The ALI_FB_CTD implements a down counter with charge function. The internal logic is implemented by the function block `FB_CTD_LINT`:

1. **Load**

An event at socket **LD** (via `LD.E1`) transfers the data value from **PV** (via `PV.D1`) to the internal counter. The counter value is then set to the preset value.

1. **Count Down**

An event at socket **CD** (via `CD.E1`) decrements the current counter value by 1, provided it is greater than 0.

1. **Output Signaling**

The current counter value is always output via plug **CV** (as a LINT).

- The plug **Q** returns `true` when the counter reaches **zero** (Boolean value via the AX adapter).
- The **CNF** event is sent after **every** processing operation (CD, LD, and PV).

1. **Event Passing**

The incoming events from CD, LD, and PV are all combined at the **REQ** input of the internal function block. Its **CNF** output is then distributed to the output adapters (Q.E1, CV.E1) and to the external event output CNF.

- **Always Triggering**: The function block sends the output events (Q.E1, CV.E1, CNF) with **every** update – even if the counter value does not change (e.g., after repeated CD resets to 0). For change-based triggering, a `AX_D_FF` (edge detector) must be interposed.
- **Adapter Coupling**: The use of unidirectional adapters (AX, ALI) enables flexible interconnection in IEC 61499 networks without rigid data and event connections.
- **LINT Values**: The counter operates with 64-bit integers, suitable for large counting ranges.
- **Internal Structure**: The function block delegates all counting logic to the proven standard FB `FB_CTD_LINT` from the `iec61131::counters` library.

The ALI_FB_CTD does **not have an explicit state machine** in the FB network. Its behavior is purely event-driven and combinatorial:

Input event	Action
LD activated	Counter reading = Preset value
CD activated	Decrement counter reading (if > 0)
PV activated	No counter change, but a CNF event is sent. The data value from PV is not directly adopted – an LD is required.

The current counter reading and the Boolean output are updated after each step.

- **Piece Counter in Manufacturing**: At the end of a production step, a pulse is sent to CD; the counter counts down from a predefined quantity (PV). At zero, Q is activated and signals, for example, “Batch complete”.
- **Time Control with Pulse Counting**: A clock generator sends pulses to CD; after a predefined number (PV), an event is triggered.
- **Maintenance Interval**: The counter serves as a countdown in maintenance cycles; an alarm is triggered when it reaches 0.

Function Block	Special Feature

ALI_FB_CTD (this function block)	Uses AX and ALI adapters; always triggers; suitable for adapter-based architectures.
FB_CTD_LINT (Standard)	Pure data/event function block without adapters; event triggering directly via the interfaces.
CTU (Upward Counter)	Counts upwards instead of downwards; different application logic.
Counter Function Blocks with Edge Suppression	They have their own filter logic (e.g., AX_D_FF) and only trigger on actual value changes.

The ALI_FB_CTD is particularly suitable for adapter-based environments where simple, reliable downcounting without additional filters is desired.

The **ALI_FB_CTD** is a robust downcounter for LINT values, specifically designed for adapter technology in IEC 61499 systems. It offers a clear, adapter-based interface and is reliable and tested thanks to the internal use of `FB_CTD_LINT`. Its "always-trigger" behavior makes it suitable for applications where every state change at the input should be immediately forwarded. Where change-based triggering is required, a simple filter block can be added. Overall, it represents a valuable addition to adapter-oriented automation solutions.

Conclusion

ALI_FB_CTU

• – ○ • – ○ • – ○ •

Introduction

The **ALI_FB_CTU** is a 64-bit integer counter (LINT). It serves as an adapter wrapper for the IEC 61131 counter module *FB_CTU_LINT* and provides all input and output signals via standardized adapter interfaces (AX and ALI). This ensures a clear separation of event and data flows and facilitates reuse in different project environments.

Interface Structure

Event Inputs

The module does not have separate, discrete event inputs. The triggering events are received via the adapters **CU**, **R**, and **PV**. Each of these adapters provides an event (E1) and a corresponding data value (D1). An incoming event at any of these adapters initiates processing.

Event Outputs

- **CNF** (Execution Confirmation): Outputs after each complete processing run, regardless of whether the CU, R, or PV triggered the event.
- **Q** (Adapter AX): Provides the output event (E1), which is output in parallel with the CNF event.
- **CV** (Adapter ALI): Also outputs an event (E1), synchronized with the CNF event.

Data Inputs

The module does not have separate, discrete data inputs. All input data is provided via the adapter interfaces:

- **CU.D1** – Count-Up Signal (BOOL)
- **R.D1** – Reset Signal (BOOL)
- **PV.D1** – Preset Value (LINT)

Data Outputs

The module does not have separate, discrete data outputs. The output data is provided via the adapter interfaces:

- **Q.D1** – Counter Output (BOOL): becomes TRUE as soon as the current counter reading is ≥ PV.
- **CV.D1** – Current Counter Reading (LINT)

Adapters

Direction	Name	Type	Description

Sockets (Inputs)	CU	AX	Count-Up: Event + BOOL signal
	R	AX	Reset: Event + BOOL signal
	PV	ALI	Preset value: Event + LINT value
Plugs (Outputs)	Q	AX	Output signal: Event + BOOL value
	CV	ALI	Counter reading: Event + LINT value

Functionality

The **ALI_FB_CTU** encapsulates an internal *FB_CTU_LINT*. Every incoming event at one of the three adapters **CU**, **R**, or **PV** is forwarded to the REQ event of the internal block. Simultaneously, the respective data values are passed to the corresponding inputs (*CU*, *R*, *PV*). The internal counter operates according to the IEC 61131 definition of a CTU:

- **On event at CU**: The counter reading is incremented by 1, provided the corresponding data bit is TRUE.
- **On event at R**: The counter reading is reset to 0.
- **On event at PV**: The passed value is stored as the new preset value.

After each processing operation, the internal block outputs a CNF event. This is passed to all three output adapters (CNF, Q, CV) so that all outputs are updated synchronously. The output **Q** becomes TRUE if and only if the current counter reading is greater than or equal to the preset value. The current counter reading can be read at any time via **CV**.

Technical Features

- **Adapter-based interface**: All signals are exchanged via standardized adapters (AX for binary, ALI for numeric values). This simplifies integration with heterogeneous systems and promotes reusability.
- **64-bit resolution**: The counter uses the LINT (Signed 64-bit Integer) data type, enabling very large counting ranges.
- **Shared trigger**: CU, R, and PV all trigger the same internal REQ. If multiple adapters are active simultaneously, all associated data values are processed in one step – the internal block evaluates the signals in parallel.
- **Note on output behavior**: The block fires the AX output event (Q.E1) with *every* update – even if the output state remains unchanged. If only "on-change" triggering is required, an AX_D_FF (turn-on delay/event filter) must be connected to the output.

State Overview

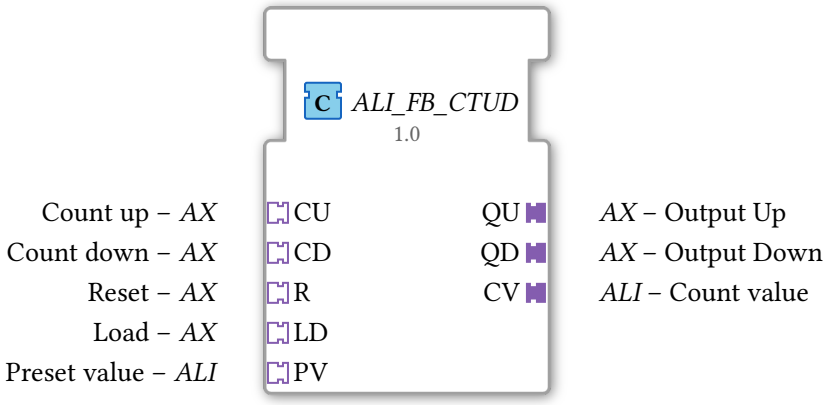
The internal state is determined by the counter reading (64-bit integer) and the Boolean output Q. There is no explicit state machine; the function block operates in an event-driven manner:

State Component	Possible Values	Description
Counter Reading (CV)	0 … 2^{63}-1	Current Count Value
Output Q	FALSE / TRUE	TRUE if CV ≥ PV

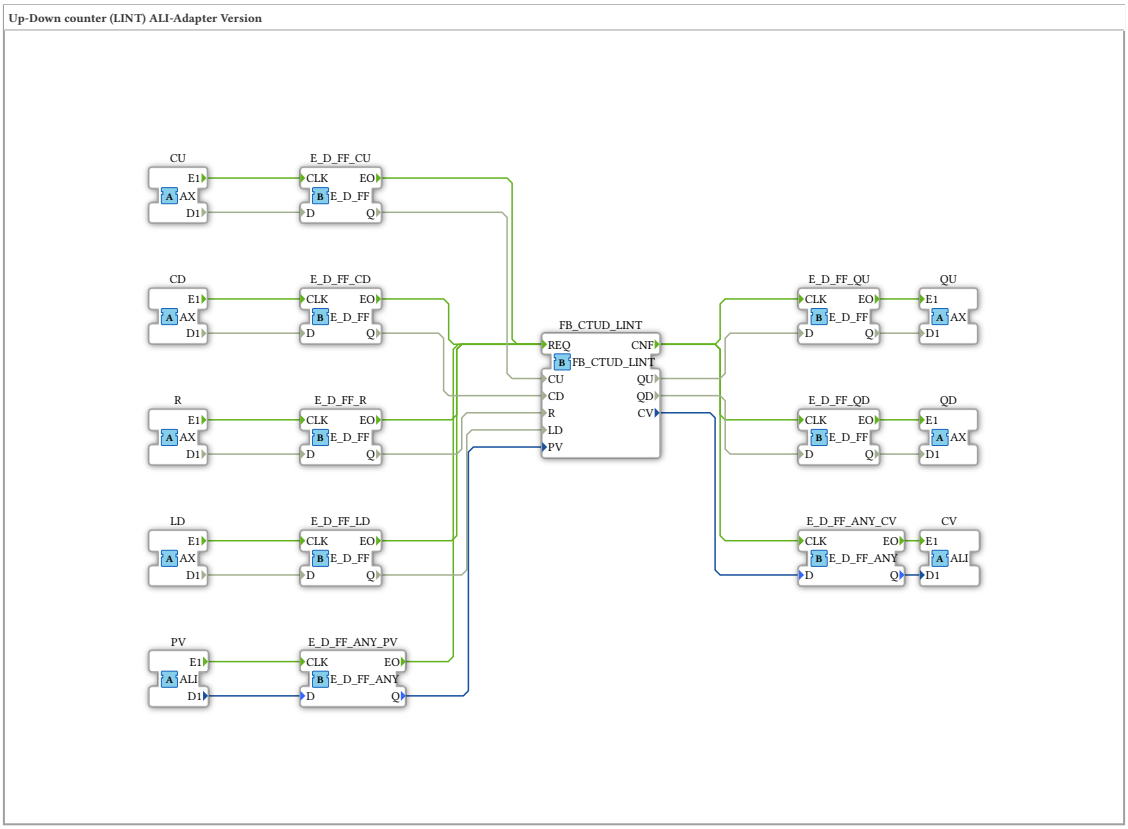
Application Scenarios

- **Event Counting**: Counting pulses in production facilities, conveyor belts, or energy meters.
- **Quantity Monitoring**: Recording the number of units produced and triggering a signal when a threshold is reached.
- **Reset-controlled counters**: Resetting the counter to zero after a manual or automatic reset.
- **Preset-based control**: Dynamically changing the setpoint during operation (e.g., batch changes).

Comparison with similar function blocks



- **Compared to a direct FB_CTU_LINT**: The ALI_FB_CTU abstracts the interfaces at the adapter level. This allows the signals to be connected to other function blocks that also use AX/ALI adapters, regardless of the specific implementation.
- **Compared to a standard CTU with BOOL inputs**: The ALI_FB_CTU allows the connection of adapters that bundle both events and data. This reduces the number of separate lines and makes the design clearer.



- **Compared to a CTU with INT/DINT**: The use of LINT covers a significantly larger value range, which is advantageous for high-resolution counting tasks or long-term monitoring.

Conclusion

The **ALI_FB_CTU** is a powerful, adapter-based up-counter for industrial automation environments. It combines proven IEC 61131 counter logic with modern adapter interfaces and offers simple, readable connectivity to other components. Its 64-bit resolution, shared event processing of all inputs, and the ability to dynamically set thresholds make it a flexible solution for a wide range of counting and monitoring tasks.

ALI_FB_CTUD

• – ○ • – ○ • – ○ •

Introduction

The function block **ALI_FB_CTUD** implements an up/down counter with a value range of type **LINT** (64-bit integer). It is specifically designed for use with **ALI adapters** and encapsulates a standard-

compliant counter according to IEC 61131-3 (FB_CTUD_LINT). Control and output are exclusively via adapter interfaces, allowing for flexible integration into adapter-based architectures.

Interface Structure

Event Inputs

The function block does not have direct event inputs. All control events are received via the **sockets** (adapters):

- **CU.E1** – Count Up event
- **CD.E1** – Count Down event
- **R.E1** – Reset event
- **LD.E1** – Load preset value event
- **PV.E1** – Apply preset value event

Note: All five events trigger a common internal processing cycle.
*Note: **CU.E1** – Count Up event *Note: **CU.E1** – Count Down event *CT ...

Event Outputs

- **CNF** (Event) – Execution Confirmation

Additionally, the following events are output via the **Plugs** (Output Adapters):

- **QU.E1** – Event when the counter value increases (Output Up)
- **QD.E1** – Event when the counter value decreases (Output Down)
- **CV.E1** – Event when the counter value changes (Count Value)

Special Note: These events are triggered with **every** update (regardless of the input event). For change-triggered triggering, it is recommended to use an AX_D_FF block beforehand.

Data Inputs

The data values are provided via the **sockets**:

- **CU.D1** (BOOL) – Count Up Enable
- **CD.D1** (BOOL) – Count Down Enable
- **R.D1** (BOOL) – Reset Signal
- **LD.D1** (BOOL) – Load Signal
- **PV.D1** (LINT) – Preset Value

Data Outputs

The results data are provided via the **plugs**:

- **QU.D1** (BOOL) – Signal: Counter value > 0 (e.g., for the “Up” output)
- **QD.D1** (BOOL) – Signal: Counter value < 0 (für „Down“-Ausgang, abhängig von interner Logik)
- **CV.D1** (LINT) – aktueller Zählerwert

Adapter

Typ	Richtung	Adapter-Typ	Beschreibung
CU	Socket	`adapter::types::unidirectional::AX`	Aufwärtszähl-Eingang (Ereignis+BOOL)
CD	Socket	`adapter::types::unidirectional::AX`	Abwärtszähl-Eingang (Ereignis+BOOL)
R	Socket	`adapter::types::unidirectional::AX`	Reset-Eingang (Ereignis+BOOL)
LD	Socket	`adapter::types::unidirectional::AX`	Load-Eingang (Ereignis+BOOL)
PV	Socket	`adapter::types::unidirectional::ALI`	Preset-Wert-Eingang (Ereignis+LINT)
QU	Plug	`adapter::types::unidirectional::AX`	Aufwärts-Ausgang (Ereignis+BOOL)
QD	Plug	`adapter::types::unidirectional::AX`	Abwärts-Ausgang (Ereignis+BOOL)
CV	Plug	`adapter::types::unidirectional::ALI`	Zählerwert-Ausgang (Ereignis+LINT)

Funktionsweise

Der Baustein enthält einen internen Funktionsblock **FB_CTUD_LINT**, der die eigentliche Zählerlogik nach IEC 61131-3 implementiert. Jedes Ereignis an einem der fünf Sockets (CU.E1, CD.E1, R.E1, LD.E1, PV.E1) löst eine Verarbeitung aus: Die zugehörigen booleschen Daten (CU.D1, CD.D1, R.D1, LD.D1) und der Preset-Wert (PV.D1) werden an den internen Baustein weitergeleitet und dort synchron ausgewertet. Der interne Baustein berechnet daraufhin den neuen Zählerstand und die Ausgangssignale QU, QD und CV. Nach Abschluss der Berechnung wird das Ausgangsereignis **CNF** gesendet und gleichzeitig werden die Ereignisse **QU.E1**, **QD.E1** und **CV.E1** auf den entsprechenden Plugs ausgegeben.

Die Verwendung von Adaptern ermöglicht eine lose Kopplung: Die eigentlichen Signalquellen (z. B. Sensoren oder Bedienelemente) und -senken (z. B. Aktoren oder Anzeigen) werden über Adapterverbindungen angebunden, ohne dass die internen Daten- und Ereignisleitungen direkt sichtbar sind.

Technische Besonderheiten

- **Datenbereich**: 64-Bit vorzeichenbehaftete Ganzzahl (LINT), geeignet für große Zählerstände.
- **Adapter-getriebene Schnittstelle**: Keine direkten Ereignis- oder Dateneingänge; alle Steuerungen erfolgen über AX- und ALI-Adapter.
- **Immerwährende Ereignisausgabe**: Die Ausgangsereignisse (QU.E1, QD.E1, CV.E1) werden bei **jedem** Verarbeitungszyklus ausgegeben, unabhängig davon, ob sich der Zählerstand tatsächlich geändert hat. Dieses Verhalten ist im Quellcode explizit dokumentiert – für eine änderungsbasierte Auslösung wird die Verwendung eines AX_D_FF-Filters empfohlen.
- **Interner Standard-Baustein**: Der FB_CTUD_LINT entspricht der IEC 61131-3-Definition eines Auf-/Abwärtszählers.

Zustandsübersicht

Eine formale Zustandsmaschine ist nicht extern sichtbar. Der interne Zustand besteht aus dem aktuellen **Zählerwert** (CV) und den internen Flags **QU** (z. B. „Wert > 0“) and **QD** (e.g., “Value < 0”). The state is updated with each input event according to the following priority:

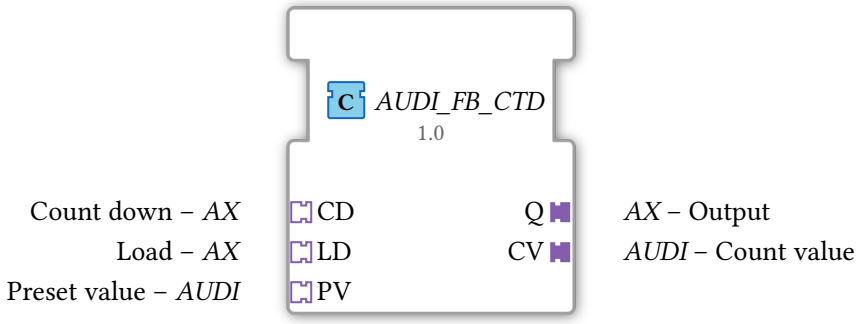
1. **Reset (R)**: sets CV to 0.
2. **Load (LD)**: adopts PV as the new CV.
3. **Count Up (CU)**: increments CV by 1 if CU.D1 = TRUE.
4. **Count Down (CD)**: decrements CV by 1 if CD.D1 = TRUE.

The flags QU and QD are then calculated from the new CV.

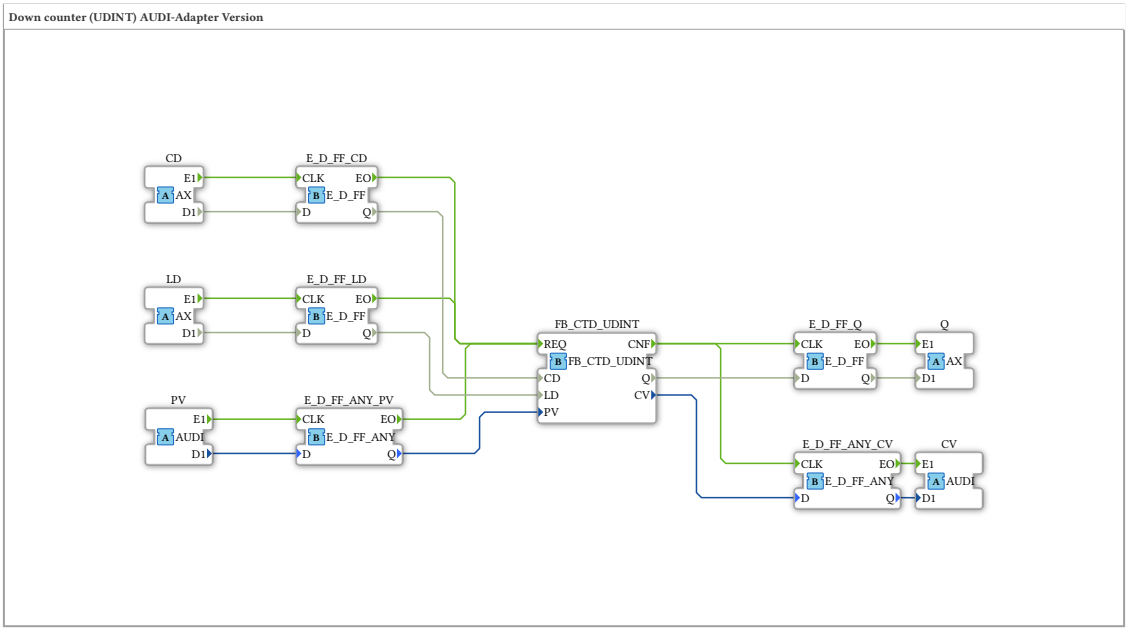
Application Scenarios

- **Production Counting**: Recording workpieces or cycles – counting up on entry, counting down on exit.
- **Position Monitoring**: Counting up/down steps in a linear drive.
- **Inventory Management**: Counting storage units with manual correction via Load/Reset.
- **Adapter-based control systems**: Integration into architectures that rely on unidirectional adapters (AX/ALI), e.g., distributed automation nodes.

Comparison with similar function blocks



The standard IEC 61131-3 function block **CTUD** (e.g., `FB_CTUD_INT`) typically works with smaller data types (INT, DINT) and offers direct event and data inputs. The **ALI_FB_CTUD** extends this concept with:



- **LINT data type** for very large counter ranges.
- **Adapter interfaces** (AX/ALI) instead of free inputs/outputs.
- **Continuous event output** as opposed to purely change-driven output.

Conclusion

The **ALI_FB_CTUD** is a powerful up/down counter for 64-bit numbers that integrates seamlessly into adapter-based automation environments. Its structure allows for a clear separation of control and data flows and facilitates reuse in modular control systems. The continuous event output should be considered during project planning – a downstream filter block may be required to prevent unwanted edge counts.

AUDI_FB_CTD

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_FB_CTD** implements a down counter based on the UDINT data type. It is specifically designed for use with adapter interfaces and uses the types `AX` and `AUDI` for event-driven communication. The actual counting logic is executed by an internal function block of type `iec61131::counters::FB_CTD_UDINT`. This function block fires an event on the output channel `CD`, `LD`, or `PV` with every update—regardless of whether the input was triggered by `CD`, `LD`, or `PV`. For change-based triggering, the use of a downstream `AX_D_FF` filter is recommended.

Interface Structure

Event Inputs

This function block does not have direct event inputs. All events are supplied via the connected **sockets** (adapter inputs).

Socket (Adapter)	Type	Description
`CD`	`AX`	Countdown Event
LD`	`AX`	Load Event
PV`	`AUDI`	Preset Value Event

Event Outputs

Name	Type	Description
CNF`	Event	Acknowledge event after each processing step

Data Inputs

Data is transmitted via sockets as part of the adapter protocol.

Socket (Adapter)	Data Type	Meaning
CD.D1	BOOL	Countdown command (TRUE = count)
LD.D1	BOOL	Load preset value command
PV.D1	UDINT	Preset counter value

Data Outputs

The output data is displayed via the plugs.

Plug (Adapter)	Data Type	Meaning
Q.D1	BOOL	Counter value = 0 (TRUE when reached)
CV.D1	UDINT	Current Counter Value

Adapter

Direction	Name	Type	Description
Socket	CD	AX	Event-Driven Count Pulse (Down)
Socket	LD	AX	Event-Driven Preset Loading
Socket	PV	AUDI	Event-Driven Preset Selection
Plug	Q	AX	Output signal: Counter reading = 0
Plug	CV	AUDI	Output signal: Current counter value

Functionality

Internally, a standardized IEC 61131 down counter (FB_CTD_UDINT) is used. The adapter events CD.E1, LD.E1, and PV.E1 are combined into a single REQ event of the internal module. This causes the internal counter to be recalculated with every external event.

- **CD (Count Down)**: If the data signal CD.D1 = TRUE is present, the current counter value is decremented by 1. With FALSE, the value remains unchanged.
- **LD (Load)**: If LD.D1 = TRUE is present, the counter is set to the value of PV.D1.
- **PV (Preset Value)**: This event updates the stored preset value; a subsequent LD event adopts this value.

After each calculation, the output data CV (current counter value) and Q (TRUE if CV = 0) are output via the corresponding plugs. Simultaneously, the acknowledgment event CNF is triggered.

Technical Features

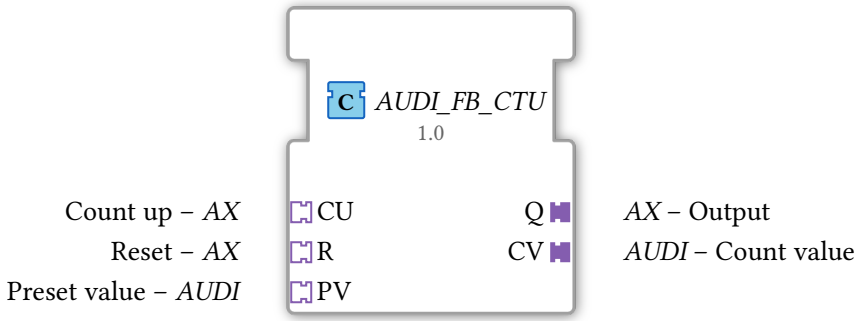
- **Event Behavior**: For every input event (CD, LD, or PV), the output channel Q is activated. This means that a Q.E1 event is sent even if the counter value or the Q state has not changed. This can lead to an unnecessarily high number of events in the subsequent logic.
- **Filtering Recommendation**: If the output event should only be triggered when Q actually changes state, an **AX_D_FF** (flip-flop) should be used as a filter. This suppresses repetitions.
- **Adapter-Based Connection**: All inputs and outputs are made via standardized adapters (AX, AUDI). This simplifies modular wiring and reuse in different environments.

State Overview

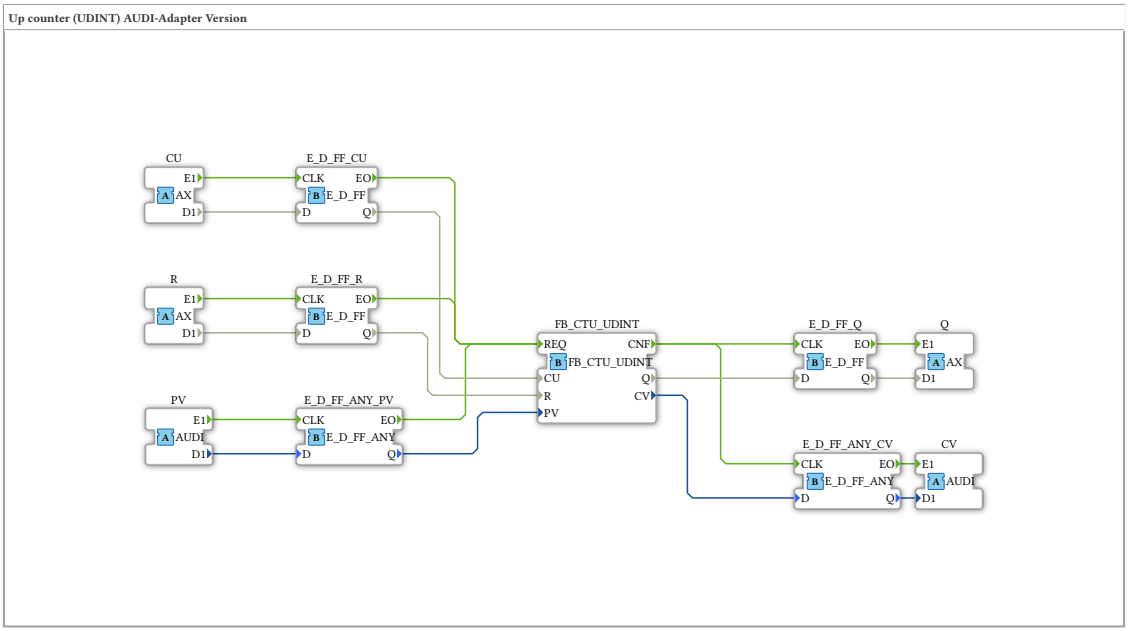
The component has no explicit states. The internal counter operates according to the rules of an IEC 61131 CTD component. The current counter value is determined by the data signals.

Application Scenarios

- **Event-driven Down Count**: Used in automation systems where a counter value is decremented by external events (e.g., number of workpieces processed).
- **Modular Control Components**: Integration into adapter-based architectures where standardized interfaces facilitate data exchange between different functional blocks.
- **Timer Simulation**: Combined with a clock generator to count a defined number of cycles and trigger an action when zero is reached.



Comparison with Similar Function Blocks



- **Standard CTD** (e.g., `FB_CTD_UDINT`): Has direct input/output variables, no adapters. The `AUDI_FB_CTD`, on the other hand, encapsulates the logic and provides the signals via adapters, enabling a clean separation of event and data channels.
- **Upward Counting Unit (CTU)**: Unlike the `AUDI_FB_CTD`, a CTU counts upwards. Both can be implemented using adapters, but are designed for different counting directions.
- **Always fire feature**: Many standard counters only output a signal when the initial state changes. The `AUDI_FB_CTD` does this with every processing step, which is a unique feature and can be an advantage or disadvantage depending on the application.

Conclusion

The `AUDI_FB_CTD`This is a flexible, adapter-based down counter for UDINT values. Its strength lies in its modular connectivity via standardized interfaces. However, developers should be aware of its unique event behavior (output pulse with each update) and correct it with a filter if necessary. This function block is well-suited for event-driven counting tasks in heterogeneous control environments.

AUDI_FB_CTU

• – ○ • – ○ • – ○ •

Introduction

The **AUDI_FB_CTU** is an up counter for the **UDINT** data type (32-bit unsigned) that connects via standard **AUDI adapters**. The function block encapsulates the IEC 61131 counting function in an adapter-based architecture and allows triggering of count pulses, reset, and preset operations via adapter events. Every counting-relevant operation (count pulse, reset, setting the preset value) necessarily triggers an output event – regardless of whether the counter value or the output value changes. If only change-based triggering is required, a downstream AX_D_FF function block must be used.

Interface Structure

Event Inputs

The module does not have traditional event inputs. Instead, the triggering events are introduced **via the adapter sockets**:

- **CU.E1** – Event from the *Count up* adapter: a rising pulse increments the counter by 1.
- **R.E1** – Event from the *Reset* adapter: resets the counter to 0.
- **PV.E1** – Event from the *Preset value* adapter: adopts the current value at the preset input as the new preset value (takes effect immediately, without changing the counter).

All three events are internally multiplexed onto the **REQ** event of the embedded IEC function block `FB_CTU_UDINT`. This means that each of these external pulses triggers processing.

Event Outputs

- **CNF** – Confirmation Event (EventOutput): This event is output after each processing of an incoming event. It is connected to the output adapters so that the connected components are informed about a completed counting operation.

In addition, the following **adapter events** are triggered (via internal wiring):

- **Q.E1** – Event of the *Output* adapter (type AX): Signals the availability of a new output value Q.
- **CV.E1** – Event of the *Count value* adapter (type AUDI): Signals the availability of a new counter reading CV.

These adapter events fire **simultaneously with CNF**, meaning that all three output events are activated simultaneously for every counting-relevant event.

Data Inputs

Data is also provided **via the adapter sockets**:

- **CU.D1** (UDINT, via adapter CU) – Count pulse: Only the value 0 or 1 is evaluated; a positive edge transition (0⟶1) results in an increment. (The adapter provides the event itself; additionally, the data value can be used, for example, as an edge-weighted signal.)
- **R.D1** (UDINT, via adapter R) – Reset signal: A value ≠ 0 resets the counter.
- **PV.D1** (UDINT, via adapter PV) – Preset value: The value present here is adopted as the new preset value upon arrival of the PV.E1 event. (The data value is only read in the event of an explicit PV event.)

Data Outputs

- **Q.D1** (BOOL, via adapter Q) – Output signal: `TRUE` when the current meter reading is ≥ **PV** (Preset Output).
- **CV.D1** (UDINT, via adapter CV) – Current meter reading (Count Value).

Adapters

Adapter Type	Direction	Name	Short Description
`AX` (unidirectional)	Socket (Input)	CU	Provides the count pulse event and an edge-weighted data value.
`AX` (unidirectional)	Socket (Input)	R	Provides the reset event and reset switch.
`AUDI` (unidirectional)	Socket (Input)	PV	Provides the preset event and preset numeric value.
`AX` (unidirectional)	Plug (Output)	Q	Provides the output binary (Q) as an event and data value.
`AUDI` (unidirectional)	Plug (Output)	CV	Provides the current counter reading as an event and data value.

Functionality

The **AUDI_FB_CTU** delegates all its counting logic to the internal IEC block `FB_CTU_UDINT`. For each incoming event (CU.E1, R.E1, or PV.E1), its **REQ** input is activated. The internal counter then executes the following logic:

1. **Reset first**: If **R** ≠ 0, the counter is set to 0.
2. **Count pulse**: If **CU** ≠ 0 and a rising edge transition has occurred since the last call, CV is incremented by 1.
3. **Preset takeover**: If **PV.E1** has been triggered, the value at PV is stored as the new threshold (PV).
4. **Comparison**: If CV ≥ PV (stored preset value), **Q** = TRUE; otherwise, it is FALSE.

After processing, the events **CNF**, **Q.E1**, and **CV.E1** are output simultaneously, regardless of whether Q or CV has changed.

Technical Features

- **Adapter-Based**: All inputs and outputs are implemented as standardized unidirectional adapters (`AX` for binary, `AUDI` for numeric values). This allows for flexible interconnection in adapter-oriented architectures.
- **Event Multiplexing**: The three input events (CU, R, PV) are multiplexed onto a common REQ. This simplifies internal wiring but means that a reset or preset operation also triggers the output event.
- **No On-Change Filtering**: As described in the header comment, the function block fires **always** on every processing operation. For change-only triggering, an AX_D_FF must be added (e.g., on Q and CV).
- **Data Width**: All counter and preset values are implemented as **UDINT** (32-bit unsigned).
- **State Maintenance**: The internal counter stores the current counter value and the preset threshold across multiple calls.

State Overview

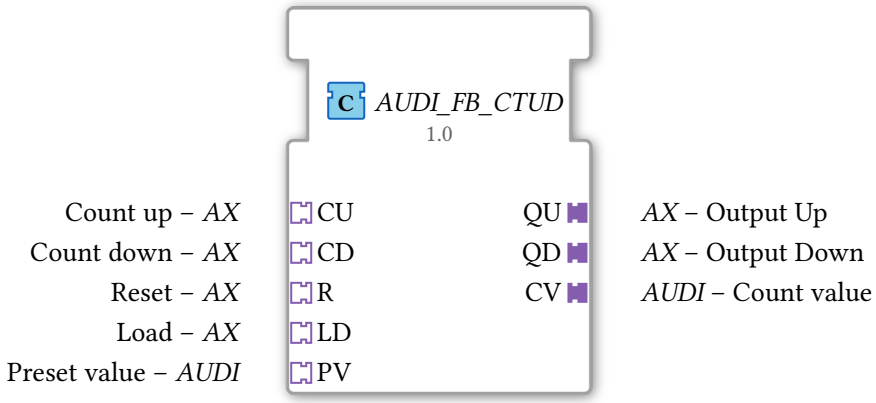
The function block does **not have its own state machine** (ECC). The state logic is entirely contained within the embedded IEC function block `FB_CTU_UDINT`. Its essential states are:

- **Idle**: Waiting for an event (CU.E1, R.E1, or PV.E1).
- **Processing** (during internal processing): Evaluating the input data (CU, R, PV), updating the counter and the Q and CV outputs.
- **Emitting**: Outputting the CNF, Q.E1, and CV.E1 events.

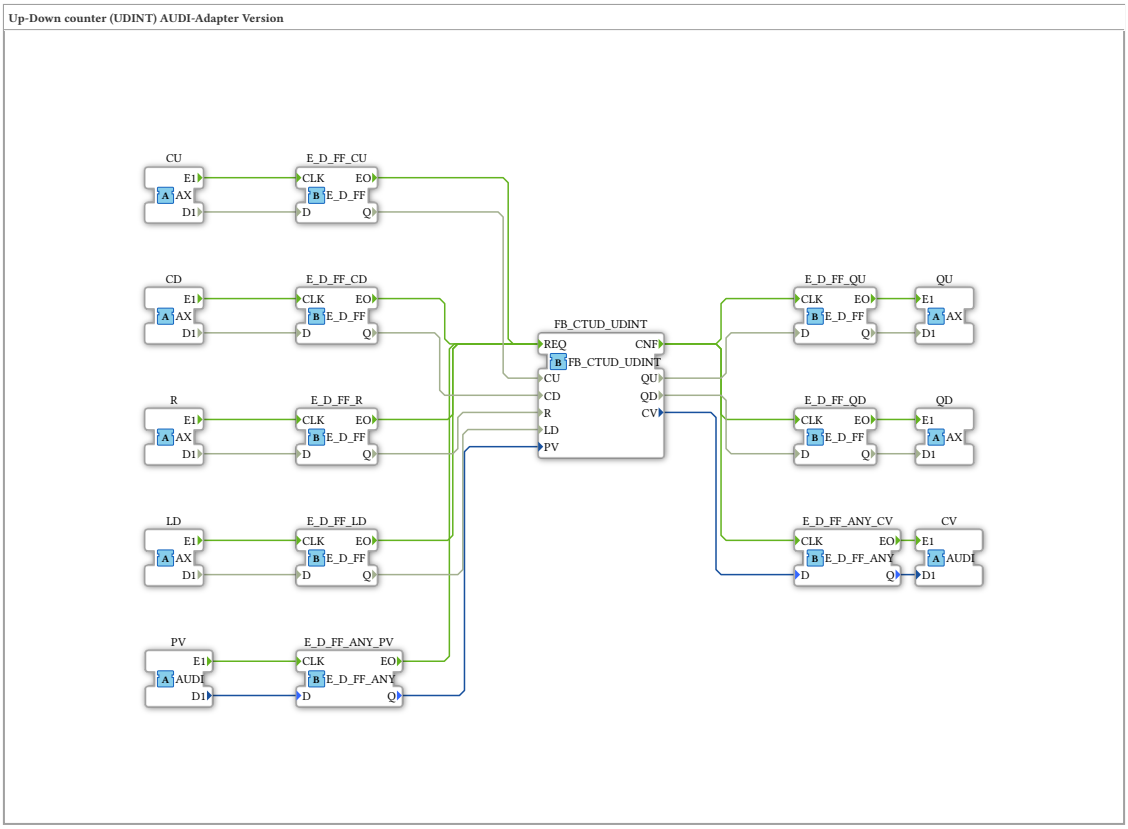
An explicit error state is not provided.

Application Scenarios

- **Event counting in adapter-based automation systems** – e.g., counting workpieces on a conveyor belt, where the sensor is connected via an AX adapter.
- **Time or pulse counter with reset** – The reset adapter can, for example, be a manual push button.
- **Reaching a threshold** – The PV input allows for dynamic threshold setting; as soon as the counter reading reaches or exceeds this value, Q becomes active.
- **Integration into modular systems** – Thanks to the standardized adapters (AUDI, AX), the module can be easily integrated into existing adapter-based libraries.



Comparison with similar modules



- **Unlike classic IEC CTU modules** (e.g.,`CTU_UDINT` (without adapter): These have direct event and data inputs but do not require adapter wrappers. The AUDI_FB_CTU offers the advantage of a standardized interface but requires specific adapter mapping.
- **Unlike CTU blocks with on-change triggering**: Blocks that only fire when there are actual value changes avoid unnecessary event floods. The AUDI_FB_CTU always fires, which can be compensated for by adding an AX_D_FF.
- **Comparison to the AUDI_FB_CTD** (down counter): The internal IEC block would then be `FB_CTD_UDINT`; interfaces and behavior are analogous, only the counting direction and the condition for Q differ (Q is active when CV ≤ 0).

Conclusion

The **AUDI_FB_CTU** is a robust, adapter-based up counter that can be seamlessly integrated into adapter-oriented automation solutions. High interoperability is achieved through the encapsulation of a standardized IEC counter and the use of AUDI/AX adapters. The characteristic of firing on every event is acceptable for many applications or can be corrected by downstream filtering. This component is particularly suitable for modular, expandable control architectures based on adapter protocols.

AUDI_FB_CTUD

• – ○ • – ○ • – ○ •

Introduction

The **AUDI_FB_CTUD** is an up/down counter with a value range for unsigned 32-bit integers (UDINT). It is implemented as a pure adapter version, meaning all inputs and outputs are provided via adapter interfaces. The function block encapsulates the standardized IEC 61131 function block `FB_CTUD_UDINT` and extends its functionality with an adapter-based interface. All output adapters are cyclically updated upon each triggering event (CU, CD, R, LD, or PV). If change-triggered (edge-sensitive) triggering is required, the use of a `AX_D_FF` as a filter block is recommended.

Interface Structure

Event Inputs

The function block has no discrete event inputs at the top level. All events are transmitted via the incoming adapter interfaces (sockets) of type `AX`.

Event Outputs

Name	Type	Comment
`CNF`	`Event`	Execution acknowledgment – is output each time an incoming event is processed.

Events are also sent via the outgoing adapters (plugs).

Data Inputs

There are no direct data inputs at the top level. All data values are provided via sockets `CU.D1`, `CD.D1`, `R.D1`, `LD.D1`, and `PV.D1`.

Data Outputs

There are no direct data outputs at the top level. The result data is output via plugs `QU.D1`, `QD.D1`, and `CV.D1`.

Adapters

Direction	Name	Type	Comment
Socket (Input)	`CU`	`adapter::types::unidirectional::AX`	Count up – Event and data (BOOL) for counting up
Socket (Input)	`CD`	`adapter::types::unidirectional::AX`	Count down – Event and data (BOOL) for counting down
Socket (Input)	`R`	`adapter::types::unidirectional::AX`	Reset – Event and data (BOOL) for resetting the counter
Socket (Input)	`LD`	`adapter::types::unidirectional::AX`	Load – Event and data (BOOL) for loading the preset value
Socket (Input)	`PV`	`adapter::types::unidirectional::AUDI`	Preset value – Event and data (UDINT) for the default value
Plug (Output)	`QU`	`adapter::types::unidirectional::AX`	Output Up – Event and data (BOOL), active when the current count reaches 0
Plug (Output)	`QD`	`adapter::types::unidirectional::AX`	Output Down – Event and data (BOOL), active when the current count reaches >= PV
Plug (Output)	`CV`	`adapter::types::unidirectional::AUDI`	Count value – Event and data (UDINT) with the current count value

Functionality

The `AUDI_FB_CTUD` internally uses the `FB_CTUD_UDINT` function block from the IEC 61131 library. All events received via the sockets (from `CU`, `CD`, `R`, `LD`, and `PV`) are routed to the `REQ` input of the internal function block. The corresponding data is routed to the appropriate inputs (`CU`, `CD`, `R`, `LD`, `PV`). The internal function block processes the request and updates its outputs. Upon successful processing, the event `CNF` is triggered, and simultaneously, the output adapters `QU`, `QD`, and `CV` are supplied with their new data and events.

The internal function block processes the request and updates its outputs. **Important:** This function block fires the output events (`QU.E1`, `QD.E1`, `CV.E1`) during **every** processing of an incoming event. No edge detection is performed.

Technical Features

- **Pure Adapter Interface:** This function block has no traditional inputs/outputs, but only adapters (sockets and plugs). This enables flexible integration into adapter-based automation architectures.
- **Use of Unidirectional Adapters:** The adapters `AX` and `AUDI` are defined as unidirectional. This ensures a clear direction for data and event flows.
- **Encapsulation of the IEC 61131 standard:** The counting logic conforms to the standardized `CTUD` function block, which increases portability and maintainability.
- **Range:** The counter value is implemented as `UDINT` (unsigned, 0…2^{32}–1).

State Overview

The internal `FB_CTUD_UDINT` cycles through the following states, depending on the incoming commands:

Condition	Action
`CU` = TRUE (rising edge) and `CD` = FALSE	Counter increments by 1
`CD` = TRUE (rising edge) and `CU` = FALSE	Counter decreases by 1
`R` = TRUE (rising edge)	Counter is reset to 0
`LD` = TRUE (rising edge)	Counter is set to the value of `PV`
Simultaneous `CU` and `CD` edges	Counter value remains unchanged (priority: none)

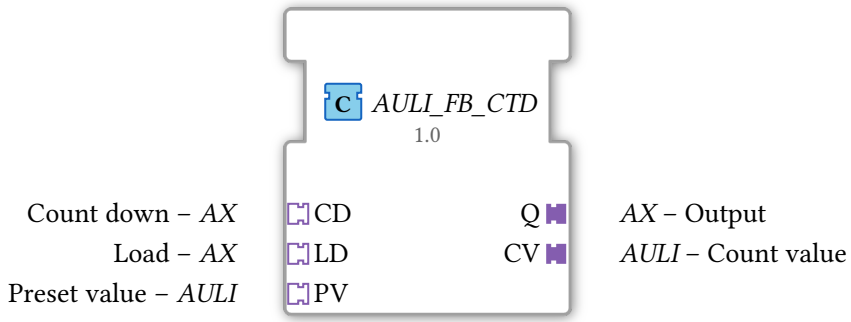
QU = TRUE	Current value = 0
QD = TRUE	Current value ≥ PV

Application Scenarios

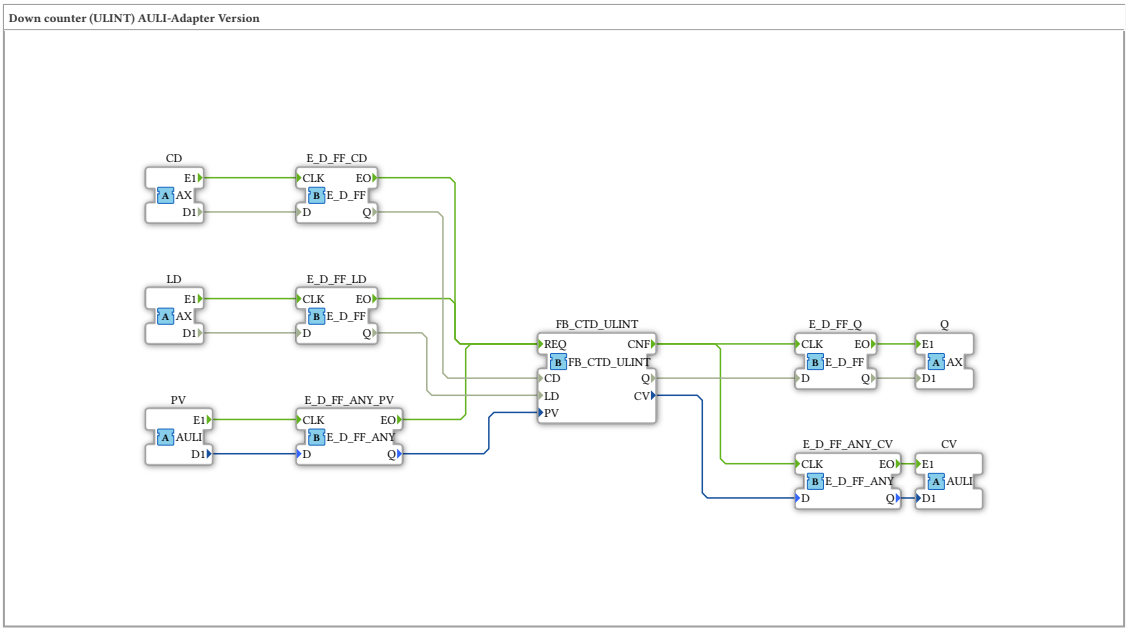
- **Piece Counter in Production Plants:** Recording of products on a conveyor line, using CU and CD for accurate counting during forward and reverse movements.
- **Inventory Management:** Counting inbound and outbound shipments, with reset during inventory and load for target values.
- **Event Counter in Building Automation:** Recording of passenger flows (e.g., in elevators) with an additional reset function.
- **Adapter-based systems:** Integration into distributed control environments based on the adapter concept of the 4diac IDE (e.g., AUTOSAR-like communication).

Comparison with similar components

Feature	AUDI_FB_CTUD	Standard CTUD (IEC 61131)
Interface	Pure adapters (sockets/plugs)	Direct event and data inputs/outputs
Data format	UDINT (via AUDI adapter)	UDINT (direct)
Event behavior	Every incoming event triggers all outputs	Event is only output when relevant changes occur
Flexibility	Higher through adapter-based cabling	Lower, but simpler in classic PLC environments
Recommended filter	Additional AX_D_FF for edge-triggered output	No filter needed, as it is edge-sensitive



Conclusion



The AUDI_FB_CTUDis a high-performance up/down counter whose adapter-based interface makes it particularly suitable for modern, modular automation solutions. It combines the proven IEC 61131 counting logic with the flexibility of 4diac adapter technology. Users should note, however, that output events are triggered with every processing operation, not just changes – a downstream edge filter may be necessary. With its clear structure and standardized data types, it represents a robust component for counting tasks in industrial control systems.

AULI_FB_CTD

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_FB_CTD** implements a **down counter** based on the data type `ULINT` (unsigned long integer). It is implemented as an **adapter version** and encapsulates the standard function block `FB_CTD_ULINT` from the IEC 61131-3 library. The block allows modular connection via the adapter interfaces CD (Count Down), LD (Load), and PV (Preset Value), as well as the output of the current count value (CV) and a binary signal (Q) via corresponding plug adapters.

Interface Structure

Event Inputs

The function block has **no direct event inputs**. Triggering occurs exclusively via the **event channels of the socket adapters**:

Adapter	Event Port	Description
CD	CD.E1	Count Down Pulse
LD	LD.E1	Load Preset Value Pulse
PV	PV.E1	Preset Value Update

Note: Each of these events triggers processing of the internal counter. The counter is always recalculated – regardless of whether the value actually changes.

Event Outputs

Name	Description
CNF	Confirmation after each processing

Additionally, the plug adapters provide **two event outputs**:

Adapter	Event Port	Description
Q	Q.E1	Outputs with every processing
CV	CV.E1	Outputs with every processing

Note: Since the events fire with every update (CD, LD, PV), it is recommended to filter a change edge with a `AX_D_FF` if necessary (see Technical Specifications).

Data Inputs

Data is also provided via the **socket adapters**:

Adapter	Data Port	Data Type	Description
CD	CD.D1	`BOOL`	Count pulse (rising edge)
LD	LD.D1	`BOOL`	Load command (rising edge)
PV	PV.D1	`ULINT`	Preset value (loaded during LD or PV update)

Data Outputs

Data is output via the **Plug Adapters**:

Adapter	Data Port	Data Type	Description
Q	Q.D1	`BOOL`	Counter reading = 0 (output signal)
CV	CV.D1	`ULINT`	Current counter reading

Adapter

Direction	Adapter type	Short description
Socket	`AX` (bidirectional)	Countdown control (Event + BOOL)
Socket	`AX` (bidirectional)	Load Control (Event + BOOL)
Socket	`AULI` (bidirectional)	Preset Value (Event + ULINT)
Plug	`AX` (bidirectional)	Output Q (Event + BOOL)
Plug	`AULI` (bidirectional)	Counter Value Output (Event + ULINT)

Functionality

This function block encapsulates the IEC 61131-3 function `FB_CTD_ULINT`. The internal logic is triggered by events from the three socket adapters:

1. **CD Event (Count Down):**

On a rising edge of `CD.D1` and a simultaneous event on `CD.E1`, the counter value is decremented by 1 (provided it is > 0). The new value is output at plug `CV`.

1. **LD Event (Load):**

On a rising edge of `LD.D1` and an event on `LD.E1`, the current preset value (`PV.D1`) is loaded into the counter. The counter value is then set to the preset value.

1. **PV Event (Preset Value Update):**

An event on `PV.E1` updates the internally stored preset value (without changing the counter). This is useful for dynamically changing the preset during operation.

After each processing operation, the confirmation event `CNF` is sent, along with the events on the plug adapters `Q.E1` and `CV.E1`. The data `Q.D1` and `CV.D1` are updated accordingly.

Technical Features

- **ULINT Data Type:**

The module uses unsigned 64-bit integers (ULINT), enabling counting ranges from 0 to 2^{64}-1 – suitable for very large counting tasks.

- **Adapter-Based Connection:**

All inputs and outputs are via adapters (`AX` for binary signals, `AULI` for ULINT values). This allows for clean encapsulation and modular wiring in the 4diac IDE.

- **Event Output on Every Update:**

The module fires the output events on every incoming event (CD, LD, PV) – even if the counter reading or output value does not change. This creates **permanent triggering** of the downstream network.
→ **Recommendation:** Use a `AX_D_FF` (differentiator/filter) at the outputs if you only want to react to value changes.

- **No internal state machine:**

The function block itself does not have its own state machine; the state logic (e.g., rising edge detection) is handled by the internal `FB_CTD_ULINT`.

State Overview

Internally, the function block only manages the **counter value** (CV) and the **current preset value** (PV). There is no explicit state machine. The possible actions are:

State / Action	Trigger	Result
Count Down	CD Event & CD.D1=TRUE	CV := CV - 1 (if CV>0)
Load	LD event & LD.D1=TRUE	CV := PV (current preset)
Preset Update	PV event	PV is overwritten (CV remains unchanged)

The output `Q` is set to `TRUE` when `CV = 0` is present; otherwise, it is `FALSE`..

Application Scenarios

- **Large-Range Piece Counter:**

Detection of production quantities with a value range > 32 bits (e.g., 10 billion pieces).

- **Preselection or Sequence Control:**

Used as a downward counter in a sequence where a signal is triggered upon reaching the value 0 (e.g., batch end).

- **Dynamic Preset Values:**

Changing the end-of-count value during operation via the PV event, without affecting the current counter reading.

- **Modular Systems:**

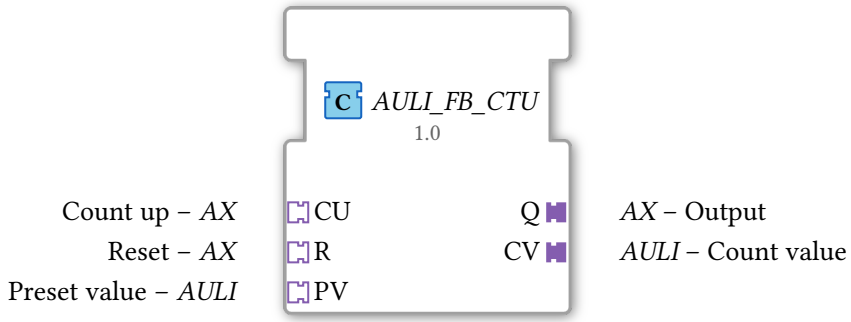
Integration into larger control architectures that rely entirely on adapter communication (e.g., via the Eclipse 4diac adapter mechanism).

Comparison with Similar Components

Component	Data Type	Interface	Special Feature
`FB_CTD_ULINT`	ULINT	Standard I/O	Basic down counter without adapter
AULI_FB_CTD	ULINT	Adapter (AX, AULI)	Adapter-encapsulated, all events result in an update
`FB_CTD` (Standard)	INT/UINT	Standard I/O	Usually 16-bit or 32-bit, fixed event logic

The **AULI_FB_CTD** offers more flexible integration into complex networks due to its adapter coupling, but has the "side effect" that output events are sent even if the values remain unchanged. For applications that should only fire upon a value change, the basic function block `FB_CTD_ULINT` or a combination with an edge detector (`AX_D_FF`) is preferable.

Conclusion



The **AULI_FB_CTD** is a powerful down counter for 64-bit values that is integrated into 4diac projects via adapter interfaces. It is particularly suitable for large counting ranges and modular control topologies. The continuous event output requires careful handling of the downstream network, but this can be mitigated by suitable filter blocks (e.g., `AX_D_FF`). Thanks to the encapsulation of the proven `FB_CTD_ULINT`, its operation is robust and standards-compliant.

AULI_FB_CTU

• – ○ • – ○ • – ○ •

The function block **AULI_FB_CTU** implements an up counter based on the ULINT (unsigned long integer) data type. It is designed as an IEC 61499-compliant component with an **AULI adapter interface**. Internally, the counter uses a standardized IEC 61131-3 CTU component (`FB_CTU_ULINT`) and makes its functionality available via adapter ports. Events are triggered with every update – regardless of a value change.

No dedicated event inputs. Events are received exclusively via the **AX adapters** of the sockets (CU, R, PV).

Name	Type	Comment
CNF	Event	Execution Confirmation – triggered with each counter update

No direct data inputs. The required data (CU pulse, reset signal, preset value) is provided via the **AULI or AX adapters** of the sockets.

No direct data outputs. The result values (current counter value CV and threshold status Q) are output via the **AULI or AX adapters** of the plugs.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

| Direction | Adapter Name | Type | Comment | **Socket (Input)** | CU | `adapter::types::unidirectional::AX` | Count-Up Pulse (Event + Data) | **Socket (Input)** | R | `adapter::types::unidirectional::AX` | Reset Pulse (Event + Data) | **Socket (Input)** | PV | `adapter::types::unidirectional::AULI` | Preset Value (Comparison Value for Q Output) | **Plug (Output)** | Q | `adapter::types::unidirectional::AX` | Counter Reading ≥ Preset? (Boolean Status) | | **Plug (Output)** | CV | `adapter::types::unidirectional::AULI` | Current Meter Reading (ULINT) |

Functionality

This module encapsulates an IEC 61131-3 compliant CTU meter (`FB_CTU_ULINT`). Events and data are received via the **socket adapters**:

- **CU Update**: A rising edge at CU triggers a counting step (CV = CV + 1).
- **R Update**: A reset resets the meter reading (CV = 0).
- **PV Update**: The preset value is applied; CV is compared to PV with each counting step.

The event at a socket is internally routed to the `REQ` input of the embedded CTU block. After processing, the `CNF` event of the CTU block is forwarded to all three outputs:

- **Q-Plug**: Outputs the status event (Q.E1) – sent **with every update**, regardless of whether the boolean value has changed.
- **CV-Plug**: Outputs the event (CV.E1) – also **with every update**.
- **CNF-Event**: Provided as an external event.

The data flows are analogous: The socket data (CU.D1, R.D1, PV.D1) is transferred to the corresponding data inputs of the internal counter. The output data (Q.D1, CV.D1) is output via the plugs.

- **Always Update**: The function block triggers the output events (Q.E1, CV.E1, CNF) with **every** incoming event (CU, R, PV) – even if the counter reading or the Q value does not change.
- **Filter Recommendation**: If triggering is only desired upon an actual value change, the use of an **AX_D_FF** function block as a pre-filter is recommended (see comment in the identification).
- **Data Width**: The counter uses the ULINT data type (64-bit unsigned integer), suitable for large counting ranges.
- **Adapter Interface**: All inputs and outputs are handled via standardized adapters (`AX` for Boolean/ event-based values, `AULI` for ULINT values). This facilitates modular design and reuse in adapter-based projects.
- **No Top-Level State Machine**: The function block is purely transaction-based: Every incoming event triggers immediate processing.

The function block does not have its own state machine. The internal `FB_CTU_ULINT` can pass through the following states (simplified):

- **Idle**: Waiting for an event.
- **Increment**: Upon a CU event, the internal counter is incremented.
- **Reset**: Upon a R event, the counter is reset to 0.
- **Preset Update**: The comparison value is updated upon a PV event.

