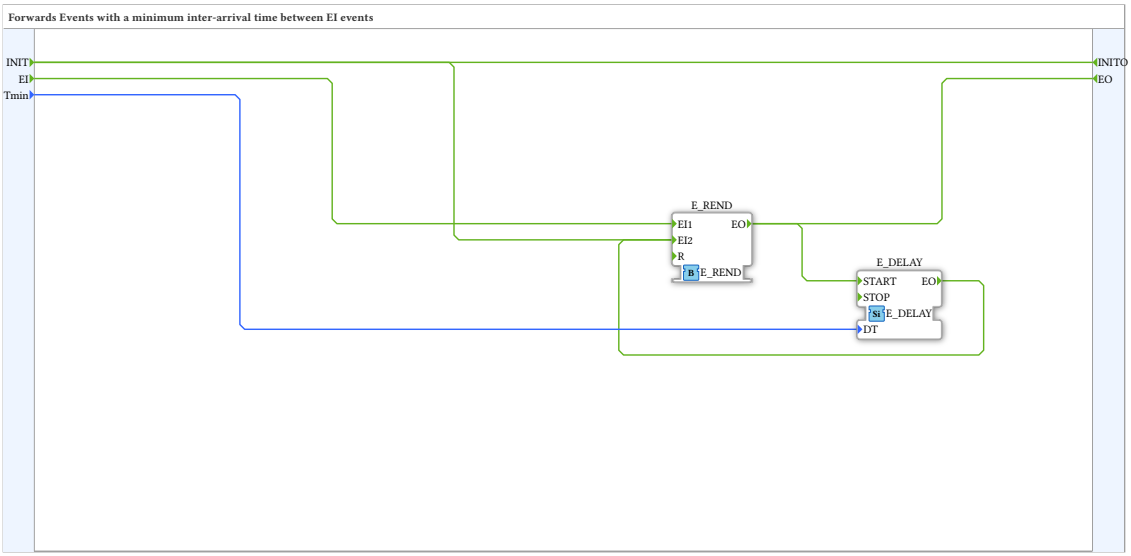
1. `E_TABLE_CTRL` receives the `START` command and calculates the first delay time, `DT0`.
2. It sends `DT0` via `CLK0` to the `E_DELAY` block.
3. `DT0` to `CLK0`.
4. `E_DELAY` 3. After `E_DELAY` has expired, it signals this via its `EO` output back to the `CLK` input of `E_TABLE_CTRL`.
5. `E_TABLE_CTRL` then calculates the next delay time, and the cycle repeats.

This block thus encapsulates the pure state logic (which step is next, how long it takes), while `E_DELAY` executes the actual time delay.

This block therefore encapsulates the pure state logic (which step is next, how long it takes), while `E_DELAY` performs the actual time delay.

🛠️ Related Exercises

- Exercise_175

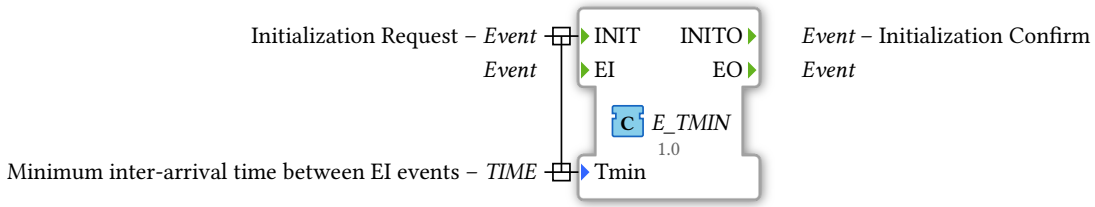


Conclusion

The E_TABLE_CTRL function block extends the possibilities of table-driven event generation:

- Flexible configuration of multiple time intervals
- Precise control of complex processes
- Robust state machine implementation

Thanks to its array-based timing, it is ideally suited for applications with variable process steps. Integration as a BasicFB ensures reliable operation in IEC 61499-based control systems.



2.11.3.57 E_TMIN

• — ○ • — ○ • — ○ •

Introduction

`E_TMIN` (minimum inter-arrival time) is a composite function block that only forwards incoming events at `EI` to `EO` if at least the time span `Tmin` has passed since the last forwarded event. It acts as an event throttle (rate limiter) for arbitrary event streams.

Interface Structure

Event Inputs

- **INIT**: Initialization, carries `Tmin`.
- **EI**: Incoming event to be throttled.

Event Outputs

- **INITO**: Confirms the initialization.
- **EO**: The throttled output event.

Data Inputs

- **Tmin** (TIME): Minimum spacing between two consecutive `EI` events that actually result in `EO`.

Functionality

Internally, `E_TMIN` uses an `E_REND` (rendezvous of two events) and an `E_DELAY`: when `EI` arrives, it is forwarded to `E_REND.EI1`. `E_REND` fires `EO` once it has received at least one event on both `EI1` and `EI2` — initially `EI2` is already "pre-filled" via `INIT`, so the first `EI` is passed through immediately. Every event let through by `E_REND` simultaneously starts `E_DELAY` with time `Tmin`; only once it elapses does it deliver the next `EI2` event to `E_REND`, meaning the next `EI` can pass through at the earliest after `Tmin`.

Technical Features

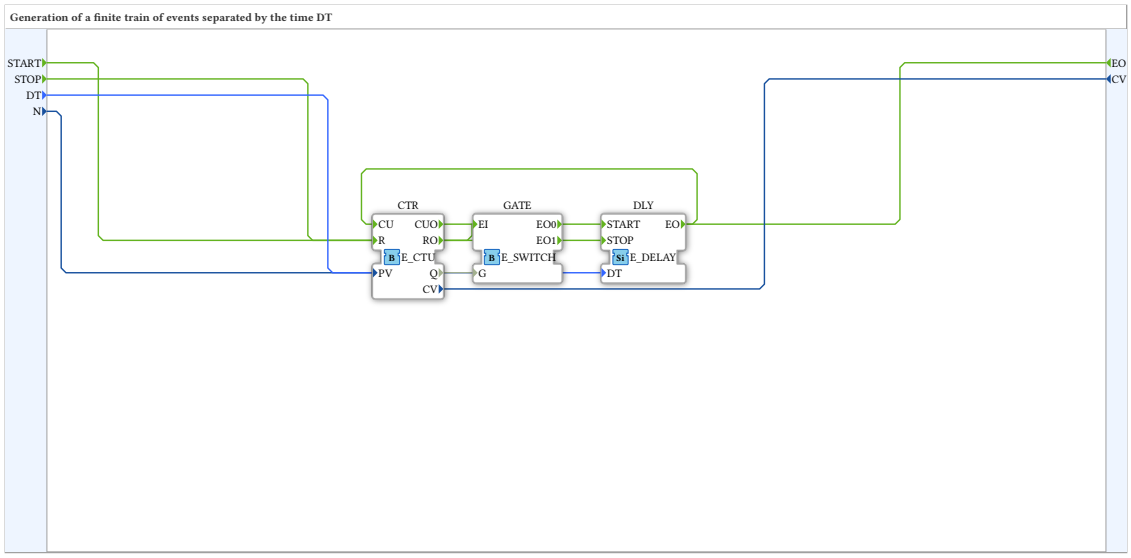
- **Built from two standard elements**: `E_TMIN` is pure wiring composed of `E_REND` and `E_DELAY`, with no ECC of its own.
- **First event unthrottled**: The first `EI` after `INIT` is passed through immediately; throttling only kicks in afterwards.
- **Building block for the `_TMIN` family**: Used internally by E_D_FF_TMIN and E_D_FF_ANY_TMIN to additionally throttle their `EO` outputs.

State Overview

Stateless wiring logic: `E_REND` internally remembers whether an `EI2` (from `E_DELAY`) has already arrived, `E_DELAY` restarts after every event it lets through.

Application Scenarios

- **Throttling rapidly changing sensor events** so downstream logic (e.g. logging, network transmission) isn't overloaded by too high an event rate.
- **Building block inside E_D_FF_TMIN/E_D_FF_ANY_TMIN** to additionally time-limit change events.



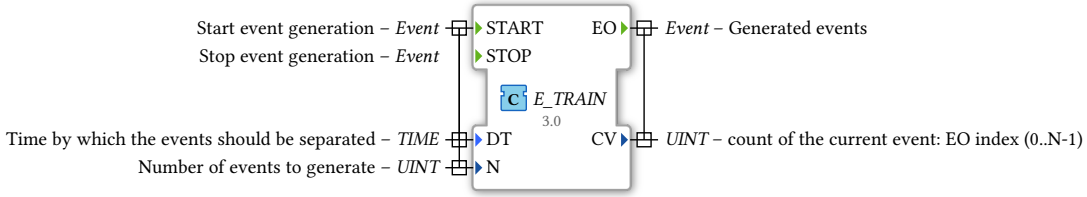
Comparison with similar function blocks

- **`E_REND`**: the internally used synchronization basis, without a time component.
- **`E_DELAY`**: the internally used timer.
- E_D_FF_TMIN / E_D_FF_ANY_TMIN: additionally combine `E_TMIN` with a data latch (`E_D_FF`/`E_D_FF_ANY`).

Conclusion

`E_TMIN` is a simple but effective event-throttling block composed of two standard elements (`E_REND`, `E_DELAY`) that guarantees a minimum spacing time between passed-through events.

2.11.3.58 E_TRAIN



Start event generation -
Stop event generation -

Time by which the events should be seperated -
Number of events to generate -

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_TRAIN` (Event Train) is a function block according to IEC 61499 that generates a finite sequence of events (“event train”) at fixed time intervals. After starting, `N` events are generated at intervals of `DT`.

Interface Structure

Event Inputs:

- **START**: Starts the generation of the event sequence.
- **Related Data**: `DT`, `N`
- **STOP**: Prematurely stops the ongoing generation of the event sequence.

Event Outputs:

- **EO (Event Output)**: The output event that is triggered periodically.
- **Related Data**: `CV`

Data Inputs:

- **DT (Delay Time)**: The time interval between each `EO` event (Data type: `TIME`).
- **N**: The total number of events to be generated (Data type: `UINT`).

Data Outputs:

- **CV (Current Value)**: The counter value indicating the index of the currently triggered event (0 to N-1) (Data type: `UINT`).

Functionality

1. **Start of the Sequence**: A `START` event triggers the function block. An internal counter is reset, and the parameters `N` (count) and `DT` (time interval) are applied. The timer for the first event is started.
2. **Event Generation**:

- After the time specified in `DT` has elapsed, the first `EO` event is triggered. The output of `CV` has the value `0`.
- Immediately afterward, the timer for the next event is restarted.
- After another time interval `DT`, the next `EO` event is triggered with `CV=1`.

1. **End of Sequence**: This cycle repeats until `N` events have been generated. After the last event (with `CV = N-1`) is triggered, the function block stops automatically.
2. **Stop**: A `STOP` event can terminate the sequence prematurely at any time.

Technical Features

- **Pulse Generator**: Generates a fixed number of pulses at constant intervals.
- **Internal Counter**: The module uses an internal counter (`E_CTU`) to track the number of generated events.
- **Sequence Counter**: The output (`CV`) provides valuable information about the current position in the sequence.

Application Scenarios

- **Stepper Motor Control**: Generates an exact number of steps (`N`) at a defined speed (determined by `DT`).
- **Dosing Processes**: Triggers dispensing processes (`N`) at intervals of `DT`.
- **Test Sequences**: Sending a defined number of test triggers to a device under test.

⚖️ Comparison with similar building blocks

Feature	E_TRAIN	E_CYCLE	E_TABLE
Event Interval	Fixed (`DT`)	Fixed (`DT`)	Variable (Array `DT`)
Event Count	Finite (`N`)	Infinite	Finite (`N`)
Counter Output (`CV`)	Yes	No	Yes

🛠️ Related Exercises

- Exercise_035a2
- Exercise_035a2_AX
- Exercise_091

Conclusion

The `E_TRAIN` module is ideal for applications requiring a fixed number of events within a constant time interval. It combines the functionality of a clock (`E_CYCLE`) with a counter to generate a controlled, finite pulse sequence. The `CV` output provides useful feedback on the sequence's progress.

2.11.3.59 E_TRIG

• – ◦ • – ◦ • – ◦ •

Introduction

The `E_TRIG` is a special service function block according to IEC 61499. Its function is to programmatically trigger *unconnected* event inputs of a specific type (name) within a resource. This enables advanced control and initialization scenarios.

Interface Structure

Event Inputs:

- **REQ (Request)**: Triggers the trigger mechanism.
- **Connected Data**: `EVENTTYPE`

Event Outputs:

- **CNF (Confirmation)**: Confirms that the trigger command has been issued.

Data Inputs:

- **EVENTTYPE**: The name of the event inputs to be triggered (data type: `STRING`).
- **Default Value**: 'EInit'

Functionality

1. **Trigger Request**: Upon a `REQ` event, the function block reads the string at the `EVENTTYPE` input.
2. **Internal Triggering**: The function block instructs the 4diac runtime environment (the resource) to find all *unconnected* event inputs of function blocks within the same resource whose name matches the `EVENTTYPE` string.
3. **Event Generation**: The runtime environment triggers these found event inputs.
4. **Acknowledgement**: Immediately after the command is issued, the `E_TRIG` block triggers its `CNF` event.

Example: Suppose several function blocks in a resource have an unconnected input named `INIT`. A `E_TRIG` block with `EVENTTYPE = 'INIT'` would, upon a `REQ` event, trigger all these `INIT` inputs simultaneously to force a re-initialization of these blocks.

Technical Features

- **Service Block**: This is not a simple logic block, but an interface to a special service of the 4diac runtime environment.

Example: - **Effects Unconnected Inputs**: This functionality explicitly targets inputs that are not graphically wired in the network. This is a powerful feature, but it should be used with caution.

- **Default Use Case `EInit`**: The default value 'EInit' indicates the primary use case: manually triggering initialization events that are normally executed only once when a resource starts.

Application Scenarios

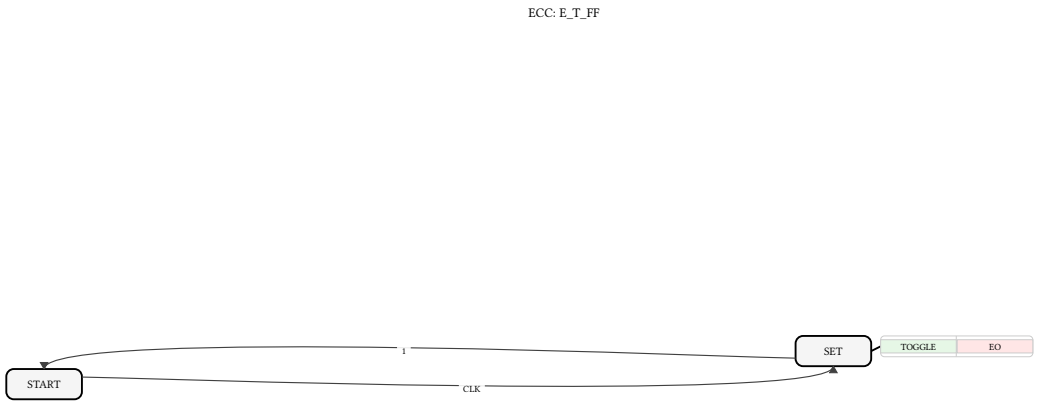
- **Manual Re-Initialization**: Resetting parts of an application to a defined initial state without having to restart the entire resource.
- **Dynamic Configuration**: After loading a new configuration, relevant components can be made to adopt the new parameters via a targeted `E_TRIG` call.
- **Testing and Debugging**: Manually triggering specific events in a running application for testing purposes.

🛠️ Related Exercises

- Exercise_176

Conclusion

The `E_TRIG` building block is a tool for advanced use cases and for developers with in-depth knowledge of the 4diac execution environment. It offers a powerful method to bypass the standard, graphically defined



event flow logic and interact directly with the runtime environment. It should be used with caution, as its effect is not immediately apparent from the graphical network.

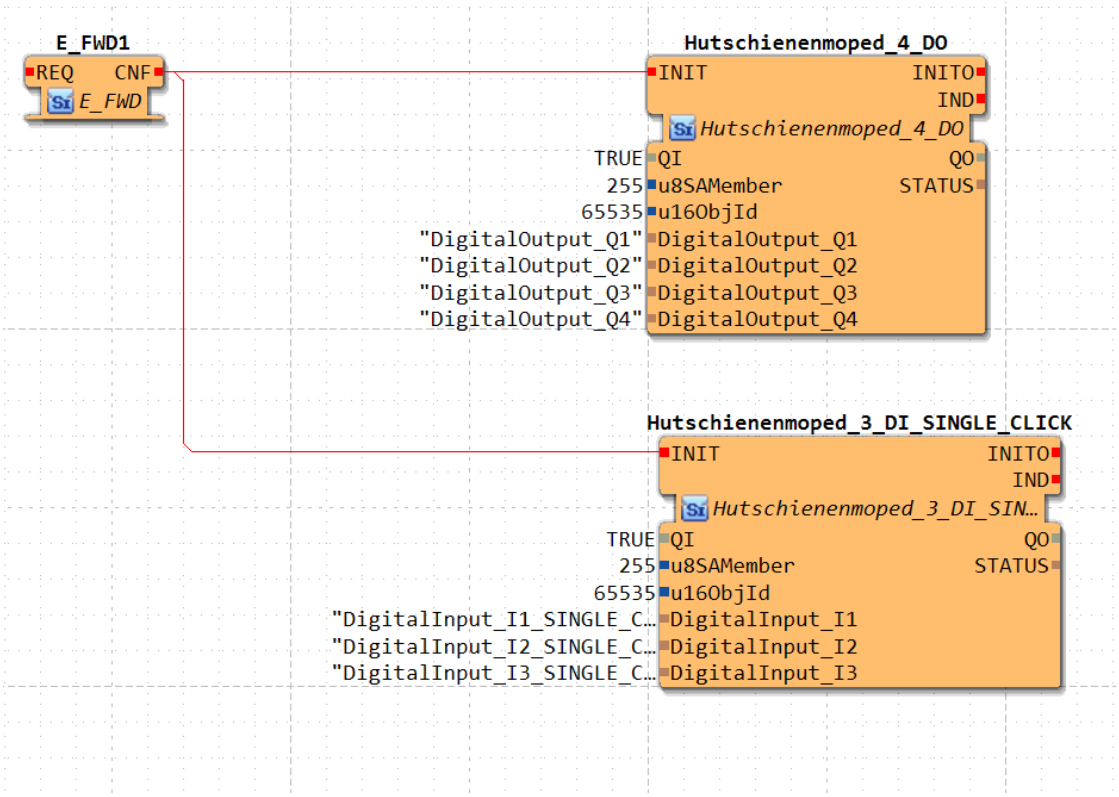
- The E_T_FF in IEC 61499: Modular Toggle for Industry 4.0
- The E_T_FF_SR Component: Heart of IEC 61499 – Storing, Switching, Responding
- Unpacking E_T_FF_SR: The Secret Toggle Switch of Industrial Control Systems

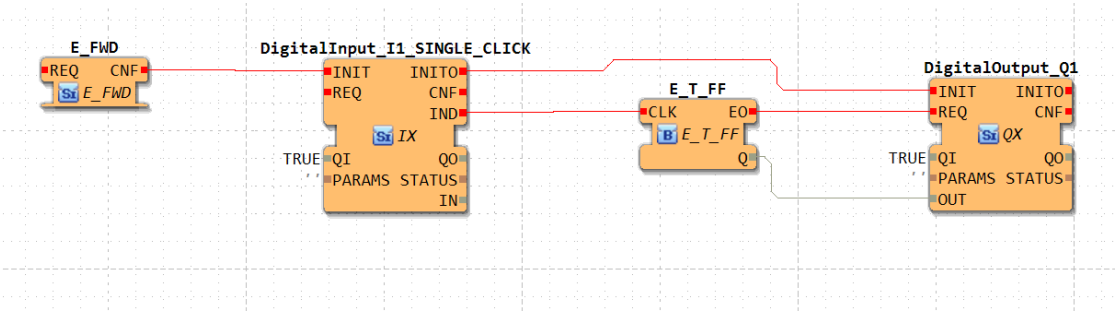
The `E_T_FF` (Event-driven Toggle Flip-Flop) is an event-driven toggle switch that changes its state (`Q`) with each incoming clock event (`CLK`). It is the digital equivalent of an impulse relay, where a short pulse permanently changes the state.

- **CLK (Clock)**: The clock event that toggles the state of `Q`.
- **EO (Event Output)**: Triggered when the state of `Q` changes.
- **Associated Data**: `Q`
- **Q**: The current state of the flip-flop (data type: `BOOL`).



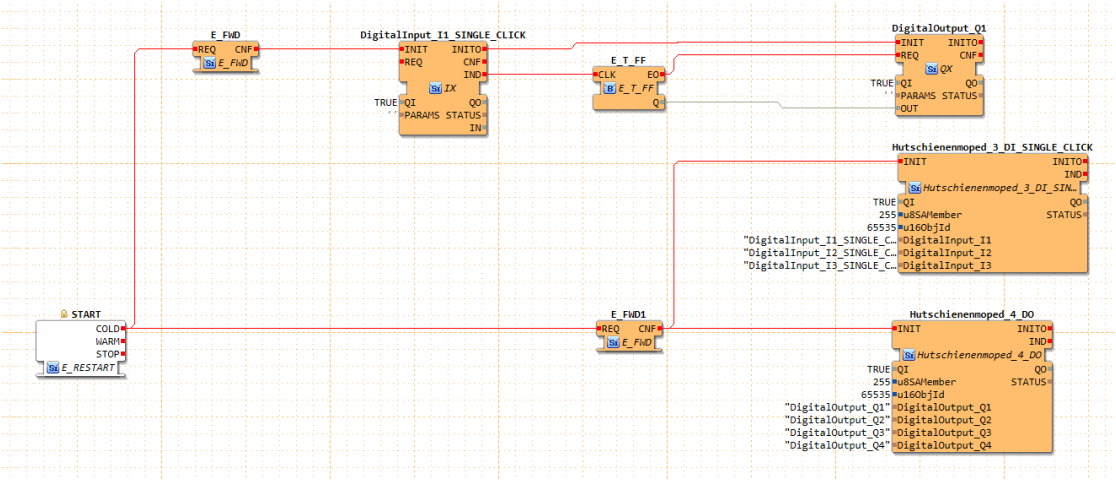
The `E_T_FF` component is a simple toggle flip-flop:

1. **State Change**: Upon each incoming `CLK` event, the output `Q` changes its state: If `Q` was `TRUE`, it becomes `FALSE`, and if `Q` was `FALSE`, it becomes `TRUE`.
2. **Event Triggering**: Each state change of `Q` triggers the `EO` event.



- **Impulse Switch Analogy**: The component behaves like an impulse switch: A short pulse (`CLK`) switches the light (`Q`) on, the next pulse switches it off.
- **Memory Function**: `Q` stores the last state of the flip-flop.
- **Stateless Between Clock Cycles**: Changes to the `CLK` input only affect `Q` at the time of the event.

A push button logic for a lamp can be implemented using a `E_T_FF`:



- **Concept**: A push button generates a `CLK` event. Each press turns the lamp (`Q`) on or off.

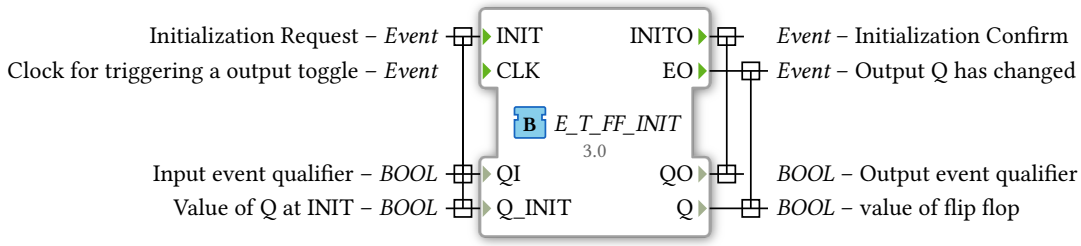
Conclusion



2.11.3.61 E_T_FF_INIT

• — ○ • — ○ • — ○ •

Introduction

`E_T_FF_INIT` (toggle flip-flop with initialization) combines the toggling behaviour of a toggle flip-flop (output `Q` switches state on every `CLK` event) with an explicit `INIT`/`INITO` interface for setting a defined start value.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `QI` and `Q_INIT`.
- **CLK**: Clock event, triggers a state change of `Q`.

Event Outputs

- **INITO**: Confirms (de-)initialization, carries `QO`.
- **EO**: Triggered on every `CLK` event, carries `Q`.

Data Inputs

- **QI** (BOOL): Input event qualifier — `TRUE` initializes, `FALSE` deinitializes.
- **Q_INIT** (BOOL): The value `Q` is set to during initialization.

Data Outputs

- **QO** (BOOL): Output event qualifier, mirrors `QI`.
- **Q** (BOOL): The current state of the flip-flop.

Functionality

`INIT` with `QI = TRUE` initializes `Q` via `Q_INIT` (states `Init` ⟶ `SET`/`RESET`, depending on `Q_INIT`). During normal operation, every `CLK` event flips the state: from `SET` to `RESET` and back, each confirmed via `EO` carrying the current `Q`. `INIT` with `QI = FALSE` deinitializes the block (`DeInit` ⟶ `START`).

Technical Features

- **Toggle instead of set/reset**: Unlike E_RS_SYM_INIT/E_SR_SYM_INIT, which have separate `S`/`R` inputs, `E_T_FF_INIT` has only a single clock input `CLK` that toggles between `SET` and `RESET` on every event.
- **Same INIT/DeInit structure** as the `_SYM_INIT` blocks: `QI` switches between initialization and deinitialization, `Q_INIT` determines the start value.

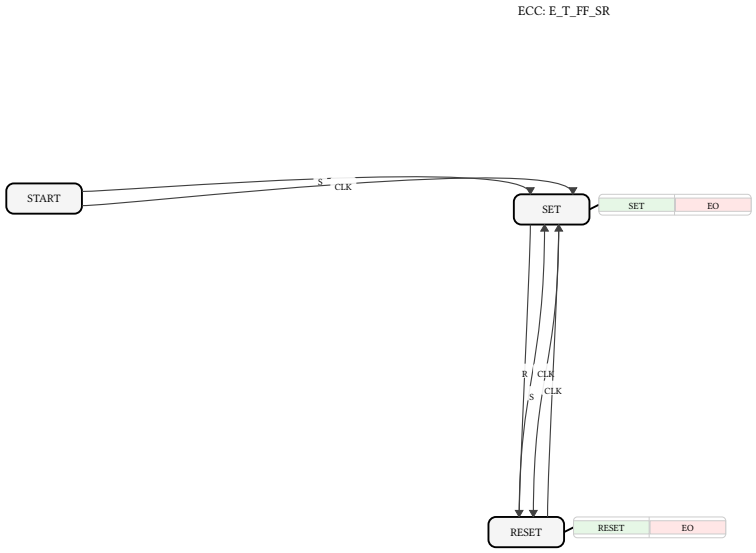
State Overview

State	Meaning
START	Unconfigured initial state
Init	Initialization in progress, `QO := QI`
DeInit	Deinitialization in progress, `QO := FALSE`
SET	`Q = TRUE`, switches to `RESET` on `CLK`
RESET	`Q = FALSE`, switches to `SET` on `CLK`

Application Scenarios

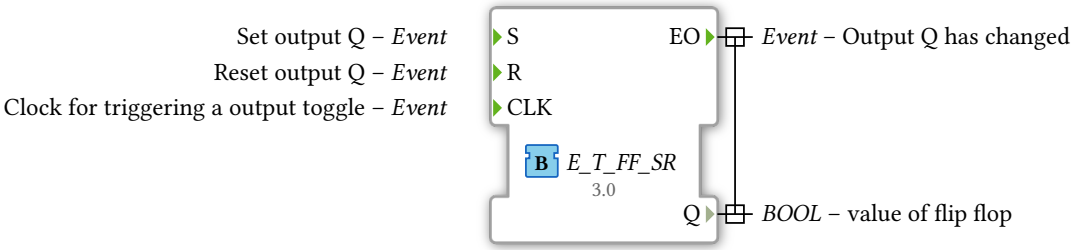
- **Blink logic with a defined start state**: A signal should toggle on every clock tick, but start with a known initial value (`Q_INIT`) after system startup instead of a random state.
- **Frequency division**: `E_T_FF_INIT` halves the event frequency from `CLK` to `EO` (returns to the same state every second `CLK`), with a controlled start value.

Comparison with similar function blocks



- **`E_T_FF`**: the same basic toggle functionality without an `INIT`/`INITO` interface.
- E_RS_SYM_INIT / E_SR_SYM_INIT: the same INIT/DeInit structure, but with separate set/reset inputs instead of a single clock input.
- E_T_FF_SR_SYM / E_T_FF_SR_SYM_INIT: additionally combine `S`/`R` inputs with the toggle behaviour.

Conclusion



`E_T_FF_INIT` provides a toggle flip-flop with a configurable, reliably defined start value and is suitable for blink and frequency-divider logic where the state after system startup must not be left to chance.

2.11.3.62 E_T_FF_SR

🎧 Podcast

- The E_T_FF_SR Block: The Heart of IEC 61499 – Storing, Switching, Responding
- Unpacking E_T_FF_SR: The Secret Toggle Switch of Industrial Control Systems The `E_T_FF_SR` (Event-driven Toggle Flip-Flop with Set/Reset) is an extended bistable function block according to IEC 61499. It combines the functionality of a `E_T_FF` (Toggling) with additional `S` (Set) and `R` (Reset) inputs.

- **S (Set)**: Sets the output `Q` to `TRUE`.
- **R (Reset)**: Sets the output `Q` to `FALSE`.
- **CLK (Clock)**: Triggers a toggle of the output `Q`.
- **EO (Event Output)**: Triggered when the state of `Q` changes.
- **Associated Data**: `Q`
- **Q**: The current state of the flip-flop (data type: `BOOL`).

Data Outputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

The E_T_FF_SR is a stateful component whose output Q is influenced by three event inputs:

1. **Set (S)**: When a S event occurs, Q is set to TRUE. If Q was previously FALSE, EO is triggered.
2. **Reset (R)**: When a R event occurs, Q is set to FALSE. If Q was previously TRUE, EO is triggered.
3. **Toggling (CLK)**: When a CLK event occurs, Q is toggled. If Q changes its state, EO is triggered.

The function block starts in the START state (implies Q is undefined/FALSE).

- If the first event is S, Q is set to TRUE.
- **If the first event is CLK, Q is set to TRUE** (not toggled from FALSE to TRUE). Subsequent CLK events will then toggle normally.
- **Asynchronous Set/Reset**: The S and R inputs can overwrite the state of Q at any time.
- **Toggle Function**: The CLK input allows for easy state switching.
- **No Prioritization (Dominance)**: As with E_RS and E_SR, there is no fixed priority when S, R, or CLK arrive simultaneously. The processing order of the 4diac runtime environment determines the final state.
- **Initial Behavior with CLK**: Upon receiving a CLK event from the START state, the function block is initially set (Q=TRUE) instead of toggling. This should be considered during system initialization.
- **Control with Manual Override**: A toggle switch (CLK) for a lamp, which can be switched directly on (S) or off (R) if needed (e.g., for safety reasons).
- **Mode Switching**: Switch between different modes (CLK), with the option to directly access a basic mode (R) or a special mode (S).
- **Error Reset and Toggle**: An error state can be set using S, acknowledged using R, and the error handling state can be toggled using CLK.
- Exercise_004a7
- Exercise_006a
- Exercise_006a2
- Exercise_006a3
- Exercise_006a4
- Exercise_179
- Exercise_180

The E_T_FF_SR block offers maximum flexibility for memory and control tasks by combining the toggle function with direct set and reset capabilities. combined. The specific behaviors of the START state and the lack of a prioritization guarantee for simultaneous events must be carefully considered during implementation.

2.11.3.63 E_T_FF_SR_SYM

• – ○ • – ○ • – ○ •

Introduction

`E_T_FF_SR_SYM` combines the functionality of E_RS_SYM (bistable set/reset with symmetric start-up) and a toggle flip-flop in a single block: in addition to the `S` and `R` inputs, it has a clock input `CLK` that toggles output `Q` independently of `S`/`R`.

Interface Structure

Event Inputs

- **S (Set)**: Sets `Q` to `TRUE`.
- **R (Reset)**: Sets `Q` to `FALSE`.

- **CLK**: Inverts the current state of Q (toggle).

Event Outputs

- **EO**: Triggered after every S, R, or CLK event, carries Q.

Data Outputs

- **Q** (BOOL): The current state.

Functionality

From the initial state START, S, R, **and** CLK all lead to a defined follow-up state (CLK leads to SET) — the symmetric start-up behaviour of E_RS_SYM applies here to all three events. During normal operation (states SET/RESET), S switches to SET, R to RESET, and CLK switches to the *opposite* state each time (toggle) — independent of the preceding S/R call. Every transition sets Q accordingly and triggers EO.

Technical Features

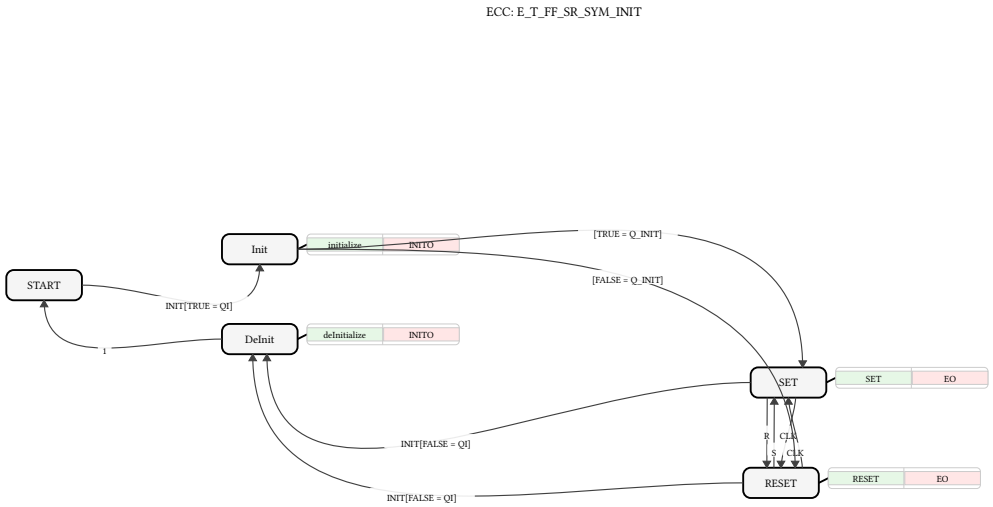
- **Combined set/reset/toggle behaviour**: Unlike E_T_FF, which only toggles, Q can here be set deliberately via S/R as well as toggled via CLK.
- **Symmetric start-up for all three inputs**: START reacts to S, R, and CLK equally well-defined.
- **No init mechanism**: For a configurable start value, see E_T_FF_SR_SYM_INIT.

State Overview

State	Meaning
START	Initial state, reacts symmetrically to S, R, CLK
SET	Q = TRUE; R⟶RESET, CLK⟶RESET
RESET	Q = FALSE; S⟶SET, CLK⟶SET

Application Scenarios

- **Manual operation with clock override**: A state can be either deliberately set/reset (S/R, e.g. by an operator) or toggled by a clock (CLK, e.g. by a timer), without needing two separate blocks.
- **Blink logic with override**: A blink signal (CLK) can be overridden at any time by an explicit S/R.

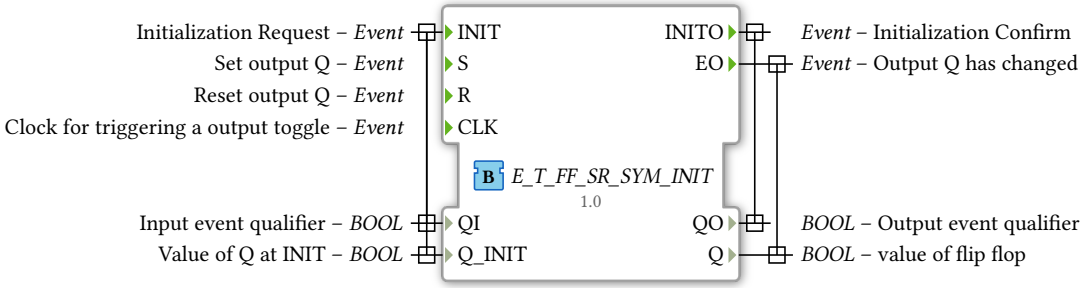


Comparison with similar function blocks

- **E_RS_SYM**: the same set/reset logic, but without the CLK toggle input.
- **E_T_FF**: pure toggle block without S/R.
- **E_T_FF_SR_SYM_INIT**: the same functionality, extended with INIT/INITO.

Conclusion

E_T_FF_SR_SYM combines deliberate set/reset with toggle functionality in a single block with guaranteed, well-defined start-up behaviour, making it suitable wherever both modes of operation are needed at once.



2.11.3.64 E_T_FF_SR_SYM_INIT

• – ○ • – ○ • – ○ •

Introduction

`E_T_FF_SR_SYM_INIT` extends E_T_FF_SR_SYM with an explicit `INIT`/`INITO` interface: the start value of `Q` is not determined by the first `S`, `R`, or `CLK` event, but is set deliberately via `Q_INIT`.

Interface Structure

Event Inputs

- **INIT**: Initialization request, carries `QI` and `Q_INIT`.
- **S (Set)**: Sets `Q` to `TRUE`.
- **R (Reset)**: Sets `Q` to `FALSE`.
- **CLK**: Inverts the current state of `Q`.

Event Outputs

- **INITO**: Confirms (de-)initialization, carries `QO`.
- **EO**: Triggered after every `S`, `R`, or `CLK` event, carries `Q`.

Data Inputs

- **QI** (BOOL): Input event qualifier — `TRUE` initializes, `FALSE` deinitializes.
- **Q_INIT** (BOOL): The value `Q` is set to during initialization.

Data Outputs

- **QO** (BOOL): Output event qualifier.
- **Q** (BOOL): The current state.

Functionality

`INIT` with `QI = TRUE` initializes `Q` via `Q_INIT` (`Init` ⟶ `SET`/`RESET`). During normal operation, `S`/`R` switch deliberately, `CLK` toggles between `SET` and `RESET` — identical to E_T_FF_SR_SYM, but without its symmetric start-up behaviour from `START`, since the start value instead comes from `INIT`. `INIT` with `QI = FALSE` deinitializes the block back to state `START`.

Technical Features

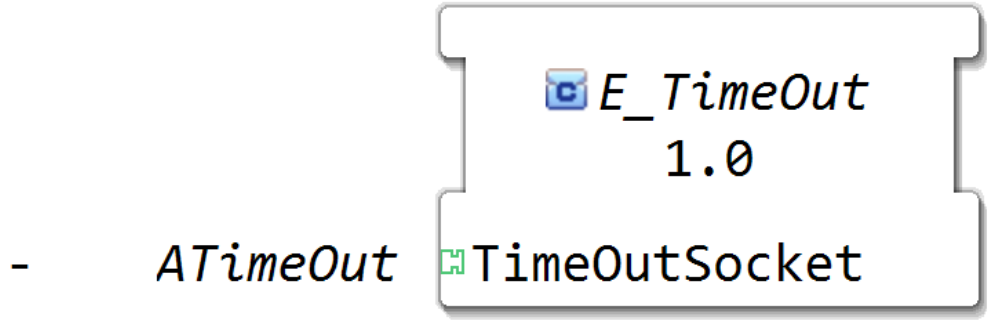
- **Combines all three mechanisms**: deliberate set/reset (`S`/`R`), toggle (`CLK`), and configurable initialization (`INIT`/`Q_INIT`) in a single block.
- **Same INIT/DeInit structure** as E_RS_SYM_INIT, E_SR_SYM_INIT, and E_T_FF_INIT.

State Overview

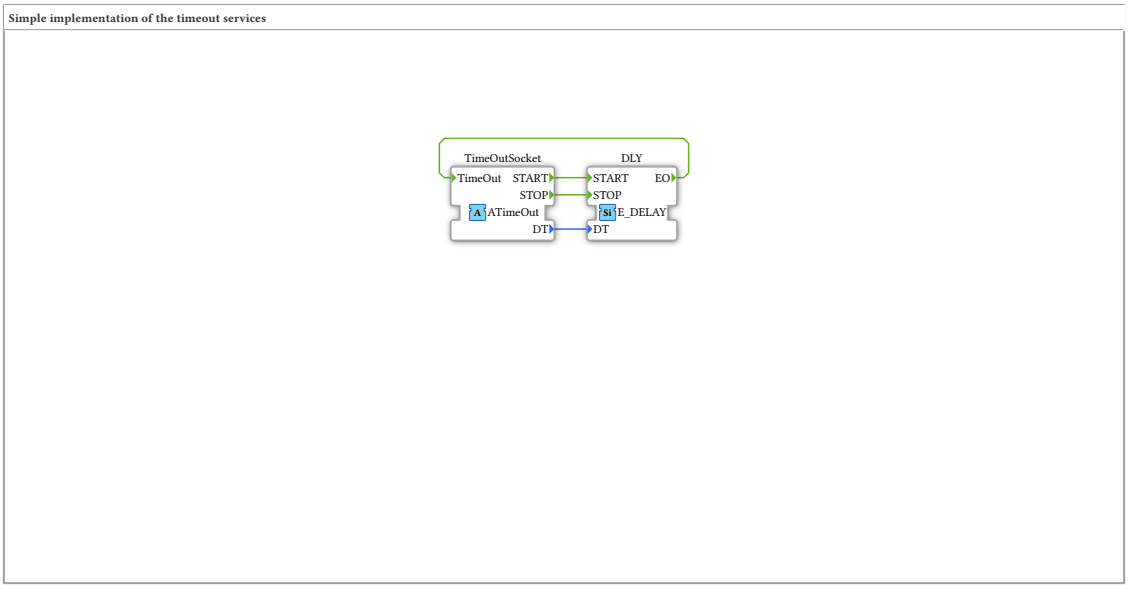
State	Meaning
START	Unconfigured initial state
Init	Initialization in progress, `QO := QI`
DeInit	Deinitialization in progress, `QO := FALSE`
SET	`Q = TRUE`; `R`/`CLK`⟶RESET
RESET	`Q = FALSE`; `S`/`CLK`⟶SET

Application Scenarios

- **Fully-featured operator/blink element** with a defined start value: combines manual set/reset, clock-driven toggling, and a start state that can be configured at startup.



Comparison with similar function blocks

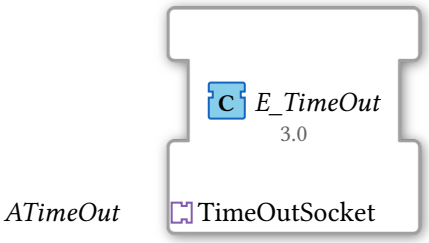


- **E_T_FF_SR_SYM**: the same functionality without `INIT`/`INITO`.
- **E_T_FF_INIT**: only toggle + init, without `S`/`R`.
- **E_RS_SYM_INIT** / **E_SR_SYM_INIT**: only set/reset + init, without `CLK`.

Conclusion

`E_T_FF_SR_SYM_INIT` is the functionally most complete block in the `E_*_SYM` family, combining set/reset, toggle, and configurable initialization in a single function block.

2.11.3.65 E_TimeOut



• – ○ • – ○ • – ○ •

Introduction

The **E_TimeOut** is a standards-compliant function block (IEC 61499-1) for implementing timeout services. Version 1.0 offers simple yet effective timeout functionality through internal use of an E_DELAY block. The **E_TimeOut** is a composite function block. Within the network of a composite function block, each adapter added to its interface is represented by an adapter block, which looks like a function block. The interface elements of this adapter block are connected like a function block.

Interface Structure

Adapter Interface (Socket Perspective)

The block uses a **socket** `TimeOutSocket` of type `ATimeOut`. Since this is a socket, the signal directions are inverted compared to the adapter definition (plug):

- **Inputs (received from the socket)**:
- `START`: Starts the internal timer.
- `STOP`: Stops the internal timer.
- `DT` (TIME): The delay time to be used.
- **Output (sent to the socket)**:
- `TimeOut`: Signaled to the connected plug after the specified time has elapsed.

Internal Components

- `DLY` (E_DELAY): Core component for time control

Functionality

1. **Timeout Initialization**:

- Upon a `START` event at the socket, the timer starts with the configured `DT` value.
- Any further `START` event while the timer is running is ignored.

1. **Timeout Termination**:

- A `STOP` event immediately terminates the active timer. No `TimeOut` event is generated.

1. **Timeout Trigger**:

- After `DT` expires, the `TimeOut` event is generated once.

Technical Features

✓ **Adapter-based** interface (`ATimeOut`).
✓ **Simple, non-retriggerable timeout logic**.
✓ **Deterministic** timing behavior.

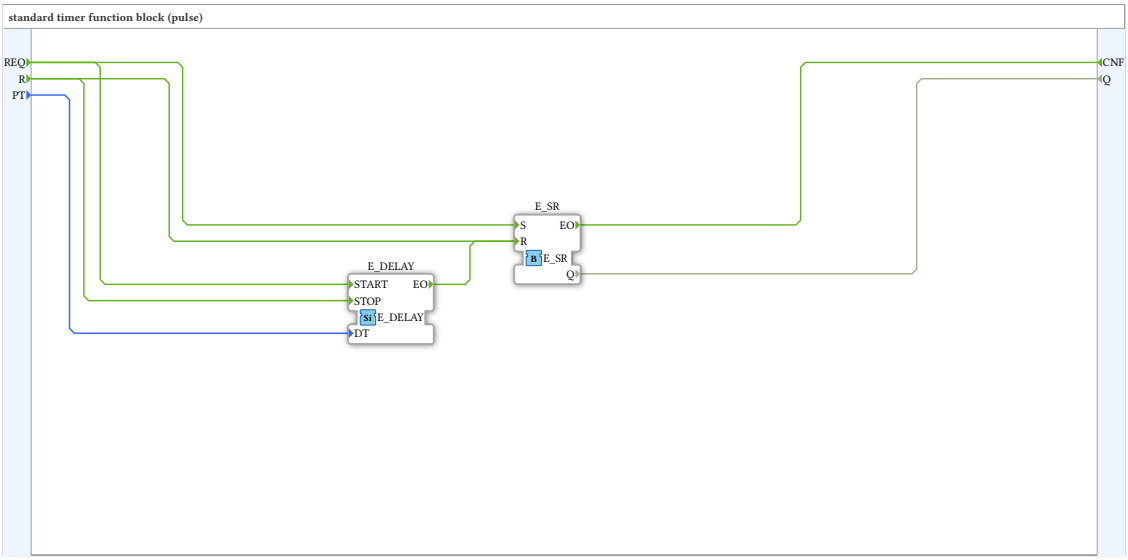
Application Scenarios

- **Network Communication**: Monitoring for a response within a fixed timeframe. When the response arrives, the timer is canceled via `STOP`.
- **Device Control**: Simple watchdog functions that do not require resetting.
- **Process Monitoring**: Ensuring that a process step does not exceed a maximum duration.

⚖️ **Comparison with E_RTimeOut**

Feature	E_TimeOut (this one)	E_RTimeOut
Internal Block	E_DELAY	E_RDELAY
`START` on running timer	Ignored	Restarts timer
Adapter Type	ATimeOut	ARTimeOut

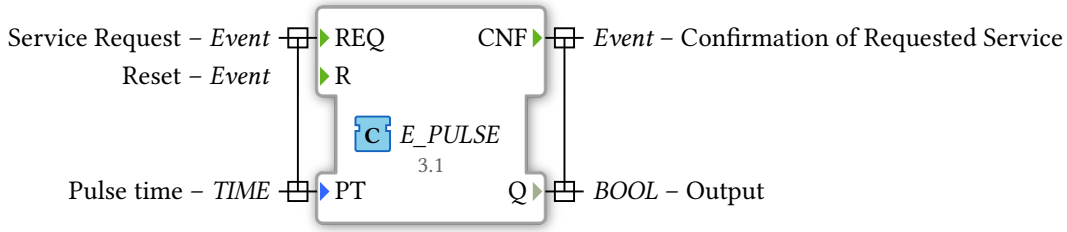
🛠️ **Related exercises**



- Uebung_035
- Uebung_035a
- Uebung_035a1_AX
- Uebung_035a2
- Uebung_035a2_AX
- Uebung_035a3
- Uebung_035a3_AX
- Uebung_035c
- Exercise_036
- Exercise_037
- Exercise_038
- Exercise_038_AX
- Exercise_039
- Exercise_039a

Conclusion

The E_TimeOut block provides a robust basic implementation for non-retriggerable timeout requirements. It is ideal for cases where a timer is started and should either run to completion or be explicitly aborted. For scenarios that require “re-triggering” or resetting the timer (such as a watchdog that is periodically “kicked”), the `E_RTimeOut` block is the better choice.



2.11.3.66 timers

E_PULSE

Important note: This function block requires only one event and no cyclic calls. It has no output ET and does not display the elapsed time.

• – ◦ • – ◦ • – ◦ •

The following text was generated by https://chat.deepseek.com/ on February 5, 2025, and has not yet been proofread (HF)

The E_PULSE function block in IEC 61499: An overview

Introduction

IEC 61499 is an international standard that enables the modeling of distributed industrial control systems. A central concept in this standard is the function block (FB), which serves as a fundamental component for the control logic. The **E_PULSE** (Event-driven Pulse) function block is an example of such a function block used in IEC 61499 to generate a pulse of a specific duration. This paper describes the structure, behavior, and application of the E_PULSE function block using the provided source code. A particularly noteworthy aspect is that this function block **also functions when called non-cyclically** because it is internally based on the **E_DELAY** function block from IEC 61499.

Structure of the E_PULSE Function Block

The E_PULSE function block is a **Composite Function Block (CFB)** specified according to IEC 61499. A CFB consists of an interface and an internal network of function blocks that work together to achieve the desired behavior.

Interface

The interface of the E_PULSE block consists of:

- **Event Inputs**:
- **REQ (Request)**: This event triggers the execution of the block. It is linked to the input variable **PT** (Pulse Time).
- **R (Reset)**: This event resets the timer.

- **Event Output**:
- **CNF (Confirmation)**: This event is triggered when the execution of the block is complete. It is linked to the output variable **Q**.
- **Input Variable**:
- **PT (Pulse Time)**: This is a time variable (TIME) that defines the duration of the pulse.
- **Output Variable**:
- **Q (Output)**: This is a Boolean variable that indicates the state of the pulse. It is **TRUE** as long as the pulse is active.

Internal Network (FBNetwork)

The E_PULSE block uses two internal function blocks to implement the desired behavior:

1. **E_DELAY**: This block implements the delay time **PT**. When the **START** event occurs, the timer starts running. When the delay time has elapsed, the **EO** event is triggered.
2. **E_SR**: This block is a bistable element that stores the pulse state. When the **S** event occurs, the output **Q** is set to **TRUE**. When the **R** event occurs, the output **Q** is set to **FALSE**.

Behavior of the E_PULSE Block

The E_PULSE block behaves like a pulse generator that produces a pulse with a specific duration **PT**. The behavior of the function block can be described as follows:

1. **Pulse Start**: When the **REQ** event occurs, the timer is started, and the output **Q** is set to **TRUE**.
2. **Pulse Duration**: The output **Q** remains **TRUE** until the delay time **PT** has elapsed.
3. **Pulse End**: Once the delay time **PT** has elapsed, the output **Q** is set to **FALSE**, and the **CNF** event is triggered to signal the end of the pulse.
4. **Reset**: When the **R** event occurs, the timer is reset, and the output **Q** is set to **FALSE**.

Independence from Cyclic Calling

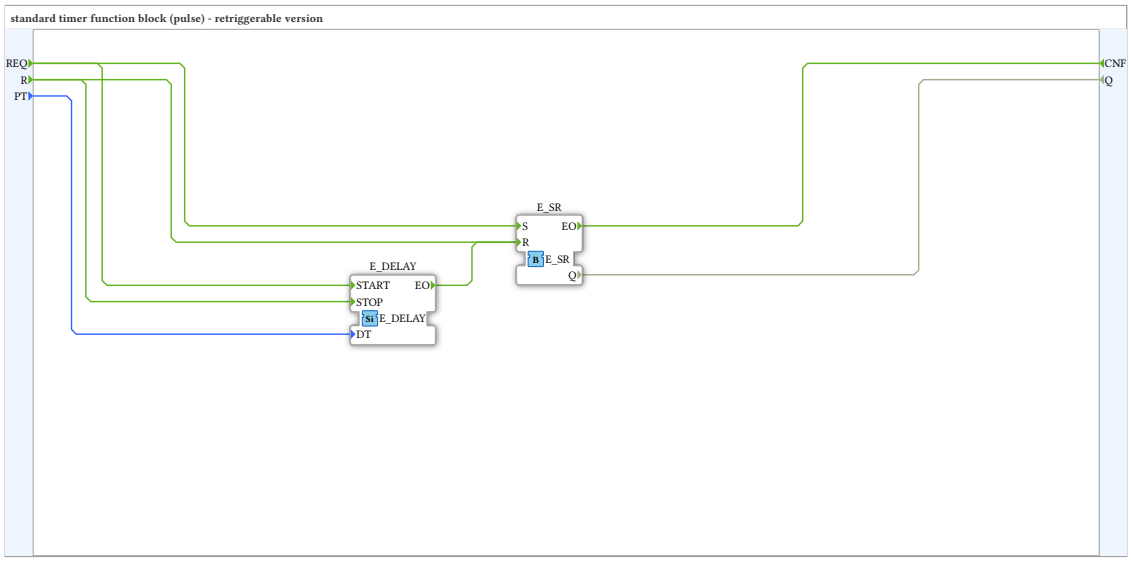
A key advantage of the E_PULSE function block is that it **does not need to be called cyclically** to function correctly. This is because the function block is internally based on the **E_DELAY** function block, which is specified in IEC 61499. The **E_DELAY** function block is an event-driven timer that operates independently of the cyclic call of the parent function block. This means that the E_PULSE function block can also be used in systems that do not operate cyclically, such as event-driven or distributed control systems.

Application Examples

The E_PULSE function block can be used in various industrial control applications, especially in scenarios where a pulse of a specific duration is required. Some examples are:

- **Machine Control**: The function block can be used to generate a short pulse that activates a machine for a specific period of time, for example, to start or stop a process.
- **Lighting Control**: This function block can be used in lighting systems to switch on the light for a specific period of time, e.g., for emergency lighting.
- **Valve Control**: This function block can be used to open a valve for a specific period of time, e.g., to release a specific quantity of liquid or gas.

🛠️ Related Exercises

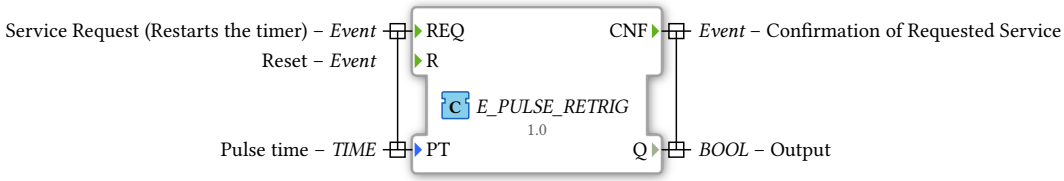


- Exercise_020h
- Exercise_020i

Conclusion

The E_PULSE function block is a versatile function block in IEC 61499 that implements a pulse with a specific duration. Due to its internal use of the **E_DELAY** function block, it can function correctly **even when not called cyclically**. This makes it particularly suitable for event-driven and distributed control systems where cyclic calls are not always guaranteed.

The provided source code demonstrates how the E_PULSE function block can be implemented in practice and offers a solid foundation for developing similar function blocks in industrial control systems. Its independence from cyclic calls is a crucial advantage that makes the function block suitable for a wide range of applications.



E_PULSE_RETRIG

• – ○ • – ○ • – ○ •

Introduction

`E_PULSE_RETRIG` is the retriggerable variant of `E_PULSE`: it generates a `TRUE` pulse of duration `PT` on `Q`, but restarts the pulse from the beginning on every new `REQ` event instead of ignoring a running interval.