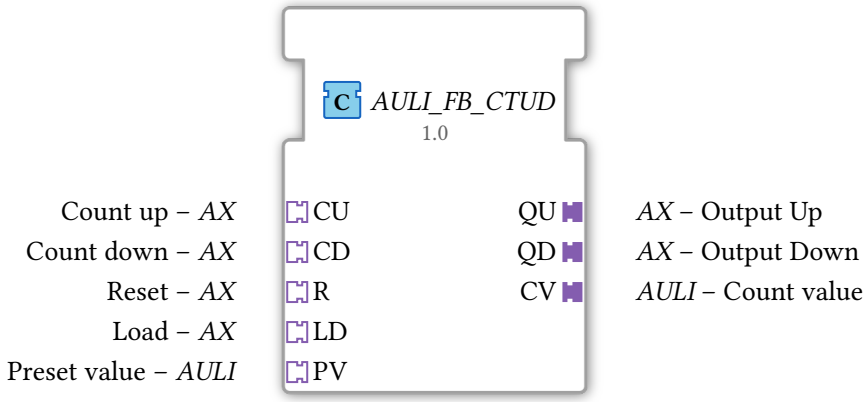
After each processing operation, the outputs are updated and the CNF event is sent.

- **High-Frequency Pulse Counting**: Acquisition of counting pulses (e.g., encoders, clock signals) with 64-bit resolution.
- **Threshold Monitoring**: Counting of products or events up to a configurable threshold (PV); the Q output is activated upon reaching this threshold.

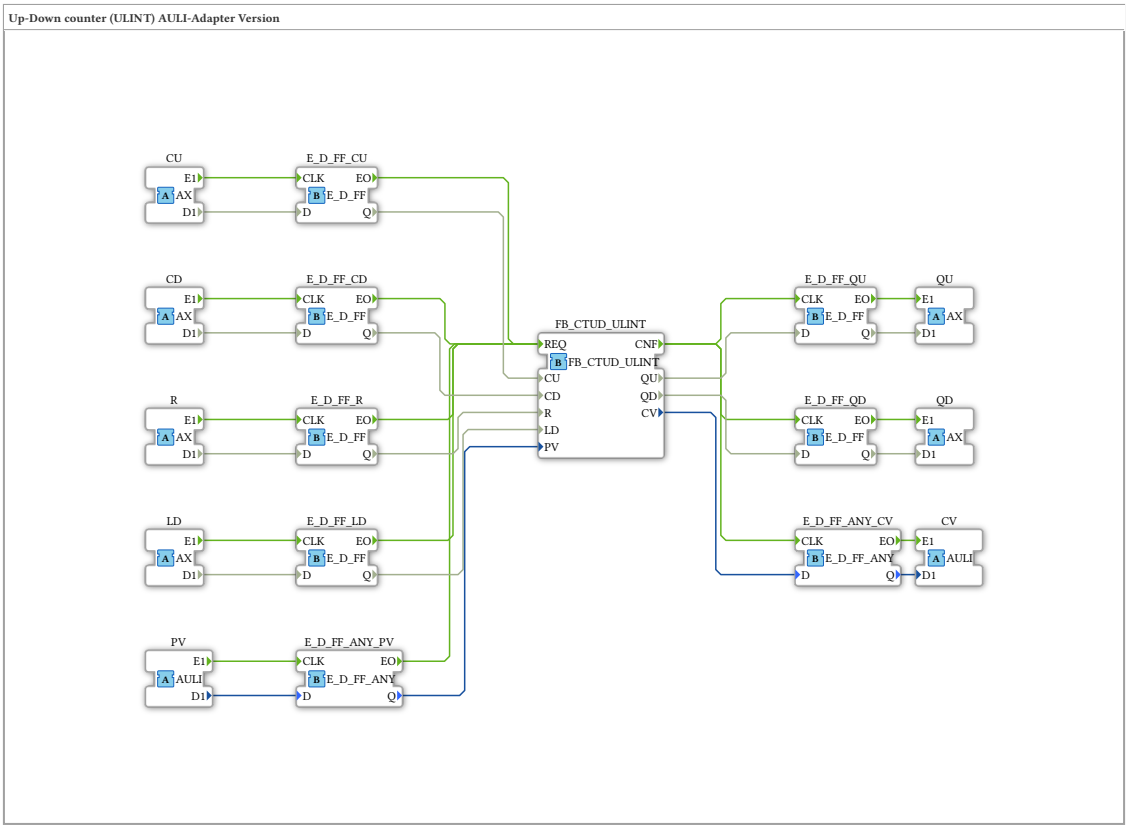
- **Reset-Controlled Batch Counting**: After an R pulse, the counter starts from zero; the current count is output via CV.
- **Adapter-Based Automation Modules**: Easy integration into systems that rely on AX/AULI adapters (e.g., standardized I/O modules).
- **Standard CTU (IEC 61131-3)**: Typically offers separate event and data ports. The `AULI_FB_CTU` encapsulates these in adapters, which simplifies bus-level wiring.
- **CTU with Change Detection**: Some counter function blocks only fire output events when a value changes. This function block triggers with every update – resulting in deterministic behavior (one event per input event), but may require downstream filters.
- **CTU as a Basic Function Block**: Other implementations use their own state machine; this function block delegates the logic to an embedded block, thus remaining lean.

The **AULI_FB_CTU** offers an IEC 61499-compliant, adapter-based increment counter function with ULINT data width. Its strengths lie in its modular interface and reliable event triggering with every update. For applications requiring only change detection, an external filter block (AX_D_FF) is recommended. Overall, the block is suitable for a wide range of counting scenarios in industrial automation, especially in adapter-oriented architectures.

Technical Features



State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

AULI_FB_CTUD

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_FB_CTUD** implements an up/down counter for unsigned 64-bit integers (ULINT). It exclusively uses adapter interfaces according to the IEC 61499-2 standard for event and data connections. The block encapsulates the standard FB `FB_CTUD_ULINT` and extends its inputs and outputs with adapter-based connections, enabling flexible and standardized integration into adapter-oriented architectures.

Interface Structure

Event Inputs

The block does not have any traditional event inputs. Instead, the counter events are transmitted via the **adapter sockets**:

- **CU** (Count Up) – Event via `CU.E1`
- **CD** (Count Down) – Event via `CD.E1`
- **R** (Reset) – Event via `R.E1`
- **LD** (Load) – Event via `LD.E1`
- **PV** (Preset Value) – Event via `PV.E1`

Event Outputs

- **CNF** – Standard event output, triggered with every counter update.

Additionally, events are output via the **adapter plugs**:

- **QU.E1** – Counter overflow event (maximum value reached)
- **QD.E1** – Counter underflow event (value 0)
- **CV.E1** – Update the current counter reading

Data Inputs

The block does not have separate data inputs. All input data is provided via the adapter sockets:

- **CU.D1** (BOOL) – Enables increment (TRUE increments the counter at CU.E1)

- **CD.D1** (BOOL) – Enables decrement
- **R.D1** (BOOL) – Enables reset
- **LD.D1** (BOOL) – Enables load
- **PV.D1** (ULINT) – Value for the load operation

Data Outputs

There are no separate data outputs. The output data is sent via the adapter plugs:

- **QU.D1** (BOOL) – Signals reaching the maximum value
- **QD.D1** (BOOL) – Signals reaching 0
- **CV.D1** (ULINT) – Current counter reading

Adapter

Adapter	Direction	Type	Purpose
CU	Socket	AX	Count Up – Event + Boolean enable
CD	Socket	AX	Count Down – Event + Boolean enable
R	Socket	AX	Reset – Event + Boolean enable
LD	Socket	AX	Load – Event + Boolean enable
PV	Socket	AULI	Preset Value – Event + ULINT value
QU	Plug	AX	Output Up – Event + Boolean State
QD	Plug	AX	Output Down – Event + Boolean State
CV	Plug	AULI	Current Value – Event + ULINT Counter Value

Functionality

The function block reacts to events at the input adapters (`CU.E1`, `CD.E1`, `R.E1`, `LD.E1`, `PV.E1`). For each event, the corresponding data value (`DX.D1`) is evaluated:

- **CU**: When `CU.E1` and `CU.D1 = TRUE` occur, the counter is incremented.
- **CD**: When `CD.E1` and `CD.D1 = TRUE` are encountered, the counter is decremented.
- **R**: When `R.E1` and `R.D1 = TRUE` are encountered, the counter is reset to 0.
- **LD**: When `LD.E1` and `LD.D1 = TRUE` are encountered, the counter is set to the value of `PV.D1`.

After each processing operation, the event `CNF` is output. Simultaneously, the output adapters are updated:

- `QU.D1` becomes `TRUE` when the counter reaches its maximum value (`2^64 - 1`).
- `QD.D1` becomes `TRUE` when the counter value is 0.
- `CV.D1` provides the current counter value.

The entire process is synchronous – each incoming event triggers a calculation and subsequently the output of the results.

Technical Features

- **Adapter-based communication**: All inputs and outputs are handled via adapters (sockets/plugs). This enables a decoupled connection between components and simplifies reuse in different contexts.
- **Unidirectional Adapters**: The adapters used (AX, AULI) are unidirectional – sockets receive, plugs send.
- **Trigger Behavior**: The function block fires the output events (`QU.E1`, `QD.E1`, `CV.E1`) on **every** counter update (including reset or load). For change-based triggering, an AX_D_FF (differentiator) must be used.
- **Value Range**: The counter operates in the range 0 ... 2^64-1 (ULINT). Overflows are signaled by `QU`, underflows by `QD`.

State Overview

The function block does not have an explicit state machine; The counter behavior is implemented by the internal function `FB_CTUD_ULINT`. Essentially, three states are distinguished:

1. **Normal Operation** – The counter value is between 1 and `2^64-2`. Neither `QU` nor `QD` are active.
2. **Overflow** – The counter has reached its maximum value. `QU.D1 = TRUE`.

3. **Underflow** – The counter reading is 0. `QD.D1 = TRUE`.

After a reset (`R`) or load (`LD`), the counter can immediately jump to one of these states.

Application Scenarios

- **Industrial Piece Counters**: Recording production quantities with up-and-down counting (e.g., good/bad parts).
- **Pallet or Workpiece Tracking**: Counting inputs and outputs in a buffer memory.
- **Event-Driven Systems**: Combination with sensors (light barriers, proximity switches) via the adapter interfaces.
- **Adapter-Based Control Architectures**: Seamless integration into projects that utilize the socket/plug concept of IEC 61499-2.

Comparison with Similar Components

Component	Properties
`FB_CTUD_ULINT`	Same counter logic, but with separate event and data inputs/outputs (no adapters).
AULI_FB_CTU`	Up counter only, as an adapter version.
AULI_FB_CTD`	Down counter only, as an adapter version.
CTUD` (Standard IEC 61499)	Similar functionality, but usually with different data types (e.g., INT) and without an adapter.

The `AULI_FB_CTUD` combines up and down counting in one block and offers particularly flexible integration with other adapter-based components via its adapter interfaces.

Conclusion

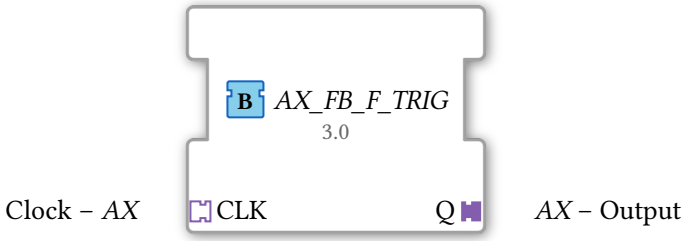
The `AULI_FB_CTUD`This is a high-performance up/down counter for ULINT values, distinguished by its complete adapter interface. It combines proven counting logic with the flexibility of the IEC 61499-2 adapter concept. Thanks to its standardized event and data transmission via plugs and sockets, it is particularly suitable for modular, reusable control applications. Its ease of use and integrated overflow/underflow detection make it a reliable building block in many industrial counting tasks.

Numerical Index (iec61131-3)

Here you will find all exercises from the `iec61131-3` workspace in ascending order.

AX_FB_F_TRIG

ECC: AX_FB_F_TRIG



Insert placeholder for the function block image here, if available

• – ◦ • – ◦ • – ◦ •

Introduction

The **AX_FB_F_TRIG** function block (Falling Edge Trigger with AX Adapter) is used to detect a falling edge (signal change from TRUE to FALSE) within an adapter-based architecture. It implements the logic of a standard IEC 61131-3 function block (`F_TRIG`), but uses **AX Adapters** to encapsulate data and event signals, thus reducing wiring complexity in IEC 61499 applications.

Interface Structure

The function block does not use traditional separate event and data pins, but instead utilizes adapter interfaces.

Event Inputs

- *No direct event inputs (encapsulated in adapter `CLK`).*

Event Outputs

- *No direct event outputs (encapsulated in adapter `Q`).*

Data Inputs

- *No direct data inputs (encapsulated in adapter `CLK`).*

Data Outputs

- *No direct data outputs (encapsulated in adapter `Q`).*

Adapter

Name	Type	Comment	Description
CLK	`adapter::types::unidirectional::AX`	Clock	**Socket (Input):** The input adapter that provides the signal to be monitored. Typically contains an event (`E1`) and a Boolean data value (`D1`).
Q	`adapter::types::unidirectional::AX`	Output	**Plug (Output):** The output adapter that sends the result of the edge detection.

Functionality

The function block monitors the logical state of the data input in adapter `CLK` (field `D1`). For each event at input `CLK` (`E1`), the following algorithm is executed:

1. The function block checks whether a transition from **TRUE** (High) to **FALSE** (Low) has occurred. 2. An internal memory (`MEM`) is used to store the inverted state of the last cycle.
2. The logic is: `Q.D1 := NOT CLK.D1 AND NOT MEM`.
3. The memory is updated: `MEM := NOT CLK.D1`.

Behavior:

- When the input signal changes from 1 to 0, the output `Q.D1` is set to TRUE for exactly one cycle.
- In all other cases (0->0, 0->1, 1->1), the output remains FALSE.
- The result is signaled via the event `Q.E1`.

Technical Features

- **Adapter Technology:** By using the `AX` adapter (generic data type, interpreted here as Boolean), event flow and data flow are bundled. This results in clearer function block diagrams.
- **Internal Storage:** The function block has an internal variable `MEM` (initial value TRUE) to reference the previous state of the input signal.
- **Minimalist ECC:** The state machine (ECC) consists of only a single state, which ensures very fast and direct algorithm execution.

State Overview

The function block's Execution Control Chart (ECC) is very simple:

- **REQ (State):** This is the only state.
- **Transition:** It is triggered by the event `CLK.E1` (from the input adapter).
- **Action:** Executes the algorithm `REQ` and then triggers the output event `Q.E1`.

Application Scenarios

The **AX_FB_F_TRIG** is suitable for various control tasks where "switching off" or "releasing" needs to be detected:

- **Button Evaluation:** Detects when a button is released (falling edge).
- **Sensors:** Triggers an action when a workpiece leaves a sensor area (light barrier becomes clear).
- **Alarm Reset:** Detects when an error signal is no longer present.
- **Structured Programming:** Used in complex applications that rely heavily on adapters to avoid "spaghetti code" (many individual connection lines).

⚖️ Comparison with similar function blocks

Function Block	Difference
F_TRIG (Standard)	Uses separate `CLK` (BOOL) and `Q` (BOOL) pins, as well as separate `REQ`/`CNF` events. Functionally identical, but with a different interface.
AX_FB_R_TRIG	The counterpart to this function block. It detects the **rising edge (0 to 1).

E_F_TRIG	Event-based trigger in IEC 61499, often operates purely at the event level without encapsulated data adapters.

Conclusion

The **AX_FB_F_TRIG** is an essential component for developers who rely on adapter-based designs within the 4diac IDE and IEC 61499. It offers the reliable functionality of classic edge detection, packaged in a modern, bandwidth-efficient interface.

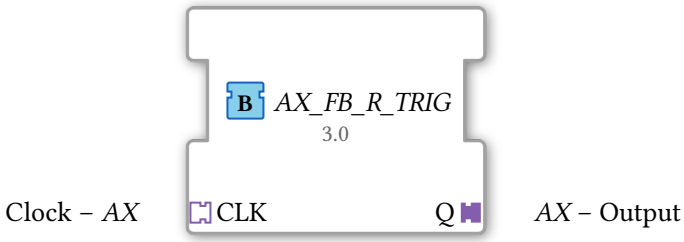
]



AX_FB_R_TRIG

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_FB_R_TRIG** (Rising Trigger with AX Adapter) is used to detect the rising edge of a Boolean signal. Unlike the standard `R_TRIG` block according to IEC 61131-3, this block uses **AX adapters** for input and output. It encapsulates the edge detection logic in an adapter-based architecture, which simplifies integration into systems that use `adapter::types::unidirectional::AX`. The goal is to generate a `TRUE` signal at the output when the input signal transitions from `FALSE` to `TRUE`.

Interface Structure

Event Inputs

This block has no direct event inputs. Event control is handled via the adapter `CLK`.

Event Outputs

This block has no direct event outputs. Event forwarding is handled via the adapter `Q`.

Data Inputs

This block has no direct data inputs. Data is received via the adapter `CLK`.

Data Outputs

This block has no direct data outputs. Data is output via the adapter `Q`.

Adapters

Name	Type	Comment
CLK	`adapter::types::unidirectional::AX`	**Socket (Input):** The clock input being monitored. Contains the data signal (D1) and the associated event (E1).
Q	`adapter::types::unidirectional::AX`	**Plug (Output):** The pulse output. Provides `TRUE` only on a rising edge at input `CLK`.

Functionality

The component implements the classic logic of a "Rising Edge Detector":

1. The component waits for an event at the adapter input `CLK` (signal `CLK.E1`).
2. As soon as the event occurs, the algorithm `REQ` is executed.
3. The algorithm checks the current value of the data input (`CLK.D1`) and compares it to the stored state from the previous cycle (`MEM`).

- **Logic:** `Q.D1 := CLK.D1 AND NOT MEM`

1. If `CLK.D1` is true (`TRUE`) and the stored value `MEM` was false (`FALSE`), the output `Q.D1` is set to `TRUE`. In all other cases, `Q.D1` is `FALSE`.
2. The internal memory `MEM` is then updated with the current value of `CLK.D1`.
3. Finally, the event is triggered at the output adapter `Q` (`Q.E1`) to inform subsequent function blocks.

Technical Features

- **Adapter Encapsulation:** The function block is specifically designed for the type `adapter::types::unidirectional::AX`. This adapter type typically bundles an event (`E1`) and a Boolean data point (`D1`). This reduces the visible wiring in the application diagram, as event and data flow are combined in a single connection line.
- **Internal Memory:** The block uses an internal Boolean variable `MEM` to store the state of the input signal between executions.

State Overview

The block is based on a very simple Execution Control Chart (ECC) with only one state:

- **State `REQ`:** This is the only state.
- **Transition:** The block remains in this state and responds to the input adapter event `CLK.E1`.
- **Action:** On each event, the algorithm `REQ` is executed, and the output adapter event `Q.E1` is sent.

Application Scenarios

- **Signal Conditioning:** Converting a continuous signal (e.g., switch is ON) into a single pulse to trigger an action exactly once when the device is switched on.
- **Wiring Simplification:** Used in systems that consistently rely on adapter technology to minimize the number of visible connections between functional blocks.
- **Start Trigger:** Detects when a process or machine is started (transition from 0 to 1).

⚖️ Comparison with Similar Components

- **`R_TRIG` (Standard):** The functional core is identical. The difference lies in the interface: `R_TRIG` uses separate `CLK` (BOOL) and `REQ` (Event) inputs, as well as `Q` (BOOL) and `CNF` (Event) outputs. `AX_FB_R_TRIG` uses adapters.
- **`AX_FB_F_TRIG`:** The counterpart to this function block, which reacts to falling edges (high-to-low).

Conclusion

The **AX_FB_R_TRIG** is an essential utility function block for developers working with AX adapters within the 4diac environment. It offers the robust functionality of standard edge detection, packaged in a modern, adapter-based interface, resulting in cleaner and more modular control applications.

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_AX_SEL_AUDI** implements a binary selection between two input values. It acts as a multiplexer, switching one of the two inputs to the output depending on a selector signal. Communication occurs exclusively via unidirectional adapters that encapsulate both event and data signals. This allows for flexible and type-specific integration into existing signal paths.

Interface Structure

Event Inputs

The function block does not have dedicated event inputs. However, events are provided via the **Selector Adapter G**:

- **G.E1**: Event signal that triggers the selection logic.

Event Outputs

The function block does not have dedicated event outputs. Events are output via the **Output Adapter OUT**:

- **OUT.E1**: Acknowledge signal triggered after successful completion of the selected input.

Data Inputs

The FB does not have dedicated data inputs. Data values are provided via the following adapters:

- **IN0.D1** (Type: AUDI) – first selectable data value
- **IN1.D1** (Type: AUDI) – second selectable data value
- **G.D1** (Type: AX) – selector field for determining the active source

Data Outputs

The FB does not have dedicated data outputs. The selected data value is output via the **Output Adapter OUT**:

- **OUT.D1** (Type: AUDI) – selected data value (corresponds to IN0.D1 or IN1.D1)

Adapters

Adapter	Direction	Type	Comment
IN0	Socket (Input)	`adapter::types::unidirectional::AUDI`	First selectable input
IN1	Socket (Input)	`adapter::types::unidirectional::AUDI`	Second selectable input
G	Socket (Input)	`adapter::types::unidirectional::AX`	Selector (Event + Data)
OUT	Plug (Output)	`adapter::types::unidirectional::AUDI`	Output field with event and data

Functionality

The function block internally contains an instance of the IEC 61131 function block `F_SEL` (from the library `iec61131::selection`). The logic proceeds as follows:

1. **Triggering**: An event at **G.E1** (via the selector adapter) starts the processing.
2. **Data Collection**: The values received from **IN0.D1**, **IN1.D1**, and **G.D1** are forwarded to the `F_SEL` function block.
3. **Selection**: `F_SEL` checks the value of **G.D1**. Typical Semantics (depending on the data type `AX`):

- If the selector field is **False** (or 0), **IN0** is selected.
- If the selector field is **True** (or not equal to 0), **IN1** is selected.

1. **Output**: The selected signal is passed on to **OUT.D1**. Simultaneously, an event is sent to **OUT.E1** to inform downstream processing.

The internal flow is event-driven and avoids continuous read accesses, enabling efficient communication in time-controlled environments.

Technical Features

- **Pure Adapter Communication**: All interfaces are defined as unidirectional adapters. Event and data paths are combined within a single adapter, simplifying configuration in the 4diac IDE.
- **Reuse of IEC 61131 libraries**: The selection logic is fully implemented by the standard function block `F_SEL`, which requires no additional state machines or complex algorithms.
- **Type safety**: The adapters are specialized for the user-defined types `AUDI` and `AX`. This prevents miscoupling with incompatible signals at design time.
- **No state of its own**: The function block itself is stateless – it simply forwards the signals to the internal `F_SEL`. The internal function block manages the selection logic autonomously.

State overview

The function block **AUDI_AX_SEL_AUDI** does **not have its own state machine**. The entire selection logic is executed by the inner `F_SEL` block, which itself is a pure function block without state memory. Therefore, its behavior is **stateless**:

- After receiving an event at **G.E1**, the selection is made immediately and the result is output to **OUT.D1**.
- There are no initialization, wait, or error states; the block is always ready for a new selector request.

Application Scenarios

This block is ideally suited for the following applications in automation technology:

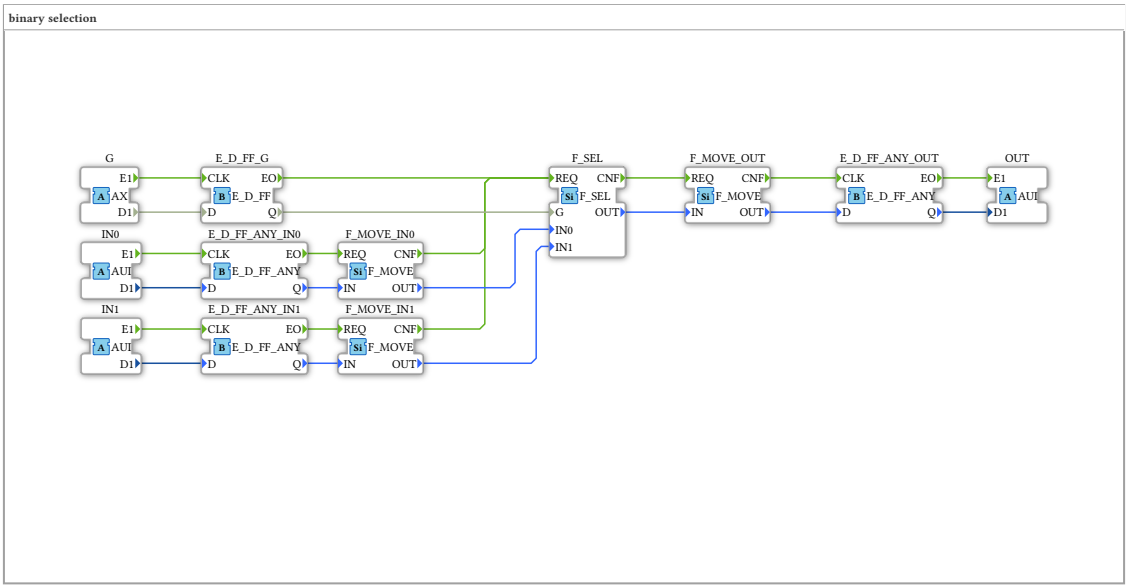
- **Signal switching** between two sensors (e.g., temperature sensors, pressure transducers) depending on an operating mode or a manual switch.
- **Bypass selection** in control paths: if one channel malfunctions, the system automatically switches to a backup channel.
- **Parameter selection**: a selector field is used to choose between two fixed parameter sets (e.g., for different products).
- **Test Mode**: Switching between a real and a simulated signal for commissioning or maintenance.

The use of user-defined adapter types (`AUDI`, `AX`) allows for easy adaptation to project-specific data structures.

Comparison with Similar Function Blocks

Criterion	**AUDI_AX_SEL_AUDI**	Simple Boolean MUX (e.g., `F_SEL`)
Interface	Pure adapters (event and data encapsulated)	Separate input/output pins
Data Type	User-defined types (`AUDI`, `AX`)	Arbitrary (configurable)
Selector	Event-driven (via adapter)	Data-driven, without extra events
Reusability	Higher due to type safety and encapsulation	More flexible, but loosely coupled
Complexity	Medium (adapters require prior knowledge)	Low (direct pins)

The **AUDI_AX_SEL_AUDI** offers higher integration into adapter-based architectures and is particularly suitable for modular, type-bound systems, while a pure `F_SEL` is more universal.



Conclusion

The **AUDI_AX_SEL_AUDI** is a specialized binary selector that leverages the advantages of adapter-based communication in 4diac. By encapsulating event and data paths in a single adapter, signal wiring in the overall system is reduced and type safety is increased. Internal delegation to the proven `F_SEL` block from the IEC 61131 library ensures robust, stateless selection logic. This block is ideally suited for use in modular control projects where clear interfaces and easy reusability are paramount.

AUI_AX_SEL_AUI

Binary selection

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUI_AX_SEL_AUI** implements a binary selection between two input values of type **AUI**. The decision as to which input is passed to the output is made via a third adapter of type **AX**, which serves as a selector. The block encapsulates the function **F_SEL** defined in IEC 61131-3 and provides it as an adapter-based component.

Interface Structure

Event Inputs

- **G.E1** (via adapter G): Triggers the selection processing as soon as an event is present at the selector adapter.

Event Outputs

- **OUT.E1** (via adapter OUT): Is triggered after the selected value is present at the output.

Data Inputs

- **G.D1** (via adapter G): The selecting value (e.g., BOOL or numeric) that determines whether **IN0** or **IN1** is selected.
- **IN0.D1** (via adapter IN0): First input value of type **AUI**.
- **IN1.D1** (via adapter IN1): Second input value of type **AUI**.

Data Outputs

- **OUT.D1** (via adapter OUT): The selected value (type **AUI**), according to the selection logic.

Adapters

- **G** (socket, type `adapter::types::unidirectional::AX`): Provides the selection signal.
- **IN0** (socket, type `adapter::types::unidirectional::AUI`): First data channel.
- **IN1** (Socket, type `adapter::types::unidirectional::AUI`): Second data channel.
- **OUT** (Plug, type `adapter::types::unidirectional::AUI`): Result channel.

Functionality

The function block operates event-driven via the adapter interfaces. As soon as an event arrives at selector **G.E1**, the internal function block **F_SEL** is activated. **F_SEL** checks the value **G.D1**:

- If **G.D1** = `FALSE` (or 0), the value of **IN0.D1** is passed to output **OUT.D1**.
- If **G.D1** = `TRUE` (or not equal to 0), **IN1.D1** is selected.

After the selection is complete, **F_SEL.CNF** signals the event **OUT.E1** to inform the consumer of the new valid output value.

Technical Features

- The function block is implemented as a **Composite FB** – its behavior results from the internal circuitry of a standardized **F_SEL** block (IEC 61131-3).
- Data is transmitted via adapters of type **AUI** and **AX**. These adapter types are defined as unidirectional channels whose internal data structure is not specified in detail (e.g., integer, real, or user-defined structs).
- Selection is purely combinatorial, but only after a triggering event at the selector. A simple data change without an event does not result in an output update.

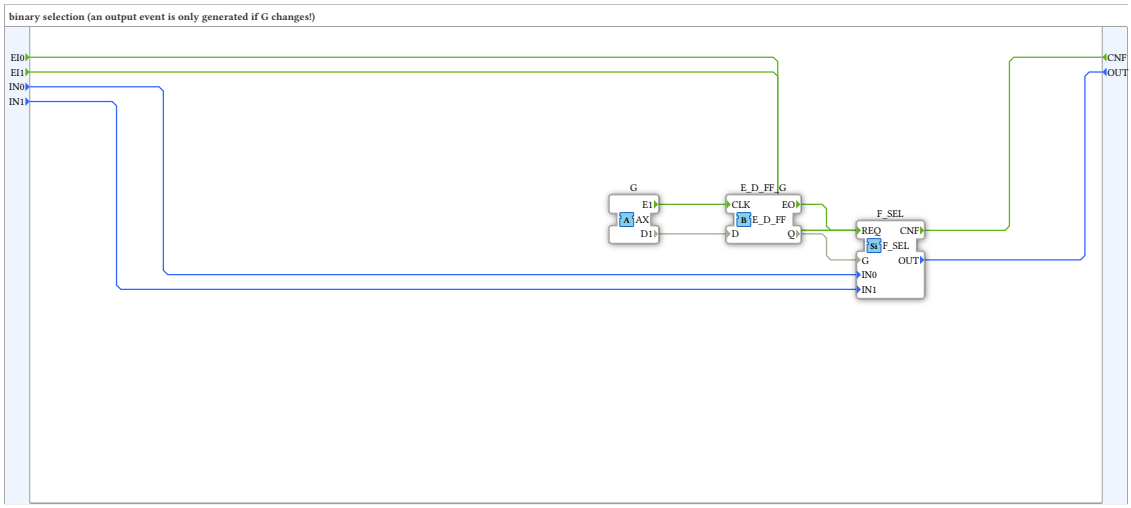
State Overview

Since this is a composite FB without its own state machine, there are no explicit states. The logic is purely event-driven:

1. **Wait for event** – as long as no **G.E1** is received, the output remains unchanged.
2. **Perform selection** – after **G.E1**, the corresponding input is selected and the output is set.
3. **Signal output** – **OUT.E1** is generated after successful selection.

Application Scenarios

- **Switching between two measured values** (e.g., temperature from sensor A or B) based on a control signal.
- **Operating mode switching** in automation technology, where different control variables are activated depending on the mode.
- **Redundant signal sources** – if the primary channel (IN0) fails, the selector can switch to the secondary channel (IN1).

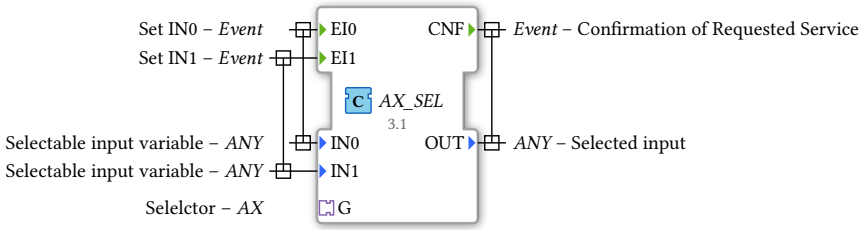


Comparison with similar components

- **MUX (Multiplexer)**: A multiplexer selects from more than two inputs; **AUI_AX_SEL_AUI** is specialized for two inputs and uses adapters instead of individual signals.
- **F_SEL (Standard IEC 61131)**: The internal function block offers identical functionality, but without adapter encapsulation. This function block extends it with an adapter-based interface, which facilitates reuse in adapter-oriented architectures.
- **SEL (Selection)**: Similar logic, but usually defined as a pure function block without event control. Here, the selection is explicitly triggered by an event.

Conclusion

AUI_AX_SEL_AUI is an adapter-based composite function block for simple binary selection between two AUI data streams. The use of `F_SEL` internally ensures robust and standards-compliant selection logic. The function block is particularly suitable for modular automation solutions where data is exchanged via unidirectional adapters.



AX_SEL

• – ○ • – ○ • – ○ •

Introduction

The AX_SEL function block is a binary selector used to choose between two input values. It belongs to the category of standard selection functions according to IEC 61131-3 and enables flexible data selection based on a control signal.

Interface Structure

Event Inputs

- **EI0** - Set IN0 (data association: `IN0`)
- **EI1** - Set IN1 (data association: `IN1`)

Event Outputs

- **CNF** - Confirmation of Requested Service

Data Inputs

- **IN0** (ANY) - Selectable input variable
- **IN1** (ANY) - Selectable input variable

Data Outputs

- **OUT** (ANY) - Selected input

Adapters

- **G** (adapter::types::unidirectional::AX) - Unidirectional adapter for control

Functionality

The AX_SEL function block selects between two input values (IN0 and IN1) and outputs the selected value at output OUT. The selection is controlled via the connected adapter G: `G.E1` clocks an internal D flip-flop (`E_D_FF_G`) that takes over `G.D1` and supplies it as selector `G` to `F_SEL`. `F_SEL` is triggered by the flip-flop event (G has changed) and directly by `EI0` and `EI1`; its `CNF` is output as the block's `CNF` and the selected

value is then available at OUT. An output event is therefore generated only on an event at `G.E1`, `EI0` or `EI1`. ...

Technical Features

- Uses the ANY data type for maximum flexibility in inputs and outputs
- Implemented as a unidirectional adapter for easy control
- Supports various data types through the use of ANY

State Overview

The function block has a simple state:

- **Ready**: Waits for a control signal from adapter G
- Upon receiving an event (`EI0`, `EI1` or `G.E1`), the corresponding input is selected and the CNF event is triggered

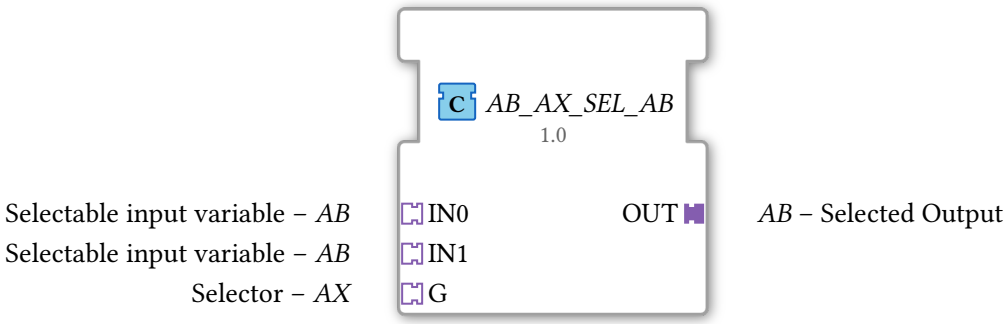
Application Scenarios

- Selection between two different sensors
- Switching between operating modes
- Selection of data sources depending on operating states
- Switching between manual and automatic control

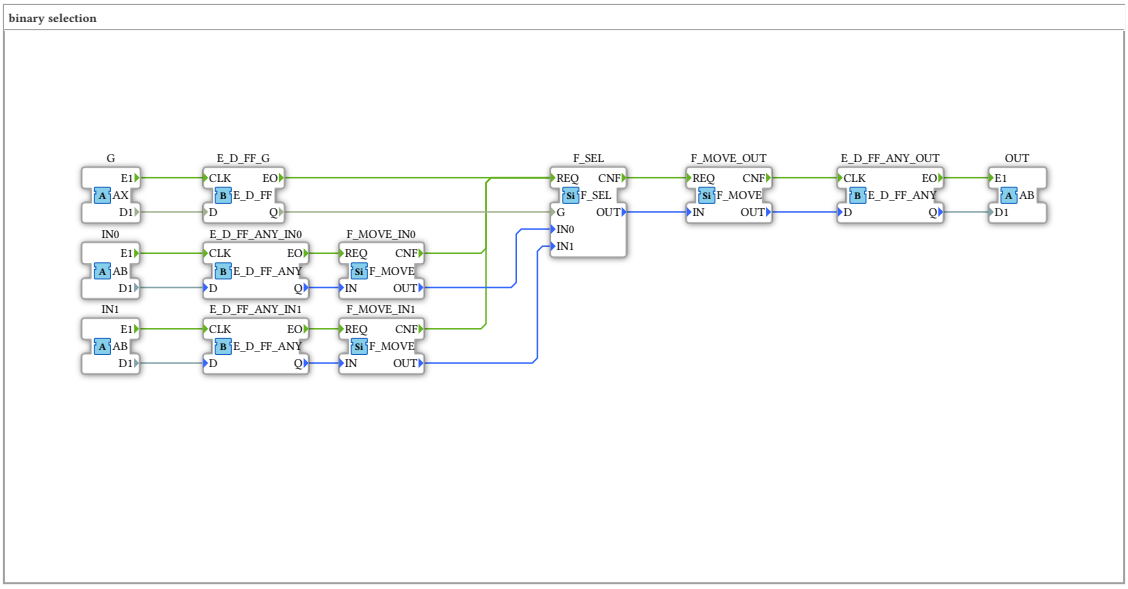
⚖️ Comparison with Similar Function Blocks

Compared to other selection blocks, AX_SEL offers:

- Greater flexibility through the ANY data type
- Easy integration through the unidirectional adapter
- Standardized interface according to IEC 61131-3



Comparison with F_SEL



Conclusion

The AX_SEL function block provides a simple and flexible solution for binary selection tasks in control systems. By using the ANY data type and standardized adapter interfaces, it enables versatile application in various automation projects.

Adapter

AB_AX_SEL_AB

• – ○ • – ○ • – ○ •

The function block `AB_AX_SEL_AB` is a composite function block for IEC 61499 that implements binary selection at the adapter level. Based on a control signal from a selector adapter (`G`), it selects between the signals of two input adapters (`IN0` and `IN1`) and forwards the selected signal to an output adapter (`OUT`).

This block is particularly suitable for event-driven architectures where data streams need to be routed flexibly without disrupting the encapsulation of the adapter interfaces.

Since this is an adapter-based function block, the classic event and data inputs are completely encapsulated within the adapter interfaces.

No direct event inputs are available. Control is achieved via events within the adapters.
No direct event outputs are available. Signaling is achieved via events within the output adapter.
No direct data inputs are available.
No direct data outputs are available.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

Name	Direction	Type	Description
OUT	Plug (Consumer)	`adapter::types::unidirectional::AB`	The selected output. Outputs the forwarded signal.
IN0	Socket (Provider)	`adapter::types::unidirectional::AB`	First selectable input (selected when selector `G` is in state `FALSE`).
IN1	Socket (Provider)	`adapter::types::unidirectional::AB`	Second selectable input (selected when selector `G` is in state `TRUE`).
G	Socket (Provider)	`adapter::types::unidirectional::AX`	Selector adapter (control signal for selection).

Note on adapter types:

- AB represents a unidirectional adapter that carries a byte data signal (D1/D) and an event (E1).
- AX represents a unidirectional adapter that carries a Boolean data signal (D1/D) and an event (E1).

Functionality

Inside the function block is a network of standard function blocks (IEC 61131-3 and IEC 61499) that implements the logic:

1. **Event and Data Acquisition:**

- When an event (IN0, IN1, G) arrives at one of the input adapters (IN0, IN1, G), the corresponding value (D1) is temporarily stored via an edge-triggered memory element (D flip-flop E_D_FF or E_D_FF_ANY).

1. **Data Conversion / Buffering:**

- The function blocks F_MOVE_IN0 and F_MOVE_IN1 copy the byte values of the inputs to the selection element.

1. **Selection Logic (F_SEL):**

- The standard selection function block F_SEL (from the IEC 61131-3 Library) performs the actual selection:
- If the signal from the selector adapter G equals FALSE, the signal from IN0 is passed through to the output.
- If the signal from selector adapter G equals TRUE, the signal from IN1 is passed through to the output.

1. **Output:**

- The selected value is transferred via another conversion block (F_MOVE_OUT with data type BYTE) to an output flip-flop (E_D_FF_ANY_OUT).
- This flip-flop generates the corresponding output event (OUT.E1) at plug OUT and provides the selected data value (OUT.D1).
- **Event-driven data routing:** Any change to the inputs IN0 or IN1, as well as to the selector G, triggers an update and calculation of the output. No cyclic polling occurs.
- **Decoupling via memory elements:** The use of E_D_FF and E_D_FF_ANY ensures that the data is consistently transferred and that no uncontrolled signal changes (race conditions) occur at the output.
- **Decoupling via memory elements:** The use of E_D_FF and E_D_FF_ANY ensures that the data is transferred consistently and that no uncontrolled signal changes (race conditions) occur at the output.
- – **Typing:** The internal processing of the data is fixed to the data type BYTE (defined via the attribute DataType="BYTE" on the F_MOVE blocks).

State Selector G	Event at Input	Behavior at Output OUT
FALSE	Event at IN0	Value from IN0 is passed to OUT; Event OUT.E1 is triggered.
FALSE	Event sent to IN1	The value of IN1 is updated internally, but **not** passed to OUT.
TRUE	Event sent to IN0	The value of IN0 is updated internally, but **not** passed to OUT.
TRUE	Event sent to IN1	The value of IN1 is passed to OUT; Event OUT.E1 is triggered.
Switch FALSE → TRUE	Event on G	The currently stored value of IN1 is passed to OUT; OUT.E1 is triggered.
Switch TRUE → FALSE	Event on G	The currently stored value of IN0 is passed to OUT; OUT.E1 is triggered.

- **Signal Switching at the Field Level:** Switching between the signal from an active sensor (IN1) and a predefined substitute/error value (IN0) in case of a fault.

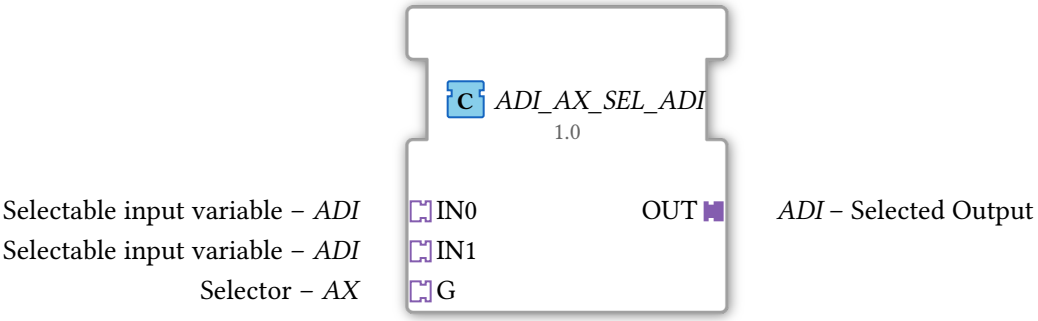
- **Manual/Automatic Switching:** Forwarding of control bytes, whereby values from the automatic control are used in automatic mode (`G = TRUE`), while manually specified values are sent to the actuators in manual mode (`G = FALSE`).
- **Recipe or Mode Selection:** Dynamic path selection for configuration or status data in complex process controls.

Comparison with Similar Function Blocks

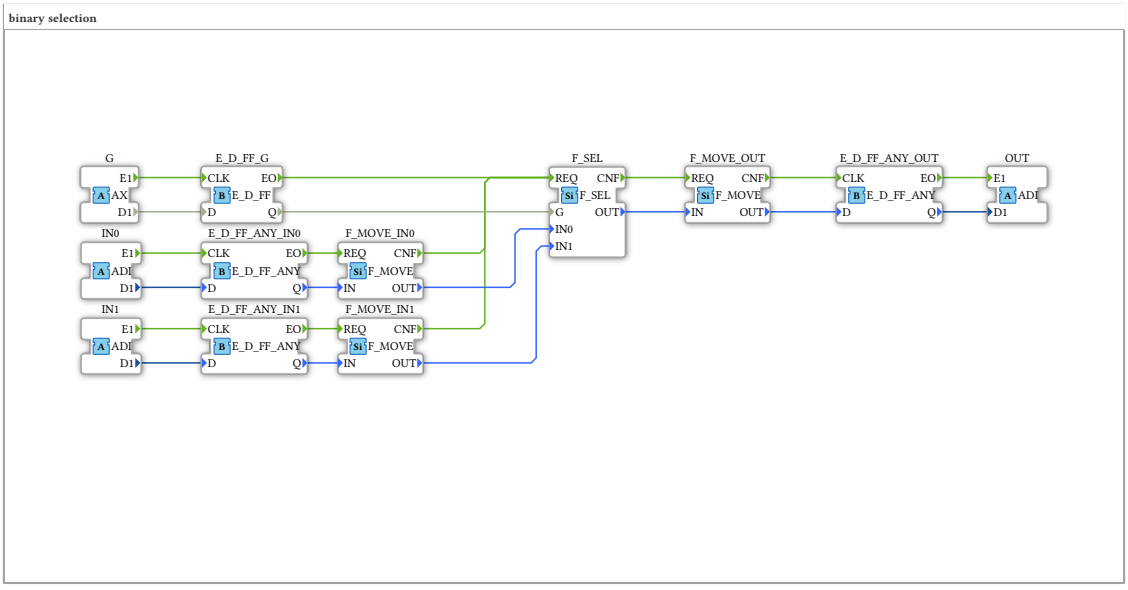
Compared to the standard function block `F_SEL`, `AB_AX_SEL_AB` operates directly at the adapter level.

- While `F_SEL` requires manual wiring of discrete data lines and separate trigger events, `AB_AX_SEL_AB` encapsulates this logic.
- This saves engineering time, reduces the number of visible connections in the 4diac IDE Application Editor, and minimizes potential errors when linking data and event streams.

The `AB_AX_SEL_ABis` a robust and reusable auxiliary building block for signal routing based on byte adapters. Through the consistent encapsulation of the selection and synchronization logic, it significantly contributes to the clarity and modularization of control programs in the 4diac IDE.



Technical Features



State Overview

Application Scenarios

Conclusion

ADI_AX_SEL_ADI

No image available

• – ○ • – ○ • – ○ •

Introduction

The function block `ADI_AX_SEL_ADI` is used for binary selection between two analog or integer input signals transmitted via unidirectional adapters. Based on the state of a digital selector signal, either the value of the first or the second input is passed through to the output.

The block is implemented as a composite function block (FB) and uses internally standardized selection and copy functions according to IEC 61131-3, which have been adapted for the event-driven IEC 61499 adapter architecture.

Interface Structure

The interface of this function block is implemented entirely via adapters. There are no direct elementary data or event inputs outside of the adapter structures.

Event Inputs

No direct event inputs available (events are received via the adapter interfaces).

Event Outputs

No direct event outputs available (events are sent via the adapter interfaces).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Plugs (Connectors - Outputs)

- **OUT** (Type: `adapter::types::unidirectional::ADI`):

The selected output. Sends the selected data signal (`D1`) and the associated update event (`E1`).

Sockets (Inputs)

- **IN0** (Type: `adapter::types::unidirectional::ADI`):

First selectable input. This value is passed through to the output when the selection signal `G` is set to `FALSE` (0).

- **IN1** (Type: `adapter::types::unidirectional::ADI`):

Second selectable input. This value is passed through to the output when the selection signal `G` is set to `TRUE` (1).

- **G** (Type: `adapter::types::unidirectional::AX`):

The selector (gate) for controlling the selection process. A change in state controls the switching between `IN0` and `IN1`.

Functionality

The internal structure of `ADI_AX_SEL_ADI` operates purely event-driven:

1. **Input Acquisition**:

When an event (`E1`) arrives at one of the inputs (`IN0`, `IN1`) or at the selector (`G`), the corresponding internal data value (`D1`) is acquired via event-driven memory elements (`E_D_FF_ANY` or `E_D_FF`).

1. **Data Buffering**:

The function blocks `F_MOVE_IN0` and `F_MOVE_IN1` copy the data (interpreted as data type `DINT`) to the central selection function block `F_SEL`.

1. **Selection Logic**:

The function block `F_SEL` (corresponding to the classic `SEL` standard function block from IEC 61131-3) evaluates the control signal `G`:

- If the signal from adapter `G` is equal to `FALSE`, the signal from `IN0` is selected.

- If the signal from adapter G is equal to TRUE, the signal from IN1 is selected.

1. **Output**:

The selected value is passed via F_MOVE_OUT to the output flip-flop E_D_FF_ANY_OUT. This flip-flop sets the value D1 on output adapter OUT and immediately triggers the corresponding event OUT.E1 to inform downstream components about the data change.

Technical Features

- **Adapter Encapsulation**: By using adapters (ADI and AX), the number of visible connection lines in the 4diac application diagram is drastically reduced, improving clarity and maintainability.
- **Data Type Specification**: The internal copy operations (F_MOVE_IN0, F_MOVE_IN1, and F_MOVE_OUT) are permanently configured for the data type DINT (Double Integer).
- **Real-Time Pass-Through**: The function block responds instantly to every edge of the input signals as well as the selection signal.

-

State Overview

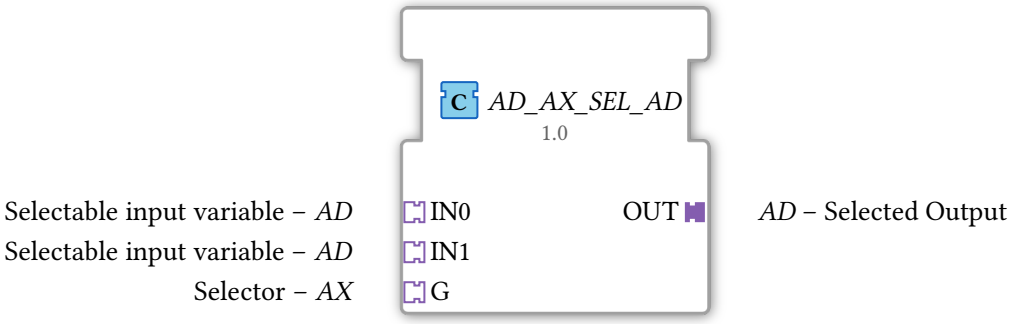
Since this is a purely data-flow and event-driven network function block (Composite FB), it does not have an internal state machine (ECC). Its behavior can be described statically as follows:

State Selector G	Event at Input	Behavior at Output OUT
FALSE	Any Event	OUT.D1 receives the value of IN0.D1; OUT.E1 is triggered.
TRUE	Any Event	OUT.D1 receives the value from IN1.D1; OUT.E1 is triggered.

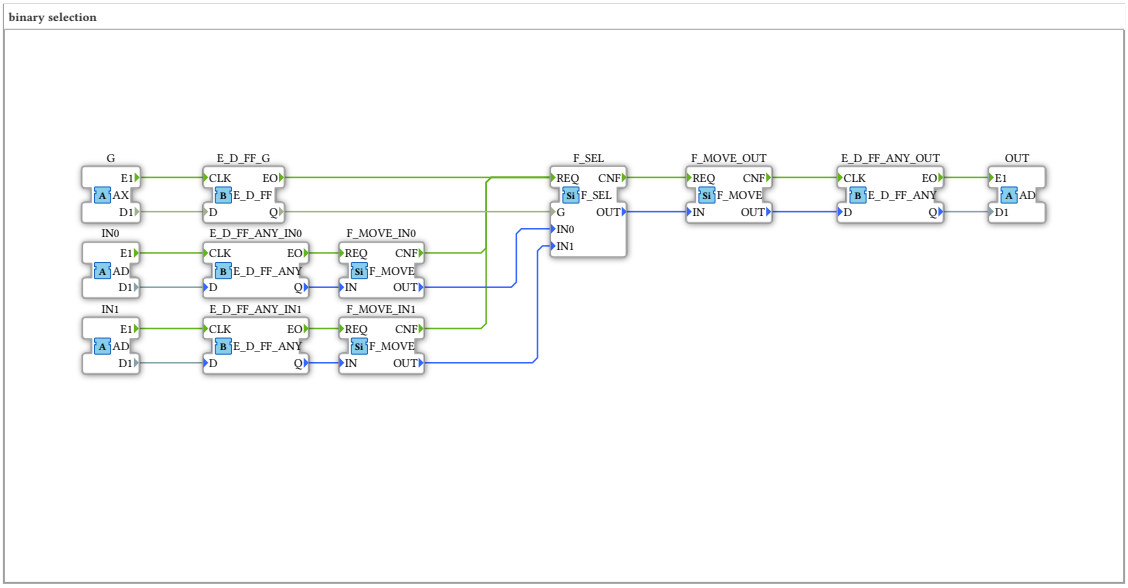
–

Application Scenarios

- **Manual/Automatic Switching**: Selection between a manually specified setpoint (e.g., via an HMI at IN1) and an automatically calculated controller setpoint (at IN0).
- **Sensor Redundancy**: Switching to a backup sensor (IN1) if diagnostic logic detects a fault in the main sensor (IN0) and sets the signal G to TRUE.
- **Recipe Control**: Dynamic selection of various predefined process parameters during operation.



Comparison with Similar Function Blocks



- **Standard F_SEL**: The standard selection function block works with elementary data types and requires explicit event connections for triggers and confirmations. ADI_AX_SEL_ADI fully automates this process via structured adapter channels.
- **Analog Multiplexers**: Unlike multiplexers with an indefinite number of channels, this function block specializes in fast and efficient binary selection (1 out of 2).

Conclusion

The ADI_AX_SEL_ADI is an extremely useful auxiliary function block for IEC 61499 applications in the 4diac IDE. It combines the proven selection logic of IEC 61131-3 with the modern, clean design principles of adapter-based event-oriented communication.

AD_AX_SEL_AD

• – ○ • – ○ • – ○ •

The function block `AD_AX_SEL_AD` performs binary selection between two input signals provided via adapter structures. Based on the state of a selection signal (G), either the value of input `IN0` or input `IN1` is passed to output `OUT`. Internally, the block is implemented as a composite function block and utilizes standardized IEC 61499 and IEC 61131 mechanisms to ensure event-driven, type-safe signal propagation.

The interfaces of this function block are implemented entirely via adapters, enabling modular and clear wiring within the application network.

This function block does not have direct event inputs on the housing. Event control is implicit via the adapters.

This function block does not have direct event outputs on the housing. Event forwarding is implicit via the adapters.

This component has no direct data inputs on its housing.

This component has no direct data outputs on its housing.

Data Outputs

Data Inputs

Event Inputs

Interface Structure

Introduction

Adapters

- **Sockets (Input Adapters):**
- `IN0` (Type: `adapter::types::unidirectional::AD`): First selectable input channel (selected when `G` is in the state `FALSE`).
- `IN1` (Type: `adapter::types::unidirectional::AD`): Second selectable input channel (selected when `G` is in state `TRUE`).
- `G` (Type: `adapter::types::unidirectional::AX`): Selector signal for controlling the selection.
- **Plugs (Output Adapters):**
- `OUT` (Type: `adapter::types::unidirectional::AD`): The selected output channel that carries the value of the selected input.

Functionality

The module encapsulates an internal network of control and conversion modules:

1. **Signal Buffering and Acquisition:** As soon as data changes on the adapters `IN0`, `IN1`, or `G`, the corresponding adapter event `E1` triggers the internal flip-flops (`E_D_FF` or `E_D_FF_ANY`).
2. **Data Forwarding:** The data values (`D1`) of inputs `IN0` and `IN1` are read via internal data converters (`F_MOVE` of type `DWORD`) and made available to the selection block `F_SEL`.
3. **Selection Logic (`F_SEL`):**

- If the signal `FALSE` is present at selector `G`, the block switches the signal from `IN0` to the output.
- – If the signal `TRUE` is present at selector `G`, the function block switches the signal from `IN1` to the output.

1. **Output Synchronization:** The selected value is passed via another function block `F_MOVE` to an output flip-flop (`E_D_FF_ANY_OUT`). This flip-flop generates the output event `E1` at output adapter `OUT` and places the selected value at `D1`.

- **Adapter Encapsulation:** The use of unidirectional adapters (`AD` and `AX`) simplifies signal routing and avoids loose data and event lines.
- **Type Independence via DWORD:** The internal data paths use the `DWORD` data type to represent the adapter data, enabling flexible transmission of different data formats.
- **Near-Real-Time Response:** Every edge or value change at the input or selector adapters immediately results in an output update.

As a composite function block, this module does not have its own Execution Control Chart (ECC). The behavior is purely data- and event-driven through the internal interaction of the standard function blocks (FBs):

- **Event on `IN0` or `IN1`:** Updates the respective internal value buffer. If the affected input is currently active, the new value is immediately output to `OUT`.
- **Event on `G`:** Switches the active channel and outputs the value of the newly selected channel to `OUT`.
- **Sensor Redundancy:** Switches between a primary sensor (`IN0`) and a redundant backup sensor (`IN1`) in case of signal loss or malfunction.
- **Setpoint Switching:** Switching between manual and automatic setpoint operation in industrial processes.
- **Signal Multiplexing:** Structured forwarding of control data in modular systems.
- **Standard `F_SEL`:** The classic `F_SEL` function block according to IEC 61131-3 operates directly on elementary data types and requires manual wiring of trigger events. `AD_AX_SEL_AD` encapsulates this logic and makes it directly available for adapter-based architectures.

- **Multiplexer (MUX):** A classic MUX allows selection from more than two channels using an integer value. `AD_AX_SEL_AD` is optimized for simple binary decisions (either/or) and thus saves processing resources.

The `AD_AX_SEL_AD` is a robust and efficient auxiliary module for event-driven signal switching. Thanks to the consistent use of adapters, it integrates perfectly into modern, service-oriented control architectures within 4diac.

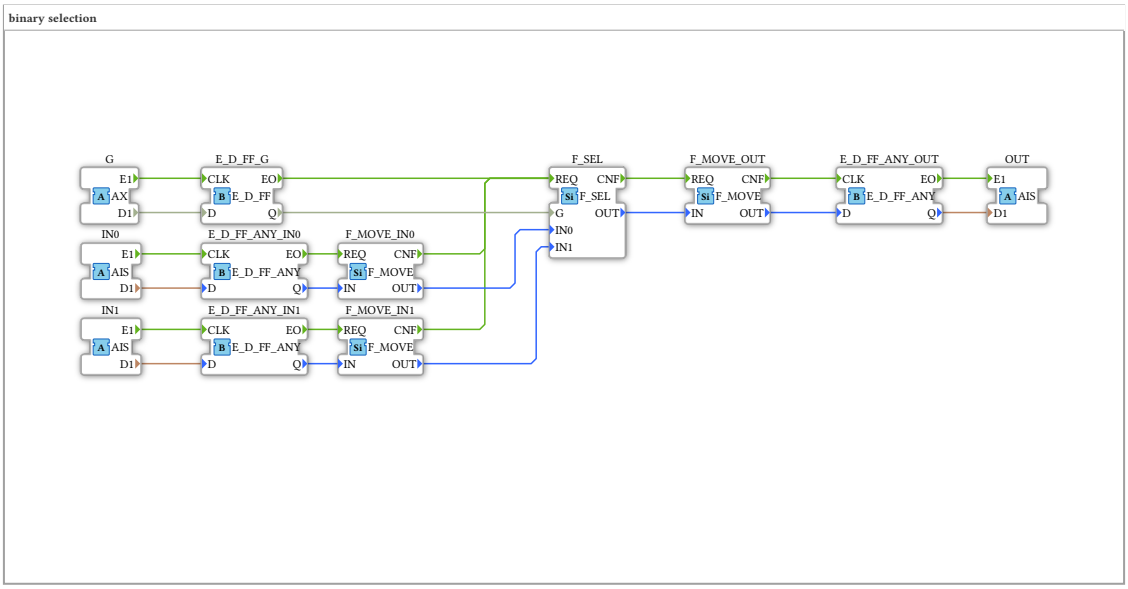
State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

AIS_AX_SEL_AIS

• – ○ • – ○ • – ○ •

Introduction

The function block **AIS_AX_SEL_AIS** is a binary selection block for the IEC 61499 architecture in the 4diac IDE. It dynamically selects between two unidirectional analog input signals based on the state of a selection signal (gate) and forwards the selected signal to the output.

Internally, the block uses the classic selection logic of the standardized `SEL` block (known from IEC 61131-3), but is fully optimized for event-driven execution according to IEC 61499 and encapsulates the data and event streams using standardized adapters.

Interface Structure

The function block uses an adapter-based interface design. It has no directly accessible event- or data-based inputs and outputs at the main level, but handles all communication via plugs and sockets.

Event Inputs

No direct event inputs are available. Event processing is handled encapsulated via the adapter interfaces.

Event Outputs

No direct event outputs are available. Event output is handled encapsulated via the output adapter.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Sockets (Input Interfaces)

- **G** (Type: `adapter::types::unidirectional::AX`): The selector input (gate). Determines which of the two inputs (`IN0` or `IN1`) is routed to the output.
- **IN0** (Type: `adapter::types::unidirectional::AIS`):

The first selectable input channel. This channel is activated when the selector `G` is in the state `FALSE` (0).

- **IN1** (Type: `adapter::types::unidirectional::AIS`):

The second selectable input channel. This channel is activated when the selector `G` is in the state `TRUE` (1).

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::AIS`):

The selected output channel. It provides the value of the currently active input channel and the corresponding update event.

Functionality

Inside the FB, a network of standard function blocks synchronizes the adapter events and makes the logical selection:

1. **Event Synchronization & Signal Storage:**

Data arriving at the adapters `IN0`, `IN1`, and `G` is temporarily stored in data flip-flops (`E_D_FF_ANY` and `E_D_FF`, respectively) each time a corresponding adapter event (`E1`) arrives. This ensures that the data values are stably available for further processing.

The data arriving at the adapters `IN0`, `IN1`, and `G` are temporarily stored in data flip-flops (`E_D_FF_ANY` and `E_D_FF`) whenever a corresponding adapter event (`E1`) arrives. This ensures that the data values are stably available for further processing. 2. **Data Provisioning:**

The function blocks `F_MOVE_IN0` and `F_MOVE_IN1` copy the cached data (interpreted as data type `STRING`) and forward it to the actual selection core.

1. **Selection Process (F_SEL):**

The core function block `F_SEL` (type `iec61131::selection::F_SEL`) evaluates the state of the selector `G`:

- If `G` = `FALSE`, the value of `IN0` is selected.
- If `G` = `TRUE`, the value of `IN1` is selected.

1. **Output Transfer:**

The selection result is transferred via the function block `F_MOVE_OUT` to the output flip-flop `E_D_FF_ANY_OUT`. This triggers the event `E1` at the output adapter `OUT` and places the selected data value at the output `D1`.

Technical Features

- **Adapter Encapsulation:** By using unidirectional adapters (`AIS` and `AX`), the application diagram in the 4diac IDE remains uncluttered, as data and event lines are bundled into a single connection.

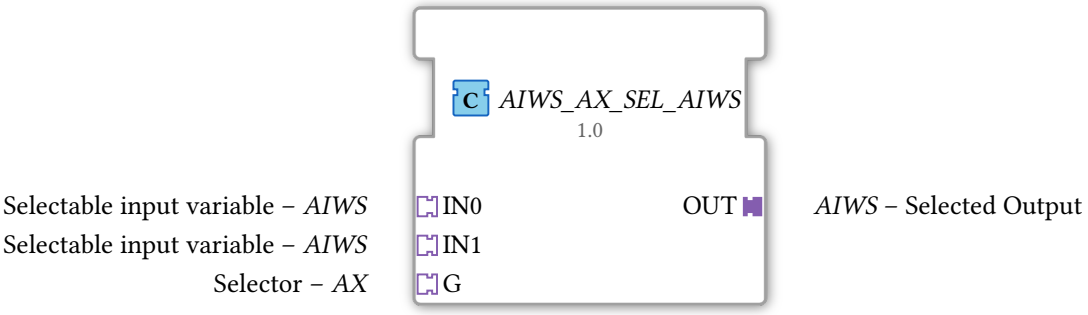
- **Asynchronous Event Handling:** Any change to one of the inputs (`IN0`, `IN1`) or to the selector (`G`) automatically retriggers the selection process and updates the output accordingly.
- **Asynchronous Event Handling:** * **Data Type Specification:** The internal data copiers (`F_MOVE`) are hard-coded to the data type `STRING`, indicating that the signals to be switched are transmitted as strings in the `AIS` adapter.

State Overview

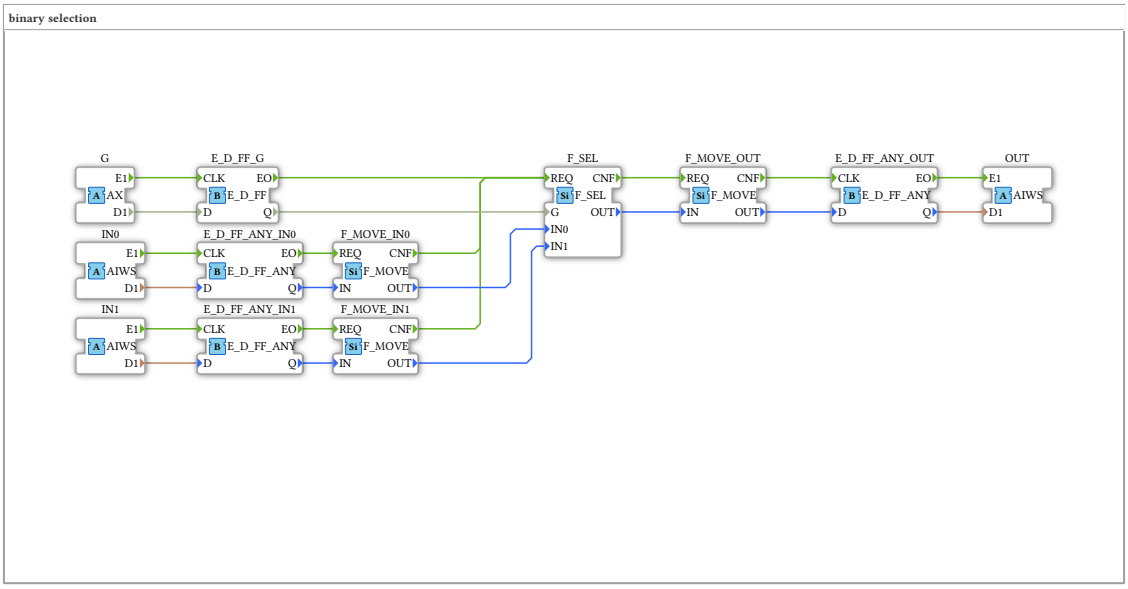
Selector State (`G`)	Last Event on…	Active Output (`OUT.D1`)	Description
`FALSE`	`IN0.E1` or `G.E1`	Value of `IN0.D1`	Input 0 is active. Changes to `IN1` have no effect on the output.
`TRUE`	`IN1.E1` or `G.E1`	Value of `IN1.D1`	Input 1 is active. Changes to `IN0` have no effect on the output.

Application Scenarios

- **Sensor Redundancy / Failsafe Systems:** Switching between a primary sensor and a backup sensor in case of signal loss or malfunction.
- **Operating Mode Selection:** Dynamically forwarding different parameter sets (e.g., automatic vs. manual setpoints) to an actuator. * **Signal Routing in Agricultural Machinery (ISOBUS Context):** Channel control for analog process values or status messages in complex control networks.



Comparison with Similar Function Blocks



- **Classic `SEL` (IEC 61131-3):** The classic `SEL` function block does not have event control and is purely data flow-oriented. `AIS_AX_SEL_AIS` extends this principle to include event-based control for distributed systems.
- **Standard Selection Function Blocks without Adapters:** Typical IEC 61499 selection functions often use many individual event and data pins. This function block offers significantly improved maintainability and modularity in system design thanks to its adapter interfaces.

Conclusion

The **AIS_AX_SEL_AIS** is a specialized and high-performance solution for signal switching in the 4diac IDE. Its strict use of adapters and reliable internal event processing make it ideally suited for clean, modular software architectures in the fields of industrial automation and agricultural technology.

AIWS_AX_SEL_AIWS

(No image available)

• – ○ • – ○ • – ○ •

The function block `AIWS_AX_SEL_AIWS` is used for binary selection between two unidirectional adapter signals of type `AIWS`. Which of the two inputs is switched to the output is controlled by a control adapter of type `AX`.

The function block encapsulates the classic selection logic (comparable to the `SEL` standard function block from IEC 61131-3) within the event-driven environment of IEC 61499. This enables clean, modular, and transparent signal switching directly at the adapter level, eliminating the need to individually wire event and data lines in the higher-level system.

Because it is an adapter-based function block, the block itself does not have direct, classic event or data inputs and outputs on its outer casing. All communication is handled via the adapter interfaces.

No direct event inputs available (events are received via the adapter sockets).
No direct event outputs available (events are sent via the adapter plug).
No direct data inputs available.
No direct data outputs available.

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Sockets (Input Adapters)

- **`G`** (Type: `adapter::types::unidirectional::AX`):

The selector adapter. The data signal it contains determines which input is activated.

- **`IN0`** (Type: `adapter::types::unidirectional::AIWS`):

The first selectable input adapter. This is passed through to the output when the selector signal is in the state `FALSE` (0).

- **`IN1`** (Type: `adapter::types::unidirectional::AIWS`):

The second selectable input adapter. This is passed through to the output when the selector signal is in the state TRUE (1).

Plugs (Output Adapters)

- **OUT** (Type: adapter::types::unidirectional::AIWS):

The output adapter. It outputs the data and events of the currently selected input (IN0 or IN1).

Functionality

The function block's internal network implements signal forwarding and event synchronization as follows:

1. **Event Acquisition and Buffering:**

As soon as the event E1 arrives at one of the sockets (G, IN0, or IN1), the corresponding data value D1 is temporarily stored via an internal event-driven flip-flop (E_D_FF for the selector and E_D_FF_ANY for the data).

1. **Data Conversion / Assignment:**

The data from inputs IN0 and IN1 are transferred to the selection block via internal assignment elements (F_MOVE) of type WSTRING.

1. **Selection Process (F_SEL):**

The internal function block F_SEL (IEC 61131-3 SEL) evaluates the state of the selector from the adapter G:

- If the signal from G is in the state FALSE, the signal from IN0 is passed to the output.
- If the signal from G is in the state TRUE, the signal from IN1 is passed to the output.
- If the signal from G is in the state TRUE, the signal from IN1 is passed to the output. 4. **Output:**

The selected signal is passed via another F_MOVE block and an output flip-flop (E_D_FF_ANY_OUT) to data point D1 of the output plug OUT. Simultaneously, the event E1 is triggered at the output to inform subsequent blocks about the data update.

- **Data type WSTRING:** The adapter data is processed internally via F_MOVE blocks with the data type WSTRING. This means that the user data within the AIWS adapter is transmitted and switched as wide strings.
- **Event Decoupling:** By using flip-flops (E_D_FF), it is ensured that any change to the inputs or the selector results in an immediate and consistent update of the output.

The logical mapping of the output, depending on the selector G, is as follows:

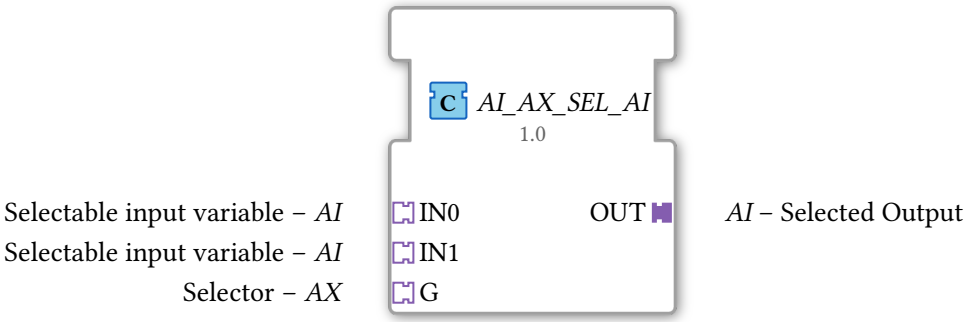
State of G (selector)	Active path	Data value to OUT.D1	Event to OUT.E1
FALSE	IN0	Value of IN0.D1	Triggered by events at IN0.E1 or G.E1
TRUE	IN1	Value of IN1.D1	Triggered by events at IN1.E1 or G.E1

- **Switching Analog Values with Status (formatted as WSTRING):** Redundant sensor systems where, in case of a fault, the system should switch from sensor 1 (IN0) to a backup sensor 2 (IN1).
- **Dynamic Text or Recipe Selection:** Switching configuration strings, log messages, or setpoints that are routed to an HMI or control unit via adapter structures.
- **Signal Routing:** Flexible routing in modular industrial plants where data streams need to be redirected depending on the operating mode (e.g., automatic vs. manual operation).

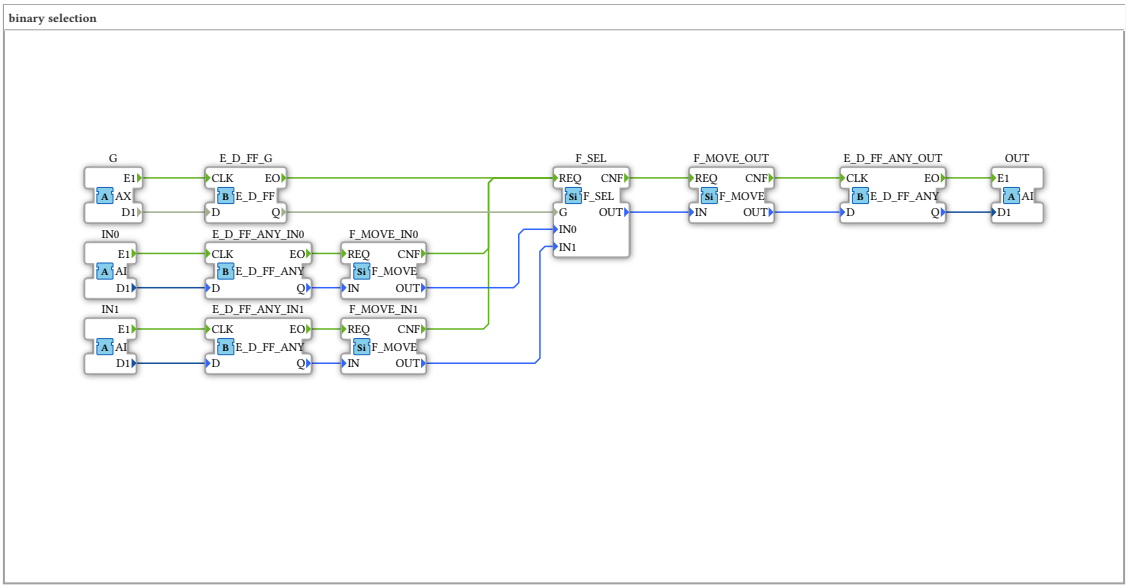
Comparison with Similar Function Blocks

- **Standard SEL (IEC 61131-3):** The classic SEL function block operates on elementary data types (e.g., INT, REAL, STRING) and does not have native event control or adapter support. AIWS_AX_SEL_AIWS extends this principle for IEC 61499 by providing direct switching for complex adapter types.
- **Multiplexer (MUX):** A classic multiplexer allows selection from more than two channels via an integer index. The AIWS_AX_SEL_AIWS is optimized for fast and resource-efficient binary selection (2 channels).

The AIWS_AX_SEL_AIWS is a highly specialized auxiliary module for IEC 61499 systems (such as 4diac-ide) that elegantly and deterministically switches complex data and event streams between two adapters. It significantly reduces "spaghetti code" and confusing wiring in graphical programming environments.



Technical Features



State Overview

Application Scenarios

Conclusion

AI_AX_SEL_AI

(No image available)

• – ○ • – ○ • – ○ •

The function block `AI_AX_SEL_AI` is a binary selector (multiplexer) for analog signals based on the IEC 61499 architecture. It serves to select one of two analog input signals based on a control signal (selector) and forward it to the output. The unique feature of this block lies in its consistent use of adapters, which significantly simplifies and structures the cabling within the 4diac-ide development environment.

The function block does not have traditional discrete inputs and outputs for data and events at its main level. Instead, all communication is implemented via standardized adapters.

No direct event inputs available (fully encapsulated via adapters).
No direct event outputs available (fully encapsulated via adapters).
No direct data inputs available (fully encapsulated via adapters).
No direct data outputs available (fully encapsulated via adapters).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- **G** (Type: `adapter::types::unidirectional::AX`): The selector input. This adapter provides the control signal (Boolean state) that determines which of the two analog inputs is routed to the output.
- **IN1** (Type: `adapter::types::unidirectional::AI`): Selectable analog input 1. This input is enabled when the selector signal `G` is in the state `TRUE` (1).
- **OUT** (Type: `adapter::types::unidirectional::AI`): Selected analog output. It outputs the signal of the currently active input (`IN0` or `IN1`).

Plugs (Ausgangs-Schnittstellen)

Sockets (Eingangs-Schnittstellen)

Functionality

The module's internal logic controls the data and event flow as follows:

1. **Event Control & Data Acquisition:**

- Each time an event (`E1`) arrives at one of the input adapters (`IN0`, `IN1`, or `G`), the corresponding data element (`D1`) is temporarily stored via internal edge- or event-triggered memory modules (`E_D_FF` and `E_D_FF_ANY`).
- – Internal `F_MOVE` function blocks convert and pass the values (as data type `INT`) to the central selection function block.

1. **Selection Logic:**

- The core function block `F_SEL` (a standardized IEC 61131-3 selection function block) evaluates the control signal `G`.
- If the control signal `G` is `FALSE`, the value of `IN0` is selected.
- – If the control signal `G` is on `TRUE`, the value of `IN1` is selected.

1. **Output:**

- After successful selection, the selected value is passed via another `F_MOVE` block and an output flip-flop (`E_D_FF_ANY_OUT`) to the output plug `OUT`.
- Simultaneously, the output event `OUT.E1` is triggered to inform subsequent blocks about the value change.

- **Data Type Specification:** Internally, the function block uses the data type `INT` (integer) for analog values, which is defined by the parameterization of the internal `F_MOVE` instances.
- **Adapter-Based Architecture:** By encapsulating events and data in the adapters `AI` (Analog Input) and `AX` (Auxiliary Control), the number of connection lines in the higher-level system diagram is drastically reduced.
- **Event-Driven Propagation:** Every update of an input (regardless of whether it is the data or the selector) triggers the recalculation and output of an event at the output.

–

The function block operates purely on an event- and data-flow-driven basis. There are no complex internal states (no state machine/ECC in the classical sense), but rather a direct dependency of the output on the inputs:

Selector input (`G.D1`)	Active path	Output value (`OUT.D1`)	Output event (`OUT.E1`)
`FALSE`	`IN0`	Value of `IN0.D1`	Triggered on every event
`TRUE`	`IN1`	Value of `IN1.D1`	Triggered on every event

- **Redundant Sensors:** Switching between a primary and a secondary (backup) analog sensor in the event of a detected failure.
- **Manual/Automatic Switching:** Selection between a manually setpoint (e.g., via an HMI connected to `IN0`) and an automatically calculated controller setpoint (connected to `IN1`).
- **Recipe-Controlled Signal Redirection:** Dynamic assignment of analog process parameters based on the current operating state of a system.

–

- **Standard `F_SEL` (IEC 61131-3):** The classic `F_SEL` function block requires discrete pins for events and data. The `AI_AX_SEL_AI` module encapsulates this functionality in user-friendly adapter structures, increasing reusability and clarity in complex IEC 61499 applications.
- **Classic Multiplexers (e.g., MUX):** While a multiplexer often handles multiple channels (e.g., 4 or 8), this module is optimized as a slim, highly efficient 2-way selector switch for dedicated analog signals.

The `AI_AX_SEL_AI` module provides an elegant, adapter-based solution for the binary selection of analog signals in distributed control systems. Thanks to the clean separation and encapsulation of the interfaces in standardized adapters, it is ideally suited for use in modular and service-oriented automation architectures within Eclipse 4diac.

Comparison with Similar Function Blocks

Conclusion

ALI_AX_SEL_ALI

[Image of the function block]

• – ○ • – ○ • – ○ •

Introduction

The function block `ALI_AX_SEL_ALI` is a binary selection block designed for use with unidirectional adapters. It allows you to select between two input signals based on a selector signal and then output the selected signal. This block encapsulates the standard selection logic and adapts it to an event-driven adapter interface.

Interface Structure

Because it is an adapter-based function block, it does not have direct, traditional event or data inputs at the top level. All communication is handled via adapters.

Event Inputs

No direct event inputs available (control is via the adapters).

Event Outputs

No direct event outputs available (control is via the adapters).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Interfaces)

- **G** (`adapter::types::unidirectional::AX`): The selector adapter (gate). It controls which of the two inputs is routed to the output.
- **IN0** (`adapter::types::unidirectional::ALI`): The first selectable input adapter (selected by default for `G = FALSE`).
- **IN1** (`adapter::types::unidirectional::ALI`): The second selectable input adapter (selected at `G = TRUE`).

Plugs (Output Interfaces)

- **OUT** (`adapter::types::unidirectional::ALI`): The output adapter that provides the selected signal and the corresponding event.

Functionality

The function block operates as a multiplexer for the adapter signals:

1. **Event Detection**: As soon as an event (`IN0`, `IN1`) is received by one of the input adapters (`G`) or the selector adapter (`G`), it is intercepted via internal edge-triggered flip-flops (`E_D_FF` and `E_D_FF_ANY`, respectively).
2. **Data Buffering**: The data from the inputs (`IN0.D1` and `IN1.D1`) are passed via internal `F_MOVE` function blocks (configured to the data type `LINT`) to the central selection function block `F_SEL`.
3. **Selection**: The function block `F_SEL` evaluates the state of the selector `G.D1`:

- If `G.D1` is set to `FALSE`, the value of `IN0` is selected.
- If `G.D1` is set to `TRUE`, the value of `IN1` is selected.

1. **Output**: The selected value is passed to the flip-flop `E_D_FF_ANY_OUT`. This updates the output data point `OUT.D1` and simultaneously triggers the output event `OUT.E1`.

Technical Features

- **Data Type Specificity**: The internal shift blocks (`F_MOVE`) are fixed to the data type `LINT` (Long Integer). This means that the data transmitted via the `ALI` adapter is interpreted and processed as `LINT`.
- **Event Decoupling**: The use of flip-flops (`E_D_FF`) ensures that data changes at the inputs arrive at the output consistently and synchronously with the corresponding events.

State Overview

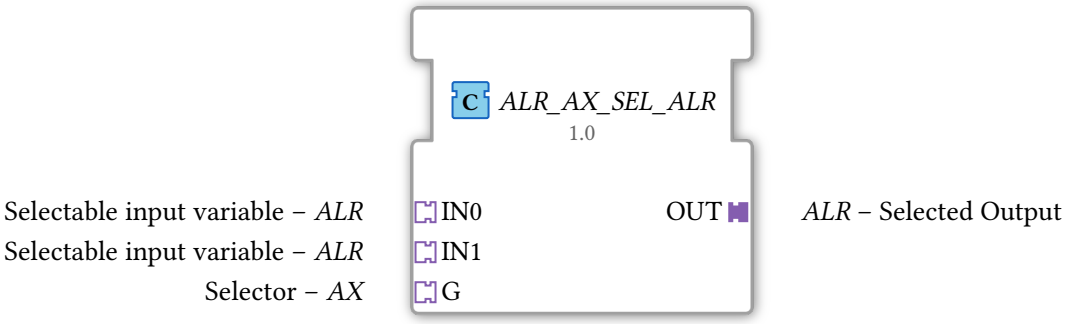
The function block does not have its own state hierarchy (no ECC) because it is implemented as a composite network function block (FB). Its behavior is purely data- and event-flow-driven:

State Selector (`G.D1`)	Trigger Event	Action / Result
`FALSE`	Event on `IN0.E1`, `IN1.E1`, or `G.E1`	The value of `IN0.D1` is passed to `OUT.D1`; `OUT.E1` is triggered.
`TRUE`	Event on `IN0.E1`, `IN1.E1`, or `G.E1`	The value of `IN1.D1` is passed to `OUT.D1`; `OUT.E1` is triggered.

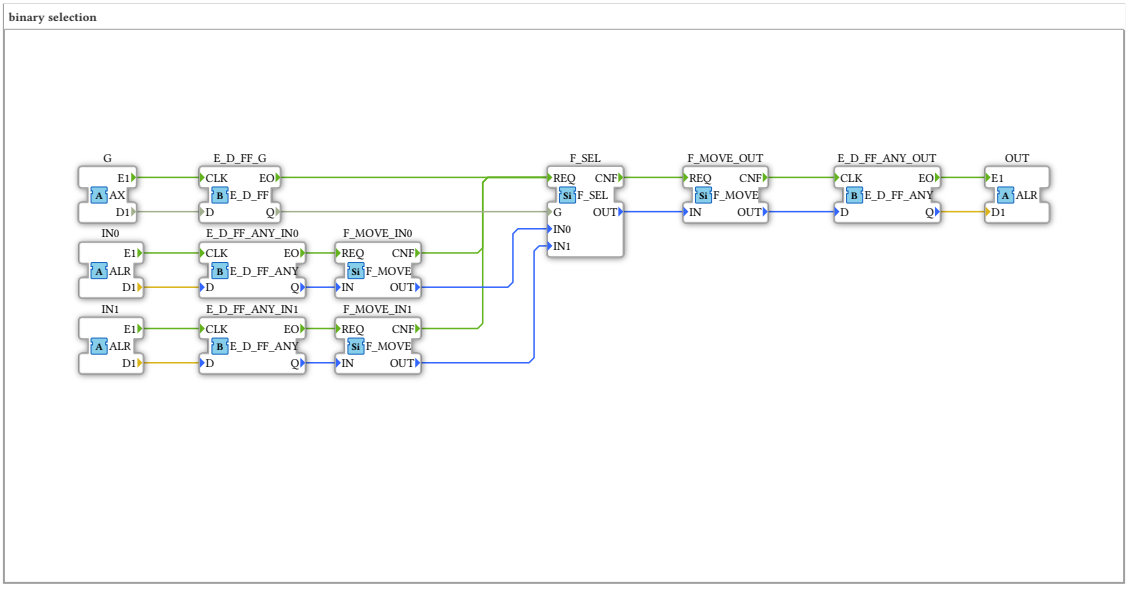
Application Scenarios

- **Setpoint Switching**: Selection between an automatic setpoint (e.g., calculated by a controller) and a manually specified setpoint in an industrial plant.
- **Sensor Redundancy**: Switching between two redundant sensors (e.g., in case of failure or for calibration) that provide their data via standardized adapter interfaces.
- **Recipe-Controlled Path Selection**: Dynamic selection of process parameters based on a binary control signal in the sequence program.

–



Comparison with Similar Function Blocks



- **F_SEL (Standard IEC 61131-3)**: The standard selection effect block works directly with elementary data types and requires explicit event connections. `ALI_AX_SEL_ALI` encapsulates this component and extends it with direct support for the more structured and cleaner use of unidirectional adapters (`ALI`/`AX`).
- **Classic Multiplexers (MUX)**: While a MUX can often handle multiple channels (e.g., 4, 8), this component is strictly optimized for binary selection (2 channels) but offers streamlined adapter integration.

Conclusion

The `ALI_AX_SEL_ALI` is a specialized auxiliary component that simplifies signal and event routing in complex 4diac systems. By encapsulating the adapter logic, it significantly improves the clarity of the application network by eliminating the need for manually unpacking and repackaging adapter signals.

ALR_AX_SEL_ALR

• – ○ • – ○ • – ○ •

The function block ALR_AX_SEL_ALR is used for binary selection between two analog input signals provided by adapters of type ALR. This selection is controlled by a selector adapter of type AX. The selected signal is passed on to an output adapter of type ALR.

The function block is internally based on the IEC 61131-3 selection function F_SEL and is optimized for event-driven IEC 61499 architectures.

Since this component is designed as an adapter coupler, it does not have any classic, direct event or data interfaces at the top level. All communication is handled via sockets (input adapters) and plugs (output adapters).

No direct event inputs available.
No direct event outputs available.
No direct data inputs available.
No direct data outputs available.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- **Sockets (Input Interfaces):**
- `IN0` (Type: `adapter::types::unidirectional::ALR`): First selectable input channel (switched to output when selector `G` has the value `FALSE`).
- `IN1` (Type: `adapter::types::unidirectional::ALR`): Second selectable input channel (switched to output when selector `G` has the value `TRUE`).
- `G` (Type: `adapter::types::unidirectional::AX`): Selector input for controlling channel selection.
- **Plugs (Output Interfaces):**
- `OUT` (Type: `adapter::types::unidirectional::ALR`): Output carrying the selected signal.

Functionality

This module implements a software-controlled 1-out-of-2 selection based on adapters:

1. **Event Buffering:** Incoming events and data at sockets `IN0`, `IN1`, and `G` are buffered via internal event D flip-flops (`E_D_FF` and `E_D_FF_ANY`, respectively) to ensure consistent data transfer.
2. **Value Transfer:** Data values are prepared for the data type `LREAL` via internal assignment elements (`F_MOVE`).
3. **Selection Logic (`F_SEL`):** Selection is performed using the standard selection block:

- If the signal at `G.D1` equals `FALSE`, the value of `IN0.D1` is passed to the output.
- If the signal at `G.D1` equals `TRUE`, the value of `IN1.D1` is passed to the output.

1. **Output Triggering:** Any change to one of the inputs or the selector triggers an update of the output adapter `OUT`, signaled by the event `OUT.E1` and the new data value `OUT.D1`.

- **Precise Data Processing (LREAL):** The internal data paths are designed for the data type `LREAL`, enabling lossless transmission of highly accurate analog measurements.
- **Adapter Encapsulation:** The use of standardized adapters (`ALR`, `AX`) eliminates the need for complex individual wiring of data and event pins in the application editor.
- **Event-driven:** The output reacts dynamically and without delay to value changes and triggers at the inputs.

The behavior of the function block is determined by the data and event flow in the internal network:

State Selector `G.D1`	Channel Passed	Output Value `OUT.D1`	Output Event `OUT.E1`
`FALSE`	Channel 0 (`IN0`)	Value of `IN0.D1`	Triggers on events on `IN0.E1` or changes to `G`
`TRUE`	Channel 1 (`IN1`)	Value of `IN1.D1`	Triggered by events on `IN1.E1` or a change in `G`

- **Sensor Redundancy / Failover:** Switching between a primary sensor (`IN0`) and a backup sensor (`IN1`) in case of failure or signal interference, controlled by a diagnostic signal at `G`.
- **Setpoint Switching:** Switching between an automatic setpoint and a manual target value in process control loops.
- **Recipe and Parameter Set Selection:** Dynamic assignment of different analog process parameters based on the current plant state.

Compared to a classic IEC 61131-3 `SEL` function block, `ALR_AX_SEL_ALR` completely encapsulates the signal paths in adapter structures. This significantly reduces the visual complexity in 4diac application diagrams, as only structured adapter lines need to be drawn instead of multiple individual connections.

The ALR_AX_SEL_ALR is a robust and reusable function block for structured signal switching in IEC 61499. Through the consistent use of adapters and the support of high-resolution LREAL data, it is ideally suited for modern control concepts in industrial automation.

Comparison with Similar Function Blocks

Conclusion

AL_AX_SEL_AL

(No image available)

• – ○ • – ○ • – ○ •

Introduction

The function block AL_AX_SEL_AL is an event-driven selector (binary selection) for IEC 61499 systems in the 4diac IDE. It acts as a multiplexer, forwarding data from one of two input adapters to an output adapter based on the state of a selector signal. The block consistently leverages the advantages of adapters to neatly encapsulate data and event streams and minimize the complexity of the wiring in the application diagram.

Interface Structure

Since this function block is internally structured as a network and is entirely based on adapter interfaces, it does not have any directly accessible, traditional input or output variables.

Event Inputs
No direct event inputs are available. Event control is handled implicitly via the connected adapters.

Event Outputs
No direct event outputs are available. Event forwarding is handled implicitly via the output adapter.

Data Inputs
No direct data inputs are available.

Data Outputs
No direct data outputs are available.

Adapters

Plugs
- **`OUT`** (Type: `adapter::types::unidirectional::AL`):

The selected output. This adapter outputs the selected data (`D1`) and the associated update event (`E1`).

Sockets
- **`G`** (Type: `adapter::types::unidirectional::AX`):

The selector input (gate/selector). Controls which of the two inputs (`IN0` or `IN1`) is routed to the output.

- **`IN0`** (Type: `adapter::types::unidirectional::AL`):

The first selectable input channel. This is active and routed to the output when the selector `G` is in the state `FALSE` (or logic 0).

- **`IN1`** (Type: `adapter::types::unidirectional::AL`):

The second selectable input channel. This is active and is passed to the output when the selector `G` has the state `TRUE` (or logic 1).

Functionality
The component implements classic multiplexer logic (equivalent to `SEL` in IEC 61131-3) in the IEC 61499 context:

1. **Event Handling & Buffering:**

When an event occurs on one of the input adapters (`IN0`, `IN1`) or the selector adapter (`G`), internal D flip-flops (`E_D_FF` and `E_D_FF_ANY`, respectively) capture the data values and store them temporarily.

1. **Data Type Conversion:**

The buffered data values are forwarded to the central selection block via internal transfer blocks (`F_MOVE` with the data type `LWORD`).

1. **Selection Logic (`F_SEL`):**

The core of the network evaluates the state of the selector `G`:

- If `G` equals `FALSE`, the signal from `IN0` is passed to the output.
- If `G` equals `TRUE`, the signal from `IN1` is passed to the output.

1. **Output:**

After a successful selection, the result is transferred via another flip-flop to the plug `OUT` and made available there simultaneously with an event (`OUT.E1`).

Technical Features
- **Type Openness through LWORD Abstraction:** The internal use of `LWORD` (64-bit) for the copy operations (`F_MOVE`) allows for high flexibility in the data being transferred, as various bit and integer patterns can be transmitted without information loss.
- **Full Event Control:** Any change to any input or selector triggers an immediate recalculation. This ensures that consistent and up-to-date data is always available at the output.

State Overview

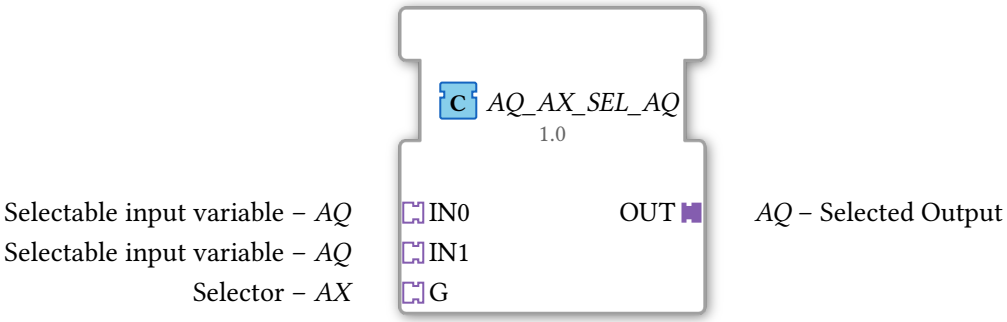
Selector State (G.D1)	Output Value (OUT.D1)	Trigger Event
FALSE (0)	Value of IN0.D1	Event on IN0 or G
TRUE (1)	Value of IN1.D1	Event on IN1 or G

Application Scenarios

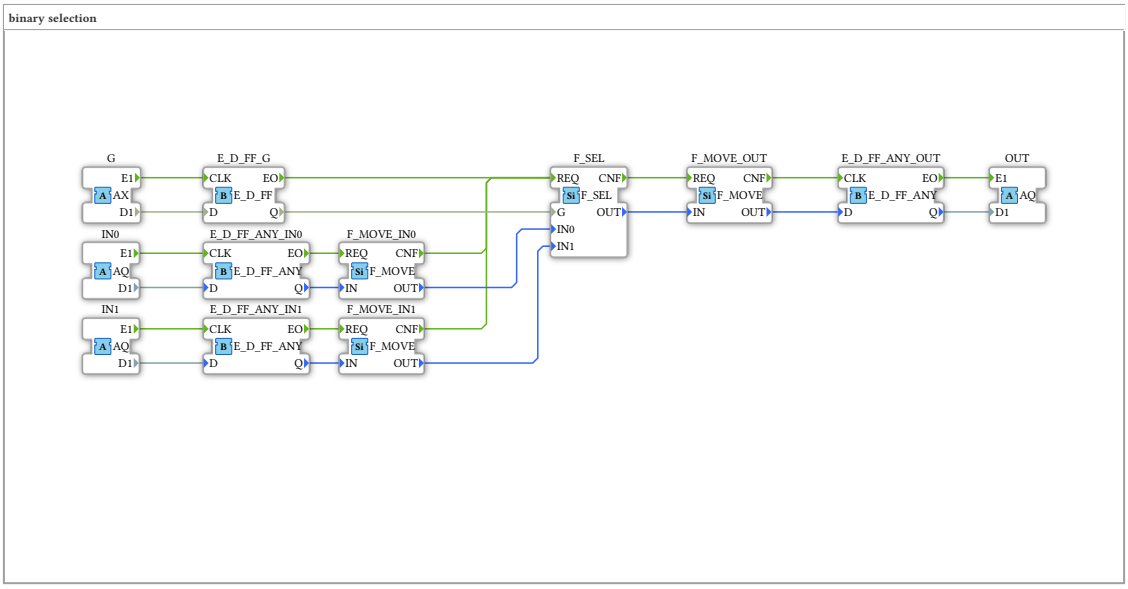
- **Setpoint Switching:** Switching between a standard setpoint (IN0) and an alternative setpoint (IN1) based on an external control signal.
- **Manual/Automatic Operation:** Switching a control signal for a valve or motor between a manually specified value (e.g., from a visualization) and the calculated value of an automatic controller.
- – **Sensor Redundancy:** Dynamic switching to a backup sensor (IN1) if the primary sensor (IN0) is flagged as faulty via a diagnostic function (switching controlled by the fault bit on G).

Comparison with Similar Function Blocks

Compared to a standard SEL function block from the IEC 61131-3 library, AL_AX_SEL_AL offers the following advantages:



- **Reduced Wiring Effort:** Encapsulation in adapters eliminates the need to run separate event and data lines. A single connection path per channel is sufficient.



- **Reduced Wiring Effort:** Encapsulation in adapters eliminates the need for separate event and data lines. A single connection path per channel is sufficient.
- – **Event Coupling:** The function block inherently responds to the event triggers integrated into the adapters, eliminating the need for manual event-based linking in the FBD (Function Block Diagram).

Conclusion

The AL_AX_SEL_AL function block is an efficient and clean solution for switching tasks in complex 4diac applications. Through the consistent use of unidirectional adapters, it promotes modular software design and ensures clear control topologies while providing robust, event-driven signal processing.

AQ_AX_SEL_AQ

• – ○ • – ○ • – ○ •

The function block `AQ_AX_SEL_AQ` is used for binary selection between two analog or value-based input signals provided via adapters. A selector adapter controls which of the two inputs is passed through to the output. The block encapsulates the classic selection logic and prepares it for event-driven execution in IEC 61499 environments.

The function block communicates exclusively via standardized adapter interfaces. This simplifies modeling in the application network, as related data and event lines are transmitted together.

The block does not have direct event inputs. Event processing is handled implicitly via the events of the connected input adapters (`IN0`, `IN1`, `G`).

The function block does not have direct event outputs. Events are forwarded via the output adapter (`OUT`).

There are no direct data inputs on the function block interface. Data is transmitted encapsulated via the sockets.

There are no direct data outputs. Data is provided encapsulated via the plug.

- **G** (Type: `adapter::types::unidirectional::AX`):
- **Description**: Selector (selection signal).
- **Data**: `D1` (Selector state).
- **Event**: `E1` (Trigger on selector value change).
- **IN0** (Type: `adapter::types::unidirectional::AQ`):
- **Description**: First selectable input channel (selected at `G = FALSE`).
- **Data**: `D1` (Input value).
- **Event**: `E1` (Trigger on value change at IN0).
- **IN1** (Type: `adapter::types::unidirectional::AQ`):
- **Description**: Second selectable input channel (selected with `G = TRUE`).
- **Data**: `D1` (Input value).
- **Event**: `E1` (Trigger on value change at IN1).
- **OUT** (Type: `adapter::types::unidirectional::AQ`):
- **Description**: The selected output channel.
- **Data**: `D1` (Output value of the selected input).
- **Event**: `E1` (Output event for signaling a new valid value).

Sockets (Eingangs-Schnittstellen)

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

Functionality

The function block is implemented internally as a function block network and operates according to the following sequence:

1. **Event Acquisition**: As soon as an event `E1` arrives at one of the inputs (`IN0`, `IN1`) or the selector (`G`), it is intercepted and synchronized via edge- or value-triggered auxiliary function blocks (`E_D_FF` and `E_D_FF_ANY`).
2. **Data Buffering**: The current values of the adapter inputs are buffered in the internal network using function blocks `F_MOVE` and formatted according to the specified type.
3. **Selection Logic**: The internal core function block `F_SEL` (based on the standardized selection function according to IEC 61131-3) evaluates the state of the selector:

- If `G.D1` is set to `FALSE`, the value of `IN0` is passed through.
- If `G.D1` is set to `TRUE`, the value of `IN1` is passed through.

1. **Output**: The selected value is passed to the output plug `OUT.D1`. Simultaneously, the output event `OUT.E1` is triggered to inform subsequent program components in the control network about the value change.

- **Event-Data Consistency**: The use of internal D flip-flops ensures that the data values are read and processed at the exact moment the corresponding change event occurs.
- **Typing**: The function block internally uses `F_MOVE` with the data type `BYTE` to encapsulate and assign the adapter data. This means that the `AQ` interfaces used transmit binary- or byte-compatible data structures.

State Overview

Since `AQ_AX_SEL_AQ` is a purely data- and event-driven combination block without its own internal state machine (ECC), its behavior can be described using the following logical table:

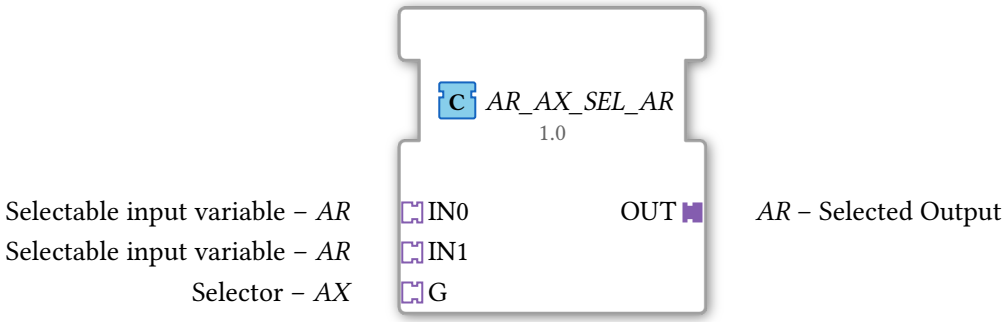
Selector (`G.D1`)	Value `IN0.D1`	Value `IN1.D1`	Output (`OUT.D1`)	Behavior of the Output Event (`OUT.E1`)
FALSE	`Wert_A`	`Wert_B`	**`Wert_A`**	Fires as soon as an event occurs at `IN0.E1`, `IN1.E1`, or `G.E1`.
TRUE	`Wert_A`	`Wert_B`	**`Wert_B`**	Fires as soon as an event occurs at `IN0.E1`, `IN1.E1`, or `G.E1`.

- **Sensor Redundancy / Switchover**: Automatic or manual switching between a primary sensor (`IN0`) and a secondary/backup sensor (`IN1`) in case of a fault via the control signal `G`.
- **Manual/Automatic Operation**: Selection of setpoints for actuators. In automatic mode (`G = TRUE`), the calculated controller value (`IN1`) is used; in manual mode (`G = FALSE`), a predefined fixed value or a manually specified parameter (`IN0`) is used.
- **Recipe-Controlled Parameterization**: Dynamic switching of process limits during operation.

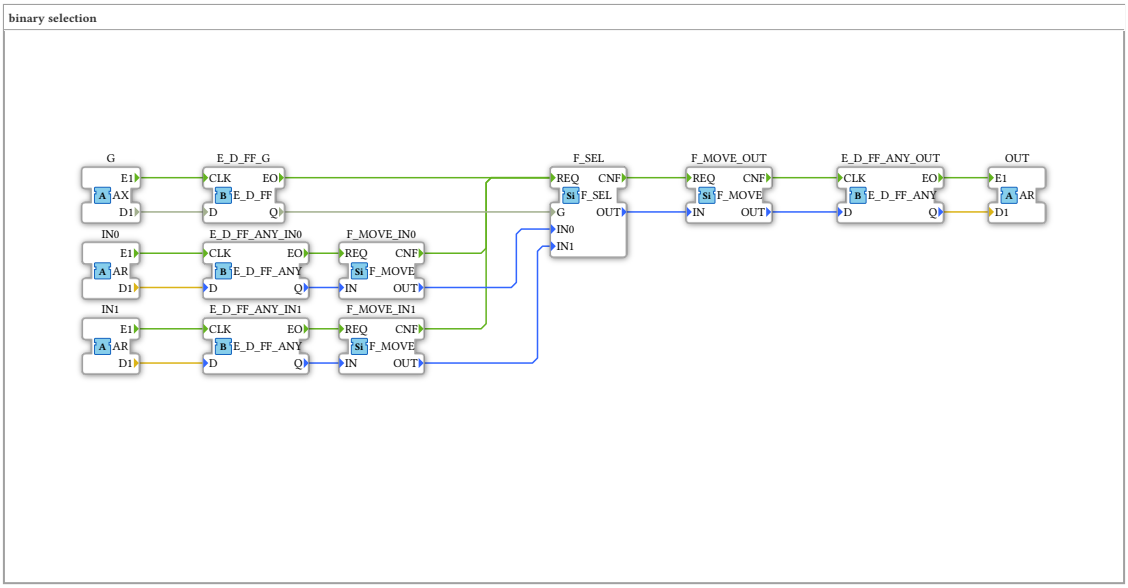
2.6 · Comparison with Similar Components

- **Standard SEL (IEC 61131-3)**: The classic SEL component has no event control and reacts purely cyclically to incoming data. AQ_AX_SEL_AQ extends this functionality with the event-based paradigm of IEC 61499.
- **Classic Multiplexers (MUX)**: While a multiplexer usually selects from a large number of inputs, this component is specifically limited to efficient 1-out-of-2 selection (binary selection), which minimizes parameterization and wiring effort.

The AQ_AX_SEL_AQ is a useful infrastructure component for modular 4diac applications. By completely encapsulating the signals in adapter connections, it significantly contributes to clarity in the application window and ensures robust, event-driven signal forwarding.



Technical Features



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

AR_AX_SEL_AR

• – ○ • – ○ • – ○ •

The function block AR_AX_SEL_AR is used for binary selection between two analog input signals transmitted via adapters. Based on the state of a selector signal, one of the two inputs is passed through to the output.

By consistently using adapters instead of traditional discrete data and event pins, the complexity of the wiring in the higher-level IEC 61499 application diagram is significantly reduced.

Since this function block relies entirely on adapter-based communication, it has no direct, traditional event or data interfaces at the top level. All communication is handled via the declared adapters.

No direct event inputs available (events are received via the adapter interfaces).
No direct event outputs available (events are sent via the adapter interfaces).
No direct data inputs available.
No direct data outputs available.

Event Inputs

Interface Structure

Introduction

Adapters

- **G** (Type: `adapter::types::unidirectional::AX`):

The selector adapter. The signal present here controls which of the two inputs (`IN0` or `IN1`) is passed to the output.
The first selectable signal input. This value is passed to output `OUT` when selector `G` is in state `FALSE` (0).

- **IN1** (Type: `adapter::types::unidirectional::AR`):

The second selectable signal input. This value is passed to output `OUT` when selector `G` is in state `TRUE` (1).

- **OUT** (Type: `adapter::types::unidirectional::AR`):

The selected output adapter. It provides the value of the currently active input, including the corresponding update event.

Plugs (Ausgangsschnittstellen)

Sockets (Eingangsschnittstellen)

Functionality

Inside the function block `AR_AX_SEL_AR` is a network of standard IEC 61131-3 and IEC 61499 components that process the adapter signals:

1. **Event and Data Acquisition:**

As soon as an event `E1` arrives at one of the input adapters (`IN0`, `IN1`, or `G`), it is intercepted by internal edge-triggered flip-flops (`E_D_FF` or `E_D_FF_ANY`). The corresponding data values (`D1`) are temporarily stored.

1. **Data Conversion:**

The values of the analog inputs are routed through conversion blocks of type `F_MOVE` (configured to data type `REAL`) to ensure consistent data processing.

1. **Selection Logic (Multiplexing):**

The standard selection block `F_SEL` performs the actual selection:

- If the value of `G.D1` equals `FALSE`, the signal from `IN0` is passed to the output.
- If the value of `G.D1` is equal to `TRUE`, the signal is passed on to `IN1`.

1. **Output:**

The selected signal is passed via another `F_MOVE` block to the output flip-flop `E_D_FF_ANY_OUT`. This flip-flop generates the output event `E1` at plug `OUT` and makes the selected value available to `OUT.D1`.

- **Unidirectional Adapter Structure:** The function block uses unidirectional adapter types (`AR` for analog values, `AX` for binary values), ensuring clear and interference-free signal direction within the system.
- **Type Consistency:** Internally, the function block uses the data type `REAL` for analog signals (configured via the attributes of the `F_MOVE` function blocks).

- **Event-Driven:** The output is recalculated and updated immediately as soon as either the selection `G` changes or new values are signaled at the inputs `IN0` or `IN1`.

The behavior can be described using the following simple logic table:

State Selector (`G.D1`)	Value at Output (`OUT.D1`)	Triggering Event
`FALSE`	Value of `IN0.D1`	Event at `IN0.E1` or Change at `G.E1`
`TRUE`	Value of `IN1.D1`	Event at `IN1.E1` or Change at `G.E1`

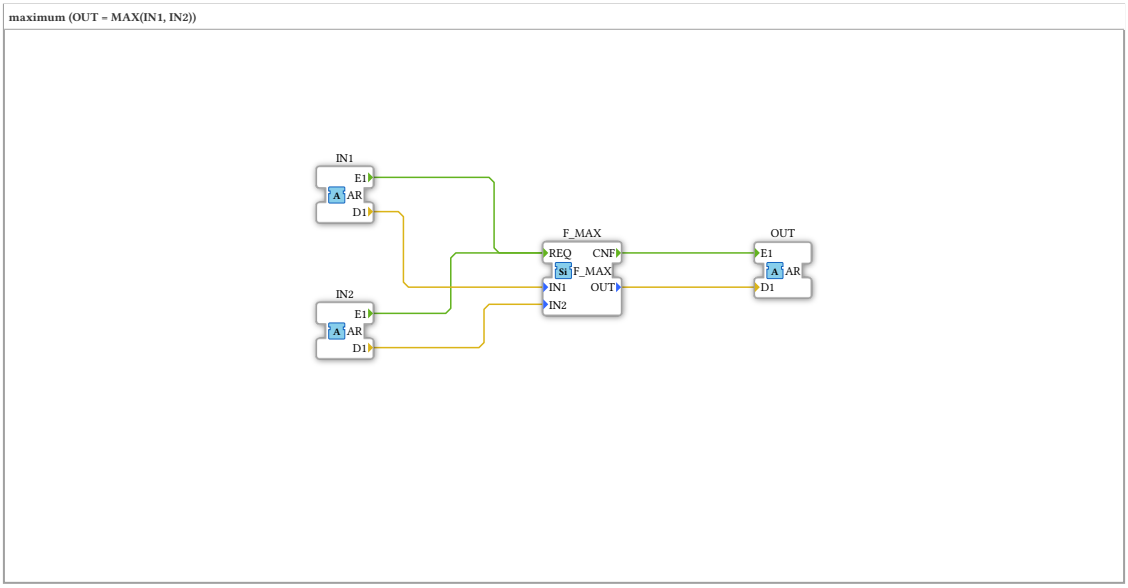
- **Sensor Redundancy:** Switching between a primary and a secondary analog sensor (e.g., temperature sensor or pressure sensor) in case of primary sensor failure.
- **Manual/Automatic Switching:** Optionally applying an automatic control value (e.g., calculated by a PID controller) or a manually specified setpoint to an actuator.
- **Signal Routing:** Dynamic path selection in more complex process engineering or agricultural control applications.

–

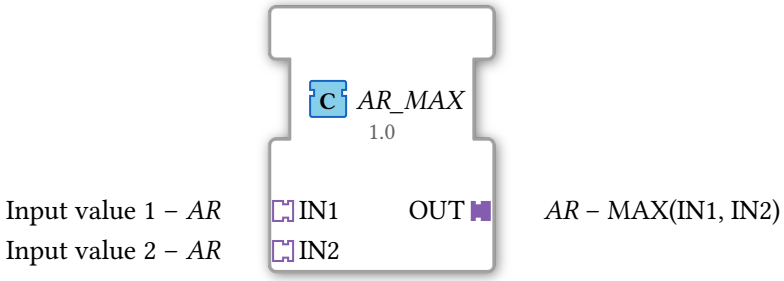
Compared to the standard IEC 61131 function block `F_SEL`, `AR_AX_SEL_AR` offers the advantage of complete encapsulation via adapters. While the standard `F_SEL` requires events and data to be wired and synchronized separately in the network, `AR_AX_SEL_AR` reduces the wiring effort in the higher-level system to just three connections (two input adapters, one output adapter) plus the selection signal.

The `AR_AX_SEL_AR` is an extremely useful auxiliary component for IEC 61499 applications. By abstracting the data and event streams into standardized adapter channels, it ensures a streamlined application design and simplifies the implementation of switching and redundancy logic for analog signals.

Technical Features



State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

AR_MAX

Introduction

The function block `AR_MAX` is used to determine the maximum value of two analog input signals transmitted via adapters (`AR`). It compares the data values of the two input sockets `IN0` and `IN1` and passes the larger value to the output plug `OUT`.

By consistently using adapters instead of traditional discrete data and event pins, the complexity of the wiring in the higher-level IEC 61499 application diagram is significantly reduced.

Interface Structure

Since this function block relies entirely on adapter-based communication, it has no direct, traditional event or data interfaces at the top level. All communication is handled via the declared adapters.

Event Inputs

No direct event inputs available (events are received via the adapter interfaces).

Event Outputs

No direct event outputs available (events are sent via the adapter interfaces).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Interfaces)

- **IN0** (Type: `adapter::types::unidirectional::AR`): The first analog input signal adapter.
- **IN1** (Type: `adapter::types::unidirectional::AR`): The second analog input signal adapter.

Plugs (Output Interfaces)

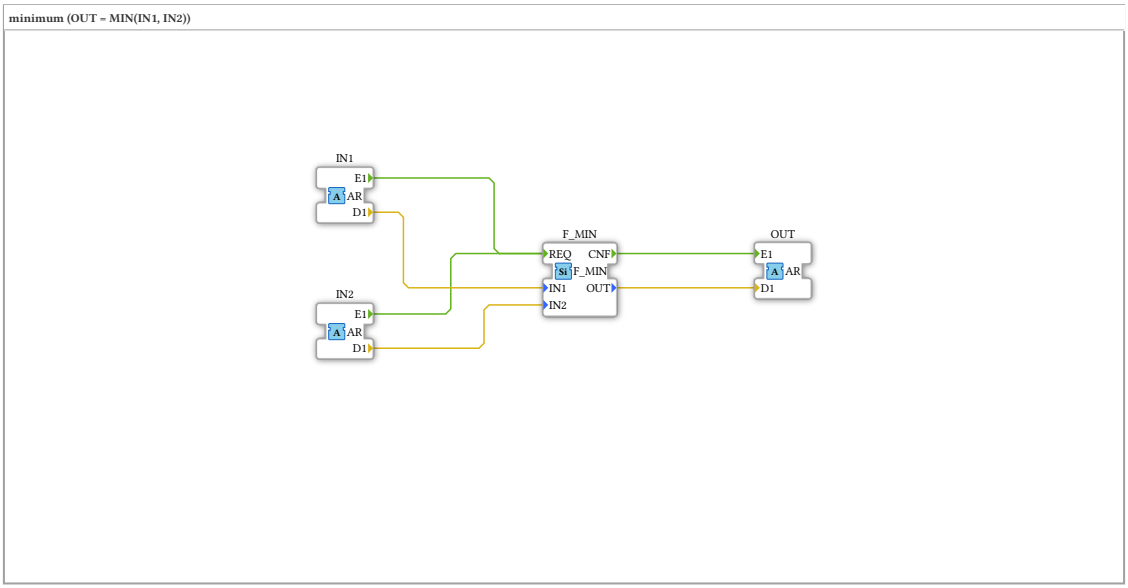
- **OUT** (Type: `adapter::types::unidirectional::AR`): The output adapter. It provides the maximum value $\max(\text{IN0.D1}, \text{IN1.D1})$ including the corresponding update event.

Functionality

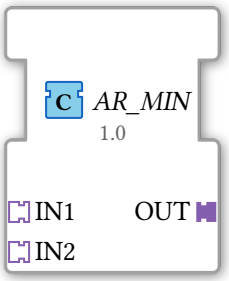
As soon as an event `E1` arrives at either input adapter (`IN0` or `IN1`), the function block compares the current data values `IN0.D1` and `IN1.D1`:

$$\text{OUT.D1} = \max(\text{IN0.D1}, \text{IN1.D1}) \tag{2.122}$$

The computed maximum value is set on `OUT.D1` and emitted along with output event `OUT.E1`.



Technical Features



- **Unidirectional Adapter Structure**: Uses standardized `AR` adapter channels for clear signal direction.
- **Event-Driven**: Recalculation and output occur immediately upon arrival of a new measurement at `IN0` or `IN1`.
- **Type Consistency**: Operates internally using the floating-point data type `REAL`.

Conclusion

The AR_MAX is a useful selection block for calculating extreme values (maximum selection) in adapter-based IEC 61499 applications.

AR_MIN

Input value 1 – *AR*
Input value 2 – *AR*

AR – MIN(IN1, IN2)

Introduction

The function block AR_MIN is used to determine the minimum value of two analog input signals transmitted via adapters (AR). It compares the data values of the two input sockets IN0 and IN1 and passes the smaller value to the output plug OUT.

By consistently using adapters instead of traditional discrete data and event pins, the complexity of the wiring in the higher-level IEC 61499 application diagram is significantly reduced.

Interface Structure

Since this function block relies entirely on adapter-based communication, it has no direct, traditional event or data interfaces at the top level. All communication is handled via the declared adapters.

Event Inputs

No direct event inputs available (events are received via the adapter interfaces).

Event Outputs

No direct event outputs available (events are sent via the adapter interfaces).

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Interfaces)

- **IN0** (Type: `adapter::types::unidirectional::AR`): The first analog input signal adapter.
- **IN1** (Type: `adapter::types::unidirectional::AR`): The second analog input signal adapter.