Interface Structure

Event Inputs

- **REQ**: Starts (or retriggers) the pulse, carries `PT`.
- **R**: Immediately aborts the running pulse.

Event Outputs

- **CNF**: Confirmation, carries `Q`.

Data Inputs

- **PT** (TIME): Duration of the pulse.

Data Outputs

- **Q** (BOOL): `TRUE` during the pulse duration, otherwise `FALSE`.

Functionality

Every `REQ` event simultaneously sets `E_SR.S` (⟶ `Q := TRUE`) and restarts `E_DELAY` with time `PT` — a new `REQ` during a running pulse thus restarts the `E_DELAY` timer from scratch instead of waiting for the original pulse to elapse. When `E_DELAY` elapses, `E_SR.R` is triggered (`Q := FALSE`). An `R` event stops the timer immediately and resets `Q` to `FALSE` directly.

Technical Features

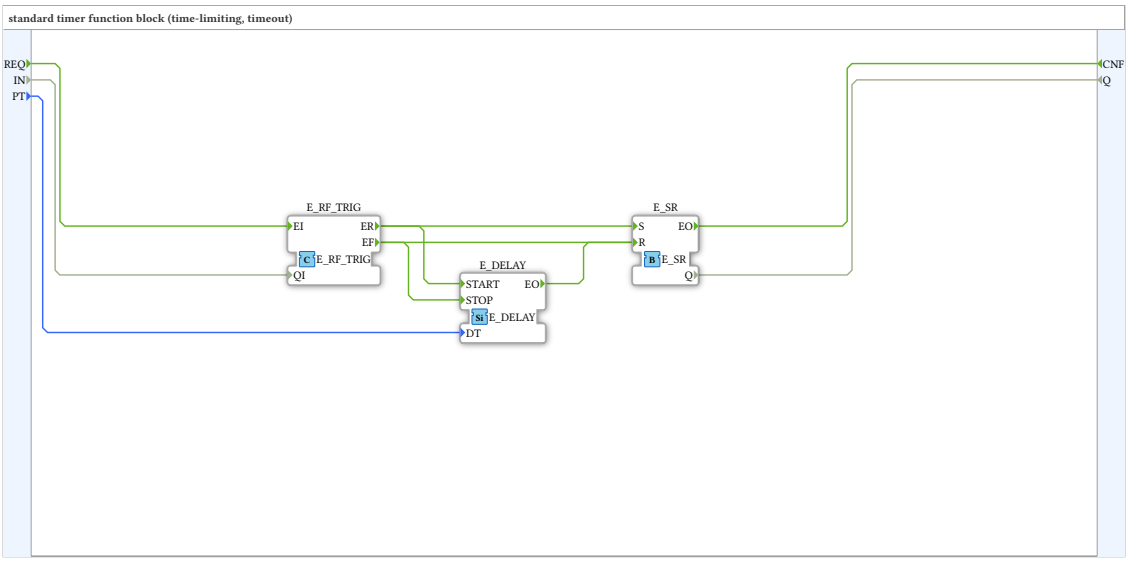
- **Retriggerable**: The key difference to `E_PULSE` (not retriggerable) is that every `REQ` restarts the `E_DELAY` timer — a pulse can thus be extended indefinitely through repeated `REQ` events.
- **Composed of `E_DELAY` + `E_SR`**: pure wiring, no ECC of its own.

State Overview

Stateless wiring logic: `E_SR` holds the current `Q` state, `E_DELAY` restarts on every `REQ`.

Application Scenarios

- **Dead-time/watchdog logic**: `Q` should remain `TRUE` as long as `REQ` events keep arriving regularly (e.g. a sensor heartbeat), and only become `FALSE` once `PT` has elapsed since the last `REQ` without a further one.
- **Extendable pulses**, e.g. a light that restarts its on-duration on every new motion detection (`REQ`) instead of timing out.

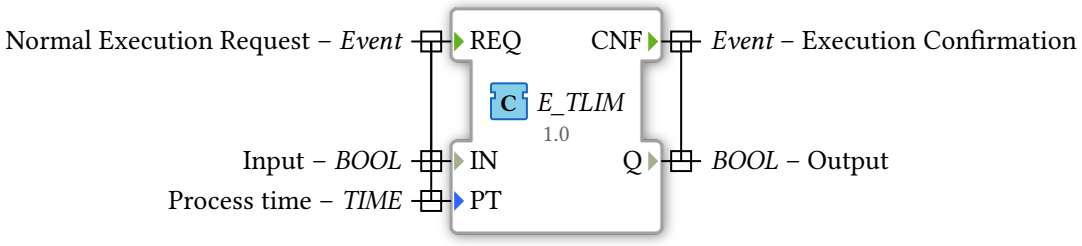


Comparison with similar function blocks

- **`E_PULSE`**: the same base functionality, but not retriggerable (`REQ` during a running pulse has no effect).
- **E_TP_RETRIG**: retriggerable pulse, triggered by a rising edge of `IN` instead of a separate `REQ` event.

Conclusion

`E_PULSE_RETRIG` provides an extendable `TRUE` pulse whose duration restarts on every `REQ` event, suiting watchdog and dead-time applications where a running pulse should be kept alive by repeated requests.



E_TLIM

• – ○ • – ○ • – ○ •

Introduction

`E_TLIM` (time-limiting) limits how long `Q` can stay `TRUE` at most: as soon as `IN` switches to `TRUE`, `Q` also becomes `TRUE`; if `IN` stays `TRUE` longer than `PT`, `Q` automatically switches to `FALSE` once `PT` elapses (timeout). If `IN` already falls back to `FALSE` before `PT` elapses, `Q` follows immediately.

Interface Structure

Event Inputs

- **REQ**: Trigger, carries `IN` and `PT`.

Event Outputs

- **CNF**: Confirmation, carries `Q`.

Data Inputs

- **IN** (BOOL): The input state being monitored.
- **PT** (TIME): Maximum time `Q` may stay `TRUE` after a rising edge of `IN`.

Data Outputs

- **Q** (BOOL): `TRUE` while `IN` is `TRUE` and `PT` has not yet elapsed.

Functionality

`E_RF_TRIG` detects edge transitions of `IN`: a rising edge (`ER`) starts `E_DELAY` (with `PT`) and sets `E_SR.S` (→ `Q := TRUE`). A falling edge (`EF`) immediately stops `E_DELAY` and sets `E_SR.R` (→ `Q := FALSE`) — so `IN` always wins over the timeout. If `E_DELAY` instead runs to completion (because `IN` stayed `TRUE` longer than `PT`), this also triggers `E_SR.R`, causing `Q` to fall back to `FALSE` even without a falling edge of `IN` (the timeout case).

Technical Features

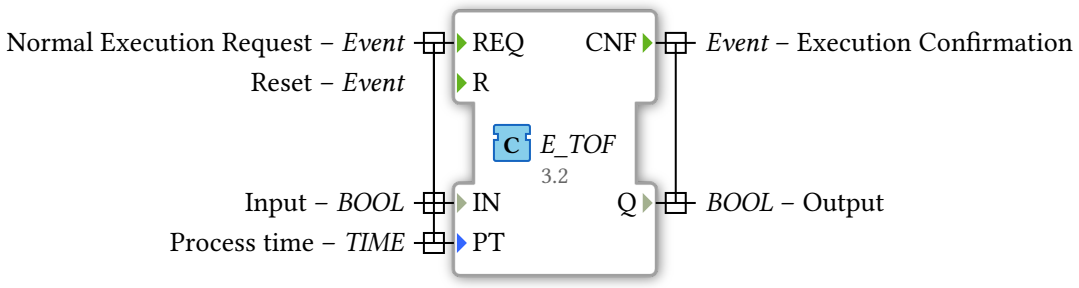
- **Two paths to `Q := FALSE`**: either a falling edge of `IN` (regular case) or `PT` elapsing (timeout case) — both go through `E_SR.R`.
- **Composed of three standard blocks**: `E_RF_TRIG` (edge detection) + `E_DELAY` (timeout timer) + `E_SR` (state storage), no ECC of its own.

State Overview

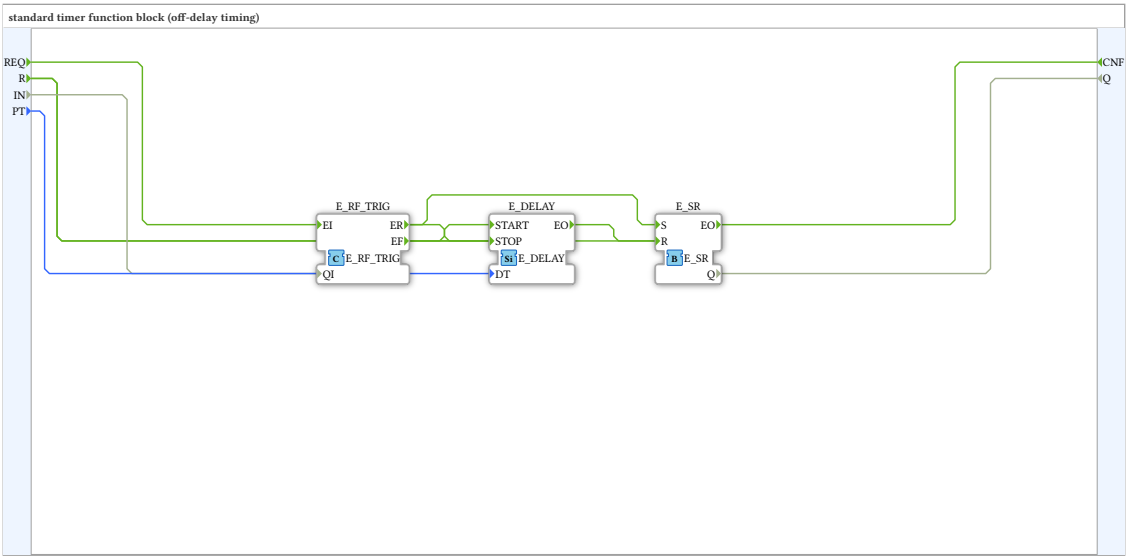
State (implicit via `E_SR`/`E_DELAY`)	Meaning
Q = FALSE, timer inactive	Idle, `IN = FALSE`
Q = TRUE, timer running	`IN` is `TRUE`, `PT` not yet elapsed
Q = FALSE (timeout)	`IN` was `TRUE` longer than `PT`, automatically reset

Application Scenarios

- **Monitoring maximum durations**: A signal may be active for at most `PT` (e.g. a maximum on-time for an actuator as a safety limit); if `IN` stays active longer, `Q` is automatically reset.
- **Timeout monitoring of process steps**: `IN` marks the running step, `Q` indicates whether the step is still within the allowed time `PT`.



Comparison with similar function blocks



- **`E_TON`/`E_TOF`** (standard IEC 61131-3 timers): delay the *turning on* or *turning off* of `Q` relative to `IN`, but do not limit its maximum on-time.
- **E_PULSE_RETRIG** / **E_TP_RETRIG**: generate a pulse of fixed duration, regardless of how long `IN`/`REQ` actually stays active.
- **`E_RF_TRIG`**: the internally used edge detection.

Conclusion

`E_TLIM` limits the maximum on-time of a `BOOL` signal and is a simple timeout guard for actuators or process steps where staying too long in the `TRUE` state should be ended automatically.

- E_TOF vs. FB_TOF: The event timer that doesn't tick cyclically – a revolution for automation systems?
- FB_TOF and E_TOF: Delay timers in IEC 61131-3 and 61499

IEC 61499 is an international standard that enables the modeling of distributed industrial control systems. A central concept in this standard is the function block (FB), which serves as a fundamental component for the control logic. The **E_TOF** (Event-driven Off-Delay Timer) function block is an example of such a function block used in IEC 61499 to model a delayed shutdown function. This paper describes the structure, behavior, and application of the E_TOF function block using the provided source code. A particularly noteworthy aspect is that this function block **also functions when called non-cyclically** because it is internally based on the **E_DELAY** function block from IEC 61499.

The E_TOF function block is a **Composite Function Block (CFB)** specified according to IEC 61499. A CFB consists of an interface and an internal network of function blocks that work together to implement the desired behavior.

Struktur des E_TOF-Bausteins

Introduction

Der Baustein E_TOF in der IEC 61499: Ein Überblick

Beschreibung

Interface

The interface of the E_TOF block consists of:

- **Event Inputs**:
- **REQ (Request)**: This event triggers the execution of the block. It is linked to the input variables **IN** and **PT**.
- **R (Reset)**: This event resets the timer.
- **Output Event**:
- **CNF (Confirmation)**: This event is triggered when the execution of the block is complete. It is linked to the output variable **Q**.
- **Input Variables**:
- **IN (Input)**: This is a Boolean variable that controls the state of the timer. If **IN** is set to **TRUE**, the timer starts. If **IN** is set to **FALSE**, the delay time begins.
- **PT (Process Time)**: This is a time variable (TIME) that defines the delay time after which the output **Q** is set to **FALSE**.
- **Output Variable**:
- **Q (Output)**: This is a Boolean variable that indicates the timer's state. It remains **TRUE** until the delay time **PT** has elapsed.

Internal Network (FBNetwork)

The E_TOF block uses three function blocks internally to implement the desired behavior:

1. **E_SWITCH**: This block controls the flow of events based on the input **IN**. If **IN** is set to **TRUE**, the event is forwarded to **E_RS.S**. If **IN** is set to **FALSE**, the event is forwarded to **E_DELAY.START**.
2. **E_DELAY**: This block implements the delay time **PT**. When the **START** event occurs, the timer starts running. When the delay time has elapsed, the **EO** event is triggered.
3. **E_RS**: This block is a bistable element that stores the timer's state. When the **S** event occurs, the output **Q** is set to **TRUE**. When the **R** event occurs, the output **Q** is set to **FALSE**.

The E_TOF block behaves like an off-delay timer, implementing a delayed shutdown function. The block's behavior can be described as follows:

1. **Timer Start**: When the **REQ** event occurs and the input variable **IN** is set to **TRUE**, the timer starts. The output **Q** is set to **TRUE**.
2. **Delay Time**: When the input variable **IN** is set to **FALSE**, the delay time **PT** begins. The output **Q** remains **TRUE** until the delay time has elapsed.
3. **Delay Time Expiration**: Once the delay time **PT** has elapsed, the output **Q** is set to **FALSE**, and the **CNF** event is triggered to signal the end of the delay.
4. **Reset**: When the **R** event occurs, the timer is reset, and the output **Q** is set to **FALSE**.

A key advantage of the E_TOF block is that it **does not need to be called cyclically** to function correctly. This is because the block is internally based on the **E_DELAY** block specified in IEC 61499. The **E_DELAY** block is an event-driven timer that operates independently of the cyclic call of the parent block. This means that the E_TOF block can also be used in systems that do not operate cyclically, such as event-driven or distributed control systems.

The E_TOF block can be used in various industrial control applications, especially in scenarios where a delayed shutdown function is required. Some examples are:

- **Machine Control**: The block can be used to ensure that a machine continues to run for a specific period of time after being switched off, for example, to complete processes or to implement safety precautions.
- **Lighting Control**: The block can be used in lighting systems to keep the light on for a specific period of time after the switch has been turned off.
- **Valve Control**: This function block can be used to keep a valve open for a specific period of time after it has closed, for example, to release pressure.
- Exercise_020e

The E_TOF function block is a versatile function block in IEC 61499 that implements a delayed shutdown function. Due to its internal use of the **E_DELAY** function block, it can function correctly **even if it is not called cyclically**. This makes it particularly suitable for event-driven and distributed control systems where cyclic calls are not always guaranteed.

The provided source code demonstrates how the E_TOF function block can be implemented in practice and provides a solid foundation for developing similar function blocks in industrial control systems. The independence from cyclical calls is a crucial advantage that makes the component suitable for a wide variety of applications.

The fact that it doesn't require cyclical calls is a key advantage.## ⚖️ Comparison of E_TOF and FB_TOF

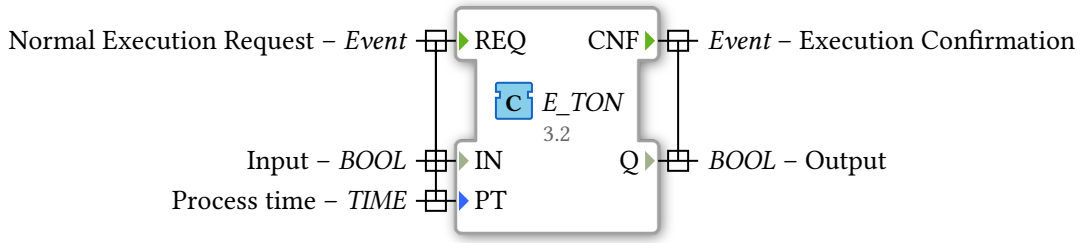
Verhalten des E_TOF-Bausteins

Chapter 1: The FB_TOF Block

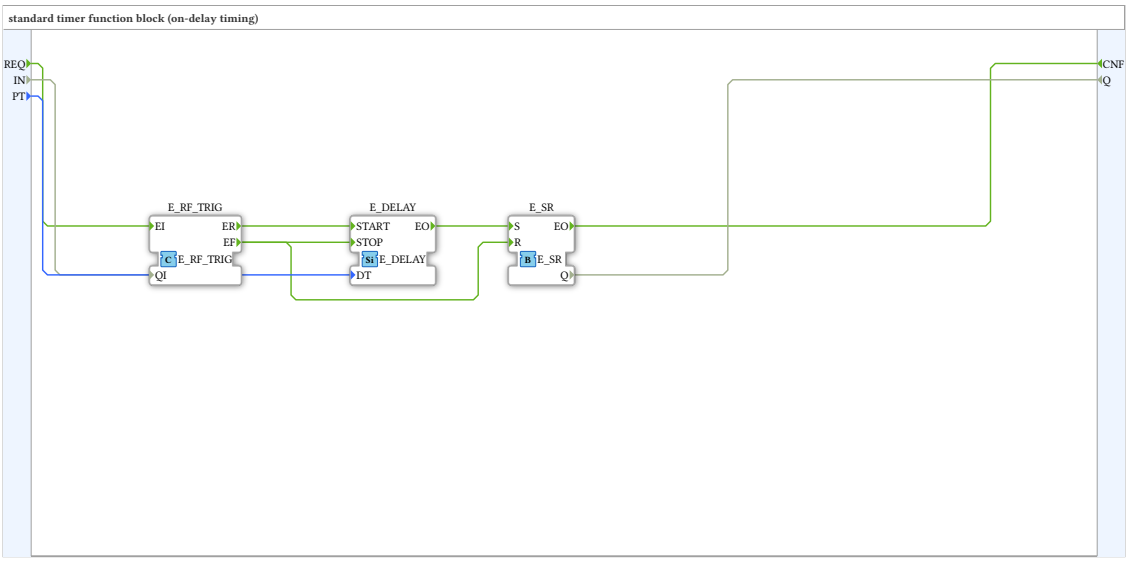
The **FB_TOF** (Off-Delay Timer) is a standardized function block according to IEC 61131-3 that implements a delayed shutdown function. A key feature of this block is the **ET** (Elapsed Time) output, which displays

the elapsed time since the start of the delay. This output is particularly useful for monitoring the progress of the delay time and for use in control logic.

However, a critical aspect of the FB_TOF block is that it **must be called cyclically** to function correctly. This means that the block must be executed in every cycle of the PLC program to correctly calculate the elapsed time **ET** and maintain the delay time **PT**. If the function block is not called regularly, the timer cannot function correctly, and the delay time may not be adhered to. This dependence on cyclic calling makes the FB_TOF function block ideal for traditional PLC systems that operate in fixed cycles.



The **E_TOF** (Event-driven Off-Delay Timer) is a function block according to IEC 61499 that also implements a delayed shutdown function. Unlike the FB_TOF, the E_TOF **does not have an ET** output that displays the elapsed time. Instead, the E_TOF is internally based on the **E_DELAY** function block specified in IEC 61499, which provides an event-driven delay function.



A key advantage of the E_TOF function block is that it **does not need to be called cyclically** to function correctly. Since the internal **E_DELAY** block operates independently of the cyclic call of the parent block, the E_TOF block can also be used in systems that do not operate cyclically, such as event-driven or distributed control systems. This makes the E_TOF block particularly flexible and suitable for modern, distributed control architectures where cyclic calls are not always guaranteed.

In summary, the FB_TOF block, with its **ET** output, enables detailed monitoring of elapsed time but requires a cyclic call. The E_TOF block, on the other hand, does without the **ET** output but offers the flexibility to operate independently of cyclic calls, making it ideal for event-driven systems.

E_TON

Podcast

- E_TON in Industrial Automation: How a Simple Timer Creates Safety and Stability

Text

The **E_TON** function block is a standardized function block type (FBType) according to the **IEC 61499** standard, used for **On-Delay Timers** in industrial automation systems. This function block allows a

signal to be switched on with a time delay, which is required in many control applications, for example, to safely control machines or processes.

General Description

- **Name**: E_TON
- **Type**: Standard Timer Function Block (On-Delay Timing)
- **Purpose**: This function block is used to implement a time-delayed turn-on function. It is particularly useful in applications where a delay is required when a signal is switched on.
- **License**: This function block is licensed under the Eclipse Public License 2.0 (EPL-2.0).

Interface Description

Event Inputs:

1. **REQ** (Normal Execution Request):

- **Type**: Event
- **Description**: This event triggers the normal execution of the function block. It is used to start or update the timer.
- **Associated Variables**:
- **IN**: The input value that starts the timer.
- **PT**: The specified duration for the on-delay.

Event Outputs:

1. **CNF** (Execution Confirmation):

- **Type**: Event
- **Description**: This event confirms the execution of the function block. It is triggered when the timer expires or a state change occurs.
- **Associated Variable**:
- **Q**: The output value indicating the timer's state.

Input Variables:

1. **IN**:

- **Type**: BOOL
- **Description**: The input value that starts the timer. When **IN** is set to `TRUE`, the turn-on delay (**PT**) starts. The output **Q** is only set to `TRUE` after the **PT** time has elapsed.

1. **PT**:

- **Type**: TIME
- **Description**: The preset duration for the on-delay. This time is measured from the moment **IN** is set to `TRUE`.

Output Variables:

1. **Q**:

- **Type**: BOOL
- **Description**: The output value that indicates the timer's state. **Q** is set to `TRUE` after the on-delay (**PT**) has elapsed.

–

Functionality

1. **On-Delay**:

- When **IN** is set to `TRUE`, the on-delay timer (**PT**) starts.
- After **PT** expires, **Q** is set to `TRUE`.
- If **IN** is set to `FALSE` during the timer, the timer stops, and **Q** remains at `FALSE`.

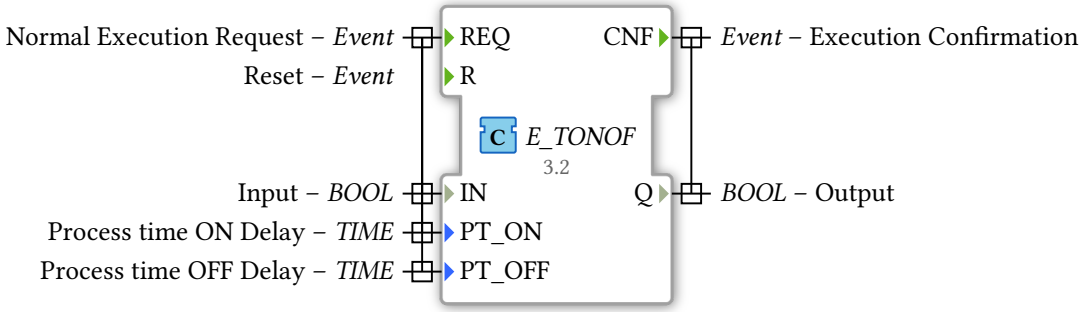
1. **Confirmation of Execution (CNF)**:

- The **CNF** event is triggered when the timer expires and **Q** is set to `TRUE`.

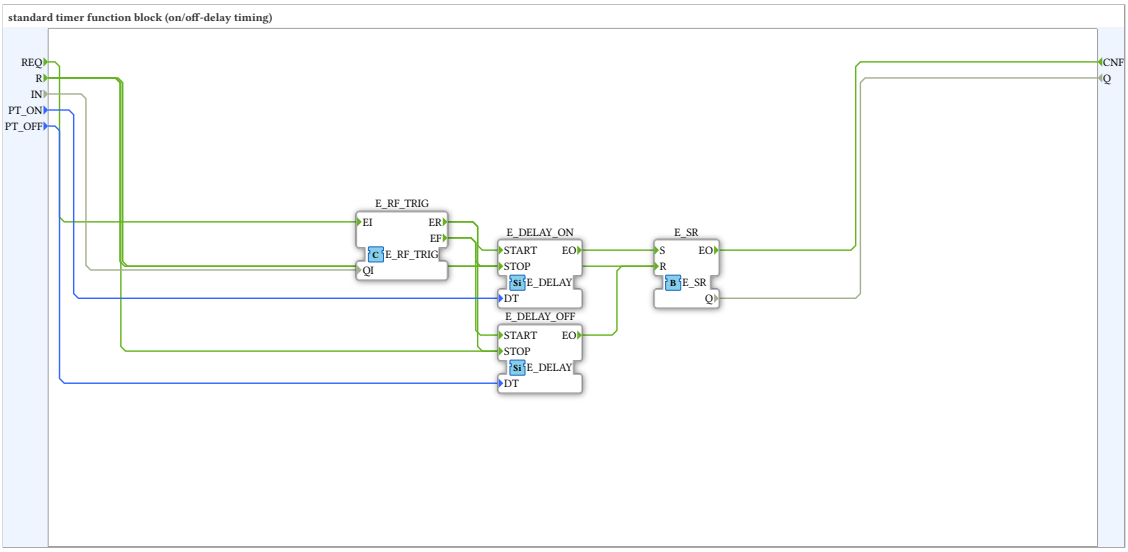
–

Application Examples

- **Machine Control**: Delayed response to sensors or switching commands, e.g., to prevent motor overload.
- **Process Automation**: Time-controlled switching operations in industrial processes, e.g., in conveyor belts or heating controls.



Summary



The **E_TON** function block is a simple yet powerful tool in IEC 61499 for implementing time-delayed turn-on operations in industrial automation systems. It provides a reliable way to turn on signals with a defined delay, which is essential in many control applications. The function block is easy to configure and can be used in a variety of scenarios where a time delay is required.

E_TONOF

Important note: This function block requires only one event and no cyclic calls. It does not have an output ET and does not display the elapsed time.

Description

The **E_TONOF** function block is a standardized function block type (FBType) according to the **IEC 61499** standard, used for time-delayed switching operations in industrial automation systems. This function block combines the functions of an **On-Delay Timer** and an **Off-Delay Timer** in a single block. It allows for the time delay of both the switching on and off of a signal.

General Description

- **Name**: E_TONOF
- **Type**: Standard Timer Function Block (On/Off Delay Timing)
- **Purpose**: This function block is used to implement time-delayed switching operations in control systems. It is particularly useful in applications where a delay is required when switching signals on or off.
- **License**: This function block is licensed under the Eclipse Public License 2.0 (EPL-2.0).

Interface Description

Event Inputs:

1. **REQ** (Normal Execution Request):

- **Type**: Event
- **Description**: This event triggers the normal execution of the function block. It is used to start or update the timer.
- **Associated Variables**:
- **IN**: The input value that starts the timer.
- **PT_ON**: The preset duration for the on-delay.
- **PT_OFF**: The preset duration for the off-delay.

1. **R** (Reset):

- **Type**: Event
- **Description**: This event resets the timer. When this event is triggered, the timer is stopped, and all internal states are reset.

Event Outputs

1. **CNF** (Execution Confirmation):

- **Type**: Event
- **Description**: This event confirms the execution of the function block. It is triggered when the timer has expired or a state change has occurred.
- **Associated Variable**:
- **Q**: The output value indicating the timer's state.

Input Variables:

1. **IN**:

- **Type**: BOOL
- **Description**: The input value that starts the timer. When **IN** is set to `TRUE`, the on-delay starts. When **IN** is set to `FALSE`, the off-delay starts.

1. **PT_ON**:

- **Type**: TIME
- **Description**: The preset duration for the on-delay. This time is measured from the moment **IN** is set to `TRUE`.

1. **PT_OFF**:

- **Type**: TIME
- **Description**: The preset duration for the off-delay. This time is measured from the moment **IN** is set to `FALSE`.

Output Variables:

1. **Q**:

- **Type**: BOOL
- **Description**: The output value that indicates the timer's state. **Q** is set to `TRUE` after the On-Delay has elapsed and remains at `TRUE` until the Off-Delay has elapsed.

_

Functionality

1. **On-Delay**:

- When **IN** is set to `TRUE`, the On-Delay timer (**PT_ON**) starts.
- After **PT_ON** expires, **Q** is set to `TRUE`.

1. **Off-Delay**:

- When **IN** is set to `FALSE`, the off-delay timer (**PT_OFF**) starts.
- **Q** remains at `TRUE` until **PT_OFF** expires, and is then reset to `FALSE`.

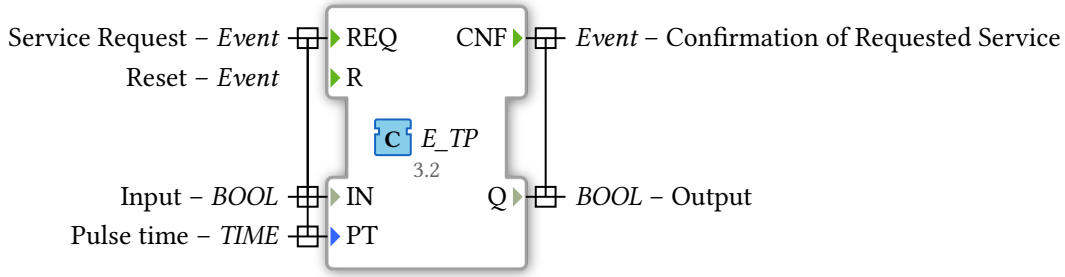
1. **Reset**:

- When the **R** event is triggered, the timer is reset, and **Q** is immediately set to `FALSE`.

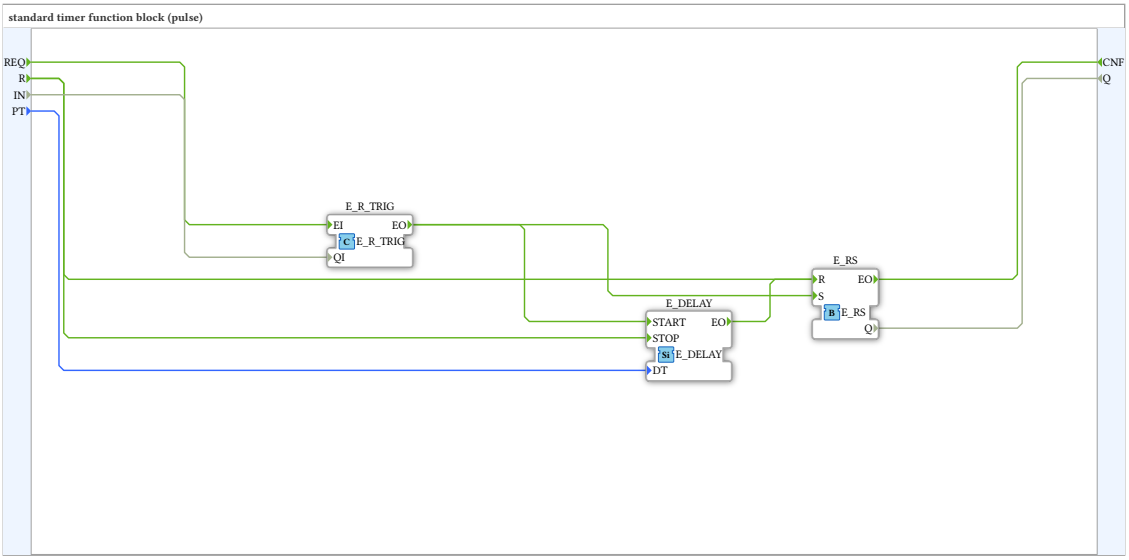
–

Application Examples

- **Machine Control**: Delayed response to sensors or switching commands, e.g. B. to prevent motor overload.
- **Process Automation**: Time-controlled switching operations in industrial processes, e.g., in conveyor belts or heating controls.



Summary



The **E_TONOF** block is a powerful tool in IEC 61499 for implementing time-delayed switching operations in industrial automation systems. It combines the functions of a switch-on and switch-off delay timer in a single block and also offers the option of resetting the timer via a reset event. This makes it particularly flexible and versatile for use in complex control tasks.

- Exercise_020g

E_TP

Important note: This function block requires only one event and no cyclic calls. It does not have an output ET and does not display the elapsed time.

Description

The **E_TP** function block (also known as **Pulse Generator** or **Timer Pulse**) is a standardized function block (FB) according to the **IEC 61499** (DIN EN 61499) standard. This block is used to generate a pulsating output that is activated for a specific duration when an input signal is received. It is particularly useful in control applications where time-controlled actions are required.

Description of the E_TP Block

General Function:

- The **E_TP** block generates a pulsating output (**Q**) that is activated for a predefined time (**PT**) as soon as an input signal (**IN**) is received.
- When the input signal **IN** is set to **TRUE**, the output **Q** is set to **TRUE** for the duration **PT**. After the time **PT** has elapsed, **Q** is reset to **FALSE**, regardless of the state of **IN**.
- The block has a reset function (**R**) that resets the timer and immediately sets the output **Q** to **FALSE**, regardless of whether the time **PT** has expired or not.

Interfaces:

1. **Event Inputs:**

- **REQ (Service Request):** This event is triggered when the timer is to be started. It is linked to the input variables **IN** and **PT**.
- **R (Reset):** This event is triggered to reset the timer. It is linked to the input variable **IN**.

1. **Output Events:**

- **CNF (Confirmation of Requested Service):** This event is triggered when the timer expires and the output **Q** is reset. It is linked to the output variable **Q**.

1. **Input Variables:**

- **IN (BOOL):** The input that starts the timer. When **IN** is set to **TRUE**, the timer starts.
- **PT (TIME):** The specified duration for which the output **Q** is activated.

1. **Output Variables:**

- **Q (BOOL):** The output that is set to **TRUE** for the duration **PT** after **IN** has been activated.

Behavior:

- When **IN** is set to **TRUE**, the output **Q** is immediately set to **TRUE** and remains active for the duration **PT**.
- After the time **PT** has elapsed, **Q** is automatically reset to **FALSE**.

- When the reset event **R** is triggered, the timer is immediately reset, and **Q** is set to **FALSE**, regardless of whether the time **PT** has elapsed or not.

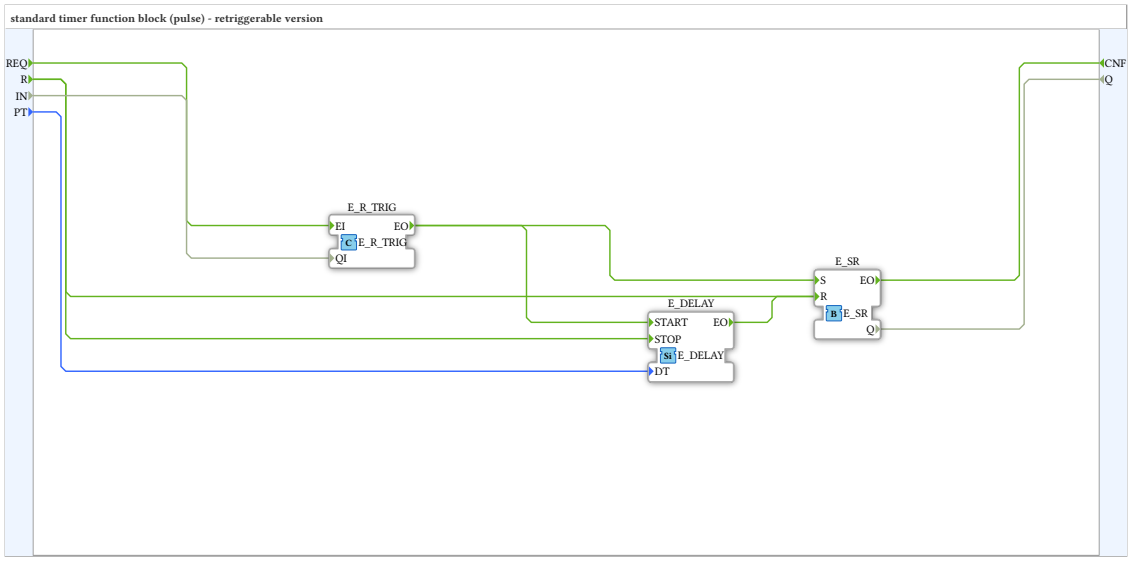
Application Examples:

- **Machine Control:** This function block can be used to activate a machine for a specific time, e.g., to switch on a motor for a set duration.
- **Flashing Light Control:** This function block can be used to activate a flashing light for a specific time.
- **Delayed Actions:** In scenarios where an action should be performed after a certain delay, this function block can be used to implement the delay.

Versioning:

- **Version 1.0:** Original version of the function block, created by Franz Hoepfinger on March 4, 2024.
- **Version 1.1:** A reset function was added to allow manual resetting of the timer. This version was released on April 23, 2024.

Summary



The **E_TP** function block is a useful tool in IEC 61499-based control technology for implementing time-controlled actions. Its simple interface and clear behavior make it easy to integrate into various control applications. The reset function in version 1.1 increases the flexibility of the function block, as the timer can now be reset manually.

The **E_TP** function block is a useful tool in IEC 61499-based control technology for implementing time-controlled actions.

E_TP_RETRIG

• — ○ • — ○ • — ○ •

Introduction

`E_TP_RETRIG` is the retriggerable variant of the standard timer `E_TP`: on every rising edge of `IN`, it generates a `TRUE` pulse of duration `PT` on `Q` — unlike `E_TP`, however, a new rising edge during a running pulse restarts it instead of being ignored.

Interface Structure

Event Inputs

- **REQ**: Checks `IN` for a rising edge, carries `IN` and `PT`.
- **R**: Immediately aborts the running pulse.

Event Outputs

- **CNF**: Confirmation, carries `Q`.

Data Inputs

- **IN** (BOOL): The input to check for rising edges.
- **PT** (TIME): Duration of the pulse.

Data Outputs

- **Q** (BOOL): `TRUE` during the pulse duration.

Functionality

`E_R_TRIG` detects rising edges of `IN` on every `REQ`. Every detected edge sets `E_SR.S` (⟶ `Q := TRUE`) and simultaneously restarts `E_DELAY` (with `PT`) — a new rising edge during a running pulse thus extends it instead of being ignored. When `E_DELAY` elapses, it sets `E_SR.R` (⟶ `Q := FALSE`). An `R` event stops the timer immediately and resets `Q` directly.

Technical Features

- **Retriggerable via an `IN` edge rather than `REQ` alone**: Unlike E_PULSE_RETRIG, which retriggers on *every* `REQ` event, `E_TP_RETRIG` only reacts to actual rising edges of `IN` — repeated `REQ` events while `IN` is already held `TRUE` without a new edge do not trigger a new pulse.
- **Composed of three standard blocks**: `E_R_TRIG` + `E_DELAY` + `E_SR`, no ECC of its own.

State Overview

Stateless wiring logic: `E_SR` holds the `Q` state, `E_DELAY` restarts on every detected rising edge of `IN`.

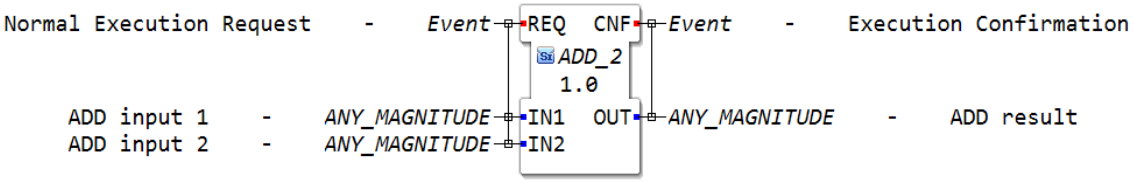
Application Scenarios

- **Extendable pulses triggered by edge transitions**: e.g. motion-sensor-controlled lighting, where every new motion (rising edge of `IN`) restarts the on-duration.
- **Debounced but extendable response to a digital input**, where only genuine edge transitions — not mere `REQ` repetitions — should trigger a new pulse run.

Comparison with similar function blocks

- **`E_TP`**: the same base functionality, but not retriggerable.
- E_PULSE_RETRIG: retriggerable pulse, triggered by *every* `REQ` event instead of an `IN` edge.
- E_TLIM: limits the on-time of `IN` itself, instead of generating a fixed pulse.

Conclusion

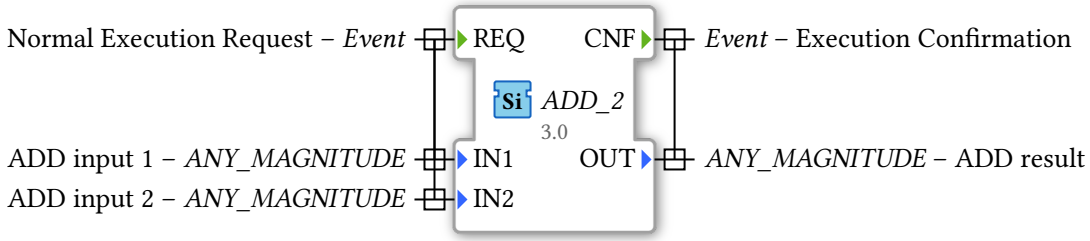


`E_TP_RETRIG` provides an edge-triggered, extendable pulse of fixed duration and is suitable for applications where repeated genuine edge transitions — not mere `REQ` repetitions — should keep the pulse alive.

2.11.4 iec61131-3

2.11.4.1 Arithmetic Functions

Here you will find standard functions for arithmetic operations (addition, subtraction, multiplication, division, etc.).



ADD_2

• – ◦ • – ◦ • – ◦ •

Introduction

The **ADD_2** is a generic function block for adding two values, developed under the EPL-2.0 license. Version 1.0 supports various numeric data types according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with input values)

Event Outputs

- `CNF`: Calculation confirmation (with result)

Data Inputs

- `IN1` (ANY_MAGNITUDE): First summand
- `IN2` (ANY_MAGNITUDE): Second summand

Data Outputs

- `OUT` (ANY_MAGNITUDE): Sum result

Functionality

1. **Calculation Request**:

- `REQ` event with Values for IN1 and IN2

1. **Addition**:

- Type-preserving calculation (IN1 + IN2)
- Supported types: INT, DINT, REAL, LREAL, etc.

1. **Result Output**:

- `CNF` event with calculated OUT value
- Automatic type adjustment

Technical Features

✓ **Generic Implementation** (GEN_ADD) ✓ **Type-Flexible** Inputs/Outputs ✓ **IEC 61131-3 compliant** ✓ **Deterministic** calculation

Supported Data Types

Type	Example
INT	123 + 456 = 579
REAL	1.23 + 4.56 = 5.79
TIME	T#1s + T#2s = T#3s
LREAL	1.23e10 + 4.56e10

Application Scenarios

- **Process Control**: Signal Processing
- **Data Analysis**: Measurement Aggregation
- **Machine Control**: Position Calculation
- **Energy Management**: Consumption Summing

⚖️ Comparison with Similar Function Blocks

Feature	ADD_2	ADD_4	MUL_2
Operation	Addition	Addition	Multiplication
Inputs	2	4	2
Type Support	ANY_MAG	ANY_MAG	ANY_MAG

Error Handling

- Type incompatibility results in:
- OUT = 0 (for numeric types)
- Empty value (for other types)
- No exception generation

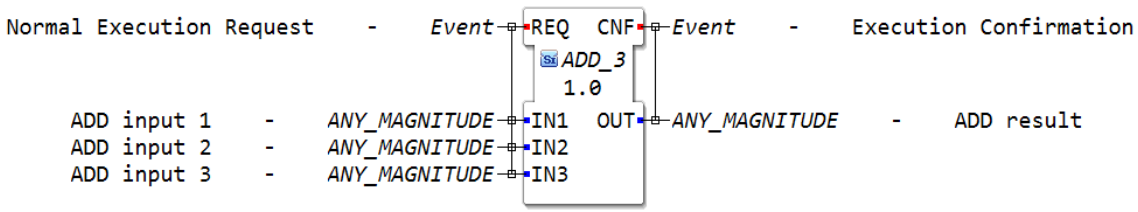
- Exercise_111

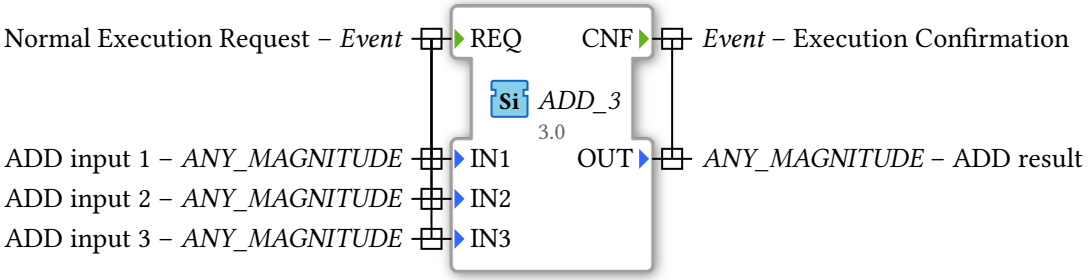


Conclusion

The ADD_2 block offers a flexible solution for arithmetic operations:

- Simple yet powerful addition
- Broad type support
- Standards-compliant implementation

Especially valuable for applications requiring type-safe calculations with variable inputs. The generic implementation allows for reuse in a wide variety of control contexts.



ADD_3

• – ◦ • – ◦ • – ◦ •

Introduction

The **ADD_3** is an enhanced version of the adder for calculating the sum of three values, developed under the EPL-2.0 license. Version 1.0 offers type-safe addition for various numeric data types according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with three input values)

Event Outputs

- `CNF`: Calculation confirmation (with sum result)

Data Inputs

- `IN1` (ANY_MAGNITUDE): First addend
- `IN2` (ANY_MAGNITUDE): Second addend
- `IN3` (ANY_MAGNITUDE): Third addend

Data Outputs

- `OUT` (ANY_MAGNITUDE): Result of addition (IN1 + IN2) + IN3)

Operating Principle

1. **Requirement**:

- The `REQ` event triggers the calculation
- All three input values are evaluated simultaneously

1. **Calculation**:

- Type-preserving summation
- Supports all ANY_MAGNITUDE types:
- Integers (INT, DINT)
- Floating-point numbers (REAL, LREAL)
- Time values (TIME, LTIME)

1. **Result Output**:

- The `CNF` event with the calculated OUT value
- Automatic type conversion for mixed inputs

Technical Features

✓ **Three-input addition** in a single operation ✓ **Generic implementation** (GEN_ADD class) ✓ **Broad type support** (ANY_MAGNITUDE) ✓ **Deterministic execution**

Typical Use Cases

- **Measurement Aggregation**: Summing data from multiple sensors
- **Energy Balancing**: Calculating total energy consumption
- **Positioning Technology**: Multidimensional coordinates
- **Production Statistics**: Quantity measurement

⚖️ Comparison with ADD_2

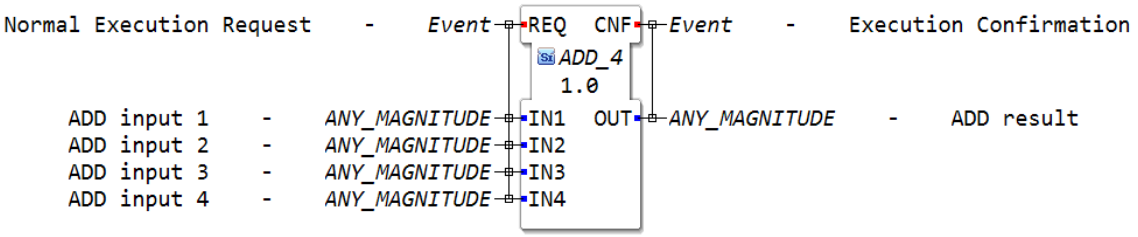
Feature	ADD_3	ADD_2
Inputs	3	2
Calculation	IN1+IN2+IN3	IN1+IN2
Performance	Higher efficiency with 3 inputs	Lightweight

Error Handling

- In case of type incompatibility:
- OUT = 0 (numeric types)
- Empty value (non-numeric types)
- Execution is not aborted

🛠️ Related Exercises

- Exercise_087
- Exercise_087a1

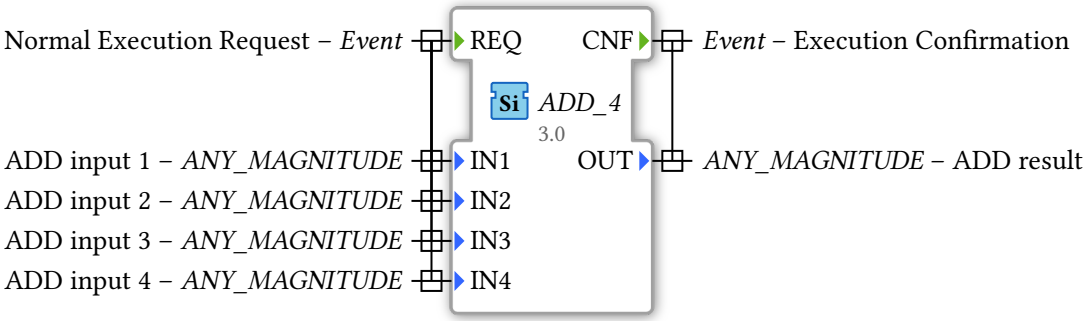


Conclusion

The ADD_3 block expands the possibilities of type-safe addition:

- Efficient triple summation
- Consistent type handling
- Optimized performance compared to serial ADD_2 usage

Particularly advantageous for applications with multiple values to be aggregated. The generic implementation allows for maximum flexibility in heterogeneous control environments.



ADD_4

• – ◦ • – ◦ • – ◦ •

Introduction

The **ADD_4** is a powerful function block for summing four values, developed under the EPL-2.0 license. As part of the GEN_ADD class, version 1.0 offers a type-safe implementation according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with four input values)

Event Outputs

- `CNF`: Calculation confirmation (with total result)

Data Inputs

- `IN1` (ANY_MAGNITUDE): First addend
- `IN2` (ANY_MAGNITUDE): Second addend
- `IN3` (ANY_MAGNITUDE): Third addend
- `IN4` (ANY_MAGNITUDE): Fourth addend

Data Outputs

- `OUT` (ANY_MAGNITUDE): Result of addition (IN1+IN2+IN3+IN4)

Functional Features

1. **Calculation Triggering**:

- A single `REQ` event processes all four inputs
- Parallel value acquisition

1. **Type Handling**:

- Automatic type conversion for mixed inputs
- Result in the "largest" input type

1. **Calculation Order**:

- Mathematically associative (IN1+(IN2+(IN3+IN4)))
- Guaranteed reproducible results

Technical Specifications

✓ **Four-input addition** in one operation ✓ **Full ANY_MAGNITUDE support** ✓ **Optimized calculation performance** ✓ **Deterministic behavior**

Supported Data Types

Category	Examples
Integers	INT, DINT, UDINT
Floating Point	REAL, LREAL
Time Values	TIME, LTIME
Special Types	DATE_AND_TIME

Application Scenarios

- **Energy Monitoring**: Summing of Consumers
- **Production Control**: Quantity Measurement of Multiple Lines
- **Measurement Data Analysis**: Aggregation of Sensor Values
- **Robot Control**: Multidimensional Position Calculation

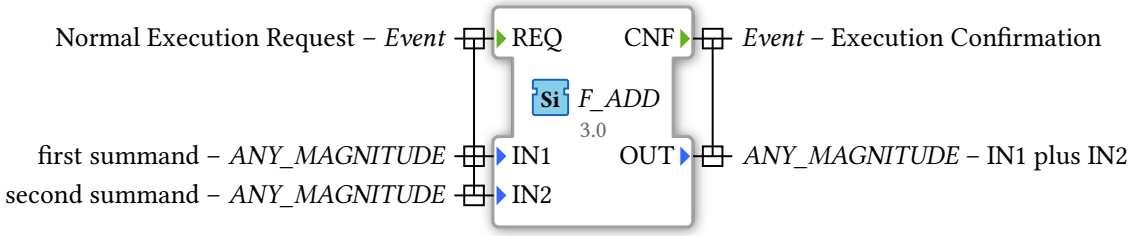
⚖️ Comparison with Other Adders

Function Block	Inputs	Advantages
ADD_2	2	Simplest Variant
ADD_3	3	Compromise
ADD_4	4	Maximum Integration

Error Management

- **Type Conflicts**: Result 0 in case of incompatibility
- **Overflow**: Wrap-around depending on data type
- **Status Feedback**: Via accompanying logic

Conclusion



The ADD_4 block offers maximum efficiency for summation tasks:

- Compact quadruple calculation
- Broadest type support
- Optimized performance

Ideal for complex control applications with multiple values to be aggregated. The generic implementation as GEN_ADD enables maximum flexibility with type-safe execution.

F_ADD

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_ADD** is a standards-compliant arithmetic function block according to IEC 61131-3, developed by TU Wien ACIN under the EPL-2.0 license. Version 1.0 enables type-safe addition of values (ANY_MAGNITUDE) for industrial control applications.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with input values)

Event Outputs

- `CNF`: Calculation confirmation (with result)

Data Inputs

- `IN1` (ANY_MAGNITUDE): First operand
- `IN2` (ANY_MAGNITUDE): Second operand

Data Outputs

- `OUT` (ANY_MAGNITUDE): Sum of IN1 and IN2

Functionality

1. **Activation**:

- Triggered by the `REQ` event
- Processes both input values simultaneously

1. **Type Handling**:

- Supports all ANY_MAGNITUDE types:
- Numeric types (INT, DINT, REAL, LREAL)
- Time types (TIME, LTIME)
- Automatic type conversion

1. **Computation**:

- Executes IN1 + IN2

- Maintains the highest input accuracy

1. **Result Output**:

- `CNF` event with computation result
- Latency: One execution cycle

Technical Specifications

✓ Generic Type Support (ANY_MAGNITUDE) **✓ Deterministic Execution ✓ Overflow Protection ✓ IEC 61131-3 Compliant**

Supported Data Types

Category	Examples
Integers	INT, DINT, UINT, UDINT
Floating Point	REAL, LREAL
Time	TIME, LTIME
Mixed	INT + REAL ⟶ REAL

Application Examples

- **Process Control**: Signal Conditioning
- **Measurement Systems**: Sensor Value Aggregation
- **Motion Control**: Position Calculations
- **Energy Management**: Consumption Summing

⚖️ **Comparison with Similar Function Blocks**

Feature	F_ADD	F_SUB	F_MUL
Operation	Addition	Subtraction	Multiplication
Input Types	ANY_MAGNITUDE	ANY_MAGNITUDE	ANY_NUM
Output Type	Equals Input Type	Equals	Equals

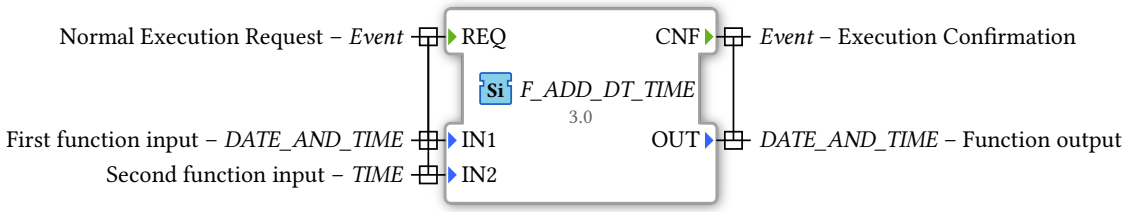
Error Handling

- **Overflow**: Wrap-around for integers, ±INF for floating-point numbers
- **Type Mismatch**: Automatic type matching
- **Invalid Input**: Returns 0/default value

Special Notes

- For time calculations: TIME + TIME ⟶ TIME
- Mixed operations use the “higher” type
- No implicit scaling (e.g., 100ms + 1s = 1100ms)

Conclusion



The F_ADD block offers essential arithmetic functions:

- Robust, type-safe addition
- Consistent behavior across all data types
- Seamless integration into control algorithms

Its standardized implementation makes it a reliable component for industrial automation systems that require precise arithmetic operations with various data types.

F_ADD_DT_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_ADD_DT_TIME** function block is a specialized function module for adding time values to date/time values, developed under the EPL 2.0 license. Version 1.0 enables precise time calculations using DATE_AND_TIME and TIME data types.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with input values)

Event Outputs

- `CNF`: Calculation confirmation (with result)

Data Inputs

- `IN1` (DATE_AND_TIME): Output date/time
- `IN2` (TIME): Duration for addition

Data Outputs

- `OUT` (DATE_AND_TIME): Result of the addition

Functionality

1. **Activation**:

- Triggered by the `REQ` event
- Processes DATE_AND_TIME and TIME values

1. **Calculation**:

- Adds time duration (IN2) to timestamp (IN1)
- Automatically takes into account:
- Leap years
- Month lengths
- Time zones (if configured)

1. **Result output**:

- `CNF` event with new DATE_AND_TIME
- Format: DT#2023-12-31-23:59:59

Technical Specifications

✓ Precise time/date arithmetic ✓ Automatic calendar calculation
✓ IEC 61131-3 compliant ✓ Deterministic execution

Application examples

- **Process control**: Due date calculations
- **Production planning**: Scheduling adjustments
- **Maintenance systems**: Maintenance interval calculation
- **Data logging**: Timestamp corrections

Special notes

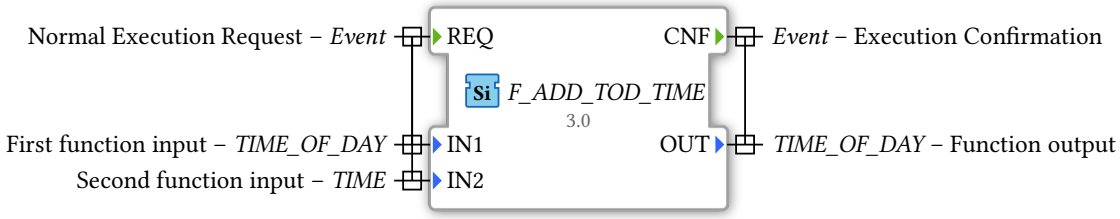
- **Scope of validity**:
- Supports date range 1970-2099
- Time resolution: 1 millisecond

- **Error cases**:
- In case of overflow: Wrap-around within the valid range
- In case of invalid input: OUT = IN1

⚖️ Comparison with standard F_ADD

Feature	F_ADD_DT_TIME	F_ADD
Input type 1	DATE_AND_TIME	ANY_MAGNITUDE
Input type 2	TIME	ANY_MAGNITUDE
Operation	Specialized time addition	Generic addition

Conclusion



The F_ADD_DT_TIME function block offers essential functions for time calculations:

- Precise handling of date/time operations
- Automatic calendar corrections
- Reliable integration into control systems

Particularly valuable for applications requiring complex time calculations with automatic consideration of calendar rules. The specialized implementation guarantees correct results for all valid input values.

F_ADD_TOD_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_ADD_TOD_TIME** function block is a specialized function module for adding time values to times of day, developed under the EPL 2.0 license. Version 1.0 enables precise time calculations using TIME_OF_DAY and TIME data types.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with input values)

Event Outputs

- `CNF`: Calculation confirmation (with result)

Data Inputs

- `IN1` (TIME_OF_DAY): Output time (time of day)
- `IN2` (TIME): Duration for addition

Data Outputs

- `OUT` (TIME_OF_DAY): Result of the addition

Functionality

1. **Activation**:

- Triggered by the `REQ` event
- Processes TIME_OF_DAY and TIME values

1. **Calculation**:

- Adds time duration (IN2) to time of day (IN1)
- Automatically takes into account:
- Day transitions (24-hour format)
- Millisecond accuracy

1. **Result Output**:

- `CNF` event with new TIME_OF_DAY
- Format: TOD#23:59:59.999

Technical Specifications

✓ Precise Time of Day Calculation ✓ Automatic Day Transition ✓ IEC 61131-3 Compliant ✓ Millisecond Accurate Calculation

Application Examples

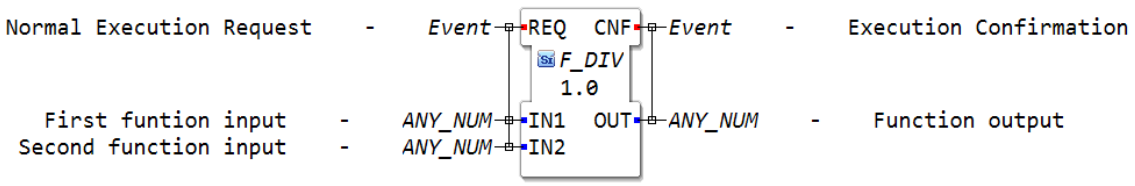
- **Shift Planning**: Working Time Calculations
- **Lighting Control**: Daylight Simulation
- **Production Processes**: Time-Controlled Sequences
- **Scheduling Systems**: Arrival Time Calculations

Special Notes

- **Scope of Application**:
- 00:00:00.000 to 23:59:59.999
- If the limit is exceeded: Wrap-around (e.g., 25:00:00 ⟶ 01:00:00)
- **Error Cases**:
- In case of overflow: Cyclic incrementing
- In case of invalid input: OUT = IN1

⚖️ Comparison with similar function blocks

Feature	F_ADD_TOD_TIME	F_ADD_DT_TIME
Input Type 1	TIME_OF_DAY	DATE_AND_TIME
Output Type	TIME_OF_DAY	DATE_AND_TIME
Range	Daily Cycle	Absolute Date

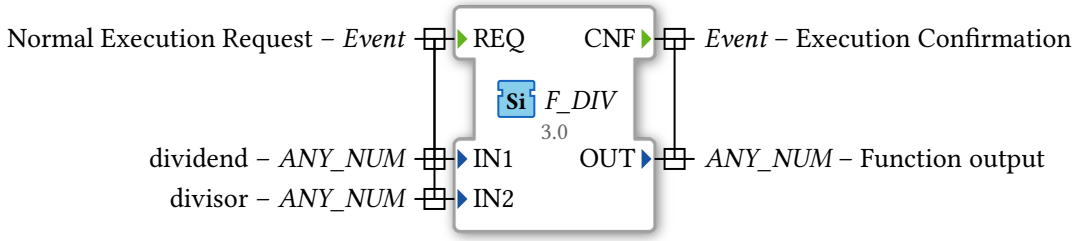


Conclusion

The F_ADD_TOD_TIME function block offers essential functions for calculating the time of day:

- Precise handling of time-of-day operations
- Automatic handling of day transitions
- Optimized performance for real-time applications

Ideal for control applications that require recurring time-of-day-based operations. The specialized implementation guarantees correct results in 24-hour format.



F_DIV

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_DIV** is a standards-compliant function block for dividing numeric values, developed under the EPL-2.0 license. Version 1.0 enables type-safe division of various numeric data types according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with dividend and divisor)

Event Outputs

- `CNF`: Calculation confirmation (with division result)

Data Inputs

- `IN1` (ANY_NUM): Dividend (numerator)
- `IN2` (ANY_NUM): Divisor (denominator)

Data Outputs

- `OUT` (ANY_NUM): Result of division (IN1 / IN2)

Functional Principle

1. **Calculation Trigger**:

- `REQ` event with values for IN1 and IN2
- Both inputs must be of type ANY_NUM

1. **Division**:

- Type-preserving calculation (IN1 / IN2)
- Supported types:
- Integers (INT, DINT)
- Floating-point numbers (REAL, LREAL)
- Mixed types (automatic conversion)

1. **Result Output**:

- `CNF` event with calculated OUT value
- Floating-point result for integer division

Technical Features

✓ **Type-safe division** (ANY_NUM support) ✓ **Automatic type conversion** ✓ **IEC 61131-3 compliant** ✓ **Deterministic execution**

Error Handling

- **Division by zero**:
- OUT = 0 (for Integers)
- OUT = INF/NAN (for floating-point numbers)
- No execution abort
- **Type incompatibility**:
- OUT = 0
- No exception generation

Application Scenarios

- **Process control**: Control deviation calculation
- **Data analysis**: Normalization of measured values
- **Machine control**: Speed calculations
- **Energy management**: Efficiency calculations

⚖️ Comparison with similar function blocks

Feature	F_DIV	F_MUL	F_ADD
Operation	Division	Multiplication	Addition
Inputs	2	2	2
Type support	ANY_NUM	ANY_NUM	ANY_NUM

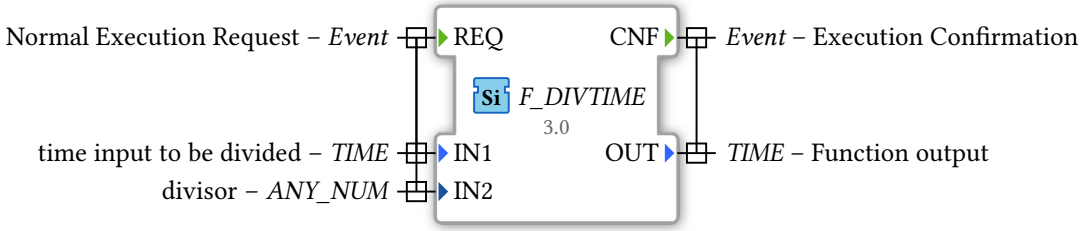
Supported Data Types

Category	Examples
Integers	INT, DINT, UDINT
Floating Point	REAL, LREAL
Type Combinations	INT/REAL, DINT/LREAL

🛠️ Related Exercises

- Exercise_111

Conclusion



The F_DIV function block offers a robust solution for division operations:

- Type-safe calculation
- Flexible input combinations
- Standards-compliant implementation

Particularly valuable for applications requiring precise calculations with variable inputs. Automatic type conversion and error handling make it a reliable function block in industrial control systems.

F_DIVTIME

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_DIVTIME** function block is a specialized function module for dividing time values by numerical factors, developed under the EPL 2.0 license. Version 1.0 enables precise time calculations using TIME and ANY_NUM data types.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with input values)

Event Outputs

- `CNF`: Calculation confirmation (with result)

Data Inputs

- `IN1` (TIME): Time duration to be divided
- `IN2` (ANY_NUM): Divisor (numeric value)

Data Outputs

- `OUT` (TIME): Result of the division (IN1 / IN2)

Functionality

1. **Activation**:

- Triggered by the `REQ` event
- Processes TIME values and numeric divisors

1. **Calculation**:

- Divides time value (IN1) by numeric value (IN2)
- Performs automatic type conversion
- Calculation accurate to milliseconds

1. **Result Output**:

- `CNF` event with new TIME value
- Format: T#1d5h30m15s250ms

Technical Specifications

✓ Precise Time Division ✓ Support for ANY_NUM divisors ✓ Calculation accurate to milliseconds ✓ Automatic Type Conversion

Application Examples

- **Process Optimization**: Average Cycle Time Calculation
- **Production Planning**: Time Allocation to Stations
- **Robot Control**: Speed Adjustment
- **Energy Management**: Consumption Time Calculations

Error Handling

- **Division by Zero**:
- OUT = T#0s
- No Aborting Execution
- **Type Incompatibility**:
- OUT = IN1 (original value is retained)
- No exception generation

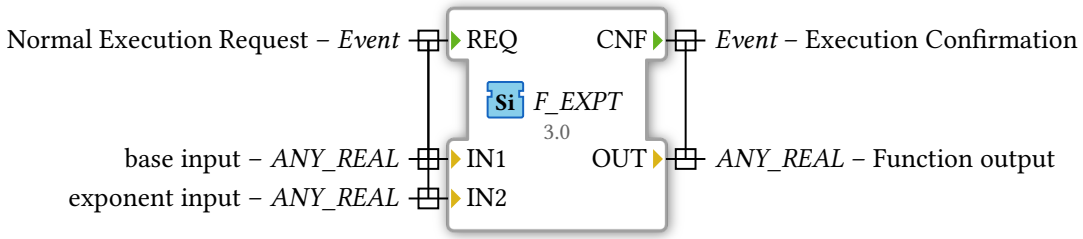
Special Notes

- **Calculation Accuracy**:
- Minimum 1 millisecond
- Rounding to the nearest millisecond
- **Validity Range**:
- Positive time values (T#0s to T#106751d23h47m16s854ms)
- Divisor must be positive

⚖️ **Comparison with Standard F_DIV**

Feature	F_DIVTIME	F_DIV
Input Type 1	TIME	ANY_NUM
Input Type 2	ANY_NUM	ANY_NUM
Output Type	TIME	ANY_NUM

Conclusion



The F_DIVTIME function block offers essential functions for time-based calculations:

- Precise division of time values
- Flexible input parameters
- Reliable error handling

Especially valuable for applications requiring the division of time intervals. The specialized implementation guarantees correct results for all valid input combinations.

F_EXPT

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_EXPT** function block is a mathematical function module for calculating power values, developed under the EPL-2.0 license. Version 1.0 enables the calculation of base-exponent combinations with ANY_REAL data types.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with base and exponent)

Event Outputs

- `CNF`: Calculation confirmation (with result)

Data Inputs

- `IN1` (ANY_REAL): Base value
- `IN2` (ANY_REAL): Exponent

Data Outputs

- `OUT` (ANY_REAL): Result of exponentiation (IN1^IN2)

Functionality

1. **Activation**:

- Triggered by the `REQ` event
- Processes two ANY_REAL values

1. **Calculation**:

- Calculates IN1 raised to the power of IN2
- Supports all REAL and LREAL combinations
- Automatic type conversion (higher accuracy)

1. **Result Output**:

- `CNF` event with calculated power value
- Result in the more accurate input type

Technical Specifications

✓ Precise power calculation
✓ Support for REAL and LREAL
✓ Automatic type conversion
✓ IEC 61131-3 compliant

Application Examples

- **Physical calculations**: Acceleration formulas
- **Financial mathematics**: Compound interest calculation
- **Control engineering**: Nonlinear characteristics

- **Signal processing**: Exponential filters

Error Handling

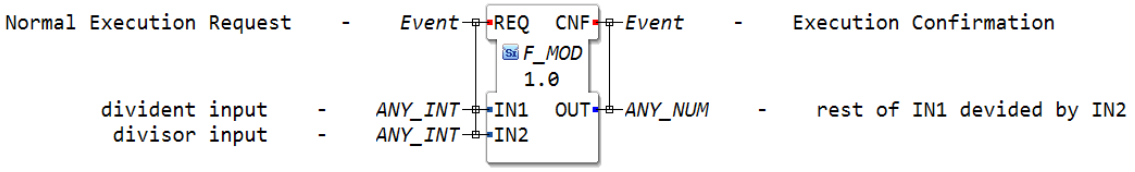
- **Invalid inputs**:
- Negative base with non-integer exponent: OUT = 0
- Zero to a negative exponent: OUT = +INF
- Infinity calculations according to IEEE 754

Special Notes

- **Accuracy**:
- LREAL inputs produce LREAL results
- REAL inputs produce REAL results
- Mixed inputs: LREAL result
- **Performance**:
- LREAL calculations require more cycles
- For real-time applications, prefer REAL

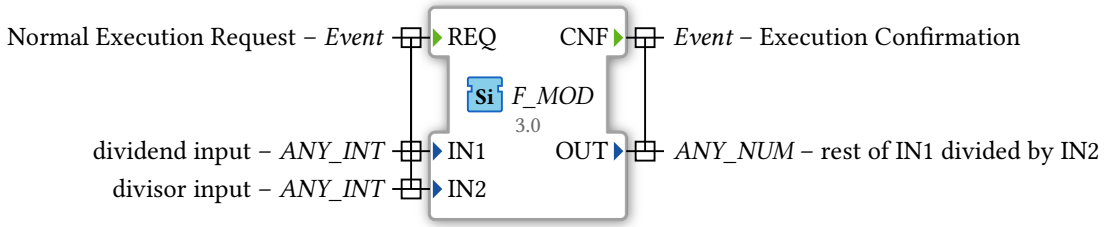
⚖️ **Comparison with similar building blocks**

Feature	F_EXPT	F_LN	F_POWER
Function	a^b	ln(a)	a^b
Input types	ANY_REAL	ANY_REAL	ANY_NUM
Accuracy	High	High	Medium



Conclusion

The F_EXPT function block offers powerful mathematical functions:



- Precise exponential calculations
- Flexible input combinations
- Reliable error handling

Indispensable for advanced control algorithms requiring nonlinear calculations. Its standards-compliant implementation enables its use in demanding industrial applications.

F_MOD

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_MOD** is an arithmetic function block for calculating the remainder of a division, developed under the EPL-2.0 license. Version 1.0 enables the modulo operation for integer data types according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with dividend and divisor)

Event Outputs

- `CNF`: Calculation confirmation (with remainder)

Data Inputs

- `IN1` (ANY_INT): Dividend (integer)
- `IN2` (ANY_INT): Divisor (integer)

Data Outputs

- `OUT` (ANY_NUM): Remainder of division (IN1 mod IN2)

Functionality

1. **Activation**:

- Triggered by the `REQ` event
- Processes two integer values

1. **Modulo Operation**:

- Calculates IN1 modulo IN2
- Formula: OUT = IN1 - (IN1 / IN2) * IN2
- Supported types: INT, DINT, UINT, UDINT

1. **Result Output**:

- `CNF` event with residual value
- Sign corresponds to dividend (IN1)

Technical Specifications

✓ Integer Modulo Operation ✓ Support for Signed and Unsigned Types ✓ IEC 61131-3 Compliant ✓ Deterministic Execution

Application Examples

- **Cyclic Counting**: Ring Buffer Indices
- **Time Calculations**: Weekday Determination
- **Message Processing**: Checksum Calculation
- **Positioning**: Stepper Motor Control

Error Handling

- **Division by Zero**:
- OUT = IN1 (Original value is retained)
- No execution interruption
- **Type incompatibility**:
- Automatic type matching
- No exception generation

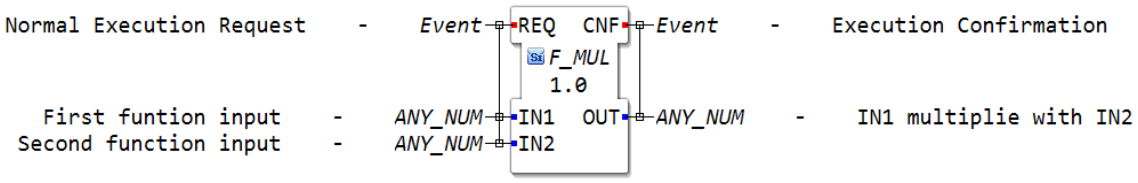
Special Notes

- **Sign handling**:
- Result has the sign of the dividend
- Example: (-7 mod 3) = −1
- **Performance**:
- Optimized calculation for all integer types
- One cycle latency

⚖️ Comparison with similar function blocks

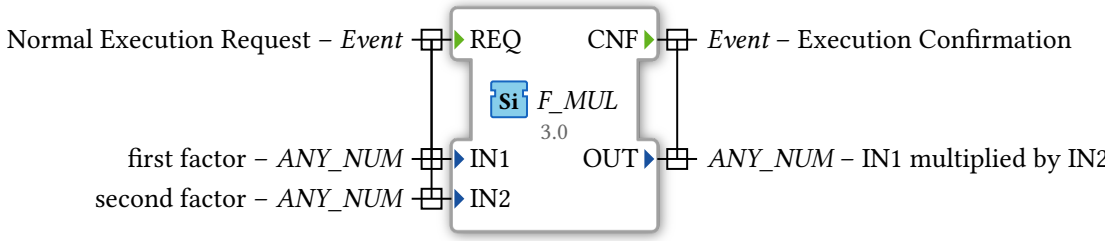
Feature	F_MOD	F_DIV	F_REM

Operation	Modulo	Division	Remainder
Input types	ANY_INT	ANY_NUM	ANY_NUM
Output type	ANY_NUM	ANY_NUM	ANY_NUM



Conclusion

The F_MOD function block offers essential functions for cyclic calculations:



- Efficient residual value calculation
- Flexible type support
- Reliable error handling

Indispensable for control applications with periodic patterns or index calculations. Its standards-compliant implementation enables its use in real-time systems with deterministic requirements.

F_MUL

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_MUL** is a standards-compliant function block for multiplying numeric values, developed under the EPL-2.0 license. Version 1.0 enables type-safe multiplication of various numeric data types according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with two factors)

Event Outputs

- `CNF`: Calculation confirmation (with result)

Data Inputs

- `IN1` (ANY_NUM): First factor
- `IN2` (ANY_NUM): Second factor

Data Outputs

- `OUT` (ANY_NUM): Product of the multiplication (IN1 × IN2)

Operating Principle

1. **Calculation Trigger**:

- `REQ` event with values for IN1 and IN2
- Both inputs must be of type ANY_NUM be

1. **Multiplication**:

- Type-preserving calculation (IN1 × IN2)
- Supported types:
- Integers (INT, DINT)
- Floating-point numbers (REAL, LREAL)
- Mixed types (automatic conversion)

1. **Result output**:

- `CNF` event with calculated product
- Result in the "largest" input type

Technical Features

✓ **Type-safe multiplication** (ANY_NUM support) ✓ **Automatic type conversion** ✓ **Overflow protection** ✓ **Deterministic execution**

Application Scenarios

- **Process control**: Scaling calculations
- **Data analysis**: Measured value processing
- **Machine control**: Position calculations
- **Energy management**: Power calculations

Error handling

- **Overflow handling**:
- Wrap-around in case of Integers
- ±INF (± infinity) on floating-point overflow
- **Type incompatibility**:
- OUT = 0
- No exception generation

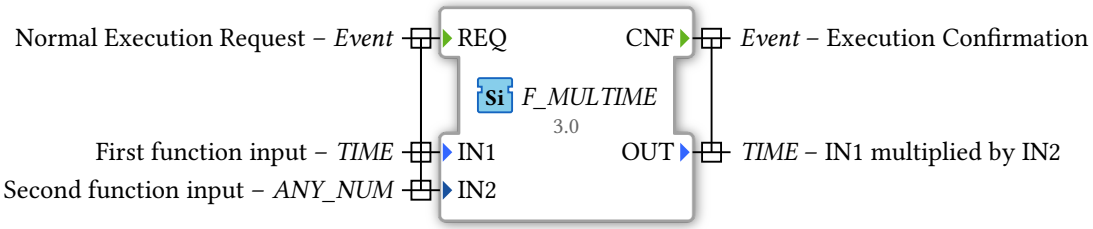
⚖️ **Comparison with similar function blocks**

Feature	F_MUL	F_ADD	F_DIV
Operation	Multiplication	Addition	Division
Inputs	2	2	2
Type support	ANY_NUM	ANY_NUM	ANY_NUM

🛠️ **Related Exercises**

- Exercise_034b

Conclusion



The F_MUL function block offers a robust solution for multiplication operations:

- Precise type-preserving calculations
- Flexible input combinations
- Standards-compliant implementation

Particularly valuable for applications that need to implement scaled calculations or physical formulas. Automatic type conversion makes it a versatile tool in industrial control systems.

F_MULTIME

• − ◦ • − ◦ • − ◦ •

Introduction

The **F_MULTIME** function block is a standards-compliant function block for multiplying time values by numerical factors, developed under the EPL-2.0 license. Version 1.0 enables type-safe scaling of time intervals according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with time value and multiplier)

Event Outputs

- `CNF`: Calculation confirmation (with scaled time value)

Data Inputs

- `IN1` (TIME): Time value (base value)
- `IN2` (ANY_NUM): Scaling factor

Data Outputs

- `OUT` (TIME): Scaled time value (IN1 × IN2)

Functional Principle

1. **Calculation Trigger**:

- `REQ` event with time value (IN1) and factor (IN2)
- IN1 must be of type TIME, IN2 must be of type ANY_NUM

1. **Multiplication**:

- Time value is converted to nanoseconds
- Multiplication by a numeric factor
- Conversion back to TIME data type

1. **Result Output**:

- `CNF` event with scaled time value
- Result always of type TIME

Technical Features

✓ **Type-safe time value processing**
  ✓ **Precise nanosecond calculation**
  ✓ **Automatic type conversion** (ANY_NUM ⟶ REAL)
  ✓ **Overflow protection** (limit to maximum TIME value)

Application Scenarios

- **Cycle time adjustment**: Scaling of time intervals
- **Process control**: Lengthening/shortening of timeouts
- **Motion control**: Speed adjustments
- **Scheduling**: Dynamic Schedule Scaling

Error Handling

- **Overflow Handling**:
- Limit to T#24d20h31m23s647ms (Maximum)
- No wrap-around for time values

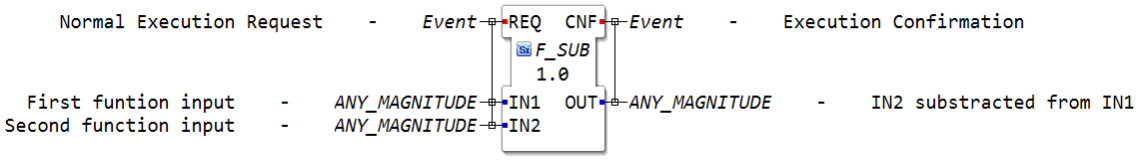
- **Type Incompatibility**:
- OUT = T#0s
- No exception generation

⚖️ Comparison with Similar Function Blocks

Feature	F_MULTIME	F_MUL	F_DIVTIME
Operation	Time Multiplication	Numeric Multiplication	Time Division
Inputs	TIME × ANY_NUM	ANY_NUM × ANY_NUM	TIME ÷ ANY_NUM
Output Type	TIME	ANY_NUM	TIME

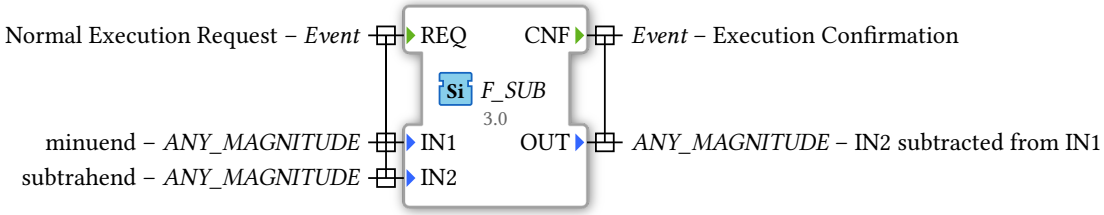
🛠️ Related Exercises

- Exercise_020c2



Conclusion

The F_MULTIME function block offers a specialized solution for scaling time values:



- Industrial-grade precision (nanosecond basis)
- Safe type conversion
- Robust overflow handling

Essential for applications with dynamically adjustable time parameters and cyclical control processes.

F_SUB

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_SUB** is a standards-compliant function block for subtracting numeric values, developed under the EPL-2.0 license. Version 1.0 enables type-safe subtraction of various numeric data types according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with minuend and subtrahend)

Event Outputs

- `CNF`: Calculation confirmation (with result)

Data Inputs

- `IN1` (ANY_MAGNITUDE): Minuend (value from which to subtract)
- `IN2` (ANY_MAGNITUDE): Subtrahend (value to be subtracted)

Data Outputs

- `OUT` (ANY_MAGNITUDE): Difference of the subtraction (IN1 - IN2)

Operating Principle

1. **Calculation Trigger**:

- `REQ` event with values for IN1 and IN2
- Both inputs must be of type ANY_MAGNITUDE

1. **Subtraction**:

- Type-preserving calculation (IN1 - IN2)
- Supported types:
- Integers (INT, DINT)
- Floating-point numbers (REAL, LREAL)
- Time values (TIME, DATE)
- Mixed types (automatic conversion)

1. **Result output**:

- `CNF` event with calculated difference
- Result in the "largest" input type

Technical Features

✓ **Type-safe subtraction** (ANY_MAGNITUDE support) ✓ **Automatic type conversion** ✓ **Underrun protection** ✓ **Deterministic execution**

Application Scenarios

- **Process control**: Deviation Calculation
- **Data Analysis**: Difference Calculation of Measured Values
- **Machine Control**: Position Differences
- **Time Control**: Time Interval Calculations

Error Handling

- **Underflow Handling**:
- Wrap-around for integers
- -INF for floating-point underflow
- **Type Incompatibility**:
- OUT = 0
- No Exception Generation

⚖️ Comparison with Similar Function Blocks

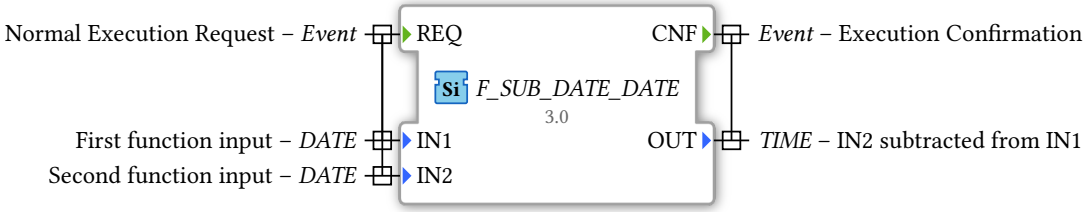
Feature	F_SUB	F_ADD	F_MUL
Operation	Subtraction	Addition	Multiplication
Inputs	2	2	2
Type Support	ANY_MAGNITUDE	ANY_NUM	ANY_NUM

🛠️ Related Exercises

- Exercise_040
- Exercise_040_2
- Exercise_040_AX
- Exercise_041
- Exercise_072c

Conclusion

The F_SUB function block offers a robust solution for subtraction operations:



- Precise type-preserving calculations
- Flexible input combinations

- Standards-compliant implementation

Particularly valuable for applications that need to implement difference calculations or relative changes. Automatic type conversion makes it an indispensable tool in industrial control systems.

F_SUB_DATE_DATE

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_SUB_DATE_DATE** function block is a standards-compliant function block for calculating time differences between two date values, developed under the EPL-2.0 license. Version 1.0 enables the precise calculation of time intervals according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with start and end date)

Event Outputs

- `CNF`: Calculation confirmation (with time difference)

Data Inputs

- `IN1` (DATE): Start date (minuend)
- `IN2` (DATE): End date (subtrahend)

Data Outputs

- `OUT` (TIME): Calculated time interval (IN1 - IN2)

Operating Principle

1. **Calculation Trigger**:

- `REQ` event with two DATE values
- Both inputs must be of type DATE

1. **Difference Calculation**:

- Conversion of both date values to seconds since January 1, 1970
- Subtraction of the timestamps (IN1 - IN2)
- Conversion to the TIME data type

1. **Result Output**:

- `CNF` event with calculated time interval
- Positive values if IN1 > IN2, negative values if IN1 < IN2

Technical Features

✓ **Precise Time Difference** (Accurate to the Day) ✓ **Leap Year Consideration**
✓ **Negative Time Intervals** for Retrospective Calculations ✓ **Platform-Independent Time Calculation**

Application Scenarios

- **Process Duration Calculation**: Production time between two dates
- **Maintenance Intervals**: Remaining time until next maintenance
- **Project Planning**: Time remaining until deadline

- **Inventory Management**: Shelf Life Calculation

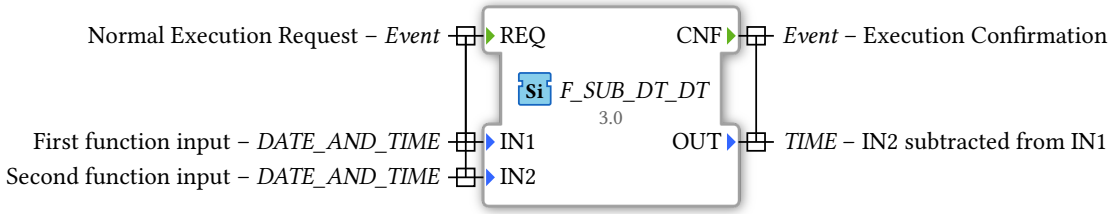
Error Handling

- **Date Limits**:
- Supports the range 1970-01-01 to 2106-02-07
- On exceedance: OUT = T#0s
- **Type Incompatibility**:
- OUT = T#0s
- No exception generation

⚖️ **Comparison with Similar Function Blocks**

Feature	F_SUB_DATE_DATE	F_SUB_TIME	F_SUB_DT_DT
Input Types	DATE - DATE	TIME - TIME	DT - DT
Output Type	TIME	TIME	TIME
Accuracy	Day-accurate	Nanosecond	Microsecond

Conclusion



The F_SUB_DATE_DATE function block offers an optimized solution for date differences:

- Calendar-accurate calculations
- Easy handling of time intervals
- Standards-compliant implementation

Particularly valuable for applications with deadline-related calculations and long-term scheduling.

F_SUB_DT_DT

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_SUB_DT_DT** is a standards-compliant function block for the precise calculation of time differences between two timestamps (DATE_AND_TIME), developed under the EPL-2.0 license. Version 1.0 enables microsecond-accurate time interval calculations according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with start and end timestamps)

Event Outputs

- `CNF`: Calculation confirmation (with time difference)

Data Inputs

- `IN1` (DATE_AND_TIME): Start time (minuend)
- `IN2` (DATE_AND_TIME): End time (subtrahend)

Data Outputs

- `OUT` (TIME): Calculated time interval (IN1 - IN2)

Functional Principle

1. **Calculation Trigger**:

- `REQ` event with two DATE_AND_TIME values
- Format: DT#1970-01-01-00:00:00 to DT#2106-02-07-06:28:15

1. **Difference Calculation**:

- Conversion to epoch microseconds
- Subtraction of timestamps (IN1 - IN2)
- Conversion to TIME data type

1. **Result Output**:

- `CNF` event with calculated interval
- Positive values for IN1 > IN2, negative values for IN1 < IN2

Technical Features

✓ **Microsecond Accuracy**
✓ **Time Zone-Independent Calculation** (UTC Base)
✓ **Full Calendar Arithmetic** (Leap Seconds, Month Lengths) ✓ **Cross-Platform Consistency**

Application Scenarios

- **Process Analysis**: Precise Machine Runtime Measurement
- **Laboratory Automation**: Precise Response Time Calculation
- **Energy Monitoring**: Consumption Period Differences
- **PLC Diagnostics**: Event Timestamp Evaluation

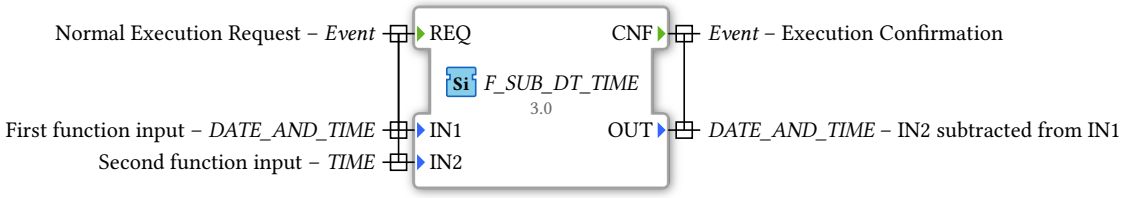
Error Handling

- **Time Range Exceedance**:
- Supports DT#1970-01-01-00:00:00 to DT#2106-02-07-06:28:15
- On Overflow: OUT = T#0s
- **Invalid Inputs**:
- OUT = T#0s for invalid timestamps
- No Exception Generation

⚖️ Comparison with Similar Function Blocks

Feature	F_SUB_DT_DT	F_SUB_DATE_DATE	F_SUB_TIME
Accuracy	Microseconds	Days	Nanoseconds
Input Type	DATE_AND_TIME	DATE	TIME
Typical Application	Process Diagnostics	Scheduling	Cycle Time

Conclusion



The F_SUB_DT_DT block offers the most precise solution for timestamp discrepancies:

- Industrial-grade microsecond accuracy
- Calendar-accurate UTC calculations
- Robust handling of large time intervals

Essential for high-precision process analysis and technical diagnostic systems.

F_SUB_DT_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_SUB_DT_TIME** function block is a standards-compliant function block for subtracting time intervals from timestamps, developed under the EPL-2.0 license. Version 1.0 enables precise time calculations according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with timestamp and time interval)

Event Outputs

- `CNF`: Calculation confirmation (with corrected timestamp)

Data Inputs

- `IN1` (DATE_AND_TIME): Base time
- `IN2` (TIME): Time interval to be subtracted

Data Outputs

- `OUT` (DATE_AND_TIME): Calculated time (IN1 - IN2)

Functional Principle

1. **Calculation Trigger**:

- `REQ` event with DATE_AND_TIME and TIME value
- Time range: DT#1970-01-01-00:00:00 to DT#2106-02-07-06:28:15

1. **Time Calculation**:

- Conversion to epoch microseconds
- Subtraction of the time interval
- Calendar-accurate back-calculation

1. **Result Output**:

- `CNF` event with new timestamp
- Automatic calendar correction (leap years, month ends)

Technical Features

✓ Microsecond accuracy ✓ Complete calendar arithmetic ✓ Negative time intervals (time shift into the future) **✓ Cross-platform consistency**

Application Scenarios

- **Scheduling**: Deadline calculation
- **Process control**: Predetermining start times
- **Maintenance systems**: Planning preventive maintenance Maintenance
- **Data Analysis**: Historical Time Correction

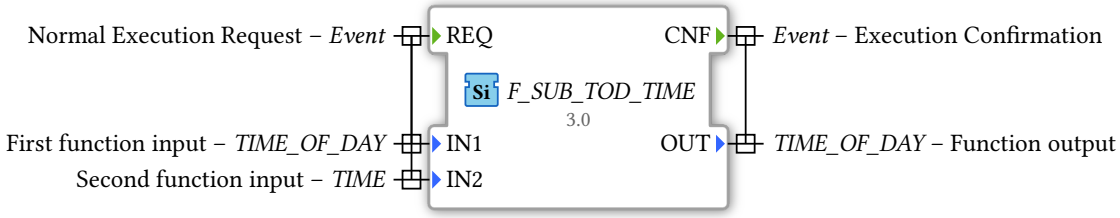
Error Handling

- **Time Range Exceedance**:
- In case of underflow: OUT = DT#1970-01-01-00:00:00
- In case of overflow: OUT = DT#2106-02-07-06:28:15
- **Special Cases**:
- IN2 = T#0s ⟶ OUT = IN1
- IN2 negative ⟶ Addition at time

⚖️ Comparison with similar function blocks

Feature	F_SUB_DT_TIME	F_ADD_DT_TIME	F_SUB_DT_DT
Operation	Time - Interval	Time + Interval	Time - Time
Result	DATE_AND_TIME	DATE_AND_TIME	TIME
Accuracy	Microseconds	Microseconds	Microseconds

Conclusion



The F_SUB_DT_TIME function block offers a reliable solution for time calculations:

- Industrial-grade precision
- Full calendar support
- Intuitive handling of time intervals

Essential for all applications involving date-related calculations and historical time analysis.

F_SUB_TOD_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_SUB_TOD_TIME** function block is a standards-compliant function block for subtracting time intervals from times of day (TIME_OF_DAY), developed under the EPL 2.0 license. Version 1.0 enables time-of-day-related calculations according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with time of day and time interval)

Event Outputs

- `CNF`: Calculation confirmation (with corrected time of day)

Data Inputs

- `IN1` (TIME_OF_DAY): Base time of day (TOD#hh:mm:ss)
- `IN2` (TIME): Time interval to be subtracted

Data Outputs

- `OUT` (TIME_OF_DAY): Calculated time of day (IN1 - IN2)

Operating Principle

1. **Calculation Trigger**:

- `REQ` event with TIME_OF_DAY and TIME value
- Valid range: TOD#00:00:00 to TOD#23:59:59.999999

1. **Time Calculation**:

- Conversion to seconds since midnight
- Subtraction of the time interval
- Time-of-day calculation with overflow handling

1. **Result Output**:

- `CNF` event with new time of day
- Automatic 24-hour overflow (circular calculation)

Technical Features

✓ **Microsecond Accuracy** ✓ **24-hour Overflow Handling** (circular time of day) ✓ **Negative Intervals** (time addition) ✓ **Real-time Calculation**

Application Scenarios

- **Shift Planning**: Calculating the start of work
- **Lighting Control**: Correct sunrise times
- **Production Planning**: Calculate machine run times
- **Traffic Control Systems**: Schedule adjustments

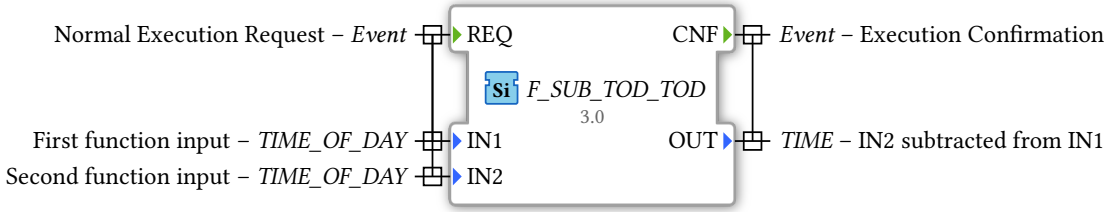
Error Handling

- **Overflow Handling**:
- In case of overrun: circular calculation (modulo 24h)
- Example: TOD#01:00:00 - T#2h = TOD#23:00:00
- **Special Cases**:
- IN2 = T#0s ⟶ OUT = IN1
- IN2 negative ⟶ Add the time (TOD#10:00 + T#−2h = TOD#12:00)

⚖️ **Comparison with similar function blocks**

Feature	F_SUB_TOD_TIME	F_ADD_TOD_TIME	F_SUB_DT_TIME
Operation	Time of Day - Interval	Time of Day + Interval	Timestamp - Interval
Result	TIME_OF_DAY	TIME_OF_DAY	DATE_AND_TIME
Overflow	24-hour Circular	24-hour Circular	Calendar-based

Conclusion



The F_SUB_TOD_TIME block offers an optimized solution for time-of-day calculations:

- Precise circular time calculation
- Easy handling of shift and operating hours
- Intuitive handling of day transitions

Ideal choice for all applications with time-of-day-dependent controls.

F_SUB_TOD_TOD

• − ◦ • − ◦ • − ◦ •

Introduction

The **F_SUB_TOD_TOD** function block is a standards-compliant function block for calculating time differences between two times of day (TIME_OF_DAY), developed under the EPL-2.0 license. Version 1.0 enables precise time-of-day calculations according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ`: Calculation request (with start and end time of day)

Event Outputs

- `CNF`: Calculation confirmation (with time difference)

Data Inputs

- `IN1` (TIME_OF_DAY): Start time of day (TOD#hh:mm:ss)
- `IN2` (TIME_OF_DAY): End time of day

Data Outputs

- `OUT` (TIME): Calculated time interval (IN1 - IN2)

Operating Principle

1. **Calculation Trigger**:

- `REQ` event with two TIME_OF_DAY values
- Valid range: TOD#00:00:00 to TOD#23:59:59.999999

1. **Difference Calculation**:

- Conversion of both values to seconds since midnight
- Difference calculation with 24-hour overflow consideration
- Result as TIME data type

1. **Result Output**:

- `CNF` event with calculated interval
- Positive values for IN1 > IN2 (within the same day)
- Negative values at the end of the day

Technical Features

✓ Microsecond Accuracy ✓ Automatic 24-hour Overflow Handling
✓ Bidirectional Difference Calculation
✓ Real-Time Capable Execution

Application Scenarios

- **Time and Attendance Recording**: Shift Duration Calculation
- **Energy Management**: Peak Load Analysis
- **Production Logistics**: Throughput Time Measurement
- **Building Automation**: Daylight Utilization Times

Error Handling

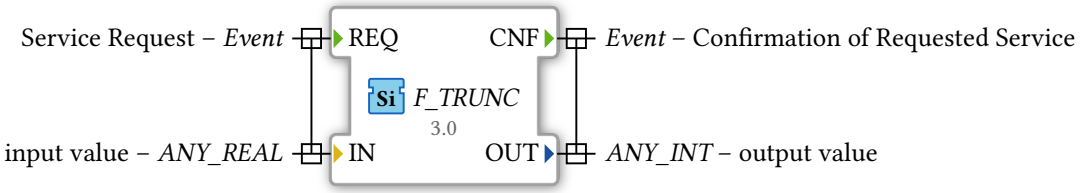
- **Special Cases**:
- IN1 = IN2 ⟶ OUT = T#0s
- Across midnight: OUT = -(24h - Difference)
- Example: TOD#01:00:00 - TOD#23:00:00 = T#−22h
- **Limit Values**:
- Maximum Difference: ±T#23:59:59.999999
- No Overflow Exception

⚖️ Comparison with Similar Function Blocks

Feature	F_SUB_TOD_TOD	F_SUB_DT_DT	F_SUB_TIME
Input Types	TOD - TOD	DT - DT	TIME - TIME
Output Type	TIME	TIME	TIME
Special Features	24-hour circular	Calendar-based	Simple difference

Conclusion

The F_SUB_TOD_TOD function block offers the optimal solution for calculating time-of-day differences:



- Precise handling of day transitions
- Simple measurement of operating time intervals

- Standards-compliant implementation

Especially valuable for all applications with time-of-day-dependent process analyses.

F_TRUNC

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_TRUNC** function block is a standards-compliant function block for rounding floating-point numbers toward zero, developed under the EPL-2.0 license. Version 1.0 enables type-safe conversion according to the IEC 61131-3 standard.

•

Interface Structure

Event Inputs

- `REQ`: Calculation request (with input value)

Event Outputs

- `CNF`: Calculation confirmation (with rounded value)

Data Inputs

- `IN` (ANY_REAL): Input value (floating-point number)

Data Outputs

- `OUT` (ANY_INT): Rounded integer value

Functional Principle

1. **Calculation Trigger**:

- `REQ` event with an ANY_REAL value
- Supported types: REAL, LREAL

1. **Truncation Operation**:

- Removes decimal places without Rounding
- Example: 3.9 ⟶ 3, −2.7 ⟶ −2
- No mathematical rounding (≠ F_ROUND)

1. **Result Output**:

- `CNF` event with integer result
- Automatic type conversion (INT, DINT, etc.)

Technical Features

✓ Lossless Type Conversion
✓ Consistent Truncation Toward Zero
✓ Deterministic Execution
✓ No Overflow Exceptions

Application Scenarios

- **Data Preprocessing**: Index Calculations
- **Measurement Processing**: Discretization
- **Control Logic**: Integer Position Calculations

- **Financial Calculations**: Currency Conversions

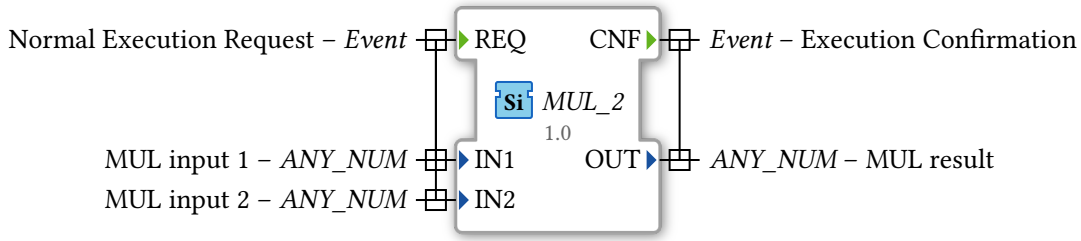
Error Handling

- **Value Range Exceedance**:
- For values that are too large: Limit to the target type maximum
- No exception generation
- **Special Cases**:
- NaN ⟶ 0

±INF ⟶ Maximum value of the target type

⚖️ **Comparison with similar function blocks**

Feature	F_TRUNC	F_ROUND	F_FLOOR
Operation	Direction Zero	Mathematical	Round Down
Example	3.9 ⟶ 3	3.9 ⟶ 4	3.9 ⟶ 3
Example	−2.7 ⟶ −2	−2.7 ⟶ −3	−2.7 ⟶ −3



Conclusion

The F_TRUNC function block offers a precise solution for integer conversion:

- Predictable behavior (truncation toward zero)
- Type-safe floating-point-to-integer conversion
- Robust handling of extreme values

Essential for all applications with precise range boundaries and index calculations.

MUL_2

• – ◦ • – ◦ • – ◦ •

Introduction

The **MUL_2** is a generic function block that calculates the arithmetical product of two numeric inputs (`OUT = IN1 * IN2`). The data types of the ports (`ANY_NUM`) are fixed on instantiation; the native implementation is `GEN_MUL`.

Interface Structure

Event Inputs

- **REQ**: normal execution request (with `IN1`, `IN2`)

Event Outputs

- **CNF**: execution confirmation (with `OUT`)

Data Inputs

- **IN1** (ANY_NUM): first factor
- **IN2** (ANY_NUM): second factor

Data Outputs

- **OUT** (ANY_NUM): product

Adapters

No adapters are used.

Functionality

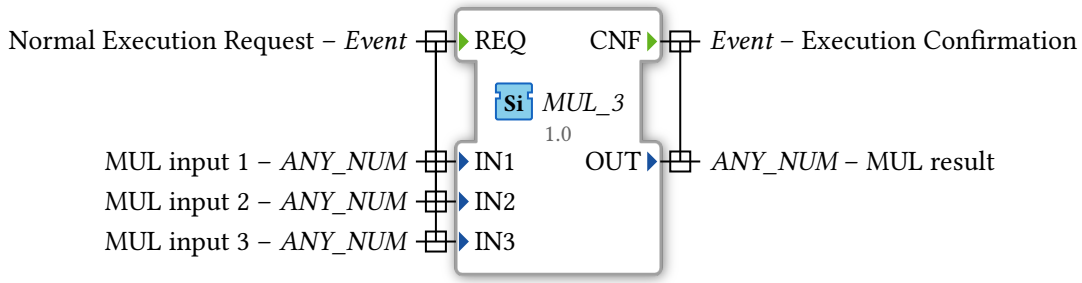
On `REQ`, `IN1` and `IN2` are read, multiplied, and the product is output at `OUT` together with the event `CNF`.

Technical Details

- Generic block (generic class `GEN_MUL`): the port types are `ANY_NUM` and are fixed per instance
- Stateless service interface block

Application Scenarios

- Scaling a value by a factor in an event network
- Area, power or quantity calculations from two quantities



⚖️ Comparison with Similar Blocks

`ADD_2` correspondingly forms the sum of two values; for multiplication with adapters, there are the AR-based variants in the adapter library.

Conclusion

`MUL_2` multiplies two numeric values of arbitrary `ANY_NUM` type in an event-driven way.

MUL_3

• – ◦ • – ◦ • – ◦ •

Introduction

MUL_3 is a generic function block that calculates the arithmetic product of three numeric inputs (`OUT = IN1 * IN2 * IN3`). The data types of the ports (`ANY_NUM`) are fixed at instantiation; the native implementation is `GEN_MUL`.

Interface Structure

Event Inputs

- **REQ**: normal execution request (with `IN1`, `IN2`, `IN3`)

Event Outputs

- **CNF**: execution confirmation (with `OUT`)

Data Inputs

- **IN1** (ANY_NUM): first factor
- **IN2** (ANY_NUM): second factor
- **IN3** (ANY_NUM): third factor

Data Outputs

- **OUT** (ANY_NUM): product

Adapters

No adapters are used.

Functionality

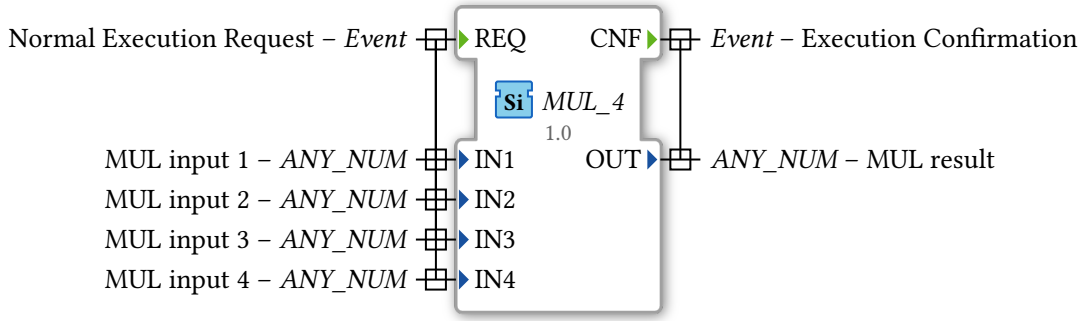
On REQ, IN1, IN2 and IN3 are read, multiplied, and the product is output at OUT together with the event CNF.

Technical Details

- Generic block (generic class GEN_MUL): the port types are ANY_NUM and are fixed per instance
- Stateless service interface block

Application Scenarios

- Product of three quantities in an event network (e.g. volume calculation from length, width, height)



⚖️ Comparison with Similar Building Blocks

MUL_2 multiplies two values, MUL_3 three.

Conclusion

MUL_3 multiplies three numeric values of any ANY_NUM type in an event-driven manner.

MUL_4

• – ◦ • – ◦ • – ◦ •

Introduction

The **MUL_4** is a generic function block that calculates the arithmetic product of four numeric inputs (OUT = IN1 * IN2 * IN3 * IN4). The data types of the ports (ANY_NUM) are fixed at instantiation; the native implementation is GEN_MUL.

Interface Structure

Event Inputs

- **REQ**: normal execution request (with IN1, IN2, IN3, IN4)

Event Outputs

- **CNF**: execution confirmation (with OUT)

Data Inputs

- **IN1** (ANY_NUM): first factor
- **IN2** (ANY_NUM): second factor
- **IN3** (ANY_NUM): third factor
- **IN4** (ANY_NUM): fourth factor

Data Outputs

- **OUT** (ANY_NUM): product

Adapters

No adapters are used.

Functionality

On REQ, IN1, IN2, IN3 and IN4 are read, multiplied and the product is output at OUT together with the event CNF.

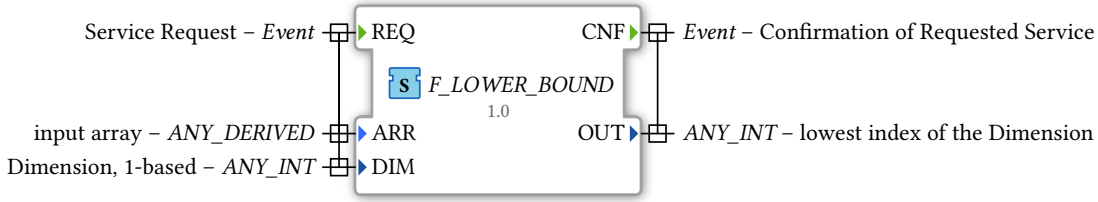
Technical Details

- Generic block (generic class `GEN_MUL`): the port types are `ANY_NUM` and are fixed per instance
- Stateless service interface block
- Version 1.0 (2026-08-28)

Application Scenarios

- Product of four quantities in an event network

⚖️ Comparison with Similar Building Blocks



`MUL_2` multiplies two values, `MUL_3` three, `MUL_4` four.

Conclusion

`MUL_4` multiplies four numeric values of any `ANY_NUM` type in an event-driven manner.

2.11.4.2 Arrays

F_LOWER_BOUND

• – ◦ • – ◦ • – ◦ •

Introduction

`F_LOWER_BOUND` returns the lower index bound of a selected dimension of an array of arbitrary type. Together with F_UPPER_BOUND, it forms the basis for generic, size-independent array processing — e.g. `F_LEN_ARRAY` (see `utils::arrays`) is computed from both bounds.

Interface Structure

Event Inputs

- **REQ**: Triggers the query, carries `ARR` and `DIM`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **ARR** (ANY_DERIVED): The array whose index bound is to be determined.
- **DIM** (ANY_INT, default `UDINT#1`): The array dimension to consider, 1-based.

Data Outputs

- **OUT** (ANY_INT): The lowest index of the selected dimension.

Functionality

On `REQ`, the block determines the lower index bound of the dimension of `ARR` selected via `DIM` and outputs it via `OUT`. `CNF` is then triggered.

Technical Features

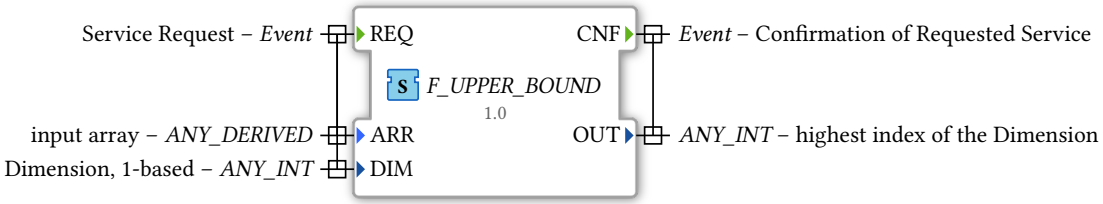
- **`ANY_DERIVED` input**: `ARR` accepts arrays of any element type and any dimensionality.
- **1-based dimension selection**: `DIM = 1` denotes the first dimension; for multi-dimensional arrays, this lets a specific dimension be queried.
- **Not necessarily `0`/greater than `0`**: IEC 61131-3 arrays can be declared with arbitrary index bounds (including negative, or not starting at `0`) — `F_LOWER_BOUND` returns the actually declared bound, making no assumption about its value.