Plugs (Output Interfaces)

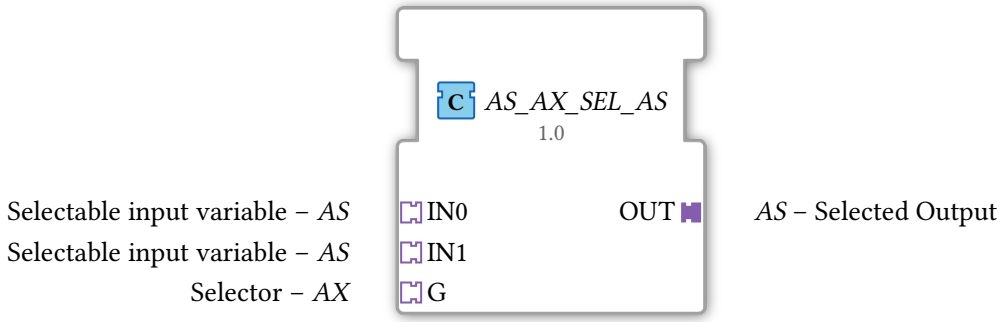
- **OUT** (Type: `adapter::types::unidirectional::AR`): The output adapter. It provides the minimum value $\min(\text{IN0.D1}, \text{IN1.D1})$ including the corresponding update event.

Functionality

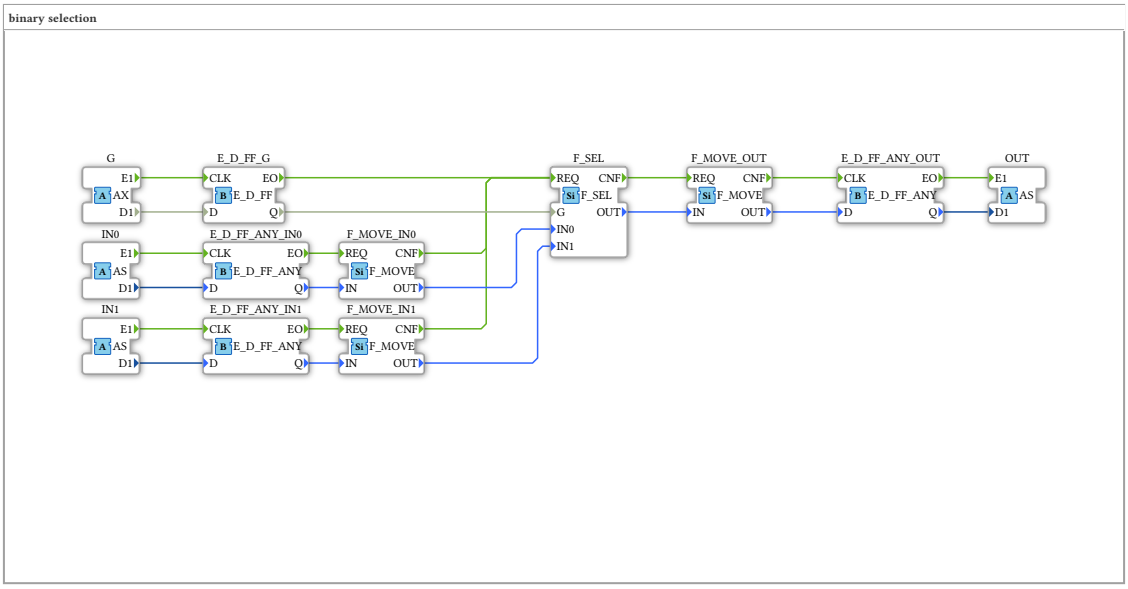
As soon as an event `E1` arrives at either input adapter (`IN0` or `IN1`), the function block compares the current data values `IN0.D1` and `IN1.D1`:

$$\text{OUT.D1} = \min(\text{IN0.D1}, \text{IN1.D1}) \tag{2.123}$$

The computed minimum value is set on `OUT.D1` and emitted along with output event `OUT.E1`.



Technical Features



- **Unidirectional Adapter Structure**: Uses standardized `AR` adapter channels for clear signal direction.
- **Event-Driven**: Recalculation and output occur immediately upon arrival of a new measurement at `IN0` or `IN1`.
- **Type Consistency**: Operates internally using the floating-point data type `REAL`.

Conclusion

The `AR_MIN` is a useful selection block for calculating extreme values (minimum selection) in adapter-based IEC 61499 applications.

AS_AX_SEL_AS

(No image available)

• – ○ • – ○ • – ○ •

Introduction

The function block `AS_AX_SEL_AS` is used for binary selection between two input signals provided via adapters. Based on the state of a selection adapter (`G`), either the value of input `IN0` or input `IN1` is passed to output `OUT`.

This function block encapsulates the classic multiplexer function (according to `SEL` from IEC 61131-3) in an event-driven IEC 61499 architecture using unidirectional adapters. This significantly simplifies signal wiring in complex control applications.

Interface Structure

The function block does not have any classic event- or data-based inputs and outputs at the main level. All communication is handled via adapter interfaces.

Event Inputs

No direct event inputs are available. Event processing is encapsulated via the adapter sockets.

Event Outputs

No direct event outputs are available. Event forwarding is encapsulated via the output adapter's plug.

Data Inputs

No direct data inputs available.

Data Outputs

No direct data outputs available.

Adapters

Sockets (Input Interfaces)

- **G** (Type: `adapter::types::unidirectional::AX`):
- **Description:** Selector interface. Determines which input is routed to the output.
- **Event:** `E1` (Trigger for updating the selection signal).
- **Data:** `D1` (Boolean value; determines the active path).
- **IN0** (Type: `adapter::types::unidirectional::AS`):

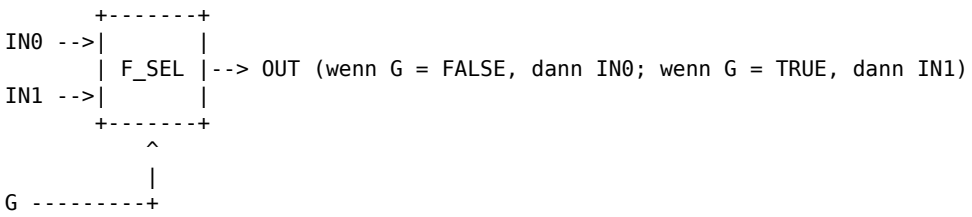
Description: First selectable data channel (selected when `G` has the value `FALSE`).
Event: `E1` (signals new data to `IN0`).
Data: `D1` (data value of the first channel).
IN1 (Type: `adapter::types::unidirectional::AS`):

Description: Second selectable data channel (selected when G has the value TRUE).
Event: E1 (signals new data to D1). * **Event:** E1 (Signals new data to IN1).

- **Data:** D1 (Data value of the second channel).

Plugs (Output Interfaces)

- **OUT** (Type: adapter::types::unidirectional::AS):
- **Description:** The selected output channel that mirrors the data of the active input.
- **Event:** E1 (Triggered when a new selected value is output).
- **Data:** D1 (The forwarded data value from IN0 or IN1).



Functionality

Inside the function block is a network of standard function blocks that processes the adapter signals:

1. **Signal Storage (Latch):** The data received via the adapters (G.D1, IN0.D1, IN1.D1) is temporarily stored in event-triggered D flip-flops (E_D_FF and E_D_FF_ANY, respectively) upon the occurrence of the respective event (E1).
2. **Data Conversion & Forwarding:** The cached data of types IN0 and IN1 are transferred to the central selection block via F_MOVE blocks. Internally, these operations are configured for the data type SINT (Short Integer).
3. **Selection Logic (F_SEL):** The block F_SEL (IEC 61131-3 Selection) performs the actual selection:

- If the state of selector G is equal to FALSE, the value of IN0 is passed through.
- If the state of selector G is equal to TRUE, the value of IN1 is passed through.

1. **Output Triggering:** After successful selection, the result is passed via another F_MOVE block to the output flip-flop E_D_FF_ANY_OUT. This flip-flop generates the output event OUT.E1 and places the selected value on OUT.D1.

Technical Features

- **Data Type Specificity:** Although the adapters can be flexibly configured, the internal conversion elements (F_MOVE) are fixed to the data type **SINT**. The module is therefore specifically designed for selecting signed 8-bit integers (short integers).
- **Event-Driven:** Any change or event at the inputs IN0, IN1, or G triggers the chain and updates the output OUT.

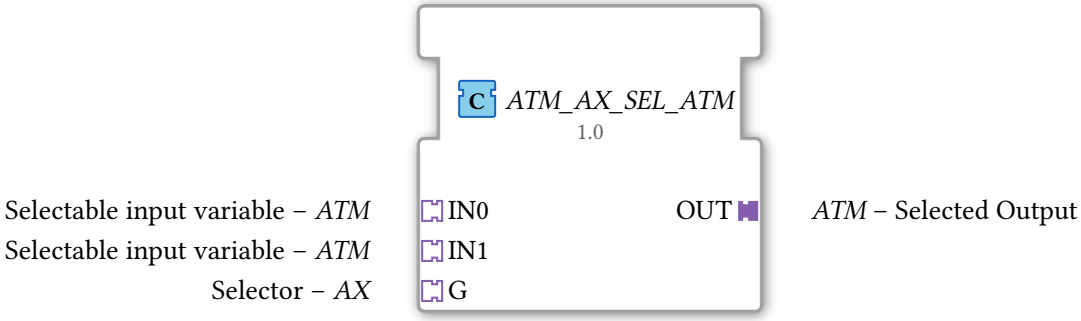
State Overview

The following table shows the logical behavior of the function block based on the selection signal G.D1:

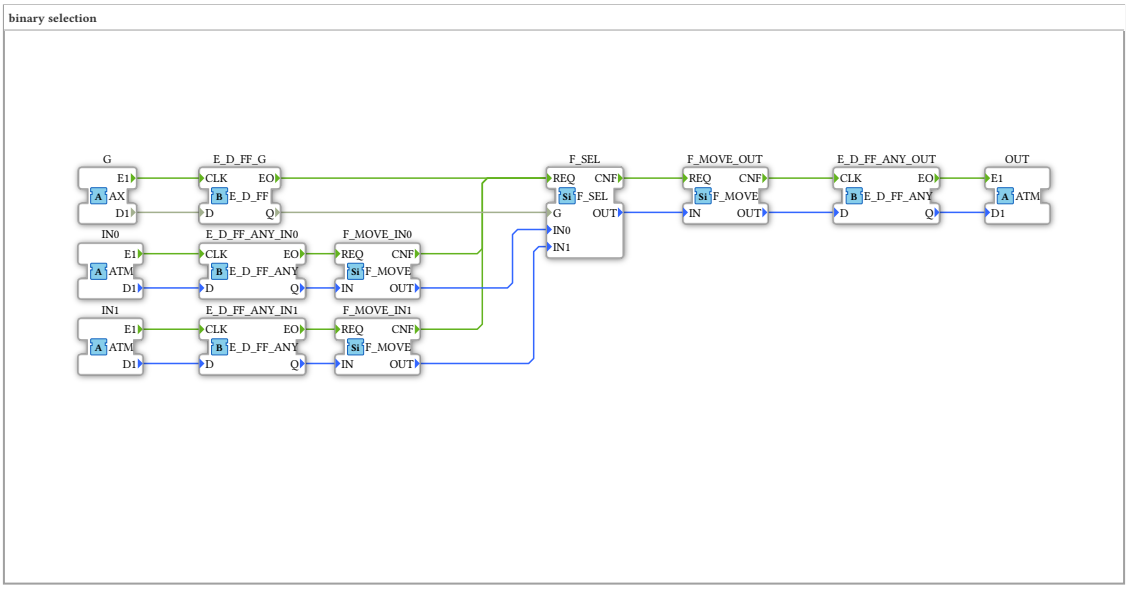
State G.D1	Selected Path	Output Value (OUT.D1)	Output Event (OUT.E1)
FALSE	Channel 0 (IN0)	Value of IN0.D1	Triggered on value change/event
TRUE	Channel 1 (IN1)	Value of IN1.D1	Triggered on value change/event

Application Scenarios

- **Operating Mode Switching:** Routing of setpoints (e.g., switching between a manually specified SINT value and an automatic setpoint).
- **Signal Source Selection:** Dynamic selection between two sensor values or parameter configurations distributed throughout the system via standardized unidirectional adapter structures.
- **Channel Bonding:** Reducing wiring effort in 4diac applications by encapsulating data and events in adapters.



Comparison with Similar Function Blocks



- **`F_SEL` (Standard Selection Function Block):** Works directly with standard data types and requires explicit event connections at the application level. `AS_AX_SEL_AS`, on the other hand, fully encapsulates this logic and uses adapters, resulting in a clearer application diagram.
- **Other adapter-based selectors:** These differ primarily in the data types supported by the adapters (e.g., `INT`, `REAL` instead of `SINT`).

Conclusion

The `AS_AX_SEL_AS` block provides an elegant, clean, and reusable solution for implementing binary signal switching based on unidirectional adapters in the 4diac IDE. The internal use of standardized components ensures deterministic behavior in the event-driven system.

ATM_AX_SEL_ATM

• – ○ • – ○ • – ○ •

Introduction

The function block `ATM_AX_SEL_ATM` serves as a binary selector (multiplexer) for adapter interfaces according to the IEC 61499 standard. Based on the state of a selection adapter (`G` of type `AX`), it allows dynamic selection between two input adapters (`IN0` and `IN1` of type `ATM`) and forwards the selected signal to the output adapter (`OUT` of type `ATM`). The function block operates purely event-driven and is internally designed for processing time-based signals (`TIME`).

Interface Structure

The function block does not have any directly accessible standard event or data pins. All communication is elegantly encapsulated via sockets (input adapters) and plugs (output adapters).

Event Inputs

No direct event inputs are available on the function block body. Event control is implicit via the adapter sockets.

Event Outputs

No direct event outputs are available on the function block body. Event signaling is implicit via the adapter plug.

Data Inputs

No direct data inputs are available on the FB body.

Data Outputs

No direct data outputs are available on the FB body.

Adapters

Sockets (Input Interfaces)

- **IN0** (Type: `adapter::types::unidirectional::ATM`):

The first selectable input adapter (corresponds to the selection in logical `FALSE`).

- **IN1** (Type: `adapter::types::unidirectional::ATM`):

The second selectable input adapter (corresponds to the selection in logical `TRUE`).

- **G** (Type: `adapter::types::unidirectional::AX`):

The selector adapter. The signal applied here determines which of the two inputs is routed to the output.

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::ATM`):

The output adapter that carries the data and events of the currently selected input (`IN0` or `IN1`).

Functionality

The internal structure of the `ATM_AX_SEL_ATM` consists of a network of standardized auxiliary components that ensure reliable and consistent signal transmission:

1. **Event Acquisition and Buffering**:

As soon as an event (`E1`) arrives at one of the sockets (`IN0`, `IN1`, or `G`), it is captured via edge-triggered flip-flops (`E_D_FF_ANY` or `E_D_FF`). The data values (`D1`) are stabilized and passed to internal buffers.

As soon as an event (`E1`) arrives at one of the sockets (`E_D_FF_ANY` or `E_D_FF`), it is captured via edge-triggered flip-flops. 2. **Data Conversion**:

The data from inputs `IN0` and `IN1` are buffered via two `F_MOVE` function blocks (configured to the data type `TIME`) and made available for the selection logic.

1. **Selection**:

The function block `F_SEL` (a standard selection block according to IEC 61131-3) evaluates the state of selector `G`:

- If the signal from `G` is equal to `FALSE`, the value from `IN0` is selected.
- If the signal from `G` is equal to `TRUE`, the value from `IN1` is selected.

1. **Output**:

The selected value is passed via another `F_MOVE` module to the output adapter `OUT`, whereupon the output event (`OUT.E1`) is triggered simultaneously.

Technical Features

- **Adapter Encapsulation**: By using adapters instead of individual pins, the number of connection lines in the overall control diagram is drastically reduced, which improves the readability of the entire system.
- **Data Type Focus**: The function block is internally optimized for the data type `F_MOVE` (time values) through the parameterization of the `F_MOVE` function blocks.

- **Event Integrity**: The use of event flip-flops ensures that no signal changes are lost and the output is only updated when relevant input data or the selector actually changes.

State Overview

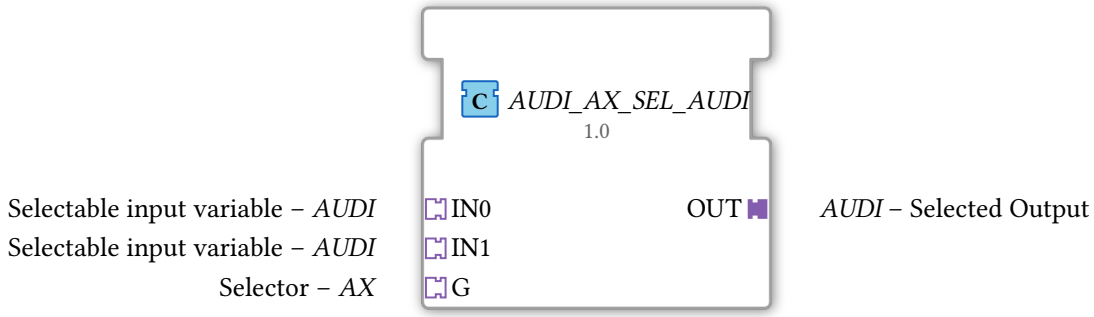
Since this is a composite function block network (FB), the function block does not have its own classic ECC (Event Execution Control) state machine. Its behavior is purely data flow and event-driven:

State Selector `G.D1`	Triggering Event	State Output `OUT.D1`	Output Event
`FALSE`	Change to `IN0.E1` or `G.E1`	Value of `IN0.D1`	`OUT.E1`
`TRUE`	Change to `IN1.E1` or `G.E1`	Value of `IN1.D1`	`OUT.E1`

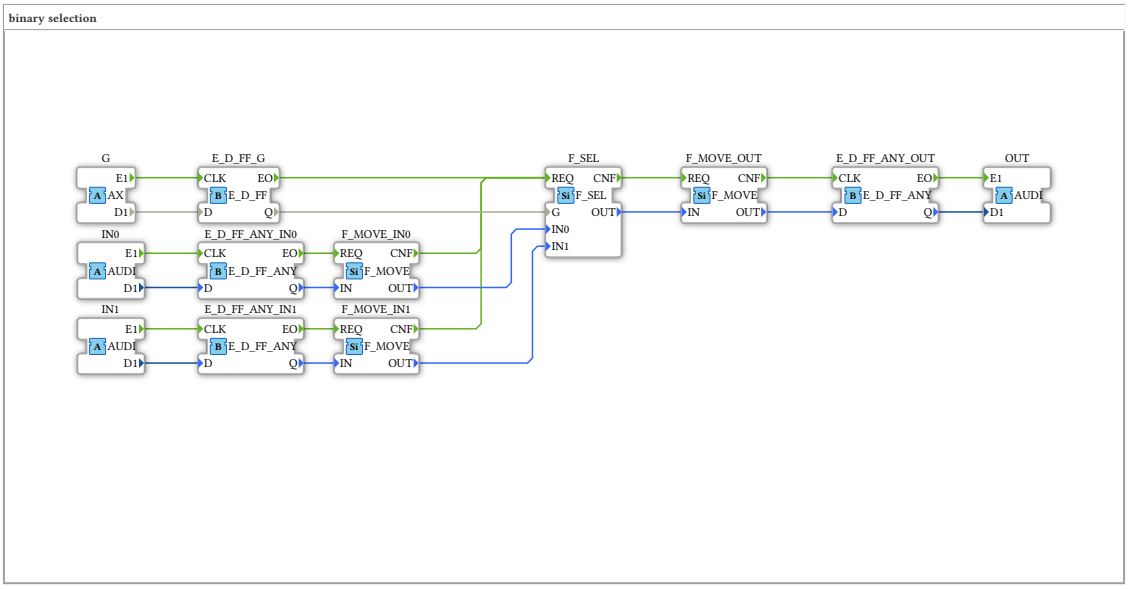
Application Scenarios

- **Process Time Switching**: In industrial or agricultural processes where switching between two different cycle, rinsing, or delay times (e.g., summer/winter operation or recipe A/recipe B) is required.
- **Setpoint Switching**: Dynamic selection of a time-based setpoint from two different sources based on a higher-level operating mode.

–



Comparison with Similar Function Blocks



- **Standard `F_SEL`**: The classic `F_SEL` function block operates directly on elementary data types and does not have integrated event control for adapters. `ATM_AX_SEL_ATM` moves this logic to the structured adapter level.
- – **Standard Multiplexer**: Unlike general-purpose multiplexers, which often feature complex bus structures, this component is highly specialized, extremely lightweight, and perfectly matched to the combination of `ATM` and `AX` adapters.

Conclusion

The `ATM_AX_SEL_ATM` is a robust and reusable auxiliary component for modern control architectures according to IEC 61499. It elegantly solves the task of binary signal switching for time-based data streams, leveraging the advantages of adapter technology.

AUDI_AX_SEL_AUDI

(No image available)

• – ○ • – ○ • – ○ •

Introduction

The function block `AUDI_AX_SEL_AUDI` serves as a binary selector (selection switch) for unidirectional communication adapters. Based on the state of a control signal at a selector adapter, it allows the data and event stream between two alternative input adapters to be redirected to a single output adapter.

The block encapsulates the necessary synchronization and conversion logic to ensure a clean separation of events and data flows within IEC 61499 applications.

Interface Structure

Event Inputs

No direct event inputs are defined on the block interface. Event processing is fully encapsulated via the connected adapters.

Event Outputs

No direct event outputs are defined on the function block interface. Event forwarding is handled entirely via the output adapter.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

Sockets (Input Connections)

- **IN0** (Type: `adapter::types::unidirectional::AUDI`):

First selectable input adapter. Data and events arriving here are passed through to the output when the selection signal `G` has the logical state `FALSE` (or `0`).

- **IN1** (Type: `adapter::types::unidirectional::AUDI`):

Second selectable input adapter. Data and events arriving at this adapter are passed to the output when the selection signal `G` has the logical state `TRUE` (or `1`).

- **G** (Type: `adapter::types::unidirectional::AX`):

Selector adapter. The signal on this adapter determines which of the two inputs (`IN0` or `IN1`) is routed to the output.

Plugs (Output Connections)

- **OUT** (Type: `adapter::types::unidirectional::AUDI`):

Output adapter. Outputs the data and the corresponding trigger event of the currently selected input.

Functionality

The internal behavior of the function block is implemented by a network of standard function blocks:

1. **Event and Data Synchronization**:

The signals received via the sockets (`IN0`, `IN1`, `G`) are first processed through edge- or level-triggered D flip-flops (`E_D_FF` and `E_D_FF_ANY`). This ensures that data values (`D1`) and events (`E1`) are processed synchronously.

1. **Data Conversion**:

The synchronized data values from the two inputs are transferred to the selection block via two transfer blocks (`F_MOVE` with the data type `UDINT`).

1. **Selection Control**:

The function block `F_SEL` (IEC 61131-3 Selection) performs the actual logical switching:

- If the control signal of the adapter `G` is `0` (`FALSE`), the value of `IN0` is selected.
- If the control signal of the adapter `G` is `1` (`TRUE`), the value of `IN1` is selected.

1. **Output**:

The selected result is transferred via another transfer block (`F_MOVE_OUT`) to the output flip-flop `E_D_FF_ANY_OUT`. This flip-flop generates the output event `OUT.E1` and makes the selected data value available to `OUT.D1`.

Technical Features

- **UDINT Data Processing**: Although the adapters are of the generic type `AUDI`, the user data (`D1`) is explicitly processed and transmitted internally as `UDINT` (Unsigned Double Integer / 32-bit integer).
- **Event-driven behavior**: Any change to the inputs or the selector triggers a recalculation via the internal coupling network and the output event of the adapter `OUT`.
- **Encapsulation**: By using adapters instead of individual event and data ports, the wiring effort in the overall system diagram is drastically reduced.

State overview

Since the function block is structured as a function block network, it does not have a classic state machine (ECC). The logical behavior can instead be described using the following function table:

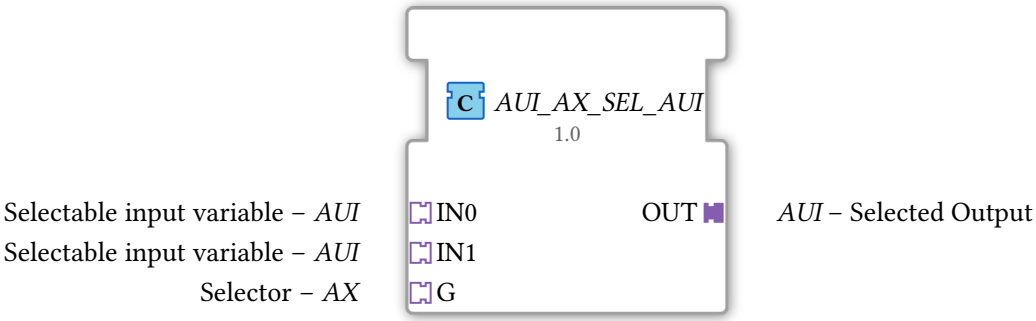
State Selector (`G.D1`)	Triggering event	Active data path	Value at output (`OUT.D1`)	Event at output (`OUT.E1`)
`FALSE`	Event on `IN0.E1` or `G.E1`	`IN0` -> `OUT`	Equivalent to `IN0.D1`	Triggered
`TRUE`	Event on `IN1.E1` or `G.E1`	`IN1` -> `OUT`	Equivalent to `IN1.D1`	Triggered

---

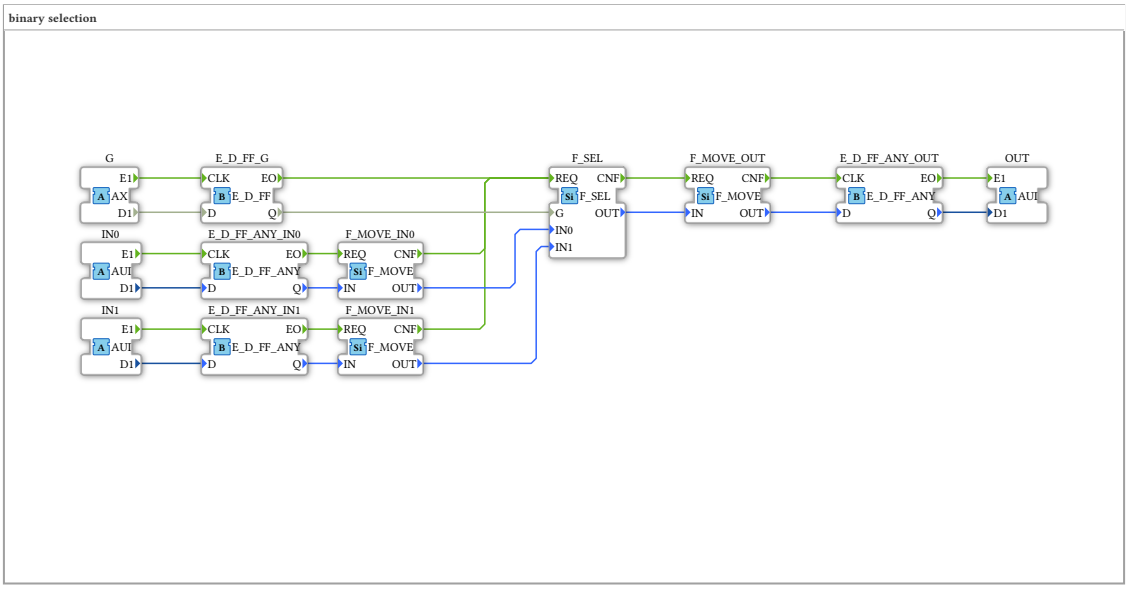
Application Scenarios

- **Setpoint Switching**: Switching between an automatic setpoint (e.g., from a PID controller at `IN1`) and a manual setpoint (e.g., from a visualization at `IN0`) via a selection signal at `G`.
- **Sensor Redundancy**: Fail-safe switching between a primary sensor and a backup sensor in case of signal interference.
- **Recipe Control**: Selection of different predefined parameter profiles during operation.
-

Comparison with Similar Function Blocks



Compared to the standard selection function block `F_SEL` from the IEC 61131-3 library, `AUDI_AX_SEL_AUDI` offers the advantage of direct interaction with structured, unidirectional adapters (`AUDI` and `AX`). Using the standard `F_SEL` function block would require manually splitting all event and data lines of the adapters, connecting them individually, and then reconnecting them, which is error-prone and makes the application diagram cluttered.



–

Conclusion

The `AUDI_AX_SEL_AUDI` function block offers an elegant, clean, and reusable solution for signal switching in 4diac-based control architectures. Through the consistent use of adapters, he makes a significant contribution to the modularity and clarity of complex control programs.

AUI_AX_SEL_AUI

No image available

• – ○ • – ○ • – ○ •

Introduction

The function block `AUI_AX_SEL_AUI` is a composite function block for 4diac-ide. It performs binary selection between two analog or numeric input signals provided via adapters. Based on the state of a selection adapter, the block switches one of the two input signals to the output.

Interface Structure

The function block does not have any traditional, direct event or data channels on its main interface. All communication is handled via adapters.

Event Inputs
No direct event inputs available.

Event Outputs
No direct event outputs available.

Data Inputs
No direct data inputs available.

Data Outputs
No direct data outputs available.

Adapters

Sockets (Input Adapters)
- **IN0** (Type: `adapter::types::unidirectional::AUI`): Unidirectional adapter for the first selectable input signal. This signal is passed to the output if the selector `G` has the value `FALSE`.
- **IN1** (Type: `adapter::types::unidirectional::AUI`): Unidirectional adapter for the second selectable input signal. This signal is passed to the output when the selector `G` has the value `TRUE`.
- **G** (Type: `adapter::types::unidirectional::AX`): Unidirectional selector adapter. Determines which of the two input signals is passed through.

Plugs (Output Adapters)
- **OUT** (Type: `adapter::types::unidirectional::AUI`): Unidirectional adapter for the selected output signal.

Functionality
Inside the module is a defined network of standard function blocks that processes the adapter signals:

1. **Buffering & Synchronization:**

Events (`E1`) and data (`D1`) arriving via the adapters `IN0`, `IN1`, and `G` are buffered and synchronized using event-data flip-flops (`E_D_FF` and `E_D_FF_ANY`).

1. **Data Conversion:**

The buffered numeric values of the inputs are forwarded to the actual selection block via internal `F_MOVE` blocks (configured to the data type `UINT`).

1. **Selection:**

The standard selection block `F_SEL` (according to IEC 61131-3) performs the actual selection:

- If the value at selector `G` equals `FALSE`, the signal from `IN0` is selected.
- If the value at selector `G` equals `TRUE`, the signal from `IN1` is selected.

1. **Output:**

The selection result is transferred to the output plug `OUT` via a further buffer containing `F_MOVE` and `E_D_FF_ANY`. Simultaneously, the output event at the plug is triggered to inform subsequent function blocks of the new value.

Technical Features
- **Pure Adapter Interface:** This function block is specifically designed for use in modern, adapter-based architectures. This results in a very clean and clear application diagram, as loose data and event lines are bundled within adapters.

** * **Event-driven:** Any change (sending an event) to the inputs `IN0`, `IN1`, or the selector `G` triggers an immediate recalculation and results in an update of the output `OUT`.

- **Typing:** The internal conversion and forwarding blocks primarily work with the data type `UINT`.

State Overview

Since this is a composite function block, it does not have its own state machine (ECC). Its behavior is purely data- and event-driven:

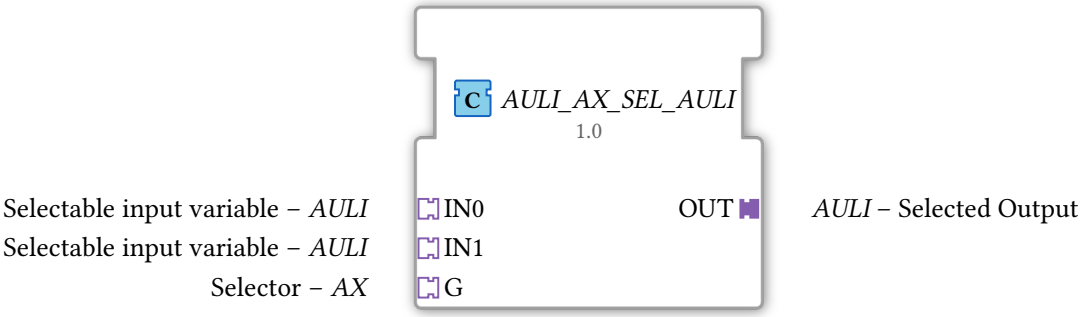
State Selector `G` (value of D1)	Output `OUT` (value of D1)	Triggering of `OUT.E1`
`FALSE` (0)	Corresponds to the value of `IN0`	Yes, on change/event to `IN0` or `G`
`TRUE` (1)	Corresponds to the value of `IN1`	Yes, on change/event to `IN1` or `G`

Application Scenarios

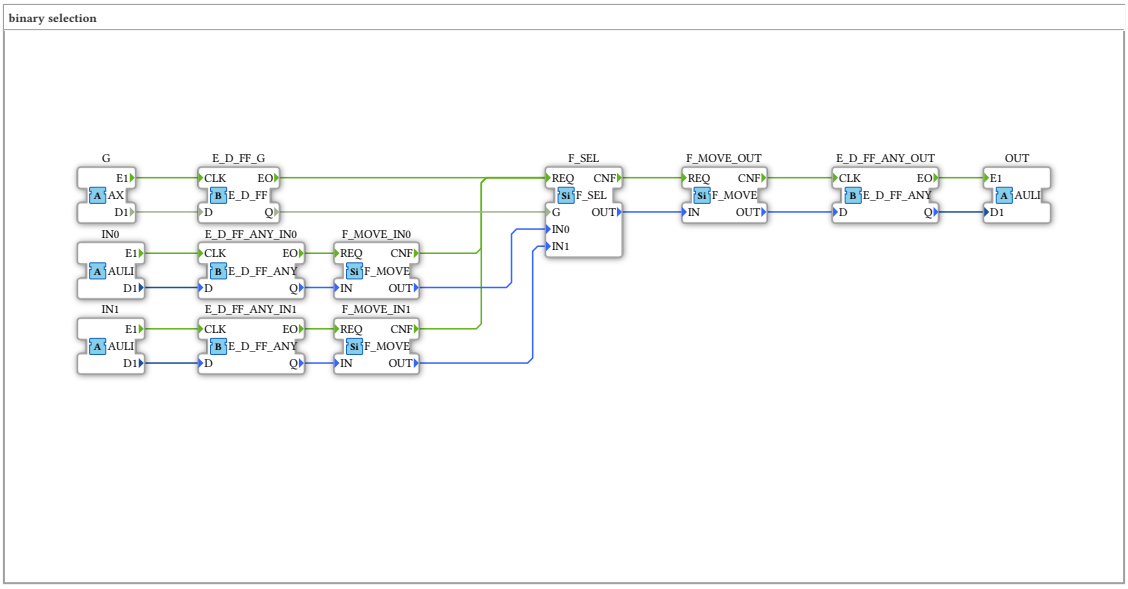
- **Setpoint Switching:** Switching between a manually setpoint (e.g., via an HMI at `IN0`) and an automatic setpoint (e.g., from a calculation logic at `IN1`).
- **Sensor Redundancy:** Switching between two analog sensors (e.g., primary sensor at `IN1` and backup sensor at `IN0`) in case of a fault via a control signal at `G`.
- **Operating Mode Selection:** Selection of different analog control parameters depending on the current machine state.
-

Comparison with Similar Components

The classic standard component `F_SEL` requires direct data lines (e.g., `ANY_ELEMENTARY`) and manual event wiring for calculation triggering (`REQ`/`CNF`).



The component `AUI_AX_SEL_AUI` encapsulates this complete logic, including event synchronization and buffering. It is therefore ideally suited for modularized software architectures where signal groups are already available as adapters by default.



–

Conclusion

`AUI_AX_SEL_AUI` significantly simplifies signal routing in 4diac applications. It combines the proven selection logic of IEC 61131-3 with the structural advantages of event-driven adapters in IEC 61499.

AULI_AX_SEL_AULI

• — ○ • — ○ • — ○ •

Introduction

The function block `AULI_AX_SEL_AULI` serves as a binary selector (multiplexer) in the 4diac framework. Based on a control signal from a selector adapter (`G`), it allows selection between two input signals from adapter inputs (`IN0` and `IN1`) and forwarding the selected signal to an output adapter (`OUT`).

The unique feature of this function block lies in the consistent use of unidirectional adapters for encapsulating events and data, resulting in a clean and modular structure within the higher-level application network.

Interface Structure

Since this function block is entirely adapter-based, it has no direct, traditional event or data channels on its outer boundary. All communication is encapsulated within the adapters.

Event Inputs

No direct event inputs are available. Event control is implicit via the input adapters.

Event Outputs

No direct event outputs are available. Event output is implicit via the output adapter.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

Sockets (Input Adapters)

- **G** (Type: `adapter::types::unidirectional::AX`):

The selector channel. The signal present here controls which of the two inputs is routed to the output.

* **IN0 (Type: `adapter::types::unidirectional::AULI`)**

The first selectable input channel. This value is passed to the output when the selector `G` is in the state `FALSE` (0).

- **IN1** (Type: `adapter::types::unidirectional::AULI`):

The second selectable input channel. This value is passed to the output when the selector `G` is in the state `TRUE` (1).

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AULI`):

The selected output channel, which carries the signal from the selected input (`IN0` or `IN1`).

Functionality

Internally, the module is based on a network of standard function blocks from IEC 61131 and IEC 61499:

1. **Event Acquisition:** As soon as an event arrives at one of the inputs (`IN0.E1`, `IN1.E1`) or at the selector (`G.E1`), it is intercepted via edge-triggered event flip-flops (`E_D_FF` and `E_D_FF_ANY`, respectively), and the current data value (`D1`) is temporarily stored.
2. **Data Conversion & Transport:** The input data values are transferred to the central selection block via conversion blocks (`F_MOVE` with the data type `ULINT`).
3. **Selection Logic (Multiplexing):** The block `F_SEL` (Standard Selection) evaluates the state of the selector:

- If the value of `G` is equal to `FALSE`, the value of `IN0` is selected.
- If the value of `G` is equal to `TRUE`, the value of `IN1` is selected.

1. **Output:** After successful selection, the result is sent via a further conversion block (`F_MOVE_OUT`) to the output flip-flop (`E_D_FF_ANY_OUT`). This triggers the output event `OUT.E1` and assigns the selected value to `OUT.D1`.

Technical Features

- **Data Type Specificity:** Internally, the selection operates on the data type `ULINT` (Unsigned Long Integer / 64-bit). This makes the function block particularly suitable for processing high-resolution counter values, timestamps, or large ID numbers.
- **Adapter Encapsulation:** By using adapters (`AULI` and `AX`), signal and event lines are bundled. This prevents "spaghetti code" in the system design.
- **Event-Driven:** The function block operates purely event-driven. No cyclic calculations are performed, which conserves resources.

State Overview

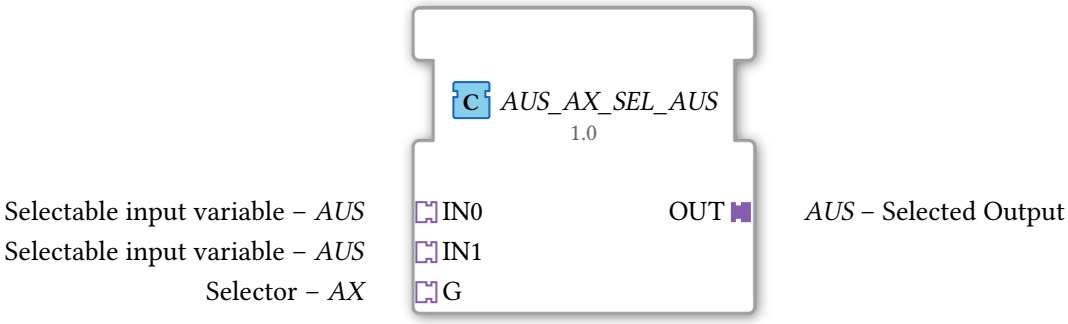
The function block does not have its own explicit state chain (Execution Control Chart, ECC) because it is implemented as a pure network (FBNetwork). Its behavior is purely data- and event-flow-driven:

Trigger Event	State Selector (`G.D1`)	Resulting Behavior	Output Event
Event on `G.E1`, `IN0.E1`, or `IN1.E1`	`FALSE`	Value of `IN0.D1` is copied to `OUT.D1`	`OUT.E1`
Event on `G.E1`, `IN0.E1`, or `IN1.E1`	`TRUE`	Value of `IN1.D1` is copied to `OUT.D1`	`OUT.E1`

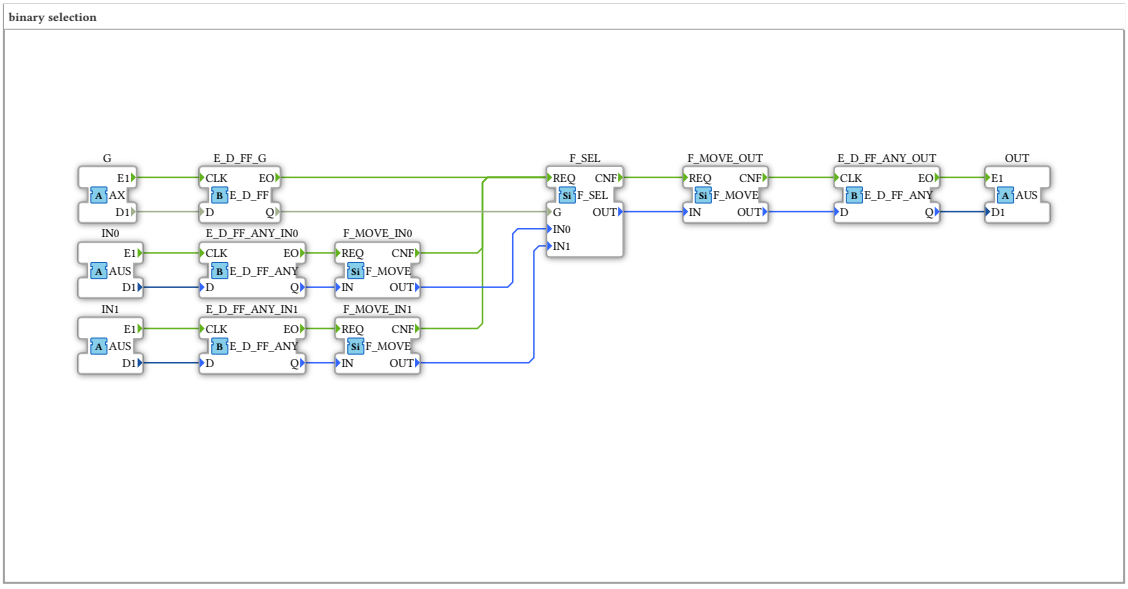
Application Scenarios

- **Sensor Redundancy:** Switching between a primary sensor (`IN0`) and a backup sensor (`IN1`) based on a status signal (`G`).
- **Setpoint Switching:** Switching between an automatic setpoint (e.g., from a recipe control system) and a manually set user-defined setpoint.
- **Operating Mode Switching:** Routing of different data streams depending on the active system status (e.g., normal operation vs. maintenance mode).

2.7 · Comparison with Similar Components



Compared to the classic standard selector block `F_SEL`, `AULI_AX_SEL_AULI` offers the following advantages:



- **No manual wiring of events:** With `F_SEL`, data and event lines must be manually synchronized. Here, this happens automatically within the block through the use of adapters.
- **Increased type safety & clarity:** Connection errors in the higher-level control diagram are minimized because adapters can only be connected to matching counterparts.

Conclusion

The `AULI_AX_SEL_AULI` is a robust, reusable, and event-driven selector block for 64-bit integer values. It is ideally suited for modern, component-based software architectures in IEC 61499, where clarity and standardized interfaces are paramount.

OFF_AX_SEL_OFF

(No image available)

• – ○ • – ○ • – ○ •

The function block **OFF_AX_SEL_OFF** is a binary selector (multiplexer) for IEC 61499 systems. It is used to select between two input adapters (`IN0` and `IN1`) based on the state of a selection signal (selector `G`) and to forward the selected value to the output adapter (`OUT`).

The block uses unidirectional adapter structures, which enables clean encapsulation of data and event streams and simplifies visual routing within the development environment.

Since this function block is implemented as a composite network and is entirely adapter-based, it has no direct, traditional event or data channels at its main level. All communication is bundled within the adapters.

No direct event inputs are available (events are received via the adapter interfaces).
No direct event outputs are available (events are sent via the adapter interfaces).
No direct data inputs are available.
No direct data outputs are available.

Interface Structure

Introduction

Adapters

Sockets (Input Adapters)

- **G** (Type: `adapter::types::unidirectional::AX`):
- **Description:** Selector signal.
- **Content:** Contains the selection event `E1` and the associated data signal `D1` (usually interpreted as Boolean), which determines which input is enabled.
- **IN0** (Type: `adapter::types::unidirectional::AUS`):
- **Description:** First selectable input. Passed to the output when the selector `G` is in the state `FALSE` (or `0`).
- **Content:** Event `E1` and data signal `D1` (Data Type: `USINT`).
- **Content:** Event `E1` and data signal `D1` (Data Type: `USINT`). * **IN1** (Type: `adapter::types::unidirectional::AUS`):
- **Description:** Second selectable input. It is routed to the output when selector `G` is in state `TRUE` (or `1`).
- **Content:** Event `E1` and data signal `D1` (Data Type: `USINT`).

Plugs (Output Adapters)

- **OUT** (Type: `adapter::types::unidirectional::AUS`):
- **Description:** The selected output. Receives the data and events of the currently enabled input.
- **Content:** Event `E1` and data signal `D1` (Data type: `USINT`).

Functionality

The module encapsulates an internal network that extracts and processes the adapter signals and routes them via standardized IEC 61131-3 and IEC 61499 modules:

1. **Data Acquisition:** As soon as an event (`G`, `IN0`, or `IN1`) arrives at one of the input adapters (`G`, `IN0`, or `IN1`), the corresponding data value (`D1`) is temporarily stored using flip-flops (`E_D_FF` or `E_D_FF_ANY`).
2. **Value Transfer:** The values of inputs `IN0` and `IN1` are transferred to the central selection block via copy operations (`F_MOVE` with the data type `USINT`).
3. **Selection:** The internal block `F_SEL` (standard IEC 61131-3 selector) decides based on the state of `G.D1`:

- If `G.D1` = `0` (or `FALSE`), the value of `IN0` is set to the output.
- If `G.D1` = `1` (or `TRUE`), the value of `IN1` is set to the output.

1. **Output:** The result is passed via another flip-flop (`E_D_FF_ANY_OUT`) to the output adapter `OUT`, triggering the event `OUT.E1` simultaneously with the provision of the data on `OUT.D1`.

- **Event-driven:** The output is updated immediately with every change to the inputs or the selector and assigned a new event.
- **Data Type Specific:** Internally, the processing of the data channels is designed for the type `USINT` (defined by the attributes of the internal `F_MOVE` instances).
- **Adapter Encapsulation:** Facilitates the clean design of application diagrams, as complex data and event pairs are represented as a single connection (bus).

Since this is a composite function block without its own Execution Control Chart (ECC), its behavior is determined purely by the signal flow:

State Selector (`G.D1`)	Trigger Event	Output Activity (`OUT`)
`0` / `FALSE`	Any (`G.E1`, `IN0.E1`, `IN1.E1`)	Returns the value of `IN0.D1`; triggers `OUT.E1`.
`1` / `TRUE`	Any (`G.E1`, `IN0.E1`, `IN1.E1`)	Returns the value of `IN1.D1`; Triggers `OUT.E1`.

- **Setpoint Switching:** Dynamic switching of a target variable (e.g., a speed or stage of type `USINT`) between automatic operation (`IN1`) and manual operation (`IN0`).
- **Recipe Selection:** Selection between two predefined operating modes or parameter sets in a machine via a higher-level controller.
- **Fault Protection:** Rapid switching to a substitute value (`IN0`) if a main signal path is faulty.

2.8 · Comparison with Similar Modules

Compared to the standard selection module `F_SEL` from the IEC 61131-3 library, `AUS_AX_SEL_AUS` offers the decisive advantage of being able to work directly with manufacturer-specific or standardized unidirectional adapters (`AUS` and `AX`). While event and data lines in IEC 61499 have to be laboriously wired individually for `F_SEL`, this is done fully automatically within the module.

Compared to the standard selection module `F_SEL` from the IEC 61131-3 library, `AUS_AX_SEL_AUS` offers the crucial advantage of being able to work directly with manufacturer-specific or standardized unidirectional adapters (`AUS` and `AX`). While event and data lines in `F_SEL` have to be laboriously wired individually according to IEC 61499, this is done fully automatically within the module itself. ## Conclusion

The **AUS_AX_SEL_AUS** function block represents an important bridge for modern, adapter-based IEC 61499 architectures. It combines the proven selection logic of IEC 61131-3 with the advantages of event-driven adapter coupling, thus significantly contributing to the clarity and maintainability of control software.

Comparison with Similar Function Blocks

Conclusion

AW_AX_SEL_AW

(No image available)

• – ○ • – ○ • – ○ •

Introduction

The function block `AW_AX_SEL_AW` is used for binary selection between two analog or word-based input signals via a binary selector. The block is specifically designed for use with adapter-based interfaces in 4diac-ide (IEC 61499). It encapsulates the classic selection logic (`SEL`) and makes it available via unidirectional adapters for `WORD` data (`AW`) and binary control signals (`AX`).

Interface Structure

Event Inputs

There are no direct event inputs at the block level. Event processing is fully encapsulated via the adapter interfaces.

Event Outputs

There are no direct event outputs at the block level. Event output is fully encapsulated via the adapter interfaces.

Data Inputs

There are no direct data inputs at the block level.

Data Outputs

There are no direct data outputs at the block level.

Sockets (Input Interfaces)

- **G** (Type: `adapter::types::unidirectional::AX`):
- Selection input (selector). Determines which of the two inputs is passed through to the output.
- **IN0** (Type: `adapter::types::unidirectional::AW`):
- First selectable input channel (selected when `G` is in state `FALSE` or `0`).
- **IN1** (Type: `adapter::types::unidirectional::AW`):
- Second selectable input channel (selected when `G` is in state `TRUE` or `1`).

Plugs (Output Interfaces)

- **OUT** (Type: `adapter::types::unidirectional::AW`):
- Selected output channel carrying the value of the selected input.

Functionality

The module is internally based on a network of standard function blocks to implement event-driven selection:

1. **Signal Buffering:** Events (`E1`) and data (`D1`) received via the adapters `IN0`, `IN1`, and `G` are buffered using D flip-flops (`E_D_FF` and `E_D_FF_ANY`, respectively). This ensures that the data is consistently available as soon as an event occurs.
2. **Data Forwarding:** The data from the WORD adapters is passed to the central selection block via `F_MOVE` blocks (configured to the data type `WORD`).
3. **Selection Logic (F_SEL):** The block `F_SEL` (standard selection function) evaluates the state of the selector `G`:

- If `G.Q` = `FALSE`, the value of `IN0` is passed to the output.
- If `G.Q` = `TRUE`, the value of `IN1` is passed to the output.

1. **Output Triggering:** Any change to the inputs or the selector triggers the process via the event connections. The selected value is passed from the output buffer `E_D_FF_ANY_OUT` to the output plug `OUT`, and the corresponding output event `OUT.E1` is triggered.

Technical Features

- **Adapter Encapsulation:** By exclusively using adapters, the cabling effort in the higher-level system is drastically reduced, as data and event lines are bundled in a single adapter channel.
- **Unidirectional Data Transmission:** The adapter types used, `AW` (Word Adapter) and `AX` (Bit/Boolean Adapter), are unidirectional, defining a clear signal flow direction.
- **Data Type:** The internal processing of analog values is fixed to the data type `WORD`.

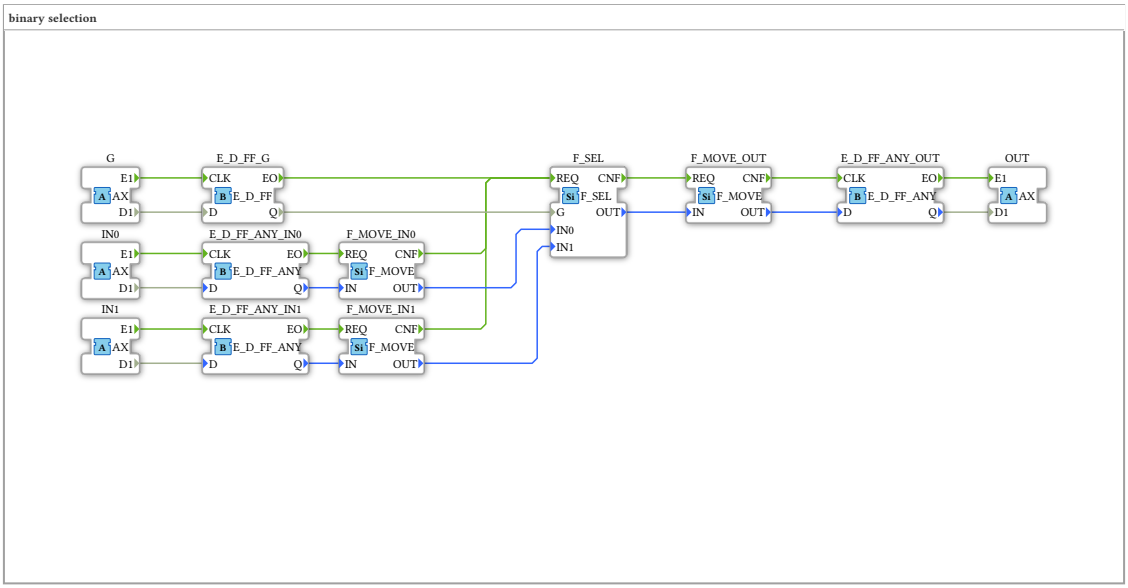
State Overview

Since this is a composite function block (FB) without its own state machine (ECC), its behavior is directly determined by the data and event flow of the internal components:

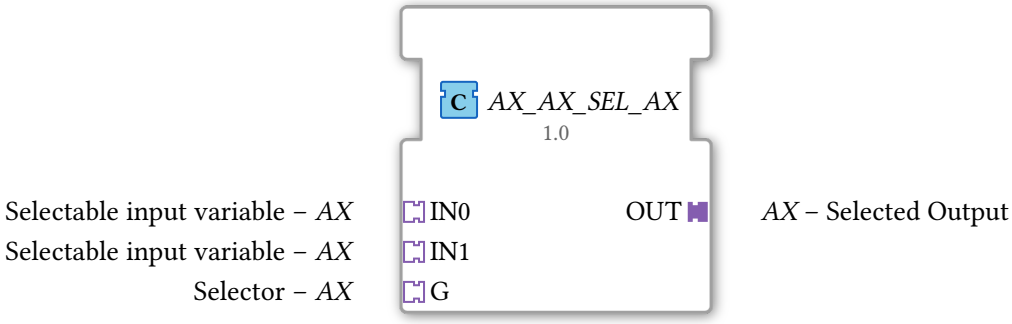
- **Event on G.E1:** The selector value is updated. The selection logic switches accordingly and updates the output `OUT`.
- **Event on IN0.E1 / IN1.E1:** The input data is updated. If the changed input corresponds to the channel currently selected via `G`, the new value is immediately forwarded to `OUT`, triggering the event `OUT.E1`.

Application Scenarios

- **Setpoint Switching:** Optionally specify a setpoint (e.g., speed, pressure, temperature coded as `WORD`) from an automatic program (`IN1`) or manual operation (`IN0`).
- **Signal Routing:** Dynamic routing of data streams within modular control architectures.
- **Redundant Sensors:** Switching between a primary sensor and a backup sensor in case of signal errors.



Comparison with Similar Function Blocks



- **Standard `F_SEL` (IEC 61131-3):** The standard selection function block works with direct elementary data types (e.g., WORD, BOOL) and does not have integrated event control for IEC 61499. `AW_AX_SEL_AW` extends this functionality with event coupling and packages it in standardized adapters.
- **Multiplexer (MUX):** A multiplexer allows selection from more than two channels using an integer index (INT). `AW_AX_SEL_AW`, on the other hand, is optimized for fast, binary selection (2 channels via BOOL/AX).

Conclusion

The `AW_AX_SEL_AW` is a robust and reusable auxiliary module for structured programming in IEC 61499. It is ideally suited for applications that rely on a clean interface architecture using adapters and simplifies signal switching in industrial environments.

AX_AX_SEL_AX

• – ○ • – ○ • – ○ •

Introduction

The function block `AX_AX_SEL_AX` is used for binary selection between two Boolean signals transmitted via standardized adapters. It represents an IEC 61499-compliant encapsulation of the classic IEC 61131-3 `SEL` function. By using adapters, both the data values and the associated events are transmitted together, which significantly reduces the wiring effort in control application design.

Interface Structure

Event Inputs

This function block does not have direct event inputs. Event control is handled entirely via the adapters.

Event Outputs

This function block has no direct event outputs. Event output is handled entirely via the adapters.

Data Inputs

This function block has no direct data inputs.

Data Outputs

This function block has no direct data outputs.

Adapters

Sockets (Input Interfaces)

- **IN0** (Type: `adapter::types::unidirectional::AX`):

Selectable input adapter 0. The value applied here is passed to the output when the selection signal G is in the state FALSE.

- **IN1** (Type: adapter::types::unidirectional::AX):

Selectable input adapter 1. The value applied here is passed to the output when the selection signal G is in the state TRUE.

- **G** (Type: adapter::types::unidirectional::AX):

Selector adapter. Determines which of the two inputs (IN0 or IN1) is connected to the output.

Plugs (Output Interfaces)

- **OUT** (Type: adapter::types::unidirectional::AX):

Output adapter that outputs the selected signal (D1) and the corresponding confirmation event (E1).

Functionality

Internally, the AX_AX_SEL_AX is based on an event-driven network that processes the input signals from the sockets and outputs them via the plug:

1. **Event Detection:** Every arrival of an event (E1) at the adapters IN0, IN1, or G triggers an internal edge-triggered flip-flop (E_D_FF or E_D_FF_ANY, respectively).
2. **Data Buffering & Transport:** The data values (D1) from the adapters are forwarded to the central selection block F_SEL via conversion blocks of type F_MOVE (configured to data type BOOL).
3. **Selection Logic:**

- If the signal at adapter G equals FALSE, the internal block F_SEL switches the value of IN0 to the output.
- – … * If the signal at adapter G equals TRUE, the value of IN1 is set to the output.

1. **Output:** The selected value is passed to the flip-flop of the output adapter, which triggers the event OUT.E1 and updates the data point OUT.D1.

Technical Features

- **Typing to BOOL:** The internal data copiers (F_MOVE) are hard-coded to the data type BOOL. Therefore, this specific function block is optimized for selecting Boolean states.
- **Event Synchronization:** The internal use of E_D_FF and E_D_FF_ANY ensures that data changes at the inputs are immediately and consistently transferred to the output without any cycle delay.

State Overview

Since this is a composite function block (FB), its behavior is directly determined by the data and event flow:

State Selector G.D1	Output OUT.D1	Behavior on Event at Inputs
FALSE	Value of IN0.D1	Events at IN0.E1 or G.E1 trigger an update of OUT.E1.
TRUE	Value of IN1.D1	Events at IN1.E1 or G.E1 trigger an update of OUT.E1.