State Overview

Stateless: every `REQ` immediately results in the query and `CNF`.

Application Scenarios

- **Generic array processing**: Loops that iterate over an array's elements independent of its actually declared size/index bounds.
- **Building block for length calculation**: `F_LEN_ARRAY` (`utils::arrays`) combines `F_LOWER_BOUND` with `F_UPPER_BOUND` to compute the element count of a dimension.



Comparison with similar function blocks

- F_UPPER_BOUND: the other index bound of the same dimension.
- **`F_LEN_ARRAY`** (`utils::arrays`): computes the element count from `F_LOWER_BOUND` and `F_UPPER_BOUND`.

Conclusion

`F_LOWER_BOUND` provides the lower index bound of an array dimension and is a fundamental building block for generic, size-independent array processing in IEC 61131-3 applications.

F_UPPER_BOUND

• – ◦ • – ◦ • – ◦ •

Introduction

`F_UPPER_BOUND` returns the upper index bound of a selected dimension of an array of arbitrary type. Together with F_LOWER_BOUND, it forms the basis for generic, size-independent array processing — e.g. `F_LEN_ARRAY` (see `utils::arrays`) is computed from both bounds.

Interface Structure

Event Inputs

- **REQ**: Triggers the query, carries `ARR` and `DIM`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **ARR** (ANY_DERIVED): The array whose index bound is to be determined.
- **DIM** (ANY_INT, default `UDINT#1`): The array dimension to consider, 1-based.

Data Outputs

- **OUT** (ANY_INT): The highest index of the selected dimension.

Functionality

On `REQ`, the block determines the upper index bound of the dimension of `ARR` selected via `DIM` and outputs it via `OUT`. `CNF` is then triggered.

Technical Features

- **`ANY_DERIVED` input**: `ARR` accepts arrays of any element type and any dimensionality.
- **1-based dimension selection**: `DIM = 1` denotes the first dimension; for multi-dimensional arrays, this lets a specific dimension be queried.
- **Not necessarily `0`/greater than `0`**: IEC 61131-3 arrays can be declared with arbitrary index bounds (including negative, or not starting at `0`) — `F_UPPER_BOUND` returns the actually declared bound, making no assumption about its value.

State Overview

Stateless: every `REQ` immediately results in the query and `CNF`.

Application Scenarios

- **Generic array processing**: Loops that iterate over an array's elements independent of its actually declared size/index bounds.
- **Building block for length calculation**: `F_LEN_ARRAY` (`utils::arrays`) combines `F_UPPER_BOUND` with `F_LOWER_BOUND` to compute the element count of a dimension.

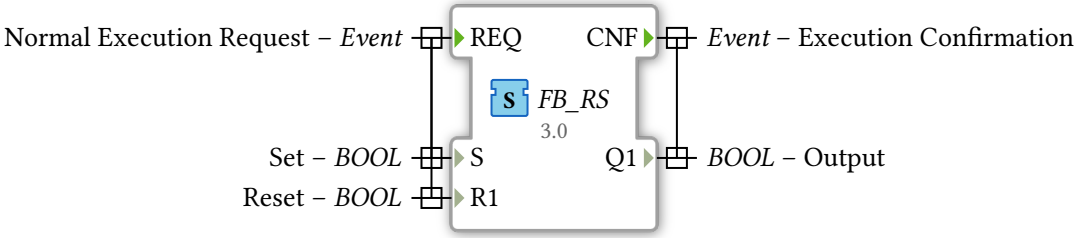
Comparison with similar function blocks

- **F_LOWER_BOUND**: the other index bound of the same dimension.
- **`F_LEN_ARRAY`** (`utils::arrays`): computes the element count from `F_UPPER_BOUND` and `F_LOWER_BOUND`.

Conclusion

`F_UPPER_BOUND` provides the upper index bound of an array dimension and is a fundamental building block for generic, size-independent array processing in IEC 61131-3 applications.

2.11.4.3 Bistable Elements



Here you will find functional building blocks for bistable elements (flip-flops).

FB_RS

• – ◦ • – ◦ • – ◦ •

Introduction

The FB_RS function block is a bistable element that functions as a set-reset flip-flop (RS flip-flop). It stores a state and changes it based on the input signals S (Set) and R1 (Reset). The block is implemented according to the IEC 61499-1 standard and is suitable for control applications that require state storage.

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request. Triggers the execution of the function block. Linked to the data inputs S and R1.

Event Outputs

- **CNF**: Execution Confirmation. Outputs after the inputs have been processed. Linked to the data output Q1.

Data Inputs

- **S (BOOL)**: Set input. Sets output Q1 to TRUE if S is TRUE and R1 is FALSE.
- **R1 (BOOL)**: Reset input. Sets output Q1 to FALSE if R1 is TRUE.

Data Outputs

- **Q1 (BOOL)**: Output. Represents the stored state of the RS flip-flop.

Adapters

No adapters available.

Functionality

The FB_RS processes inputs S and R1 on every REQ event. Output Q1 is updated according to the following logic:

- If R1 is TRUE, Q1 is set to FALSE (Reset takes priority).
- If S is TRUE and R1 is FALSE, Q1 is set to TRUE.
- If both inputs are FALSE, Q1 retains its previous state.

The logic is implemented using the following algorithm:
ALGORITHM REQ Q1 := (NOT R1) AND (S OR Q1); END_ALGORITHM

Technical Features

- **IEC 61131-3 Compliance**: This component precisely replicates the behavior of the classic `RS` flip-flop. Since the inputs `S` and `R1` are data inputs that are sampled simultaneously during the `REQ` event, logical prioritization is necessary.
- **Reset Dominance (Priority)**: The reset input (`R1`) takes precedence. If `S` and `R1` are simultaneously `TRUE`, the output `Q1` is set to `FALSE`.
- **Storage Behavior**: The block retains its state as long as there is no change to `S` or `R1` (or no `REQ` event occurs).

Storage Behavior: The block retains its state as long as there is no change to `S` or `R1` (or no `REQ` event occurs).

State Overview

The `FB_RS` evaluates the inputs at `REQ`:

1. **Q1 = FALSE**: If `R1` is TRUE (regardless of `S`). -> **Reset Dominance**
2. **Q1 = TRUE**: If `S` is TRUE AND `R1` is FALSE.
3. **Q1 Unchanged**: If both are FALSE.

Application Scenarios

- Storage of switching states in control applications according to IEC 61131-3 logic.
- Implementation of interlock logic (e.g., emergency stop circuits) where switching off (reset) must always take precedence.

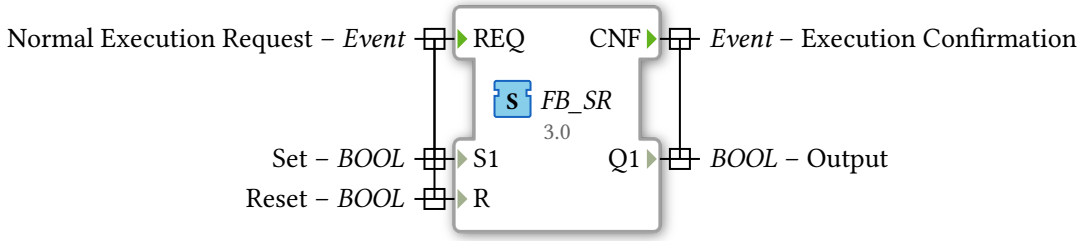
⚖️ Comparison with similar building blocks

- **E_RS**: The `E_RS` is purely event-driven (“Last Event Wins”). The `FB_RS`, on the other hand, evaluates static signals at time `REQ` and enforces reset dominance.
- **FB_SR**: The counterpart with **set dominance**.

🛠️ Related Exercises

- Exercise_006e2
- Exercise_006e2_AX
- Exercise_160b2
- Exercise_160b2_AX

Conclusion



The FB_RS is a fundamental and robust function block for state storage in IEC 61499-based control systems. Its simple and clear logic makes it particularly suitable for applications requiring reliable set-reset behavior. Prioritizing the reset input ensures that safety functions can be executed reliably.

FB_SR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_SR` is a bistable element that functions as a set-reset flip-flop (SR flip-flop). It stores a state based on the input signals and retains this state until it is changed by new input signals.

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request (trigger for executing the function block)

Event Outputs

- **CNF**: Execution Acknowledgement (triggered after processing the inputs)

Data Inputs

- **S1** (BOOL): Set Input (sets output `Q1` to `TRUE` if `TRUE`)
- **R** (BOOL): Reset Input (sets output `Q1` to `FALSE` if `TRUE`)

Data Outputs

- **Q1** (BOOL): Output (stored state of the flip-flop)

Adapter

No adapters available.

Functionality

The function block `FB_SR` processes the inputs `S1` (Set) and `R` (Reset) according to the following logic:

- If `S1` is `TRUE`, `Q1` is set to `TRUE`.
- If `R` is `TRUE`, `Q1` is set to `FALSE`.
- If both inputs are `FALSE`, `Q1` retains its previous state.

The logic is implemented using the following algorithm:
ALGORITHM REQ Q1 := S1 OR ((NOT R) AND Q1); END_ALGORITHM

Technical Features

- **IEC 61131-3 Compliance**: This function block precisely replicates the behavior of the classic `SR` flip-flop. Since the inputs `S1` and `R` are data inputs that are sampled simultaneously during the `REQ` event, logical prioritization is necessary.
- **Set Dominance**: The function block implements **set priority**. If `S1` and `R` are simultaneously `TRUE`, the output `Q1` is set to `TRUE`.
- **Trigger**: Execution (logic calculation) occurs only on the event `REQ`.

State Overview

The state of the flip-flop (`Q1`) depends on the current values of `S1` and `R` (at the time of `REQ`):

- `S1 = TRUE`: `Q1` is set to `TRUE` (independently of `R`). -> **Set Dominance**
- `R = TRUE` AND `S1 = FALSE`: `Q1` is set to `FALSE`.
- `S1 = FALSE` and `R = FALSE`: `Q1` remains unchanged.

Application Scenarios

- Storage of binary states in control applications where IEC 61131-3 behavior is required.
- Use in switching networks where the dominance of the set signal is necessary for safety or process reasons.

⚖️ Comparison with similar building blocks

- **E_SR**: The `E_SR` is purely event-driven. There are no simultaneous signals and therefore no dominance in this sense (the last event wins). The `FB_SR`, on the other hand, evaluates static signals at time `REQ` and enforces set dominance.
- **FB_RS**: The counterpart with **reset dominance** (reset priority).

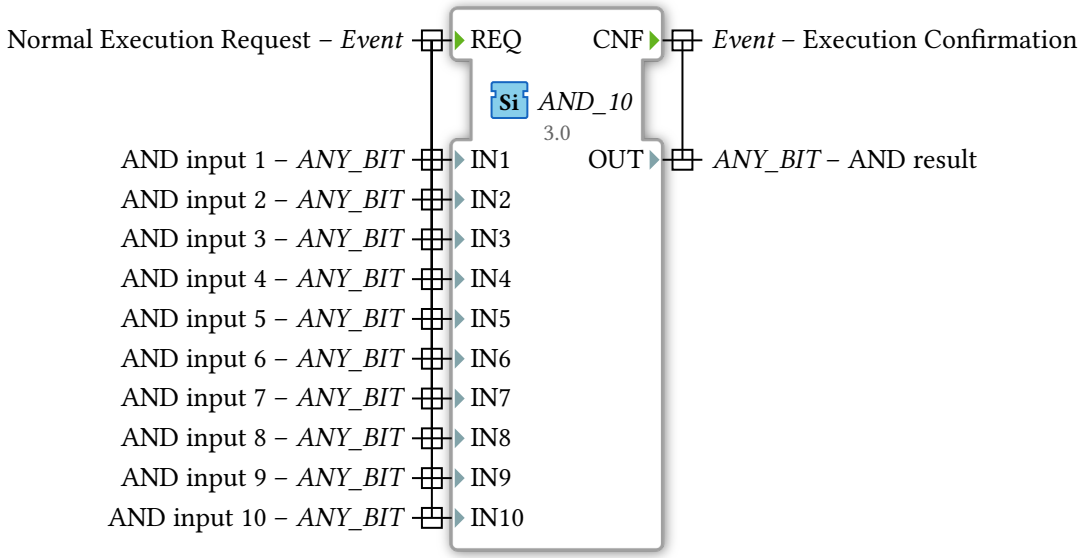
🛠️ Related Exercises

- Exercise_006e1
- Exercise_006e1_AX

Conclusion

The `FB_SR` is a basic and efficient function block for storing binary states in control applications. Its simple logic and clear interface make it ideal for use in various industrial automation solutions.

2.11.4.4 Bitwise Operators



Here you will find functions for bitwise logic operations (AND, OR, XOR, shift, rotate).

AND_10

• – ◦ • – ◦ • – ◦ •

Introduction

The `AND_10` function block is a generic building block for calculating a bitwise logical AND operation. It supports up to 10 input variables and is classified according to the IEC 61131-3 standard. This function block is part of the `iec61131::bitwiseOperators` package and is suitable for applications requiring logical operations at the bit level.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. It is linked to all inputs (`IN1` to `IN10`).

Event Outputs

- **CNF**: Signals the completion of the calculation. Linked to output `OUT`.

Data Inputs

- **IN1** to **IN10** (`ANY_BIT`): Up to 10 input variables for bitwise AND operation. Each input can be any bit data type (e.g., BOOL, BYTE, WORD, DWORD).

Data Outputs

- **OUT** (`ANY_BIT`): Result of the bitwise AND operation of all inputs. The data type corresponds to that of the inputs.

Adapters

- No adapters available.

Functionality

The `AND_10` function block performs a bitwise logical AND operation on the values of all active inputs (`IN1` to `IN10`). The result is output at `OUT` as soon as the `REQ` event is received. The calculation is confirmed by the `CNF` event.

Technical Features

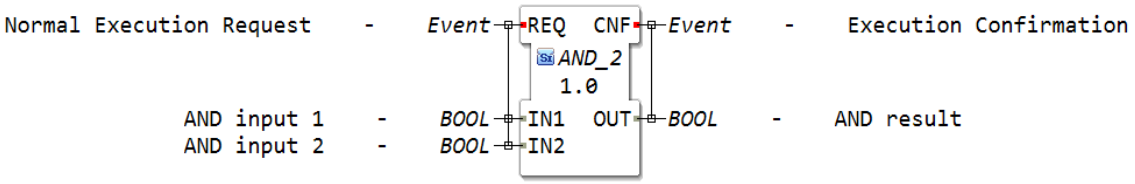
- **Generic Implementation**: The function block uses the generic class `GEN_AND`, which allows for flexible use with various bit data types.
- **Scalability**: Supports up to 10 inputs, enabling more complex logical operations.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Calculation State**: Executes the AND operation as soon as `REQ` is activated.
3. **Output State**: Outputs the result via `OUT` and signals completion with `CNF`.

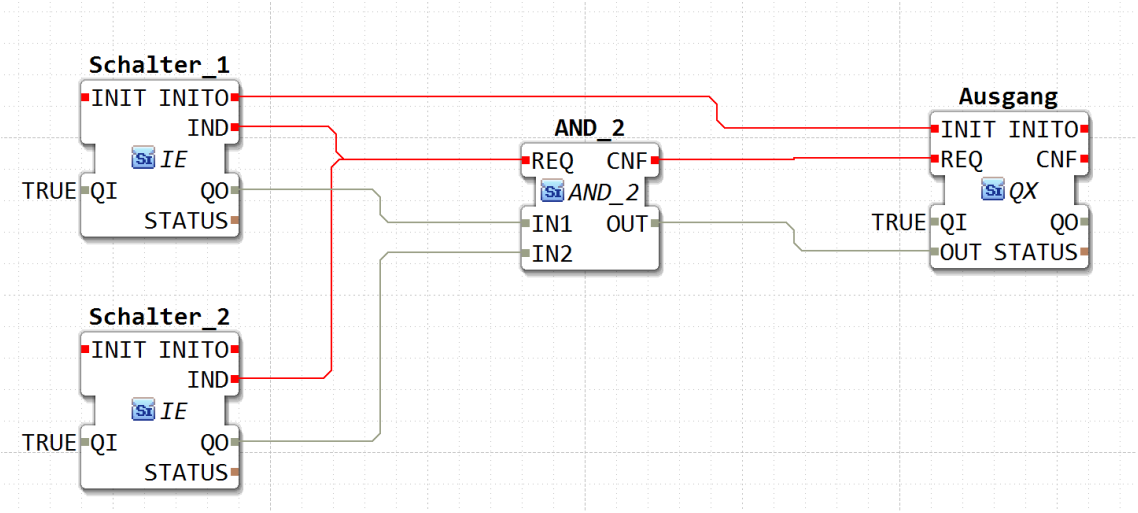
Application Scenarios

- Logical filtering of signal groups.
- Bitwise masking of data values.
- Control logic in industrial automation systems.



⚖️ Comparison with Similar Function Blocks

- **Standard AND Function Block**: Typically supports only 2 inputs. `AND_10` offers greater flexibility with 10 inputs.
- **Generic Logic Blocks**: Similarly generic blocks could support fewer inputs or more specific data types.

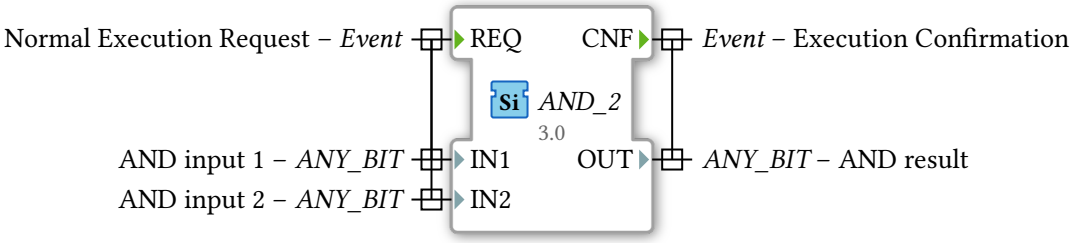


Conclusion

The `AND_10` function block is a versatile tool for bitwise logic operations in IEC 61131-3-based control systems. Its generic nature and support for up to 10 inputs make it particularly useful for complex logic tasks.

AND_2

OUT is only switched when a Boolean signal is present at IN1 and IN2, e.g., from a switch.



The same principle applies to all other “AND” blocks, except that all IN inputs must always be True.

• – ◦ • – ◦ • – ◦ •

Introduction

The AND_2 function block is a generic block for calculating the bitwise Boolean AND operation. It implements a standard function according to IEC 61131-3 and can be used with any bit data type.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation of the AND operation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1** (ANY_BIT): AND input 1 - first operand for the bitwise AND operation
- **IN2** (ANY_BIT): AND input 2 - second operand for the bitwise AND operation

Data Outputs

- **OUT** (ANY_BIT): AND result - result of the bitwise AND operation

Adapters

No adapter interfaces are available.

Functionality

Upon arrival of the REQ event, the function block performs a bitwise AND operation between the two input values IN1 and IN2. The result is output at the data output OUT, and simultaneously, the CNF event is generated to confirm execution.

The operation is performed separately for each bit of the input values:

- Bit = 1 if both corresponding bits of the inputs are 1
- Bit = 0 if at least one of the corresponding bits of the inputs is 0

Technical Features

- **Generic Data Type**: Uses ANY_BIT, which allows its use with various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- **Bitwise Operation**: Performs the AND operation at the bit level
- **Event-Driven**: Execution is driven by events, not by cycle times

State Transitions

1. **Wait State**: Block waits for REQ event
2. **Compute State**: Upon REQ event, IN1 and IN2 are processed
3. **Output State**: Result is output to OUT and a CNF event is generated
4. Returns to Wait State

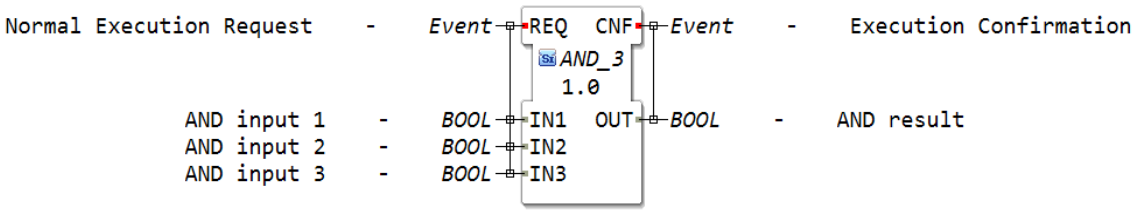
Application Scenarios

- Bitmask operations in control applications
- Filtering of data by masking unwanted bits
- Logical operations in digital circuits
- Data preprocessing in communication protocols

⚖️ Comparison with similar building blocks

Compared to other logical operation blocks:

- AND_2 is generic and supports various bit data types
- Operates bitwise, unlike purely Boolean AND blocks
- Event-driven, unlike cycle-driven blocks

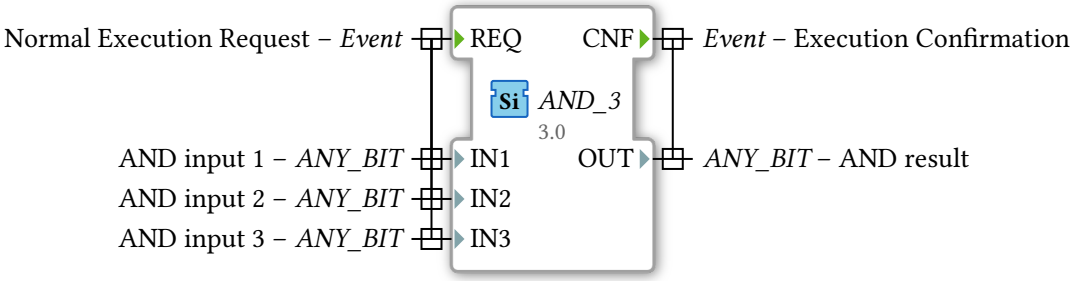


🛠️ Related exercises

- Exercise_002a
- Exercise_002a_AX
- Exercise_002b2
- Exercise_002b3_AX
- Exercise_006a3_AX
- Exercise_088

Conclusion

The AND_2 function block offers a flexible and standards-compliant solution for bitwise AND operations in IEC 61131-3 based control systems. Its generic nature allows for use in a wide range of applications, while its event-driven architecture ensures efficient resource utilization.



AND_3

• – ○ • – ○ • – ○ •

Introduction

The AND_3 function block is a generic function block for calculating the bitwise logical AND operation with three inputs. It performs a bitwise AND operation on three input values and outputs the result. The function block supports all ANY_BIT data types and is therefore flexible for use with different bit widths.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation of the AND operation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1**: AND input 1 (ANY_BIT)
- **IN2**: AND input 2 (ANY_BIT)
- **IN3**: AND input 3 (ANY_BIT)

Data Outputs

- **OUT**: AND result (ANY_BIT)

Adapters

No adapters available.

Functionality

Upon arrival of the REQ event, the AND_3 block performs a bitwise AND operation on the three input values IN1, IN2, and IN3. The result is output at the OUT data output, and simultaneously a CNF event is generated to signal successful computation.

The operation follows the formula: OUT = IN1 ∧ IN2 ∧ IN3

Technical Features

- Generic function block that works with all ANY_BIT data types (BOOL, BYTE, WORD, DWORD, LWORD)
- Supports three inputs for extended AND operations
- Type safety through consistent use of the same data type for all inputs and outputs

State Transitions

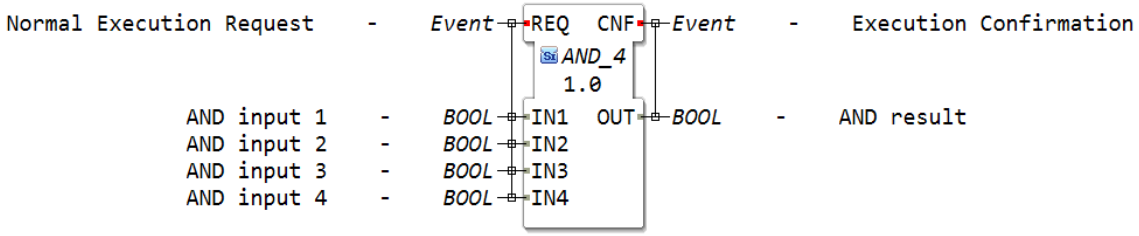
1. **Wait State**: The function block waits for a REQ event
2. **Calculation State**: Upon REQ, the inputs are processed
3. **Output State**: The result is output to OUT and a CNF event is generated
4. Return to Wait State

Application Scenarios

- Bitmask operations in control applications
- Multiple condition checks in logic circuits
- Signal processing with multiple input signals
- Filter operations in data processing systems

⚖️ Comparison with Similar Function Blocks

Compared to Compared to standard two-input AND gates, AND_3 offers the ability to process three inputs simultaneously, reducing the number of gates required in more complex circuits. AND_3 provides greater flexibility compared to fixed-bit-width gates due to its generic ANY_BIT typing.

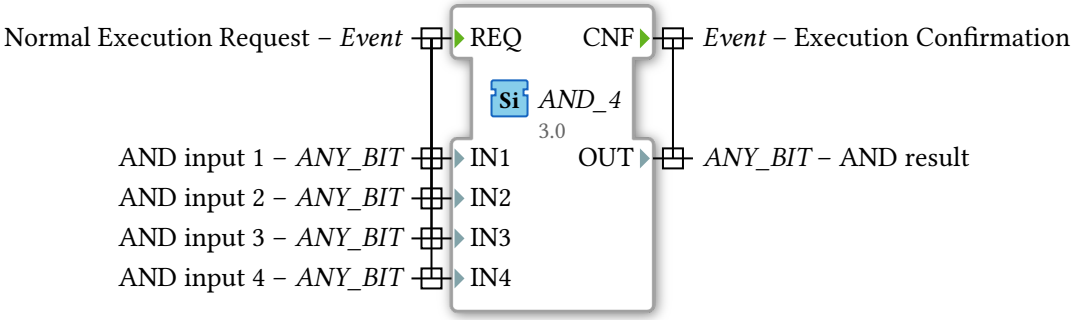


🛠️ Related Exercises

- Exercise_002a6_AX

Conclusion

The AND_3 function block is a versatile and efficient gate for bitwise AND operations with three inputs. Its generic nature makes it suitable for various applications and data types, while its clear event-driven handling enables reliable integration into control systems.



AND_4

• – ◦ • – ◦ • – ◦ •

Introduction

The AND_4 function block is a generic function block for calculating bitwise Boolean AND operations. It processes four input values and performs a logical AND operation at the bit level. The function block is classified according to the IEC 61131-3 standard and supports any bit data type.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1**: AND input 1 (ANY_BIT data type)
- **IN2**: AND input 2 (ANY_BIT data type)
- **IN3**: AND input 3 (ANY_BIT data type)
- **IN4**: AND input 4 (ANY_BIT data type)

Data Outputs

- **OUT**: AND result (ANY_BIT data type)

Adapters

No adapter interfaces are available.

Functionality

Upon receiving the REQ event, the AND_4 block performs a bitwise AND operation on all four input values. The result is output at the OUT data output, and simultaneously, the CNF event is triggered to confirm successful calculation. The operation is performed separately for each bit of the input values.

Technical Features

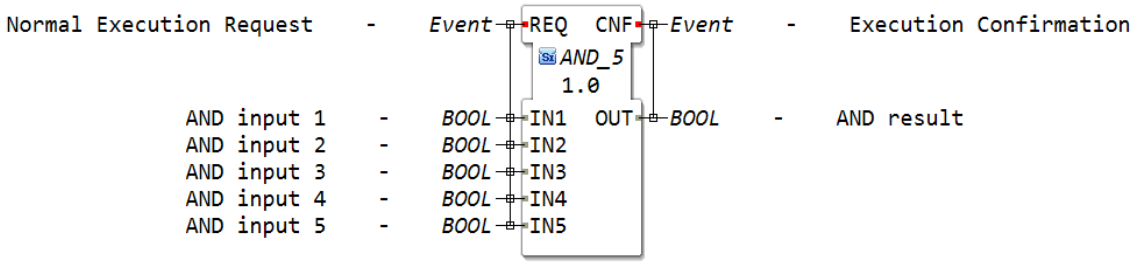
- Supports the generic data type ANY_BIT, enabling use with various bit data types such as BOOL, BYTE, WORD, DWORD, etc.
- Four independent inputs for flexible linking options
- Event-driven execution for deterministic behavior
- Compatible with the IEC 61131-3 standard

State Transitions

1. **Wait State**: Block waits for a REQ event
2. **Compute State**: Upon receiving a REQ, all four inputs are bitwise ANDed
3. **Output State**: Result is output to OUT, and a CNF event is triggered
4. Returns to Wait State

Application Scenarios

- Bitmask operations in control applications
- Parity checks and error detection
- Signal processing in industrial automation systems
- Logical operations of multiple digital signals
- Filter operations in data processing systems

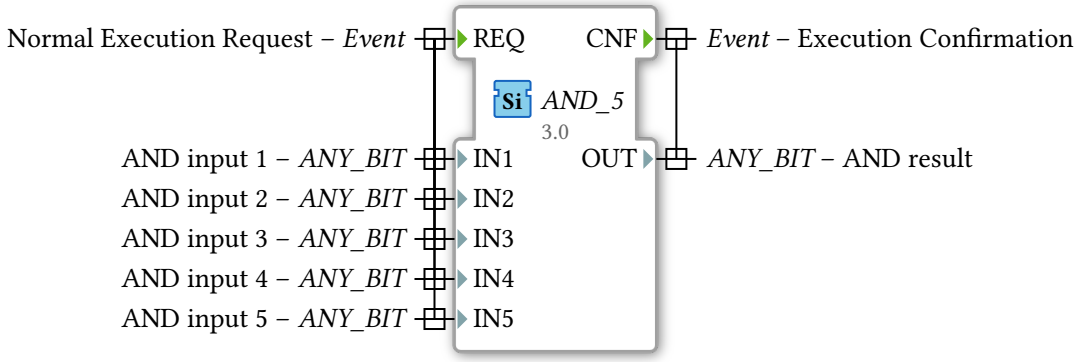


⚖️ Comparison with Similar Blocks

Compared to Compared to standard AND blocks with fewer inputs, AND_4 offers the ability to combine four signals simultaneously, enabling more complex logical operations in a single step. Compared to sequential AND operations using multiple blocks, AND_4 provides a more compact and user-friendly solution.

Conclusion

The AND_4 function block represents an efficient and flexible solution for bitwise AND operations with four inputs. Its generic nature allows for use in various applications, while its event-driven architecture ensures reliable integration into more complex control systems.



AND_5

• – ◦ • – ◦ • – ◦ •

Introduction

The AND_5 function block is a generic function block for calculating bitwise logical AND operations with five inputs. It implements a standard bitwise operation according to IEC 61131-3 and can work with any bit data type.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation of the AND operation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1**: AND input 1 (ANY_BIT data type)
- **IN2**: AND input 2 (ANY_BIT data type)
- **IN3**: AND input 3 (ANY_BIT data type)
- **IN4**: AND input 4 (ANY_BIT data type)
- **IN5**: AND input 5 (ANY_BIT data type)

Data Outputs

- **OUT**: AND result (ANY_BIT data type)

Adapters

No adapter interfaces are available.

Functionality

Upon arrival of the REQ event, the function block performs a bitwise AND operation on all five inputs. The result is output at the OUT data output, and simultaneously, the CNF event is sent to confirm the completion of the calculation.

The operation is performed separately for each bit position:

$OUT_i = IN1_i \wedge IN2_i \wedge IN3_i \wedge IN4_i \wedge IN5_i$

Technical Features

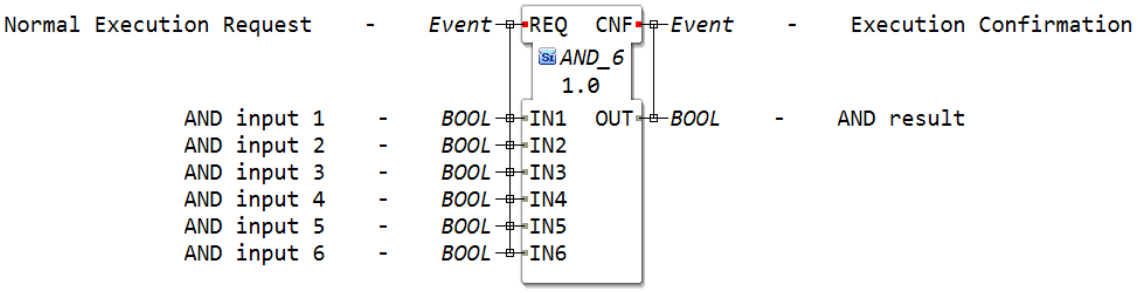
- **Generic Data Type**: Uses ANY_BIT, making the block compatible with various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- **Five Inputs**: Allows the combination of up to five different bit values
- **Event-Driven**: The calculation is only performed when requested by the REQ event

State Transitions

1. **Wait State**: Block waits for REQ event
2. **Calculation State**: Upon REQ input, all inputs are combined bitwise using an AND operation
3. **Output State**: Result is output to OUT and a CNF event is sent
4. Returns to Wait State

Application Scenarios

- Bitmask operations in control applications
- Multiple condition checks in safety systems
- Signal processing with multiple input signals
- Filter operations in data processing systems

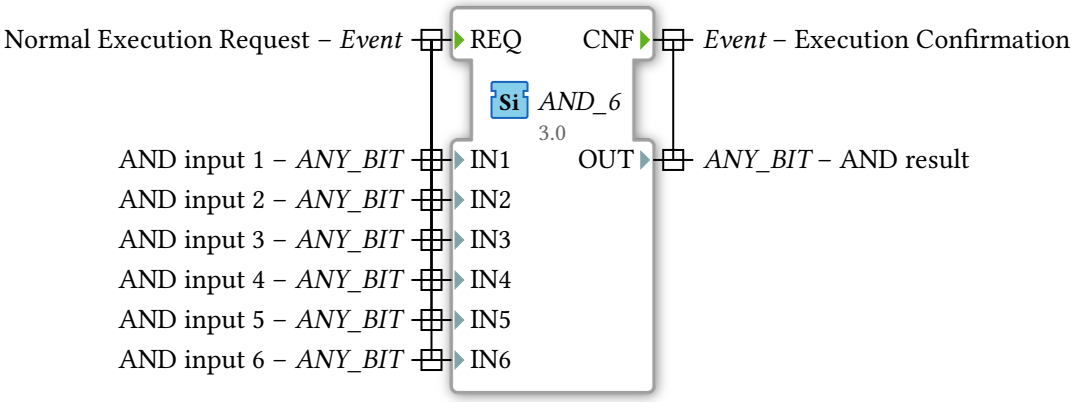


⚖️ Comparison with similar function blocks

- **AND_2**: Provides only two inputs for AND operation
- **OR_5**: Performs bitwise OR operations with five inputs
- **XOR_5**: Performs bitwise exclusive OR operations

Conclusion

The AND_5 function block offers a flexible and efficient solution for bitwise AND operations with five inputs. Its generic nature allows its use with various bit data types, making it a versatile building block for complex logic operations in automation applications.



AND_6

• – ◦ • – ◦ • – ◦ •

Introduction

The AND_6 function block is a generic function block for calculating the bitwise Boolean AND operation with six inputs. It implements a standard function according to IEC 61131-3 and performs a logical AND operation at the bit level for up to six input values.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): Starts the execution of the AND operation. Triggers the processing of the input data.

Event Outputs

- **CNF** (Execution Confirmation): Signals the completion of the calculation and the availability of the result.

Data Inputs

- **IN1** (ANY_BIT): AND Input 1
- **IN2** (ANY_BIT): AND Input 2
- **IN3** (ANY_BIT): AND Input 3
- **IN4** (ANY_BIT): AND Input 4
- **IN5** (ANY_BIT): AND Input 5

- **IN6** (ANY_BIT): AND Input 6

Data Outputs

- **OUT** (ANY_BIT): AND result of the bitwise operation of all six inputs

Adapter

No adapter interfaces available.

Functionality

When the REQ event is triggered, the AND_6 block performs a bitwise AND operation on all six input values. The operation is performed separately for each bit position: The result bit at position i is only 1 if all six input bits at position i have the value 1. Once the calculation is complete, the CNF event is triggered and the result is made available at the OUT output. ...

Technical Features

- Uses the generic data type ANY_BIT, which supports various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- All inputs must have the same data type
- The result has the same data type as the inputs
- Implemented as a generic function block with the class 'GEN_AND'

State Transitions

1. **Wait State**: Block waits for a REQ event
2. **Compute State**: On REQ, all inputs are performed with a bitwise AND operation
3. **Output State**: Result is output to OUT and a CNF event is triggered
4. Returns to Wait State

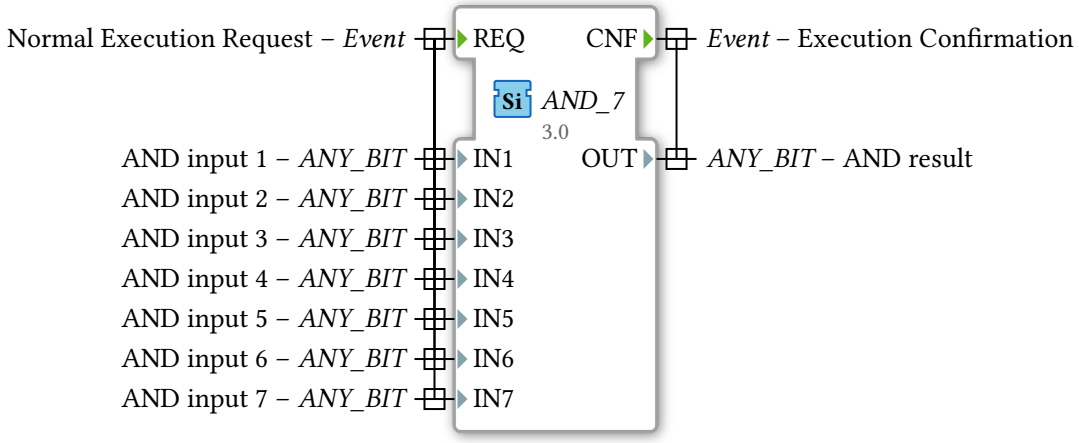
Application Scenarios

- Bitmask operations in control applications
- Multiple condition checks in logic circuits
- Signal processing with multiple input signals
- Safety-related circuits with multiple monitoring signals

⚖️ Comparison with Similar Blocks

Compared to simpler AND blocks With fewer inputs, AND_6 allows you to combine up to six signals simultaneously, simplifying the program structure and requiring fewer logic blocks. Compared to serial AND operations, it offers improved clarity and lower latency.

Conclusion



The AND_6 function block provides an efficient and clear solution for complex bitwise AND operations with up to six inputs. Its generic implementation enables its use with various bit data types, making it a versatile tool in automation technology.

AND_7

• – ◦ • – ◦ • – ◦ •

Introduction

The AND_7 function block performs a bitwise logical AND operation on up to seven input variables. It is a generic function block that can work with various bit data types (ANY_BIT). The block is classified according to the IEC 61131-3 standard and is suitable for use in control and automation systems.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): Starts the execution of the function block. It is used with all seven input variables (IN1 to IN7).

Event Outputs

- **CNF** (Execution Confirmation): Signals successful execution and returns the result of the AND operation via the variable OUT.

Data Inputs

- **IN1** (ANY_BIT): First input for the AND operation
- **IN2** (ANY_BIT): Second input for the AND operation
- **IN3** (ANY_BIT): Third input for the AND operation
- **IN4** (ANY_BIT): Fourth input for the AND operation
- **IN5** (ANY_BIT): Fifth input for the AND operation
- **IN6** (ANY_BIT): Sixth input for the AND operation
- **IN7** (ANY_BIT): Seventh input for the AND operation

Data Outputs

- **OUT** (ANY_BIT): Result of the bitwise AND operation of all input values

Adapters

This function block does not use adapters.

Functionality

The AND_7 block performs a bitwise AND operation on all active inputs (IN1 to IN7) on every REQ event. The result is output to OUT, and the CNF event is triggered. The block is generic and can work with various bit data types (such as BOOL, BYTE, WORD, DWORD, LWORD).

Technical Features

- Supports the generic data type ANY_BIT
- Implemented as a generic function block (GEN_AND)
- Part of the iec61131::bitwiseOperators package
- EPL-2.0 license

State Overview

The block has no internal state. On every REQ event, the operation is executed immediately, and the result is returned via CNF.

Application Scenarios

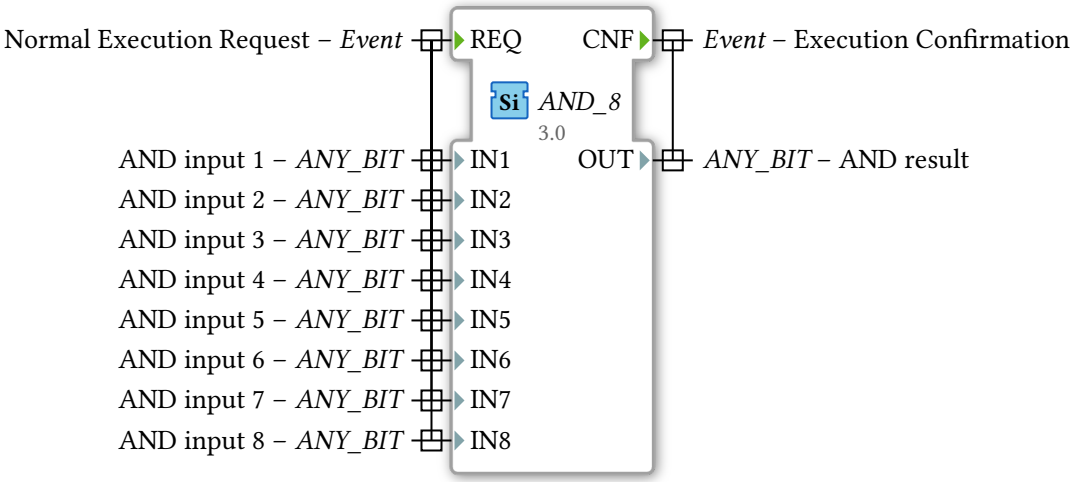
- Bitwise mask operations in control applications
- Logical combination of multiple digital signals

- Signal processing in automation systems
- Generic logic operations in IEC 61131-3 compliant systems

⚖️ Comparison with similar blocks

- Standard AND blocks typically offer only 2-4 inputs
- AND_7 enables the processing of up to seven inputs in a single operation
- More flexible than type-specific blocks due to its generic implementation

Conclusion



The AND_7 function block offers enhanced AND logic functionality for systems that require the processing of multiple input signals in a single operation. Its generic nature and IEC 61131-3 compatibility make it a versatile tool for automation applications.

AND_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_8` performs a bitwise logical AND operation on up to eight inputs. It is a generic function block that can work with various bit data types. The block is classified according to the IEC 61131-3 standard and is used for processing Boolean operations.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. The operation is executed when this event occurs. It is linked to all data inputs (`IN1` to `IN8`).

Event Outputs

- **CNF**: Confirms the execution of the function block. This event is output after the calculation and is linked to the data output `OUT`.

Data Inputs

- **IN1** to **IN8** (`ANY_BIT`): Eight inputs for bitwise AND operations. Each input can accept any bit data type (e.g., BOOL, BYTE, WORD, DWORD, LWORD).

Data Outputs

- **OUT** (`ANY_BIT`): The result of the bitwise AND operation on all inputs. The data type corresponds to that of the inputs.

Adapters

The function block does not have any adapters.

Adapters ## Functionality

The `AND_8` block performs a bitwise AND operation on the values of all active inputs (`IN1` to `IN8`). The result is output at `OUT`. The operation is initiated by the event `REQ` and acknowledged by `CNF`.

Technical Features

- **Generic Implementation**: The block can work with different bit data types because the inputs and outputs are of type `ANY_BIT`.
- **Flexible Number of Inputs**: Up to eight inputs can be used, and not all of them need to be configured.

State Overview

1. **Idle State**: The block waits for the event `REQ`.
2. **Execution State**: At `REQ`, the inputs are processed and the result is calculated.
3. **Acknowledgement State**: After the calculation, `CNF` is triggered and the result is output to `OUT`.

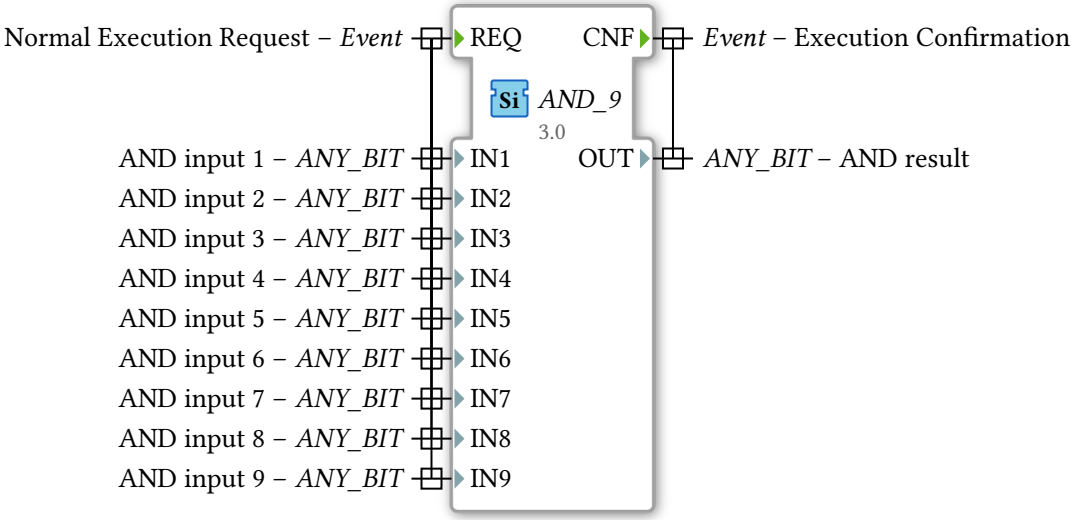
Application Scenarios

- Logical combination of multiple bit signals in control applications.
- Filtering of signals by bitwise masking.
- Generic processing of bit data in complex automation systems.

⚖️ Comparison with Similar Blocks

- **AND (Standard)**: Standard AND block with typically two inputs. `AND_8` offers greater flexibility through eight inputs and generic types.
- **GEN_AND**: Generic AND implementation that serves as the basis for `AND_8`. `AND_8` is a specialized version with a fixed number of inputs.

Conclusion



The `AND_8` function block is a powerful tool for bitwise logic operations in IEC 61131-3 compliant control systems. Its generic nature and flexible number of inputs make it particularly versatile.

AND_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_9` performs a bitwise logical AND operation on up to nine input variables. It is a generic function block that can work with various bit data types. The block is classified according to the IEC 61131-3 standard and is suitable for automation applications.

Interface Structure

Event Inputs

- `REQ` (Normal Execution Request): Starts the execution of the function block. The operation is executed when this event occurs.

Event Outputs

- `CNF` (Execution Confirmation): Signals successful completion of the operation.

Data Inputs

- `IN1` to `IN9` (ANY_BIT): Up to nine input variables on which the bitwise AND operation is performed. Each input can have any bit data type (e.g., BOOL, BYTE, WORD, DWORD, LWORD).

Data Outputs

- `OUT` (ANY_BIT): The result of the bitwise AND operation on all input variables. The data type corresponds to that of the input variables.

Adapters

No adapters are available.

Functionality

The function block `AND_9` performs a bitwise AND operation on the values of the input variables `IN1` through `IN9`. The result is output to `OUT`. The operation is initiated by the event `REQ` and confirmed upon completion by the event `CNF`.

Technical Features

- **Generic Implementation**: The function block can work with various bit data types, enabling high flexibility.
- **Scalability**: Supports up to nine input variables, allowing for more complex logical operations.

State Overview

1. **Idle State**: Waits for the event `REQ`.
2. **Execution State**: Performs the bitwise AND operation.
3. **Acknowledge State**: Sends the event `CNF` and outputs the result to `OUT`.

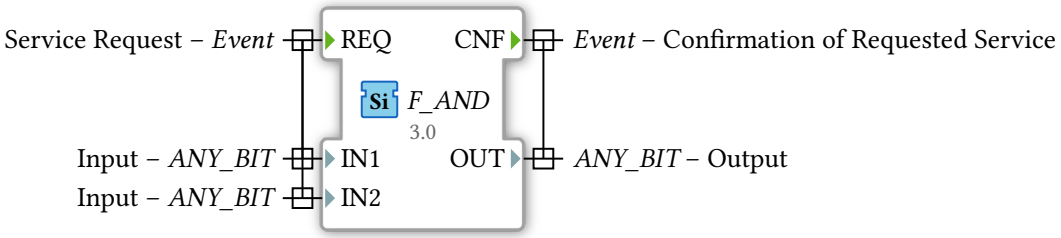
Application Scenarios

- Logical combination of multiple digital signals in automation technology.
- Filtering of signals using logical masks.
- Implementation of safety functions where multiple conditions must be met simultaneously.

⚖️ Comparison with Similar Function Blocks

- **AND (Standard)**: By default, many PLC systems only support two-input AND operations. `AND_9` extends this functionality to up to nine inputs.
- **GEN_AND**: The generic AND block on which `AND_9` is based can be configured for various data types and a variable number of inputs.

Conclusion



The `AND_9` function block is a powerful tool for bitwise logic operations in automation technology. Its generic nature and support for up to nine inputs make it particularly flexible and versatile. Ideal for applications requiring complex logical operations.

F_AND

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_AND` is a standardized bitwise Boolean AND operator according to IEC 61131-3. It performs a bitwise AND operation on two input variables and outputs the result. This block is particularly useful for logical operations in control applications.

Interface Structure

Event Inputs

- **REQ**: Service Request. Triggers the execution of the AND operation. Linked to the data inputs `IN1` and `IN2`.

Event Outputs

- **CNF**: Confirmation of the requested service. Triggered after successful execution of the operation. Linked to the data output `OUT`.

Data Inputs

- **IN1**: First input for the bitwise AND operation. Type: `ANY_BIT`.
- **IN2**: Second input for the bitwise AND operation. Type: `ANY_BIT`.

Data Outputs

- **OUT**: Result of the bitwise AND operation. Type: `ANY_BIT`.

Adapters

- No adapters available.

Functionality

The `F_AND` block performs a bitwise AND operation between the input variables `IN1` and `IN2` when the event `REQ` is triggered. The result is passed to the output `OUT`, and the event `CNF` is triggered to confirm successful execution.

Technical Features

- Supports the data type `ANY_BIT`, which means that various bit types such as `BOOL`, `BYTE`, `WORD`, `DWORD`, etc., can be used.
- The block conforms to the IEC 61131-3 standard and is classified as a “standard bitwise boolean function”.

State Overview

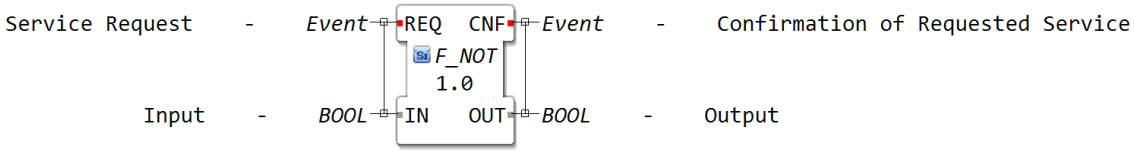
1. **Idle State**: Waits for the `REQ` event.
2. **Execution State**: Executes the bitwise AND operation when `REQ` is received.
3. **Acknowledgement State**: Sends the `CNF` event and outputs the result to `OUT`.

Application Scenarios

- Logical controls in industrial automation systems.
- Bitwise mask operations in data processing applications.
- Combination with other logic blocks for complex control logic.

⚖️ Comparison with Similar Blocks

- **F_OR**: Performs a bitwise OR operation.
- **F_XOR**: Performs a bitwise exclusive OR operation.
- **F_NOT**: Performs a bitwise negation.

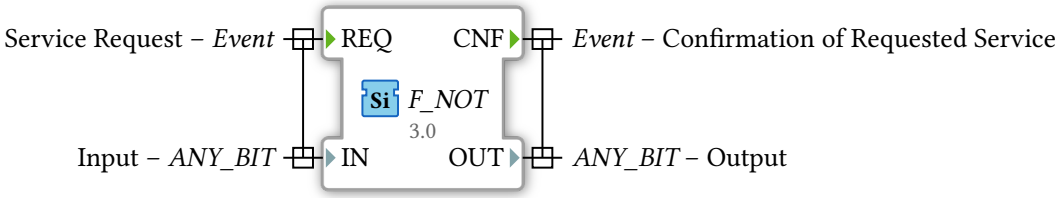


🛠️ Related Exercises

- Exercise_002a2
- Exercise_002a2_AX

Conclusion

The F_AND function block is a fundamental building block for bitwise logic operations in IEC 61131-3 compliant control systems. Its simple and standardized interface makes it reliable and versatile for use in various automation applications.



F_NOT

• – ◦ • – ◦ • – ◦ •

Introduction

The F_NOT function block implements a bitwise logical NOT operation according to the IEC 61131-3 standard. It performs a bitwise inversion of the input value and outputs the result.

Interface Structure

Event Inputs

- **REQ**: Service Request - Triggers the calculation of the NOT operation

Event Outputs

- **CNF**: Confirmation of Requested Service - Signals the completion of the calculation

Data Inputs

- **IN**: Input value of type ANY_BIT - The value to be inverted

Data Outputs

- **OUT**: Output value of type ANY_BIT - The inverted result

Adapters

No adapters available

Functionality

Upon receiving a REQ event, the F_NOT block performs a bitwise logical NOT operation on the input value IN. Each bit of the input value is inverted (0 becomes 1, 1 becomes 0). The result is output at output OUT and confirmed by the CNF event.

Technical Features

- Supports the ANY_BIT data type, enabling use with various bit data types (BOOL, BYTE, WORD, DWORD, etc.)
- Real-time capable execution
- Standard-compliant implementation according to IEC 61131-3

State Transition

1. Wait state for REQ event
2. On REQ: Execute the NOT operation
3. Output the result to OUT
4. Send the CNF event

5. Return to wait state

Application Scenarios

- Bit manipulation in control programs
- Inversion of status bits
- Logical negation of conditions
- Signal inversion in digital circuits

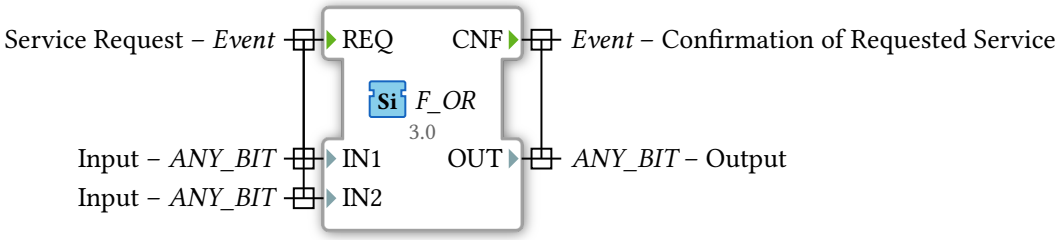
⚖️ Comparison with Similar Function Blocks

Compared to other logical operations such as F_AND or F_OR, F_NOT performs only a unary operation (one operand), while other logical function blocks typically implement binary operations (two operands).

🛠️ Related Exercises

- Exercise_006a3_sub

Conclusion



The F_NOT function block offers a standards-compliant, efficient solution for bitwise inversion operations in IEC 61131-3 compliant control systems. Its simple interface and universal ANY_BIT type support make it a versatile building block for various applications.

F_OR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_OR` implements a bitwise OR operation according to the IEC 61131-3 standard. It performs a logical OR operation on two input variables of type `ANY_BIT` and outputs the result.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the OR operation. Upon this event, the inputs `IN1` and `IN2` are evaluated.

Event Outputs

- **CNF**: Signals the successful completion of the operation. This event is output along with the result `OUT`.

Data Inputs

- **IN1**: First input for the bitwise OR operation (Type: `ANY_BIT`).
- **IN2**: Second input for the bitwise OR operation (Type: `ANY_BIT`).

Data Outputs

- **OUT**: Result of the bitwise OR operation (Type: `ANY_BIT`).

Adapters

This function block does not use any adapters.

Functionality

When the `REQ` event is triggered, the `F_OR` block performs a bitwise OR operation on the values at `IN1` and `IN2`. The result is output to `OUT`, and the `CNF` event signals successful computation.

Technical Features

- **Type Flexibility**: Supports all `ANY_BIT` data types (e.g., BOOL, BYTE, WORD, DWORD, LWORD).
- **Simple Implementation**: No state machine is required, as this is a static operation.

State Overview

The function block has no internal state machine, as the operation is performed directly upon the occurrence of the `REQ` event.

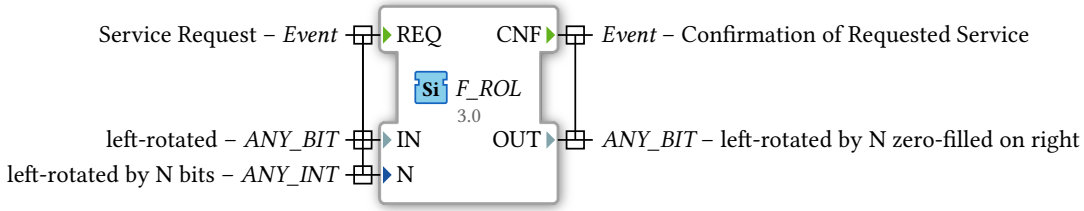
Application Scenarios

- Bitwise operation in control algorithms
- Mask operations in signal processing
- Logical combination of digital signals

⚖️ Comparison with similar function blocks

- **F_AND**: Performs a bitwise AND operation
- **F_XOR**: Performs a bitwise exclusive OR operation
- **F_NOT**: Performs a bitwise negation

Conclusion



The `F_OR` function block offers a simple and efficient way to perform bitwise OR operations in IEC 61131-3 compliant control systems. Its type flexibility and direct operation make it a universally applicable function block for logical operations.

F_ROL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ROL` (Rotate Left) performs a bitwise left rotation. It rotates the input value a specified number of bits to the left. The bits rotated out on the left side are inserted again on the right side. This is a cyclic operation in which no bits are lost.

Interface Structure

Event Inputs

- **REQ**: Service request that triggers the execution of the left rotation. It is linked to the data inputs `IN` and `N`.

Event Outputs

- **CNF**: Confirmation of the completed service. Linked to the data output `OUT`.

Data Inputs

- **IN**: The input value to be rotated. The data type is `ANY_BIT` (any bit type).
- **N**: The number of bits by which the input value should be rotated. The data type is `ANY_INT` (any integer type).

Data Outputs

- **OUT**: The result of the left rotation. The data type is `ANY_BIT` (the same as the input value).

Adapters

- No adapters available.

Functionality

The function block `F_ROL` performs a bitwise left rotation of the input value `IN` by `N` bits. Bits that fall outside the range on the left side are reinserted on the right side. This is a true rotation; no bits are padded with zeros.

Technical Features

- Supports any bit type (`ANY_BIT`) for the input value `IN` and the output value `OUT`.
- The number of rotations `N` can be any integer value (`ANY_INT`).
- The operation is cyclical, meaning that if `N` is greater than the bit length of `IN`, the rotation is performed modulo the bit length.
- Unlike a shift, no bits are lost during rotation.

State Overview

1. **Initial State**: Waits for the event `REQ`.
2. **Execution State**: Upon receiving `REQ`, the left rotation is performed and the result is output via `OUT`. The event `CNF` is triggered.
3. **Return to Initial State**: After `CNF` is triggered, the block returns to its initial state.

Application Scenarios

- Bitwise manipulation of data in control applications.
- Cryptographic operations requiring bitwise rotations.
- Signal processing where data bits need to be shifted cyclically.
- Checksum calculations and data encoding.

⚖️ Comparison with Similar Components

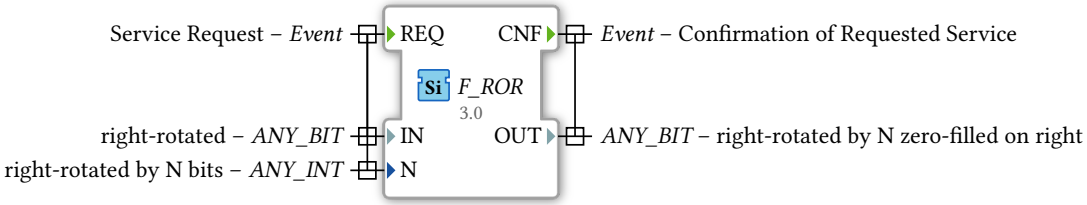
- **F_SHL (Shift Left)**: Shifts bits to the left and pads the resulting free positions on the right with zeros. This is not a cyclic operation.
- **F_ROR (Rotate Right)**: Performs a right rotation, rotating bits from right to left.
- **F_ROL vs. F_SHL**: While F_SHL performs a shift with zero padding, F_ROL performs a cyclic rotation without zero padding.

Conclusion

The function block `F_ROL` is an efficient tool for bitwise left rotations in control applications. Its flexibility in supporting various bit and integer types makes it versatile. The cyclic nature of the rotation ensures that no data bits are lost, making it particularly suitable for applications with strict data integrity requirements. The clear distinction between rotation (cyclic) and shift (with zero padding) is crucial for correct application.

–

Changes at a Glance:



- Correction of the description: With ROL, the rotated-out bits are reinserted on the right, not padded with zeros.
- Clarification that this is a true cyclic rotation.
- Improved distinction between rotation (ROL/ROR) and shift (SHL/SHR).
- Consistent wording throughout the document.

F_ROR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ROR` (Rotate Right) performs a bitwise right rotation. It belongs to the category of standardized bit shift functions according to IEC 61131-3. The block rotates the input data a specified number of bits to the right and fills the freed bits with the bits rotated out.

Interface Structure

Event Inputs

- `REQ`: Service request that triggers the operation. Linked to the data inputs `IN` and `N`.

Event Outputs

- `CNF`: Confirmation of the operation performed. Linked to the data output `OUT`.

Data Inputs

- `IN`: The input value to be rotated (Type: `ANY_BIT`).
- `N`: The number of bits by which the input value should be rotated right (Type: `ANY_INT`).

Data Outputs

- `OUT`: The result of the right rotation (Type: `ANY_BIT`).

Adapters

No adapters available.

Functionality

The function block performs a bitwise right rotation of the input value `IN` by `N` bits. The bits rotated out are then reinserted on the left side. This differs from a simple right shift, where the freed bits are padded with zeros.

Technical Features

- Supports all `ANY_BIT` data types for the input value `IN` and the output value `OUT`.
- The parameter `N` can accept any `ANY_INT` data type.
- The operation is independent of the word length of the input value.

State Overview

The function block has no internal state. The operation is re-executed with each `REQ` event.

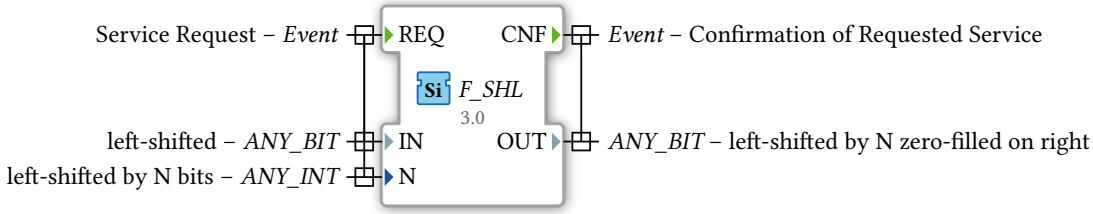
Application Scenarios

- Cryptographic operations requiring bitwise rotations.
- Signal processing requiring bitwise manipulation of data.
- Low-level hardware controllers requiring bitwise operations.

⚖️ Comparison with Similar Components

- `F_SHR` (Shift Right): Performs a right shift, but pads the freed bits with zeros.
- `F_ROL` (Rotate Left): Performs a left rotation, similar to `F_ROR`, but in the opposite direction.

Conclusion



The `F_ROR` function block is a useful tool for applications requiring bitwise rotations. Its simple interface and support for various data types make it versatile. Unlike simple shift operations, it preserves all bits of the input value, making it indispensable for certain applications.

F_SHL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_SHL performs a left shift on any bit data type. The bits of the input value are shifted left by a specified number of positions, and the resulting free positions on the right are padded with zeros. This block is classified according to the IEC 61131-3 standard and is suitable for bitwise operations.

Interface Structure

Event Inputs

- **REQ**: Service request. Triggers the left shift. Linked to the data inputs IN and N.

Event Outputs

- **CNF**: Confirmation of the requested service. Signals the completion of the operation. Linked to the data output OUT.

Data Inputs

- **IN**: The input value to be left-shifted. The data type is ANY_BIT (any bit data type).
- **N**: The number of positions to shift. The data type is ANY_INT (any integer data type).

Data Outputs

- **OUT**: The result of the left shift. The data type is the same as the input value IN. The resulting free positions on the right are padded with zeros.

Adapters

No adapters are defined.

Adapters ## Functionality

The function block F_SHL performs a bitwise left shift of the input value IN by N positions. The bits are shifted to the left, and the newly created positions on the right side are padded with zeros. The operation is triggered by the event REQ and acknowledged by CNF.

Technical Features

- Supports any bit data type (ANY_BIT) for the input value IN.
- The number of shifts N can be any integer data type (ANY_INT).
- The operation is standardized according to IEC 61131-3.

State Overview

1. **Idle State**: Waits for the event REQ.
2. **Execution State**: Performs the left shift when REQ is received.
3. **Acknowledge State**: Sends CNF after the operation is complete.

Application Scenarios

- Bit manipulation in control applications.
- Shift operations in digital signal processing algorithms.
- General bitwise operations in IEC 61131-3 compliant control systems.

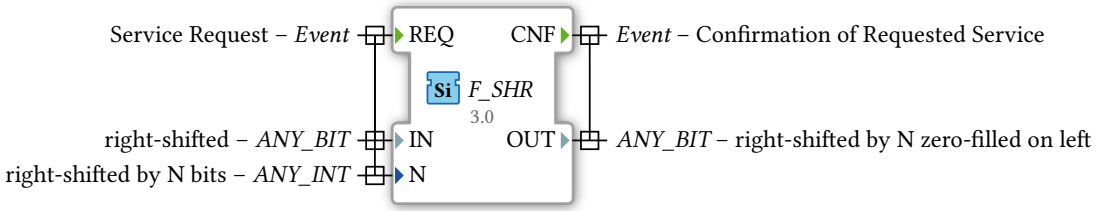
⚖️ Comparison with Similar Function Blocks

- **F_SHR**: Performs a right shift, unlike the left shift of F_SHL.
- **F_ROL** and **F_ROR**: Rotate bits instead of shifting them, with overflowing bits being reinserted on the other side.

🛠️ Related Exercises

- Exercise_034

Conclusion



The F_SHL function block is an efficient tool for bitwise left shifts in control systems. Its flexibility in supporting various bit and integer data types makes it versatile. Clear event handling and compliance with the IEC 61131-3 standard ensure reliable integration into existing systems.

F_SHR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_SHR performs a bitwise right shift. It is part of the standard bit operators according to IEC 61131-3 and is used for logical and arithmetic operations in control applications.

Interface Structure

Event Inputs

- REQ: Starts the right shift. It is linked to the data IN and N.

Event Outputs

- CNF: Confirms the completion of the right shift. Returns the result OUT.

Data Inputs

- IN (ANY_BIT): The input value to be shifted right.
- N (ANY_INT): The number of bits to shift.

Data Outputs

- OUT (ANY_BIT): The result of the right shift. The freed bits on the left are padded with zeros.

Adapters

No adapters available.

Functionality

1. Upon a REQ event, the value IN is shifted right by N bits.
2. The freed bits on the left side are padded with zeros (logical right shift).
3. The result is output via OUT, triggering the CNF event.

Technical Features

- Supports all bit data types (ANY_BIT), e.g. B. BOOL, BYTE, WORD, DWORD, LWORD.
- N can use any integer type (ANY_INT), e.g. B. SINT, INT, DINT, LINT, USINT, UINT, UDINT, ULINT.
- The right shift is independent of the sign (logical shift).

Status Overview

- **Idle**: Waiting for REQ.
- **Processing**: Performing the right shift.
- **Completed**: Sending CNF with the result.

Application Scenarios

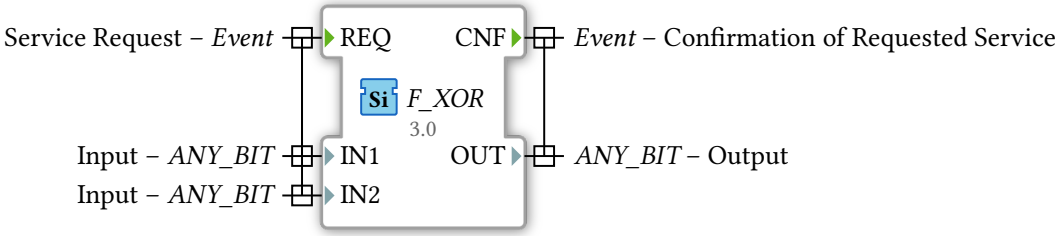
- Bit manipulation in control algorithms.
- Data compression or extraction.

- Fast division by powers of two (for unsigned numbers).

⚖️ Comparison with similar function blocks

- `F_SHL`: Performs a left shift.
- `F_ROR`/`F_ROL`: Rotation operations instead of shifts.
- `F_SHR` is specific for logical right shifts (zero padding).

Conclusion



The `F_SHR` function block is an efficient tool for bitwise operations in IEC 61131-3 environments. Its simple interface and standards compliance make it ideal for control applications involving bit manipulation.

F_XOR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_XOR` performs a bitwise XOR operation (exclusive OR) on two input values. It is part of the standard bitwise operations according to IEC 61131-3 and is suitable for logical processing in control applications.

Interface Structure

Event Inputs

- `REQ`: Starts the XOR operation. When activated, the input data `IN1` and `IN2` are processed.

Event Outputs

- `CNF`: Confirms successful execution of the XOR operation and outputs the result via `OUT`.

Data Inputs

- `IN1`: First input value for the XOR operation (Type: `ANY_BIT`).
- `IN2`: Second input value for the XOR operation (Type: `ANY_BIT`).

Data Outputs

- `OUT`: Result of the bitwise XOR operation (Type: `ANY_BIT`).

Adapters

No adapters available.

Functionality

When the event input `REQ` is activated, the function block performs a bitwise XOR operation between the values `IN1` and `IN2`. The result is output via the data output `OUT`, and the event `CNF` is triggered to signal the completion of the operation.

Technical Features

- Supports the data type `ANY_BIT`, meaning that various bit data types (e.g., BOOL, BYTE, WORD, DWORD) can be processed.
- The initial values of the inputs are empty, requiring explicit assignment of the input values.

State Overview

1. **Idle State**: Waits for the event `REQ`.
2. **Processing State**: Performs the XOR operation when `REQ` is activated.

3. **Output State**: Sends the result via `OUT` and triggers `CNF`.

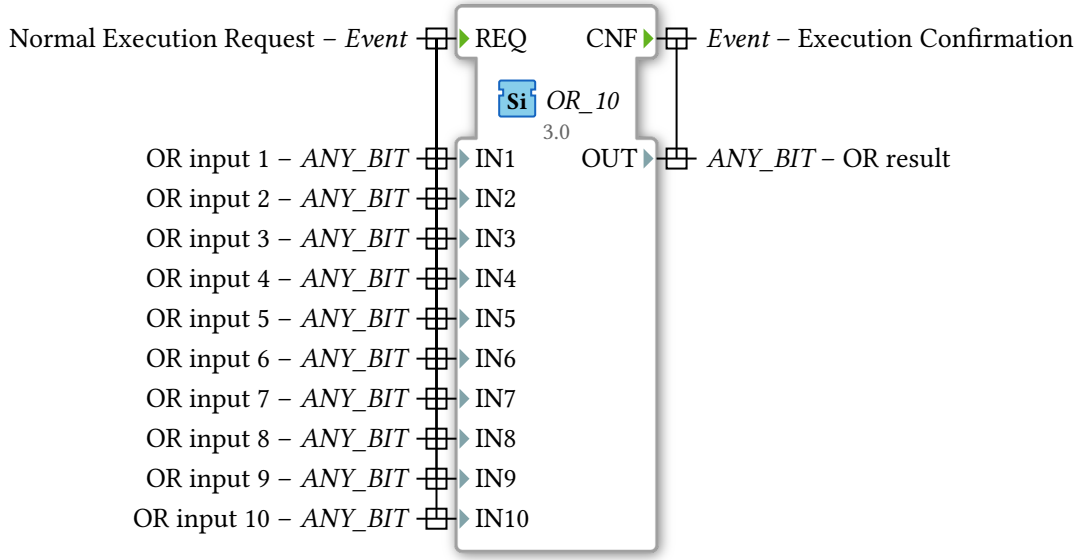
Application Scenarios

- Logical processing in control systems.
- Bitwise manipulation of data in industrial automation processes.
- Implementation of security checks or checksum calculations.

⚖️ Comparison with Similar Function Blocks

- **F_AND / F_OR**: Perform bitwise AND and OR operations, respectively, while `F_XOR` offers an exclusive OR operation. - **F_NOT**: Inverts bits while `F_XOR` compares two input values.

Conclusion



The `F_XOR` function block is an efficient tool for bitwise XOR operations in IEC 61131-3 compliant control systems. Its flexibility with the `ANY_BIT` data type makes it versatile for use in various automation applications.

OR_10

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_10` performs a bitwise OR operation on up to 10 input variables. It is a generic function block that can work with any bit data type (ANY_BIT). The block is classified according to the IEC 61131-3 standard and is used for the simple execution of logical OR operations in control applications.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. When this event is triggered, all input variables (IN1 to IN10) are read and the OR operation is performed.

Event Outputs

- **CNF**: Signals the successful completion of the OR operation. This event is output along with the result (OUT).

Data Inputs

- **IN1 to IN10**: Up to 10 input variables of type ANY_BIT, containing the values to be combined. Each variable can have any bit data type (e.g., BOOL, BYTE, WORD, DWORD, etc.).

Data Outputs

- **OUT**: The result of the bitwise OR operation on all input variables. The data type corresponds to that of the input variables.

Adapters

No adapters are defined for this function block.

Functionality

The function block performs a bitwise OR operation on all active input variables. This means that a logical OR operation is performed on each bit of the input variables. The result is output at the output variable OUT. The operation is initiated by the REQ event and confirmed by the CNF event.

Technical Features

- **Generic Implementation**: The function block can work with any bit data type, enabling high flexibility.
- **Scalability**: Up to 10 input variables can be processed, making the block suitable for more complex applications.

State Overview

1. **Idle State**: The block waits for the REQ event.
2. **Execution State**: Upon receiving REQ, the input variables are read and the OR operation is performed.
3. **Acknowledge State**: After successful operation, the CNF event is triggered, and the block returns to the idle state.

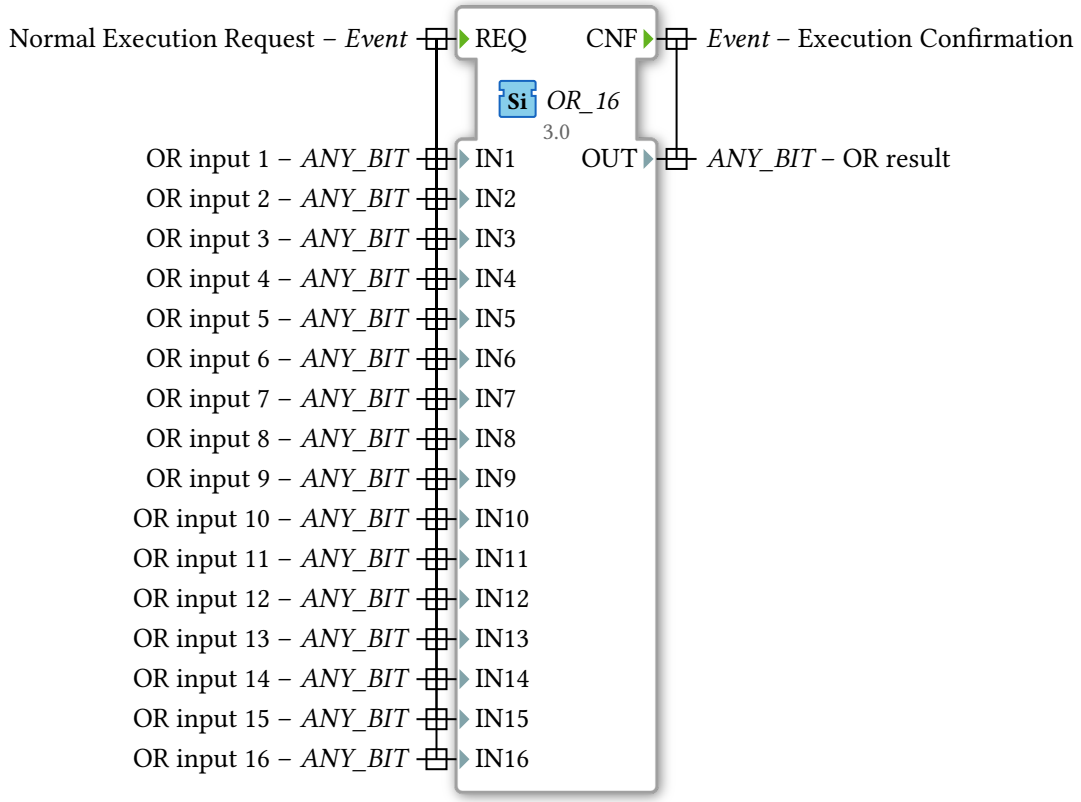
Application Scenarios

- Logical operations in control applications
- Signal processing in industrial automation systems
- Combining multiple binary signals to produce a result

⚖️ Comparison with similar function blocks

Compared to simple OR blocks with fewer inputs, OR_10 offers the ability to combine up to 10 signals, making it suitable for more complex applications. Other blocks are often limited to fewer inputs or are not implemented generically.

Conclusion



The OR_10 function block is a flexible and powerful tool for bitwise OR operations in IEC 61131-3-based control systems. Its generic nature and support for up to 10 input variables make it particularly suitable for demanding applications.

OR_16

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_16` performs a bitwise logical OR operation on up to 16 input variables. It is a generic function block that can work with various bit data types (ANY_BIT). The block is part of the package `iec61131::bitwiseOperators` and conforms to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- `REQ` (Normal Execution Request): Triggers the calculation. It is processed with all 16 input variables.

Event Outputs

- `CNF` (Execution Confirmation): Confirms the execution of the operation. Linked to the result `OUT`.

Data Inputs

16 inputs of type `ANY_BIT`:

- `IN1` to `IN16`: The input values for the OR operation. Each input is annotated as "OR input X" (where X is the input number).

Data Outputs

- `OUT` (ANY_BIT): The result of the bitwise OR operation of all input values.

Adapters

The function block does not use adapters.

Functionality

Upon receiving the `REQ` event, the block performs a bitwise OR operation on all active input values (`IN1` to `IN16`). The result is output to `OUT`, and the `CNF` event is triggered.

Technical Features

- Generic Implementation: Works with all `ANY_BIT` data types (e.g., BOOL, BYTE, WORD, DWORD, LWORD)
- Supports up to 16 input variables
- Compatible with IEC 61131-3 standard

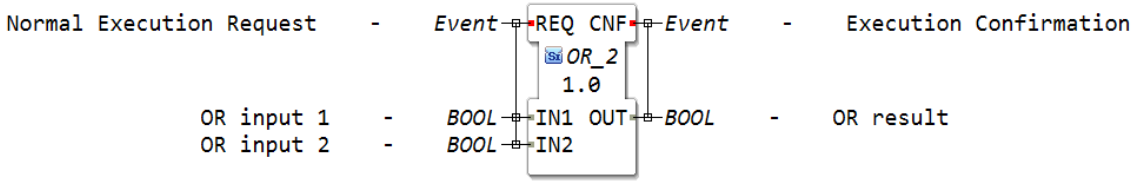
State Overview

1. Wait State: Waits for `REQ` event

2. Execute State: On REQ, inputs are processed and the result is calculated
3. Acknowledge State: Outputs the result and triggers CNF

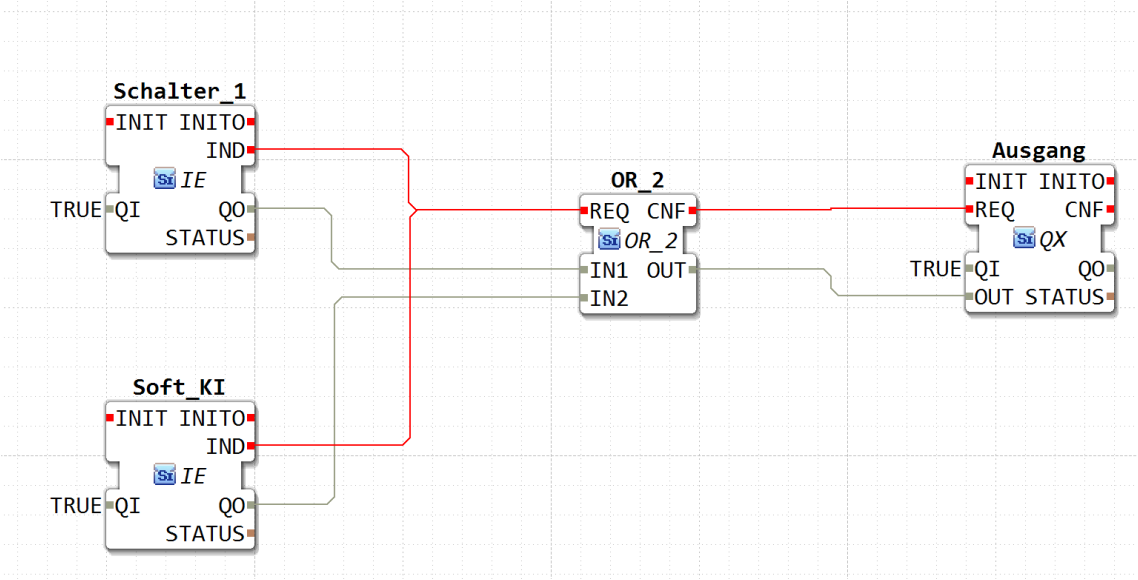
Application Scenarios

- Bitwise logic operations in control applications
- Signal processing with multiple conditions
- Generic logic blocks in libraries



⚖️ Comparison with Similar Blocks

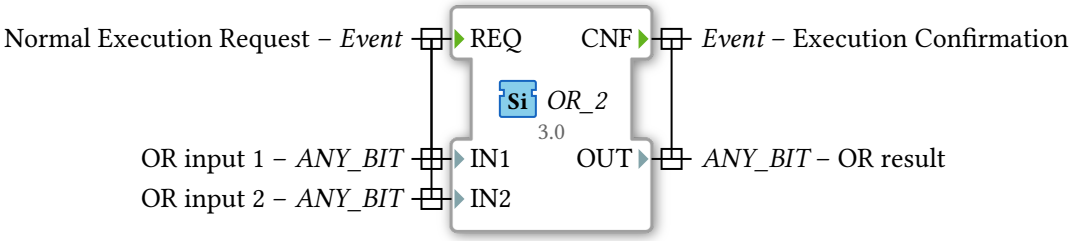
- Compared to simpler OR blocks (e.g., OR_2), it offers OR_16 offers significantly more inputs
- Similar to AND_16 or XOR_16, but with a different logical operation
- Generic implementation allows for more flexible use than type-specific blocks



Conclusion

The OR_16 function block offers a flexible and standards-compliant solution for bitwise OR operations with up to 16 inputs. Its generic nature makes it versatile, while its clear interface structure facilitates integration into various control applications.

OR_2



A common use case is a soft AI and an AUX button. TRUE dominates, so as soon as an input is TRUE, the output is set to TRUE.

• – ○ • – ○ • – ○ •

Introduction

The OR_2 function block is a generic function block for calculating bitwise Boolean OR operations. It performs a logical OR operation on two input values and outputs the result. The function block is classified according to the IEC 61131-3 standard and supports generic data types for maximum flexibility.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation of the OR operation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1**: OR input 1 (Type: ANY_BIT) - first operand for the OR operation
- **IN2**: OR input 2 (Type: ANY_BIT) - second operand for the OR operation

Data Outputs

- **OUT**: OR result (Type: ANY_BIT) - result of the bitwise OR operation

Adapters

This function block does not use adapters.

Functionality

Upon arrival of the REQ event, the OR_2 block performs a bitwise OR operation between the two input values IN1 and IN2. The result is output at the OUT data output, and simultaneously, the CNF event is generated to confirm successful calculation.

The OR operation is performed at the bit level, with each bit of the input values being processed separately. The result bit is 1 if at least one of the corresponding input bits is 1.

Technical Features

- **Generic Type Support**: Uses the ANY_BIT data type, meaning the block can work with various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- **Standard-Compliant Implementation**: Conforms to the IEC 61131-3 standard for bitwise Boolean functions
- **Event-Driven Execution**: The calculation is only performed when a REQ event is active

State Transitions

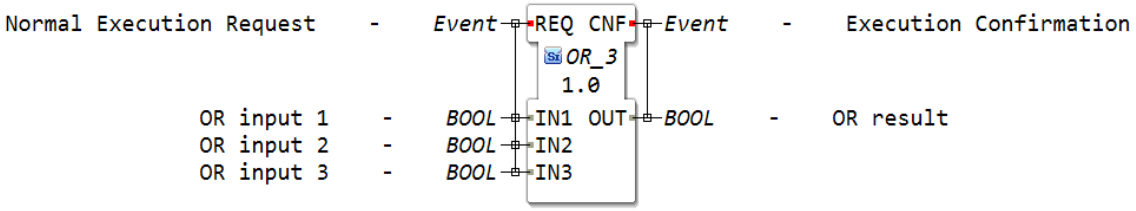
1. **Wait State**: Block waits for a REQ event
2. **Calculation State**: Upon a REQ event, IN1 and IN2 are processed
3. **Output State**: Result is output to OUT and a CNF event is generated
4. **Return**: Block returns to the wait state

Application Scenarios

- Bitwise mask operations in control applications
- Combining status flags in process control systems
- Logical operations in digital circuits
- Data manipulation in Communication Protocols

⚖️ Comparison with Similar Building Blocks

Compared to other Boolean operations like AND or XOR, OR_2 offers the specific property that the result is true if at least one of the operands is true. Unlike simple Boolean OR blocks, OR_2 supports generic bit data types, thus enabling the processing of various data widths.



🛠️ Related exercises

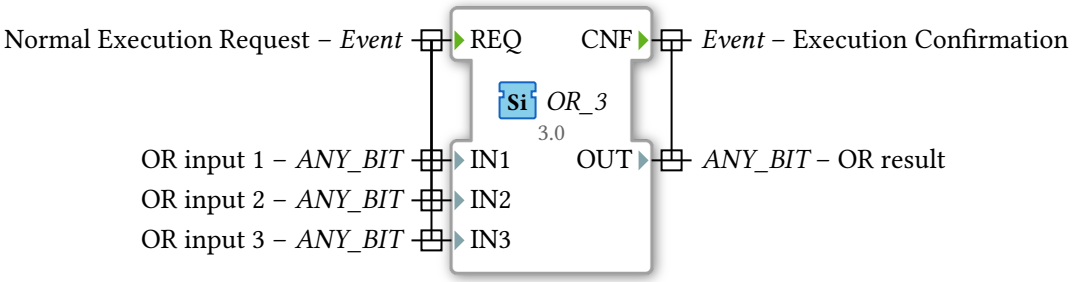
- Exercise_039_sub_Outputs
- Exercise_089
- Exercise_160_AX
- Exercise_160b2_AX
- Exercise_160b_AX

Conclusion

The OR_2 function block provides a flexible and standards-compliant solution for bitwise OR operations in automation systems. Its generic nature allows for use in various application contexts with different data types, while the event-driven architecture ensures efficient resource utilization.



OR_3

• – ◦ • – ◦ • – ◦ •

Introduction

The OR_3 function block is a generic function block for calculating bitwise Boolean OR operations with three inputs. It performs a logical OR operation at the bit level and supports various bit data types according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation of the OR operation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1**: OR input 1 (ANY_BIT data type)
- **IN2**: OR input 2 (ANY_BIT data type)
- **IN3**: OR input 3 (ANY_BIT data type)

Data Outputs

- **OUT**: OR result (ANY_BIT data type)

Adapters

No adapters available.

Functionality

The OR_3 function block performs a bitwise OR operation on the three input values IN1, IN2, and IN3 upon each REQ event. The result is output at the OUT data output, and simultaneously a CNF event is generated to signal the completion of the operation.

The operation is performed separately for each bit position: OUTi = IN1i OR IN2i OR IN3i

Technical Features

- Supports the generic ANY_BIT data type, enabling its use with various bit data types such as BOOL, BYTE, WORD, DWORD, etc.
- Implemented as a generic function block according to the IEC 61131-3 standard
- Belongs to the “iec61131::bitwiseOperators” package

State Overview

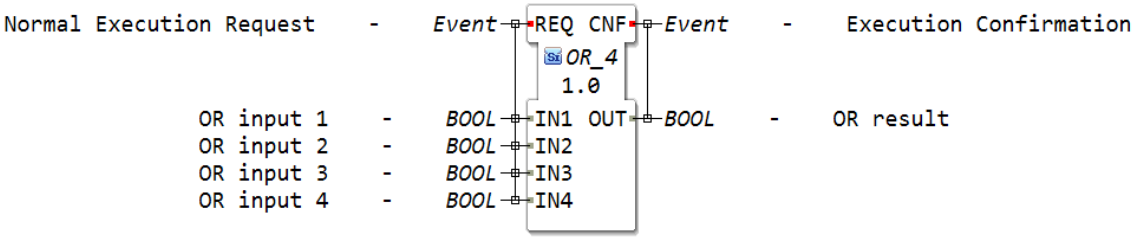
1. **Wait State**: Block waits for a REQ event
2. **Calculation State**: Inputs are processed upon a REQ event
3. **Output State**: Result is output to OUT and a CNF event is generated

Application Scenarios

- Combining multiple digital signals in control applications
- Mask operations in data processing
- Parallel processing of multiple conditions
- Signal linking in automation systems

⚖️ Comparison with similar building blocks

Compared to simple OR blocks with only two inputs, OR_3 offers the possibility of directly connecting three inputs, simplifying the program structure and avoiding additional chaining. Unlike arithmetic blocks, OR_3 operates exclusively at the bit level.

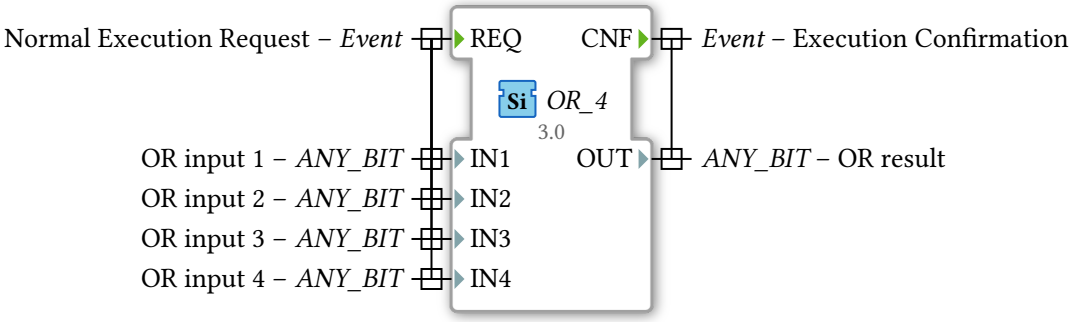


🛠️ Related Exercises

- Exercise_002a5_AX
- Exercise_002a5b_AX

Conclusion

The OR_3 function block represents an efficient and flexible solution for bitwise OR operations with three inputs. Its generic nature allows its use in various application areas and with different bit data types, making it a versatile tool in automation technology.



OR_4

• – ○ • – ○ • – ○ •

Introduction

The OR_4 function block is a generic function block for calculating bitwise OR operations with four inputs. It performs a bitwise OR operation on the input data and outputs the result. The function block is suitable for all ANY_BIT data types, thus enabling flexible use with various bit data types.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation of the OR operation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1**: OR input 1 (ANY_BIT)
- **IN2**: OR input 2 (ANY_BIT)
- **IN3**: OR input 3 (ANY_BIT)
- **IN4**: OR input 4 (ANY_BIT)

Data Outputs

- **OUT**: OR result (ANY_BIT)

Adapters

No adapters available.

Functionality

Upon arrival of the REQ event, the OR_4 block performs a bitwise OR operation on all four inputs. The operation is executed separately for each bit position: OUTi = IN1i OR IN2i OR IN3i OR IN4i. After completion of the calculation, the CNF event is output along with the result.

Technical Features

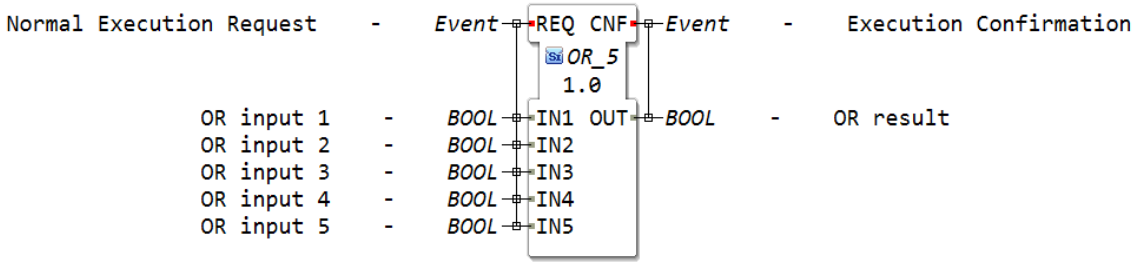
- Generic building block for ANY_BIT data types
- Supports various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- Bitwise processing of all inputs
- Four independent inputs for maximum flexibility

State Transitions

1. **Wait State**: Block waits for REQ event
2. **Compute State**: Upon REQ event, block performs OR calculation
3. **Output State**: Sends CNF event with result and returns to wait state

Application Scenarios

- Bitmask operations in control systems
- Combining multiple status bits into an overall status
- Parallel processing of multiple conditions
- Signal processing in industrial automation systems

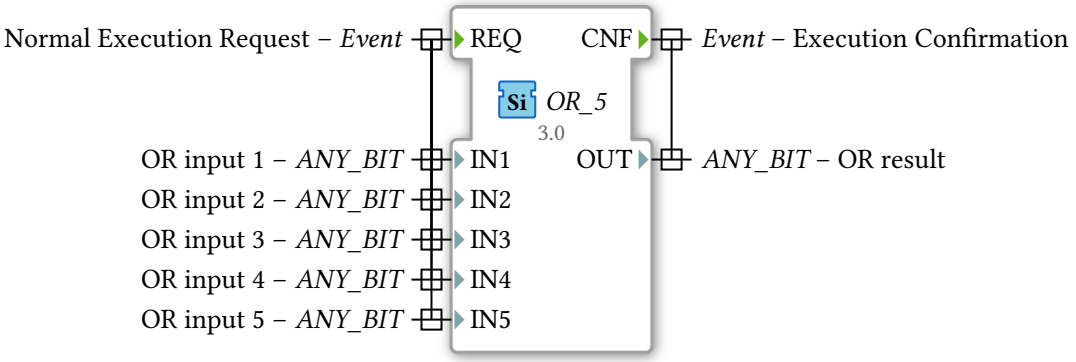


⚖️ Comparison with Similar Building Blocks

Compared to simpler OR blocks with fewer inputs, OR_4 offers the ability to process four inputs in parallel, reducing the number of blocks required in complex circuits. Compared to function blocks with fixed data types, OR_4 offers greater flexibility through the use of ANY_BIT.

Conclusion

The OR_4 function block is a versatile and efficient four-input function block for bitwise OR operations. Its generic nature allows for use in various applications, while its clear event-driven control ensures reliable integration into more complex control sequences.



OR_5

• – ◦ • – ◦ • – ◦ •

Introduction

The OR_5 function block is a generic function block for performing a bitwise OR operation with five inputs. It implements a standard bit function according to IEC 61131-3 and can work with any bit data type.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation of the OR operation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1**: OR input 1 (ANY_BIT data type)
- **IN2**: OR input 2 (ANY_BIT data type)
- **IN3**: OR input 3 (ANY_BIT data type)
- **IN4**: OR input 4 (ANY_BIT data type)
- **IN5**: OR input 5 (ANY_BIT data type)

Data Outputs

- **OUT**: OR result (ANY_BIT data type)

Adapters

No adapter interfaces are available.

Functionality

The OR_5 function block performs a bitwise OR operation on all five input values. When the REQ event is triggered, the values at IN1 to IN5 are processed, and the result is output to OUT. The CNF event signals the completion of the operation.

The OR operation is performed according to the following logic:
OUT = IN1 OR IN2 OR IN3 OR IN4 OR IN5

Technical Features

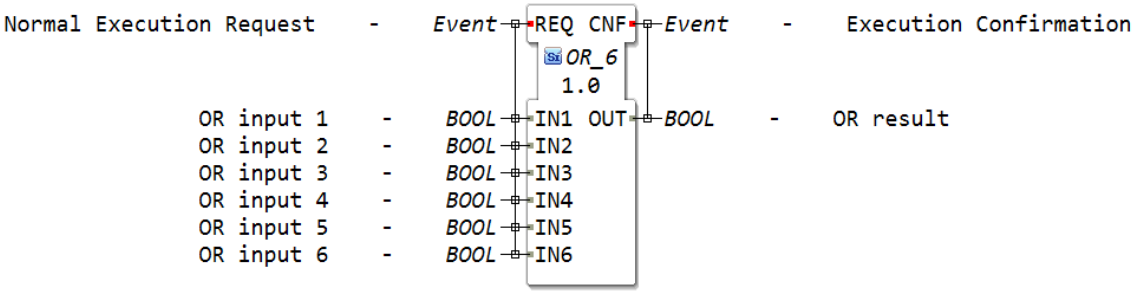
- **Generic Data Type**: Uses ANY_BIT, enabling use with various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- **Five Inputs**: Offers more flexibility than standard OR blocks with typically two inputs
- **Event-Driven**: Operates in real time with REQ/CNF signaling

State Transitions

1. **Wait State**: Block waits for a REQ event
2. **Compute State**: Upon REQ, all inputs are processed
3. **Output State**: Result is set to OUT and CNF is triggered
4. Returns to Wait State

Application Scenarios

- Combining multiple binary signals in control applications
- Monitoring systems with multiple input conditions
- Signal processing in industrial automation systems
- Use in safety circuits with multiple monitoring sensors

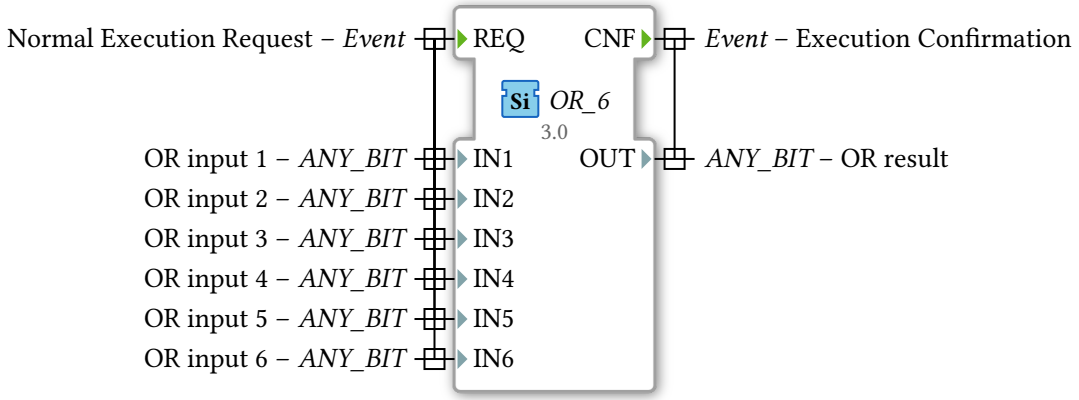


⚖️ Comparison with similar devices Function Blocks

- **Standard OR Blocks**: Typically only two inputs, OR_5 offers five inputs
- **AND Blocks**: Perform AND operations instead of OR operations
- **XOR Blocks**: Perform exclusive OR operations

Conclusion

The OR_5 function block is a versatile and powerful five-input block for bitwise OR operations. Its generic nature allows for use in various application areas, while its event-driven architecture ensures precise control over execution timing.



OR_6

• – ◦ • – ◦ • – ◦ •

Introduction

The OR_6 function block is a generic bitwise OR function block that processes six input values. It performs a bitwise logical OR operation on the six input values and outputs the result. The function block is classified according to the IEC 61131-3 standard and can work with any bit data type (ANY_BIT).

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request - triggers the calculation of the OR operation

Event Outputs

- **CNF**: Execution Acknowledgement - signals the completion of the calculation

Data Inputs

- **IN1**: OR Input 1 (ANY_BIT)
- **IN2**: OR Input 2 (ANY_BIT)
- **IN3**: OR Input 3 (ANY_BIT)
- **IN4**: OR Input 4 (ANY_BIT)
- **IN5**: OR Input 5 (ANY_BIT)
- **IN6**: OR Input 6 (ANY_BIT)

Data Outputs

- **OUT**: OR Result (ANY_BIT)

Adapters

No adapters Available.

Functionality

Upon receiving the REQ event, the OR_6 block performs a bitwise OR operation on all six input values. The operation is executed according to the following logic:

OUT = IN1 OR IN2 OR IN3 OR IN4 OR IN5 OR IN6 Once the calculation is complete, the CNF event is output along with the result value. ...

Technical Features

- **Generic Data Type**: Uses ANY_BIT, enabling use with various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- **Six Inputs**: Processes up to six input values in a single operation
- **Bitwise Operation**: Performs the OR operation at the bit level
- **Event-Driven**: Computation is only performed upon a REQ event

State Transitions

1. **Wait State**: Block waits for a REQ event
2. **Compute State**: All inputs are processed upon a REQ event
3. **Output State**: After computation, a CNF event with the result is output
4. **Return**: Returns to the wait state

Application Scenarios

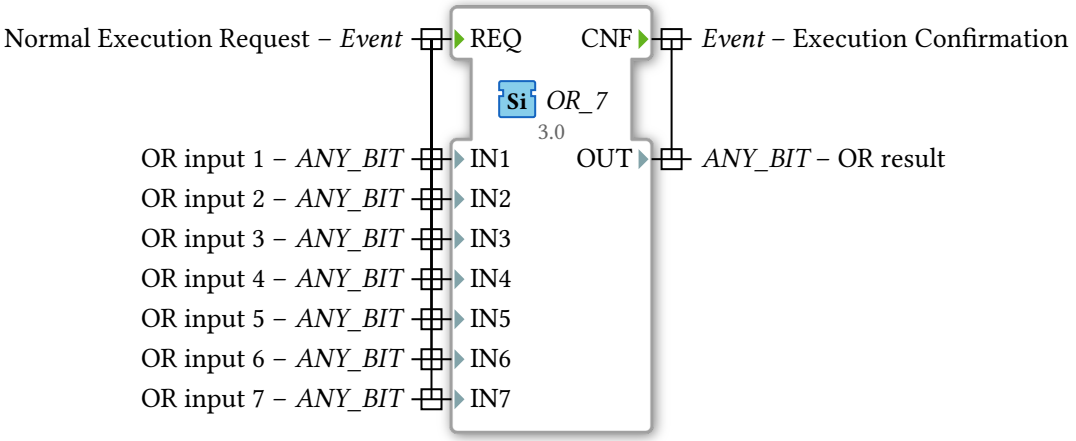
- **Bitmask Operations**: Combining multiple bitmasks
- **Control Logic**: Summarizing multiple conditions

- **Signal Processing**: Combining multiple digital signals
- **Data Filtering**: Selective activation of bits from different sources

⚖️ Comparison with similar building blocks

- **OR_2**: Processes only two inputs
- **OR_4**: Processes four inputs
- **GEN_OR**: Generic basic implementation that extends OR_6
- **XOR building blocks**: Perform exclusive OR operations

Conclusion



The OR_6 function block offers an efficient solution for bitwise OR operations with up to six input values. Its generic nature allows for maximum flexibility in using different bit data types, while the event-driven architecture ensures precise control of the calculation timing.

OR_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_7` performs a bitwise logical OR operation on up to seven input variables. It is a generic function block that can work with various bit data types (`ANY_BIT`). The block is part of the `iec61131::bitwiseOperators` library and implements a standard bitwise operation according to IEC 61131-3.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This event passes all input variables (`IN1` to `IN7`).

Event Outputs

- **CNF**: Signals the successful execution of the OR operation and returns the result via the variable `OUT`.

Data Inputs

- **IN1** to **IN7** (`ANY_BIT`): Up to seven input variables on which the bitwise OR operation is performed. Each input can have any bit data type (e.g., `BOOL`, `BYTE`, `WORD`, `DWORD`, `LWORD`).

Data Outputs

- **OUT** (`ANY_BIT`): The result of the bitwise OR operation. The data type corresponds to that of the input variables.

Adapters

The function block does not use any adapters.

Functionality

When the `REQ` event is triggered, the function block performs a bitwise OR operation on the values of the input variables `IN1` through `IN7`. The result is stored in the variable `OUT`, and the `CNF` event is triggered to indicate successful computation.

Technical Features

- **Generic Implementation**: The function block can handle various bit data types (`ANY_BIT`), making it highly versatile.
- **Scalability**: Supports up to seven input variables, enabling more complex logical operations.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Execution State**: Performs the OR operation and calculates the result.
3. **Acknowledgement State**: Triggers the `CNF` event and outputs the result via `OUT`.

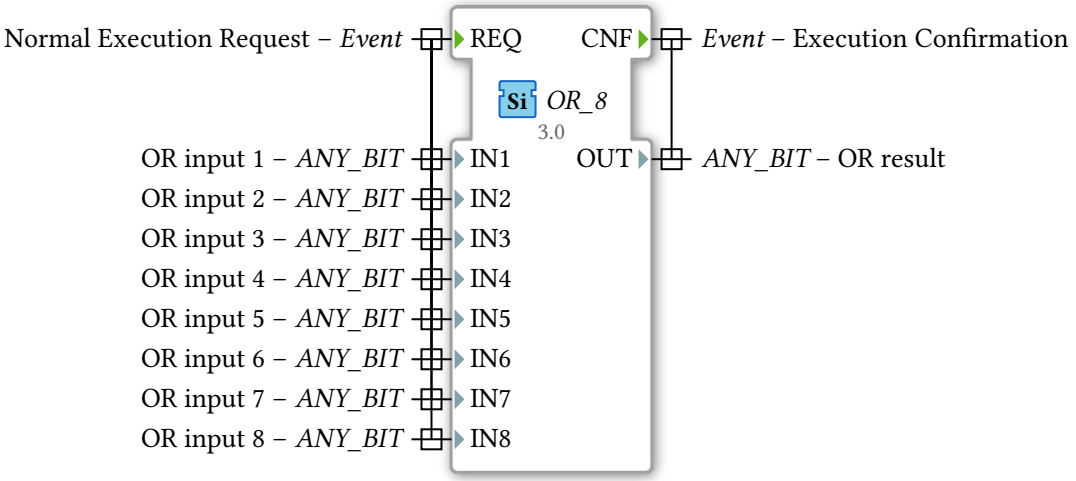
Application Scenarios

- **Logical Operations**: Combining multiple binary signals to produce a common result.
- **Control Engineering**: Used in control algorithms where multiple conditions must be met simultaneously (OR operation).
- **Data Processing**: Bitwise operations at the byte, word, or DWord level.

⚖️ Comparison with Similar Function Blocks

- **OR (Standard)**: Standard OR blocks in IEC 61131-3 typically support only two inputs. `OR_7` extends this functionality to up to seven inputs.
- **GEN_OR**: The generic OR block on which `OR_7` is based can theoretically process any number of inputs, but is less specific in its implementation.

Conclusion



The `OR_7` function block offers a flexible and powerful solution for bitwise OR operations with up to seven input variables. Its generic nature allows its use with various bit data types, making it a versatile tool in control and automation engineering.

OR_8

• – ◦ • – ◦ • – ◦ •

Introduction

The OR_8 function block is a generic function block for calculating a bitwise OR operation. It supports up to 8 inputs and is classified according to the IEC 61131-3 standard. This function block is particularly suitable for applications where multiple binary signals need to be logically combined.

Interface Structure

Event Inputs
- **REQ**: Starts the execution of the function block. It is linked to all data inputs.

Event Outputs
- **CNF**: Signals the successful execution of the function block. It is linked to the data output `OUT`.

Data Inputs
- **IN1** to **IN8**: Each of these inputs accepts an arbitrary bit type (`ANY_BIT`). These represent the operands for the OR operation.

Data Outputs
- **OUT**: Returns the result of the bitwise OR operation of inputs `IN1` to `IN8`. The data type corresponds to that of the inputs (`ANY_BIT`).

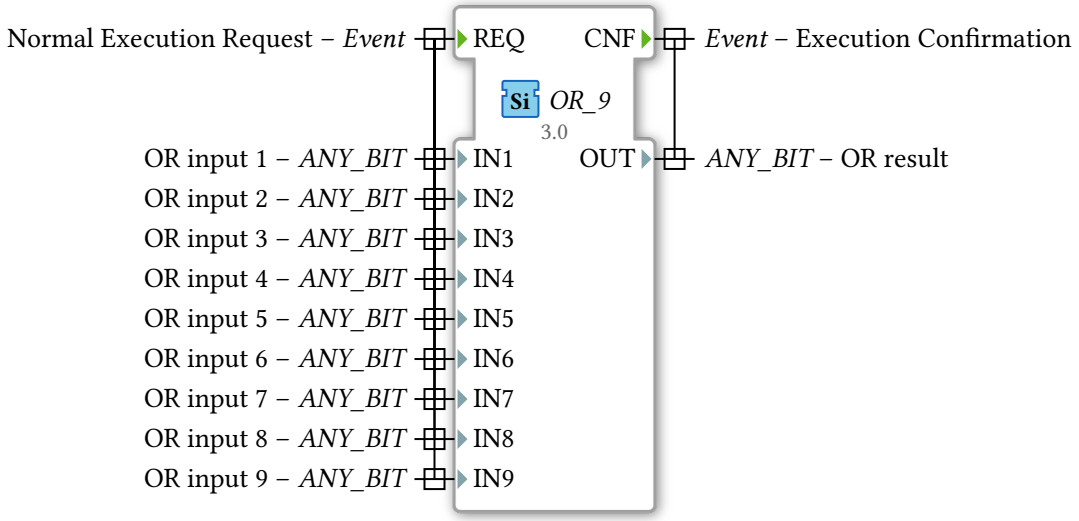
Adapters
This function block does not have any adapters.

Functionality
The OR_8 function block performs a bitwise OR operation on the values at inputs `IN1` to `IN8`. The result is output at `OUT` as soon as the event `REQ` is received. Execution is confirmed by the event `CNF`.

Technical Features
- **Generic Implementation**: The function block is generic and can work with different bit types (`ANY_BIT`).
- **Flexible Number of Inputs**: Supports up to 8 inputs, making it suitable for complex logic operations.

State Overview
1. **Idle State**: Waits for the event `REQ`.
2. **Execution State**: Performs the OR operation and sets the output `OUT`.
3. **Acknowledgement State**: Sends the event `CNF` to confirm execution.

Application Scenarios
- Logical combination of multiple sensor data.
- Control logic in industrial automation systems.
- Combination of binary control signals.



⚖️ Comparison with Similar Function Blocks
- **OR_2/OR_4**: Similar function blocks with fewer inputs (2 or 4, respectively). OR_8 offers greater flexibility for more complex applications.
- **GEN_OR**: Generic base implementation that is further specialized by OR_8.