–

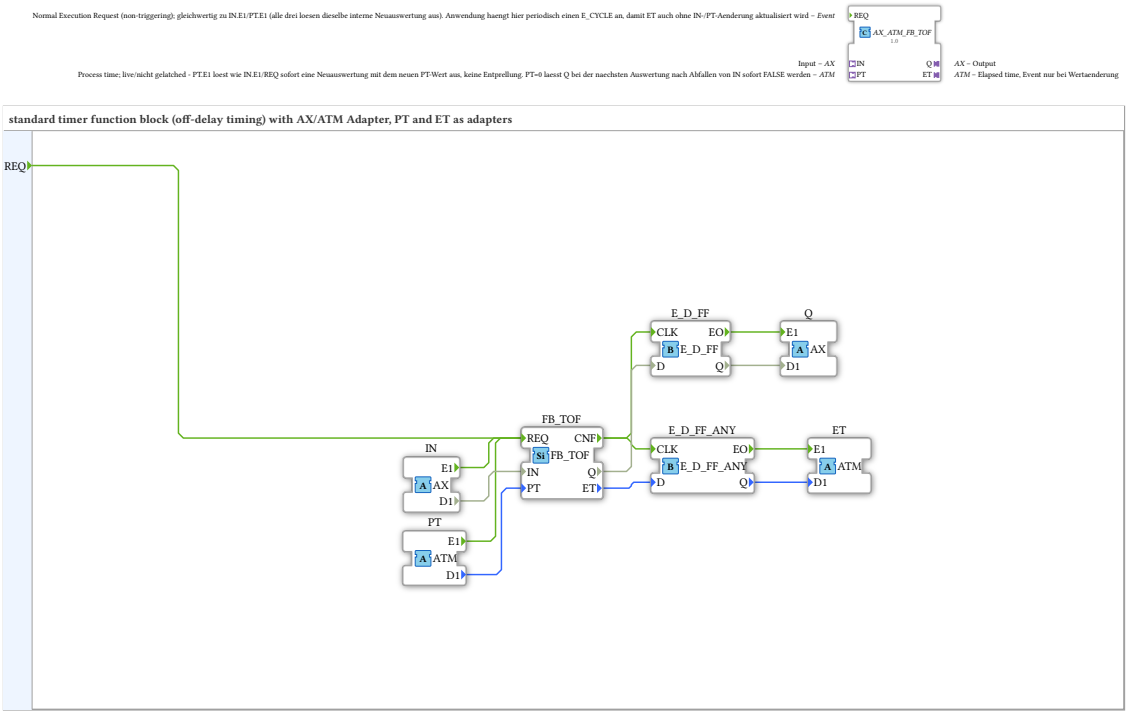
Application Scenarios

- **Operating Mode Switching:** Switching between an automatic and a manual command (e.g., opening/closing a valve).
- **Signal Redundancy:** Selection between a primary control signal and a backup signal in case of a failure.

Signal Redundancy: Selection between a primary control signal and a backup signal in case of a failure. *
Compact Application Development: Reduce “spaghetti code” and unwieldy line connections in 4diac-ide by utilizing adapter technology.

Comparison with Similar Components

- **Standard `F_SEL`:** The classic `F_SEL` component requires separate event connections (`REQ` / `CNF`) and data lines for each channel. `AX_AX_SEL_AX` simplifies this by encapsulating it in three input adapters and one output adapter.
- **Multiplexer (MUX):** While a multiplexer can switch between a large number of channels, the `AX_AX_SEL_AX`, as a binary selector, is specialized for exactly two channels, making it more resource-efficient and easier to configure.



Conclusion

The `AX_AX_SEL_AX` is a practical tool for structured application development in IEC 61499. It combines the proven selection logic of IEC 61131 with the modern advantages of adapter-based signal transmission in the 4diac-ide.

Numeric Index (iec61131-3)

Here you will find all exercises from the `iec61131-3` workspace, listed in ascending order. …

AX_ATM_FB_TOF

• — ○ • — ○ • — ○ •

Introduction

`AX_ATM_FB_TOF` is the adapter-based variant of AX_FB_TOF: the same IEC 61131-3 off-delay timer (`iec61131::timers::FB_TOF`), but with `PT` (preset time) as a socket and `ET` (elapsed time) as a plug — both of type ATM — instead of plain `TIME` data variables. Like AX_ATM_FB_TON, this lets the block be wired directly into adapter-based chains without drawing separate data connections for `PT`/`ET` at every call site.

Interface Structure

Event Inputs

- **REQ** (event, non-triggering): normal execution request. The application typically attaches an `E_CYCLE` here so `ET` keeps updating while the timer is running.

Event Outputs

None of its own; events flow exclusively through the `Q` and `ET` adapter plugs.

Data Inputs

None of its own. All data is carried through the adapter sockets.

Data Outputs

None of its own. All data is carried through the adapter plugs.

Adapters

Direction	Name	Type	Description
Socket (input)	IN	adapter::types::unidirectional::AX	Start signal
Socket (input)	PT	adapter::types::unidirectional::ATM	Preset time
Plug (output)	Q	adapter::types::unidirectional::AX	Output, stays TRUE for PT after IN falls
Plug (output)	ET	adapter::types::unidirectional::ATM	Elapsed time, event only on value change

Functionality

Internally the same standard FB_TOF block used by AX_FB_TOF is wired up, with two added E_D_FF/E_D_FF_ANY buffers:

1. IN.E1, the block's own REQ event, and PT.E1 all trigger FB_TOF.REQ together.
2. FB_TOF.Q runs through an E_D_FF (change detection) onto Q.D1/Q.E1.
3. FB_TOF.ET runs through an E_D_FF_ANY (generic change detection) onto ET.D1/ET.E1 — only on an actual value change, not on every REQ cycle.

Unlike the on-delay timer, IN = TRUE sets output Q to TRUE immediately; only once IN falls back to FALSE does the PT countdown run before Q drops back to FALSE.

Technical Details

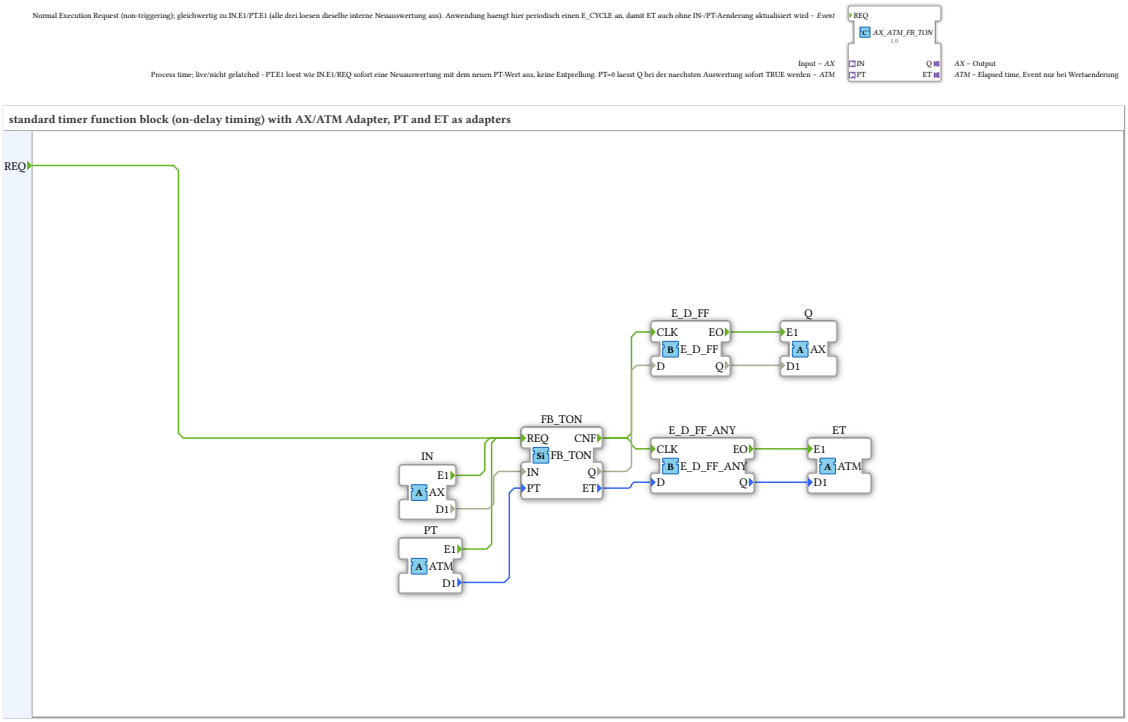
- **REQ deliberately stays a plain event, not an adapter connection**, as in AX_ATM_FB_TON — the application controls ET's update rate itself via an externally attached E_CYCLE.
- **ET events only fire on a value change**, the same principle used by ASSEMBLE_AB_FROM_AX.
- **PT is live, not latched — IN.E1, PT.E1, and REQ are equivalent triggers for FB_TOF**, exactly as in AX_ATM_FB_TON. PT.D1 sits as a plain data connection permanently wired to FB_TOF.PT, no buffering/debouncing in the adapter:
  - **PT = 0**: once IN has fallen to FALSE, Q becomes FALSE immediately at the next evaluation (no visible run-on).
  - **PT is decreased during run-on**, such that the already-elapsed ET exceeds the new preset time: Q becomes FALSE immediately.
  - **PT is increased during run-on**: Q correspondingly stays TRUE longer.
  - **Rapid consecutive PT.E1 events** each trigger their own evaluation, no coalescing.
  - **Before the very first PT.E1**, FB_TOF.PT reads TIME's default value T#0s.
- **Identical behavior in AX_ATM_FB_TON and AX_ATM_FB_TP** — all three are structurally wired identically, only the internally wrapped standard block differs.

State Overview

1. **Idle**: IN is FALSE, Q is FALSE, ET is 0.
2. **IN becomes TRUE**: Q becomes TRUE immediately, ET stays 0.
3. **IN falls to FALSE**: the timer starts, ET climbs up to PT, Q stays TRUE.
4. **Elapsed**: ET has reached PT, Q becomes FALSE.

Application Scenarios

- Run-on/coast-down times where an output needs to stay active for a defined period after an input switches off, with visible remaining time via ET.
- Anywhere AX_FB_TOF is already used but PT/ET should flow through adapter-based chains.



⚖️ Comparison with Similar Blocks

- AX_FB_TOF: identical timing behavior, but PT/ET as plain TIME data variables rather than adapters.
- AX_TOF: the events variant with no ET output.
- AX_ATM_FB_TON / AX_ATM_FB_TP: the same adapter extension for on-delay and pulse timing instead of off-delay.

Conclusion

AX_ATM_FB_TOF carries AX_FB_TOF's proven timing behavior into a fully adapter-based interface, with change detection on the ET output to avoid unnecessary events.

AX_ATM_FB_TON

• — ○ • — ○ • — ○ •

Introduction

AX_ATM_FB_TON is the adapter-based variant of AX_FB_TON: the same IEC 61131-3 on-delay timer (iec61131::timers::FB_TON), but with PT (preset time) as a socket and ET (elapsed time) as a plug — both of type ATM — instead of plain TIME data variables. This lets the block be wired directly into adapter-based chains (e.g. behind an AR_SUBSCRIBE_1 delivering a REAL seconds value written via OPC-UA, converted to TIME) without drawing separate data connections for PT/ET at every call site.

Interface Structure

Event Inputs

- **REQ** (event, non-triggering): normal execution request. The application typically attaches an E_CYCLE here so ET keeps updating while the timer is running — without an external E_CYCLE, ET would stay frozen between IN/PT events.

Event Outputs

None of its own; events flow exclusively through the Q and ET adapter plugs.

Data Inputs

None of its own. All data is carried through the adapter sockets.

Data Outputs

None of its own. All data is carried through the adapter plugs.

Adapters

Direction	Name	Type	Description
Socket (input)	IN	adapter::types::unidirectional::AX	Start signal
Socket (input)	PT	adapter::types::unidirectional::ATM	Preset time
Plug (output)	Q	adapter::types::unidirectional::AX	Output, TRUE once IN has been present for PT
Plug (output)	ET	adapter::types::unidirectional::ATM	Elapsed time, event only on value change

Functionality

Internally the same standard FB_TON block used by AX_FB_TON is wired up, with two added E_D_FF/E_D_FF_ANY buffers:

1. IN.E1, the block's own REQ event, and PT.E1 all trigger FB_TON.REQ together — each of the three sources (input changes, preset time changes, or an external cyclic nudge) should recompute the current time base.
2. FB_TON.Q runs through an E_D_FF (change detection) onto Q.D1/Q.E1 — the Q plug only fires its event when the boolean output actually changes.
3. FB_TON.ET runs through an E_D_FF_ANY (generic change detection) onto ET.D1/ET.E1 — likewise only on an actual value change, not on every REQ cycle.

Technical Details

- **REQ deliberately stays a plain event, not an adapter connection.** This lets the application decide the update rate for ET itself (e.g. via E_CYCLE), instead of the block imposing a fixed refresh rate.
- **ET events only fire on a value change**, the same principle used by ASSEMBLE_AB_FROM_AX and AB_AX_SEL_AB — prevents event flooding on every E_CYCLE tick when the time value (depending on resolution) hasn't actually changed.
- **PT is live, not latched — IN.E1, PT.E1, and REQ are equivalent triggers for FB_TON.** PT.D1 sits as a plain data connection permanently wired to FB_TON.PT; the adapter does not buffer or debounce PT. FB_TON itself doesn't distinguish which of the three events (IN.E1, PT.E1, REQ) triggered the re-evaluation — it always evaluates the *current* PT against the *current* ET. A preset time changed at runtime is therefore not frozen at IN's rising edge; it takes effect immediately at the next evaluation:
  - **PT = 0**: Q becomes TRUE immediately at the next evaluation, since ET (≥ 0) has already reached/exceeded the preset time.
  - **PT is decreased while timing is in progress**, such that the already-elapsed ET now exceeds the new, smaller preset time: Q becomes TRUE immediately at the next evaluation, instead of waiting for the originally larger preset time.
  - **PT is increased while timing is in progress**: Q correspondingly stays FALSE longer.
  - **Rapid consecutive PT.E1 events are not coalesced** — each individual event triggers its own FB_TON.REQ evaluation; there is no debounce logic in the adapter.
  - **Before the very first PT.E1**, FB_TON.PT reads TIME's default value T#0s, not a project-specific default — equivalent to the PT = 0 case above if IN becomes TRUE before that.
- **Identical behavior in AX_ATM_FB_TOF and AX_ATM_FB_TP.** All three blocks are structurally wired identically (the same IN.E1/PT.E1/REQ → REQ pattern, the same E_D_FF/E_D_FF_ANY change-detection pattern for Q/ET) — only the internally wrapped standard block (FB_TON/FB_TOF/FB_TP) differs. The PT behavior described above applies equally to all three; see their respective pages for the timer-specific PT = 0 edge cases.
- **The adapter::events::unidirectional::timers family (AX_TON etc.) has no ET output at all.** If the remaining/elapsed time is needed (e.g. for a countdown in the Visu), this iec61131-3 family is required, not the simpler events family.

State Overview

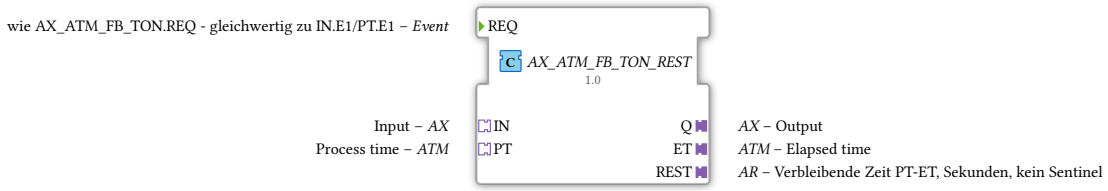
Like AX_FB_TON: no ECC of its own, a pure composite wiring pattern around the standard FB_TON.

1. **Idle**: IN is FALSE, Q is FALSE, ET is 0.
2. **Timing**: IN is TRUE, the timer runs, ET climbs up to PT, Q stays FALSE.
3. **Triggered**: ET has reached PT, Q becomes TRUE.

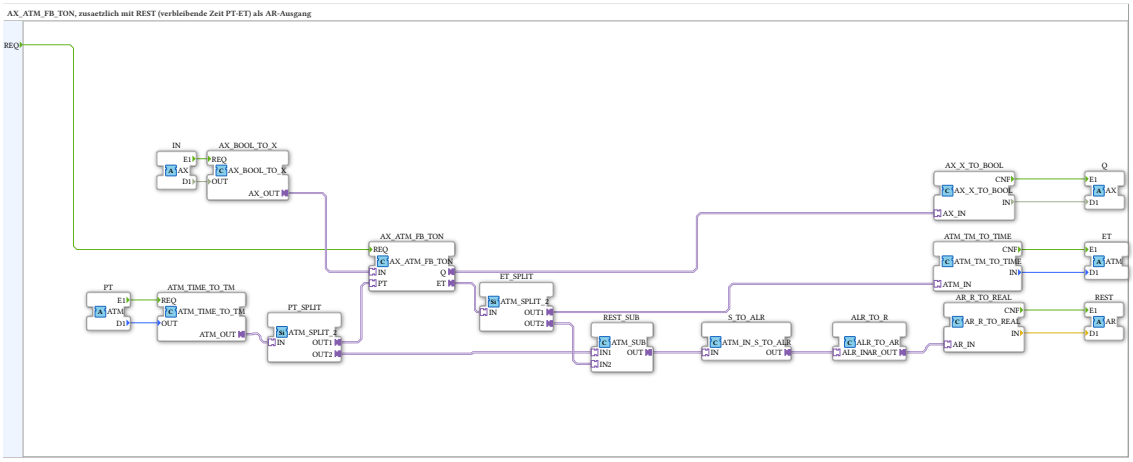
4. **Reset**: `IN` goes FALSE, `Q` becomes FALSE, `ET` becomes `0`.

Application Scenarios

- **Countdown display via OPC-UA**: feed `PT` from a subscribed REAL seconds value (e.g. `Override.Dauer`), forward `ET` (or `PT - ET` for the remaining time) to the Visu via a publish block.
- Anywhere `AX_FB_TON` is already used but `PT`/`ET` should flow through adapter-based chains instead of individual data connections.



⚖️ Comparison with Similar Blocks



- **AX_FB_TON**: identical timing behavior, but `PT`/`ET` as plain `TIME` data variables rather than adapters.
- **AX_TON**: the `events` variant with no `ET` output at all — suitable when only the timing result (`Q`) is needed, not the elapsed time.
- **AX_ATM_FB_TOF** / **AX_ATM_FB_TP**: the same adapter extension for off-delay and pulse timing instead of on-delay.

Conclusion

`AX_ATM_FB_TON` carries `AX_FB_TON`'s proven timing behavior into a fully adapter-based interface, so both the preset time and the elapsed time can flow through adapter-based networks without extra data connections — including change detection on the `ET` output to avoid unnecessary events.

AX_ATM_FB_TON_REST

• — ○ • — ○ • — ○ •

Introduction

`AX_ATM_FB_TON_REST` wraps AX_ATM_FB_TON with a third adapter plug, `REST`, carrying the remaining time (`PT - ET`) as a REAL seconds value. Several applications need not just "has the timer elapsed" (`Q`) or "how much time has passed" (`ET`), but "how much time is left" for a countdown display — computing that from `PT`/`ET` externally means repeating the same adapter chain (`ATM_SUB` → `ATM_IN_S_TO_ALR` → `ALR_TO_AR`) at every call site. This block does it once, internally, so the caller gets `REST` as a single ready-to-publish adapter plug.

Interface Structure

Event Inputs

- **REQ** (event, non-triggering): same role as on `AX_ATM_FB_TON` — the application typically attaches an `E_CYCLE` here so `ET`/`REST` keep updating while the timer is running.

Event Outputs

None of its own; events flow exclusively through the `Q`, `ET`, and `REST` adapter plugs.

Data Inputs

None of its own. All data is carried through the adapter sockets.

Data Outputs

None of its own. All data is carried through the adapter plugs.

Adapters

Direction	Name	Type	Description
Socket (input)	`IN`	`adapter::types::unidirectional::AX`	Start signal
Socket (input)	`PT`	`adapter::types::unidirectional::ATM`	Preset time
Plug (output)	`Q`	`adapter::types::unidirectional::AX`	Output, TRUE once `IN` has been present for `PT`
Plug (output)	`ET`	`adapter::types::unidirectional::ATM`	Elapsed time, event only on value change
Plug (output)	`REST`	`adapter::types::unidirectional::AR`	Remaining time `PT - ET` in seconds, no sentinel value

Functionality

Internally, a plain `AX_ATM_FB_TON` instance does the actual timing. Around it:

1. `PT` is split (`ATM_SPLIT_2`) so its value reaches both the wrapped timer's own `PT` and an `ATM_SUB` computing `PT - ET`.
2. The wrapped timer's `ET` is likewise split so it reaches both this block's own `ET` plug and the same `ATM_SUB` as the subtrahend.
3. `ATM_SUB.OUT` (an `ATM`, i.e. `TIME`) is converted to seconds via `ATM_IN_S_TO_ALR` → `ALR_TO_AR`, producing the `REST` value.
4. `Q` is passed straight through from the wrapped timer.

Why plain Socket/Plug forwarding doesn't work here, and what the block does instead: a Socket can only be *fed by* a Plug, and a Plug can only *feed* a Socket — a bare `<Connection Source="IN" Destination="InnerTimer.IN"/>` between this block's own `IN` Socket and the wrapped timer's `IN` Socket (both Sockets) is not a legal adapter connection, and the symmetric problem exists for `Q` (both Plugs). Because `AX_ATM_FB_TON_REST` is itself a `FBType` (not a `SubAppType`), reading a Socket's current value via `IN.D1`/`IN.E1` dot-access **is** legal here — the fix is therefore to bridge through the plain-variable pair at each boundary: AX_BOOL_TO_X reads `IN.D1`/`IN.E1` and re-emits it as a Plug feeding the wrapped timer's `IN` Socket; symmetrically, AX_X_TO_BOOL reads the wrapped timer's `Q` Plug and re-emits it onto this block's own `Q` Plug. The same pattern applies to `PT`/`ET` (`ATM_TIME_TO_TM`/`ATM_TM_TO_TIME`), each pair bridging one direction in and one direction out because the wrapped timer's socket and plug both need a bound value. `REST` only needs the outbound half of that pattern — it is computed purely internally and never fed from outside — so just AR_R_TO_REAL is used: it reads the internally computed `AR` (via its own `AR_IN` Socket, fed by `ALR_TO_R`'s Plug) and re-emits the plain `REAL` onto `REST`'s own Plug pins. The same Socket-can-only-be-fed-by-a-Plug rule this works around applies to any adapter type, not just `AX`/`ATM`/`AR`.

Technical Details

- **`REST` carries no sentinel convention (no "−1 = inactive").** A caller that needs one (e.g. "−1 while the timer isn't running") gates `REST` itself with an AR_AX_SEL_AR downstream, selecting between `REST` and a constant based on its own "active" condition — this block only ever reports the raw `PT - ET` difference.
- **`REST` updates on the same resolution as `ET`**, i.e. only on an actual value change (inherited from `AX_ATM_FB_TON`'s `E_D_FF_ANY` on `ET`), not on every `REQ`/`E_CYCLE` tick.
- **All of `AX_ATM_FB_TON`'s `PT` semantics apply unchanged** — `PT` is live, not latched; `PT = 0` makes `Q` (and thus a `REST` of 0) become true/reached at the very next evaluation. See AX_ATM_FB_TON for the full breakdown of these edge cases.

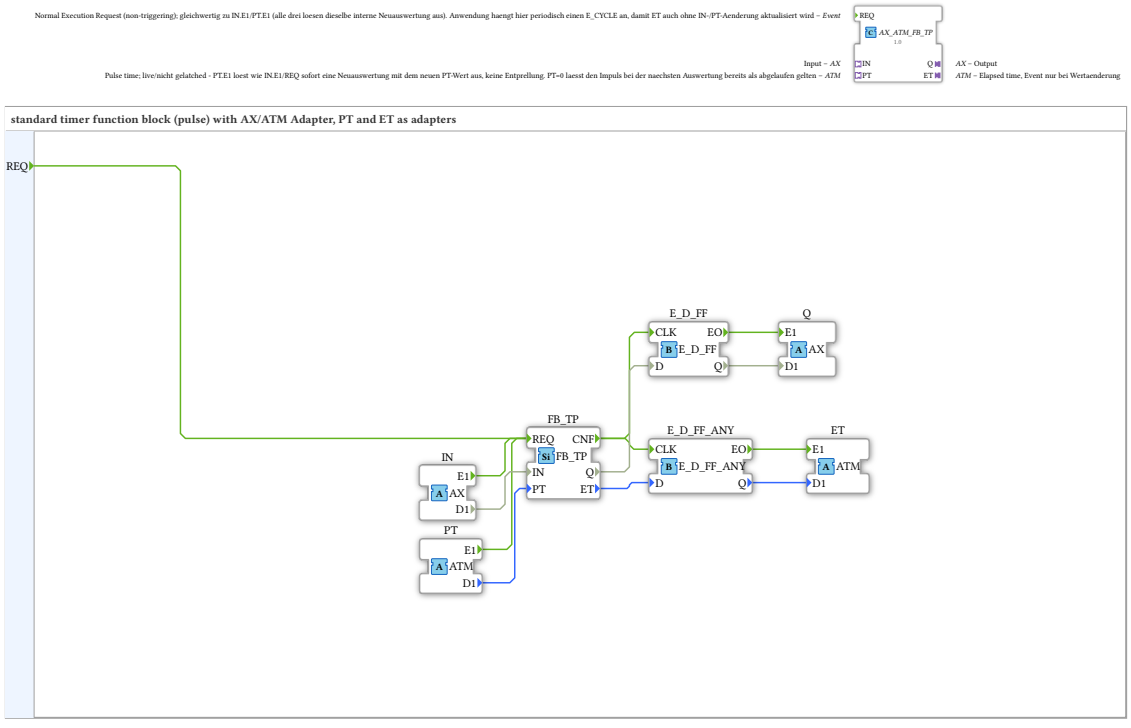
State Overview

Same four states as `AX_ATM_FB_TON`, with `REST` following `PT - ET` throughout:

1. **Idle**: `IN` is FALSE, `Q` is FALSE, `ET` is 0, `REST` equals `PT` converted to seconds.
2. **Triggered**: `ET` has reached `PT`, `REST` reaches 0, `Q` becomes TRUE.
3. **Reset**: `IN` goes FALSE, `Q` becomes FALSE, `ET` becomes 0, `REST` returns to `PT`.

Application Scenarios

- **Countdown display via OPC-UA**: feed `PT` from a subscribed REAL seconds value, publish `REST` directly to the Visu — no external `ATM_SUB/ATM_IN_S_TO_ALR/ALR_TO_AR` chain needed at the call site.
- Any place that today wires `AX_ATM_FB_TON` alongside its own copy of the `ATM_SUB/ATM_IN_S_TO_ALR/ALR_TO_AR` chain to get a remaining-time value — this block replaces all four blocks with one.



⚖️ Comparison with Similar Blocks

- AX_ATM_FB_TON: identical timing behavior and interface, minus the `REST` plug — use it when only `Q`/`ET` are needed.
- AR_AX_SEL_AR: not a replacement, but the companion block for adding a sentinel value (e.g. "−1 = inactive") on top of this block's raw `REST` output.

Conclusion

`AX_ATM_FB_TON_REST` folds the recurring "on-delay timer with a remaining-time readout" pattern — previously four separately-wired blocks per call site — into a single adapter-based block, trading a slightly more complex internal wiring (Socket/Plug bridging at every boundary) for a much simpler call site.

AX_ATM_FB_TP

• — ○ • — ○ • — ○ •

Introduction

`AX_ATM_FB_TP` is the adapter-based variant of AX_FB_TP: the same IEC 61131-3 pulse timer (`iec61131::timers::FB_TP`), but with `PT` (pulse time) as a socket and `ET` (elapsed time) as a plug — both of type ATM — instead of plain `TIME` data variables. Like AX_ATM_FB_TON, this lets the block be wired directly into adapter-based chains without drawing separate data connections for `PT`/`ET` at every call site.

Interface Structure

Event Inputs

- **REQ** (event, non-triggering): normal execution request. The application typically attaches an `E_CYCLE` here so `ET` keeps updating while the pulse is running.

Event Outputs

None of its own; events flow exclusively through the `Q` and `ET` adapter plugs.

Data Inputs

None of its own. All data is carried through the adapter sockets.

Data Outputs

None of its own. All data is carried through the adapter plugs.

Adapters

Direction	Name	Type	Description
Socket (input)	`IN`	`adapter::types::unidirectional::AX`	Start signal
Socket (input)	`PT`	`adapter::types::unidirectional::ATM`	Pulse time
Plug (output)	`Q`	`adapter::types::unidirectional::AX`	Output, TRUE for duration `PT` after a rising edge on `IN`
Plug (output)	`ET`	`adapter::types::unidirectional::ATM`	Elapsed time, event only on value change

Functionality

Internally the same standard `FB_TP` block used by `AX_FB_TP` is wired up, with two added `E_D_FF`/`E_D_FF_ANY` buffers:

1. `IN.E1`, the block's own `REQ` event, and `PT.E1` all trigger `FB_TP.REQ` together.
2. `FB_TP.Q` runs through an `E_D_FF` (change detection) onto `Q.D1`/`Q.E1`.
3. `FB_TP.ET` runs through an `E_D_FF_ANY` (generic change detection) onto `ET.D1`/`ET.E1` — only on an actual value change, not on every `REQ` cycle.

A rising edge on `IN` immediately sets `Q` to TRUE and starts the countdown; `Q` stays TRUE for the full duration `PT` regardless of whether `IN` falls back to FALSE in the meantime (a true pulse, not retriggerable).

Technical Details

- **`REQ` deliberately stays a plain event, not an adapter connection**, as in AX_ATM_FB_TON — the application controls `ET`'s update rate itself via an externally attached `E_CYCLE`.
- **`ET` events only fire on a value change**, the same principle used by ASSEMBLE_AB_FROM_AX.
- **`PT` is live, not latched — `IN.E1`, `PT.E1`, and `REQ` are equivalent triggers for `FB_TP`**, exactly as in AX_ATM_FB_TON. `PT.D1` sits as a plain data connection permanently wired to `FB_TP.PT`, no buffering/debouncing in the adapter:
  - **`PT = 0`**: the pulse is already considered elapsed at the next evaluation — from an observer's point of view, `Q` may have effectively no visible TRUE phase.
  - **`PT` is decreased while a pulse is running**, such that the already-elapsed `ET` exceeds the new preset time: `Q` becomes FALSE immediately.
  - **`PT` is increased while a pulse is running**: `Q` correspondingly stays TRUE longer.
  - **Rapid consecutive `PT.E1` events** each trigger their own evaluation, no coalescing.
  - **Before the very first `PT.E1`**, `FB_TP.PT` reads `TIME`'s default value `T#0s`.
- **Identical behavior in AX_ATM_FB_TON and AX_ATM_FB_TOF** — all three are structurally wired identically, only the internally wrapped standard block differs.

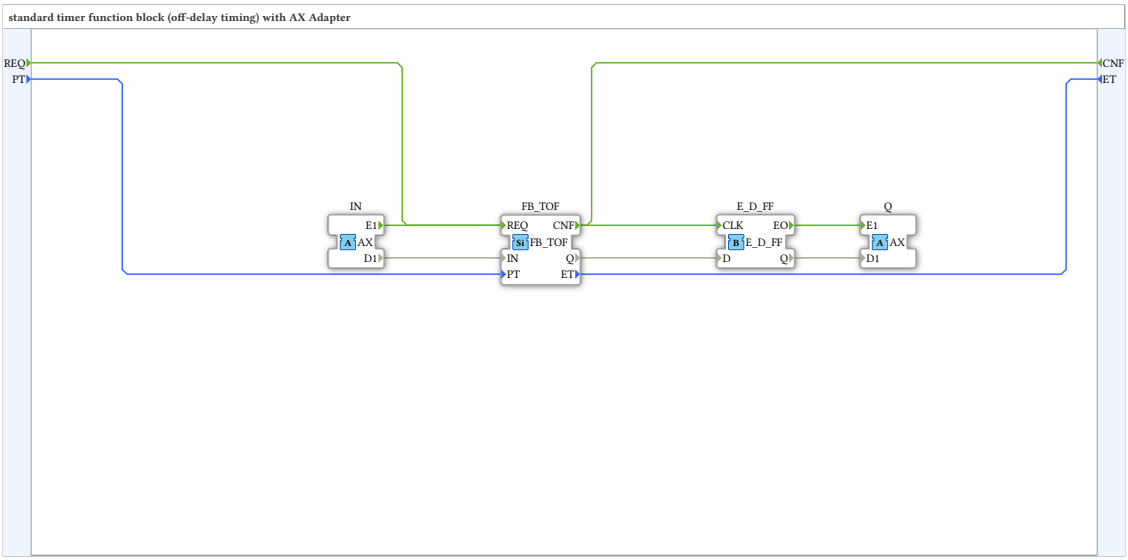
State Overview

1. **Idle**: `IN` is FALSE, `Q` is FALSE, `ET` is 0.
2. **Rising edge on `IN`**: `Q` becomes TRUE immediately, `ET` starts running.
3. **Pulse active**: `ET` climbs up to `PT`, `Q` stays TRUE — regardless of `IN`'s further behavior.

4. **Elapsed**: ET has reached PT, Q becomes FALSE.

Application Scenarios

- Fixed, non-retriggerable pulse lengths (e.g. a valve's minimum on-time) with visible time progress via ET.
- Anywhere AX_FB_TP is already used but PT/ET should flow through adapter-based chains.

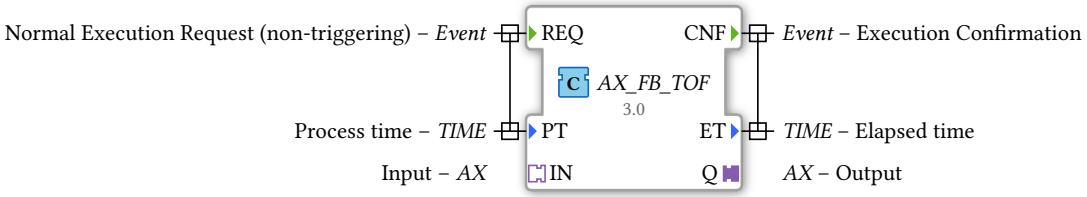


⚖️ Comparison with Similar Blocks

- **AX_FB_TP**: identical timing behavior, but PT/ET as plain TIME data variables rather than adapters.
- **AX_TP**: the events variant with no ET output.
- **AX_ATM_FB_TON** / **AX_ATM_FB_TOF**: the same adapter extension for on-delay and off-delay timing instead of a pulse.

Conclusion

AX_ATM_FB_TP carries AX_FB_TP's proven timing behavior into a fully adapter-based interface, with change detection on the ET output to avoid unnecessary events.



AX_FB_TOF

• – ○ • – ○ • – ○ •

Introduction

Important note: This function block only functions correctly if it is called cyclically. AX_FB_TOF is a standardized timer function block according to IEC 61131-3 that implements off-delay timing. The block maintains the output signal for a defined duration after the input signal is switched off.

Interface Structure

Event Inputs

- **REQ** (Event): Normal Execution Request (takes the value from PT); Calls the function block (must be called cyclically)

Event Outputs

- **CNF** (Event): Execution Confirmation (with `ET`)

Data Inputs

- **PT** (TIME): Process time - defines the duration of the turn-off delay

Data Outputs

- **ET** (TIME): Elapsed time

Adapters

- **IN** (Socket): Receives input events and data (Type: `adapter::types::unidirectional::AX`)
- **Q** (Plug): Sends output events and data (Type: `adapter::types::unidirectional::AX`)

Functionality

The AX_FB_TOF block functions as a turn-off delay timer:

1. When the input on the IN adapter becomes TRUE, the output on the Q adapter immediately switches to TRUE.
2. When the input at the IN adapter changes from TRUE to FALSE, the internal timer starts.
3. The output at the Q adapter remains TRUE while the timer is running and PT has not yet been reached.
4. After PT has elapsed, the output at the Q adapter changes to FALSE.
5. The data output ET displays the time elapsed since the input signal dropped.
6. If the input at the IN adapter becomes TRUE again while the timer is running, the timer is reset and Q remains TRUE.

Technical Features

- Implemented based on the IEC 61131-3 TOF standard
- Uses unidirectional adapters for integration into modern control concepts
- Provides an ET output for monitoring the remaining delay time
- Robust implementation for reliable overrun controllers

State Overview

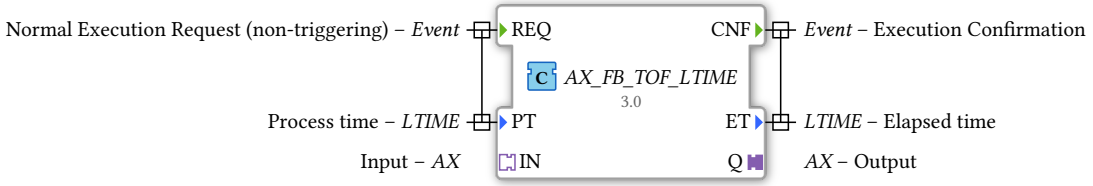
1. **Inactive**: IN is FALSE, Q is FALSE, ET is 0.
2. **Active**: IN is TRUE, Q is TRUE, ET is 0.
3. **Delay Phase**: IN changes to FALSE, timer is running, Q remains TRUE, ET increases.
4. **Expired**: ET reaches PT, Q changes to FALSE.

Application Scenarios

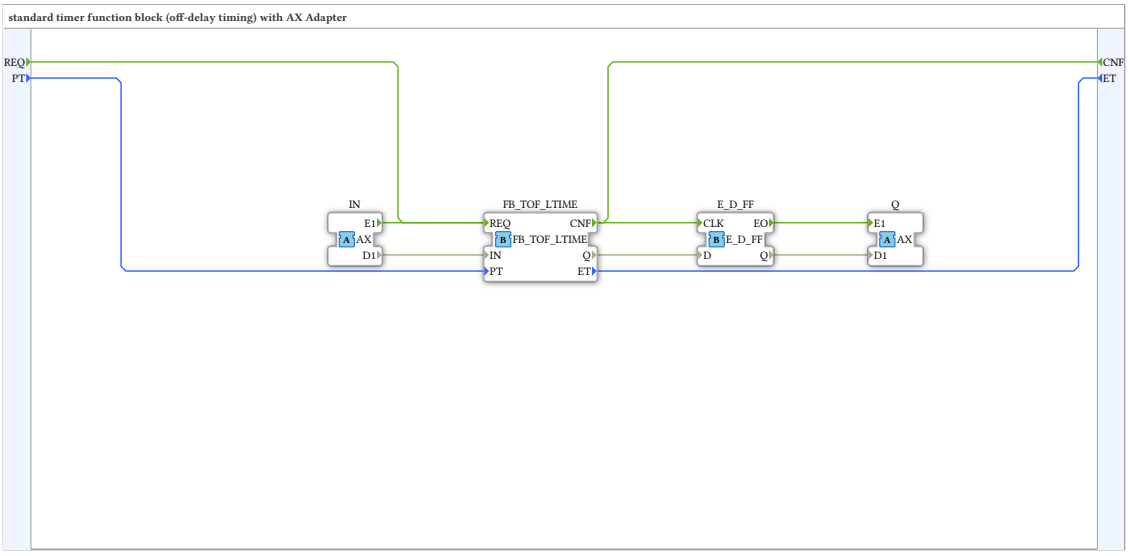
- Debouncing controls (e.g., fan control after a device is switched off)
- Debouncing of signals that might drop briefly
- Ensuring minimum runtimes after a stop command

⚖️ Comparison with similar function blocks

Compared to event-based timers such as AX_TOF, this function block follows classic PLC behavior according to IEC 61131-3 and additionally offers the ET status output.



🛠️ Related Exercises



- Exercise_020e2_AX

Conclusion

AX_FB_TOF is the ideal function block for all applications that require a precise switch-off delay with status feedback on the elapsed time.

AX_FB_TOF_LTIME

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_FB_TOF_LTIME** implements a standard timer for the off-delay according to IEC 61131-3. It is specifically designed for use with an AX adapter and uses an internal timer module and a D flip-flop to precisely represent the timing behavior. The time base uses the data type `LTIME`, resulting in high temporal resolution.

Interface Structure

Event Inputs

Event	Comment
`REQ`	Normal execution command (non-triggering) – starts or updates the timer calculation. The corresponding data input is `PT`.

Event Outputs

Event	Comment
`CNF`	Execution confirmation – signals the completion of a timer update. The corresponding data output is `ET`.

Data Inputs

Variable	Type	Comment
`PT`	`LTIME`	Process Time – The desired shutdown delay duration.

Data Outputs

Variable	Type	Comment

ET	LTIME	Elapsed Time – The time elapsed since the delay started.

Adapter

Direction	Adapter Type	Comment
Socket IN	adapter::types::unidirectional::AX	Input adapter – receives the binary control signal (e.g., via event E1 and data D1).
Plug Q	adapter::types::unidirectional::AX	Output adapter – forwards the time-delayed output signal (via event E1 and data D1).

Functionality

The module behaves like a classic time-of-flight (TOF) delay circuit:

- As long as the input IN (via the adapter) is **TRUE**, the output Q is also **TRUE**, and the elapsed time ET is set to zero.
- As soon as IN changes from **TRUE** to **FALSE**, the timing starts. The output Q remains **TRUE** for the duration of the specified time PT and only then falls to **FALSE**.
- As soon as IN changes from **TRUE** to **FALSE**, the timing measurement starts. The output Q remains **TRUE** for the duration of the specified time PT and only then falls to **FALSE**.
- As long as the input Q (via the adapter) is **TRUE**, the output PT remains **TRUE**. If IN becomes **TRUE** again before the delay time expires, the timer is reset and Q remains **TRUE**.

Event-driven processing occurs as follows:

1. The event REQ (either directly or from the adapter input IN.E1) triggers the internal timer FB_TOF_LTIME.
2. The timer calculates the elapsed time and outputs the event CNF upon completion.
3. This CNF clocks the D flip-flop E_D_FF, which stores the current timer output (Q of the timer) and passes it through to the output adapter Q.D1.
4. Simultaneously, the CNF event is forwarded to the output adapter Q.E1, so that the downstream adapter is informed of the change.

The variable ET is taken directly from the timer and displays the currently elapsed delay time at all times.

Technical Features

- **High time resolution** through the use of LTIME (Long Time) according to IEC 61131-3.
- **Adapter-based I/O** via the unidirectional AX adapter enables loose coupling between different resources (e.g., between the application and the I/O driver).
- **Standard compliance** according to IEC 61131-3 – the behavior corresponds exactly to that of a TOF timer.
- **Internal structure**: The component combines a pure timer (FB_TOF_LTIME) with an edge-triggered D flip-flop to implement the turn-off delay behavior.

State overview

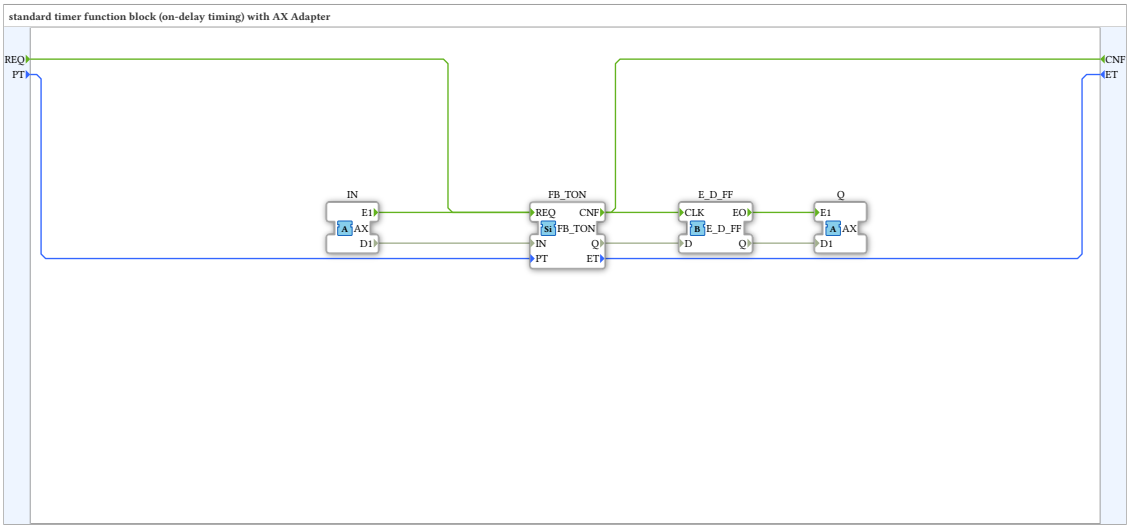
State	Input IN	Output Q	Elapsed time ET
Inactive / Ready	TRUE	TRUE	0 (Zero)
Delay in progress	FALSE ⟶ Return to TRUE possible	TRUE	0 ... PT
Delay expired	FALSE	FALSE	PT (constant)

A change from IN to **TRUE** resets the timer and immediately returns it to the "Inactive / Ready" state. A change to **FALSE** restarts the delay.

Application Scenarios

- **Run-on control** of fans, pumps, or conveyor belts after a signal is switched off.
- **Debouncing** of signals: a brief level change is filtered out by the delay.
- **Protection times** when switching inductive loads: the switch-off is delayed by a defined time.

- **Time-controlled logic** in production plants, where an output should remain active for a specific duration after the input event.

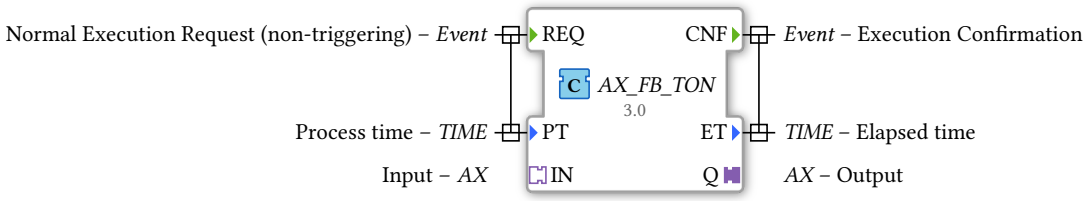


Comparison with similar function blocks

- **TON (Switch-on delay)**: The output only becomes active after a delay following the switch-on. – TOF delays the switch-off.
- **TP (Pulse)**: The output provides a pulse of a predefined length, independent of the duration of the input signal. – TOF only reacts to the falling edge.
- **RTRIG / FTRIG (Edge detection)**: Detect signal changes without a time component. – TOF combines edge detection with time control.

Conclusion

The `AX_FB_TOF_LTIME` is a powerful, standardized function block for time-critical switch-off delays in automation technology. The AX adapter allows for flexible integration into distributed systems, while the internal combination of timer and flip-flop ensures precise and reproducible timing. It is particularly suitable for applications requiring an accurate time base and a modular interface.



AX_FB_TON

• – ◦ • – ◦ • – ◦ •

Introduction

Important note: This function block only functions correctly if it is called cyclically. AX_FB_TON is a standardized timer function block according to IEC 61131-3 that implements on-delay timing and has adapter interfaces. After activation, the block waits a defined time before setting the output signal and provides the elapsed time.

Interface Structure

Event Inputs

- **REQ** (Event): Normal Execution Request (takes the value from PT); Calls the function block (must be called cyclically)

Event Outputs

- **CNF** (Event): Execution Confirmation; carries `ET`

Data Inputs

- **PT** (TIME): Process time - defines the delay duration

Data Outputs

- **ET** (TIME): Elapsed time

Adapters

- **IN** (Socket): Receives input events and data (Type: `adapter::types::unidirectional::AX`)
- **Q** (Plug): Sends output events and data (Type: `adapter::types::unidirectional::AX`)

Functionality

The AX_FB_TON block functions as a power-on delay timer. The internal timer starts when a signal is received via the IN adapter.

1. When the input on the IN adapter becomes TRUE, the timer starts running.
2. After the set process time (PT) has elapsed, the output on the Q adapter becomes TRUE.
3. The data output ET indicates the time elapsed since the timer started until PT is reached.
4. If the input on the IN adapter becomes FALSE, the timer is reset, and the output on the Q adapter also becomes FALSE.

Technical Features

- Implemented based on the IEC 61131-3 TON standard
- Uses unidirectional adapters for integration into adapter-based architectures
- Provides an ET output for monitoring the time progression
- Compatible with IEC 61131-3 and IEC 61499

State Overview

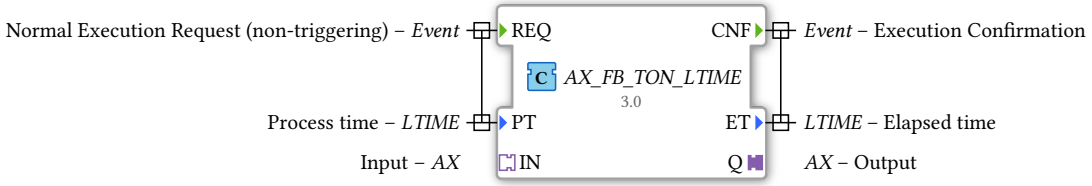
1. **Idle State**: IN is FALSE, timer inactive, Q is FALSE, ET is 0.
2. **Timing State**: IN is TRUE, timer running, ET is increasing, Q is FALSE.
3. **Triggered**: IN is TRUE, ET has reached PT, Q is TRUE.
4. **Reset**: IN becomes FALSE, timer stops, Q becomes FALSE, ET becomes 0.

Application Scenarios

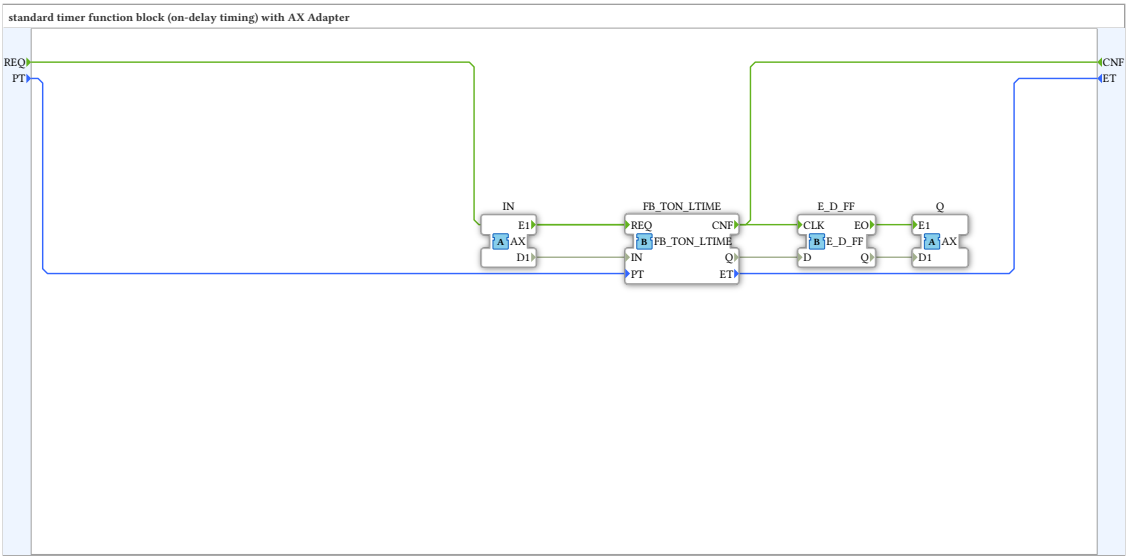
- Classic power-on delays in PLC programming
- Monitoring of process times with visualization of remaining runtime (via ET)
- Cascading of time sequences in adapter-based systems

⚖️ Comparison with similar function blocks

Compared to AX_TON, AX_FB_TON additionally offers the **ET** output for the elapsed time and strictly follows the behavior of the IEC 61131-3 TON block, while AX_TON is optimized more for the IEC 61499 E_TON.



🛠️ Related Exercises



- Exercise_020c3_AX

Conclusion

AX_FB_TON combines the proven behavior of the IEC 61131-3 TON timer with the flexibility of adapter interfaces, thus enabling precise time control with feedback of the current time status.

AX_FB_TON_LTIME

• – ○ • – ○ • – ○ •

Introduction

The **AX_FB_TON_LTIME** function block implements an on-delay timer according to IEC 61131-3 with the data type `LTIME` and an integrated **AX adapter** interface. It is particularly suitable for time-critical control tasks where both events and data must be exchanged via standardized adapters.

Interface Structure

Event Inputs

Name	Type	Description
REQ	`Event`	Normal execution trigger (not edge-triggered); The timer starts when the signal at data input `IN` or at adapter `IN.E1` is active.

Event Outputs

Name	Type	Description
CNF	`Event`	Confirmation of execution. Triggered as soon as the timer expires or the condition is met.

Data Inputs

Name	Type	Description
PT	`LTIME`	Preset time for the power-on delay.

Data Outputs

Name	Type	Description
ET	`LTIME`	Elapsed time since the start of the timer.

Adapter

Type	Direction	Description
`IN`	Socket (Input)	Unidirectional AX adapter for input data. Contains an event (`E1`) and a data value (`D1`). The event starts the timer; the data value determines the timer input (`IN`).

Q	Plug (Output)	Unidirectional AX adapter for output data. Outputs the result of the time check: 1 if the elapsed time has reached the target time, otherwise 0.

Functionality

The function block is implemented as a composite and internally contains the IEC 61131-3 timer **FB_TON_LTIME** and an edge-triggered D flip-flop (**E_D_FF**).

- **Start Conditions**: The timer starts as soon as an event arrives at the adapter IN.E1 or at the event input REQ. Simultaneously, the data value IN.D1 (or the internal timer input) must be set to TRUE.
- **Expiration**: The internal timer counts up the time. The output ET outputs the currently elapsed time.
- **End**: When the elapsed time ET reaches the target time PT, the timer output (Q) is set to TRUE. This triggers the event CNF and clocks the D flip-flop.
- **Output Adapter**: The D flip-flop stores the state and outputs it via the adapter Q.D1. The event Q.E1 signals the output change.

Technical Features

- **LTIME Data Type**: Enables very high time resolution (nanosecond range) and large time ranges.
- **Adapter Interface**: The component can be integrated into existing systems via standardized AX adapters without requiring direct event or data connections.
- **Edge-Triggered Output**: The internal D flip-flop updates the output state only on a rising edge of the timer termination – this prevents unwanted fluctuations.
- **Internal Network**: Functionality is achieved through the combination of standard function blocks, making the implementation transparent and testable.

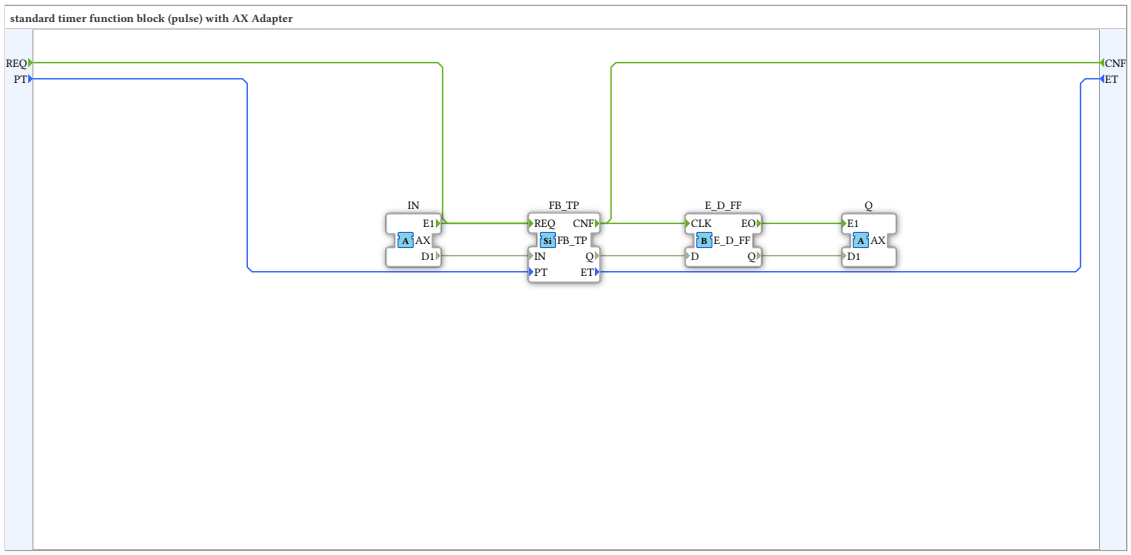
State Overview

The function block itself does not have its own state diagram, as it consists of an internal function block network. However, its behavior can be derived from the underlying IEC timer function block:

1. **Inactive** – Timer is not running, ET = 0, output Q = FALSE.
2. **Timer is running** – Input IN = TRUE, timer is incrementing ET.
3. **Expired** – ET ≥ PT; Q changes to TRUE and remains until IN falls to FALSE or a new REQ resets the timer.

Application Scenarios

- **Delayed Actuator Activation**: A valve or motor should only be activated after a defined delay time.
- **Process Synchronization**: Waiting for a signal to arrive via the adapter before triggering a time-critical action.
- **Response Time Monitoring**: Recording the elapsed time between an event and a specific condition.
- **Extension of existing AX-based systems**: Replacement of standard timer modules with the adapter variant without changing the overall structure.

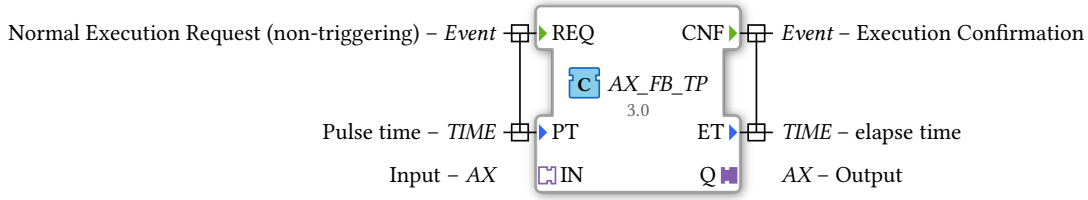


Comparison with similar modules

- **FB_TON_LTIME** (pure IEC timer): Does not have adapters and requires direct event and data connections. The AX_FB_TON_LTIME extends this with a standardized, easily connectable interface.
- **Event-driven timers** (e.g., E_TON): Often use Boolean inputs and do not have native LTIME support. The module presented here combines precise long-term measurement with flexible adapter connectivity.

Conclusion

The **AX_FB_TON_LTIME** is a powerful, adapter-based turn-on delay module for the IEC 61499 environment. It combines the advantages of the standardized IEC 61131-3 timer (LTIME, precise time measurement) with the modularity and reusability of AX adapters. The internal integration with a D flip-flop ensures reliable, edge-triggered output. It is ideally suited for time-critical controllers embedded in an adapter-based architecture model.



AX_FB_TP

• – ○ • – ○ • – ○ •

Introduction

Important note: This function block only functions correctly if it is called cyclically. AX_FB_TP is a standardized timer function block according to IEC 61131-3 that generates a pulse of defined length. A rising edge at the input generates an output pulse for the specified duration.

Interface Structure

Event Inputs

- **REQ** (Event): Normal Execution Request (takes the value from PT); Calls the function block (must be called cyclically)

Event Outputs

- **CNF** (Event): Execution Confirmation (with ET)

Data Inputs

- **PT** (TIME): Pulse time - defines the duration of the output pulse

Data Outputs

- **ET** (TIME): Elapsed Time

Adapters

- **IN** (Socket): Receives input events and data (Type: `adapter::types::unidirectional::AX`)
- **Q** (Plug): Sends output events and data (Type: `adapter::types::unidirectional::AX`)

Functionality

The AX_FB_TP block functions as a pulse generator:

1. On a rising edge (change from FALSE to TRUE) at the IN adapter, the output at the Q adapter immediately changes to TRUE.
2. The internal timer starts and runs for the duration PT.

3. The output on the Q-adapter remains TRUE for the entire duration PT, regardless of whether the input signal on the IN-adapter changes back to FALSE in the meantime.
4. While the pulse is running (as long as ET < PT), further edges at the input have no effect on the running timer (not retriggerable).
5. After the duration PT has elapsed, the output on the Q-adapter returns to FALSE.
6. The data output ET displays the time that has elapsed since the pulse started.

Technical Features

- Implemented based on the IEC 61131-3 TP standard
- Uses unidirectional adapters for clean encapsulation in adapter-based architectures
- Not retriggerable during the active pulse phase
- Precise timing control through the use of the TIME data type

State Overview

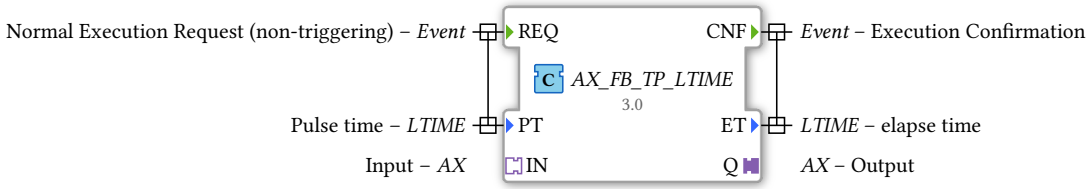
1. **Idle State**: IN is FALSE, Q is FALSE, ET is 0.
2. **Pulse Phase**: Rising edge detected at IN, Q is TRUE, ET rises to PT.
3. **End Phase**: ET has reached PT, Q changes to FALSE.
4. **Waiting for Reset**: If IN is still TRUE, Q remains FALSE and ET remains at PT until IN becomes FALSE again.