Conclusion
The OR_8 function block is a powerful tool for bitwise OR operations in industrial automation. Its generic nature and support for up to 8 inputs make it particularly versatile.

OR_9

• − ◦ • − ◦ • − ◦ •

Introduction
The OR_9 function block is a generic function block for calculating a bitwise logical OR operation. It supports up to nine input variables and outputs the result of the OR operation. The function block is part of the IEC 61131-3 standard library for bitwise Boolean functions.

Interface Structure

Event Inputs

- **REQ**: Normal execution request input. Triggers the calculation of the OR operation. Linked to all data inputs (IN1 to IN9).

Event Outputs

- **CNF**: Execution confirmation. Triggered after the calculation of the OR operation. Linked to the data output OUT.

Data Inputs

- **IN1** (ANY_BIT): OR Input 1
- **IN2** (ANY_BIT): OR Input 2
- **IN3** (ANY_BIT): OR Input 3
- **IN4** (ANY_BIT): OR Input 4
- **IN5** (ANY_BIT): OR Input 5
- **IN6** (ANY_BIT): OR Input 6
- **IN7** (ANY_BIT): OR Input 7
- **IN8** (ANY_BIT): OR Input 8
- **IN9** (ANY_BIT): OR Input 9

Data Outputs

- **OUT** (ANY_BIT): Result of the OR operation of all inputs

Adapters

This module does not have any adapters.

Functionality

The OR_9 function block performs a bitwise logical OR operation on all active inputs (IN1 to IN9) when the REQ event is received. The result is output at the OUT output, and the CNF event is triggered simultaneously.

Technical Features

- Supports the generic data type ANY_BIT for all inputs and the output
- Can work with different bit lengths (e.g., BYTE, WORD, DWORD)
- Implemented as a generic function block (GEN_OR)

State Overview

1. Wait state: Waits for a REQ event
2. Compute state: Performs an OR operation

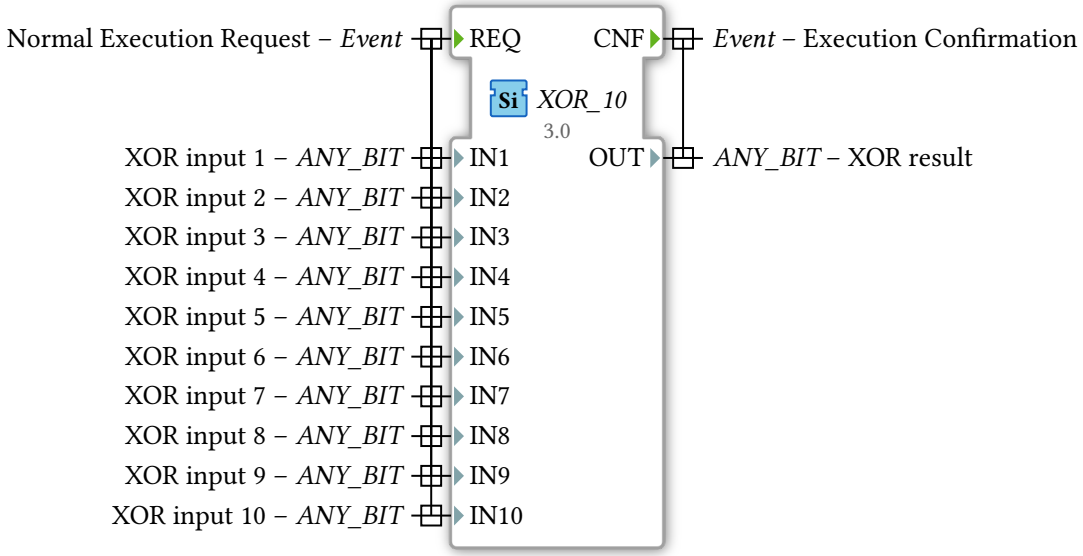
3. Output state: Sets OUT and triggers CNF
4. Returns to wait state

Application Scenarios

- Bitwise signal processing
- Combinational logic circuits
- Control logic with multiple input conditions
- Signal processing in industrial automation systems

⚖️ Comparison with Similar Function Blocks

- Compared to simpler OR function blocks, OR_9 offers the ability to process up to nine inputs
- Similar to other bitwise operators, but specifically optimized for OR operations
- Generic implementation allows for more flexible application than type-specific variants



Conclusion

The The OR_9 function block is a versatile building block for bitwise OR operations in industrial control systems. Its generic implementation and support for up to nine inputs make it particularly flexible for various applications. The clear interface structure and compliance with IEC 61131-3 enable easy integration into existing automation solutions.

XOR_10

• – ◦ • – ◦ • – ◦ •

The XOR_10 function block is a generic function block for calculating a bitwise XOR operation with up to 10 inputs. It is part of the IEC 61131-3 standard library for bitwise Boolean operations and can be used with various bit data types (ANY_BIT).

- **REQ**: Starts the calculation of the XOR operation. It connects to all data inputs (IN1 to IN10).
- **CNF**: Signals the completion of the calculation and outputs the result via the OUT output.
- **IN1** to **IN10** (ANY_BIT): Up to 10 input values for XOR calculation. Each input can contain any bit data type (BOOL, BYTE, WORD, DWORD, LWORD).
- **OUT** (ANY_BIT): Result of the bitwise XOR operation of all active inputs.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use adapters.

Upon receiving the REQ event, the function block calculates a bitwise XOR operation of all active inputs (IN1 to IN10). The result is output at the OUT output, and the CNF event is triggered.

- Result bit = 1 if an odd number of input bits at that position are 1
- Result bit = 0 if an even number of input bits at that position are 1
- Supports generic bit data types (ANY_BIT)
- Processes up to 10 input values
- All inputs must have the same data type
- Unused inputs are treated as 0
- Part of the `iec61131::bitwiseOperators` package

1. **Wait State**: Waits for REQ event
2. **Compute State**: Performs XOR operation
3. **Output State**: Sends result and CNF event
4. Returns to Wait State

- Bitwise encryption operations
- Parity checks
- Error detection in digital systems
- Control logic with multiple Input Signals
- Generic Logic Operations in Automation Systems
- Compared to simple 2-input XOR blocks, XOR_10 offers greater flexibility
- Similar to OR_10/AND_10 blocks, but with XOR logic
- Generic implementation as opposed to type-specific blocks (e.g., XOR_BOOL, XOR_WORD)

The XOR_10 function block provides a flexible solution for complex bitwise XOR operations in IEC 61131-3-based control systems. Its generic nature and support for up to 10 inputs make it particularly suitable for applications requiring more than the traditional two inputs.

XOR_2

• – ◦ • – ◦ • – ◦ •

Introduction

The XOR_2 function block is a generic function block for calculating the bitwise Boolean XOR operation. It performs an exclusive OR operation between two input values and outputs the result. The function block is suitable for all ANY_BIT data types, thus enabling flexible use with different bit lengths.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation of the XOR operation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1** (ANY_BIT): XOR input 1 - first operand for the XOR operation
- **IN2** (ANY_BIT): XOR input 2 - second operand for the XOR operation

Data Outputs

- **OUT** (ANY_BIT): XOR result - result of the bitwise XOR operation

Adapters

The function block does not have any adapter interfaces.

Functionality

Upon receiving the REQ event, the XOR_2 block performs a bitwise XOR operation between the two input values IN1 and IN2. The operation is performed separately for each bit pair of input values:

- If both bits are the same (both 0 or both 1), the result bit is set to 0.
- If the bits are different, the result bit is set to 1.

After the calculation is complete, the result is output via the OUT output, and the CNF event is sent to confirm execution.

- If the bits are different, the result bit is set to 1.

Technical Features

- **Generic Implementation**: Supports all ANY_BIT data types (BOOL, BYTE, WORD, DWORD, LWORD)
- **Bitwise Operation**: Performs the XOR operation at the bit level
- **Event-Driven Execution**: Synchronization via REQ/CNF events
- **Type Safety**: Guarantees correct operation for all supported data types

State Transitions

1. **Wait State**: Block waits for REQ event
2. **Compute State**: On REQ event, block performs XOR operation
3. **Output State**: After computation, OUT is set and a CNF event is sent
4. **Return**: Block returns to wait state

Application Scenarios

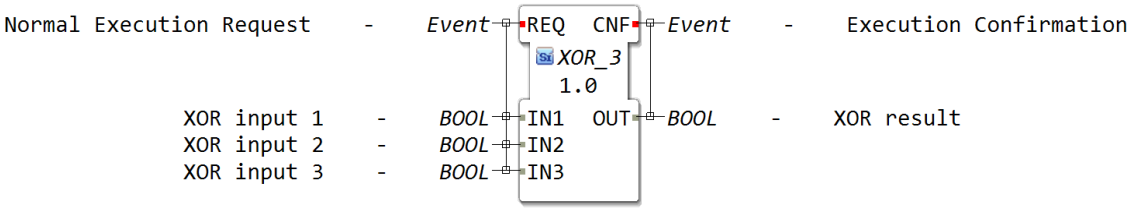
- **Bit Manipulation**: Reversing specific bits in data words
- **Parity Checking**: Creating parity bits for error detection
- **Data Encryption**: Simple cryptographic operations

- **Control Engineering**: Logical operations in automation systems
- **Data Comparison**: Detection of differences between data values

⚖️ Comparison with similar blocks

Compared to other logical blocks, XOR_2 offers:

- **Flexibility**: Support for various bit lengths through the ANY_BIT type
- **Specific Logic**: Exclusive OR operation as opposed to AND/OR operations
- **Generic Implementation**: Reusability across different data types



Conclusion

The XOR_2 function block provides an efficient and flexible solution for bitwise XOR operations in 4diac systems. Its generic nature allows for use in a wide range of applications, while its event-driven architecture ensures reliable integration into complex control systems.

XOR_3

• – ◦ • – ◦ • – ◦ •

Introduction

The XOR_3 function block is a generic function block for calculating bitwise XOR operations with three inputs. It implements the logical exclusive OR operation at the bit level according to the IEC 61131-3 standard and can be used with various bit data types.

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request - triggers the calculation of the XOR operation

Event Outputs

- **CNF**: Execution Acknowledgement - signals the completion of the calculation

Data Inputs

- **IN1**: XOR Input 1 (ANY_BIT data type)
- **IN2**: XOR Input 2 (ANY_BIT data type)
- **IN3**: XOR Input 3 (ANY_BIT data type)

Data Outputs

- **OUT**: XOR Result (ANY_BIT data type)

Adapters

The function block does not use adapters.

Functionality

Upon arrival of the REQ event, the function block performs a bitwise XOR operation on the three input values IN1, IN2, and IN3. The operation is executed separately for each bit position and corresponds to the logical function: OUT = IN1 XOR IN2 XOR IN3. After completion of the calculation, the CNF event is output along with the result value.

Technical Features

- Uses the generic data type ANY_BIT, which is compatible with various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- Implemented as a generic function block with the class 'GEN_XOR'
- Supports exactly three inputs for the XOR operation
- Conforms to the IEC 61131-3 classification for standardized bitwise Boolean functions

State Overview

The function block operates statelessly:

1. Wait state: No active calculation
2. Calculation state: The XOR operation is executed upon a REQ event
3. Output state: A CNF event with the result is output

Application Scenarios

- Bitwise encryption operations
- Parity checks in communication protocols
- Error detection in digital systems
- Control logic with multiple conditions
- Data processing in industrial automation systems

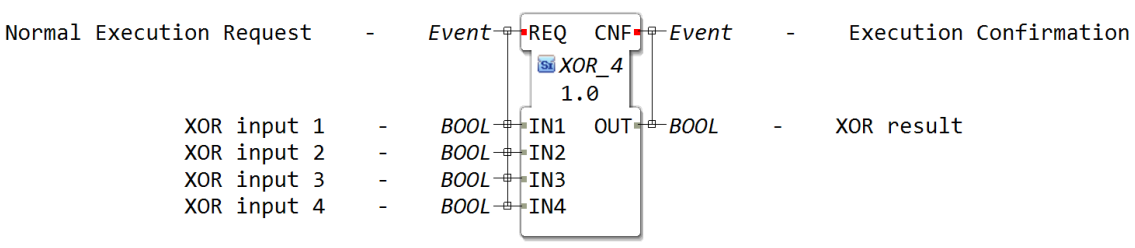
⚖️ Comparison with Similar Function Blocks

Compared to XOR_3 offers the ability to process three inputs simultaneously, unlike standard two-input XOR blocks. Compared to AND/OR operations, XOR delivers an exclusive result where the output bit is only 1 if an odd number of the input bits are 1.

🛠️ Related Exercises

- Exercise_002a7_AX

Conclusion



The XOR_3 function block provides an efficient and flexible solution for bitwise XOR operations with three inputs in 4diac systems. Its generic nature allows its use with various bit data types, making it versatile for industrial automation applications.

XOR_4

• – ◦ • – ◦ • – ◦ •

Introduction

The XOR_4 function block is a generic function block for calculating bitwise XOR operations with four inputs. It implements the exclusive OR operation at the bit level according to the IEC 61131-3 standard and can work with various bit data types.

Interface Structure

Event Inputs

- **REQ**: Normal execution request - triggers the calculation of the XOR operation

Event Outputs

- **CNF**: Execution confirmation - signals the completion of the calculation

Data Inputs

- **IN1**: XOR input 1 (ANY_BIT data type)
- **IN2**: XOR input 2 (ANY_BIT data type)
- **IN3**: XOR input 3 (ANY_BIT data type)
- **IN4**: XOR input 4 (ANY_BIT data type)

Data Outputs

- **OUT**: XOR result (ANY_BIT data type)

Adapters

The function block does not use adapters.

Functionality

Upon arrival of the REQ event, the XOR_4 block performs a bitwise XOR operation on all four inputs. The operation is executed according to the following logic:

OUT = IN1 XOR IN2 XOR IN3 XOR IN4 Once the calculation is complete, the CNF event, along with the result, is output to OUT. ...

Technical Features

- **Generic Data Type**: Uses ANY_BIT, enabling use with various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- **Four-Input XOR Operation**: Processes four inputs in a single operation
- **Event-Driven**: Execution is triggered by the REQ event
- **Standard-Compliant**: Conforms to the IEC 61131-3 standard for bitwise Boolean functions

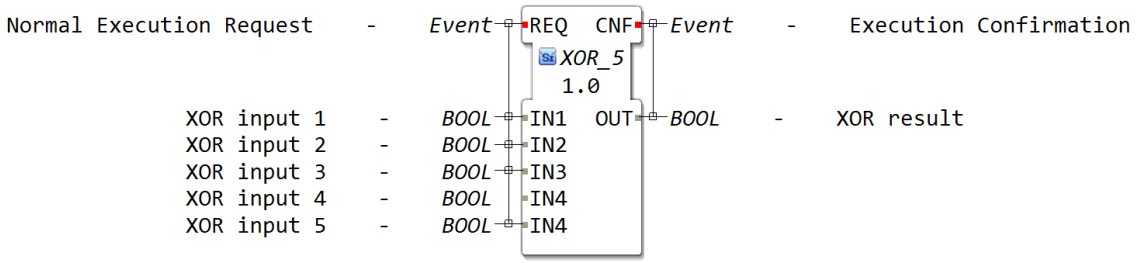
State Transitions

1. **Wait State**: Block waits for REQ event
2. **Compute State**: All inputs are processed upon REQ event
3. **Output State**: CNF event is output with the computed result
4. Returns to Wait State

Application Scenarios

- **Bit Manipulation**: Used in control applications for bitwise operations
- **Parity Checking**: Implementation of parity bits or error detection

- **Data Encryption**: Simple cryptographic operations
- **Signal Processing**: Combining multiple digital signals

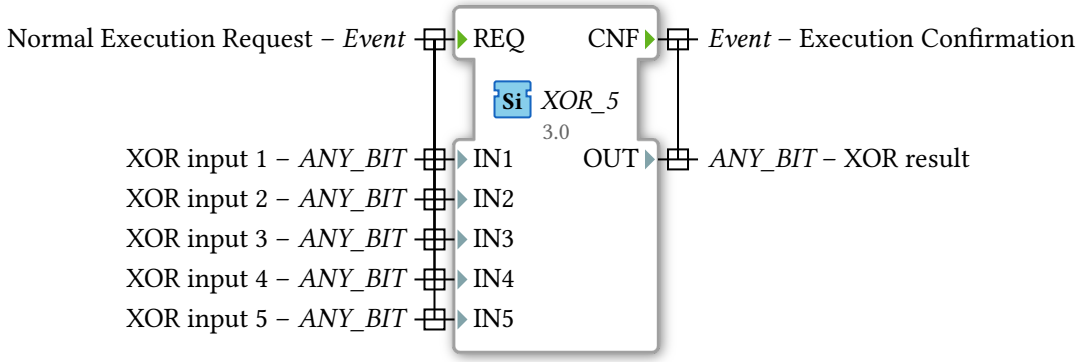


⚖️ Comparison with Similar Blocks

- **AND/OR Blocks**: Process logical AND/OR operations instead of exclusive OR
- **XOR with Fewer Inputs**: This block offers four inputs compared to standard XOR blocks, which typically have two inputs
- **Generic vs. Specific Blocks**: Can process various bit data types, while specific blocks are limited to one data type

Conclusion

The XOR_4 function block offers a flexible and standards-compliant solution for four-input bitwise XOR operations. Its generic nature allows for use in various application areas, while its event-driven architecture ensures efficient integration into control systems.



XOR_5

• – ◦ • – ◦ • – ◦ •

Introduction

The XOR_5 function block is a generic function block for calculating the bitwise Boolean XOR operation with five inputs. It implements the exclusive OR operation for arbitrary bit data types according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request - triggers the calculation of the XOR operation

Event Outputs

- **CNF**: Execution Confirmation - signals the completion of the calculation

Data Inputs

- **IN1**: XOR Input 1 (ANY_BIT data type)
- **IN2**: XOR Input 2 (ANY_BIT data type)
- **IN3**: XOR Input 3 (ANY_BIT data type)
- **IN4**: XOR Input 4 (ANY_BIT data type)
- **IN5**: XOR Input 5 (ANY_BIT data type)

Data Outputs

- **OUT**: XOR Result (ANY_BIT data type)

Adapters

No adapter interfaces are available.

Functionality

Upon arrival of the REQ event, the function block performs a bitwise XOR operation on all five input values. The result is output to the OUT output, and simultaneously, the CNF event is generated to confirm the completion of the calculation.

The XOR operation is performed according to the following principle:

- Each bit position is processed individually.
- The result bit is 1 if an odd number of input bits at that position are 1.
- The result bit is 0 if an even number of input bits at that position are 1.

Technical Features

- Uses the generic ANY_BIT data type, which is compatible with various bit data types (BOOL, BYTE, WORD, DWORD, LWORD).
- Supports the processing of five input values.
- Implemented as a generic function block according to the IEC 61131-3 standard.
- Package mapping: iec61131::bitwiseOperators

State Overview

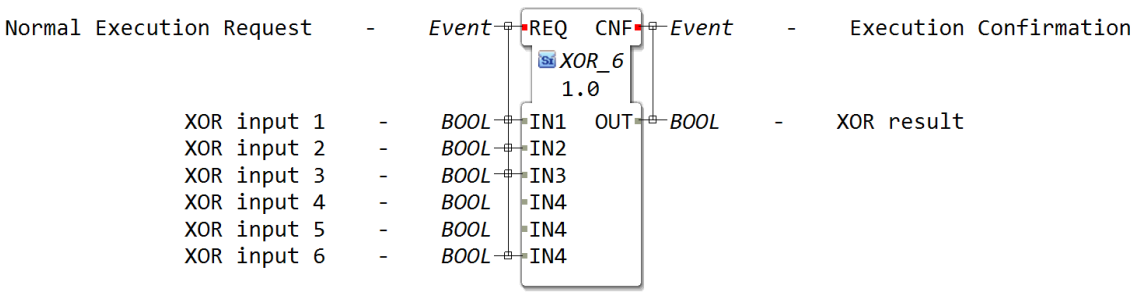
The function block has a simple state machine:

1. **Wait State**: Waiting for a REQ event.
2. **Compute State**: Processing the XOR operation.
3. **Output State**: Setting the OUT value and triggering the CNF Event

Application Scenarios

- Bitwise data processing in control systems
- Parity checks and error detection
- Cryptographic operations
- Data manipulation and transformation
- Signal processing with multiple input signals

⚖️ Comparison with similar components

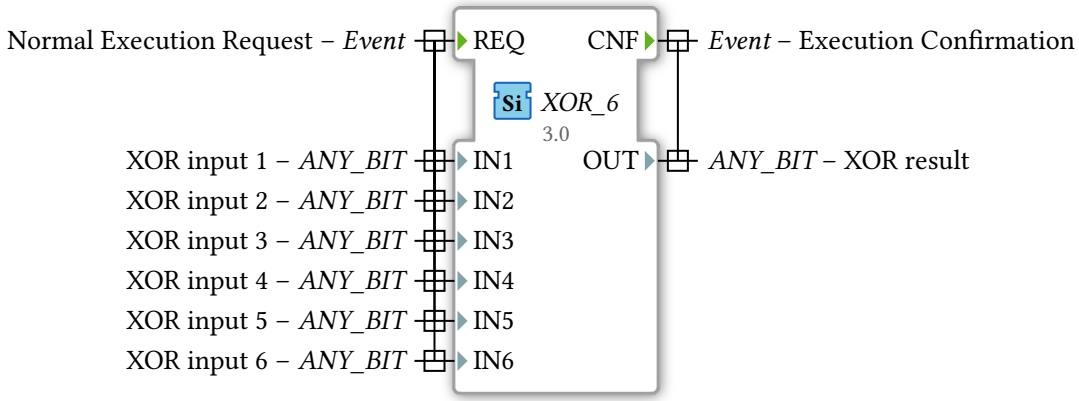


Compared to standard XOR components with fewer inputs, XOR_5 offers:

- Extended functionality with five inputs instead of two
- Greater flexibility for more complex logical operations
- Reduced chaining depth compared to serial XOR operations

Conclusion

The XOR_5 function block provides a powerful and flexible solution for bitwise XOR operations with five inputs. Its generic implementation allows its use with various bit data types, making it a versatile tool for diverse applications in automation technology.



XOR_6

• – ◦ • – ◦ • – ◦ •

Introduction

The XOR_6 function block is a generic function block for calculating bitwise XOR operations with six inputs. It implements the Boolean exclusive OR operation at the bit level according to the IEC 61131-3 standard and can work with various bit data types.

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request - triggers the calculation of the XOR operation

Event Outputs

- **CNF**: Execution Acknowledgement - signals the completion of the calculation

Data Inputs

- **IN1**: XOR Input 1 (ANY_BIT data type)
- **IN2**: XOR Input 2 (ANY_BIT data type)
- **IN3**: XOR Input 3 (ANY_BIT data type)
- **IN4**: XOR Input 4 (ANY_BIT data type)
- **IN5**: XOR Input 5 (ANY_BIT data type)
- **IN6**: XOR Input 6 (ANY_BIT data type)

Data Outputs

- **OUT**: XOR Result (ANY_BIT Data Type)

Adapter

No adapter interfaces are available.

Functionality

The XOR_6 block performs a bitwise XOR operation on all six inputs. When the REQ event is triggered, the values at IN1 to IN6 are processed, and the result is output to OUT. The operation follows the mathematical definition of the XOR function, where the result is true for each bit if an odd number of the corresponding input bits are true.

The calculation is performed according to the formula: OUT = IN1 ⊕ IN2 ⊕ IN3 ⊕ IN4 ⊕ IN5 ⊕ IN6

Technical Features

- **Generic Data Type**: Uses ANY_BIT, enabling compatibility with various bit data types (BOOL, BYTE, WORD, DWORD, LWORD)
- **Six Inputs**: Offers extended functionality compared to standard XOR blocks with fewer inputs
- **Event-Driven Execution**: Follows the 4diac execution model with REQ/CNF event pairs

State Overview

The function block has a simple state machine:

1. **Wait State**: Block waits for a REQ event

2. **Calculate State**: Processes the inputs when a REQ event is triggered
3. **Output State**: Sends a CNF event with the calculated result

Application Scenarios

- **Parity Check**: Checks the Data integrity through XOR operation of multiple data words
- **Data encryption**: Simple cryptographic operations
- **Error detection**: Generation of checksums in communication protocols
- **Control engineering**: Logical operations in automation applications

⚖️ Comparison with similar blocks

Compared to standard two-input XOR blocks, XOR_6 offers:

- Enhanced functionality with six direct inputs
- Elimination of the need to cascade multiple XOR blocks
- More compact implementation for complex XOR operations

Conclusion

The XOR_6 function block provides a powerful and flexible solution for bitwise XOR operations with multiple inputs. Its generic nature allows for broad applicability in various automation projects, while its six-input functionality supports efficient implementations of complex logical operations.

XOR_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_7` performs a bitwise XOR operation on seven input values. It is a generic function block that can be used with various bit data types (e.g., BOOL, BYTE, WORD, DWORD, LWORD). The block is classified according to the IEC 61131-3 standard and is used for processing Boolean operations.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): Triggers the calculation of the XOR operation. It is linked to all data inputs (`IN1` to `IN7`).

Event Outputs

- **CNF** (Execution Confirmation): Signals successful calculation and outputs the result via the data output `OUT`.

Data Inputs

- **IN1** (XOR input 1): First input value (Type: `ANY_BIT`).
- **IN2** (XOR input 2): Second input value (Type: `ANY_BIT`).
- **IN3** (XOR input 3): Third input value (Type: `ANY_BIT`).
- **IN4** (XOR input 4): Fourth input value (Type: `ANY_BIT`).
- **IN5** (XOR input 5): Fifth input value (Type: `ANY_BIT`).
- **IN6** (XOR input 6): Sixth input value (Type: `ANY_BIT`).
- **IN7** (XOR input 7): Seventh input value (Type: `ANY_BIT`).

Data Outputs

- **OUT** (XOR result): Result of the bitwise XOR operation (Type: `ANY_BIT`).

Adapters

No adapters available.

Functionality

The function block performs a bitwise XOR operation on the seven input values (`IN1` to `IN7`). The operation is triggered by the event `REQ`. The result is output via `OUT` and confirmed by the event `CNF`.

Technical Features

- **Generic Implementation**: Supports various bit data types (`ANY_BIT`).
- **Flexibility**: Can operate with up to seven input values.
- **Standard Compliant**: Complies with the IEC 61131-3 standard.

State Overview

The function block has no internal states. The operation is re-executed with each `REQ` event.

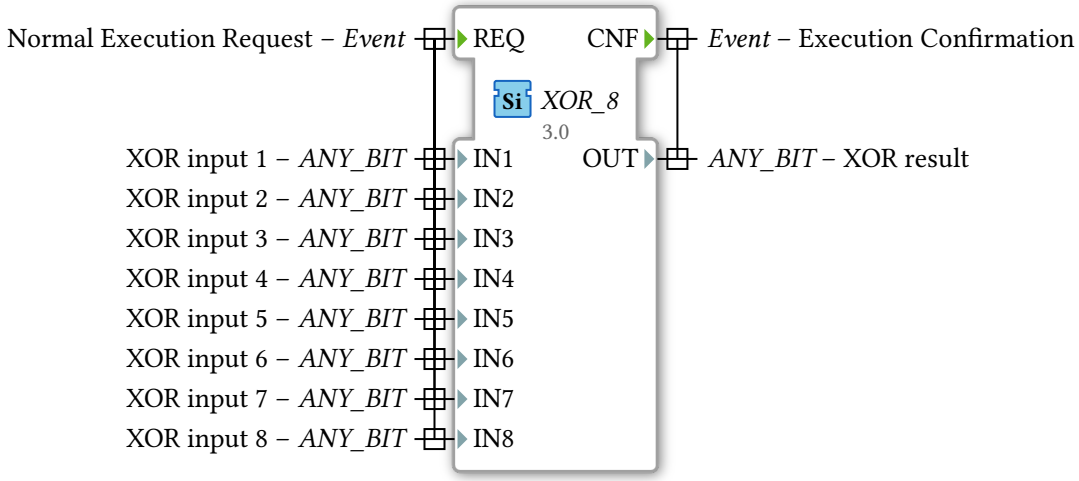
Application Scenarios

- Bitwise encryption.
- Error detection in data transmissions.
- Logical controls in automation systems.

⚖️ Comparison with Similar Function Blocks

- **XOR (Standard)**: Typically offers only two inputs, while `XOR_7` supports seven inputs.
- **AND/OR Blocks**: Perform other logical operations, while `XOR_7` is specifically optimized for the XOR operation.

Conclusion



The `XOR_7` function block is a powerful tool for bitwise XOR operations with up to seven input values. Its generic nature and standards compliance make it versatile for use in various automation and control scenarios.

XOR_8

• – ◦ • – ◦ • – ◦ •

Introduction

The XOR_8 function block performs a bitwise XOR operation on up to 8 input variables. It is a generic function block that can work with various bit data types (ANY_BIT). The block is classified according to the IEC 61131-3 standard and provides a simple way to perform XOR operations in control applications.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): Starts the calculation of the XOR operation. It is linked to all data inputs.

Event Outputs

- **CNF** (Execution Confirmation): Signals the completion of the calculation. It is linked to the data output OUT.

Data Inputs

- **IN1** (ANY_BIT): XOR Input 1
- **IN2** (ANY_BIT): XOR Input 2
- **IN3** (ANY_BIT): XOR Input 3
- **IN4** (ANY_BIT): XOR Input 4
- **IN5** (ANY_BIT): XOR Input 5
- **IN6** (ANY_BIT): XOR Input 6
- **IN7** (ANY_BIT): XOR Input 7
- **IN8** (ANY_BIT): XOR Input 8

Data Outputs

- **OUT** (ANY_BIT): Result of the XOR operation

Adapters

The function block does not have any adapter interfaces.

Functionality

Upon receiving the REQ event, the function block performs a bitwise XOR operation on all active input variables (IN1 to IN8). The result is output at OUT, and the CNF event is triggered to signal the completion of the operation.

Technical Features

- Supports the generic data type ANY_BIT, meaning that various bit data types (e.g., BOOL, BYTE, WORD, DWORD, LWORD) can be used.
- The operation is strictly bitwise.
- The function block is part of the “iec61131::bitwiseOperators” package.

State Overview

The function block has no complex states. It responds to the REQ event with an immediate calculation and output of the result.

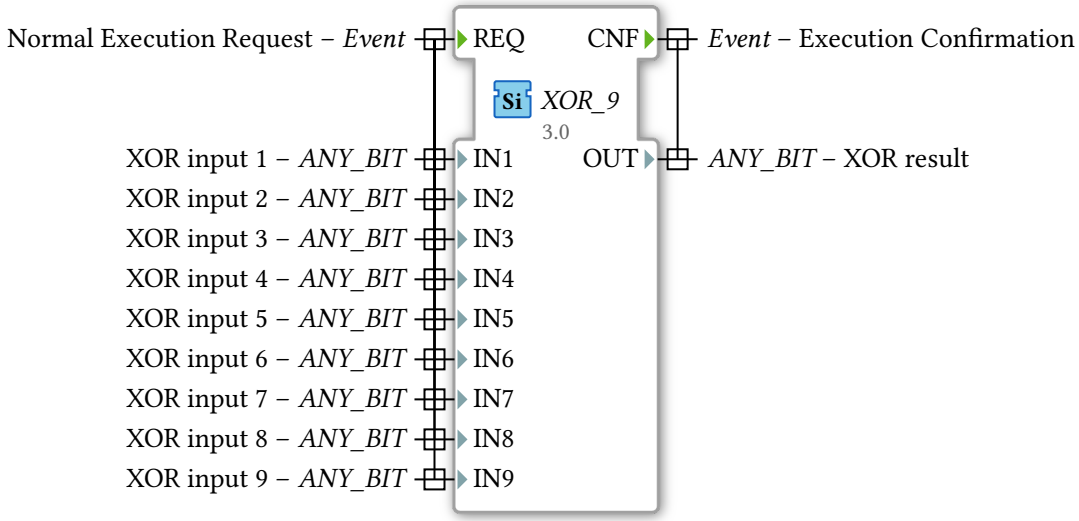
Application Scenarios

- Bitwise Checksum Calculation
- Data Encryption Operations
- Error Detection in Data Transmissions
- Control Logic with Bitwise Operations

⚖️ Comparison with Similar Function Blocks

Compared to simpler XOR blocks (e.g., with only 2 inputs), XOR_8 offers the ability to process up to 8 inputs simultaneously. Other bitwise operators (such as AND_8 or OR_8) perform similar operations with different logical combinations.

Conclusion



The XOR_8 function block provides a flexible and standards-compliant solution for bitwise XOR operations in control systems. Its generic nature allows its use with various bit data types, while support for up to 8 inputs enables more complex logical operations. Its simple interface and deterministic execution make it a reliable component for control applications.

XOR_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_9` is used for bitwise calculation of the XOR operation with up to nine inputs. It is part of the standard bit operations according to IEC 61131-3 and enables the processing of any bit data type (`ANY_BIT`).

Interface Structure

Event Inputs

- `REQ` (Normal Execution Request): Starts the calculation of the XOR operation. Triggers the evaluation of all combined data inputs.

Event Outputs

- `CNF` (Execution Confirmation): Signals the completion of the calculation and outputs the result via the data output `OUT`.

Data Inputs

- `IN1` to `IN9` (XOR input 1-9): Up to nine inputs for bitwise XOR operation. Each input supports the data type `ANY_BIT` (e.g., BOOL, BYTE, WORD, DWORD, LWORD).

Data Outputs

- `OUT` (XOR result): Result of the bitwise XOR operation of all active inputs. The data type corresponds to that of the inputs (`ANY_BIT`).

Adapters

This function block has no adapters.

Functionality

When the `REQ` event is triggered, the function block calculates the XOR operation of all passed input values (`IN1` to `IN9`). The result is output to `OUT`, and the `CNF` event signals that the result is ready.
Example (for BOOL inputs): OUT = IN1 XOR IN2 XOR ... XOR IN9`

Technical Features

- **Generic Implementation:** Supports all `ANY_BIT` data types by using the generic class `GEN_XOR`.
- **Flexible Number of Inputs:** Unused inputs are ignored (act as neutral elements).
- **Bitwise Operation:** The operation is performed separately for each bit (for multi-bit data types).

State Overview

1. **Idle:** Waits for the `REQ` event.
2. **Processing:** Performs an XOR operation and sets `OUT`.
3. **Ready:** Sends `CNF` and returns to Idle.

Application Scenarios

- Parity checking in communication protocols
- Toggles control signals (e.g., switching between states)
- Basic cryptographic operations
- Error detection in binary data

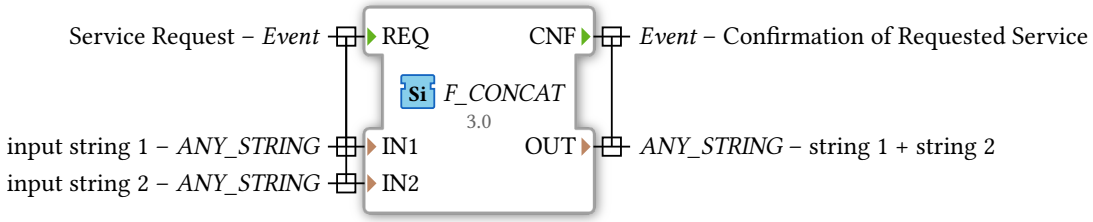
⚖️ Comparison with similar function blocks

Feature	XOR_9	Standard XOR (2 inputs)
Number of inputs	9	2
Data type	ANY_BIT	Type-dependent (e.g., BOOL)
Flexibility	High	Low

Conclusion

The `XOR_9` function block extends the classic XOR functionality by supporting multiple inputs and generic data types. Ideal for applications that require more complex bitwise operations without having to build individual function block chains. IEC 61131-3 compliance ensures broad compatibility.

2.11.4.5 String Functions



Here you will find functions for manipulating strings.

F_CONCAT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_CONCAT` is used to concatenate two strings. It is part of the standard library for character and string operations according to IEC 61131-3.

Interface Structure

Event Inputs

- `REQ` (Service Request): Starts the concatenation operation. The block requires both input strings (`IN1` and `IN2`) to execute the operation.

Event Outputs

- `CNF` (Confirmation of Requested Service): Signals the successful completion of the concatenation operation. The result is provided via the data output `OUT`.

Data Inputs

- `IN1` (input string 1): First input string of type `ANY_STRING`.
- `IN2` (input string 2): Second input string of type `ANY_STRING`.

Data Outputs

- `OUT` (string 1 + string 2): Result of concatenating `IN1` and `IN2` as `ANY_STRING`.

Adapters

This function block has no adapters.

Functionality

When the event `REQ` is triggered, the two input strings `IN1` and `IN2` are concatenated. The result is output via `OUT`, and the event `CNF` signals the successful completion of the operation.

Technical Features

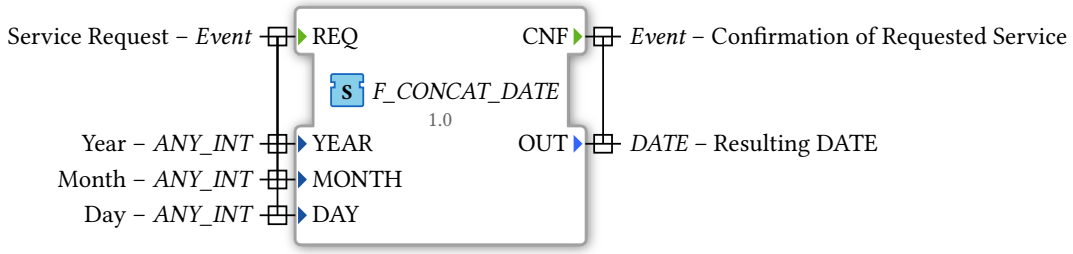
- Supports the data type `ANY_STRING`, enabling flexible use with various string types.
- Simple and direct implementation without additional parameters or complex state logic.

State Overview

The function block has no internal state. The operation is re-executed with each `REQ` event.

Application Scenarios

- Combining text segments in automated messaging systems.
- Creating dynamic strings in control logic, e.g., for logging or notifications.



⚖️ Comparison with Similar Blocks

- Unlike `F_STRING_TO_*` blocks, which convert strings, `F_CONCAT` does not perform type conversion.
- Simpler than blocks with additional formatting options like `F_STRING_FORMAT`.

Conclusion

F_CONCAT` is a basic and efficient building block for string processing in IEC 61131-3 environments. Its simplicity and direct functionality make it ideal for basic concatenation tasks.

F_CONCAT_DATE

• – ◦ • – ◦ • – ◦ •

Introduction

`F_CONCAT_DATE` combines individual date/time components (`YEAR`, `MONTH`, `DAY`) into a composite `DATE` value. It is the reverse of F_SPLIT_DATE, which splits the same `DATE` value back into its individual components.

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries `YEAR`, `MONTH`, `DAY`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **YEAR** (ANY_INT): year.
- **MONTH** (ANY_INT): month.
- **DAY** (ANY_INT): day.

Data Outputs

- **OUT** (`DATE`): The value composed from the individual components.

Functionality

On `REQ`, the input values `YEAR`, `MONTH`, `DAY` are combined into a `DATE` value and output via `OUT`. `CNF` is then triggered.

Technical Features

- **`ANY_INT` inputs**: The date/time components accept any integer type, simplifying wiring with differently typed source values.
- **No documented range checking**: The block assumes plausible input values (e.g. `MONTH` 1–12); explicit validation is the caller's responsibility.

State Overview

Stateless: every `REQ` immediately results in the merge and `CNF`.

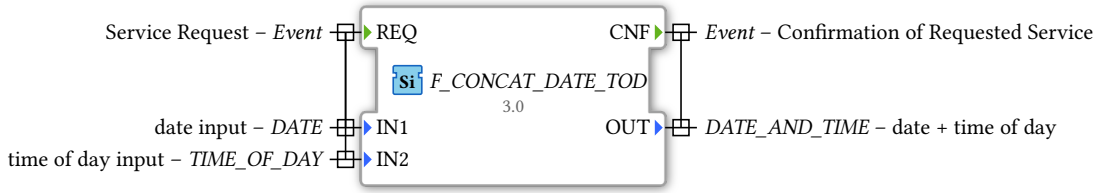
Application Scenarios

- **Building timestamps** from separately captured or computed individual values, e.g. from sensor data, user input, or communication protocols.
- **Configuration evaluation**: Combining date/time components held in individual variables into a usable `DATE` value.

Comparison with similar function blocks

- F_SPLIT_DATE: the reverse direction — splits a `DATE` value into its individual components.
- **`F_CONCAT_DATE_TOD`**: instead combines an already-complete `DATE` and `TIME_OF_DAY` value into `DATE_AND_TIME`, rather than from individual fields.

Conclusion



F_CONCAT_DATE provides a simple, direct merge of individual date/time values into a DATE value, complementing the corresponding split function F_SPLIT_DATE.

F_CONCAT_DATE_TOD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_CONCAT_DATE_TOD concatenates a date (DATE) and a time of day (TIME_OF_DAY) into a combined date and time stamp (DATE_AND_TIME). This block is particularly useful in scenarios where separate date and time information needs to be combined into a single timestamp.

Interface Structure

Event Inputs

- **REQ**: Starts the processing of the function block. When this event is triggered, the input data IN1 (date) and IN2 (time of day) are processed.

Event Outputs

- **CNF**: Signals successful processing and outputs the combined timestamp OUT.

Data Inputs

- **IN1** (DATE): Input for the date.
- **IN2** (TIME_OF_DAY): Input for the time of day.

Data Outputs

- **OUT** (DATE_AND_TIME): The combined date and time stamp generated from the inputs IN1 and IN2.

Adapters

This function block has no adapters.

Functionality

When the event REQ is triggered, the input data IN1 (date) and IN2 (time of day) are read and combined into a value DATE_AND_TIME. The result is output via the variable OUT, and the event CNF signals successful processing.

Technical Features

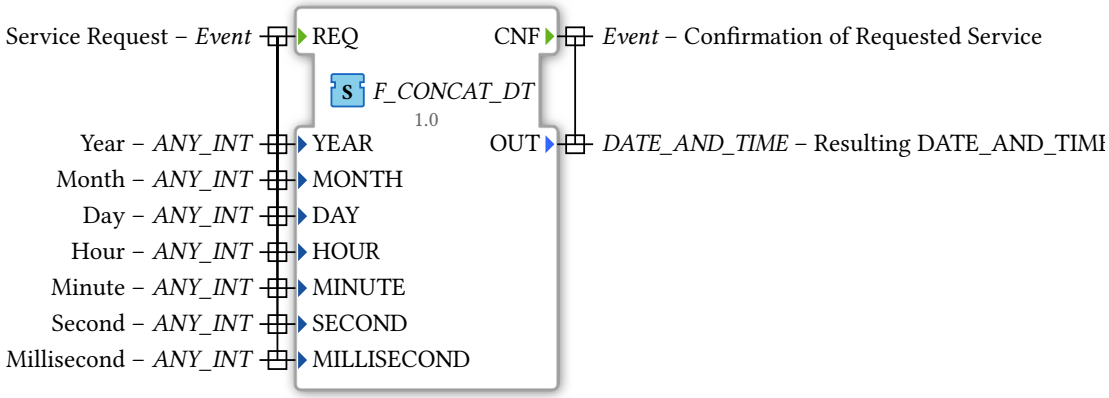
- The function block supports the standardized data types DATE, TIME_OF_DAY, and DATE_AND_TIME according to IEC 61131-3.
- Processing occurs synchronously with the triggering of the REQ event.

State Overview

1. **Idle**: Waits for the REQ event.
2. **Processing**: Processes the input data and combines it into a DATE_AND_TIME value.
3. **Output**: Outputs the result via OUT and signals CNF.

Application Scenarios

- Combining separately recorded date and time information in control systems.
- Generating timestamps for logging and monitoring purposes.



⚖️ Comparison with Similar Function Blocks

Compared to other function blocks offering similar functionality, `F_CONCAT_DATE_TOD` stands out due to its simplicity and direct processing. There are no additional parameters or complex configuration options, making it particularly suitable for simple use cases.

Conclusion

The `F_CONCAT_DATE_TOD` function block is an efficient tool for combining date and time information in control systems. Its ease of use and clear interface structure make it a reliable solution for basic timestamp operations.

F_CONCAT_DT

• – ◦ • – ◦ • – ◦ •

Introduction

`F_CONCAT_DT` combines individual date/time components (`YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`) into a composite `DATE_AND_TIME` value. It is the reverse of F_SPLIT_DT, which splits the same `DATE_AND_TIME` value back into its individual components.

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **YEAR** (ANY_INT): year.
- **MONTH** (ANY_INT): month.
- **DAY** (ANY_INT): day.
- **HOUR** (ANY_INT): hour.
- **MINUTE** (ANY_INT): minute.
- **SECOND** (ANY_INT): second.
- **MILLISECOND** (ANY_INT): millisecond.

Data Outputs

- **OUT** (`DATE_AND_TIME`): The value composed from the individual components.

Functionality

On `REQ`, the input values `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND` are combined into a `DATE_AND_TIME` value and output via `OUT`. `CNF` is then triggered.

Technical Features

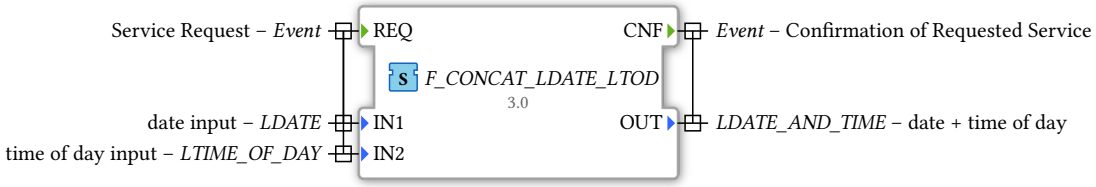
- **`ANY_INT` inputs**: The date/time components accept any integer type, simplifying wiring with differently typed source values.
- **No documented range checking**: The block assumes plausible input values (e.g. `MONTH` 1–12); explicit validation is the caller's responsibility.

State Overview

Stateless: every `REQ` immediately results in the merge and `CNF`.

Application Scenarios

- **Building timestamps** from separately captured or computed individual values, e.g. from sensor data, user input, or communication protocols.
- **Configuration evaluation**: Combining date/time components held in individual variables into a usable `DATE_AND_TIME` value.



Comparison with similar function blocks

- F_SPLIT_DT: the reverse direction — splits a `DATE_AND_TIME` value into its individual components.
- **`F_CONCAT_DATE_TOD`**: instead combines an already-complete `DATE` and `TIME_OF_DAY` value into `DATE_AND_TIME`, rather than from individual fields.

Conclusion

`F_CONCAT_DT` provides a simple, direct merge of individual date/time values into a `DATE_AND_TIME` value, complementing the corresponding split function F_SPLIT_DT.

F_CONCAT_LDATE_LTOD

• – ◦ • – ◦ • – ◦ •

Introduction

`F_CONCAT_LDATE_LTOD` concatenates a date (`LDATE`) and a time of day (`LTIME_OF_DAY`) into a combined `LDATE_AND_TIME` timestamp. It is the `L`-prefixed (64-bit resolution) counterpart to `F_CONCAT_DATE_TOD`.

Interface Structure

Event Inputs

- **REQ**: Triggers the concatenation, carries `IN1` and `IN2`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN1** (LDATE): The date.
- **IN2** (LTIME_OF_DAY): The time of day.

Data Outputs

- **OUT** (LDATE_AND_TIME): The combined date and time timestamp.

Functionality

On `REQ`, `IN1` (date) and `IN2` (time of day) are combined into an `LDATE_AND_TIME` value and output via `OUT`. `CNF` is then triggered.

Technical Features

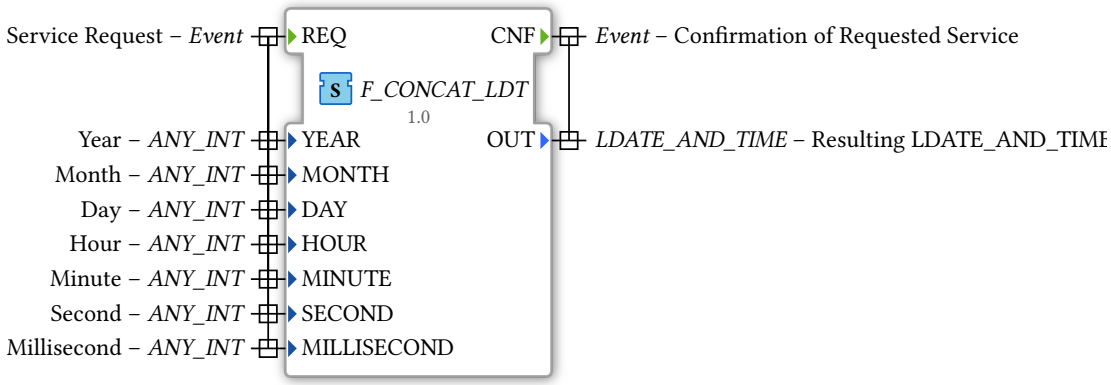
- **`L` data types**: Uses the high-resolution `LDATE`/`LTIME_OF_DAY`/`LDATE_AND_TIME` types with nanosecond resolution instead of the classic `DATE`/`TIME_OF_DAY`/`DATE_AND_TIME` types.

State Overview

Stateless: every `REQ` immediately results in the concatenation and `CNF`.

Application Scenarios

- **Combining separately captured, high-resolution date and time information** in control systems that work with `L` time types throughout.



Comparison with similar function blocks

- **`F_CONCAT_DATE_TOD`**: the same functionality with the classic `DATE`/`TIME_OF_DAY`/`DATE_AND_TIME` types.
- F_CONCAT_LDT: instead combines individual fields (`YEAR`, `MONTH`, ...) rather than already-complete `LDATE`/`LTIME_OF_DAY` values.

Conclusion

`F_CONCAT_LDATE_LTOD` provides the high-resolution variant of date/time concatenation and is suitable for applications working with `L` time types throughout.

F_CONCAT_LDT

• – ◦ • – ◦ • – ◦ •

Introduction

`F_CONCAT_LDT` combines individual date/time components (`YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`) into a composite `LDATE_AND_TIME` value. It is the reverse of F_SPLIT_LDT, which splits the same `LDATE_AND_TIME` value back into its individual components.

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **YEAR** (ANY_INT): year.
- **MONTH** (ANY_INT): month.
- **DAY** (ANY_INT): day.
- **HOUR** (ANY_INT): hour.
- **MINUTE** (ANY_INT): minute.
- **SECOND** (ANY_INT): second.
- **MILLISECOND** (ANY_INT): millisecond.

Data Outputs

- **OUT** (`LDATE_AND_TIME`): The value composed from the individual components.

Functionality

On `REQ`, the input values `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND` are combined into a `LDATE_AND_TIME` value and output via `OUT`. `CNF` is then triggered.

Technical Features

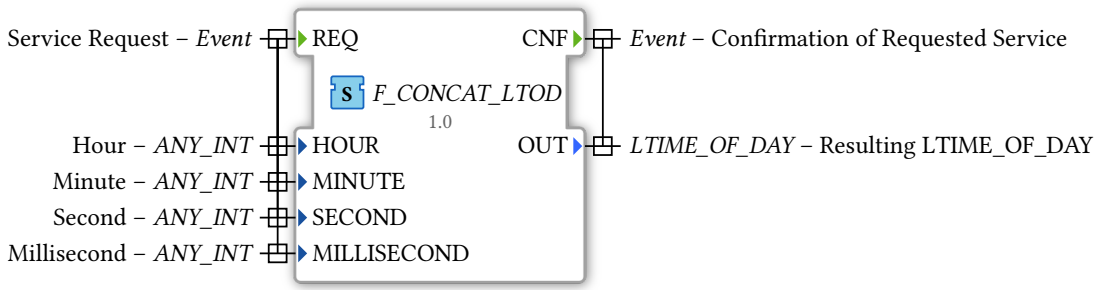
- **`ANY_INT` inputs**: The date/time components accept any integer type, simplifying wiring with differently typed source values.
- **No documented range checking**: The block assumes plausible input values (e.g. `MONTH` 1–12); explicit validation is the caller's responsibility.

State Overview

Stateless: every `REQ` immediately results in the merge and `CNF`.

Application Scenarios

- **Building timestamps** from separately captured or computed individual values, e.g. from sensor data, user input, or communication protocols.
- **Configuration evaluation**: Combining date/time components held in individual variables into a usable `LDATE_AND_TIME` value.



Comparison with similar function blocks

- F_SPLIT_LDT: the reverse direction — splits a `LDATE_AND_TIME` value into its individual components.
- **`F_CONCAT_DATE_TOD`**: instead combines an already-complete `DATE` and `TIME_OF_DAY` value into `DATE_AND_TIME`, rather than from individual fields.

Conclusion

`F_CONCAT_LDT` provides a simple, direct merge of individual date/time values into a `LDATE_AND_TIME` value, complementing the corresponding split function F_SPLIT_LDT.

F_CONCAT_LTOD

• – ◦ • – ◦ • – ◦ •

Introduction

`F_CONCAT_LTOD` combines individual date/time components (`HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`) into a composite `LTIME_OF_DAY` value. It is the reverse of F_SPLIT_LTOD, which splits the same `LTIME_OF_DAY` value back into its individual components.

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **HOUR** (ANY_INT): hour.
- **MINUTE** (ANY_INT): minute.
- **SECOND** (ANY_INT): second.
- **MILLISECOND** (ANY_INT): millisecond.

Data Outputs

- **OUT** (`LTIME_OF_DAY`): The value composed from the individual components.

Functionality

On `REQ`, the input values `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND` are combined into a `LTIME_OF_DAY` value and output via `OUT`. `CNF` is then triggered.

Technical Features

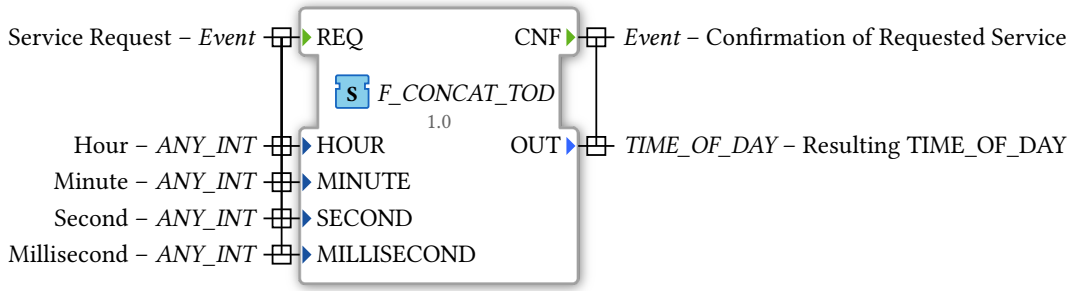
- **`ANY_INT` inputs**: The date/time components accept any integer type, simplifying wiring with differently typed source values.
- **No documented range checking**: The block assumes plausible input values (e.g. `MONTH` 1–12); explicit validation is the caller's responsibility.

State Overview

Stateless: every `REQ` immediately results in the merge and `CNF`.

Application Scenarios

- **Building timestamps** from separately captured or computed individual values, e.g. from sensor data, user input, or communication protocols.
- **Configuration evaluation**: Combining date/time components held in individual variables into a usable `LTIME_OF_DAY` value.



Comparison with similar function blocks

- F_SPLIT_LTOD: the reverse direction — splits a `LTIME_OF_DAY` value into its individual components.
- **`F_CONCAT_DATE_TOD`**: instead combines an already-complete `DATE` and `TIME_OF_DAY` value into `DATE_AND_TIME`, rather than from individual fields.

Conclusion

`F_CONCAT_LTOD` provides a simple, direct merge of individual date/time values into a `LTIME_OF_DAY` value, complementing the corresponding split function F_SPLIT_LTOD.

F_CONCAT_TOD

• – ◦ • – ◦ • – ◦ •

Introduction

`F_CONCAT_TOD` combines individual date/time components (`HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`) into a composite `TIME_OF_DAY` value. It is the reverse of F_SPLIT_TOD, which splits the same `TIME_OF_DAY` value back into its individual components.

Interface Structure

Event Inputs

- **REQ**: Triggers the merge, carries `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **HOUR** (ANY_INT): hour.
- **MINUTE** (ANY_INT): minute.
- **SECOND** (ANY_INT): second.
- **MILLISECOND** (ANY_INT): millisecond.

Data Outputs

- **OUT** (`TIME_OF_DAY`): The value composed from the individual components.

Functionality

On `REQ`, the input values `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND` are combined into a `TIME_OF_DAY` value and output via `OUT`. `CNF` is then triggered.

Technical Features

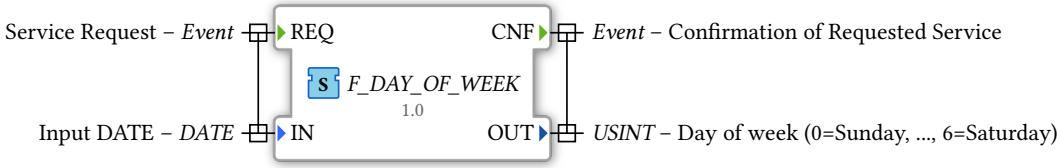
- **`ANY_INT` inputs**: The date/time components accept any integer type, simplifying wiring with differently typed source values.
- **No documented range checking**: The block assumes plausible input values (e.g. `MONTH` 1–12); explicit validation is the caller's responsibility.

State Overview

Stateless: every `REQ` immediately results in the merge and `CNF`.

Application Scenarios

- **Building timestamps** from separately captured or computed individual values, e.g. from sensor data, user input, or communication protocols.
- **Configuration evaluation**: Combining date/time components held in individual variables into a usable `TIME_OF_DAY` value.



Comparison with similar function blocks

- F_SPLIT_TOD: the reverse direction — splits a `TIME_OF_DAY` value into its individual components.
- **`F_CONCAT_DATE_TOD`**: instead combines an already-complete `DATE` and `TIME_OF_DAY` value into `DATE_AND_TIME`, rather than from individual fields.

Conclusion

`F_CONCAT_TOD` provides a simple, direct merge of individual date/time values into a `TIME_OF_DAY` value, complementing the corresponding split function F_SPLIT_TOD.

F_DAY_OF_WEEK

• – ◦ • – ◦ • – ◦ •

Introduction

`F_DAY_OF_WEEK` determines the day of the week, as a number, from a date (`DATE`). It is a simple calendar-calculation function block per IEC 61131-3.

Interface Structure

Event Inputs

- **REQ**: Triggers the calculation, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN** (DATE): The input date.

Data Outputs

- **OUT** (USINT): The day of the week (`0` = Sunday, `1` = Monday, ..., `6` = Saturday).

Functionality

On `REQ`, the algorithm's ST statement `OUT := DAY_OF_WEEK(IN)` computes the day of the week for `IN` and outputs it via `OUT`. `CNF` is then triggered.

Technical Features

- **`0–6` encoding**: Sunday is `0`, Saturday is `6` — this encoding should be kept in mind when comparing against other, possibly Monday-based day-of-week conventions.

State Overview

Stateless: every `REQ` immediately results in the calculation and `CNF`.

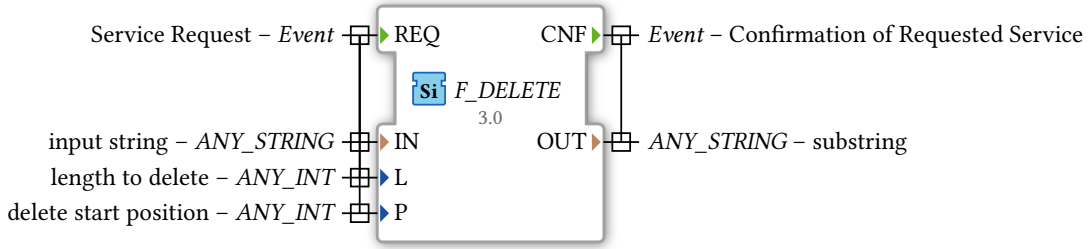
Application Scenarios

- **Day-of-week-dependent control logic**: e.g. different operating programs on weekdays vs. weekends.
- **Display/logging**: Outputting the day of the week alongside a date in displays or log entries.
- **Scheduling**: Checking whether a computed date falls on a particular day of the week.

Comparison with similar function blocks

- F_SPLIT_DATE: splits a date into year/month/day, but does not compute a day of the week.

Conclusion



`F_DAY_OF_WEEK` provides a simple calendar calculation to determine the day of the week from a `DATE` value and is suitable for day-of-week-dependent control and display logic.

F_DELETE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DELETE` is used to manipulate strings. It removes a specific number of characters (`L`) from an input string (`IN`), starting at a defined position (`P`). The result is output as a new string (`OUT`).

Interface Structure

Event Inputs

- **REQ**: Starts the processing of the function block. The corresponding data are `IN`, `L`, and `P`.

Event Outputs

- **CNF**: Signals successful processing and returns the result `OUT`.

Data Inputs

- **IN**: The input string from which characters are to be removed (Type: `ANY_STRING`).
- **L**: The number of characters to be removed (Type: `ANY_INT`).
- **P**: The starting position from which characters are to be removed (Type: `ANY_INT`).

Data Outputs

- **OUT**: The resulting string after character removal (Type: `ANY_STRING`).

Adapters

No adapters available.

Functionality

1. The function block is activated by the event `REQ`.
2. Characters `L` are removed from the string `IN`, starting at position `P`.
3. The result is stored in `OUT`, and the event `CNF` is triggered.

Technical Features

- The function block supports various string types (`ANY_STRING`), allowing for flexible use.
- The position `P` and the length `L` must be valid values within the length of `IN` to ensure correct results.

State Overview

1. **Idle**: Waits for the event `REQ`.
2. **Processing**: Processes the input data and removes the characters.
3. **Completed**: Outputs the result and signals `CNF`.

Application Scenarios

- Cleansing user input.
- Processing protocol or log data.
- Manipulating text data in automated processes.

⚖️ Comparison with Similar Building Blocks

- **F_INSERT**: Inserts characters at a specific position.
- **F_REPLACE**: Replaces characters in a string.
- **F_SUBSTRING**: Extracts a substring from a string.

Conclusion

The `F_DELETE` function block is a useful tool for manipulating strings in the 4diac IDE. Its simple and flexible interface allows it to be used in various applications to remove characters from strings.

F_FIND

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_FIND` determines the position of the first occurrence of a string (IN2) within another string (IN1). If the searched string is not found, the block returns the value 0.

Interface Structure

Event Inputs

- **REQ**: Starts the search for the string. Inputs IN1 and IN2 are linked to this event.

Event Outputs

- **CNF**: Confirms the completion of the search operation. Output OUT is linked to this event.

Data Inputs

- **IN1** (ANY_STRING): The string to be searched.
- **IN2** (ANY_STRING): The string to search for.

Data Outputs

- **OUT** (ANY_INT): The position of the first occurrence of IN2 in IN1. If not found, 0 is returned.

Adapters

No adapters are present.

Functionality

The function block `F_FIND` searches the string IN1 for the first occurrence of the string IN2. The position of the first character of the found string is returned as the result. If IN2 is not contained in IN1, 0 is returned.

Technical Features

- Supports any string type (ANY_STRING).
- Returns any integer type (ANY_INT).
- The search is case-sensitive.

State Overview

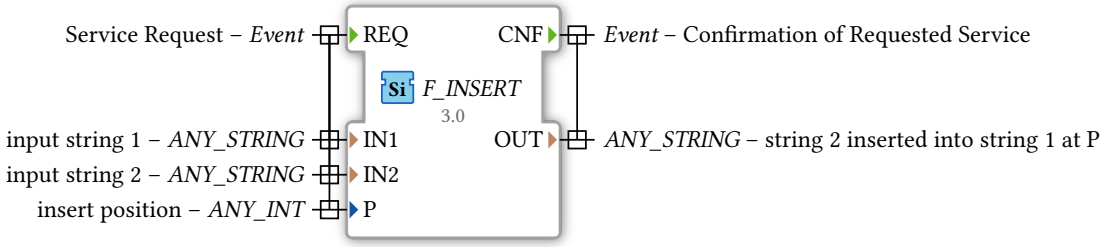
1. **Idle**: Waiting for the REQ event.
2. **Processing**: Searches IN1 for IN2.
3. **Completed**: Sends the CNF event with the result.

Application Scenarios

- Searching for substrings in text.
- Validating input data.
- Processing strings in automation processes.

⚖️ Comparison with Similar Blocks

- Compared to `F_FIND_STRING`, `F_FIND` offers similar functionality but is specifically for searching for the first position of a substring.
- Other blocks, such as `F_MID` or `F_LEFT`, offer additional string manipulation capabilities but lack a search function.



Conclusion

The `F_FIND` function block is a useful tool for searching for substrings in automation applications. Its simple and efficient implementation makes it ideal for integration into more complex control logic.

F_INSERT

• – ◦ • – ◦ • – ◦ •

The function block F_INSERT is used to manipulate character strings. It inserts one character string (IN2) into another character string (IN1) at a specific position (P). The block is part of the standard character and string functions according to IEC 61131-3.

- REQ: Service request. Triggers the execution of the function block. Linked to the data inputs IN1, IN2, and P.
- CNF: Confirmation of the requested service. Linked to the data output OUT.
- IN1 (ANY_STRING): The first input string into which IN2 is inserted.
- P (ANY_INT): The position in IN1 where IN2 is to be inserted.
- OUT (ANY_STRING): The resulting string after the insertion operation.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters available.

When the event REQ is triggered, the string IN2 is inserted into the string IN1 at the position defined by P. The result of this operation is output via the data output OUT, and the event CNF is triggered to indicate successful processing.

- Supports all string types (ANY_STRING), allowing for flexible use.
- The position P can be any integer value (ANY_INT), but must be within the length of IN1 to ensure defined behavior.

The function block has no internal state. The operation is re-executed with each REQ event.

- Text processing in automation applications.
- Dynamic creation of log messages or notifications.
- Manipulation of data strings before further processing or output.
- Similar to F_CONCAT, which, however, simply concatenates two strings without considering a specific insertion position.

Unlike F_MID, which extracts parts of a string, F_INSERT inserts one string into another.

`F_INSERT`` is a useful function block for applications that require precise string manipulation. Its simple yet effective functionality makes it a valuable tool in automation engineering.

F_LEFT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LEFT` extracts the leftmost characters `L` from the input string `IN`. It is part of the standard character and string functions according to IEC 61131-3.

Interface Structure

Event Inputs

- **REQ**: Starts the string extraction. It is linked to the data inputs `IN` and `L`.

Event Outputs

- **CNF**: Confirms successful extraction. Linked to data output `OUT`.

Data Inputs

- **IN** (`ANY_STRING`): The input string from which the leftmost characters are to be extracted.
- **L** (`ANY_INT`): The number of characters to be extracted from the left.

Data Outputs

- **OUT** (`ANY_STRING`): The extracted substring consisting of the leftmost characters of `L` from `IN`.

Adapters

No adapters are available.

Adapters ## Functionality

When the event `REQ` is triggered, the function block extracts the first characters `L` from the input string `IN` and outputs the result as `OUT`. The event `CNF` signals successful execution.

Technical Features

- Supports all string types (`ANY_STRING`).
- `L` must be a valid integer value. If `L` is greater than the length of `IN`, the entire string is returned.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Processes the input and extracts the characters.
3. **Completed**: Sends `CNF` with the result.

Application Scenarios

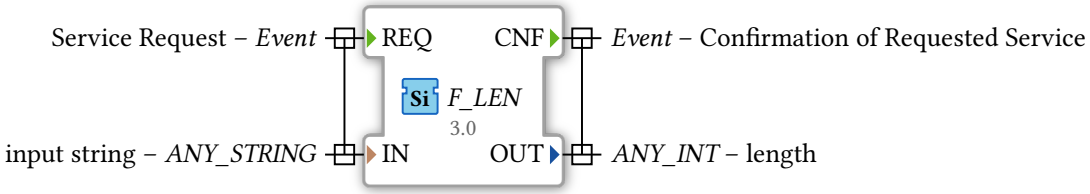
- Extracting prefixes from strings.

- Shortening strings for specific requirements.

⚖️ Comparison with Similar Function Blocks

- **F_RIGHT**: Extracts characters from the right.
- **F_MID**: Extracts characters from the middle of a string.

Conclusion



F_LEFT` is a simple and efficient function block for extracting substrings from the beginning of a string. Its use is intuitive and it meets the requirements of IEC 61131-3.

F_LEN

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LEN` is used to determine the length of an input string. It is part of the standard library for character and string functions according to IEC 61131-3.

Interface Structure

Event Inputs

- `REQ`: Service request. When this event is triggered, the string length calculation begins.

Event Outputs

- `CNF`: Acknowledgement of the service request. Triggered as soon as the calculation is complete.

Data Inputs

- `IN` (ANY_STRING): The input string whose length is to be determined.

Data Outputs

- `OUT` (ANY_INT): The length of the input string.

Adapters

No adapters available.

Functionality

The function block `F_LEN` calculates the length of the passed string (`IN`) and outputs the result as an integer (`OUT`). The calculation is started by the event `REQ` and confirmed by `CNF`.

Technical Features

- Supports all string types (`ANY_STRING`).
- Returns the length as an integer type (`ANY_INT`).

State Overview

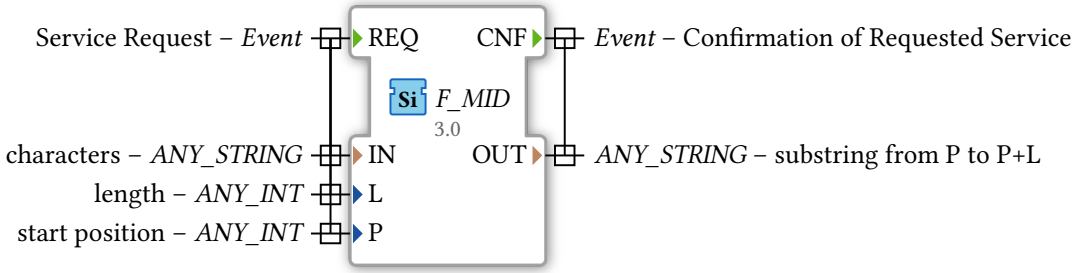
1. **Idle State**: Waits for the `REQ` event.
2. **Calculation State**: Calculates the string length.
3. **Acknowledgement State**: Sends the `CNF` event with the calculated length.

Application Scenarios

- Checking the length of user input.
- Validating string data before further processing.
- Logging and debugging string operations.

⚖️ Comparison with Similar Function Blocks

- Similar to `LEN` in other programming languages, but a standardized function block in IEC 61131-3.
- Unlike `F_MID` or `F_LEFT`, which extract parts of a string, `F_LEN` only returns the length.



Conclusion

The `F_LEN` function block is a simple yet essential tool for string processing in IEC 61131-3 environments. Its clear interface and straightforward functionality make it a reliable building block for diverse applications.

F_MID

• – ◦ • – ◦ • – ◦ •

The function block `F_MID` is used to extract a substring from a given string. A specific number of characters are extracted starting from a defined position. This function block is part of the standard character and string functions according to IEC 61131-3.

- **REQ**: Service request to execute the extraction. This is linked to the data inputs `IN`, `L`, and `P`.
- **CNF**: Confirmation of successful request execution. Linked to the data output `OUT`.
- **IN**: The input string from which the substring is to be extracted (Type: `ANY_STRING`).
- **L**: The length of the substring to be extracted (Type: `ANY_INT`).
- **P**: The starting position from which the extraction should begin (Type: `ANY_INT`).
- **OUT**: The extracted substring (Type: `ANY_STRING`).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- No adapters available.

The function block `F_MID` extracts a substring from the input string `IN`. The extraction begins at position `P` and includes `L` characters. The result is output via output `OUT` as soon as the event output `CNF` is triggered.

- The function block supports any string type (`ANY_STRING`) and integer type (`ANY_INT`).
- The function block supports arbitrary string types (`ANY_STRING`) and integer types (`ANY_INT`).
- The start position `P` and the length `L` must be valid values within the length of the input string to ensure correct results.

1. **Initialization**: The function block waits for a request via `REQ`.
2. **Processing**: Upon receiving `REQ`, the input data is processed and the substring is extracted.
3. **Output**: The extracted substring is output via `OUT`, and `CNF` is triggered.

- Extraction of substrings from longer texts or data strings.
- Use in string processing routines, e.g., for parsing data formats.

- Similar function blocks like `F_LEFT` or `F_RIGHT` extract substrings from the beginning or end of a string, while `F_MID` allows for flexible extraction from any position.

The `F_MID` function block offers a simple and efficient way to extract substrings from a given string. Its flexibility and compatibility with various string and integer types make it a useful tool in string manipulation.

F_REPLACE

• – ◦ • – ◦ • – ◦ •

Introduction

The F_REPLACE function block is used to manipulate strings. It replaces a specific number of characters (L) in the first input string (IN1) with the second input string (IN2), starting at a specified position (P).

Interface Structure

Event Inputs

- **REQ**: Service request. Triggers the replacement operation. Linked to the data inputs IN1, IN2, L, and P.

Event Outputs

- **CNF**: Confirmation of the requested service. Triggered when the replacement is complete. Linked to the data output OUT.

Data Inputs

- **IN1** (ANY_STRING): The first input string in which the replacement is performed.
- **IN2** (ANY_STRING): The second input string used as a replacement.
- **L** (ANY_INT): The number of characters to be replaced.
- **P** (ANY_INT): The starting position for the replacement in IN1.

Data Outputs

- **OUT** (ANY_STRING): The resulting string after the replacement.

Adapters

No adapters available.

Operation

The function block performs the following operation:

1. Upon receiving the REQ event, the input values IN1, IN2, L, and P are read.

2. In the string IN1, exactly L characters are replaced with the string IN2, starting at position P.
3. The result is stored in OUT, and the CNF event is triggered.

Technical Features

- Supports any string type (ANY_STRING).
- The position P and length L must be valid indices within the string IN1 to ensure correct results.

State Overview

The function block has no internal states. The operation is re-executed with each REQ event.

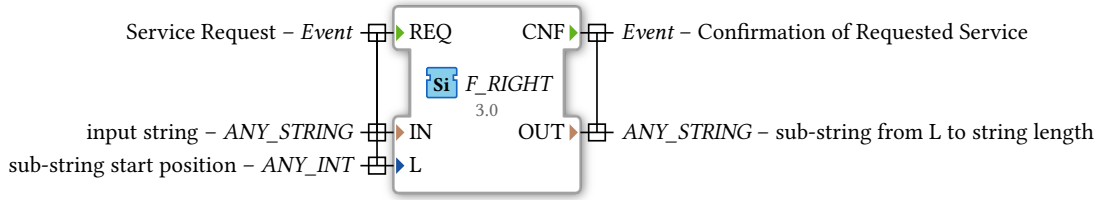
Application Scenarios

- Text processing in automation applications.
- String manipulation in protocol messages.
- Dynamic adjustment of configuration strings.

⚖️ Comparison with Similar Function Blocks

- Similar to F_INSERT, however, F_REPLACE replaces existing characters instead of inserting new ones.
- Unlike F_DELETE, F_REPLACE replaces existing characters with new ones.

Conclusion



F_REPLACE is a useful function block for string manipulation in IEC 61131-3-based controllers. Its simple and clear functionality makes it ideal for various applications in automation technology.

F_RIGHT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_RIGHT` is a standard function block for processing character strings according to the IEC 61131-3 standard. It extracts the rightmost characters `L` from the input string `IN` and outputs them as the result `OUT`. This function block is particularly useful in applications where parts of character strings need to be processed or analyzed.

Interface Structure

Event Inputs

- **REQ**: Service Request. Triggers the extraction of the rightmost characters `L`. Linked to the data `IN` and `L`.

Event Outputs

- **CNF**: Confirmation of the requested service. Linked to the result `OUT`.

Data Inputs

- **IN**: Input string from which the rightmost characters are to be extracted. The data type is `ANY_STRING`.
- **L**: Number of characters to be extracted from the right of the input string. The data type is `ANY_INT`.

Data Outputs

- **OUT**: Result string containing the extracted characters. The data type is `ANY_STRING`.

Adapters

This function block has no adapters.

Functionality

When the event `REQ` is triggered, the input string `IN` is processed. The function block extracts the rightmost characters `L` from `IN` and outputs the result via the output `OUT`. The event `CNF` signals successful processing and provides the result.

Technical Features

- Supports various string types (`ANY_STRING`), allowing for flexible use.
- The position `L` can be specified using various integer types (`ANY_INT`).
- This function block is part of the `iec61131::charString` package.

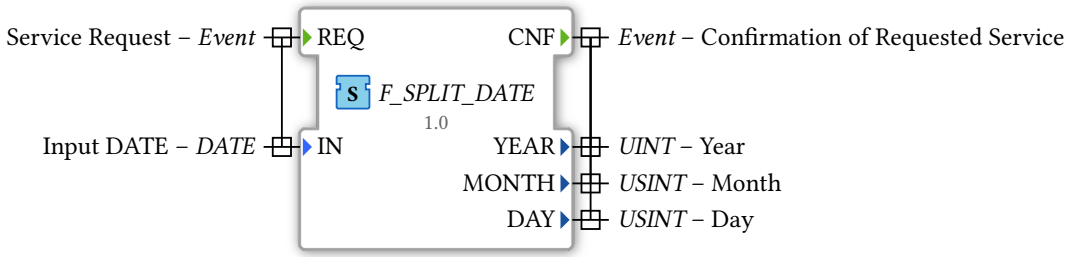
State Overview

The function block has no internal states. Processing occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Extracting file extensions from filenames.
- Processing fixed-length string formats where relevant information is located at the end of the string.
- General string manipulation in control and automation applications.

⚖️ Comparison with Similar Function Blocks



- Compared to `F_LEFT`, which extracts the leftmost characters of a string, `F_RIGHT` offers the opposite functionality.

Other string function blocks, such as `F_MID`, allow the extraction of substrings from the middle of a string, while `F_RIGHT` focuses specifically on the rightmost characters.

Conclusion

The function block `F_RIGHT` is a simple and effective building block for extracting characters from the end of a string. Its flexibility regarding supported data types makes it a versatile tool for string manipulation.

F_SPLIT_DATE

• – ◦ • – ◦ • – ◦ •

Introduction

`F_SPLIT_DATE` splits a `DATE` value into its individual date/time components (`YEAR`, `MONTH`, `DAY`). It is the reverse of F_CONCAT_DATE, which combines the same individual components back into a `DATE` value.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `YEAR`, `MONTH`, `DAY`.

Data Inputs

- **IN** (`DATE`): The date/time value to split.

Data Outputs

- **YEAR** (UINT): year.

- **MONTH** (USINT): month.
- **DAY** (USINT): day.

Functionality

On `REQ`, `IN` is split into its individual components, output via `YEAR`, `MONTH`, `DAY`. `CNF` is then triggered.

Technical Features

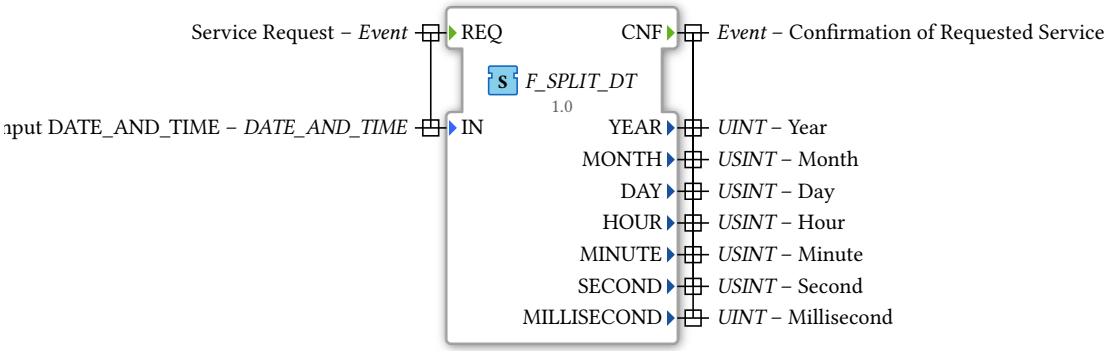
- **Fixed output types**: Unlike F_CONCAT_DATE (generic `ANY_INT`), the outputs here are fixed to concrete integer types chosen to fit each value's range (e.g. `USINT` for month/day, whose range is small).

State Overview

Stateless: every `REQ` immediately results in the split and `CNF`.

Application Scenarios

- **Displaying/processing individual date/time components**, e.g. for a formatted display on a panel or for calculations that only need a specific component.
- **Logging**: Breaking a timestamp down into its individual values for structured log output.



Comparison with similar function blocks

- **F_CONCAT_DATE**: the reverse direction — combines individual components into a `DATE` value.

Conclusion

`F_SPLIT_DATE` provides a simple, direct split of a `DATE` value into its individual components, complementing the corresponding merge function F_CONCAT_DATE.

F_SPLIT_DT

• – ◦ • – ◦ • – ◦ •

Introduction

`F_SPLIT_DT` splits a `DATE_AND_TIME` value into its individual date/time components (`YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`). It is the reverse of F_CONCAT_DT, which combines the same individual components back into a `DATE_AND_TIME` value.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`.

Data Inputs

- **IN** (`DATE_AND_TIME`): The date/time value to split.

Data Outputs

- **YEAR** (UINT): year.

- **MONTH** (USINT): month.
- **DAY** (USINT): day.
- **HOUR** (USINT): hour.
- **MINUTE** (USINT): minute.
- **SECOND** (USINT): second.
- **MILLISECOND** (UINT): millisecond.

Functionality

On `REQ`, `IN` is split into its individual components, output via `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`. `CNF` is then triggered.

Technical Features

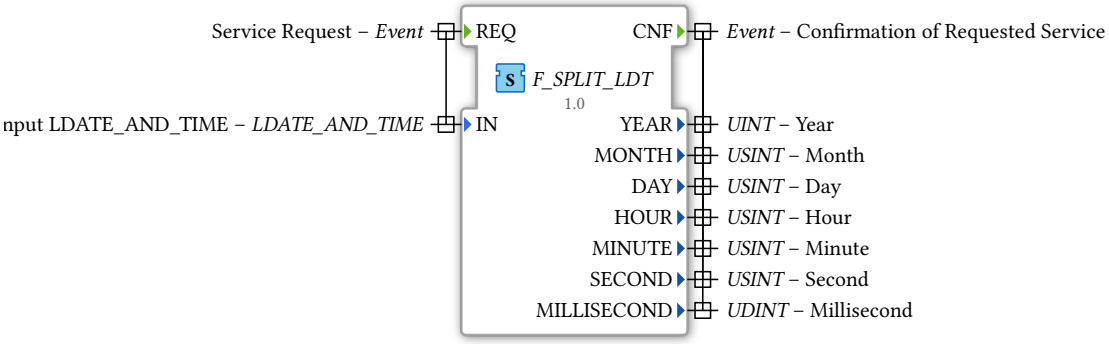
- **Fixed output types**: Unlike F_CONCAT_DT (generic `ANY_INT`), the outputs here are fixed to concrete integer types chosen to fit each value's range (e.g. `USINT` for month/day, whose range is small).

State Overview

Stateless: every `REQ` immediately results in the split and `CNF`.

Application Scenarios

- **Displaying/processing individual date/time components**, e.g. for a formatted display on a panel or for calculations that only need a specific component.
- **Logging**: Breaking a timestamp down into its individual values for structured log output.



Comparison with similar function blocks

- **F_CONCAT_DT**: the reverse direction — combines individual components into a `DATE_AND_TIME` value.

Conclusion

`F_SPLIT_DT` provides a simple, direct split of a `DATE_AND_TIME` value into its individual components, complementing the corresponding merge function F_CONCAT_DT.

F_SPLIT_LDT

• – ◦ • – ◦ • – ◦ •

Introduction

`F_SPLIT_LDT` splits a `LDATE_AND_TIME` value into its individual date/time components (`YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`). It is the reverse of F_CONCAT_LDT, which combines the same individual components back into a `LDATE_AND_TIME` value.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`.

Data Inputs

- **IN** (`LDATE_AND_TIME`): The date/time value to split.

Data Outputs

- **YEAR** (UINT): year.
- **MONTH** (USINT): month.
- **DAY** (USINT): day.
- **HOUR** (USINT): hour.
- **MINUTE** (USINT): minute.
- **SECOND** (USINT): second.
- **MILLISECOND** (UDINT): millisecond.

Functionality

On `REQ`, `IN` is split into its individual components, output via `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`. `CNF` is then triggered.

Technical Features

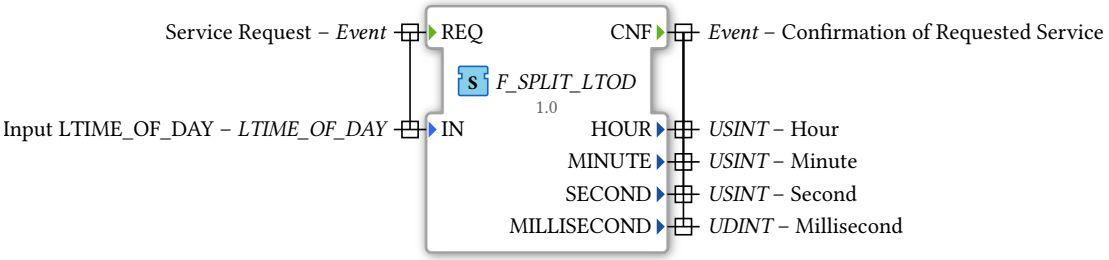
- **Fixed output types**: Unlike F_CONCAT_LDT (generic `ANY_INT`), the outputs here are fixed to concrete integer types chosen to fit each value's range (e.g. `USINT` for month/day, whose range is small).

State Overview

Stateless: every `REQ` immediately results in the split and `CNF`.

Application Scenarios

- **Displaying/processing individual date/time components**, e.g. for a formatted display on a panel or for calculations that only need a specific component.
- **Logging**: Breaking a timestamp down into its individual values for structured log output.



Comparison with similar function blocks

- **F_CONCAT_LDT**: the reverse direction — combines individual components into a `LDATE_AND_TIME` value.

Conclusion

`F_SPLIT_LDT` provides a simple, direct split of a `LDATE_AND_TIME` value into its individual components, complementing the corresponding merge function F_CONCAT_LDT.

F_SPLIT_LTOD

• – ◦ • – ◦ • – ◦ •

Introduction

`F_SPLIT_LTOD` splits a `LTIME_OF_DAY` value into its individual date/time components (`HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`). It is the reverse of F_CONCAT_LTOD, which combines the same individual components back into a `LTIME_OF_DAY` value.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`.

Data Inputs

- **IN** (`LTIME_OF_DAY`): The date/time value to split.

Data Outputs

- **HOUR** (USINT): hour.
- **MINUTE** (USINT): minute.
- **SECOND** (USINT): second.
- **MILLISECOND** (UDINT): millisecond.

Functionality

On `REQ`, `IN` is split into its individual components, output via `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`. `CNF` is then triggered.

Technical Features

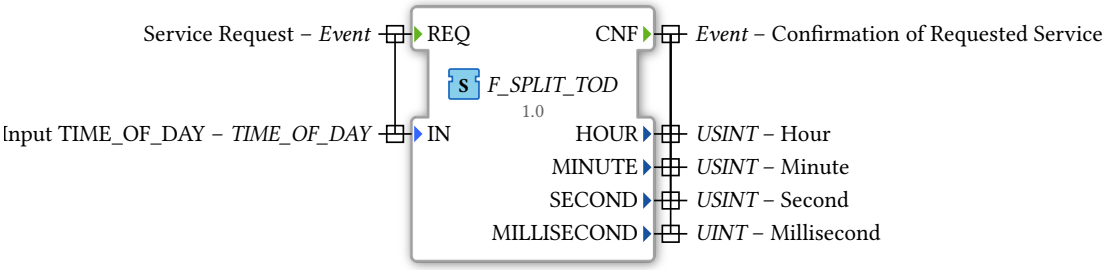
- **Fixed output types**: Unlike F_CONCAT_LTOD (generic `ANY_INT`), the outputs here are fixed to concrete integer types chosen to fit each value's range (e.g. `USINT` for month/day, whose range is small).

State Overview

Stateless: every `REQ` immediately results in the split and `CNF`.

Application Scenarios

- **Displaying/processing individual date/time components**, e.g. for a formatted display on a panel or for calculations that only need a specific component.
- **Logging**: Breaking a timestamp down into its individual values for structured log output.



Comparison with similar function blocks

- **F_CONCAT_LTOD**: the reverse direction — combines individual components into a `LTIME_OF_DAY` value.

Conclusion

`F_SPLIT_LTOD` provides a simple, direct split of a `LTIME_OF_DAY` value into its individual components, complementing the corresponding merge function F_CONCAT_LTOD.

F_SPLIT_TOD

• – ◦ • – ◦ • – ◦ •

Introduction

`F_SPLIT_TOD` splits a `TIME_OF_DAY` value into its individual date/time components (`HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`). It is the reverse of F_CONCAT_TOD, which combines the same individual components back into a `TIME_OF_DAY` value.

Interface Structure

Event Inputs

- **REQ**: Triggers the split, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`.

Data Inputs

- **IN** (`TIME_OF_DAY`): The date/time value to split.

Data Outputs

- **HOUR** (USINT): hour.
- **MINUTE** (USINT): minute.
- **SECOND** (USINT): second.
- **MILLISECOND** (UINT): millisecond.

Functionality

On `REQ`, `IN` is split into its individual components, output via `HOUR`, `MINUTE`, `SECOND`, `MILLISECOND`. `CNF` is then triggered.

Technical Features

- **Fixed output types**: Unlike F_CONCAT_TOD (generic `ANY_INT`), the outputs here are fixed to concrete integer types chosen to fit each value's range (e.g. `USINT` for month/day, whose range is small).

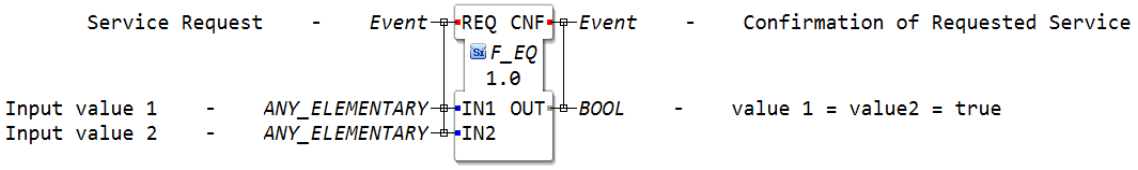
State Overview

Stateless: every `REQ` immediately results in the split and `CNF`.

Application Scenarios

- **Displaying/processing individual date/time components**, e.g. for a formatted display on a panel or for calculations that only need a specific component.
- **Logging**: Breaking a timestamp down into its individual values for structured log output.

Comparison with similar function blocks



- **F_CONCAT_TOD**: the reverse direction — combines individual components into a `TIME_OF_DAY` value.

Conclusion

`F_SPLIT_TOD` provides a simple, direct split of a `TIME_OF_DAY` value into its individual components, complementing the corresponding merge function F_CONCAT_TOD.

The EQ Operator in IEC 61499: An Introduction

IEC 61499 is a standard that deals with function block modeling for industrial process measurement and control systems. It provides a framework for developing distributed control systems based on the use of function blocks. A central element of this standard is the definition of operators used in the function blocks to perform logical and arithmetic operations. One of these operators is the EQ operator, which will be examined in more detail in this paper.

What is the EQ operator?

The EQ operator, also known as the equality operator, is a logical operator used to check whether two values are equal. In IEC 61499, this operator is frequently used in function blocks to evaluate conditions and make decisions. The EQ operator compares two input values and returns a Boolean value (TRUE or FALSE) depending on whether the values are equal or not.

Syntax and Usage

In IEC 61499, the EQ operator is typically used in the expressions of function blocks. The syntax of the EQ operator is simple:

EQ(Eingang1, Eingang2) Here, `Eingang1` and `Eingang2` are the two values to be compared. The operator returns `TRUE` if `Eingang1` and `Eingang2` are equal; otherwise, the return value is `FALSE`.

Application Examples

1. **Comparison of Sensor Values:**

Suppose a function block needs to check if two sensors are returning the same value. The EQ operator can be used to compare the values of the two sensors:

IF EQ(Sensor1, Sensor2) THEN

1. **Controlling Process Steps:**

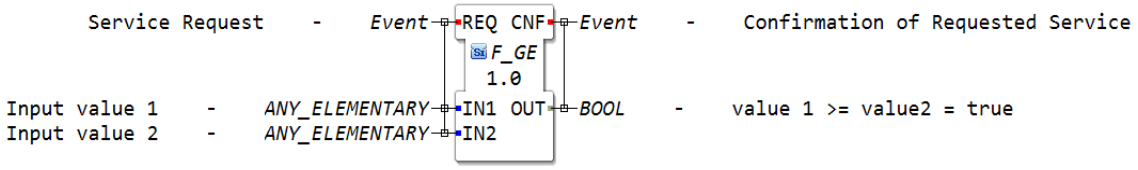
In a production process, the EQ operator can be used to check whether a specific process step has been completed. If the current step equals the target step, the next step can be initiated:

IF EQ(AktuellerSchritt, ZielSchritt) THEN

1. **Error Detection:**

The EQ operator can also be used for error detection. For example, if a target value and an actual value are compared and they do not match, an error signal can be generated:

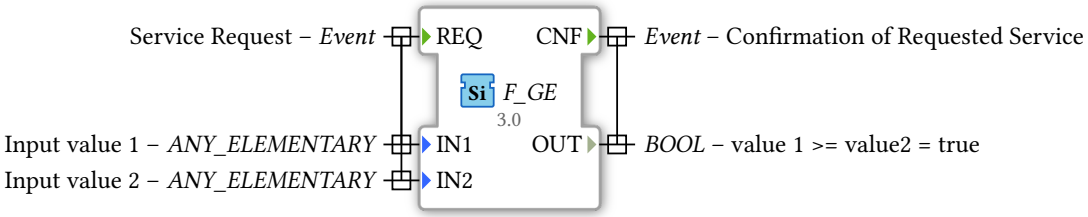
IF NOT EQ(Sollwert, Istwert) THEN



Advantages of the EQ Operator

- **Simplicity:** The EQ operator is easy to understand and use, which simplifies the development of control logic.
- **Flexibility:** The operator can be applied to various data types, including integers, floating-point numbers, and even Boolean values.
- **Efficiency:** Because the EQ operator can be used directly in function blocks, it reduces the need for additional logic and makes the code more efficient.

Conclusion



The EQ operator is a fundamental tool in IEC 61499 that simplifies the implementation of logical comparisons in industrial control systems. Its simple syntax and versatile applicability contribute to the development of robust and efficient control algorithms. Whether in sensor monitoring, process control, or fault detection, the EQ operator is an indispensable element in the world of industrial automation.

The GE Operator in IEC 61499: An Introduction

IEC 61499 is an international standard that deals with the modeling of function blocks for industrial automation systems. It provides a standardized framework for the development of distributed control systems, in which logical and arithmetic operators play a central role. One of these operators is the **GE Operator** (Greater Than or Equal To), which will be examined in more detail in this article.

What is the GE Operator?

The GE operator is a comparison operator used to determine whether one value is greater than or equal to another. In IEC 61499, this operator is frequently used in function blocks to evaluate conditions and make decisions based on numerical comparisons. The GE operator compares two input values and returns a Boolean value (`TRUE` or `FALSE`) depending on whether the first value is greater than or equal to the second.

Syntax and Usage

In IEC 61499, the GE operator is used in function block expressions. The syntax of the GE operator is as follows:

GE(Eingang1, Eingang2) Here, `Eingang1` and `Eingang2` are the two values to be compared. The operator returns `TRUE` if `Eingang1` is greater than or equal to `Eingang2`; otherwise, the return value is `FALSE`.

Application Examples

1. **Monitoring Limit Values:**

In industrial processes, it is often necessary to monitor limit values. The GE operator can be used to check whether a measured value reaches or exceeds a specific threshold:
IF GE(Messwert, Schwellenwert) THEN

1. **Controlling Production Processes:**

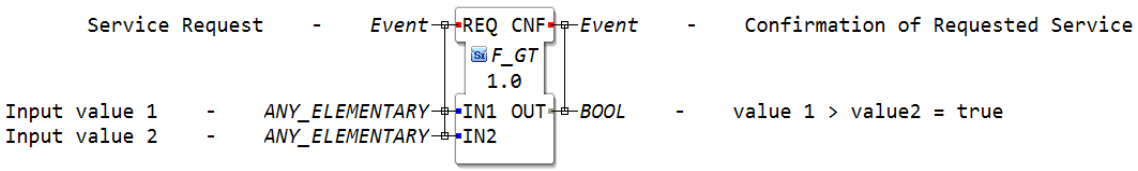
In a production process, the GE operator can be used to determine whether a specific quantity of material has been produced. If the produced quantity is greater than or equal to the target quantity, the process can be stopped:
IF GE(ProduzierteMenge, ZielMenge) THEN

1. **Temperature Control:**

In a heating system, the GE operator can be used to check whether the current temperature has reached or exceeded the setpoint. If so, the heating can be switched off:
IF GE(AktuelleTemperatur, SollTemperatur) THEN

1. **Energy Consumption Monitoring:**

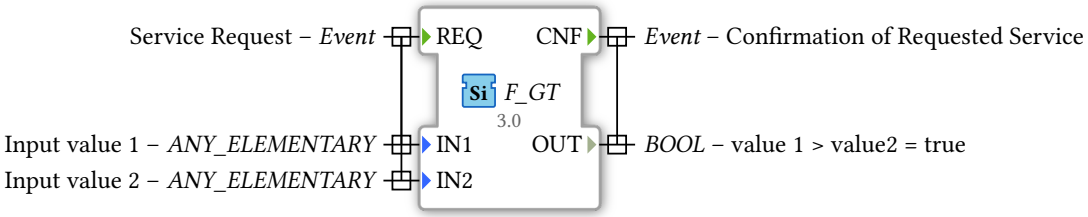
The GE Operator can also be used to monitor energy consumption. If consumption exceeds a certain threshold, energy-saving measures can be initiated:
IF GE(EnergieVerbrauch, Grenzwert) THEN



Advantages of the GE Operator

- **Simple Logic:** The GE operator allows complex conditions to be formulated in simple, easily understandable expressions.
- **Flexibility:** The operator can be applied to various numeric data types, including integers and floating-point numbers.
- **Efficiency:** By being directly integrated into function blocks, the GE operator reduces the need for additional programming and makes the code more efficient.
- **Robustness:** The GE operator helps to develop robust control algorithms based on precise numerical comparisons.

Conclusion



The GE operator is an important tool in IEC 61499 that simplifies the implementation of numerical comparisons in industrial control systems. Its ability to determine whether one value is greater than or equal to another makes it an indispensable component in process monitoring, control, and decision-making. Whether in production control, temperature regulation, or energy consumption monitoring – the GE Operator is a powerful and versatile element in the world of industrial automation. Its simplicity and efficiency contribute to the development of reliable and effective control systems.

The LE Operator in IEC 61499: An Introduction

IEC 61499 is an international standard that deals with the modeling of function blocks for industrial automation systems. It provides a standardized framework for the development of distributed control

systems, in which logical and arithmetic operators play a central role. One of these operators is the **LE operator** (Less Than or Equal To), which will be examined in more detail in this paper.

What is the LE operator?

The LE operator is a comparison operator used to determine whether one value is less than or equal to another. In IEC 61499, this operator is frequently used in function blocks to evaluate conditions and make decisions based on numerical comparisons. The LE operator compares two input values and returns a Boolean value (`TRUE` or `FALSE`) depending on whether the first value is less than or equal to the second.

Syntax and Usage

In IEC 61499, the LE operator is used in function block expressions. The syntax of the LE operator is as follows:

LE(Eingang1, Eingang2) Here, `Eingang1` and `Eingang2` are the two values to be compared. The operator returns `TRUE` if `Eingang1` is less than or equal to `Eingang2`; otherwise, the return value is `FALSE`.

Application Examples

1. **Monitoring Limit Values:**

In industrial processes, it is often necessary to monitor limit values. The LE operator can be used to check whether a measured value is below or equal to a specific threshold:

IF LE(Messwert, Schwellenwert) THEN

1. **Controlling Production Processes:**

In a production process, the LE operator can be used to determine whether a specific quantity of material has been produced. If the produced quantity is less than or equal to the target quantity, the process can continue:

IF LE(ProduzierteMenge, ZielMenge) THEN

1. **Temperature Control:**

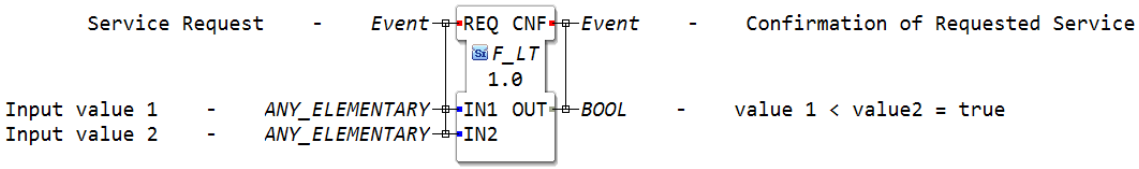
In a cooling system, the LE operator can be used to check whether the current temperature is less than or equal to the set temperature. If so, the cooling can be switched off:

IF LE(AktuelleTemperatur, SollTemperatur) THEN

1. **Energy Consumption Monitoring:**

The LE operator can also be used to monitor energy consumption. If consumption is less than or equal to a certain value, energy-saving measures can be deactivated:

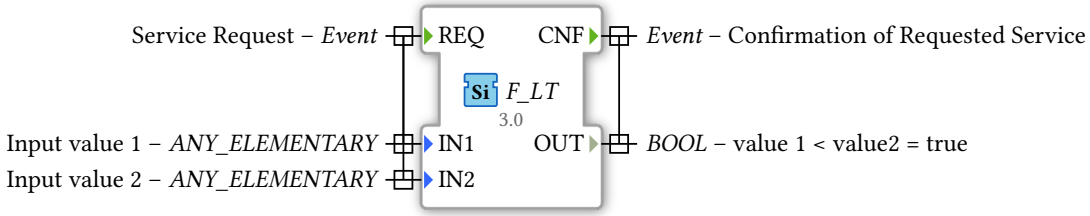
IF LE(EnergieVerbrauch, Grenzwert) THEN



Advantages of the LE Operator

- **Simple Logic:** The LE operator allows complex conditions to be formulated in simple, easily understandable expressions.
- **Flexibility:** The operator can be applied to various numeric data types, including integers and floating-point numbers.
- **Efficiency:** By being directly integrated into function blocks, the LE operator reduces the need for additional programming and makes the code more efficient.
- **Robustness:** The LE operator helps to develop robust control algorithms based on precise numerical comparisons.

Conclusion



The LE operator is an important tool in IEC 61499 that simplifies the implementation of numerical comparisons in industrial control systems. Its ability to determine whether one value is less than or equal to another makes it an indispensable component in process monitoring, control, and decision-making. Whether in production control, temperature regulation, or energy consumption monitoring – the LE operator is a powerful and versatile element in the world of industrial automation. Its simplicity and efficiency contribute to the development of reliable and effective control systems.

The following text was generated by https://chat.deepseek.com/ on February 5, 2025, and has not yet been proofread (HF)

The NE Operator in IEC 61499: An Introduction

IEC 61499 is an international standard that deals with the modeling of function blocks for industrial automation systems. It provides a standardized framework for the development of distributed control systems, in which logical and arithmetic operators play a central role. One of these operators is the **NE operator** (Not Equal), which will be examined in more detail in this article.

Interface

Event Inputs

- `REQ`: Service request (with `IN1`, `IN2`)

Event Outputs

- `CNF`: Confirmation of the requested operation (with `OUT`)

Data Inputs

- `IN1` (ANY_ELEMENTARY): Input value 1
- `IN2` (ANY_ELEMENTARY): Input value 2

Data Outputs

- `OUT` (BOOL): value 1 <> value 2 = TRUE

What is the NE operator?

The NE operator is a comparison operator used to determine whether two values are unequal. In IEC 61499, this operator is frequently used in function blocks to evaluate conditions and make decisions based on comparisons. The NE operator compares two input values and returns a Boolean value (`TRUE` or `FALSE`) depending on whether the values are unequal.

Syntax and Usage

In IEC 61499, the NE operator is used in function block expressions. The syntax of the NE operator is as follows:

NE(Eingang1, Eingang2) Here, `Eingang1` and `Eingang2` are the two values to be compared. The operator returns `TRUE` if `Eingang1` is not equal to `Eingang2`; otherwise, the return value is `FALSE`.

Application Examples

1. **Monitoring Sensor Values:**

In industrial processes, it is often necessary to monitor sensor values. The NE operator can be used to check whether two sensors are providing different values:

IF NE(Sensor1, Sensor2) THEN

1. **Control of Production Processes:**

In a production process, the NE operator can be used to determine whether a specific process step is not yet complete. If the current step is not the target step, the process can continue:

IF NE(AktuellerSchritt, ZielSchritt) THEN

1. **Temperature Control:**

In a heating system, the NE operator can be used to check if the current temperature is not equal to the set temperature. If this is the case, the heating can remain activated:

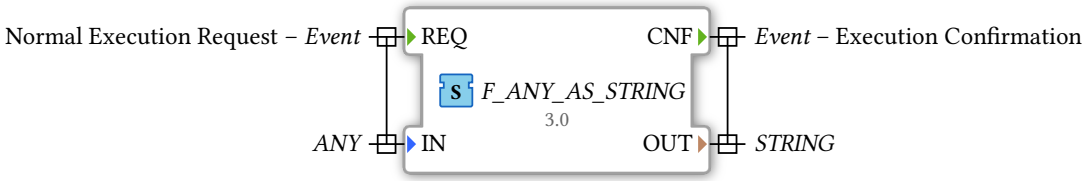
IF NE(AktuelleTemperatur, SollTemperatur) THEN

1. **Error Detection:**

The NE operator can also be used for error detection. For example, if a setpoint and an actual value are compared and they do not match, an error signal can be generated:

IF NE(Sollwert, Istwert) THEN

Advantages of the NE Operator



- **Simple Logic:** The NE operator allows complex conditions to be formulated in simple, easily understandable expressions.
- **Flexibility:** The operator can be applied to various data types, including integers, floating-point numbers, and even Boolean values.
- **Efficiency:** By being directly integrated into function blocks, the NE operator reduces the need for additional programming and makes the code more efficient.
- **Robustness:** The NE operator helps develop robust control algorithms based on precise comparisons.

Conclusion

The NE operator is an important tool in IEC 61499 that simplifies the implementation of comparisons in industrial control systems. Its ability to determine whether two values are unequal makes it an indispensable component in process monitoring, control, and decision-making. Whether in production control, temperature regulation, or fault detection – the NE operator is a powerful and versatile element in the world of industrial automation. Its simplicity and efficiency contribute to the development of reliable and effective control systems.

2.11.4.7 conversion

F_ANY_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

`F_ANY_AS_STRING` converts a value of arbitrary data type (`ANY`) into its textual representation as a `STRING`. It serves as a generic "to text" converter, e.g. for diagnostics or logging, without needing a dedicated conversion function for every data type.

Interface Structure

Event Inputs

- **REQ**: Triggers the conversion, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN** (ANY): The value to convert, of arbitrary data type.

Data Outputs

- **OUT** (STRING): The textual representation of `IN`.

Functionality

On `REQ`, the block generates a textual representation from the generically typed input `IN` and outputs it via `OUT`, then triggers `CNF`. The exact formatting follows the IEC 61131-3 literal notation of the concrete data type bound to `IN`.

Technical Features

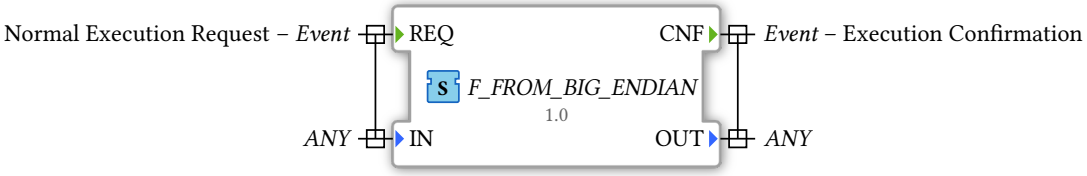
- **Generic `ANY` input**: The block accepts any IEC 61131-3 data type bound to `IN` at compile time.
- **Universal debug/logging block**: Since virtually any data type can be output as `STRING`, the block is particularly suited for generic diagnostic output.

State Overview

Stateless: every `REQ` immediately results in the conversion and `CNF`.

Application Scenarios

- **Diagnostics and logging**: Output of arbitrary process values as readable text, e.g. for log files or diagnostic displays.
- **Generic display blocks** that need a textual representation independent of the actual data type of the connected value.



Comparison with similar function blocks

- **Type-specific `*_TO_STRING` functions** (e.g. `DINT_TO_STRING`): require a dedicated instance per data type, but may offer finer-grained formatting control.

Conclusion

`F_ANY_AS_STRING` provides a convenient, generically typed text conversion for arbitrary data types and is particularly suited for diagnostics and logging applications where the concrete data type may vary.

F_FROM_BIG_ENDIAN

• – ◦ • – ◦ • – ◦ •

Introduction

`F_FROM_BIG_ENDIAN` converts a value from big-endian (most significant byte first) byte order. It belongs to the family of endian conversion functions needed for cross-platform exchange of binary data (e.g. over network protocols or with third-party systems).

Interface Structure

Event Inputs

- **REQ**: Triggers the conversion, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN** (ANY): The value to convert, of arbitrary data type.

Data Outputs

- **OUT** (ANY): The converted value, same data type as `IN`.

Functionality

On `REQ`, the block interprets the byte sequence of `IN` as a big-endian (most significant byte first)-encoded value and converts it into the target platform's native byte order. The result is output via `OUT`, then `CNF` is triggered. The bit width of the data type stays unchanged — only the byte order is adjusted.

Technical Features

- **Generic `ANY` data type**: `IN`/`OUT` adapt to whichever concrete data type is connected at compile time; the byte count follows from its size.
- **Pure byte reordering, no value reinterpretation**: The block only changes the arrangement of the bytes, not their meaning or sign.

State Overview

Stateless: every `REQ` immediately results in the conversion and `CNF`.

Application Scenarios

- **Network communication**: Many network protocols (e.g. TCP/IP headers) use big-endian ("network byte order"); `F_FROM_BIG_ENDIAN` ensures the correct byte order when sending/receiving.
- **Interoperability with third-party systems**: Exchanging binary data with systems whose native byte order differs from the target platform's.

Comparison with similar function blocks

- **`F_FROM_LITTLE_ENDIAN`**: the same conversion direction, but for the other byte order.

- **F_TO_BIG_ENDIAN**: the reverse direction for the same byte order.

Conclusion

F_FROM_BIG_ENDIAN provides a simple, generically typed byte-order conversion and is an important building block for correct interoperability with network protocols and third-party systems of differing endianness.

F_FROM_LITTLE_ENDIAN

• – ◦ • – ◦ • – ◦ •

Introduction

F_FROM_LITTLE_ENDIAN converts a value from little-endian (least significant byte first) byte order. It belongs to the family of endian conversion functions needed for cross-platform exchange of binary data (e.g. over network protocols or with third-party systems).

Interface Structure

Event Inputs

- **REQ**: Triggers the conversion, carries IN.

Event Outputs

- **CNF**: Confirms completion, carries OUT.

Data Inputs

- **IN** (ANY): The value to convert, of arbitrary data type.

Data Outputs

- **OUT** (ANY): The converted value, same data type as IN.

Functionality

On REQ, the block interprets the byte sequence of IN as a little-endian (least significant byte first)-encoded value and converts it into the target platform's native byte order. The result is output via OUT, then CNF is triggered. The bit width of the data type stays unchanged — only the byte order is adjusted.

Technical Features

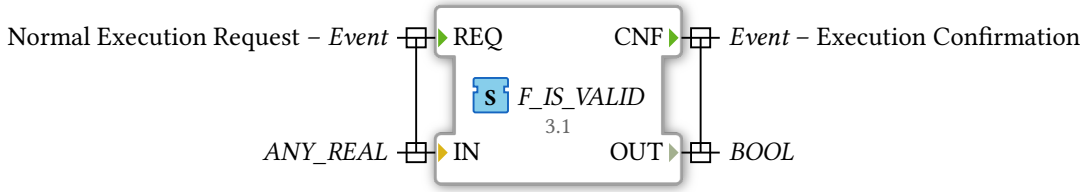
- **Generic ANY data type**: IN/OUT adapt to whichever concrete data type is connected at compile time; the byte count follows from its size.
- **Pure byte reordering, no value reinterpretation**: The block only changes the arrangement of the bytes, not their meaning or sign.