Application Scenarios

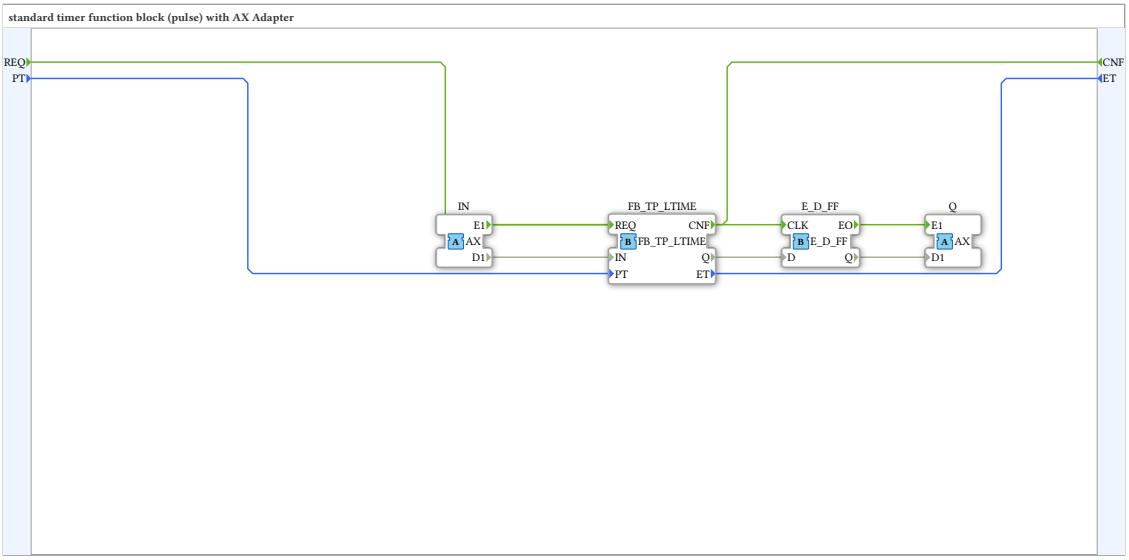
- Generation of time-limited control signals (e.g., start pulse for a motor)
- Time-limiting of operating processes
- Generation of defined signal pulses in process automation

⚖️ Comparison with similar function blocks

Compared to AX_PULSE, AX_FB_TP offers the classic IEC 61131-3 TP characteristic, including the ET status output.



🛠️ Related Exercises



- Exercise_020f2_AX

Conclusion

AX_FB_TP is the standard function block for generating stable, precisely time-defined pulses in an adapter-based environment.

AX_FB_TP_LTIME

• – ○ • – ○ • – ○ •

Introduction

The **AX_FB_TP_LTIME** is a standardized pulse timer function block (timer pulse) according to IEC 61131-3, extended by a unidirectional **AX adapter**. It is used in the 4diac IDE to generate time-limited pulses and pass the output signals to the application via an adapter. Its behavior is similar to a **TP** timer, which sets the output to TRUE for a predefined time on a rising edge at the input.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Normal execution request (non-triggering)

Event Outputs

Name	Type	Comment
CNF	Event	Execution Acknowledgement

Data Inputs

Name	Type	Comment
PT	LTIME	Pulse Time (Pulse Duration)

Data Outputs

Name	Type	Comment
ET	LTIME	Elapsed Time

Adapters

- **Plugs:**
- **Q**: Output adapter type `adapter::types::unidirectional::AX`.

This adapter passes the Boolean output signal `Q.D1` and the event `Q.E1` to the application.

- **Sockets:**
- **IN**: Input adapter type `adapter::types::unidirectional::AX`.

The function block receives the start event (via IN.E1) and, if necessary, a Boolean signal (via IN.D1) via this adapter. This signal is used internally as an enable or additional condition (not directly connected to the timer logic, but routed to an internal standard timer).

Functionality

The function block consists of two internal components:

1. **FB_TP_LTIME** – a pure pulse timer (IEC 61131-3 TP) with a time base of LTIME.
2. **E_D_FF** – an edge-triggered D flip-flop (E-D-FF according to IEC 61499) that buffers the Q output of the timer.

Procedure:

- An event via the adapter input IN.E1 or the standard event input REQ starts the timer FB_TP_LTIME (the events are internally combined – both trigger the same start).
- The timer increments the elapsed time ET and sets its internal Boolean output Q to TRUE as soon as PT is reached. After the pulse duration elapses, Q returns to FALSE and a CNF event is output.
- The CNF event clocks the D flip-flop E_D_FF, which takes over the current state of Q (i.e., TRUE during the pulse duration, FALSE afterward) and makes it available at the output Q.D1 of the adapter.
- Simultaneously, the CNF event is also directly forwarded to the output CNF of the overall module, thus informing the application about the end of the pulse.
- The output ET indicates the current elapsed time and is directly connected to the output of the internal timer.

Technical Features

- **Adapter Interface:** The function block encapsulates the timer logic in an adapter interface, allowing for easy integration into modular, adapter-based architectures.
- **D Flip-Flop for Signal Hold:** The timer's Q output is synchronized with the CNF event via a flip-flop to prevent glitches or asynchronous changes.
- **Dual Event Path:** The timer can be started via the adapter (IN.E1) or via the standard event input REQ – both are internally connected, enabling flexible control.
- **LTIME Support:** The pulse time is processed as LTIME (Long Time, 64-bit nanoseconds), enabling extremely high time resolution and large time ranges.

State Overview

Since the functional block consists of two parts, the following state behavior results for the complete module:

State	Description
IDLE	No pulse active. The adapter output Q.D1 is FALSE.
TIMING	A pulse is running – the internal timer is counting up. ET is increasing, Q.D1 is TRUE (as soon as the flip-flop was clocked at startup or after the first CNF).
DONE	The pulse is complete. CNF was output, ET is equal to PT, Q.D1 will be set to FALSE with the next CNF. The cycle starts again with a new REQ or IN.E1.

Application Scenarios

- **Pulse Output with Defined Length:** Controlling actuators (e.g., valves, lamps) that are to be switched on for a specific time.
- **Adapter-Based Subsystems:** Integrating the timer into a modular automation solution where inputs and outputs communicate via adapters (AX protocol).
- **High-Resolution Time Measurement:** Utilizing LTIME for precise timing in the micro- or nanosecond range.

Comparison with Similar Function Blocks

Function Block	Type	Feature

FB_TP_LTIME (Standard)	TP Timer	No adapter, only standard events and signals.
AX_FB_TP_LTIME (this FB)	TP Timer with AX Adapter	Enables integration into adapter-based architectures, includes a D flip-flop for signal stabilization.
FB_TON_LTIME	Turn-On Delay	Delays the activation of an output.
FB_TOF_LTIME	Turn-Off Delay	Delays the switching off of an output.

This module combines the timer function of a twisted pair (TP) with the flexibility of an adapter.

Conclusion

The **AX_FB_TP_LTIME** is a robust and precise pulse timer for the 4diac IDE. Thanks to its adapter interface and the use of `LTIME`, it is particularly well-suited for high-resolution, modular automation solutions. The internal flip-flop structure ensures clean signal transitions, and the dual event circuitry offers flexibility in control.

AX_FB_R_IO

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_FB_R_IO** implements monostable, reset-dominant behavior. It has three adapter interfaces through which it forwards an input signal (IN) to the output (OUT) if no active reset signal (RESET1) is present. The block operates on the principle: **Reset has priority**.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Name	Type	Direction	Comment
IN	unidirectional::AX	Socket	Input signal
RESET1	unidirectional::AX	Socket	Reset signal (prioritized)
OUT	unidirectional::AX	Plug	Output signal

The adapters of type `adapter::types::unidirectional::AX` each have an event output `E1` and a data output `D1` (of type BOOL). The adapter's data value is provided via `D1`, and processing is triggered by the event `E1`.

Functionality

The core logic of the component is represented by a simple state machine with a single state, `REQ`. As soon as an event arrives at one of the two input adapters (`IN.E1` or `RESET1.E1`), the algorithm `REQ` is executed. This algorithm checks the reset input:

- **If `RESET1.D1 = TRUE`**: The output `OUT.D1` is set to `FALSE`, regardless of the input signal.
- **Otherwise**: The output `OUT.D1` directly receives the value of the input signal `IN.D1`.

The event at the output adapter (`OUT.E1`) is triggered with each execution of the algorithm, so that subsequent function blocks are informed of the value change.

Technical Features

- **Reset Dominance**: The reset signal `RESET1` always takes precedence over the input signal `IN`. As long as `RESET1.D1` is active, the output `FALSE` remains active.
- **Monostable Behavior**: The function block automatically returns to the standby state (one state) after each processing operation. There is no stored state; each execution reacts immediately to the current inputs.
- **Adapter-Based Communication**: All inputs and outputs are handled via bidirectional adapters that transport both data and events. Event control is implicit via the adapter protocols.
- **Package Name**: `adapter::monostableElements` (defined in CompilerInfo).

State Overview

The function block has exactly one state:

State	Description
REQ	Start and end state. Waits for an event from `IN` or `RESET1`. After the algorithm has finished executing, the state always returns to `REQ` (no other states).

There are two transitions:

- From `REQ` to `REQ` upon event `IN.E1`
- From `REQ` to `REQ` upon event `RESET1.E1`

Both transitions return to the same state and trigger the execution of the algorithm.

Application Scenarios

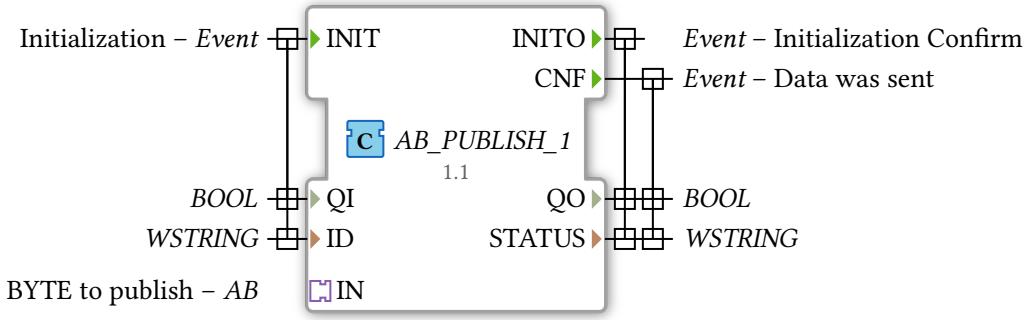
- **Enable circuit in automation technology**: A signal (e.g., machine start) is only passed to the output if no reset command (e.g., stop) is active.
- **Safety interlock**: In a control chain, a reset signal is given priority to reliably eliminate dangerous states.
- **Priority Signal Switch**: Two sources compete for one output – here, the reset function always takes precedence.

Comparison with Similar Function Blocks

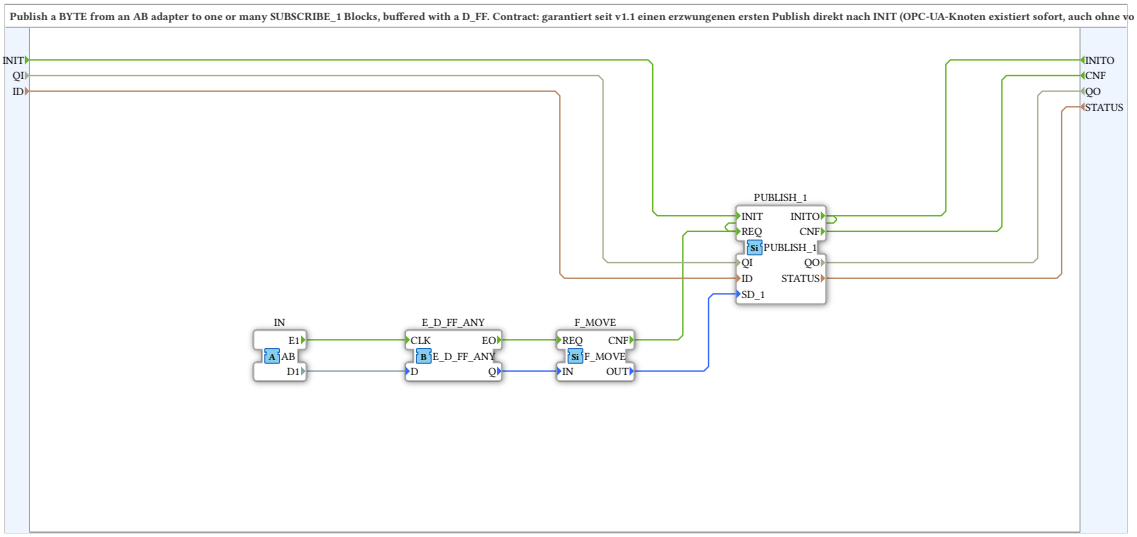
- **AX_FB_RS** (Set-Dominant): Unlike this function block, the set input has priority. `AX_FB_R_IO` is reset-dominant.
- **AX_FB_SR**: Set-reset flip-flop with equal inputs, often without priority (can lead to undefined states). `AX_FB_R_IO` avoids this through clear dominance.
- **AX_FB_MONOSTABLE**: Pure monostable flip-flops with time parameters; `AX_FB_R_IO` has no time behavior but reacts instantly to signals.

Conclusion

The function block `AX_FB_R_IO` is a simple yet reliable building block for realistically implementing prioritized reset behavior. Thanks to its adapter interface, it integrates seamlessly into event-driven automation systems. Its clear reset dominance makes it particularly suitable for safety and enabling functions where a reset signal must have absolute priority.



2.8.0.2 net



Here you will find function blocks that map network communication (publish/subscribe and OPC UA client/server) to the unidirectional adapters. These blocks encapsulate the corresponding `iec61499::net` function blocks and buffer the transmitted values using a D flip-flop.

AB_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AB_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AB adapter**. A **BYTE** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs
- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs
- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs
- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs
- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AB	Socket (Input)	Byte value to be published

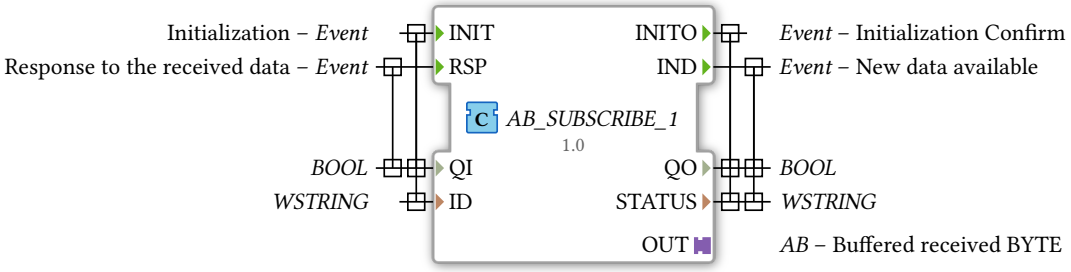
Functionality
1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AB socket `IN` delivers an event to `IN.E1`, the corresponding BYTE value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then sent externally.

Technical Features
- **Buffering with D-Flip-Flop**: The byte value to be sent is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AB adapter interface is visible externally.

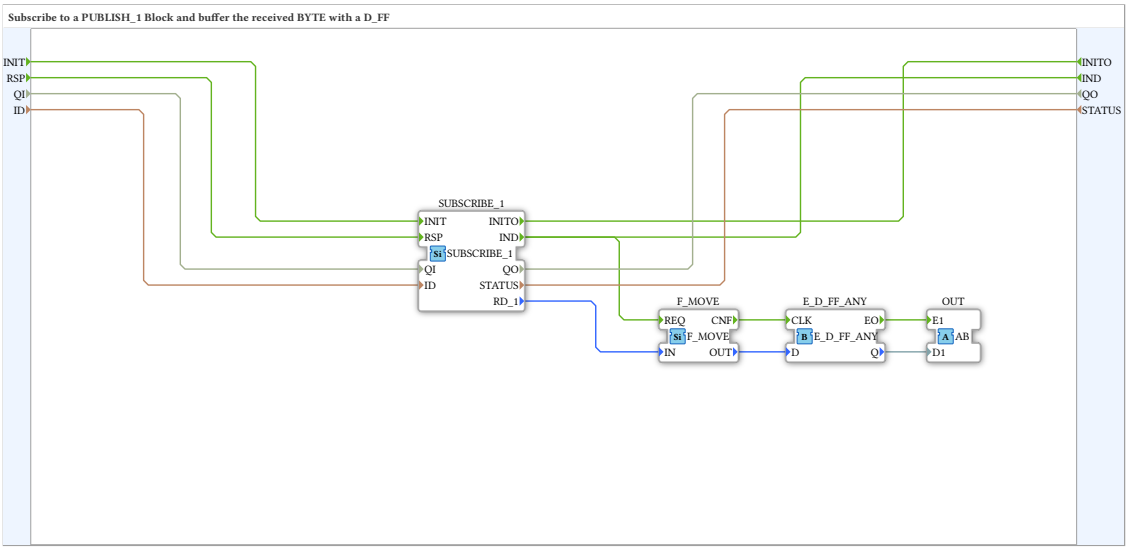
State Overview
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AB socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

Application Scenarios
- **Network Coupling in AB Applications**: Sending BYTE signals (e.g., switching commands or status bits) from adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AB adapters.

Comparison with Similar Function Blocks



- **PUBLISH_1**: The standard function block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AB_PUBLISH_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AB adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a byte value at the adapter level but lacks network functionality. **AB_PUBLISH_1** combines buffering and publishing in a single function block.



Conclusion

AB_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based BYTE processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AB interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AB_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based BYTE processing.

AB_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AB_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AB adapter**. It subscribes to a publish channel configured via `ID` and makes the received **BYTE** value buffered via a D flip-flop (E_D_FF_ANY) available at the adapter plug `OUT`. This allows for clean integration of network communication and BYTE signal processing in the AB adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AB	Plug (Output)	Buffered received BYTE value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

- **Buffering with D flip-flop**: The received BYTE value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AB adapter interface is visible externally.

State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Received**: At `IND`, the received byte value is transferred to the internal D flip-flop and output via `OUT`.

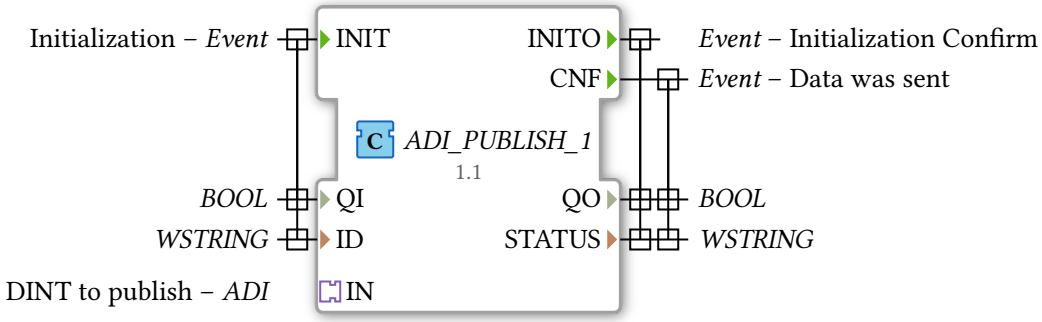
Application Scenarios

- **Network Coupling in AB Applications**: Receiving BYTE signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AB adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a cleaner fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AB adapters.

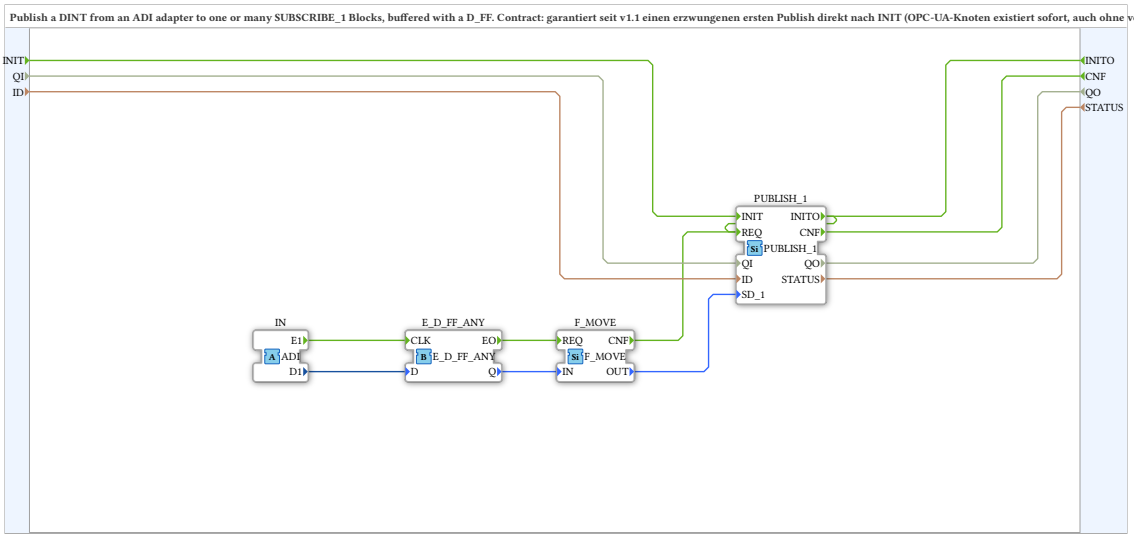
Comparison with Similar Function Blocks

- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AB_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`),

and only provides the AB adapter – making the interface significantly more compact and integrable into adapter networks.



- **AX_D_FF**: Bufferes a byte value at the adapter level but lacks network functionality. **AB_SUBSCRIBE_1** combines subscribing and buffering in a single function block.



Conclusion

AB_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based BYTE processing. The internal D flip-flop buffer keeps the received value stable until new data arrives, and the reduced AB interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AB_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based BYTE processing.

ADI_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The **ADI_PUBLISH_1** function block is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **ADI adapter**. A **DINT** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::ADI	Socket (Input)	DINT value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the ADI socket `IN` delivers an event to `IN.E1`, the DINT value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then sent out.

Technical Features

- **Buffering with D-Flip-Flop**: The DINT value to be transmitted is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the ADI adapter interface remains visible externally.

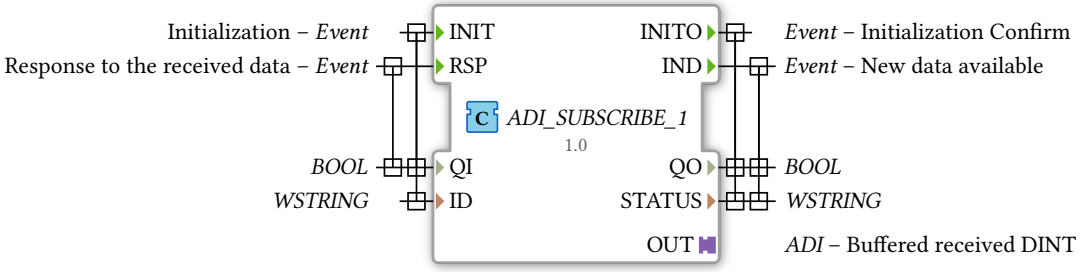
Status Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the ADI socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

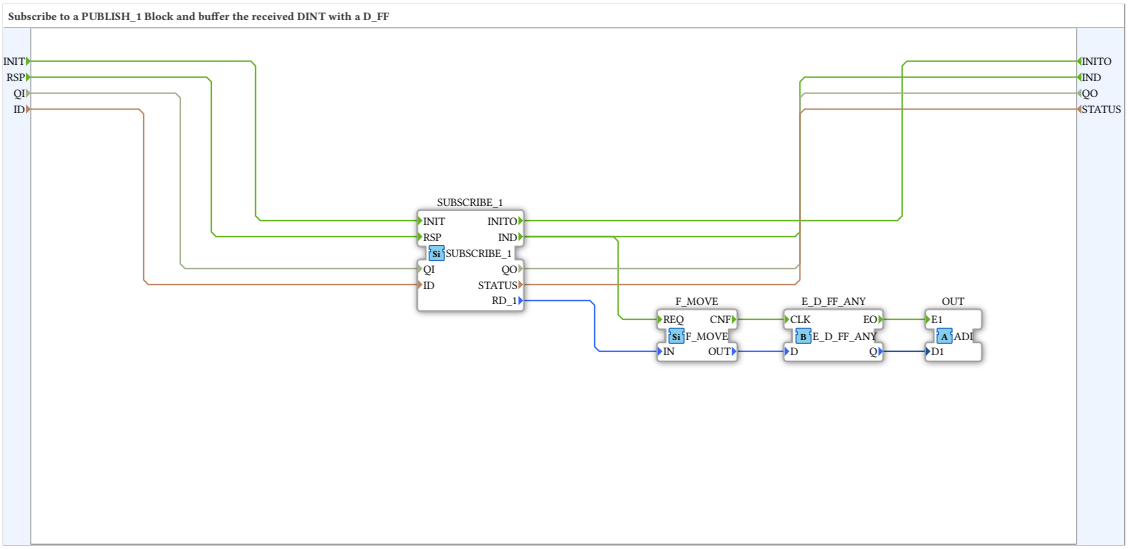
Application Scenarios

- **Network Coupling in ADI Applications**: Sending DINT signals (e.g., switching commands or status bits) from the adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between the user's own publications and subscriptions is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on ADI adapters.

Comparison with Similar Function Blocks



- **PUBLISH_1**: The standard function block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **ADI_PUBLISH_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the ADI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a DINT value at the adapter level but lacks network functionality. **ADI_PUBLISH_1** combines buffering and publishing in a single function block.



Conclusion

ADI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based DINT processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified ADI interface makes the function block ideal for fully adapter-based IEC 61499 applications.

ADI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based DINT processing.

ADI_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **ADI adapter**. It subscribes to a publish channel configured via `ID` and provides the received **DINT** value, buffered via a D flip-flop (E_D_FF_ANY), at the adapter plug `OUT`. This allows for the clean integration of network communication and DINT signal processing in the ADI adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::ADI	Plug (Output)	Buffered received DINT value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

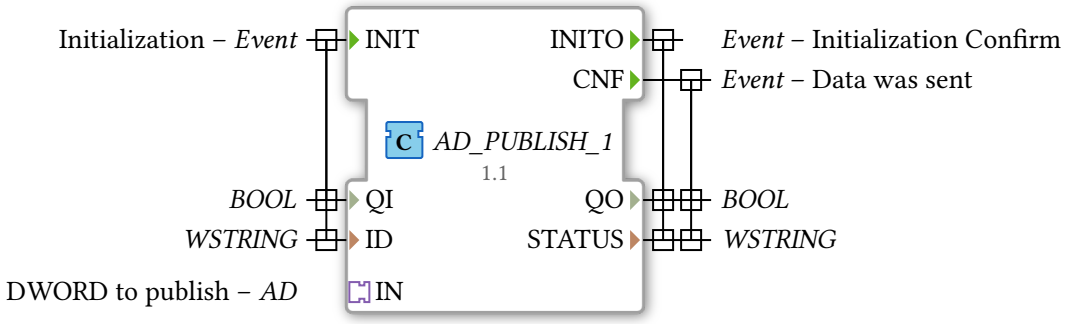
- **Buffering with D flip-flop**: The received DINT value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the ADI adapter interface is visible externally.

State Overview

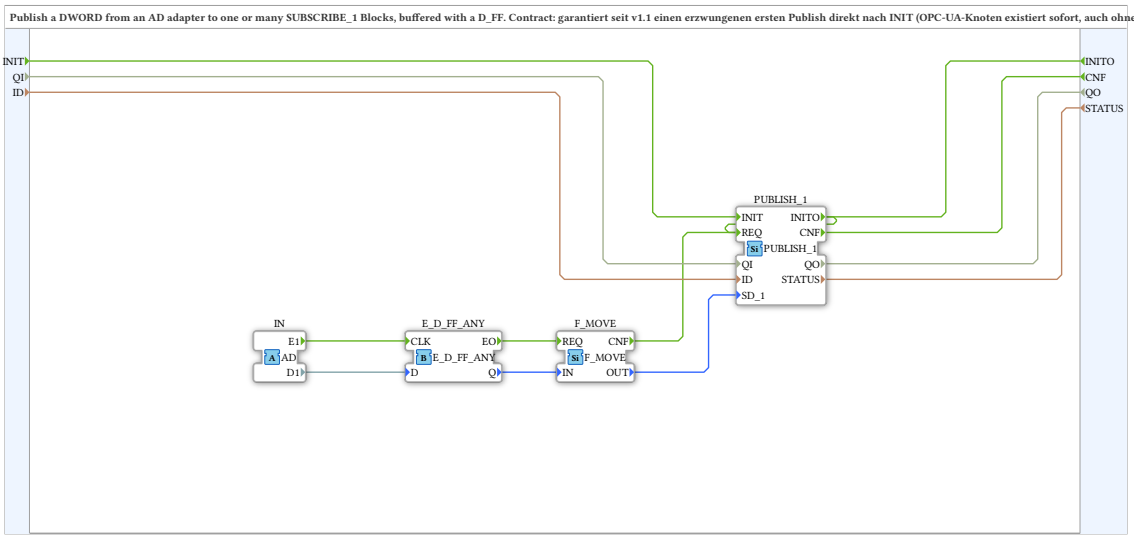
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Reception**: At `IND`, the received DINT value is transferred to the internal D flip-flop and output via `OUT`.

Application Scenarios

- **Network Coupling in ADI Applications**: Receiving DINT signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via ADI adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a clean fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on ADI adapters.



Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **ADI_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the ADI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a DINT value at the adapter level but lacks network functionality. **ADI_SUBSCRIBE_1** combines subscribing and buffering in a single function block.

Conclusion

ADI_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based DINT processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified ADI interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AD_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AD_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AD adapter**. A **DWORD** value at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AD	Socket (Input)	DWORD value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AD socket `IN` sends an event to `IN.E1`, the DWORD value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then sent externally.

Technical Features

- **Buffering with D-Flip-Flop**: The DWORD value to be sent is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents an input value that changes during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AD adapter interface is visible externally.

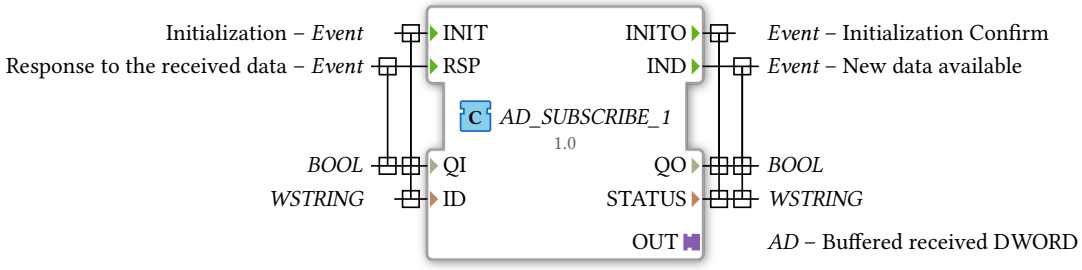
Status Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AD socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

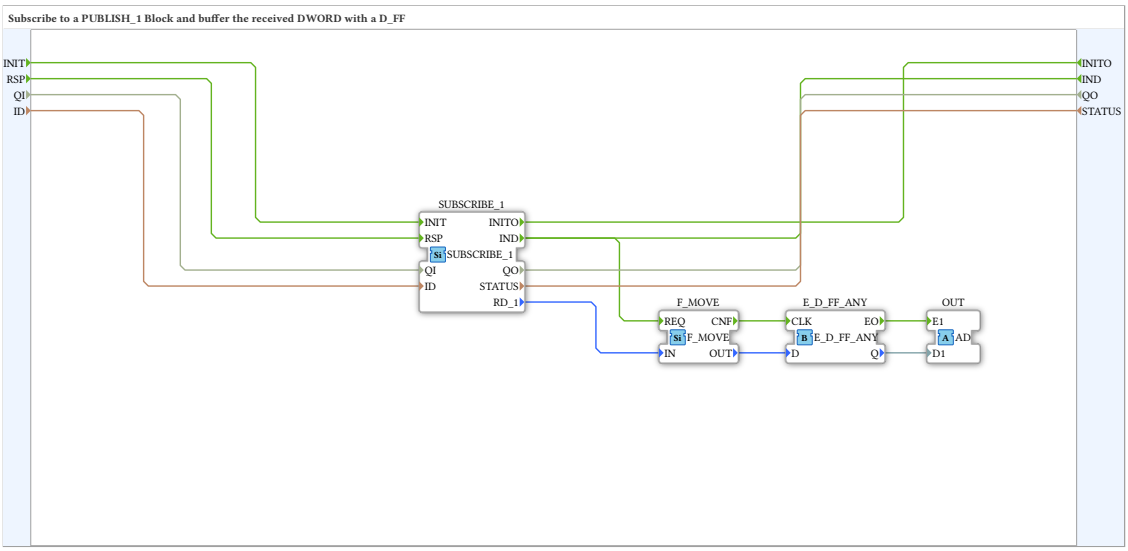
Application Scenarios

- **Network Coupling in AD Applications**: Sending DWORD signals (e.g., toggle commands or status bits) from adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AD adapters.

Comparison with Similar Function Blocks



- **PUBLISH_1**: The standard function block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AD_PUBLISH_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AD adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a DWORD value at the adapter level but lacks network functionality. **AD_PUBLISH_1** combines buffering and publishing in a single function block.



Conclusion

AD_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based DWORD processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AD interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AD_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based DWORD processing.

AD_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AD_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AD adapter**. It subscribes to a publish channel configured via `ID` and makes the received **DWORD** value buffered via a D flip-flop (E_D_FF_ANY) available at the adapter plug `OUT`. This allows for clean integration of network communication and DWORD signal processing in the AD adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description

OUT	adapter::types::unidirectional::AD	Plug (Output)	Buffered received DWORD value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

- **Buffering with D flip-flop**: The received DWORD value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AD adapter interface is visible externally.

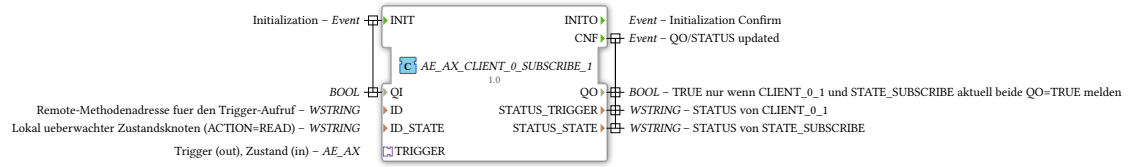
Status Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Received**: At `IND`, the received DWORD value is transferred to the internal D flip-flop and output via `OUT`.

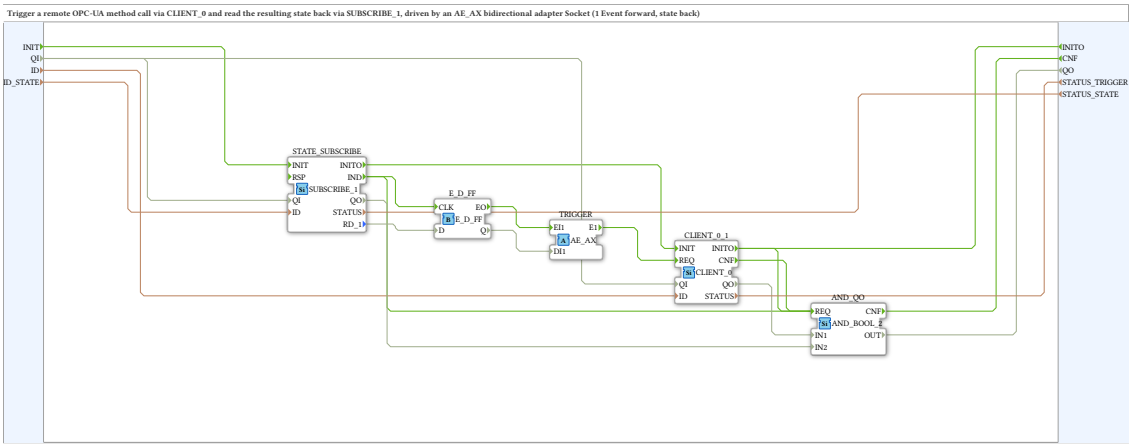
Application Scenarios

- **Network Coupling in AD Applications**: Receiving DWORD signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AD adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a clean fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AD adapters.

Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AD_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AD adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a DWORD value at the adapter level but lacks network functionality. **AD_SUBSCRIBE_1** combines subscribing and buffering in a single function block.



Conclusion

AD_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based DWORD processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AD interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AD_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based DWORD processing.

AE_AX_CLIENT_0_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The **AE_AX_CLIENT_0_SUBSCRIBE_1** function block is a composite function block that triggers a remote OPC UA **method call** via `CLIENT_0` and reads the corresponding state back via `SUBSCRIBE_1` – both behind a single bidirectional **AE_AX adapter socket**. It collapses the pattern of "one hand-wired `CLIENT_0` plus one `SUBSCRIBE_1`" into a single building block with one adapter port.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO`, `STATUS_TRIGGER`, and `STATUS_STATE`
- **CNF** (Event): `QO`/`STATUS` updated, associated with `QO`, `STATUS_TRIGGER`, and `STATUS_STATE`

Data Inputs

- **QI** (BOOL): Qualifier input for both internal connections
- **ID** (WSTRING): Remote method address for the trigger call (`CLIENT_0_1`)
- **ID_STATE** (WSTRING): Locally monitored state node for `SUBSCRIBE_1` (ACTION=READ)

Data Outputs

- **QO** (BOOL): TRUE only if `CLIENT_0_1` and `STATE_SUBSCRIBE` currently both report `QO = TRUE`
- **STATUS_TRIGGER** (WSTRING): Status information from `CLIENT_0_1`
- **STATUS_STATE** (WSTRING): Status information from `STATE_SUBSCRIBE`

Adapter

Adapter	Type	Direction	Description
TRIGGER	adapter::types::bidirectional::AE_AX	Socket – trigger (output), state (input)	Triggering event out, state back

Functionality

1. Via the `INIT` event, `STATE_SUBSCRIBE` (`SUBSCRIBE_1`) is initialized first with `QI` and `ID_STATE`; after its `INITO`, `CLIENT_0_1` is initialized with `QI` and `ID`. After both have confirmed, `INITO` is reported externally.

2. An event arriving at the adapter socket `TRIGGER.E1` directly triggers the method call `CLIENT_0_1.REQ`.
3. As soon as `STATE_SUBSCRIBE` delivers a new state value at `RD_1` via `IND`, this event clocks the internal **E_D_FF** flip-flop, which captures and holds the value stably.
4. The flip-flop's output `EO` fires `TRIGGER.EI1` with the buffered value at `TRIGGER.DI1` – so the state is reported back over the same adapter used to send the trigger out.
5. `AND_QO` (AND_BOOL_2) ANDs the `QO` outputs of `CLIENT_0_1` and `STATE_SUBSCRIBE`; every confirmation (`CLIENT_0_1.CNF` or `STATE_SUBSCRIBE.IND`) additionally triggers `CNF` externally.

Technical Features

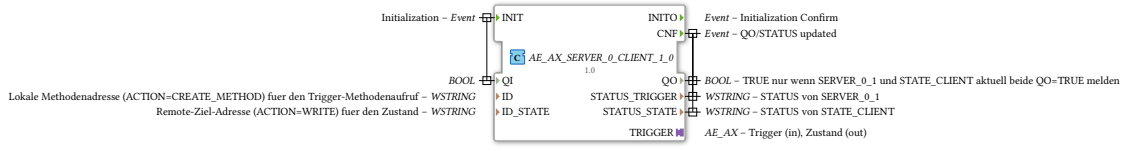
- **Two network connections behind one adapter**: `CLIENT_0` (trigger, write direction) and `SUBSCRIBE_1` (state, read direction) are combined into a single bidirectional AE_AX interface.
- **Buffering with D flip-flop**: The state received via `SUBSCRIBE_1` is stabilized via an internal `iec61499::events::E_D_FF` before being reported back over the adapter.
- **Sequential initialization**: `STATE_SUBSCRIBE` is initialized before `CLIENT_0_1` (composite FBTypes chain `INIT`/`INITO` serially through each instance).
- **Encapsulation**: Only the AE_AX adapter interface is visible externally; `CLIENT_0`'s `REQ` and `SUBSCRIBE_1`'s `IND`/`RD_1` remain internal.

State Overview

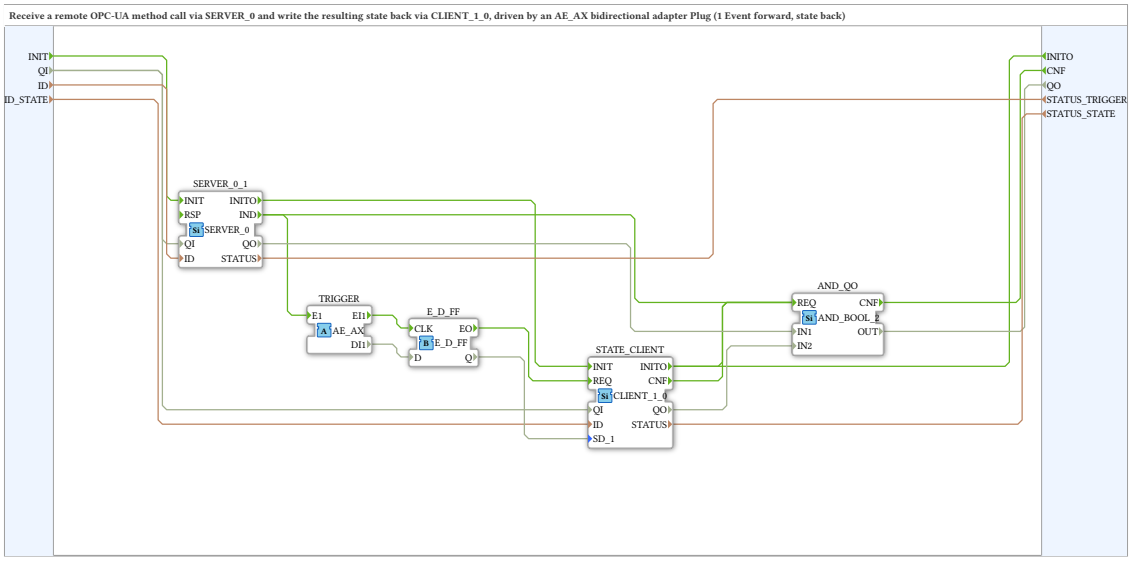
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: Both connections (trigger and state subscription) are established.
3. **Send Active**: A trigger event arriving at the adapter triggers the remote method call.
4. **State Update**: A new value from the subscription is buffered and reported back over the same adapter.

Application Scenarios

- Remotely triggering a remote action while simultaneously reading back the resulting state over a single adapter connection, e.g. for a control element that immediately shows the actual state of the remote actuator
- Reducing manual CLIENT_0/SUBSCRIBE_1 wiring to a single reusable building block



Comparison with Similar Function Blocks



- **AE_CLIENT_0**: A pure trigger without reading the state back.
- **AI_SUBSCRIBE_1**: A pure state subscription without trigger functionality.
- **ASR_AX_CLIENT_0_SUBSCRIBE_1** / **ASRT_AX_CLIENT_0_SUBSCRIBE_1**: Extend the same pattern to 2 and 3 parallel triggers.
- **AE_AX_SERVER_0_CLIENT_1_0**: The server-side counterpart – receives instead of triggering, and writes instead of subscribing.

Conclusion

AE_AX_CLIENT_0_SUBSCRIBE_1 bundles a remote trigger and a state subscription behind a single bidirectional AE_AX adapter, turning a hand-wired CLIENT_0/SUBSCRIBE_1 combination into a single reusable building block.

AE_AX_SERVER_0_CLIENT_1_0

• – ○ • – ○ • – ○ •

Introduction

The **AE_AX_SERVER_0_CLIENT_1_0** function block is a composite function block that receives a remote OPC UA **method call** via `SERVER_0` and writes the resulting state back to a remote node via `CLIENT_1_0` – both behind a single bidirectional **AE_AX adapter plug**. It is the server-side counterpart to AE_AX_CLIENT_0_SUBSCRIBE_1.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO`, `STATUS_TRIGGER`, and `STATUS_STATE`
- **CNF** (Event): `QO`/`STATUS` updated, associated with `QO`, `STATUS_TRIGGER`, and `STATUS_STATE`

Data Inputs

- **QI** (BOOL): Qualifier input for both internal connections
- **ID** (WSTRING): Local method address (ACTION=CREATE_METHOD) for the trigger method call (`SERVER_0_1`)
- **ID_STATE** (WSTRING): Remote target address (ACTION=WRITE) for the state (`STATE_CLIENT`)

Data Outputs

- **QO** (BOOL): TRUE only if `SERVER_0_1` and `STATE_CLIENT` currently both report `QO = TRUE`
- **STATUS_TRIGGER** (WSTRING): Status information from `SERVER_0_1`
- **STATUS_STATE** (WSTRING): Status information from `STATE_CLIENT`

Adapter

Adapter	Type	Direction	Description
TRIGGER	adapter::types::bidirectional::AE_AX	Plug – trigger (input), state (output)	Received event, state out

Functionality

1. Via the `INIT` event, `SERVER_0_1` is initialized first with `QI` and `ID`; after its `INITO`, `STATE_CLIENT` is initialized with `QI` and `ID_STATE`. After both have confirmed, `INITO` is reported externally.
2. A remote method call on `SERVER_0_1` generates the indication event `IND`, which is placed directly on `TRIGGER.E1` – the adapter thus reports the call inward to the downstream logic.

3. As soon as the downstream logic delivers a feedback event `TRIGGER.EI1` with data `TRIGGER.DI1` via the adapter, this clocks the internal **E_D_FF** flip-flop, which captures and holds the value stably.
4. The flip-flop's output `EO` triggers `STATE_CLIENT.REQ`; the buffered value is passed as `SD_1` and sent as an OPC UA write to the remote node configured in `ID_STATE`.
5. `AND_QO` (AND_BOOL_2) ANDs the `QO` outputs of `SERVER_0_1` and `STATE_CLIENT`; every confirmation additionally triggers `CNF` externally.

Technical Features

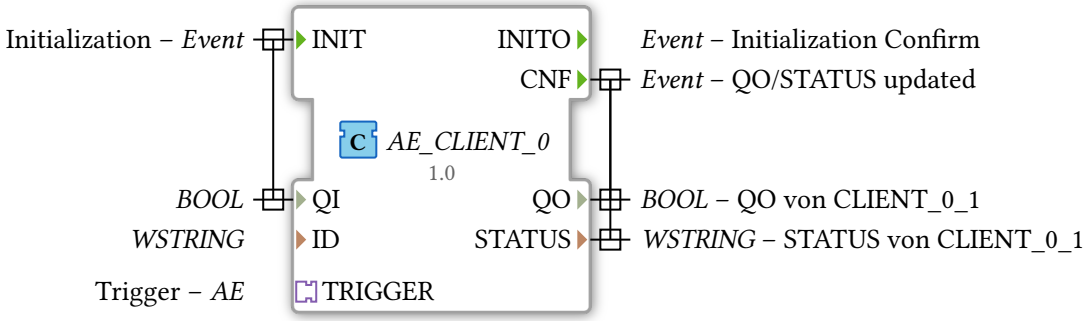
- **Two network connections behind one adapter**: `SERVER_0` (receiving, server role) and `CLIENT_1_0` (state, remote write) are combined into a single bidirectional AE_AX interface.
- **Buffering with D flip-flop**: The feedback value reported via the adapter is stabilized via an internal `iec61499::events::E_D_FF` before being sent via `CLIENT_1_0`.
- **Sequential initialization**: `SERVER_0_1` is initialized before `STATE_CLIENT` (composite FBTypes chain `INIT`/`INITO` serially through each instance).
- **Encapsulation**: Only the AE_AX adapter interface is visible externally; `SERVER_0`'s `IND` and `CLIENT_1_0`'s `REQ`/`SD_1` remain internal.

State Overview

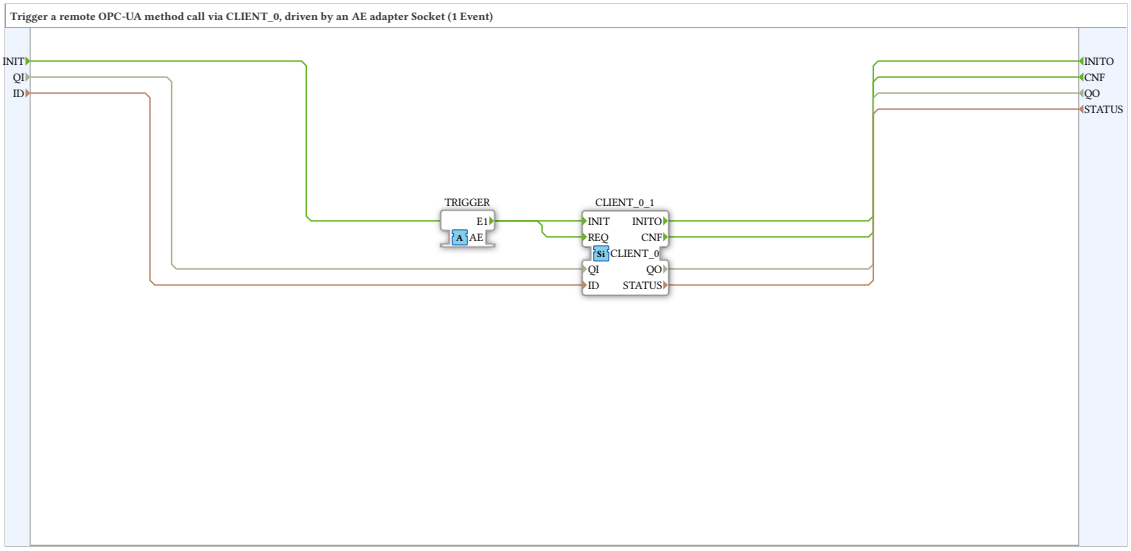
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: Both connections (server and state client) are established.
3. **Receive Active**: A remote method call is reported to the internal logic via the adapter.
4. **State Write**: A feedback value from the internal logic is buffered and sent via remote write to the configured target node.

Application Scenarios

- Receiving a remote trigger call while simultaneously writing the resulting state back to a different remote node over a single adapter connection
- Server-side counterpart to AE_AX_CLIENT_0_SUBSCRIBE_1 in distributed control architectures



Comparison with Similar Function Blocks



- **AE_AX_CLIENT_0_SUBSCRIBE_1**: The client/calling counterpart – actively triggers instead of receiving, subscribes instead of writing.
- **AX_CLIENT_1_0**: A pure remote write without a receiving side.
- **ASR_AX_SERVER_0_CLIENT_1_0** / **ASRT_AX_SERVER_0_CLIENT_1_0**: Extend the same pattern to 2 and 3 parallel receiving servers.

Conclusion

AE_AX_SERVER_0_CLIENT_1_0 bundles a receiving server and a state-writing client behind a single bidirectional AE_AX adapter, forming the server-side counterpart to AE_AX_CLIENT_0_SUBSCRIBE_1.

AE_CLIENT_0

• – ◦ • – ◦ • – ◦ •

Introduction

The **AE_CLIENT_0** function block is a composite function block that encapsulates the network-based `CLIENT_0` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AE adapter**. Every event arriving at the adapter socket `TRIGGER` triggers a remote OPC UA **method call** via `CLIENT_0` at the address configured in `ID`.

Unlike `CLIENT_1_0` (a remote write of a data value), `CLIENT_0` calls a remote **method without payload data** – the appropriate building block for event-driven trigger actions such as “Set”, “Reset”, or “Toggle” on a remote node.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that the method call has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, opens (TRUE) or closes (FALSE) the connection to the server
- **ID** (WSTRING): Remote method address for the call

Data Outputs

- **QO** (BOOL): Qualifier output, connection status (identical to `CLIENT_0_1.QO`)
- **STATUS** (WSTRING): Status information as a Unicode string (identical to `CLIENT_0_1.STATUS`)

Adapter

Adapter	Type	Direction	Description
TRIGGER	adapter::types::unidirectional::AE	Socket (Input)	Triggering event for the method call

Functionality

1. The internal `CLIENT_0_1` block is initialized with `QI` and `ID` via the `INIT` event; it establishes the connection to the remote server. Upon success, it returns `INITO`.
2. Every event arriving at the adapter socket `TRIGGER` (`TRIGGER.E1`) directly triggers the send event `REQ` of the internal `CLIENT_0_1` block.
3. `CLIENT_0_1` then calls the remote method configured in `ID` and confirms with `CNF`, which is sent out.

Technical Features

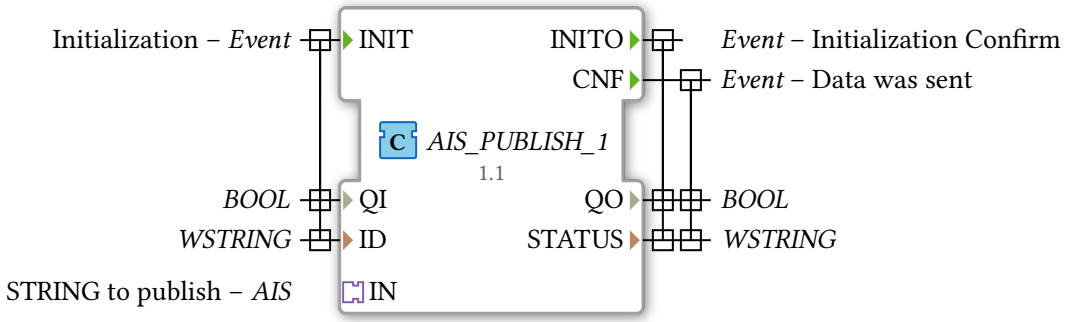
- **Pure trigger, no payload**: Unlike `AX_CLIENT_1_0`, `AE_CLIENT_0` transfers no data value – the adapter only supplies the triggering event.
- **Encapsulation**: The original event/data interface of `CLIENT_0` (including `REQ`) is moved internally; only the AE adapter interface is visible externally.
- The base building block from which ASR_CLIENT_0 (2 triggers) and ASRT_CLIENT_0 (3 triggers) are derived by wiring multiple `CLIENT_0` instances in parallel.

State Overview

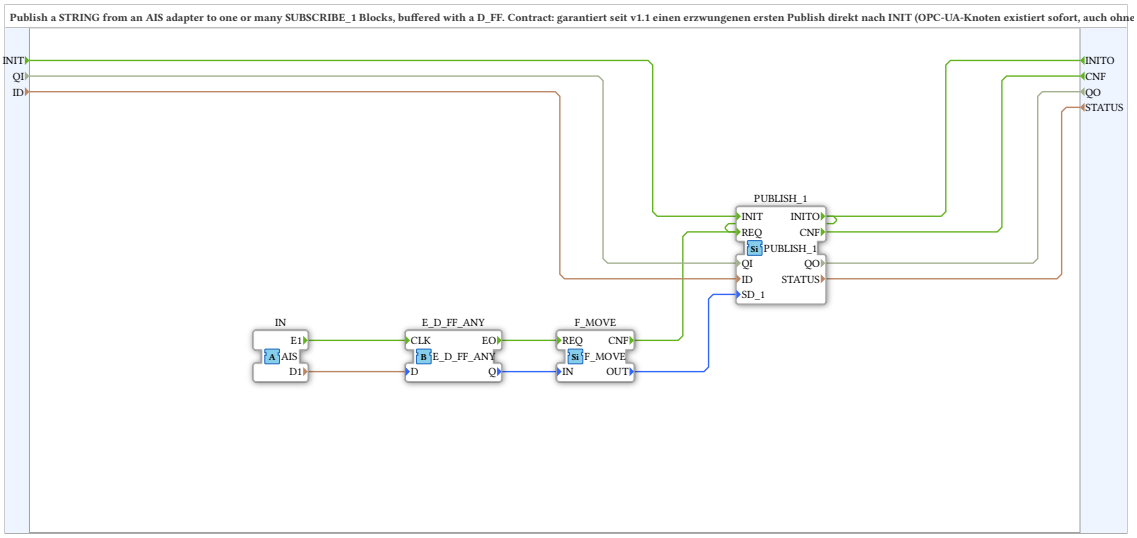
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The connection to the remote server is established, the block is ready to trigger method calls.
3. **Send Active**: An event arriving at the AE socket triggers the remote method call via the internal `CLIENT_0` block.

Application Scenarios

- Remotely triggering a single remote action (e.g. “Start”, “Trigger”) without an associated data value
- Building block for composed multi-trigger blocks such as ASR_CLIENT_0 and ASRT_CLIENT_0
- Network coupling in AE-adapter-based applications



Comparison with Similar Function Blocks



- **CLIENT_0**: The standard building block exposes its interface as events/variables (`REQ`, ...). **AE_CLIENT_0** encapsulates this building block and only provides the AE adapter.
- **AX_CLIENT_1_0**: Structurally similar, but encapsulates `CLIENT_1_0` (remote write of a data value) instead of `CLIENT_0` (pure method call without data).
- **ASR_CLIENT_0** / **ASRT_CLIENT_0**: Extend the same pattern to 2 and 3 parallel triggers (Set/Reset and Set/Reset/Toggle, respectively).

Conclusion

AE_CLIENT_0 combines the trigger semantics of the standard function block `CLIENT_0` with adapter-based event processing. The simplified AE interface makes the function block ideal for directly triggering a remote OPC UA method call in fully adapter-based IEC 61499 applications.

AIS_PUBLISH_1

• – ○ • – ○ • – ○ •

The **AIS_PUBLISH_1** function block is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AIS adapter**. A **STRING** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`
- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier
- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AIS	Socket (Input)	STRING value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AIS socket `IN` sends an event to `IN.E1`, the corresponding STRING value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then sent out.

- **Buffering with D-Flip-Flop**: The string value to be sent is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AIS adapter interface remains visible externally.

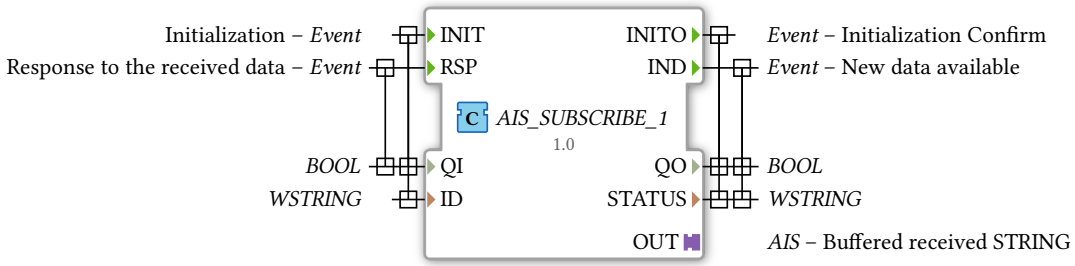
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AIS socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

- **Network Coupling in AIS Applications**: Sending STRING signals (e.g., switching commands or status bits) from the adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AIS adapters.
- **PUBLISH_1**: The standard function block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AIS_PUBLISH_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AIS adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a STRING value at the adapter level but lacks network functionality. **AIS_PUBLISH_1** combines buffering and publishing in a single function block.

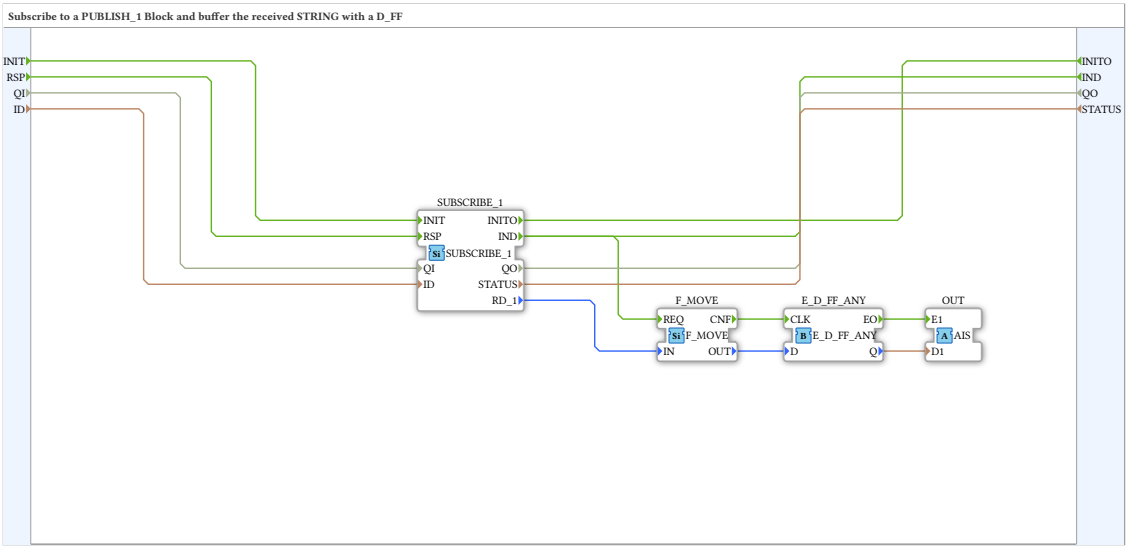
PUBLISH_1 PUBLISH_1 ## Conclusion

AIS_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based string processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AIS interface makes the function block ideal for fully adapter-based IEC 61499 applications.

Technical Features



State Overview



Application Scenarios

Conclusion

AIS_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AIS_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AIS adapter**. It subscribes to a publish channel configured via `ID` and provides the received **STRING** value, buffered via a D flip-flop (E_D_FF_ANY), at the adapter plug `OUT`. This allows for clean integration of network communication and STRING signal processing in the AIS adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AIS	Plug (Output)	Buffered received STRING value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.

5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

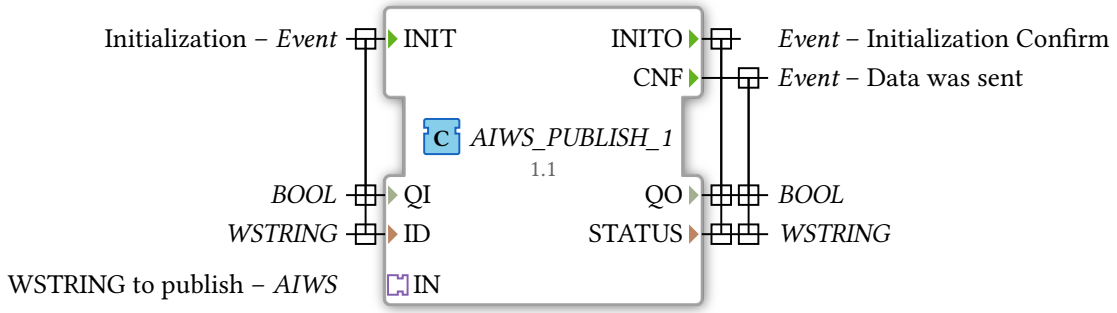
- **Buffering with D flip-flop**: The received STRING value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AIS adapter interface is visible externally.

Status Overview

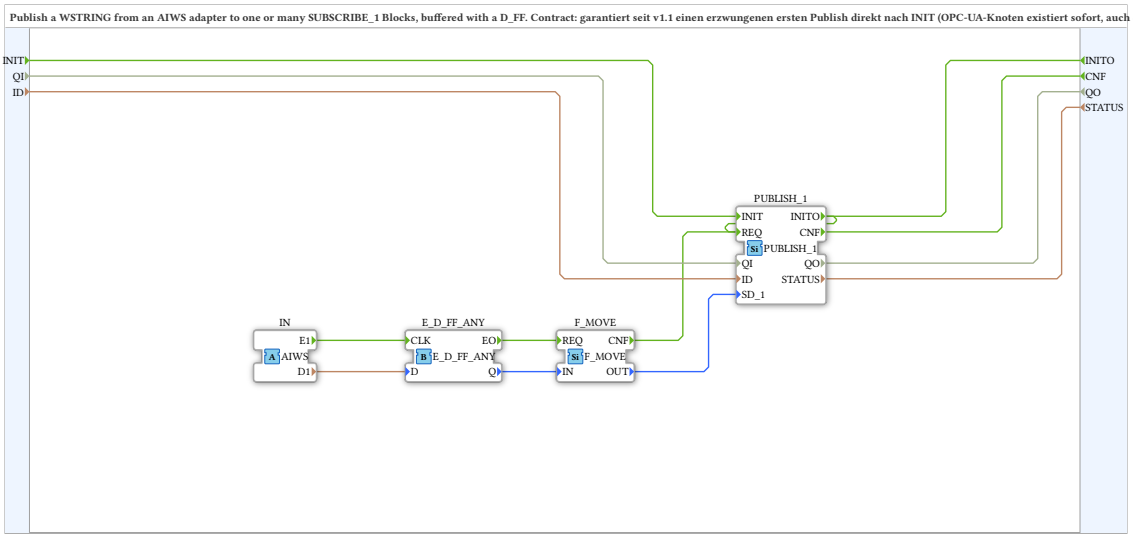
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Reception**: At `IND`, the received STRING value is transferred to the internal D flip-flop and output via `OUT`.

Application Scenarios

- **Network Coupling in AIS Applications**: Receiving STRING signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AIS adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a clean fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on AIS adapters.



Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AIS_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AIS adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a STRING value at the adapter level but lacks network functionality. **AIS_SUBSCRIBE_1** combines subscribing and buffering in a single function block.

Conclusion

AIS_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based string processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AIS interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AIWS_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AIWS_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AIWS adapter**. A **WSTRING** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AIWS	Socket (Input)	WSTRING value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AIWS socket `IN` delivers an event to `IN.E1`, the WSTRING value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then sent out.

Technical Features

- **Buffering with D-Flip-Flop**: The WSTRING value to be transmitted is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AIWS adapter interface is visible externally.

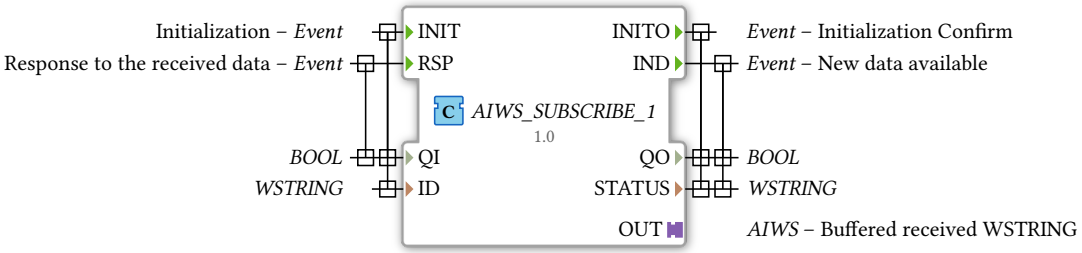
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data over the configured channel.
3. **Send Active**: An event arriving at the AIWS socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

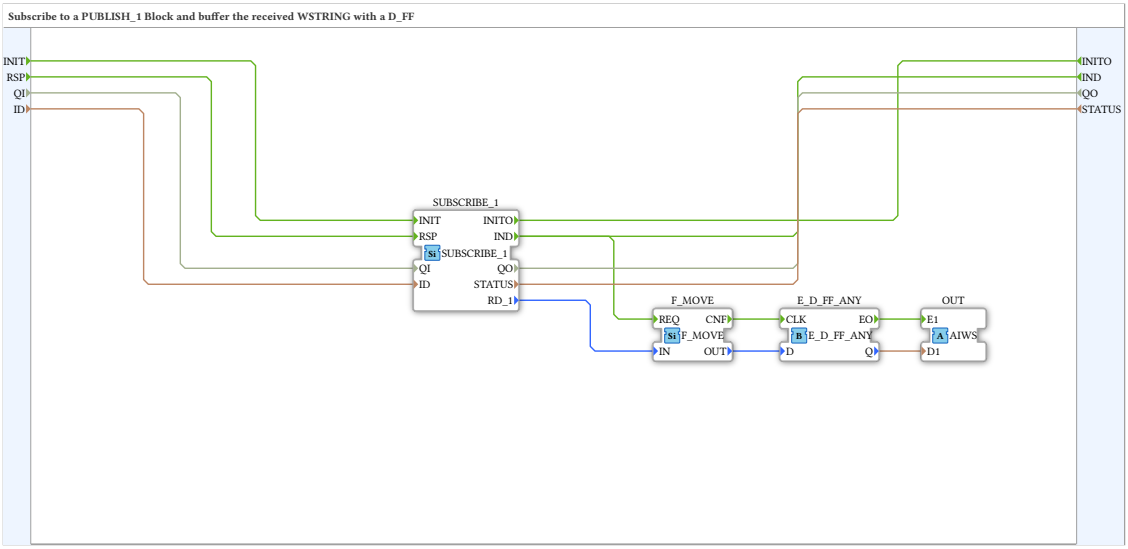
Application Scenarios

- **Network Coupling in AIWS Applications**: Sending WSTRING signals (e.g., switching commands or status bits) from adapter-based logic to remote receivers via Publish/Subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AIWS adapters.

Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AIWS_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AIWS adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a WSTRING value at the adapter level but lacks network functionality. **AIWS_PUBLISH_1** combines buffering and publishing in a single block.



Conclusion

AIWS_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based WSTRING processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AIWS interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AIWS_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based WSTRING processing.

AIWS_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AIWS_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AIWS adapter**. It subscribes to a publish channel configured via `ID` and provides the received **WSTRING** value, buffered via a D flip-flop (E_D_FF_ANY), at the adapter plug `OUT`. This allows for clean integration of network communication and WSTRING signal processing within the AIWS adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AIWS	Plug (Output)	Buffered received WSTRING value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.

4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

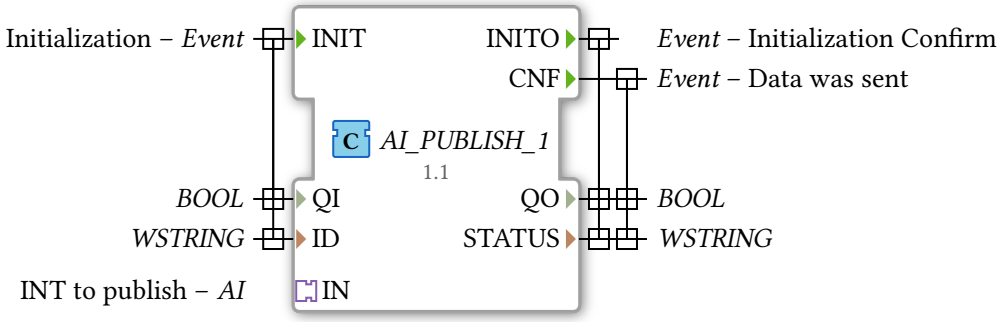
- **Buffering with D flip-flop**: The received WSTRING value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AIWS adapter interface is visible externally.

State Overview

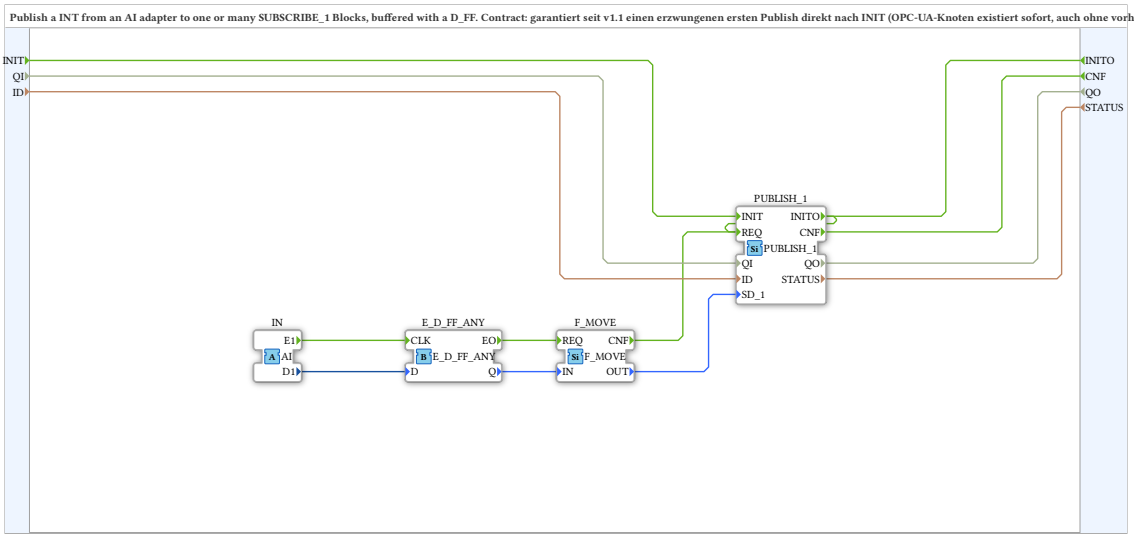
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Received**: At `IND`, the received WSTRING value is transferred to the internal D flip-flop and output via `OUT`.

Application Scenarios

- **Network Coupling in AIWS Applications**: Receiving WSTRING signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AIWS adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a cleaner fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on AIWS adapters.



Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AIWS_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AIWS adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a WSTRING value at the adapter level but lacks network functionality. **AIWS_SUBSCRIBE_1** combines subscribing and buffering in a single function block.

Conclusion

AIWS_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based WSTRING processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AIWS interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AI_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AI adapter**. An **INT** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AI	Socket (Input)	INT value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AI socket `IN` delivers an event to `IN.E1`, the INT value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then transmitted externally.

Technical Features

- **Buffering with D-Flip-Flop**: The INT value to be transmitted is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AI adapter interface is visible externally.

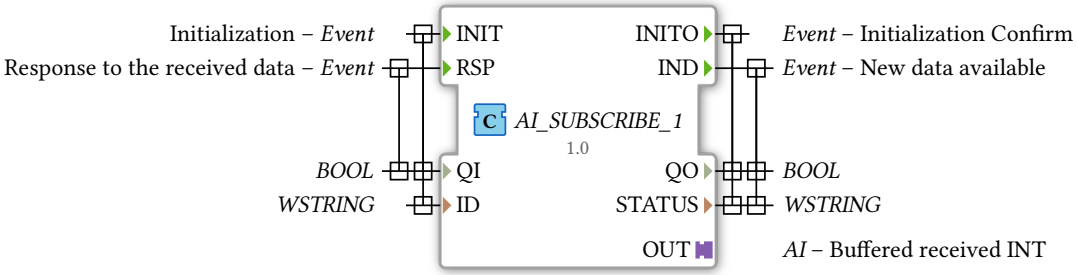
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AI socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

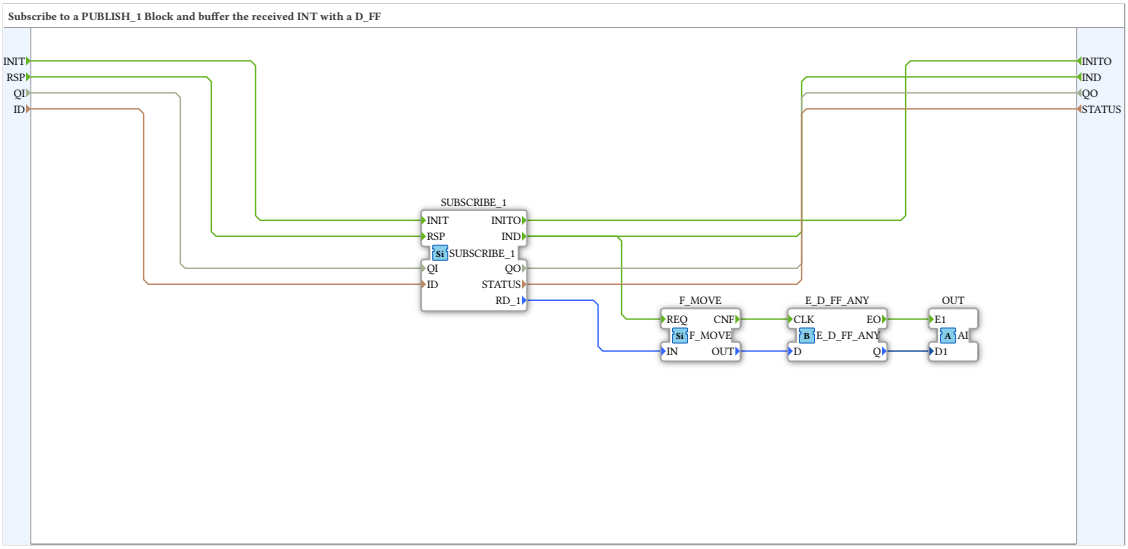
Application Scenarios

- **Network Coupling in AI Applications**: Sending INT signals (e.g., switching commands or status bits) from adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AI adapters.

Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AI_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes an INT value at the adapter level but lacks network functionality. **AI_PUBLISH_1** combines buffering and publishing in a single block.



Conclusion

AI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based INT processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AI interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based INT processing.

AI_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AI adapter**. It subscribes to a publish channel configured via `ID` and provides the received **INT** value, buffered via a D flip-flop (E_D_FF_ANY), at the adapter plug `OUT`. This allows for the clean integration of network communication and INT signal processing in the AI adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AI	Plug (Output)	Buffered received INT value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.

5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

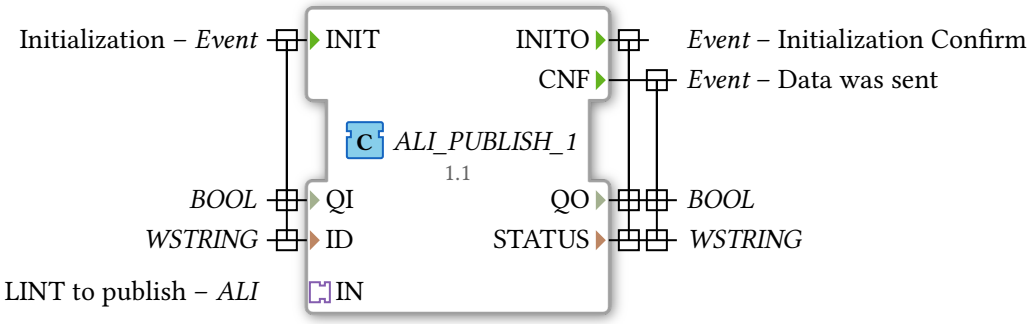
- **Buffering with D flip-flop**: The received INT value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AI adapter interface is visible externally.

State Overview

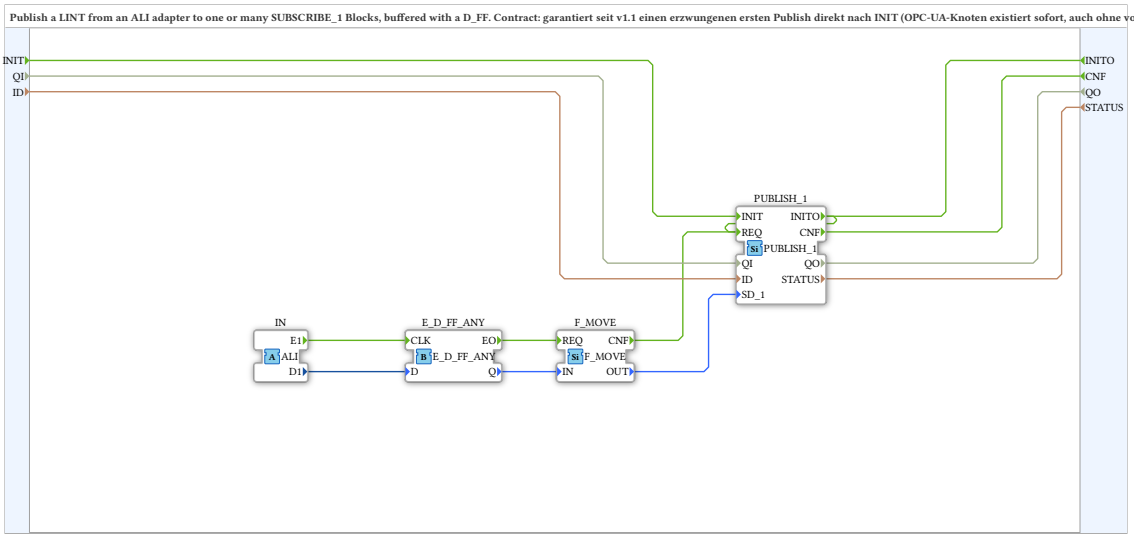
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Receipt**: At `IND`, the received INT value is transferred to the internal D flip-flop and output via `OUT`.

Application Scenarios

- **Network Coupling in AI Applications**: Receiving INT signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AI adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a clean fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AI adapters.



Comparison with Similar Building Blocks



- **SUBSCRIBE_1**: The standard building block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AI_SUBSCRIBE_1** encapsulates this building block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes an INT value at the adapter level but lacks network functionality. **AI_SUBSCRIBE_1** combines subscribing and buffering in a single building block.

Conclusion

AI_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based INT processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AI interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

ALI_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The **ALI_PUBLISH_1** function block is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **ALI adapter**. A **LINT** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::ALI	Socket (Input)	LINT value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the ALI socket `IN` sends an event to `IN.E1`, the LINT value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then transmitted externally.

Technical Features

- **Buffering with D-Flip-Flop**: The LINT value to be transmitted is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the ALI adapter interface is visible externally.

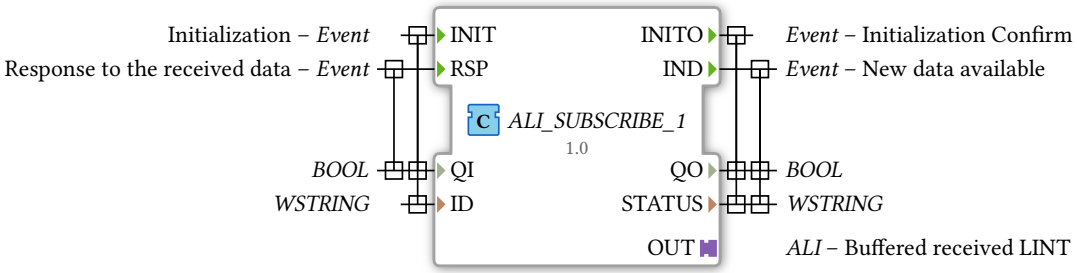
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the ALI socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

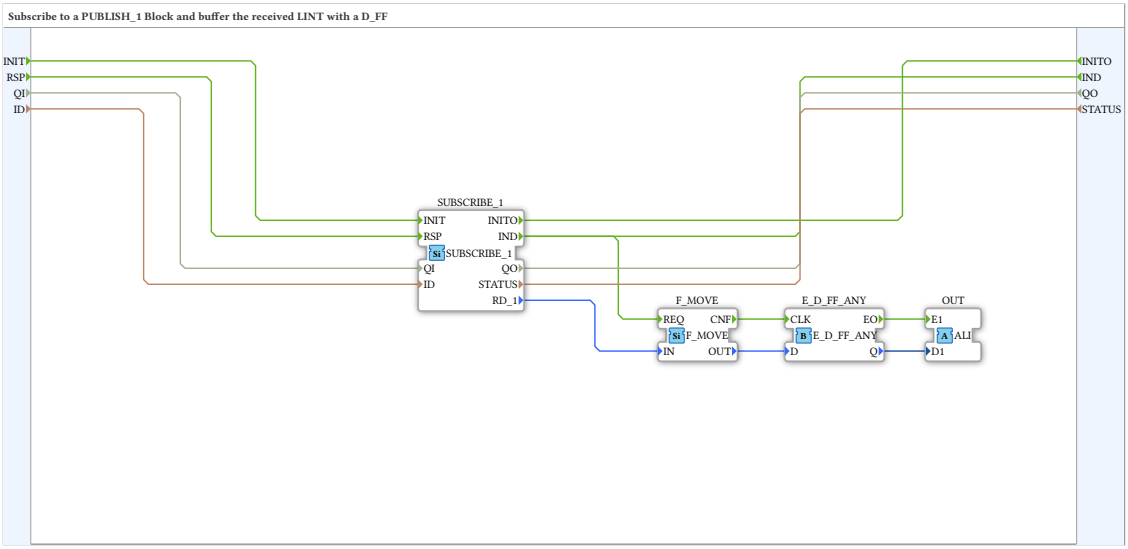
Application Scenarios

- **Network Coupling in ALI Applications**: Sending LINT signals (e.g., switching commands or status bits) from the adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on ALI adapters.

Comparison with Similar Function Blocks



- **PUBLISH_1**: The standard function block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **ALI_PUBLISH_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the ALI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a LINT value at the adapter level but lacks network functionality. **ALI_PUBLISH_1** combines buffering and publishing in a single function block.



Conclusion

ALI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based LINT processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified ALI interface makes the function block ideal for fully adapter-based IEC 61499 applications.

ALI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based LINT processing.

ALI_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **ALI_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **ALI adapter**. It subscribes to a publish channel configured via `ID` and provides the received **LINT** value, buffered via a D flip-flop (E_D_FF_ANY), at the adapter plug `OUT`. This allows for the clean integration of network communication and LINT signal processing in the ALI adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::ALI	Plug (Output)	Buffered received LINT value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.

5. The event EO of the flip-flop is transferred to the event output OUT.E1, so that downstream components are notified of the new information.

Technical Features

- **Buffering with D flip-flop**: The received LINT value is buffered via an internal iec61499::events::E_D_FF_ANY and remains stable at the output until the next value is received. EO only fires when Q changes.
- **RSP is a no-op for subscribers**: According to source code analysis of 4diac-forte (CCommFB::sendData()), the RSP event in SUBSCRIBE_1 (service type subscriber) does not execute any action – the branch != e_Subscriber is skipped. The event input pair INIT/RSP is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of SUBSCRIBE_1 (including IND/RD_1) is moved internally; only the ALI adapter interface is visible externally.

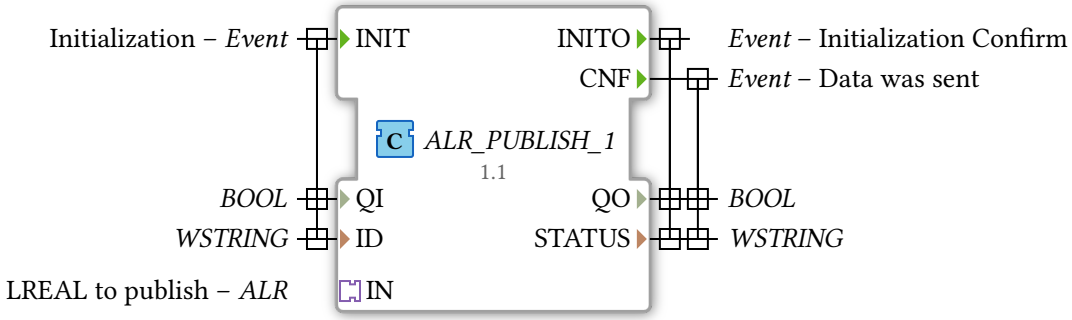
State Overview

1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Reception**: At IND, the received LINT value is transferred to the internal D flip-flop and output via OUT.

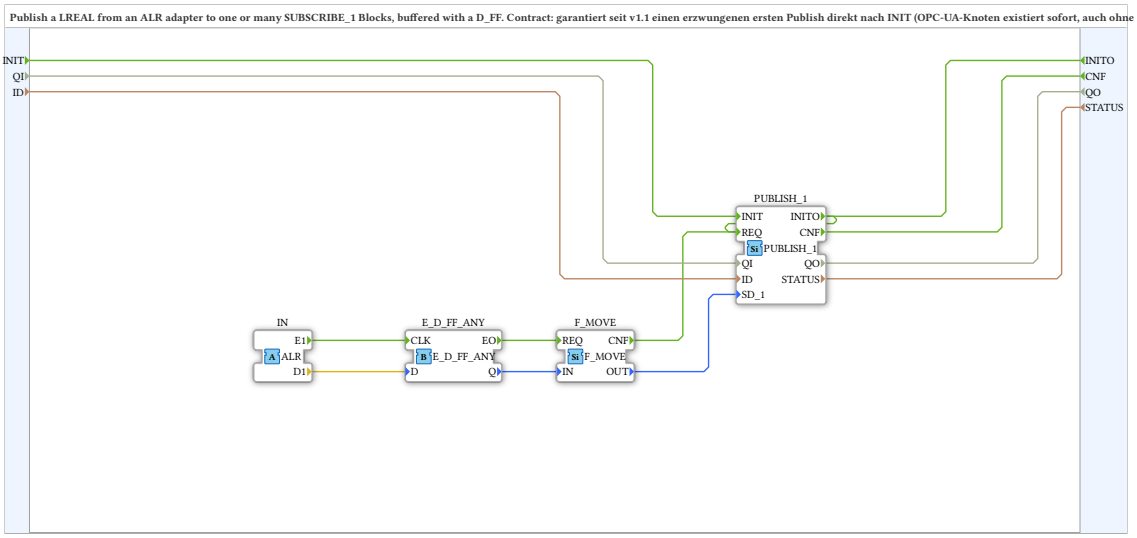
Application Scenarios

- **Network Coupling in ALI Applications**: Receiving LINT signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via ALI adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with AX_PUBLISH_1 and a true event-based E_D_FF_ANY, the feedback between SUBSCRIBE_1 and PUBLISH_1 can be decoupled (a cleaner fix compared to the interim fix with AX_D_FF).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on ALI adapters.

Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (IND, RD_1, ...). **ALI_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (E_D_FF_ANY), and only provides the ALI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a LINT value at the adapter level but lacks network functionality. **ALI_SUBSCRIBE_1** combines subscribing and buffering in a single function block.



Conclusion

ALI_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block SUBSCRIBE_1 with adapter-based LINT processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified ALI interface makes the function block ideal for fully adapter-based IEC 61499 applications.

ALI_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block SUBSCRIBE_1 with adapter-based LINT processing.

ALR_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The **ALR_PUBLISH_1** function block is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **ALR adapter**. An **LREAL** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::ALR	Socket (Input)	LREAL value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the ALR socket `IN` sends an event to `IN.E1`, the LREAL value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then sent externally.

Technical Features

- **Buffering with D-Flip-Flop**: The LREAL value to be transmitted is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the ALR adapter interface is visible externally.

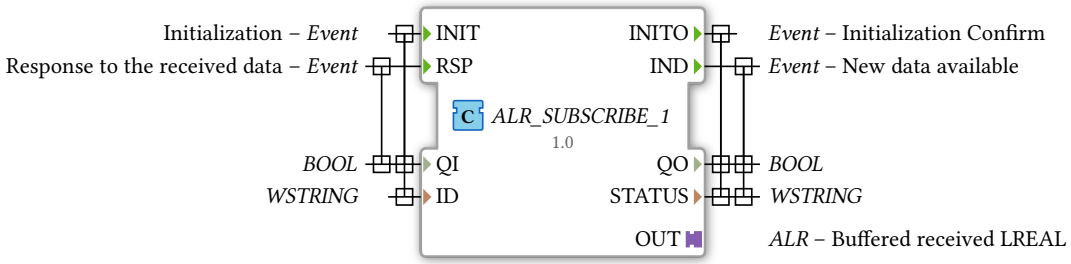
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the ALR socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

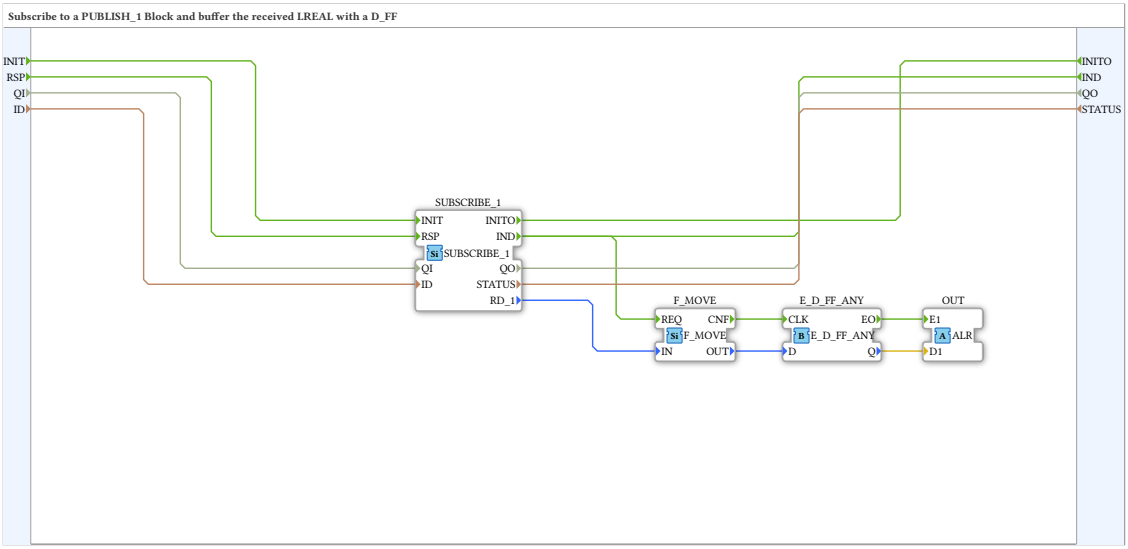
Application Scenarios

- **Network Coupling in ALR Applications**: Sending LREAL signals (e.g., switching commands or status bits) from the adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between the user's own publications and subscriptions is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on ALR adapters.

Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **ALR_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the ALR adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes an LREAL value at the adapter level but lacks network functionality. **ALR_PUBLISH_1** combines buffering and publishing in a single block.



Conclusion

ALR_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based LREAL processing. Internal D flip-flop buffering stabilizes the transmit value and decouples feedback loops; the simplified ALR interface makes the function block ideal for fully adapter-based IEC 61499 applications.

ALR_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based LREAL processing.

ALR_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **ALR adapter**. It subscribes to a publish channel configured via `ID` and provides the received **LREAL** value, buffered via a D flip-flop (E_D_FF_ANY), at the adapter plug `OUT`. This allows for clean integration of network communication and LREAL signal processing in the ALR adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::ALR	Plug (Output)	Buffered received LREAL value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.

5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

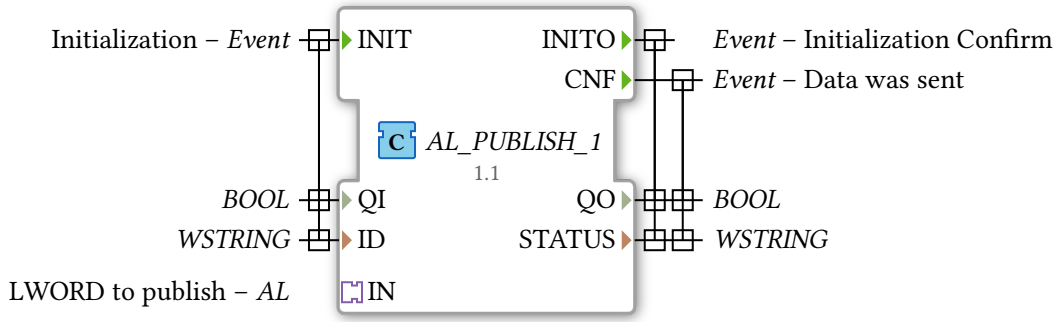
- **Buffering with D flip-flop**: The received LREAL value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the ALR adapter interface is visible externally.

State Overview

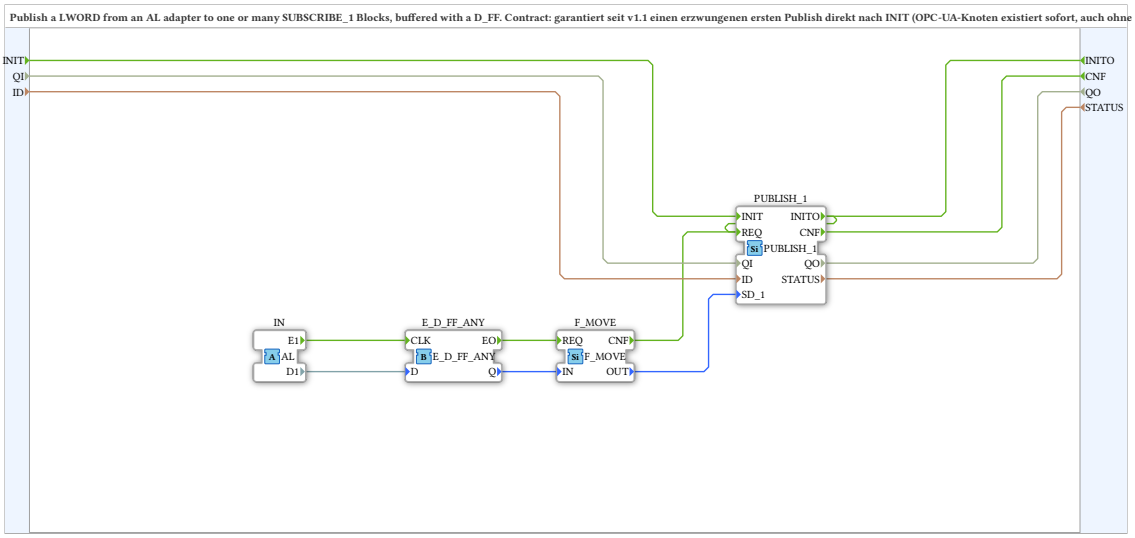
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Receipt**: At `IND`, the received LREAL value is transferred to the internal D flip-flop and output via `OUT`.

Application Scenarios

- **Network Coupling in ALR Applications**: Receiving LREAL signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via ALR adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a clean fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on ALR adapters.



Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **ALR_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the ALR adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes an LREAL value at the adapter level but lacks network functionality. **ALR_SUBSCRIBE_1** combines subscribing and buffering in a single function block.

Conclusion

ALR_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based LREAL processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified ALR interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AL_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AL adapter**. An **LWORD** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AL	Socket (Input)	LWORD value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AL socket `IN` sends an event to `IN.E1`, the LWORD value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then sent out.

Technical Features

- **Buffering with D-Flip-Flop**: The LWORD value to be sent is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents an input value that changes during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AL adapter interface is visible externally.

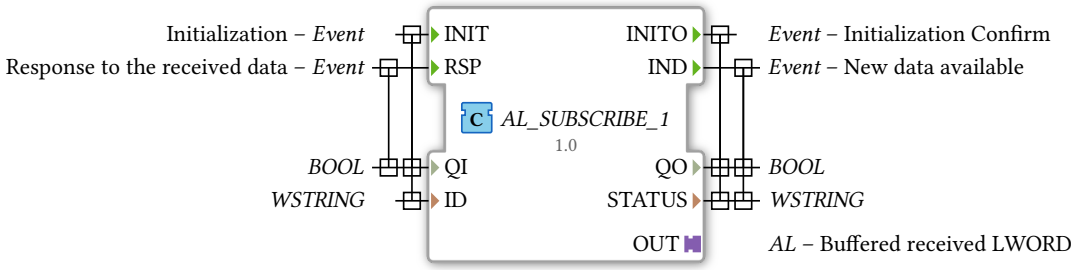
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AL socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

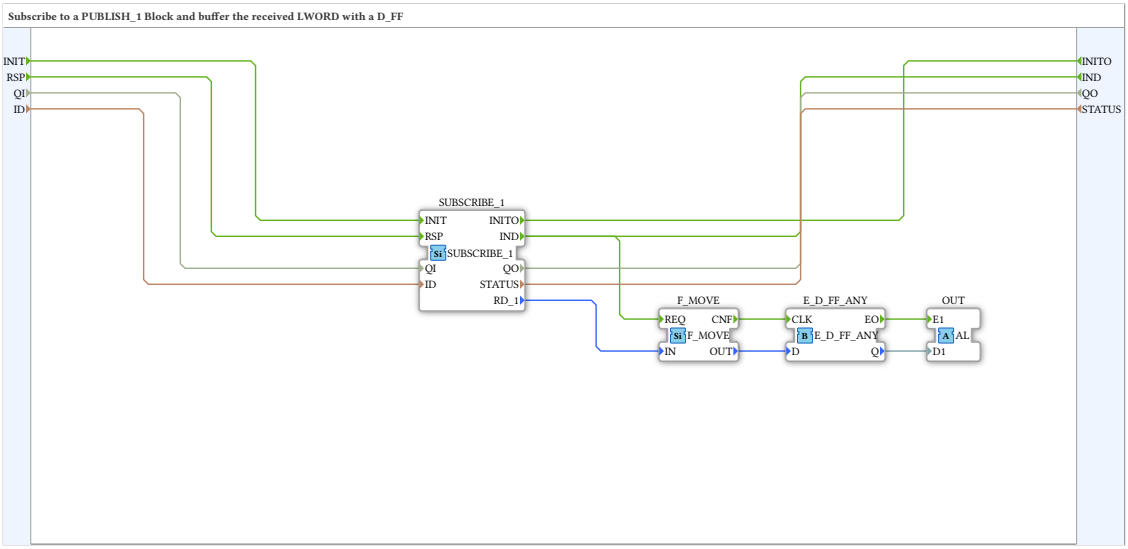
Application Scenarios

- **Network Coupling in AL Applications**: Sending LWORD signals (e.g., switching commands or status bits) from adapter-based logic to remote receivers via Publish/Subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AL adapters.

Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AL_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AL adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes an LWORD value at the adapter level but lacks network functionality. **AL_PUBLISH_1** combines buffering and publishing in a single block.



Conclusion

AL_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based LWORD processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AL interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AL_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based LWORD processing.

AL_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AL adapter**. It subscribes to a publish channel configured via `ID` and makes the received **LWORD** value buffered via a D flip-flop (E_D_FF_ANY) available at the adapter plug `OUT`. This allows for clean integration of network communication and LWORD signal processing in the AL adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AL	Plug (Output)	Buffered received LWORD value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.

4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

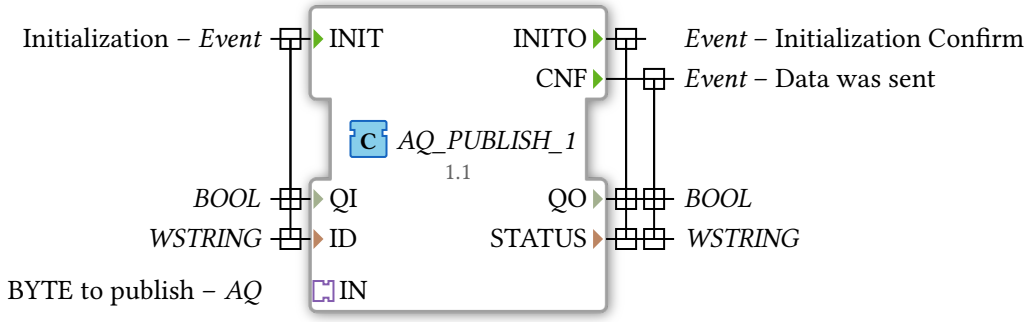
- **Buffering with D flip-flop**: The received LWORD value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AL adapter interface is visible externally.

State Overview

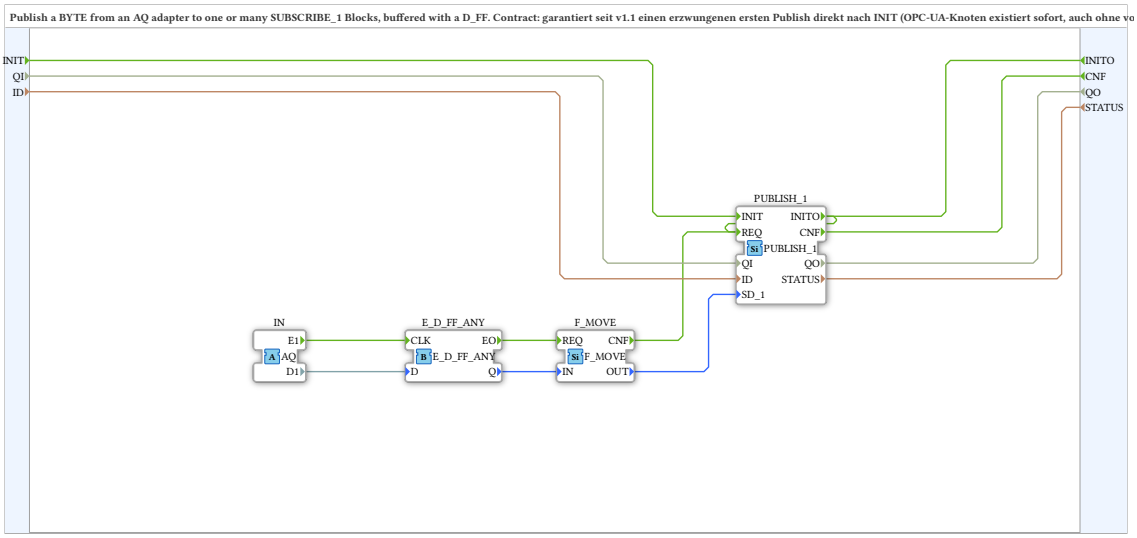
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Received**: At `IND`, the received LWORD value is transferred to the internal D flip-flop and output via `OUT`.

Application Scenarios

- **Network Coupling in AL Applications**: Receiving LWORD signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AL adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a clean fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on AL adapters.



Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AL_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AL adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes an LWORD value at the adapter level but lacks network functionality. **AL_SUBSCRIBE_1** combines subscribing and buffering in a single function block.

Conclusion

AL_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based LWORD processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AL interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AQ_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AQ_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AQ adapter**. A **BYTE** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AQ	Socket (Input)	Byte value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AQ socket `IN` sends an event to `IN.E1`, the corresponding BYTE value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then sent externally.

Technical Features

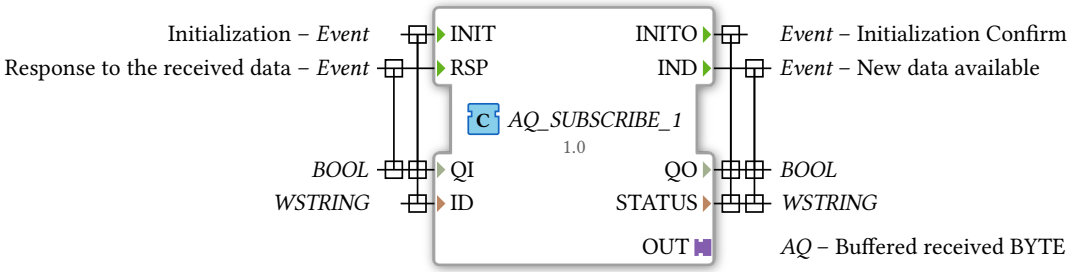
- **Buffering with D-Flip-Flop**: The byte value to be sent is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AQ adapter interface is visible externally.

State Overview

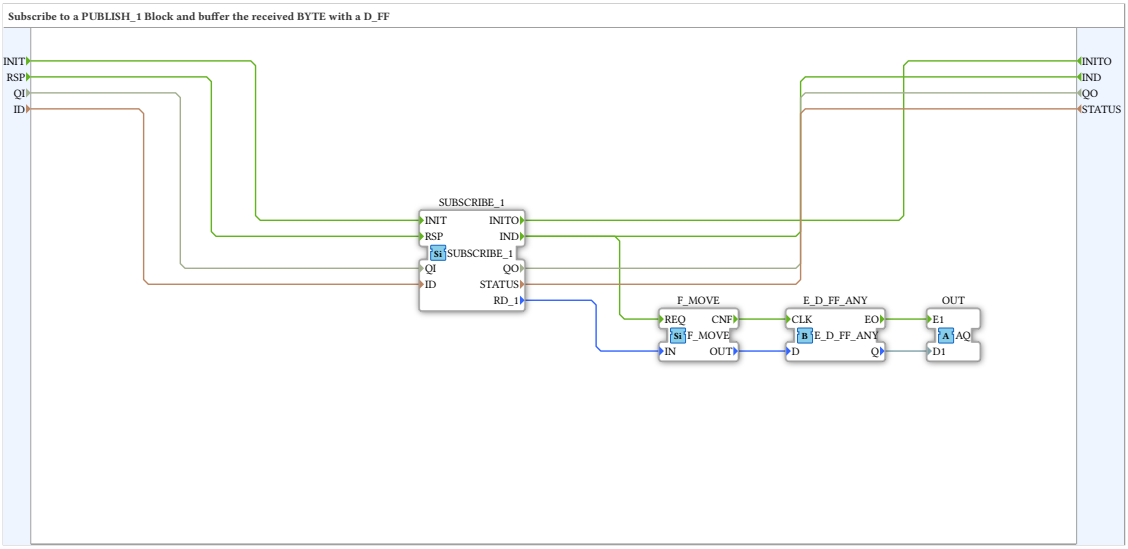
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AQ socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

Application Scenarios

- **Network Coupling in AQ Applications**: Sending BYTE signals (e.g., switching commands or status bits) from the adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AQ adapters.



Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AQ_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AQ adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a byte value at the adapter level but lacks network functionality. **AQ_PUBLISH_1** combines buffering and publishing in a single block.

Conclusion

AQ_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based BYTE processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AQ interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AQ_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AQ_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AQ adapter**. It subscribes to a publish channel configured via `ID` and makes the received **BYTE** value buffered via a D flip-flop (E_D_FF_ANY) available on the adapter plug `OUT`. This allows for clean integration of network communication and BYTE signal processing in the AQ adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AQ	Plug (Output)	Buffered received BYTE value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.

5. The event EO of the flip-flop is transferred to the event output OUT.E1, so that downstream components are notified of the new information.

Technical Features

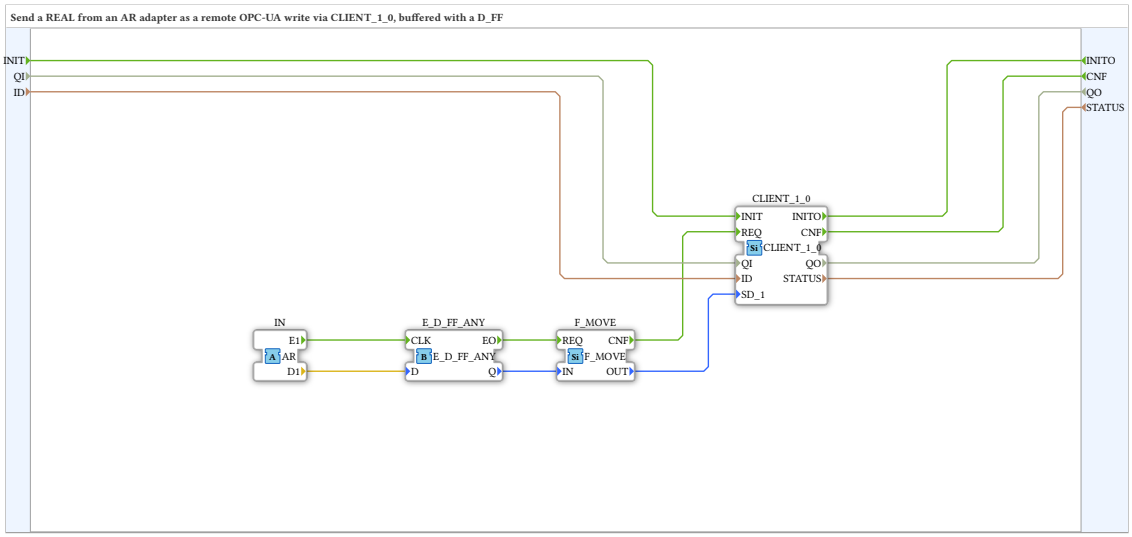
- **Buffering with D flip-flop**: The received BYTE value is buffered via an internal iec61499::events::E_D_FF_ANY and remains stable at the output until the next value is received. EO only fires when Q changes.
- **RSP is a no-op for subscribers**: According to source code analysis of 4diac-forte (CCommFB::sendData()), the RSP event in SUBSCRIBE_1 (service type subscriber) does not execute any action – the branch != e_Subscriber is skipped. The event input pair INIT/RSP is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of SUBSCRIBE_1 (including IND/RD_1) is moved internally; only the AQ adapter interface is visible externally.

State Overview

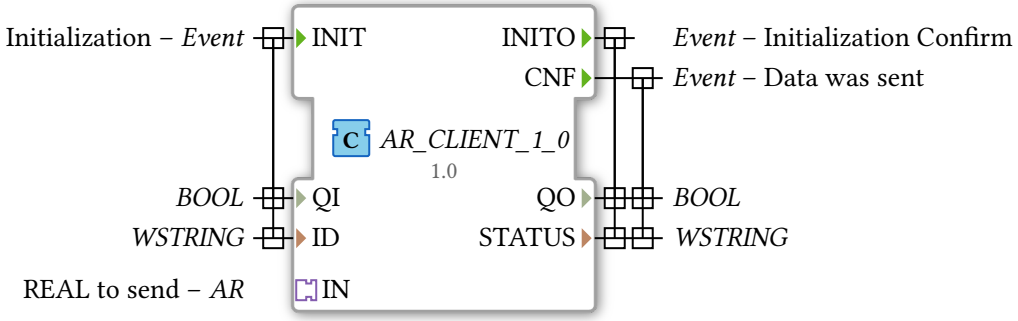
1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Received**: At IND, the received byte value is transferred to the internal D flip-flop and output via OUT.

Application Scenarios

- **Network Coupling in AQ Applications**: Receiving BYTE signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AQ adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with AX_PUBLISH_1 and a true event-based E_D_FF_ANY, the feedback between SUBSCRIBE_1 and PUBLISH_1 can be decoupled (a cleaner fix compared to the interim fix with AX_D_FF).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on AQ adapters.



Comparison with Similar Components



- **SUBSCRIBE_1**: The standard component exposes its interface as events/variables (IND, RD_1, …). **AQ_SUBSCRIBE_1** encapsulates this component, buffers the value with a D flip-flop (E_D_FF_ANY), and only provides the AQ adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a byte value at the adapter level but lacks network functionality. **AQ_SUBSCRIBE_1** combines subscribing and buffering in a single component.

Conclusion

AQ_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block SUBSCRIBE_1 with adapter-based BYTE processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AQ interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AR_CLIENT_1_0

• – ◦ • – ◦ • – ◦ •

Introduction

The **AR_CLIENT_1_0** function block is a composite function block that encapsulates the network-based `CLIENT_1_0` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AR adapter** (`REAL` data type). A **REAL** value present at the adapter socket `IN` is buffered via an internal `E_D_FF_ANY` flip-flop and then sent via `CLIENT_1_0` as an OPC UA **Write** or `CALL_METHOD` invocation to the remote node configured under `ID`.

Unlike **AR_PUBLISH_1** (local publish/subscribe), `CLIENT_1_0` actively writes to a **remote** server.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, connected to `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, connected to `QO` and `STATUS`
- **CNF** (Event): Confirmation that data was sent, connected to `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Input qualifier, opens (TRUE) or closes (FALSE) the connection to the server
- **ID** (WSTRING): Connection identifier (OPC UA address of the target node, e.g., `opc_ua[WRITE;opc.tcp://192.168.1.12:4840#;...]`)

Data Outputs

- **QO** (BOOL): Output qualifier, connection status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapters

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AR	Socket (Input)	REAL value to be sent

Functionality

1. The `INIT` event initializes the internal `CLIENT_1_0` block with `QI` and `ID`, establishing the connection to the remote server and acknowledging with `INITO` upon success.
2. When the AR socket `IN` receives an event on `IN.E1`, the REAL value at `IN.D1` is latched into the internal `E_D_FF_ANY` flip-flop.
3. The flip-flop holds the value stable and generates event `EO`.
4. `EO` triggers `F_MOVE` (`REAL` data type) to supply `CLIENT_1_0.SD_1` and fire the send event `REQ` on `CLIENT_1_0`.
5. After successful transmission, `CLIENT_1_0` confirms with `CNF`.

Technical Features

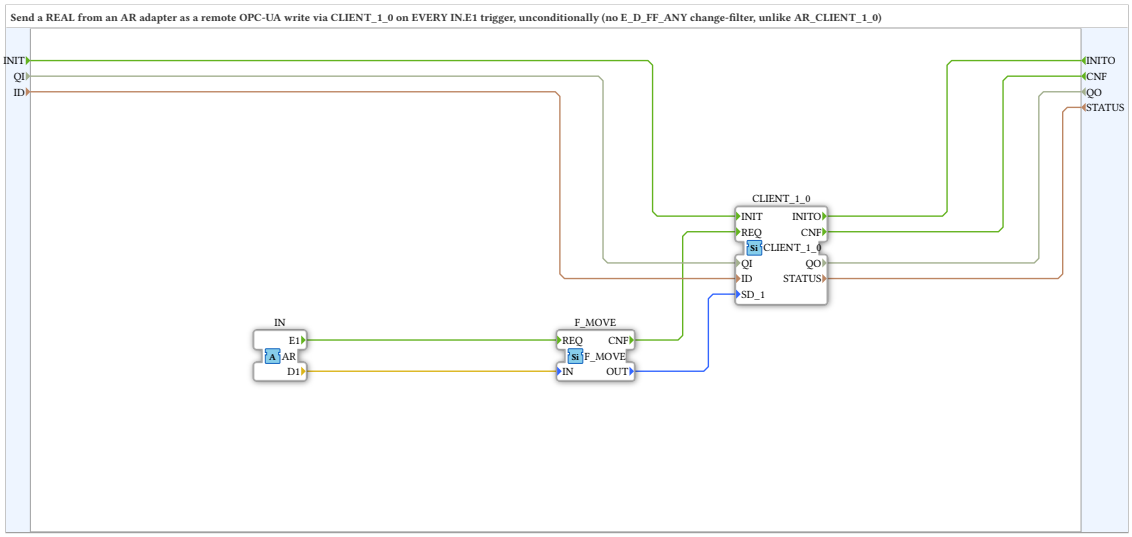
- **Buffering with E_D_FF_ANY**: The REAL value to be sent is buffered using an internal `E_D_FF_ANY`, preventing value instability during transmission.
- **Remote Write / Call Method**: `CLIENT_1_0` directly addresses a remote OPC UA server to transfer analog sensor readings or setpoints.
- **Encapsulation**: The raw `CLIENT_1_0` event/data interface is kept internal; only the clean AR adapter interface is exposed.

State Overview

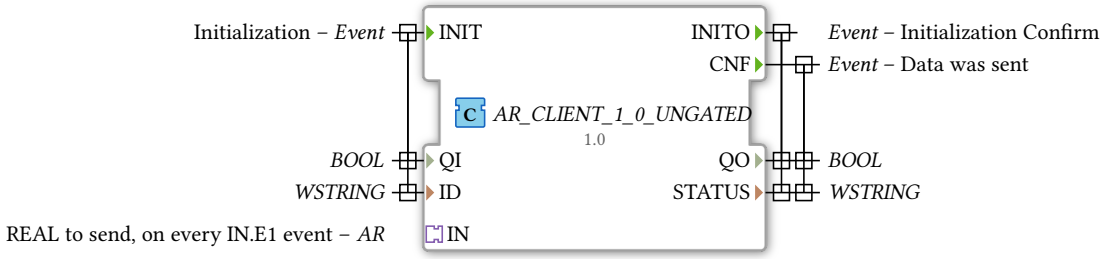
1. **Uninitialized**: The block waits for the `INIT` event.
2. **Initialized**: Connection to the remote server is established; ready to send.
3. **Send Active**: An event on the AR socket buffers the REAL value and triggers the remote write.

Application Scenarios

- **Remote Sensor Data Transmission**: Sending analog values (e.g. pressure, temperature, position) to a remote controller or HMI via OPC UA.
- **Modular Control Architectures**: Integrating distributed REAL values into libraries built consistently on AR adapters.



Comparison with Similar Blocks



- **AR_CLIENT_1_0_UNGATED**: Omits the internal `E_D_FF_ANY` flip-flop (change filter) and triggers the remote write or method call unconditionally on every `IN.E1` event — ideal for repeated VT/HMI commits of the same value.
- **AX_CLIENT_1_0**: Identical structure, but handles BOOL values via an AX adapter.
- **ATM_CLIENT_1_0**: Identical structure, but handles TIME values via an ATM adapter.
- **AR_PUBLISH_1**: Encapsulates `PUBLISH_1` instead of `CLIENT_1_0` for local publish/subscribe.