State Overview

Stateless: every REQ immediately results in the conversion and CNF.

Application Scenarios

- **Network communication**: Many network protocols (e.g. TCP/IP headers) use big-endian ("network byte order"); F_FROM_LITTLE_ENDIAN ensures the correct byte order when sending/receiving.
- **Interoperability with third-party systems**: Exchanging binary data with systems whose native byte order differs from the target platform's.



Comparison with similar function blocks

- **F_FROM_BIG_ENDIAN**: the same conversion direction, but for the other byte order.
- **F_TO_LITTLE_ENDIAN**: the reverse direction for the same byte order.

Conclusion

`F_FROM_LITTLE_ENDIAN` provides a simple, generically typed byte-order conversion and is an important building block for correct interoperability with network protocols and third-party systems of differing endianness.

F_IS_VALID

• – ◦ • – ◦ • – ◦ •

Introduction

`F_IS_VALID` checks whether a floating-point value (`REAL`/`LREAL`) is a valid, finite value — i.e. neither `NaN` (Not a Number) nor `+/-Infinity`. It guards numerical calculations against invalid intermediate results.

Interface Structure

Event Inputs

- **REQ**: Triggers the check, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN** (ANY_REAL): The floating-point value to check.

Data Outputs

- **OUT** (BOOL): `TRUE` if `IN` is a valid, finite value; `FALSE` for `NaN` or `Infinity`.

Functionality

On `REQ`, the algorithm's ST statement `OUT := IS_VALID(IN)` checks whether `IN` is neither `NaN` nor `+/-Infinity`, and outputs the result via `OUT`. `CNF` is then triggered.

Technical Features

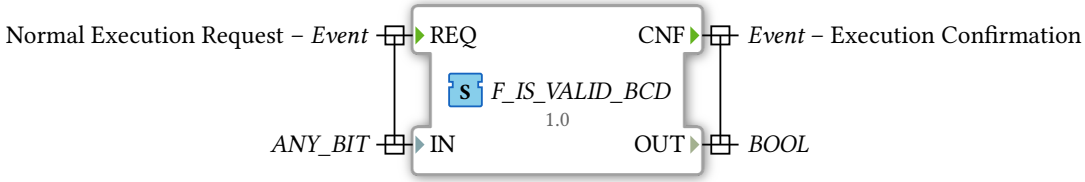
- **`ANY_REAL` input**: Accepts both `REAL` and `LREAL`.
- **Detects typical error results**: `NaN` arises e.g. from `0.0/0.0`, `Infinity` from division by `0.0` with a nonzero numerator — both classic sources of error in floating-point calculations.

State Overview

Stateless: every `REQ` immediately results in the check and `CNF`.

Application Scenarios

- **Guarding calculation chains**: Checking a floating-point result for validity before further processing, to prevent follow-on errors (e.g. `NaN` propagation).
- **Sanity checking sensor data**: Detecting faulty or out-of-range measurements.



Comparison with similar function blocks

- F_IS_VALID_BCD: the same basic idea of validity checking, but for BCD-encoded bit strings instead of floating-point numbers.

Conclusion

`F_IS_VALID` provides a simple, central validity check for floating-point values and helps catch `NaN`/`Infinity`-related follow-on errors in calculation chains early.

F_IS_VALID_BCD

• – ◦ • – ◦ • – ◦ •

Introduction

`F_IS_VALID_BCD` checks whether a bit string contains valid BCD (Binary Coded Decimal) data — i.e. whether every nibble (4-bit group) represents a value between `0` and `9`. It validates BCD-encoded values before they are converted.

Interface Structure

Event Inputs

- **REQ**: Triggers the check, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN** (ANY_BIT): The bit string to check (`BYTE`, `WORD`, `DWORD`, or `LWORD`).

Data Outputs

- **OUT** (BOOL): `TRUE` if every nibble of `IN` holds a valid BCD value (`0`–`9`); `FALSE` if at least one nibble holds an invalid value (`10`–`15`, i.e. `A`–`F`).

Functionality

On `REQ`, the algorithm's ST statement `OUT := IS_VALID_BCD(IN)` checks nibble by nibble whether every 4-bit group of `IN` represents a valid decimal digit (`0`–`9`), and outputs the result via `OUT`. `CNF` is then triggered.

Technical Features

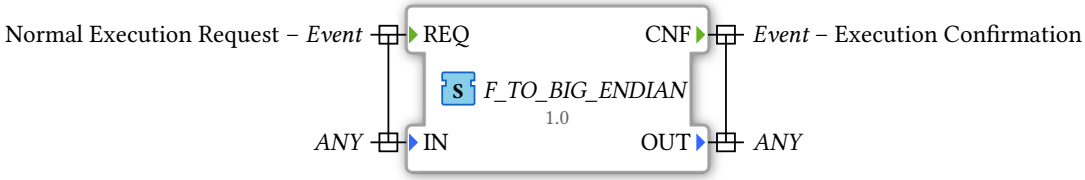
- **`ANY_BIT` input**: Accepts bit strings of any width (`BYTE`, `WORD`, `DWORD`, `LWORD`); the number of nibbles checked follows from their size.
- **Pre-check for BCD conversion**: A useful companion to the `*_BCD_TO_*` conversion blocks (cf. `F_BYTE_BCD_TO_USINT` etc.), catching invalid input data before the actual conversion.

State Overview

Stateless: every `REQ` immediately results in the check and `CNF`.

Application Scenarios

- **Validating fieldbus/protocol data** transmitted in BCD encoding, before converting it to a numeric value.
- **Error detection** for incorrectly transmitted or misinterpreted bit strings meant to be interpreted as BCD.



Comparison with similar function blocks

- F_IS_VALID: the same basic idea of validity checking, but for floating-point numbers instead of BCD bit strings.
- **`F_BYTE_BCD_TO_USINT`** and related conversion blocks: implicitly rely on the same BCD validity assumption; `F_IS_VALID_BCD` makes the check explicit and usable upstream.

Conclusion

`F_IS_VALID_BCD` provides a simple upstream check for BCD-encoded bit strings and protects downstream BCD conversion blocks from invalid input data.

F_TO_BIG_ENDIAN

• – ◦ • – ◦ • – ◦ •

Introduction

`F_TO_BIG_ENDIAN` converts a value to big-endian (most significant byte first) byte order. It belongs to the family of endian conversion functions needed for cross-platform exchange of binary data (e.g. over network protocols or with third-party systems).

Interface Structure

Event Inputs

- **REQ**: Triggers the conversion, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN** (ANY): The value to convert, of arbitrary data type.

Data Outputs

- **OUT** (ANY): The converted value, same data type as `IN`.

Functionality

On `REQ`, the block converts the natively encoded value `IN` into a big-endian (most significant byte first) byte sequence. The result is output via `OUT`, then `CNF` is triggered. The bit width of the data type stays unchanged — only the byte order is adjusted.

Technical Features

- **Generic `ANY` data type**: `IN`/`OUT` adapt to whichever concrete data type is connected at compile time; the byte count follows from its size.
- **Pure byte reordering, no value reinterpretation**: The block only changes the arrangement of the bytes, not their meaning or sign.

State Overview

Stateless: every `REQ` immediately results in the conversion and `CNF`.

Application Scenarios

- **Network communication**: Many network protocols (e.g. TCP/IP headers) use big-endian ("network byte order"); `F_TO_BIG_ENDIAN` ensures the correct byte order when sending/receiving.
- **Interoperability with third-party systems**: Exchanging binary data with systems whose native byte order differs from the target platform's.

Comparison with similar function blocks

- **`F_TO_LITTLE_ENDIAN`**: the same conversion direction, but for the other byte order.
- **`F_FROM_BIG_ENDIAN`**: the reverse direction for the same byte order.

Conclusion

`F_TO_BIG_ENDIAN` provides a simple, generically typed byte-order conversion and is an important building block for correct interoperability with network protocols and third-party systems of differing endianness.

F_TO_LITTLE_ENDIAN

• – ◦ • – ◦ • – ◦ •

Introduction

`F_TO_LITTLE_ENDIAN` converts a value to little-endian (least significant byte first) byte order. It belongs to the family of endian conversion functions needed for cross-platform exchange of binary data (e.g. over network protocols or with third-party systems).

Interface Structure

Event Inputs

- **REQ**: Triggers the conversion, carries `IN`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **IN** (ANY): The value to convert, of arbitrary data type.

Data Outputs

- **OUT** (ANY): The converted value, same data type as `IN`.

Functionality

On `REQ`, the block converts the natively encoded value `IN` into a little-endian (least significant byte first) byte sequence. The result is output via `OUT`, then `CNF` is triggered. The bit width of the data type stays unchanged — only the byte order is adjusted.

Technical Features

- **Generic `ANY` data type**: `IN`/`OUT` adapt to whichever concrete data type is connected at compile time; the byte count follows from its size.
- **Pure byte reordering, no value reinterpretation**: The block only changes the arrangement of the bytes, not their meaning or sign.

State Overview

Stateless: every `REQ` immediately results in the conversion and `CNF`.

Application Scenarios

- **Network communication**: Many network protocols (e.g. TCP/IP headers) use big-endian ("network byte order"); `F_TO_LITTLE_ENDIAN` ensures the correct byte order when sending/receiving.
- **Interoperability with third-party systems**: Exchanging binary data with systems whose native byte order differs from the target platform's.

Comparison with similar function blocks

- **`F_TO_BIG_ENDIAN`**: the same conversion direction, but for the other byte order.
- **`F_FROM_LITTLE_ENDIAN`**: the reverse direction for the same byte order.

Conclusion

`F_TO_LITTLE_ENDIAN` provides a simple, generically typed byte-order conversion and is an important building block for correct interoperability with network protocols and third-party systems of differing endianness.

F_BYTE_BCD_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_BCD_TO_USINT` converts a BCD-encoded BYTE value to a USINT value. BCD (Binary Coded Decimal) is an encoding in which each digit of a decimal number is represented by 4 bits. This function block is particularly useful in applications that need to process BCD-encoded data.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the algorithm for converting the BCD-encoded BYTE value to a USINT value is executed.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is activated once the conversion is complete.

Data Inputs

- **IN**: The BCD-encoded BYTE value to be converted to a USINT value.

Data Outputs

- **OUT**: The resulting USINT value after the conversion.

Adapters

- This function block has no adapters.

Functionality

The function block performs the conversion of a BCD-encoded BYTE value to a USINT value as soon as the event `REQ` is triggered. The conversion is performed using the built-in function `BYTE_BCD_TO_USINT`. After successful conversion, the event `CNF` is triggered to signal the completion of the operation.

Technical Features

- Conversion occurs directly and without any additional delay.
- The function block is optimized for processing BCD-encoded data.

State Overview

1. **Idle State**: The function block waits for the `REQ` event.
2. **Conversion State**: Conversion is performed when `REQ` is triggered.
3. **Completion State**: After successful conversion, `CNF` is triggered, and the function block returns to the idle state.

Application Scenarios

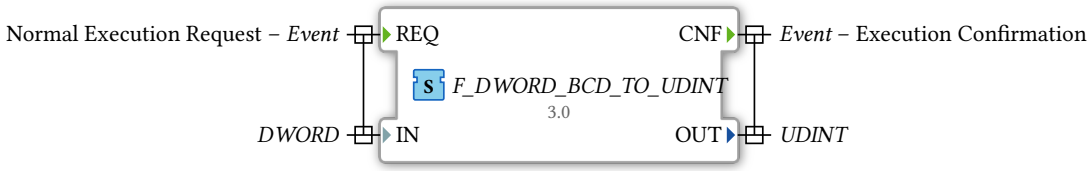
- Processing of BCD-encoded data in industrial control systems.

- Conversion of BCD-encoded sensor data into numerical values.
- Integration into control logic that needs to process BCD data.

⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion function blocks, `F_BYTE_BCD_TO_USINT` specializes in converting BCD-encoded BYTE values to USINT values.
- Other function blocks might offer additional conversion options, but they may be less efficient for this specific use case.

Conclusion



The `F_BYTE_BCD_TO_USINT` function block provides an efficient and specialized solution for converting BCD-encoded BYTE values to USINT values. Its simple and straightforward operation makes it ideal for applications requiring fast and reliable conversion.

F_DWORD_BCD_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_BCD_TO_UDINT` converts a BCD-encoded DWORD value to a UDINT value. BCD (Binary Coded Decimal) is an encoding method where each digit of a decimal number is represented by four bits. This function block is particularly useful in applications that need to process BCD-encoded data.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- `IN` (DWORD): The BCD-encoded input value to be converted to a UDINT value.

Data Outputs

- `OUT` (UDINT): The converted UDINT value.

Adapters

This function block has no adapters.

Operation

The function block performs the conversion when the `REQ` event is triggered. The conversion is performed using the function `DWORD_BCD_TO_UDINT`, which converts the BCD-encoded value `IN` into a UDINT value. After the conversion is complete, the event `CNF` is triggered, and the converted value is available at the output `OUT`.

Technical Features

- The function block has a simple structure and contains only one algorithm for the conversion.
- The conversion is performed directly without additional state management.

State Overview

The function block has no internal state. The conversion is performed anew with each `REQ` event.

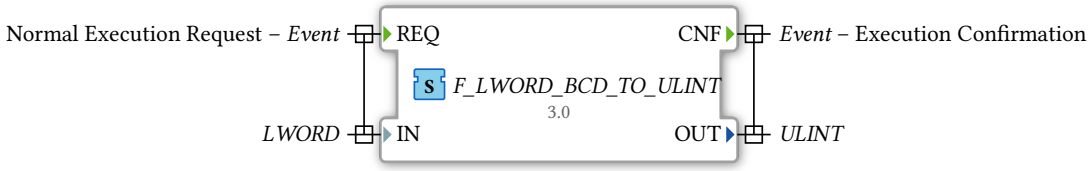
Application Scenarios

- Processing of BCD-encoded data from external devices or sensors.
- Conversion of BCD-encoded values to UDINT format for further calculations.

⚖️ Comparison with similar function blocks

- Compared to generic conversion function blocks, `F_DWORD_BCD_TO_UDINT` specializes in converting BCD-encoded DWORD values to UDINT values.
- Other conversion function blocks might offer additional features or flexibility, but may be less efficient for this specific use case.

Conclusion



The `F_DWORD_BCD_TO_UDINT` function block is an efficient tool for the specific task of BCD-to-UDINT conversion. Its simplicity and straightforward operation make it a reliable solution for applications requiring this type of conversion.

F_LWORD_BCD_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LWORD_BCD_TO_ULINT` converts a BCD-encoded `LWORD` value to a `ULINT` value. This is particularly useful in applications where BCD-encoded data needs to be processed, such as in industrial control systems or communication protocols.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input for the BCD-encoded `LWORD` value to be converted.

Data Outputs

- **OUT**: The output for the converted `ULINT` value.

Adapters

No adapters are present.

Operation

The function block performs the conversion when the `REQ` event occurs. The BCD-encoded value `LWORD` at input `IN` is converted into a value `ULINT` and made available at output `OUT`. The `CNF` event signals successful conversion.

Technical Features

- The function block uses the BCD-to-ULINT conversion algorithm defined in the IEC 61131-3 standard library.
- The conversion occurs synchronously with the `REQ` event.

State Overview

1. **Idle State**: The function block waits for the `REQ` event.

2. **Conversion State**: Upon receipt of `REQ`, the conversion is performed and the `CNF` event is triggered.

Application Scenarios

- Processing of BCD-encoded data in industrial controllers.
- Conversion of BCD-encoded values to numeric values for further calculations.

⚖️ Comparison with Similar Function Blocks

- **F_BCD_TO_ULINT**: Converts BCD-encoded values to `ULINT`, but for different data types than `LWORD`.
- **F_LWORD_TO_ULINT**: Converts `LWORD` to `ULINT`, but without BCD encoding.

Conclusion

The `F_LWORD_BCD_TO_ULINT` function block is a specialized building block for converting BCD-encoded `LWORD` values to `ULINT`. It is easy to use and particularly suitable for applications that work with BCD-encoded data.

F_UDINT_TO_BCD_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UDINT_TO_BCD_DWORD` converts an unsigned 32-bit integer value (UDINT) into a BCD-encoded DWORD. This conversion is particularly useful in applications where numeric values need to be represented or processed in a human-readable format.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: An unsigned 32-bit integer value (UDINT) to be converted into a BCD-encoded DWORD.

Data Outputs

- **OUT**: The result of the conversion as a BCD-encoded DWORD.

Adapters

No adapters are available.

Functionality

The function block performs the conversion as soon as the event `REQ` is received. The algorithm converts the value at input `IN` from UDINT to a BCD-encoded DWORD and outputs the result to `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Details

- The conversion is performed using the function `UDINT_TO_BCD_DWORD`, which is implemented in the function block's algorithm.
- The function block is part of the package `iec61131::conversion`.

State Overview

1. **Wait State**: The function block waits for the event `REQ`.

2. **Active State**: Upon receiving `REQ`, the conversion is performed and the result is output to `OUT`.
3. **Confirmation State**: After successful conversion, `CNF` is triggered, and the function block returns to the wait state.

Application Scenarios

- **Display Control**: Converting numeric values for display on seven-segment displays or LCDs.
- **Data Communication**: Preparing data for transmission in BCD-encoded protocols.
- **Printer Control**: Converting numeric values for printing in a readable format.

⚖️ Comparison with Similar Function Blocks

- **F_UDINT_TO_STRING**: Converts a UDINT to a string, but is less efficient for BCD-specific applications.
- **F_UDINT_TO_DWORD**: Performs a direct type conversion without BCD encoding.

Conclusion

The function block `F_UDINT_TO_BCD_DWORD` provides an efficient and specialized solution for converting unsigned 32-bit integers to BCD-encoded DWORDs. Its simple interface and reliable operation make it ideal for applications that require BCD encoding.

F_UINT_TO_BCD_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_BCD_WORD` converts an unsigned integer value (UINT) into a BCD-encoded word (WORD). BCD (Binary Coded Decimal) is a method for representing decimal numbers where each digit is encoded by 4 bits. This function block is particularly useful in applications where numerical values need to be output in a human-readable format, such as in display systems or printers.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The unsigned integer value (UINT) to be converted.

Data Outputs

- **OUT**: The result of the conversion as a BCD-encoded word (WORD).

Adapters

This function block does not use adapters.

Operation

When the event input `REQ` is triggered, the algorithm is executed that converts the value of `IN` into a BCD-encoded `WORD` and outputs the result to `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Features

- The function block implements direct UINT to WORD conversion using BCD encoding.

- The conversion is performed in a single algorithm step, ensuring high efficiency.

State Overview

The function block has no internal states other than the initial readiness to process the `REQ` event.

Application Scenarios

- Display controllers that require numeric values in BCD format.
- Printers and other output devices that process BCD-encoded data.
- Systems that require compatibility with legacy BCD-based components.

⚖️ Comparison with Similar Building Blocks

Compared to generic conversion building blocks, `F_UINT_TO_BCD_WORD` offers a specialized solution for BCD encoding that can be more efficient and easier to use than general-purpose conversion methods.

Conclusion

The `F_UINT_TO_BCD_WORD` function block is a specialized tool for the efficient conversion of unsigned integer values to the BCD format. Its simple interface and straightforward operation make it ideal for applications requiring fast and reliable BCD encoding.

F_ULINT_TO_BCD_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_TO_BCD_LWORD` converts a `ULINT` value (64-bit unsigned integer) to a `LWORD` value type in BCD (Binary Coded Decimal) format. This block is particularly useful in applications where numeric values need to be converted into a format compatible with BCD systems.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. The value to be converted is passed via the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is output via the data output `OUT`.

Data Inputs

- **IN**: The input for the `ULINT` value to be converted.

Data Outputs

- **OUT**: The output for the converted `LWORD` value type in BCD format.

Adapters

This function block does not have any adapters.

Functionality

The function block performs the conversion from `ULINT` to `LWORD` in BCD format as soon as the `REQ` event is triggered. The conversion is performed using the integrated function `ULINT_TO_BCD_LWORD`. Once the conversion is complete, the `CNF` event is triggered, and the converted value is available at the `OUT` output.

Technical Features

- Supports the conversion of 64-bit unsigned integer (`ULINT`) to 64-bit BCD (`LWORD`).
- No additional parameters or settings are required.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Conversion**: Performs the conversion as soon as `REQ` is activated.
3. **Completion**: Sends the `CNF` event and outputs the converted value.

Application Scenarios

- Industrial control systems that process BCD-encoded data.
- Communication with peripheral devices that expect BCD data.
- Data conversion in automation applications.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_ULINT_TO_BCD_LWORD` offers a specialized solution for conversion to the BCD format.
- Other blocks might offer additional conversion options, but they may be less efficient for this specific use case.

Conclusion

The `F_ULINT_TO_BCD_LWORD` function block is an efficient and specialized solution for converting `ULINT` to `LWORD` in BCD format. Its ease of use and direct functionality make it ideal for applications requiring fast and reliable data conversion.

F_USINT_TO_BCD_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_TO_BCD_BYTE` converts an unsigned 8-bit integer value (USINT) into a BCD-encoded byte (BYTE). BCD (Binary Coded Decimal) is an encoding in which each decimal digit is represented by four bits.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: An unsigned 8-bit integer value (USINT) to be converted to BCD.

Data Outputs

- **OUT**: The result of the conversion as a BCD-encoded byte (BYTE).

Adapters

No adapters are present.

Functionality

The function block performs the conversion when the event `REQ` occurs. The algorithm converts the input value `IN` from USINT to a BCD-encoded byte and stores the result in `OUT`. The event `CNF` is then triggered to signal the completion of the conversion.

Technical Features

- The function block is deterministic and does not perform any internal state changes.
- The conversion is performed directly via the function `USINT_TO_BCD_BYTE`.

State Overview

The function block has no internal state. The conversion is performed anew with each `REQ` event.

Application Scenarios

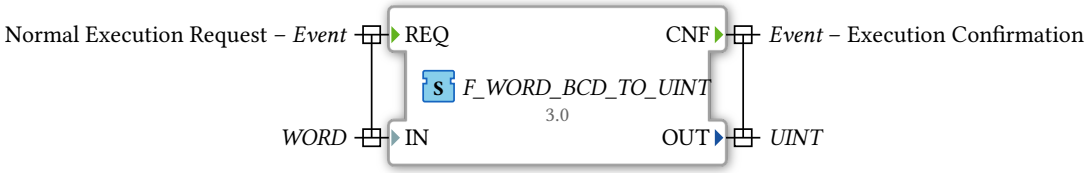
- Display control for seven-segment displays.
- Communication with devices that expect BCD-encoded data.
- Data conversion in control systems that require the BCD format.

⚖️ Comparison with Similar Function Blocks

- Unlike generic conversion blocks, `F_USINT_TO_BCD_BYTE` is specialized for converting USINT to BCD.

Other blocks might offer additional features such as error handling or different encodings, but are often more complex.

Conclusion



The function block `F_USINT_TO_BCD_BYTE` is an efficient tool for the specific task of converting USINT to BCD. Its simplicity and determinism make it a reliable choice in control applications that require BCD-encoded data.

F_WORD_BCD_TO_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_BCD_TO_UINT` converts a BCD-encoded WORD value into an unsigned integer (UINT). This is particularly useful in applications where data in BCD format needs to be processed or displayed.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs

- `IN` (WORD): The BCD-encoded input value to be converted.

Data Outputs

- `OUT` (UINT): The converted unsigned integer value.

Adapters

This function block does not use adapters.

Operation

When the `REQ` event is triggered, the BCD-encoded value at the input `IN` is converted to an unsigned integer value. The result is output at `OUT`, and the `CNF` event signals the completion of the conversion.

Technical Features

- The function block is simple and direct, without complex state logic.
- The conversion is performed using the function `WORD_BCD_TO_UINT`.

State Overview

Since it is a simple function block, there are no complex states. The block reacts directly to the `REQ` event with a conversion and the output of the result.

Application Scenarios

- Conversion of BCD-encoded data from external devices or sensors.
- Use in control systems that need to process BCD data.
- Display of BCD data in a human-readable format.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_WORD_BCD_TO_UINT` specializes in BCD to UINT conversion.
- Other blocks might support additional features such as error handling or different encoding formats, but they are more complex.

Conclusion

The `F_WORD_BCD_TO_UINT` function block is an efficient tool for the specific task of BCD to UINT conversion. Its simplicity and straightforward operation make it ideal for applications requiring fast and reliable conversions.

F_BOOL_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BOOL_AS_STRING` is used to convert a Boolean value (`BOOL`) into a string (`STRING`). This functionality is particularly useful when Boolean values are needed for output or further processing in a text format.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs

- **IN**: The Boolean value (`BOOL`) to be converted into a string.

Data Outputs

- **OUT**: The resulting string (`STRING`) representing the converted Boolean value.

Adapters

No adapters are defined for this function block.

Functionality

The function block uses a simple algorithm to convert the Boolean value `IN` into a string `OUT`. The conversion is performed by the function `BOOL_AS_STRING(IN)`, which internally converts the value of `IN` into a corresponding string (e.g., `TRUE` or `FALSE`).

Technical Features

- The function block is implemented simply and efficiently, without additional states or complex logic.
- The conversion occurs synchronously with the triggering of the `REQ` event.

State Overview

Since this is a simple function block, there are no explicit states. Execution occurs immediately upon receiving the `REQ` event.

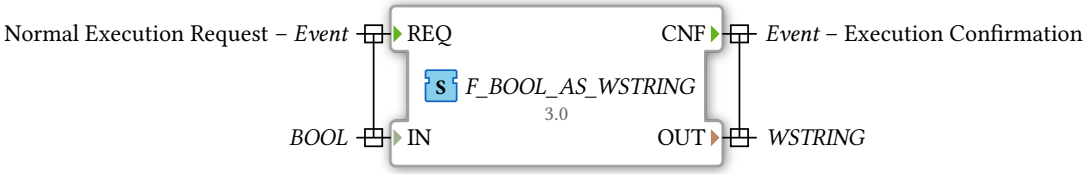
Application Scenarios

- **Logging**: Conversion of Boolean values for logging purposes.
- **User Interfaces**: Display of Boolean values in a human-readable format.
- **Data Communication**: Preparation of Boolean values for transmission as text.

⚖️ Comparison with Similar Function Blocks

- **F_STRING_TO_BOOL**: Performs the reverse conversion from `STRING` to `BOOL`.
- **F_BOOL_TO_***: Other conversion blocks that convert Boolean values into various data types.

Conclusion



The `F_BOOL_AS_STRING` function block offers a simple and effective way to convert Boolean values to strings. Its clear interface and direct functionality make it a useful tool in many use cases.

F_BOOL_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BOOL_AS_WSTRING` converts a Boolean value (`BOOL`) into a wide string (`WSTRING`). This functionality is particularly useful when Boolean values need to be output or further processed in a human-readable format.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion of the Boolean input value `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion and returns the result `OUT`.

Data Inputs

- `IN` (`BOOL`): The Boolean value to be converted.

Data Outputs

- `OUT` (`WSTRING`): The converted value as a wide string.

Adapters

No adapters available.

Functionality

This function block converts the Boolean input value `IN` into a wide string (`WSTRING`). The conversion is performed using the function `BOOL_AS_WSTRING`, which converts the value `TRUE` to `"TRUE"` and `FALSE` to `"FALSE"`. The conversion is triggered by the event `REQ`, and the result is confirmed by the event `CNF`.

Technical Features

- The function block has a simple structure and contains only one conversion algorithm.
- The conversion is performed directly and without delay.

State Overview

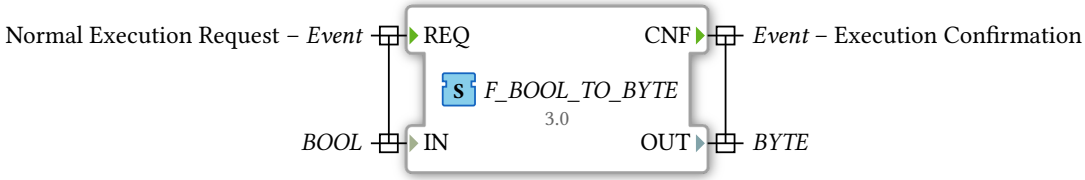
The function block has no internal states. The conversion occurs immediately after the `REQ` event is triggered.

Application Scenarios

- Displaying Boolean values in user interfaces.
- Logging Boolean states to log files.
- Further processing of Boolean values in systems that expect strings.

⚖️ Comparison with Similar Function Blocks

- Unlike `F_BOOL_TO_STRING`, this function block generates a wide string (`WSTRING`) instead of a regular string (`STRING`).
- Similar function blocks like `F_INT_AS_WSTRING` or `F_REAL_AS_WSTRING` convert other data types to `WSTRING`.



Conclusion

The function block `F_BOOL_AS_WSTRING` provides a simple and efficient way to convert Boolean values to wide strings. Its slim design makes it particularly suitable for applications where fast and uncomplicated conversion is required.

F_BOOL_TO_BYTE

• – ◦ • – ◦ • – ◦ •

The function block `F_BOOL_TO_BYTE` converts a Boolean value (`BOOL`) into a byte value (`BYTE`). This conversion is useful when Boolean signals need to be processed in systems that require byte data.

- **REQ**: This event input triggers the execution of the function block. It is linked to the data input `IN`.
- **CNF**: This event output signals the successful execution of the function block. It is linked to the data output `OUT`.
- **IN** (`BOOL`): The Boolean input value to be converted into a byte.
- **OUT** (`BYTE`): The resulting byte value after conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapters.

Functionality

The function block performs the conversion from `BOOL` to `BYTE` as soon as the event `REQ` is triggered. The Boolean value `IN` is converted to a byte value, with `FALSE` becoming `0` and `TRUE` becoming `1`. The result is output via `OUT`, and the event `CNF` signals successful execution.

- The function block is a simple function block (`SimpleFB`) and uses an ST algorithm (`ST`) for the conversion.

The function block has no internal states. Execution occurs immediately upon triggering the `REQ` event.

- **Signal Processing**: Conversion of Boolean control signals into byte values for communication with devices that expect byte data.
- **Data Logging**: Conversion of Boolean status information into byte format for storage or transmission.
- **F_BOOL_TO_INT**: Converts a Boolean value to an integer value, while `F_BOOL_TO_BYTE` is specifically optimized for byte output.
- **F_BOOL_TO_WORD**: Similar to `F_BOOL_TO_BYTE`, but designed for larger data formats (Word).

The function block `F_BOOL_TO_BYTE` is a simple and efficient tool for converting Boolean values to byte data. It is particularly suitable for applications that require a compact representation of Boolean signals in byte format. Its simple interface and direct functionality make it easy to integrate into existing systems.

Conclusion

F_BOOL_TO_DINT

• – ◦ • – ◦ • – ◦ •

The function block F_BOOL_TO_DINT converts a Boolean value (BOOL) into a 32-bit integer value (DINT). This conversion is useful when Boolean signals need to be integrated into numerical calculations or control systems.

- **REQ**: Starts the conversion. When this event is triggered, the Boolean input value (IN) is converted into a DINT value.
- **CNF**: Signals the completion of the conversion. This event is output along with the converted output value (OUT).
- **IN**: The Boolean input value (BOOL) to be converted to a DINT value.
- **OUT**: The converted 32-bit integer value (DINT). The value is 1 if IN is TRUE, otherwise 0.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapters.

Functionality

The function block performs the conversion from BOOL to DINT by converting the Boolean value TRUE to 1 and FALSE to 0. The conversion is triggered by the event REQ, and the result is confirmed by the event CNF.

- The conversion is performed using the function BOOL_TO_DINT, which is implemented in the function block's algorithm.

The function block has no internal states. The conversion occurs immediately upon triggering the REQ event.

- Integration of Boolean signals into numerical controllers.
- Conversion of switching states (TRUE/FALSE) into numerical values for further calculations.
- Interfaces between Boolean and numerical system components.
- **F_BOOL_TO_INT**: Converts BOOL to a 16-bit integer (INT). In contrast, F_BOOL_TO_DINT returns a 32-bit integer.
- **F_BOOL_TO_REAL**: Converts BOOL to a floating-point value (REAL). F_BOOL_TO_DINT, on the other hand, returns an integer value.

The function block F_BOOL_TO_DINT is a simple and efficient tool for converting Boolean values to 32-bit integers. It is particularly suitable for applications where Boolean signals need to be integrated into numerical controllers. Its deterministic operation and clear interface structure make it a reliable component in IEC 61499-based automation.

Conclusion

F_BOOL_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BOOL_TO_DWORD` converts a Boolean value (`BOOL`) into a 32-bit unsigned integer value (`DWORD`). This block is particularly useful in scenarios where Boolean signals need to be converted into numerical values, for example, for communication with systems that can only process numeric input.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The Boolean value (`BOOL`) to be converted to `DWORD`.

Data Outputs

- **OUT**: The converted 32-bit unsigned integer value (`DWORD`). The value is either `1` (TRUE) or `0` (FALSE).

Adapters

- No adapters are available.

**

Functionality

The function block performs the conversion as soon as the event `REQ` is received. The Boolean value `IN` is converted to `DWORD`:

- `TRUE` becomes `1`
- `FALSE` becomes `0`

After successful conversion, the event `CNF` is triggered, and the converted value is available at output `OUT`.

Technical Features

- The conversion occurs instantly and without delay.
- The block is deterministic and has no internal state.

State Overview

This function block has no internal states. The conversion is performed anew with each `REQ` event.

Application Scenarios

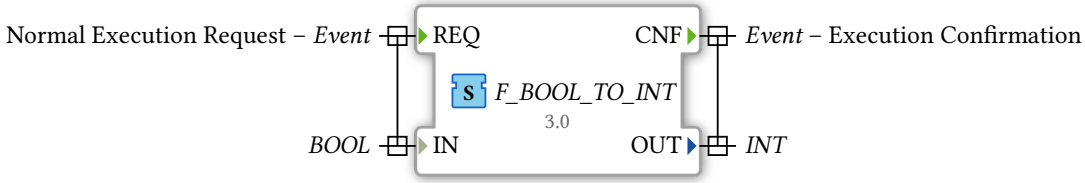
- Conversion of switching states (On/Off) into numerical control signals.

- Integration into control systems that can only process numerical inputs.
- Logging of Boolean events as numerical values.

⚖️ Comparison with Similar Blocks

- Unlike `F_BOOL_TO_INT` or `F_BOOL_TO_REAL`, this block specifically converts to a `DWORD` type, which is optimized for 32-bit systems.
- Similar blocks, such as `F_DWORD_TO_BOOL`, perform the reverse conversion.

Conclusion



The `F_BOOL_TO_DWORD` function block is a simple and efficient building block for converting Boolean values to `DWORD`. Its deterministic functionality and clear interface make it a reliable component in control and communication applications.

F_BOOL_TO_INT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_BOOL_TO_INT` converts a Boolean value (`BOOL`) into an integer value (`INT`). Specifically, `TRUE` is converted to `1`, and `FALSE` to `0`. This block is particularly useful in scenarios where Boolean logic needs to be integrated into numerical calculations.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. The input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The Boolean value (`BOOL`) to be converted.

Data Outputs

- **OUT**: The converted integer value (`INT`). `TRUE` becomes `1`, and `FALSE` becomes `0`.

Adapter

- No adapters available.

Functionality

When the event `REQ` is triggered, the Boolean value at input `IN` is read and converted into an integer value. The result is output at `OUT`, and the event `CNF` is triggered to signal the completion of the operation.

Technical Features

- The block is a simple function block (`SimpleFB`) without internal states.
- The conversion is performed directly and without delay.

State Overview

Because it is a simple function block, there are no state transitions or internal states. The operation is re-executed with each `REQ` event.

Application Scenarios

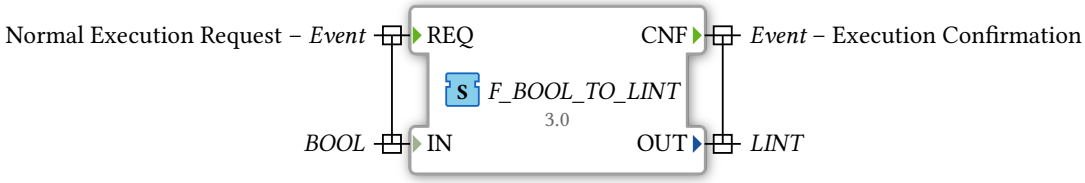
- Integration of Boolean logic into numerical control systems.

- Conversion of switching states (`TRUE`/`FALSE`) into numerical values for further calculations.
- Use in control engineering, where Boolean signals need to be converted into numerical control signals.

⚖️ Comparison with Similar Function Blocks

- **F_BOOL_TO_REAL**: Converts `BOOL` to `REAL` (floating-point number), similar to `F_BOOL_TO_INT`, but with floating-point output.
- **F_INT_TO_BOOL**: Performs the reverse conversion (`INT` to `BOOL`).

Conclusion



The `F_BOOL_TO_INT` function block is a simple yet effective tool for converting Boolean values to integer values. Its simplicity and direct operation make it ideal for applications requiring fast and straightforward conversion.

F_BOOL_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BOOL_TO_LINT` converts a Boolean value (`BOOL`) into a 64-bit integer value (`LINT`). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: This input triggers the execution of the function block. It is linked to the data input `IN`.

Event Outputs

- **CNF**: This output signals the successful execution of the function block. It is linked to the data output `OUT`.

Data Inputs

- **IN**: The input for the Boolean value (`BOOL`) to be converted.

Data Outputs

- **OUT**: The output for the converted 64-bit integer value (`LINT`).

Adapters

This function block has no adapters.

Functionality

The function block performs the conversion from `BOOL` to `LINT` when the event `REQ` is received. The conversion is performed using the function `BOOL_TO_LINT(IN)`, where the Boolean value `IN` is converted into a value `LINT`. The result is output at `OUT`, and the event `CNF` is triggered.

Technical Features

- The block is a simple function block (`SimpleFB`) and uses an ST algorithm for the conversion.
- The conversion is deterministic and occurs without delay.

State Overview

The function block has no internal state. The conversion occurs immediately upon receiving the `REQ` event.

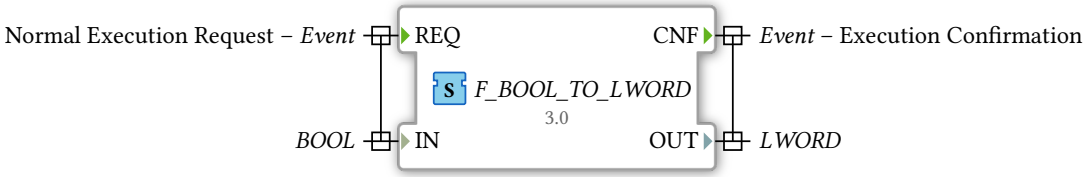
Application Scenarios

- Type conversion in control applications where Boolean values need to be converted to numeric values.
- Integration into larger systems that require consistent data type handling.

⚖️ Comparison with Similar Blocks

- Compared to other conversion blocks such as `F_BOOL_TO_INT` or `F_BOOL_TO_DINT`, this block offers higher precision through the use of the `LINT` data type (64-bit).

Conclusion



The `F_BOOL_TO_LINT` function block is an efficient tool for converting Boolean values to 64-bit integer values. Its simple and deterministic operation makes it a reliable component in control applications.

F_BOOL_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BOOL_TO_LWORD` converts a Boolean value (`BOOL`) into a 64-bit unsigned integer (`LWORD`). This conversion is particularly useful in scenarios where Boolean values need to be embedded in larger data structures or processed with other long integer values.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion. Linked to the data input `IN`.

Event Outputs

- **CNF**: Execution Confirmation. Triggered after successful conversion. Linked to the data output `OUT`.

Data Inputs

- **IN**: The Boolean value (`BOOL`) to be converted to `LWORD`.

Data Outputs

- **OUT**: The converted 64-bit unsigned integer value (`LWORD`).

Adapters

This function block does not use adapters.

Adapters ... ## Functionality

This function block converts `BOOL` to `LWORD` when the `REQ` event occurs. The Boolean value `IN` is converted to `LWORD`, while `FALSE` is converted to `0` and `TRUE` to `1`. The result is output at the data output `OUT`, and the `CNF` event is triggered to indicate successful execution.

Technical Features

- The conversion is performed using the function `BOOL_TO_LWORD`, which converts the Boolean value into a 64-bit value.
- The function block is simple and deterministic because it does not store any internal states.

State Overview

Since it is a simple function block without internal states, there are no state transitions or management.

Application Scenarios

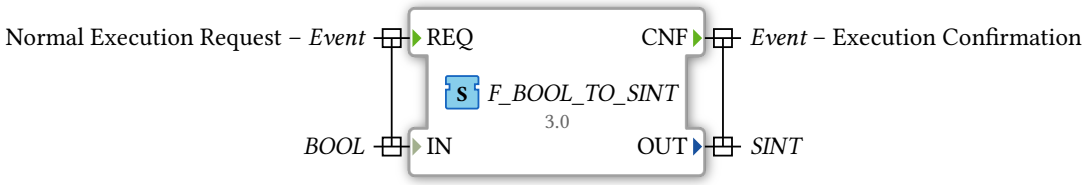
- Embedding Boolean values in larger data structures that use `LWORD`.

- Use in systems that need to process Boolean values as long integers, e.g., when communicating with external systems or storing them in databases.

⚖️ Comparison with similar function blocks

- **F_BOOL_TO_**: Similar function blocks exist for other data types (e.g., `F_BOOL_TO_BYTE`, `F_BOOL_TO_WORD`). These convert Boolean values to other integer data types with different bit widths.
- **F__TO_LWORD**: Other conversion blocks convert various data types (e.g., `INT`, `DINT`) to `LWORD`, but `F_BOOL_TO_LWORD` is specific to Boolean values.

Conclusion



The `F_BOOL_TO_LWORD` function block offers a simple and efficient way to convert Boolean values into 64-bit integer values. Its deterministic operation and clear interface structure make it a useful component in control and automation systems, especially where Boolean values need to be integrated into larger data structures.

F_BOOL_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BOOL_TO_SINT` converts a Boolean value (`BOOL`) into a signed 8-bit integer (`SINT`). This conversion is useful when Boolean values are used in calculations or controls that require integer values.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event input is triggered, the Boolean value at data input `IN` is converted to a value `SINT`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event is output along with the converted value at data output `OUT`.

Data Inputs

- **IN**: The Boolean value (`BOOL`) to be converted to a value `SINT`.

Data Outputs

- **OUT**: The converted value (`SINT`). The output value is `1` if the input is `IN` or `TRUE`; otherwise, it is `0`.

Adapters

This function block does not use any adapters.

Functionality

The function block converts the Boolean input value `IN` to a value `SINT`. The conversion is performed according to the following rule:

- `TRUE` is converted to `1`.
- `FALSE` is converted to `0`.

The conversion is triggered by the event `REQ`. After successful conversion, the event `CNF` is triggered, and the converted value is output at `OUT`.

Technical Features

- The function block is a simple algorithm (`SimpleFB`) that performs the conversion directly.
- The conversion occurs without delay as soon as the event `REQ` arrives.

State Overview

The function block has no internal state. The conversion occurs immediately upon triggering the `REQ` event.

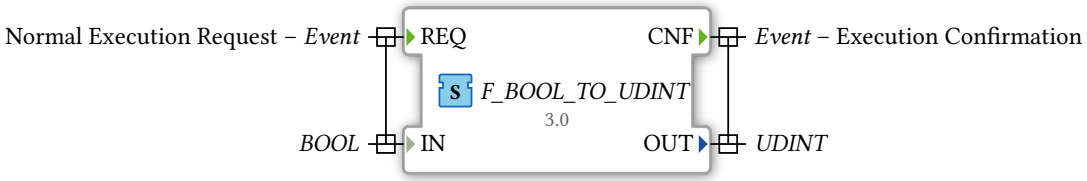
Application Scenarios

- Conversion of Boolean signals into numerical values for mathematical operations.
- Integration of Boolean control signals into systems that expect integer values.

⚖️ Comparison with Similar Function Blocks

- **F_BOOL_TO_INT**: Converts `BOOL` to a 16-bit integer (`INT`). This block is similar, but the output value has a larger bit width.
- **F_BOOL_TO_USINT**: Converts `BOOL` to an unsigned 8-bit integer (`USINT`). The difference lies in the interpretation of the output value (signed vs. unsigned).

Conclusion



The function block `F_BOOL_TO_SINT` is a simple and efficient tool for converting Boolean values to signed 8-bit integers. It is particularly useful in control systems where Boolean signals need to be converted into numerical values.

F_BOOL_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BOOL_TO_UDINT` converts a `BOOL` value to a `UDINT` value. This conversion is useful when Boolean values are used in calculations or storage operations that require a larger numeric data type.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `BOOL` to be converted.

Data Outputs

- **OUT**: The output of type `UDINT`, containing the result of the conversion.

Adapters

No adapters are supported.

Functionality

The function block performs the conversion from `BOOL` to `UDINT` when the event `REQ` is triggered. The Boolean value `TRUE` is converted to `1`, and `FALSE` to `0`. The result is output at data output `OUT`, and the event `CNF` signals successful execution.

Technical Features

- The conversion is instantaneous and without delay.
- The function block is suitable for use in real-time systems.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

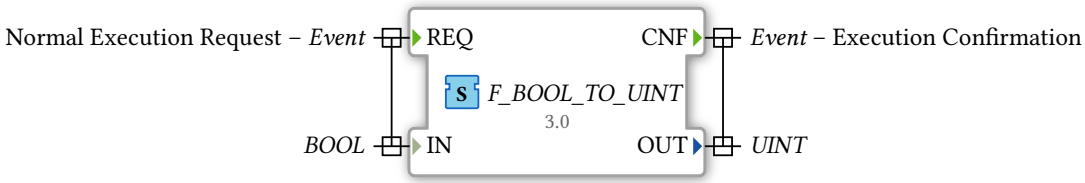
Application Scenarios

- Conversion of Boolean switching states for numerical calculations.
- Integration of Boolean signals into systems that can only process numeric values.

⚖️ Comparison with similar building blocks

- Compared to other conversion blocks such as `F_BOOL_TO_INT` or `F_BOOL_TO_DINT`, this block offers conversion to an unsigned 32-bit integer.

Conclusion



The `F_BOOL_TO_UDINT` function block is a simple and efficient building block for converting Boolean values to unsigned 32-bit integers. It is particularly useful in scenarios where Boolean signals need to be integrated into numerical processes.

F_BOOL_TO_UINT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_BOOL_TO_UINT` converts a Boolean value (`BOOL`) into an unsigned integer value (`UINT`). This conversion is particularly useful when Boolean signals need to be converted into numerical values, for example, for further calculations or control purposes.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: The Boolean input value (`BOOL`) to be converted.

Data Outputs

- **OUT**: The converted unsigned integer value (`UINT`).

Adapters

- No adapters are available.

Functionality

The function block performs the conversion by transforming the Boolean value `IN` into an unsigned integer value `OUT`. The conversion is performed according to the following rule:

- `FALSE` becomes `0`
- `TRUE` becomes `1`

The conversion is triggered by the event `REQ` and confirmed by the event `CNF`.

Technical Features

- The function block is a simple function block (`SimpleFB`) and performs the conversion in a single algorithm.
- The conversion is performed directly and without delay.

State Overview

The function block has no internal states. The conversion is performed anew with each `REQ` event.

Application Scenarios

- Conversion of Boolean sensor data into numerical values for further processing.
- Integration into control systems that require numerical values instead of Boolean values.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_BOOL_TO_INT` or `F_BOOL_TO_REAL` offer conversions to other data types, but `F_BOOL_TO_UINT` is specifically optimized for unsigned integer values.

The `F_BOOL_TO_UINT` function block is a simple and efficient tool for converting Boolean values to unsigned integers. Its clear interface and direct functionality make it a reliable component in control and automation systems.

F_BOOL_TO_ULINT

• – ◦ • – ◦ • – ◦ •

The function block `F_BOOL_TO_ULINT` converts a Boolean value (`BOOL`) into an unsigned 64-bit integer value (`ULINT`). This conversion is particularly useful in scenarios where Boolean states need to be converted into numerical values, for example, for processing in mathematical operations or for storage in databases.

- **REQ**: Normal execution request. Triggers the conversion. Linked to the data input `IN`.
- **CNF**: Execution Confirmation. Triggered after successful conversion. Linked to the data output `OUT`.
- **IN**: Input for the Boolean value (`BOOL`) to be converted.
- **OUT**: Output for the converted unsigned 64-bit integer value (`ULINT`).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters available.

Functionality

This function block performs the conversion from `BOOL` to `ULINT` when the event `REQ` is received. The Boolean value `IN` is converted to a value `ULINT`, with `FALSE` becoming `0` and `TRUE` becoming `1`. The result is output at `OUT`, and the event `CNF` is triggered.

- The function block is a simple function block (`SimpleFB`) and uses an ST algorithm for the conversion.
- The conversion is performed using the function `BOOL_TO_ULINT`, which directly converts the Boolean value into a `ULINT` value.

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

- Conversion of Boolean switching states into numerical values for further calculations.
- Integration into control systems that need to store Boolean signals in numerical databases.
- Use in data processing chains that require type conversion.
- Similar function blocks like `F_BOOL_TO_INT` or `F_BOOL_TO_DINT` convert Boolean values to other numeric types, but not to `ULINT`.
- `F_BOOL_TO_ULINT` is specific to converting to the unsigned 64-bit type and is therefore suitable for applications requiring a large range of values.

The function block `F_BOOL_TO_ULINT` provides a simple and efficient way to convert Boolean values to unsigned 64-bit integers. Its clear interface and direct operation make it ideal for applications requiring high-precision type conversion with a large range of values.

Conclusion

F_BOOL_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BOOL_TO_USINT` converts a Boolean value (`BOOL`) into an unsigned 8-bit integer (`USINT`). This conversion is useful when Boolean values need to be used in numerical operations or for communication with systems that do not directly support Boolean values.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs
- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs
- **IN**: The Boolean input value (`BOOL`) to be converted.

Data Outputs
- **OUT**: The converted unsigned 8-bit integer (`USINT`).

Adapters
This function block does not use adapters.

Functionality
The function block performs the conversion by transforming the Boolean value `IN` into a numeric value:

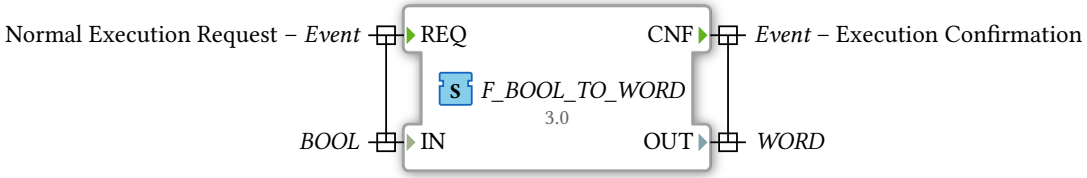
- `FALSE` is converted to `0`.
- `TRUE` is converted to `1`.

The conversion is triggered by the event `REQ`, and the result is output via the output `OUT`, accompanied by the confirmation event `CNF`.

Technical Features
- The function block is a simple function block (`SimpleFB`) and performs the conversion in a single algorithm.
- The conversion occurs directly and without delay as soon as the `REQ` event arrives.

State Overview
The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

Application Scenarios
- Conversion of Boolean switching states into numerical values for processing in mathematical operations.
- Communication with systems or devices that do not directly support Boolean values but can process numerical values.



⚖️ Comparison with Similar Function Blocks
- Compared to other conversion function blocks such as `F_BOOL_TO_INT` or `F_BOOL_TO_UINT`, `F_BOOL_TO_USINT` is specifically optimized for conversion to an unsigned 8-bit integer.

Similar function blocks can use larger or signed integer types, which may be more or less suitable depending on the use case.

Conclusion
The `F_BOOL_TO_USINT` function block is a simple and efficient tool for converting Boolean values to unsigned 8-bit integers. Its direct and lag-free operation makes it ideal for real-time applications where fast and reliable conversions are required.

F_BOOL_TO_WORD
• – ◦ • – ◦ • – ◦ •

Introduction
The function block `F_BOOL_TO_WORD` converts a Boolean value (`BOOL`) into a 16-bit word value (`WORD`). This conversion is particularly useful in scenarios where Boolean signals need to be embedded in or further processed within word data structures.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion. Linked to the data input `IN`.

Event Outputs

- **CNF**: Execution Confirmation. Triggered after successful conversion. Linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `BOOL` to be converted to `WORD`.

Data Outputs

- **OUT**: The output value of type `WORD` containing the result of the conversion.

Adapters

- No adapters available.

Functionality

This function block performs the conversion of `BOOL` to `WORD` when the event `REQ` is received. The Boolean value `IN` is converted into a 16-bit word, with `FALSE` being interpreted as `0` and `TRUE` as `1`. The result is output via `OUT`, and the event `CNF` is triggered to indicate successful conversion.

Technical Features

- The function block is a simple function block (`SimpleFB`) and uses an ST algorithm for conversion.
- The conversion is performed directly by the function `BOOL_TO_WORD(IN)`.

State Overview

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

Application Scenarios

- Embedding Boolean signals in word data structures for communication with other systems.
- Use in control logic where Boolean values need to be processed as part of larger data words.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_BOOL_TO_BYTE` or `F_BOOL_TO_DWORD` offer conversions to other data types (`BYTE` or `DWORD`). `F_BOOL_TO_WORD` is specific to 16-bit word values.

Conclusion

The function block `F_BOOL_TO_WORD` provides a simple and efficient way to convert Boolean values to word values. Its clear interface structure and direct functionality make it ideal for applications that require such conversions.

F_BYTE_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_AS_STRING` is used to convert a BYTE value into a STRING. This functionality is particularly useful when numeric data needs to be converted into a text format suitable for display or logging.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. Triggered after successful conversion.

Data Inputs

- **IN**: BYTE value to be converted into a STRING.

Data Outputs

- **OUT**: Result of the conversion as a STRING.

Adapters

This function block does not use any adapters.

Functionality

When the REQ event is triggered, the incoming BYTE value (IN) is converted to a STRING and output via the OUT output. Simultaneously, the CNF event is triggered to signal successful execution.

Technical Features

- The conversion is performed using the function `BYTE_AS_STRING`.
- The function block is simple and has no internal states or complex logic.

State Overview

Since it is a simple function block, there are no state transitions or machines.

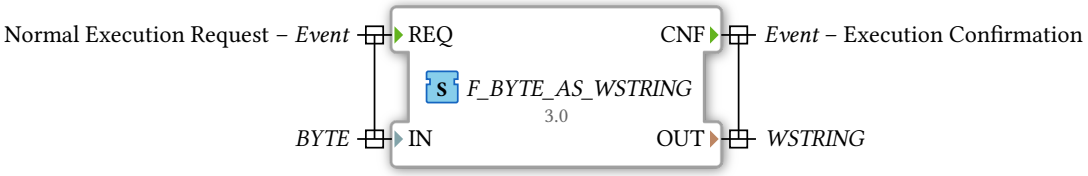
Application Scenarios

- Conversion of sensor values for display on an HMI.
- Preparation of data for logging or communication with other systems that expect string data.

⚖️ Comparison with Similar Building Blocks

- Compared to other conversion blocks like `F_WORD_AS_STRING` or `F_DWORD_AS_STRING`, this one is specifically optimized for BYTE values.
- Simpler and more specialized than generic conversion blocks.

Conclusion



The `F_BYTE_AS_STRING` function block offers a simple and efficient way to convert BYTE values to strings. Its simplicity makes it reliable and easy to integrate into various applications.

F_BYTE_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_AS_WSTRING` converts a BYTE value into a WSTRING value. This is particularly useful in scenarios where byte data needs to be further processed or output as Unicode strings.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. It is linked to the input value `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. Returns the converted value via `OUT`.

Data Inputs

- **IN** (BYTE): The byte value to be converted to a WSTRING.

Data Outputs

- **OUT** (WSTRING): The resulting Unicode string after conversion.

Adapters

- No adapters available.

Functionality