Conclusion

AR_CLIENT_1_0 bridges connection-oriented OPC UA remote writing with adapter-based REAL data handling.

AR_CLIENT_1_0_UNGATED

• – ◦ • – ◦ • – ◦ •

Introduction

The **AR_CLIENT_1_0_UNGATED** function block is a composite function block from the `adapter::net` package. It encapsulates the network-based `CLIENT_1_0` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AR adapter** (`IN`, `REAL` data type).

Unlike **AR_CLIENT_1_0**, this block **does not** contain an internal `E_D_FF_ANY` value filter (Send-on-Change). Every incoming event on `IN.E1` triggers a send request to `CLIENT_1_0.REQ` **unconditionally and without filtering**.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, connected to `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, connected to `QO` and `STATUS`
- **CNF** (Event): Confirmation that data was sent, connected to `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Input qualifier, opens (TRUE) or closes (FALSE) the connection to the server
- **ID** (WSTRING): Connection identifier (OPC UA address of the target node, e.g., `opc_ua[CALL_METHOD;opc.tcp://192.168.1.12:4840#;...]`)

Data Outputs

- **QO** (BOOL): Output qualifier, connection status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapters

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AR	Socket (Input)	REAL value to be sent (transmitted on every `IN.E1` trigger)

Functionality

1. The `INIT` event initializes the internal `CLIENT_1_0` block with `QI` and `ID`, acknowledging with `INITO` upon success.
2. When the AR socket `IN` receives an event on `IN.E1`, the event is forwarded **directly** to `F_MOVE.REQ`.
3. `F_MOVE` (`REAL`) receives the REAL value present at `IN.D1`, passes it to `CLIENT_1_0.SD_1`, and triggers `CLIENT_1_0.REQ`.
4. The `CLIENT_1_0` block executes the OPC UA remote write or method call and confirms with `CNF`.

Technical Features

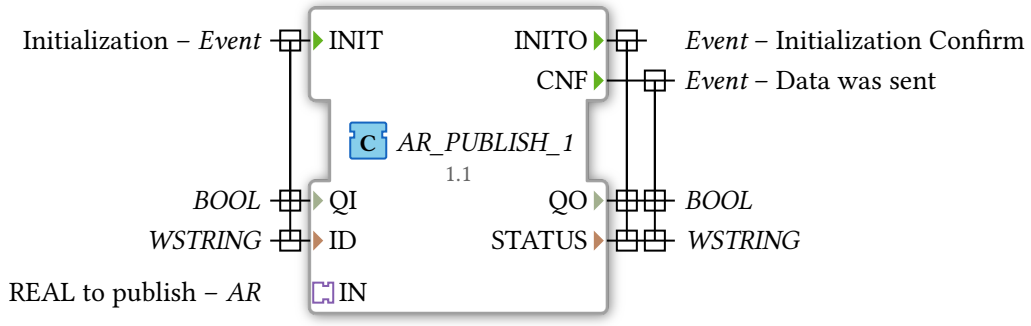
- **Unfiltered Event Triggering (Ungated)**: Because no `E_D_FF_ANY` flip-flop is included, no change filter is applied. Even if value `IN.D1` is identical to the previously transmitted value, a new `IN.E1` event forces execution.
- **Tailored for OPC UA CALL_METHOD / Remote Input**: Essential for user-interface controls (e.g. VT numeric inputs or Web HMIs) where re-committing the same numeric value must reliably invoke the remote RPC method every time.
- **Decoupled from Change-Filter Logic**: While `AR_CLIENT_1_0` is optimized for continuous send-on-change use cases, `AR_CLIENT_1_0_UNGATED` serves event-driven method execution.

State Overview

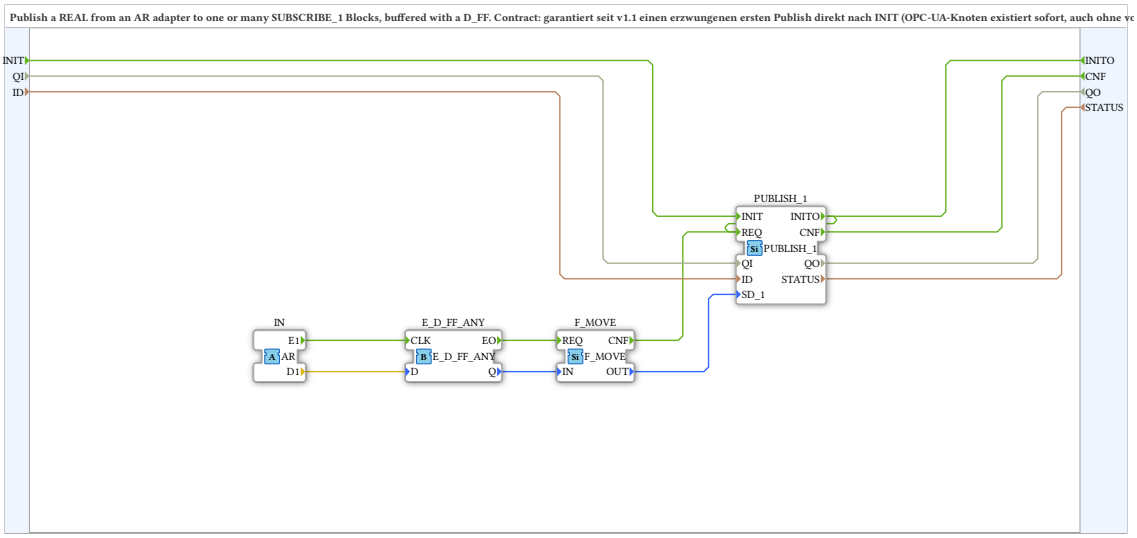
1. **Uninitialized**: The block waits for the `INIT` event.
2. **Initialized**: Connection to the server is established; ready to transmit.
3. **Send Active**: Each `IN.E1` event immediately triggers transmission via `CLIENT_1_0`.

Application Scenarios

- **Remote Method Invocations via VT/HMI**: E.g. `NumericValue_TO_CLIENT_1_0_OPC.SUB` — when an operator confirms a numeric entry on the VT, the OPC UA method must be invoked even if the entered number is unchanged.
- **Event-Driven Command Transmission**: Transferring REAL parameters where the timing of the trigger event conveys independent meaning.



Comparison with Similar Blocks



- **AR_CLIENT_1_0**: Contains an internal `E_D_FF_ANY` flip-flop that filters out unchanged values (Send-on-Change). `AR_CLIENT_1_0_UNGATED` deliberately omits this filter.
- **AX_CLIENT_1_0**: Handles BOOL values with a change filter.
- **ATM_CLIENT_1_0**: Handles TIME values with a change filter.

Conclusion

AR_CLIENT_1_0_UNGATED ensures that every trigger event on the AR adapter interface results in an OPC UA transmission — ideal for remote method calls in HMI and VT applications.

AR_PUBLISH_1

• – ○ • – ○ • – ○ •

The **AR_PUBLISH_1** function block is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AR adapter**. A **REAL** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

REAL value at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

** ## Interface Structure

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`
- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier
- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AR	Socket (Input)	REAL value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AR socket `IN` delivers an event to `IN.E1`, the REAL value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.

4. EO triggers the send event REQ of the internal PUBLISH_1 block. The buffered value Q is transmitted over the data connection as SD_1 and published on the configured channel.
5. After successful transmission, the PUBLISH_1 block confirms with CNF, which is then sent out.

- **Buffering with D-Flip-Flop**: The REAL value to be transmitted is buffered via an internal iec61499::events::E_D_FF_ANY. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based E_D_FF_ANY decouples immediate feedback loops between PUBLISH_1 and SUBSCRIBE_1 (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with AX_D_FF.
- **Encapsulation**: The original event/data interface of PUBLISH_1 (including REQ/SD_1) is moved internally; only the AR adapter interface is visible externally.

1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AR socket buffers the value and triggers transmission via the internal PUBLISH_1 block.

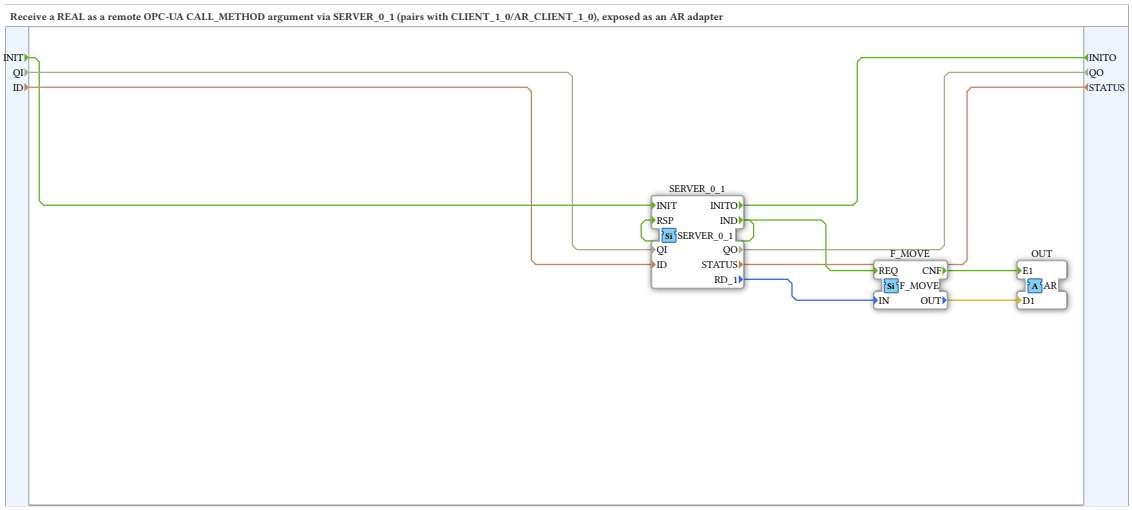
- **Network Coupling in AR Applications**: Sending REAL signals (e.g., switching commands or status bits) from the adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with AX_SUBSCRIBE_1, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AR adapters.
- **PUBLISH_1**: The standard block exposes its interface as events/variables (REQ, SD_1, ...). **AR_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (E_D_FF_ANY), and only provides the AR adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a real value at the adapter level but lacks network functionality. **AR_PUBLISH_1** combines buffering and publishing in a single block.

PUBLISH_1 PUBLISH_1 ## Conclusion

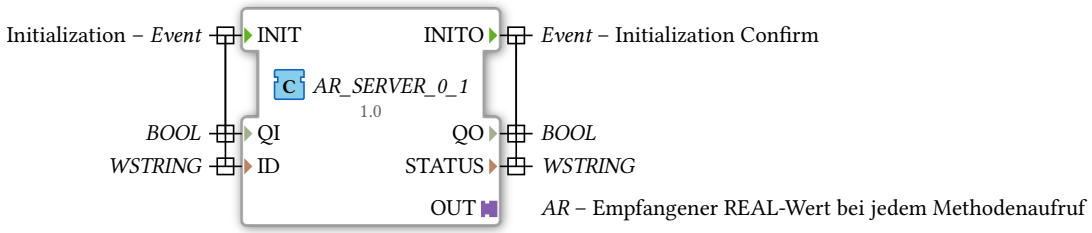
AR_PUBLISH_1 combines the publish/subscribe communication of the standard function block PUBLISH_1 with adapter-based REAL processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AR interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AR_PUBLISH_1 combines the publish/subscribe communication of the standard function block PUBLISH_1 with adapter-based REAL processing.

Technical Features



State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

AR_SERVER_0_1

• – ◦ • – ◦ • – ◦ •

Introduction

The **AR_SERVER_0_1** function block is a composite function block from the `adapter::net` package. It encapsulates the network server block `iec61499::net::SERVER_0_1` and exposes incoming OPC UA method calls (`CALL_METHOD`) for **REAL** arguments as a unidirectional **AR adapter** (`OUT`). It serves as the receiving counterpart to **AR_CLIENT_1_0** (or `CLIENT_1_0`).

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, connected to `QI` and `ID` (forwards to `SERVER_0_1.INIT`)

Event Outputs

- **INITO** (EInit): Initialization confirmation (`SERVER_0_1.INITO`), connected to `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Input qualifier, enables (TRUE) or disables (FALSE) the server
- **ID** (WSTRING): Server identifier (OPC UA server address and method specification)

Data Outputs

- **QO** (BOOL): Output qualifier, server operational status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapters

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AR	Plug (Output)	Received REAL value on each method invocation

Functionality

1. An `INIT` event at `AR_SERVER_0_1` is forwarded to the internal `SERVER_0_1.INIT` input. The server starts the OPC UA endpoint and acknowledges with `INITO` upon success.
2. Upon an incoming method call from a remote client (`CLIENT_1_0`/`AR_CLIENT_1_0`), `SERVER_0_1` emits indication event `IND` and presents the received REAL value at `RD_1`.
3. To prevent response-latency lockups (RSP latency bug), `SERVER_0_1.IND` is directly looped back to `SERVER_0_1.RSP` within the internal network, causing the server to acknowledge the method immediately.
4. Simultaneously, `IND` passes the received value through `F_MOVE` (`REAL` data type) to AR plug `OUT.D1` and fires output event `OUT.E1`.

Technical Features

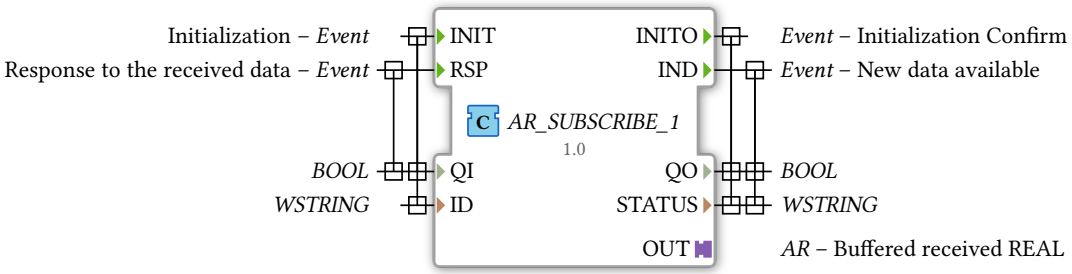
- **Direct RSP Loopback**: To eliminate 4-second server lockups caused by delayed responses, `SERVER_0_1.IND` is internally tied back to `SERVER_0_1.RSP`.
- **Seamless Adapter Integration**: The raw `RD_1` output of `SERVER_0_1` is mapped via `F_MOVE` (REAL) directly onto the AR adapter structure (`OUT.D1` / `OUT.E1`).
- **Receiving Counterpart to `AR_CLIENT_1_0`**: In IEC 61499, a `CLIENT_1_0` block (“Connect to a SERVER_0_1 block”) pairs with a `SERVER_0_1` block.

State Overview

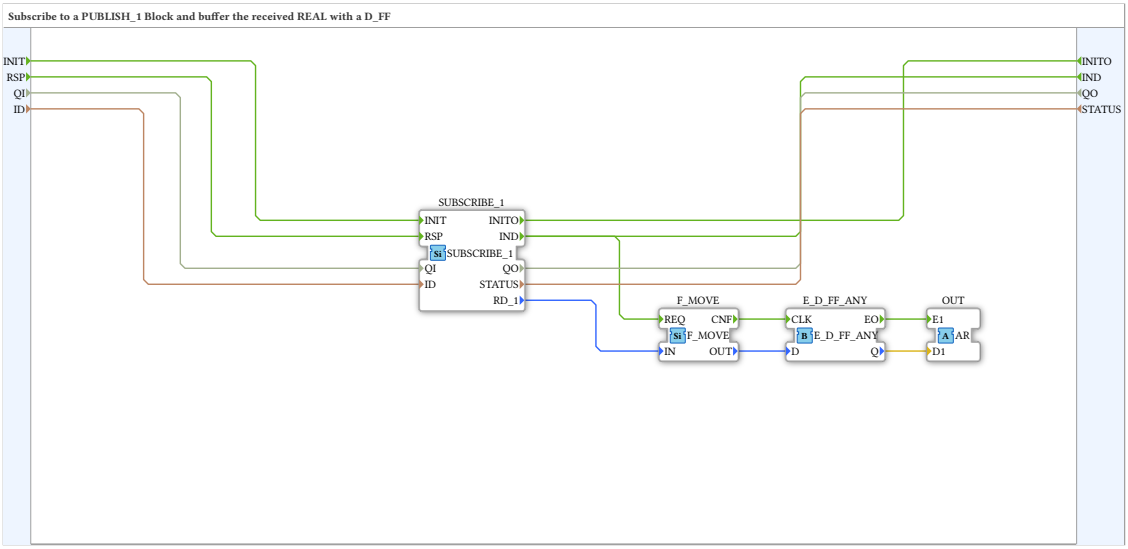
1. **Uninitialized**: The server is inactive and waiting for the `INIT` event.
2. **Listening**: The OPC UA server is active and waiting for method calls from remote clients.
3. **Indication**: A method call arrives; the REAL value is passed to the `OUT` adapter and the response is sent immediately.

Application Scenarios

- **Receiving Remote Setpoints**: Receiving analog setpoints (e.g. target pressure, target speed) from a remote control module via OPC UA `CALL_METHOD`.
- **Modular Server Architectures**: Providing OPC UA method endpoints in applications built consistently on adapters.



Comparison with Similar Blocks



- **AX_SERVER_0_1**: Receives BOOL values via an AX adapter.
- **ATM_SERVER_0_1**: Receives TIME values via an ATM adapter.
- **AR_SUBSCRIBE_1**: Encapsulates `SUBSCRIBE_1` for local publish/subscribe rather than method invocations.

Conclusion

AR_SERVER_0_1 delivers received OPC UA method invocations for REAL values over a clean AR adapter while preventing server response locks.

AR_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AR adapter**. It subscribes to a publish channel configured via `ID` and provides the received **REAL** value, buffered via a D flip-flop (E_D_FF_ANY), at the adapter plug `OUT`. This allows for clean integration of network communication and REAL signal processing in the AR adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AR	Plug (Output)	Buffered received REAL value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.

5. The event EO of the flip-flop is transferred to the event output OUT.E1, so that downstream components are notified of the new information.

Technical Features

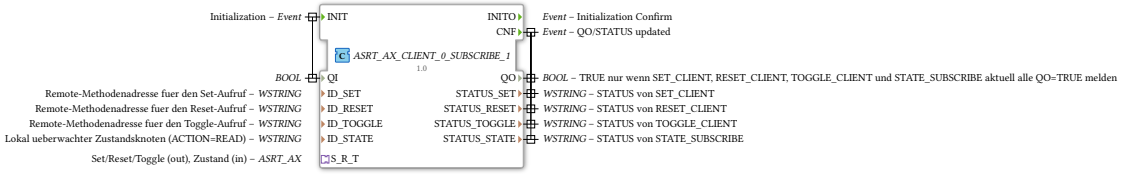
- **Buffering with D flip-flop**: The received REAL value is buffered via an internal iec61499::events::E_D_FF_ANY and remains stable at the output until the next value is received. EO only fires when Q changes.
- **RSP is a no-op for subscribers**: According to source code analysis of 4diac-forte (CCommFB::sendData()), the RSP event in SUBSCRIBE_1 (service type subscriber) does not execute any action – the branch != e_Subscriber is skipped. The event input pair INIT/RSP is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of SUBSCRIBE_1 (including IND/RD_1) is moved internally; only the AR adapter interface is visible externally.

State Overview

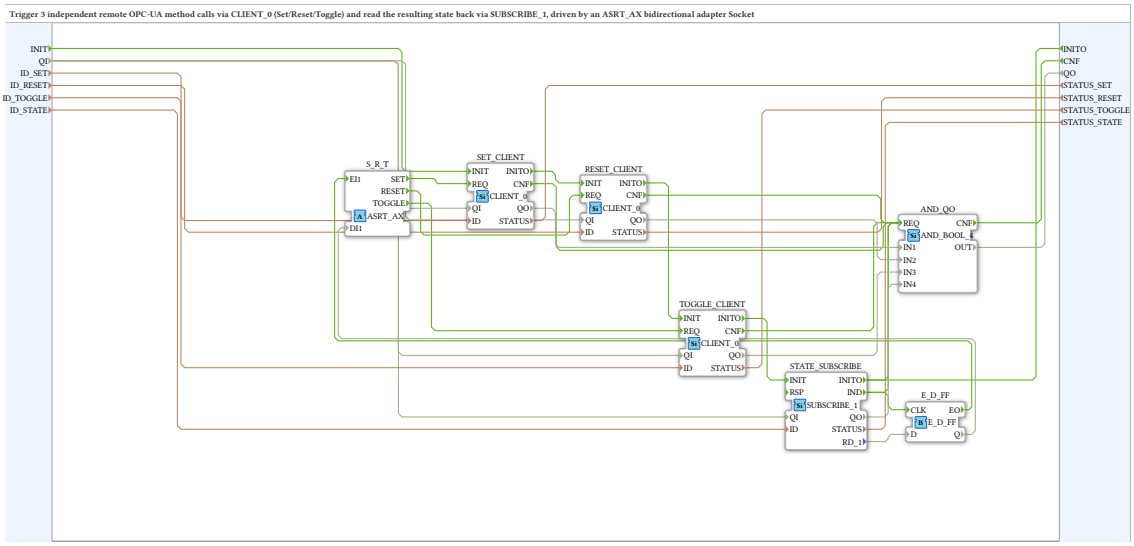
1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Receipt**: At IND, the received REAL value is transferred to the internal D flip-flop and output via OUT.

Application Scenarios

- **Network Coupling in AR Applications**: Receiving real-world signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AR adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with AX_PUBLISH_1 and a true event-based E_D_FF_ANY, the feedback between SUBSCRIBE_1 and PUBLISH_1 can be decoupled (a clean fix compared to the interim fix with AX_D_FF).
- **Modular Control Architectures**: Integrating distributed communication into libraries that consistently rely on AR adapters.



Comparison with Similar Building Blocks



- **SUBSCRIBE_1**: The standard building block exposes its interface as events/variables (IND, RD_1, …). **AR_SUBSCRIBE_1** encapsulates this building block, buffers the value with a D flip-flop (E_D_FF_ANY), and only provides the AR adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a real value at the adapter level but lacks network functionality. **AR_SUBSCRIBE_1** combines subscribing and buffering in a single building block.

Conclusion

AR_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block SUBSCRIBE_1 with adapter-based REAL processing. The internal D flip-flop buffer keeps the received value stable until new data arrives, and the reduced AR interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

ASRT_AX_CLIENT_0_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The **ASRT_AX_CLIENT_0_SUBSCRIBE_1** function block is a composite function block that triggers three independent remote OPC UA **method calls** (Set, Reset, and Toggle), each via its own `CLIENT_0` block, and reads the corresponding state back via `SUBSCRIBE_1` – all behind a single bidirectional **ASRT_AX adapter socket**. It is the variant of ASRT_CLIENT_0 extended with a state channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO`, `STATUS_SET`, `STATUS_RESET`, `STATUS_TOGGLE`, and `STATUS_STATE`
- **CNF** (Event): `QO`/`STATUS` updated, associated with the same variables

Data Inputs

- **QI** (BOOL): Qualifier input for all four internal connections
- **ID_SET** (WSTRING): Remote method address for the Set call
- **ID_RESET** (WSTRING): Remote method address for the Reset call
- **ID_TOGGLE** (WSTRING): Remote method address for the Toggle call
- **ID_STATE** (WSTRING): Locally monitored state node (ACTION=READ)

Data Outputs

- **QO** (BOOL): TRUE only if `SET_CLIENT`, `RESET_CLIENT`, `TOGGLE_CLIENT`, and `STATE_SUBSCRIBE` currently all report `QO = TRUE`
- **STATUS_SET** (WSTRING): Status information from `SET_CLIENT`
- **STATUS_RESET** (WSTRING): Status information from `RESET_CLIENT`
- **STATUS_TOGGLE** (WSTRING): Status information from `TOGGLE_CLIENT`
- **STATUS_STATE** (WSTRING): Status information from `STATE_SUBSCRIBE`

Adapter

Adapter	Type	Direction	Description
S_R_T	adapter::types::bidirectional::ASRT_AX	Socket – Set/Reset/Toggle (output), state (input)	Set/Reset/Toggle out, state back

Functionality

1. Via the `INIT` event, `SET_CLIENT`, `RESET_CLIENT`, `TOGGLE_CLIENT`, and `STATE_SUBSCRIBE` are initialized one after another. After all four have confirmed, `INITO` is reported externally.
2. `S_R_T.SET`, `S_R_T.RESET`, and `S_R_T.TOGGLE` directly trigger the corresponding `CLIENT_0` method calls.
3. As soon as `STATE_SUBSCRIBE` delivers a new state value via `IND`, this clocks the internal **E_D_FF** flip-flop, which captures and holds the value stably.
4. The flip-flop's output `EO` fires `S_R_T.EI1` with the buffered value at `S_R_T.DI1` – the state is reported back over the same adapter used to trigger Set/Reset/Toggle.
5. `AND_QO` (AND_BOOL_4) ANDs the `QO` outputs of all four internal blocks; every confirmation additionally triggers `CNF` externally.

Technical Features

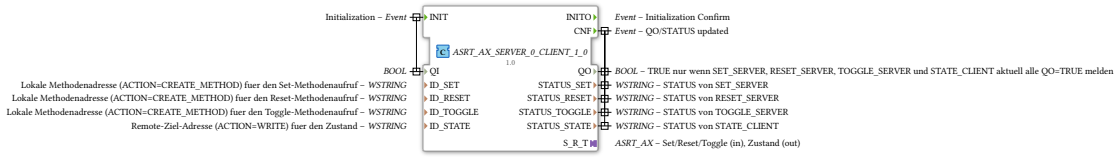
- **Four network connections behind one adapter**: Three `CLIENT_0` instances (Set, Reset, Toggle) and one `SUBSCRIBE_1` (state) are combined into a single bidirectional ASRT_AX interface.
- **Buffering with D flip-flop**: The state received via `SUBSCRIBE_1` is stabilized via an internal `iec61499::events::E_D_FF` before being reported back over the adapter.
- **Sequential initialization**: `SET_CLIENT` → `RESET_CLIENT` → `TOGGLE_CLIENT` → `STATE_SUBSCRIBE` (composite FBTypes chain `INIT`/`INITO` serially through each instance).
- **Encapsulation**: Only the ASRT_AX adapter interface is visible externally.

State Overview

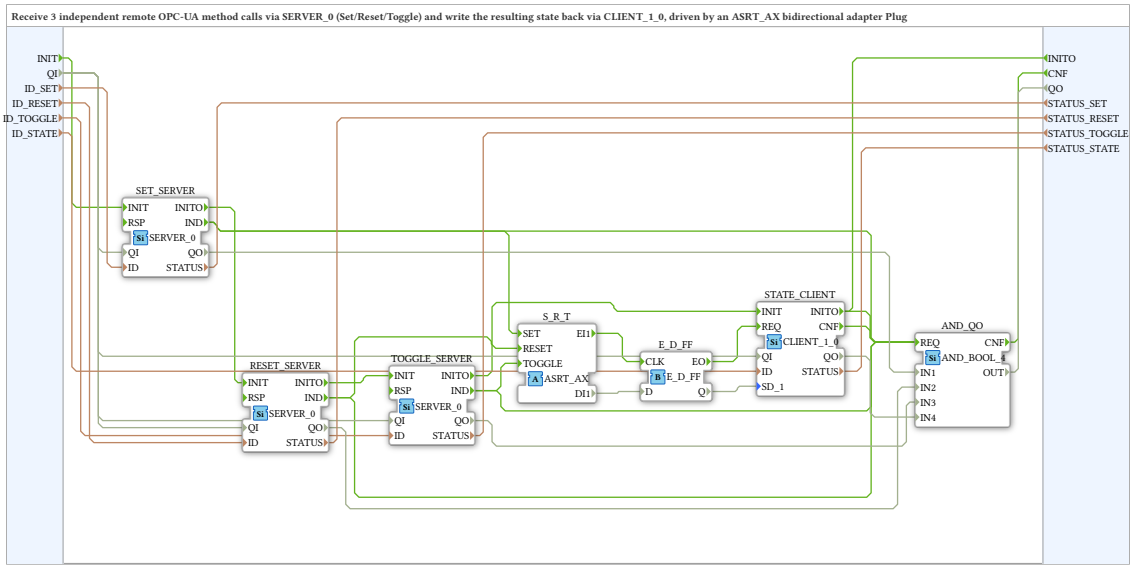
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: All four connections (Set, Reset, Toggle, state subscription) are established.
3. **Send Active**: A Set, Reset, or Toggle event arriving at the adapter triggers the corresponding remote method call.
4. **State Update**: A new value from the subscription is buffered and reported back over the same adapter.

Application Scenarios

- Remotely triggering Set/Reset/Toggle on a remote actuator while simultaneously reading back the resulting state over a single adapter connection
- Reducing manual CLIENT_0/SUBSCRIBE_1 wiring to a single reusable building block



Comparison with Similar Function Blocks



- **ASRT_CLIENT_0**: The same three triggers, but without reading the state back.
- **ASR_AX_CLIENT_0_SUBSCRIBE_1**: The same pattern with only two triggers (no Toggle).
- **ASRT_AX_SERVER_0_CLIENT_1_0**: The server-side counterpart.

Conclusion

ASRT_AX_CLIENT_0_SUBSCRIBE_1 bundles three remote triggers (Set/Reset/Toggle) and a state subscription behind a single bidirectional ASRT_AX adapter, turning a hand-wired combination into a single reusable building block.

ASRT_AX_SERVER_0_CLIENT_1_0

• – ○ • – ○ • – ○ •

Introduction

The **ASRT_AX_SERVER_0_CLIENT_1_0** function block is a composite function block that receives three independent remote OPC UA **method calls** (Set, Reset, and Toggle), each via its own `SERVER_0` block, and writes the resulting state back to a remote node via `CLIENT_1_0` – all behind a single bidirectional **ASRT_AX adapter plug**. It is the server-side counterpart to ASRT_AX_CLIENT_0_SUBSCRIBE_1.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO`, `STATUS_SET`, `STATUS_RESET`, `STATUS_TOGGLE`, and `STATUS_STATE`
- **CNF** (Event): `QO`/`STATUS` updated, associated with the same variables

Data Inputs

- **QI** (BOOL): Qualifier input for all four internal connections
- **ID_SET** (WSTRING): Local method address (ACTION=CREATE_METHOD) for the Set method call
- **ID_RESET** (WSTRING): Local method address (ACTION=CREATE_METHOD) for the Reset method call
- **ID_TOGGLE** (WSTRING): Local method address (ACTION=CREATE_METHOD) for the Toggle method call
- **ID_STATE** (WSTRING): Remote target address (ACTION=WRITE) for the state

Data Outputs

- **QO** (BOOL): TRUE only if `SET_SERVER`, `RESET_SERVER`, `TOGGLE_SERVER`, and `STATE_CLIENT` currently all report `QO = TRUE`
- **STATUS_SET** (WSTRING): Status information from `SET_SERVER`
- **STATUS_RESET** (WSTRING): Status information from `RESET_SERVER`
- **STATUS_TOGGLE** (WSTRING): Status information from `TOGGLE_SERVER`
- **STATUS_STATE** (WSTRING): Status information from `STATE_CLIENT`

Adapter

Adapter	Type	Direction	Description

S_R_T	adapter::types::bidirectional::ASRT_AX	Plug – Set/Reset/Toggle (input), state (output)	Received Set/Reset/Toggle, state out

Functionality

1. Via the `INIT` event, `SET_SERVER`, `RESET_SERVER`, `TOGGLE_SERVER`, and `STATE_CLIENT` are initialized one after another. After all four have confirmed, `INITO` is reported externally.
2. A remote Set, Reset, or Toggle call on the respective `SERVER_0` block triggers `S_R_T.SET`, `S_R_T.RESET`, or `S_R_T.TOGGLE` – all three are thus reported inward via the adapter.
3. As soon as the downstream logic delivers a feedback event `S_R_T.EI1` with data `S_R_T.DI1` via the adapter, this clocks the internal **E_D_FF** flip-flop, which captures and holds the value stably.
4. The flip-flop's output `EO` triggers `STATE_CLIENT.REQ`; the buffered value is sent as an OPC UA write to the remote node configured in `ID_STATE`.
5. `AND_QO` (AND_BOOL_4) ANDs the `QO` outputs of all four internal blocks; every confirmation additionally triggers `CNF` externally.

Technical Features

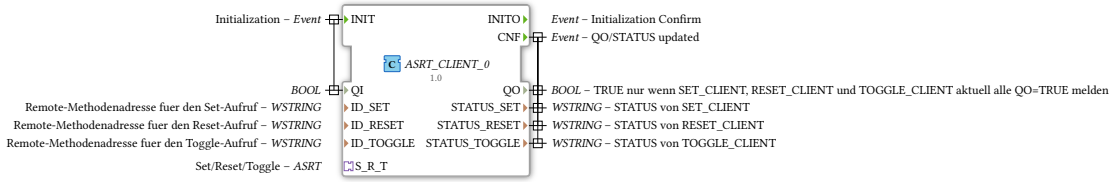
- **Four network connections behind one adapter**: Three `SERVER_0` instances (Set, Reset, Toggle) and one `CLIENT_1_0` (state) are combined into a single bidirectional ASRT_AX interface.
- **Buffering with D flip-flop**: The feedback value reported via the adapter is stabilized via an internal `iec61499::events::E_D_FF` before being sent via `CLIENT_1_0`.
- **Sequential initialization**: `SET_SERVER` → `RESET_SERVER` → `TOGGLE_SERVER` → `STATE_CLIENT` (composite FBTypes chain `INIT`/`INITO` serially through each instance).
- **Encapsulation**: Only the ASRT_AX adapter interface is visible externally.

State Overview

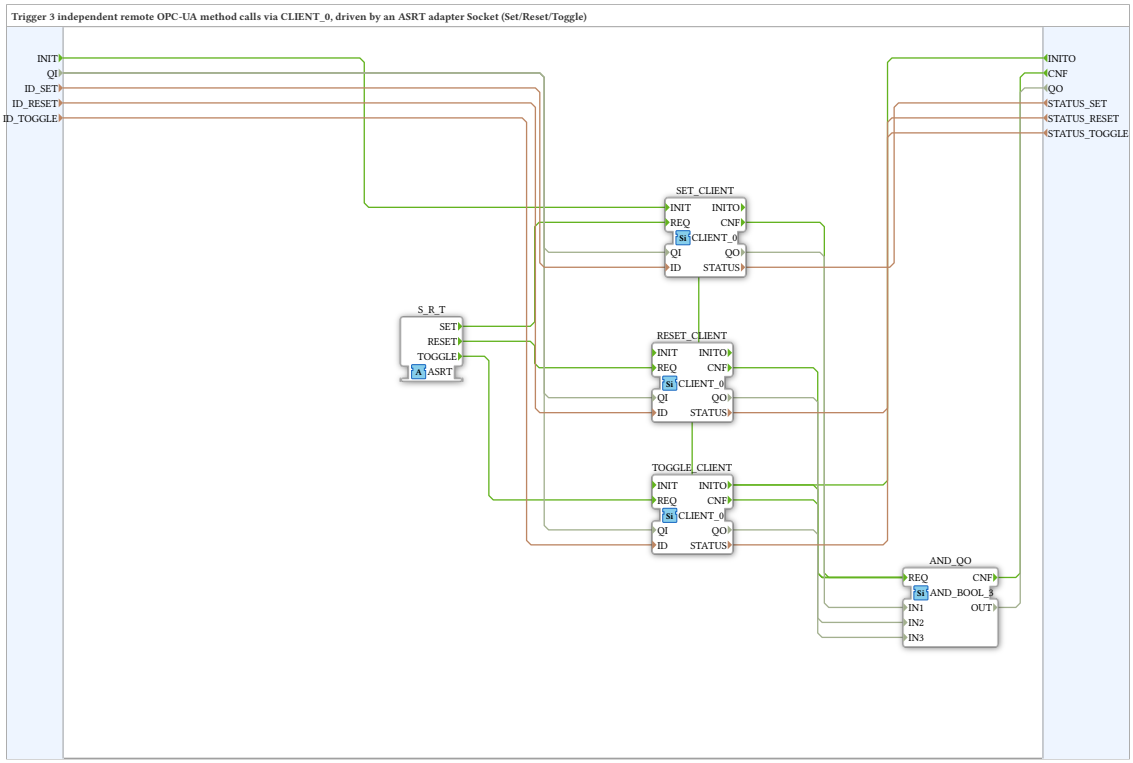
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: All four connections (Set, Reset, Toggle server, state client) are established.
3. **Receive Active**: A remote Set, Reset, or Toggle call is reported to the internal logic via the adapter.
4. **State Write**: A feedback value from the internal logic is buffered and sent via remote write to the configured target node.

Application Scenarios

- Receiving remote Set/Reset/Toggle calls while simultaneously writing the resulting state back to a different remote node over a single adapter connection
- Server-side counterpart to ASRT_AX_CLIENT_0_SUBSCRIBE_1 in distributed control architectures



Comparison with Similar Function Blocks



- **ASRT_AX_CLIENT_0_SUBSCRIBE_1**: The client/calling counterpart.
- **ASR_AX_SERVER_0_CLIENT_1_0**: The same pattern with only two receiving servers (no Toggle).

Conclusion

ASRT_AX_SERVER_0_CLIENT_1_0 bundles three receiving servers (Set/Reset/Toggle) and a state-writing client behind a single bidirectional ASRT_AX adapter, forming the server-side counterpart to ASRT_AX_CLIENT_0_SUBSCRIBE_1.

ASRT_CLIENT_0

• – ○ • – ○ • – ○ •

Introduction

The **ASRT_CLIENT_0** function block is a composite function block that triggers three independent remote OPC UA **method calls** (Set, Reset, and Toggle), each via its own `CLIENT_0` block, controlled through a single unidirectional **ASRT adapter socket**. It is the variant of ASR_CLIENT_0 extended with a third trigger.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO`, `STATUS_SET`, `STATUS_RESET`, and `STATUS_TOGGLE`
- **CNF** (Event): Confirmation that one of the method calls has been sent, associated with the same status variables

Data Inputs

- **QI** (BOOL): Qualifier input, opens (TRUE) or closes (FALSE) all three connections
- **ID_SET** (WSTRING): Remote method address for the Set call
- **ID_RESET** (WSTRING): Remote method address for the Reset call
- **ID_TOGGLE** (WSTRING): Remote method address for the Toggle call

Data Outputs

- **QO** (BOOL): TRUE only if `SET_CLIENT`, `RESET_CLIENT`, and `TOGGLE_CLIENT` currently all report `QO = TRUE`
- **STATUS_SET** (WSTRING): Status information from `SET_CLIENT`
- **STATUS_RESET** (WSTRING): Status information from `RESET_CLIENT`
- **STATUS_TOGGLE** (WSTRING): Status information from `TOGGLE_CLIENT`

Adapter

Adapter	Type	Direction	Description
S_R_T	adapter::types::unidirectional::ASRT	Socket (Input)	Set/Reset/Toggle

Functionality

1. Via the `INIT` event, the internal `SET_CLIENT`, `RESET_CLIENT`, and `TOGGLE_CLIENT` blocks are initialized one after another (chained serially through `INIT`/`INITO`) with `QI` and their respective `ID`. After all three have confirmed, `INITO` is reported externally.
2. An event at the adapter socket `S_R_T.SET`, `S_R_T.RESET`, or `S_R_T.TOGGLE` directly triggers the corresponding `CLIENT_0` method call.
3. All three `CLIENT_0` instances confirm independently with `CNF`, which is forwarded externally in each case.
4. The `AND_QO` block (AND_BOOL_3) ANDs the `QO` outputs of all three `CLIENT_0` instances into a single `QO`.

Technical Features

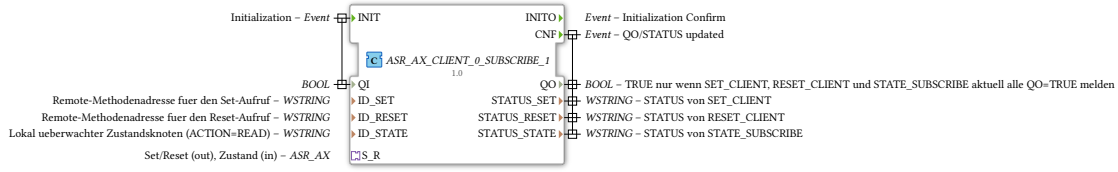
- **Three parallel CLIENT_0 instances**: Set, Reset, and Toggle are handled by separate `CLIENT_0` blocks (different `ID`s, independent connections).
- **Sequential initialization**: The three internal blocks are initialized one after another (`SET_CLIENT.INITO` → `RESET_CLIENT.INIT` → `TOGGLE_CLIENT.INIT`), since composite FBTypes must explicitly chain their `INIT`/`INITO` through each instance in series.
- **Encapsulation**: Only the ASRT adapter interface is visible externally.

State Overview

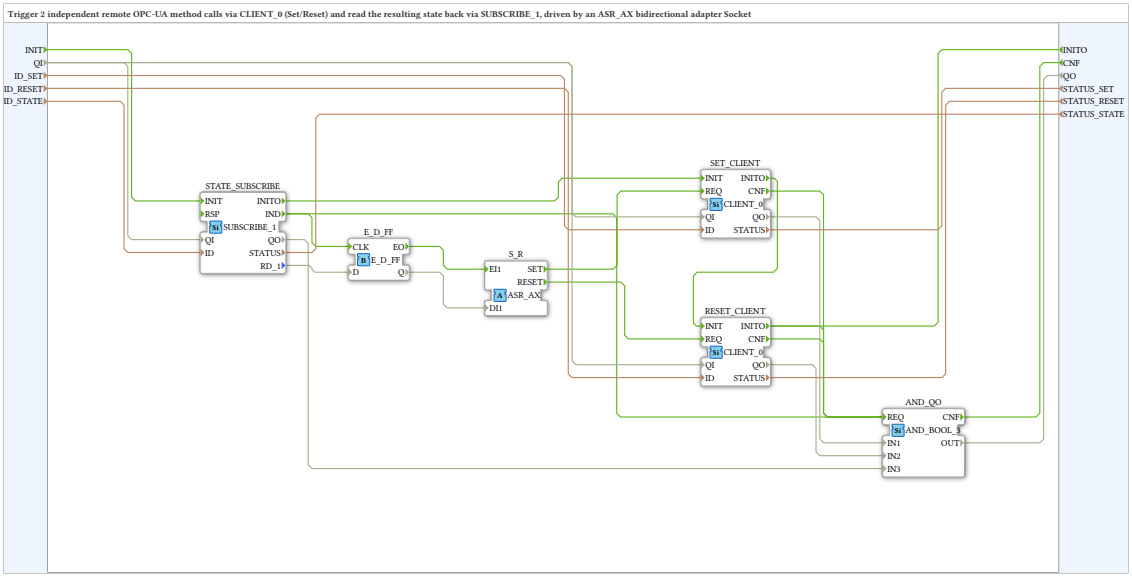
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: All three connections are established, the block is ready to trigger Set, Reset, or Toggle calls.
3. **Send Active**: An event arriving at the ASRT socket triggers the corresponding remote method call.

Application Scenarios

- Remotely triggering three independent remote actions (Set/Reset/Toggle) through a single adapter, e.g. to switch a remote actuator with an additional toggle function
- Network coupling in ASRT-adapter-based applications



Comparison with Similar Function Blocks



- **ASR_CLIENT_0**: The same base structure with only two triggers (no Toggle).
- **AE_CLIENT_0**: Reduces the same pattern to a single trigger.
- **ASRT_AX_CLIENT_0_SUBSCRIBE_1**: Combines the same three `CLIENT_0` triggers with an additional `SUBSCRIBE_1` state channel behind a bidirectional adapter.

Conclusion

ASRT_CLIENT_0 bundles three independent remote method calls (Set/Reset/Toggle) behind a single ASRT adapter socket, making it suitable for applications where a remote actuator is switched via three separate OPC UA methods.

ASR_AX_CLIENT_0_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The **ASR_AX_CLIENT_0_SUBSCRIBE_1** function block is a composite function block that triggers two independent remote OPC UA **method calls** (Set and Reset), each via its own `CLIENT_0` block, and reads the corresponding state back via `SUBSCRIBE_1` – all behind a single bidirectional **ASR_AX adapter socket**. It is the variant of ASR_CLIENT_0 extended with a state channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO`, `STATUS_SET`, `STATUS_RESET`, and `STATUS_STATE`
- **CNF** (Event): `QO`/`STATUS` updated, associated with the same variables

Data Inputs

- **QI** (BOOL): Qualifier input for all three internal connections
- **ID_SET** (WSTRING): Remote method address for the Set call
- **ID_RESET** (WSTRING): Remote method address for the Reset call
- **ID_STATE** (WSTRING): Locally monitored state node (ACTION=READ)

Data Outputs

- **QO** (BOOL): TRUE only if `SET_CLIENT`, `RESET_CLIENT`, and `STATE_SUBSCRIBE` currently all report `QO = TRUE`
- **STATUS_SET** (WSTRING): Status information from `SET_CLIENT`
- **STATUS_RESET** (WSTRING): Status information from `RESET_CLIENT`
- **STATUS_STATE** (WSTRING): Status information from `STATE_SUBSCRIBE`

Adapter

Adapter	Type	Direction	Description
S_R	adapter::types::bidirectional::ASR_AX	Socket – Set/Reset (output), state (input)	Set/Reset out, state back

Functionality

1. Via the INIT event, STATE_SUBSCRIBE is initialized first, followed one after another by SET_CLIENT and RESET_CLIENT. After all have confirmed, INITO is reported externally.
2. S_R.SET and S_R.RESET directly trigger the method calls SET_CLIENT.REQ and RESET_CLIENT.REQ respectively.
3. As soon as STATE_SUBSCRIBE delivers a new state value via IND, this clocks the internal **E_D_FF** flip-flop, which captures and holds the value stably.
4. The flip-flop's output EO fires S_R.EI1 with the buffered value at S_R.DI1 – the state is reported back over the same adapter used to trigger Set/Reset.
5. AND_QO (AND_BOOL_3) ANDs the QO outputs of all three internal blocks; every confirmation additionally triggers CNF externally.

Technical Features

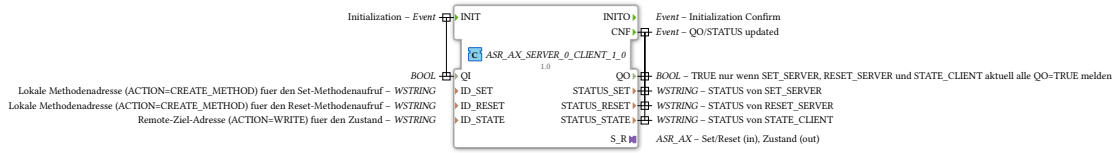
- **Three network connections behind one adapter**: Two CLIENT_0 instances (Set, Reset) and one SUBSCRIBE_1 (state) are combined into a single bidirectional ASR_AX interface.
- **Buffering with D flip-flop**: The state received via SUBSCRIBE_1 is stabilized via an internal iec61499::events::E_D_FF before being reported back over the adapter.
- **Sequential initialization**: STATE_SUBSCRIBE ⟶ SET_CLIENT ⟶ RESET_CLIENT (composite FBTypes chain INIT/INITO serially through each instance).
- **Encapsulation**: Only the ASR_AX adapter interface is visible externally.

State Overview

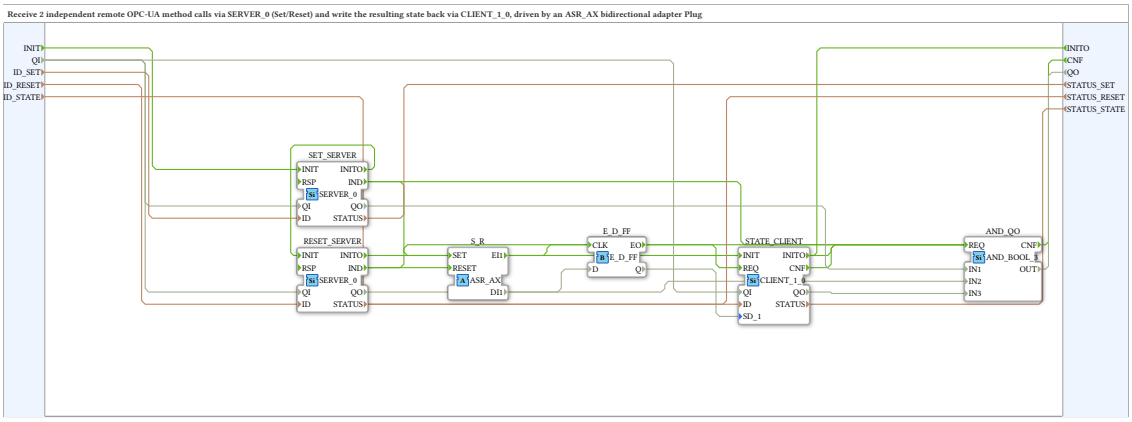
1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: All three connections (Set, Reset, state subscription) are established.
3. **Send Active**: A Set or Reset event arriving at the adapter triggers the corresponding remote method call.
4. **State Update**: A new value from the subscription is buffered and reported back over the same adapter.

Application Scenarios

- Remotely triggering Set/Reset on a remote actuator while simultaneously reading back the resulting state over a single adapter connection
- Reducing manual CLIENT_0/SUBSCRIBE_1 wiring to a single reusable building block



Comparison with Similar Function Blocks



- **ASR_CLIENT_0**: The same two triggers, but without reading the state back.
- **AE_AX_CLIENT_0_SUBSCRIBE_1**: The same pattern with only one trigger instead of two.
- **ASRT_AX_CLIENT_0_SUBSCRIBE_1**: Extends the same pattern with a third trigger (Toggle).
- **ASR_AX_SERVER_0_CLIENT_1_0**: The server-side counterpart.

Conclusion

ASR_AX_CLIENT_0_SUBSCRIBE_1 bundles two remote triggers (Set/Reset) and a state subscription behind a single bidirectional ASR_AX adapter, turning a hand-wired combination into a single reusable building block.

ASR_AX_SERVER_0_CLIENT_1_0

• — ○ • — ○ • — ○ •

Introduction

The **ASR_AX_SERVER_0_CLIENT_1_0** function block is a composite function block that receives two independent remote OPC UA **method calls** (Set and Reset), each via its own `SERVER_0` block, and writes the resulting state back to a remote node via `CLIENT_1_0` – all behind a single bidirectional **ASR_AX adapter plug**. It is the server-side counterpart to ASR_AX_CLIENT_0_SUBSCRIBE_1.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO`, `STATUS_SET`, `STATUS_RESET`, and `STATUS_STATE`
- **CNF** (Event): `QO`/`STATUS` updated, associated with the same variables

Data Inputs

- **QI** (BOOL): Qualifier input for all three internal connections
- **ID_SET** (WSTRING): Local method address (ACTION=CREATE_METHOD) for the Set method call
- **ID_RESET** (WSTRING): Local method address (ACTION=CREATE_METHOD) for the Reset method call
- **ID_STATE** (WSTRING): Remote target address (ACTION=WRITE) for the state

Data Outputs

- **QO** (BOOL): TRUE only if `SET_SERVER`, `RESET_SERVER`, and `STATE_CLIENT` currently all report `QO = TRUE`
- **STATUS_SET** (WSTRING): Status information from `SET_SERVER`
- **STATUS_RESET** (WSTRING): Status information from `RESET_SERVER`
- **STATUS_STATE** (WSTRING): Status information from `STATE_CLIENT`

Adapter

Adapter	Type	Direction	Description
S_R	adapter::types::bidirectional::ASR_AX	Plug – Set/Reset (input), state (output)	Received Set/Reset, state out

Functionality

1. Via the `INIT` event, `SET_SERVER`, `RESET_SERVER`, and `STATE_CLIENT` are initialized one after another. After all three have confirmed, `INITO` is reported externally.
2. A remote Set call on `SET_SERVER` triggers `S_R.SET`, and a remote Reset call on `RESET_SERVER` triggers `S_R.RESET` – both are thus reported inward via the adapter.
3. As soon as the downstream logic delivers a feedback event `S_R.EI1` with data `S_R.DI1` via the adapter, this clocks the internal **E_D_FF** flip-flop, which captures and holds the value stably.

4. The flip-flop's output `EO` triggers `STATE_CLIENT.REQ`; the buffered value is sent as an OPC UA write to the remote node configured in `ID_STATE`.
5. `AND_QO` (AND_BOOL_3) ANDs the `QO` outputs of all three internal blocks; every confirmation additionally triggers `CNF` externally.

Technical Features

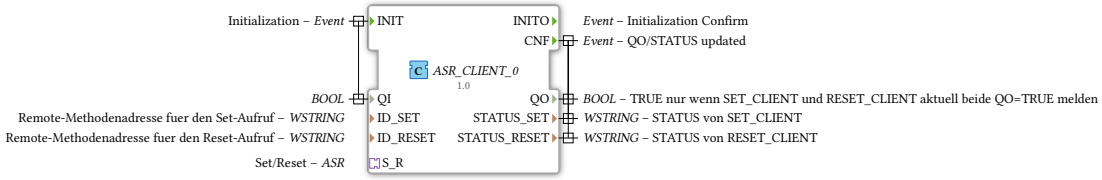
- **Three network connections behind one adapter**: Two `SERVER_0` instances (Set, Reset) and one `CLIENT_1_0` (state) are combined into a single bidirectional ASR_AX interface.
- **Buffering with D flip-flop**: The feedback value reported via the adapter is stabilized via an internal `iec61499::events::E_D_FF` before being sent via `CLIENT_1_0`.
- **Sequential initialization**: `SET_SERVER` → `RESET_SERVER` → `STATE_CLIENT` (composite FBTypes chain `INIT`/`INITO` serially through each instance).
- **Encapsulation**: Only the ASR_AX adapter interface is visible externally.

State Overview

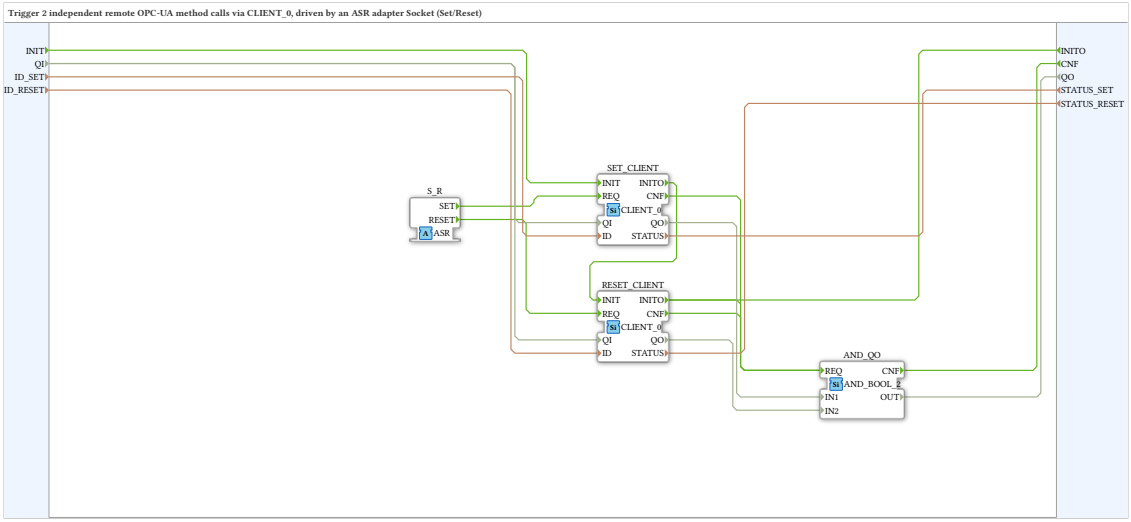
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: All three connections (Set server, Reset server, state client) are established.
3. **Receive Active**: A remote Set or Reset call is reported to the internal logic via the adapter.
4. **State Write**: A feedback value from the internal logic is buffered and sent via remote write to the configured target node.

Application Scenarios

- Receiving remote Set/Reset calls while simultaneously writing the resulting state back to a different remote node over a single adapter connection
- Server-side counterpart to ASR_AX_CLIENT_0_SUBSCRIBE_1 in distributed control architectures



Comparison with Similar Function Blocks



- **ASR_AX_CLIENT_0_SUBSCRIBE_1**: The client/calling counterpart.
- **AE_AX_SERVER_0_CLIENT_1_0**: The same pattern with only one receiving server instead of two.
- **ASRT_AX_SERVER_0_CLIENT_1_0**: Extends the same pattern with a third receiving server (Toggle).

Conclusion

ASR_AX_SERVER_0_CLIENT_1_0 bundles two receiving servers (Set/Reset) and a state-writing client behind a single bidirectional ASR_AX adapter, forming the server-side counterpart to ASR_AX_CLIENT_0_SUBSCRIBE_1.

ASR_CLIENT_0

• – ○ • – ○ • – ○ •

Introduction

The **ASR_CLIENT_0** function block is a composite function block that triggers two independent remote OPC UA **method calls** (Set and Reset), each via its own `CLIENT_0` block, controlled through a single unidirectional **ASR adapter socket**. It is the variant of AE_CLIENT_0 extended with a second trigger.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO`, `STATUS_SET`, and `STATUS_RESET`
- **CNF** (Event): Confirmation that one of the method calls has been sent, associated with `QO`, `STATUS_SET`, and `STATUS_RESET`

Data Inputs

- **QI** (BOOL): Qualifier input, opens (TRUE) or closes (FALSE) both connections
- **ID_SET** (WSTRING): Remote method address for the Set call
- **ID_RESET** (WSTRING): Remote method address for the Reset call

Data Outputs

- **QO** (BOOL): TRUE only if `SET_CLIENT` and `RESET_CLIENT` currently both report `QO = TRUE`
- **STATUS_SET** (WSTRING): Status information from `SET_CLIENT`
- **STATUS_RESET** (WSTRING): Status information from `RESET_CLIENT`

Adapter

Adapter	Type	Direction	Description
S_R	adapter::types::unidirectional::ASR	Socket (Input)	Set/Reset

Functionality

1. Via the `INIT` event, the internal `SET_CLIENT` and `RESET_CLIENT` blocks are initialized one after another (`INIT` → `INITO` → `INIT`) with `QI` and their respective `ID`. After both have confirmed, `INITO` is reported externally.
2. An event at the adapter socket `S_R.SET` directly triggers the internal `SET_CLIENT` method call; `S_R.RESET` triggers `RESET_CLIENT` accordingly.
3. Both `CLIENT_0` instances confirm independently with `CNF`, which is forwarded externally in each case.
4. The `AND_QO` block ANDs the `QO` outputs of both `CLIENT_0` instances into a single `QO`.

Technical Features

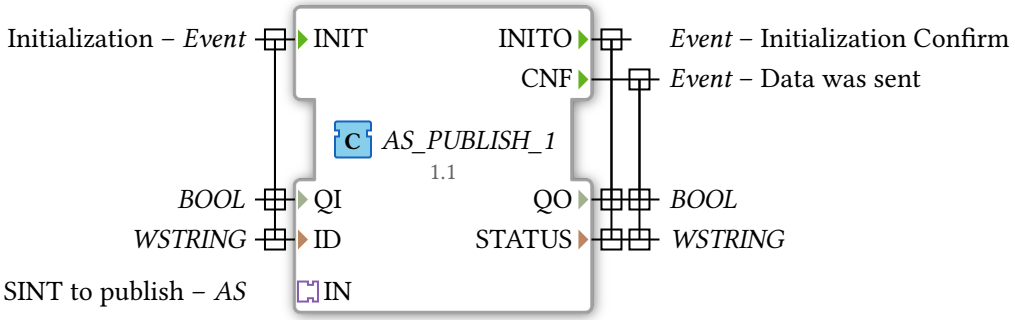
- **Two parallel CLIENT_0 instances**: Set and Reset are handled by separate `CLIENT_0` blocks (different `ID`s, independent connections).
- **Sequential initialization**: The two internal blocks are initialized one after another (`SET_CLIENT.INITO` → `RESET_CLIENT.INIT`), since composite FBTypes must explicitly chain their `INIT`/`INITO` through each instance in series.
- **Encapsulation**: Only the ASR adapter interface is visible externally.

State Overview

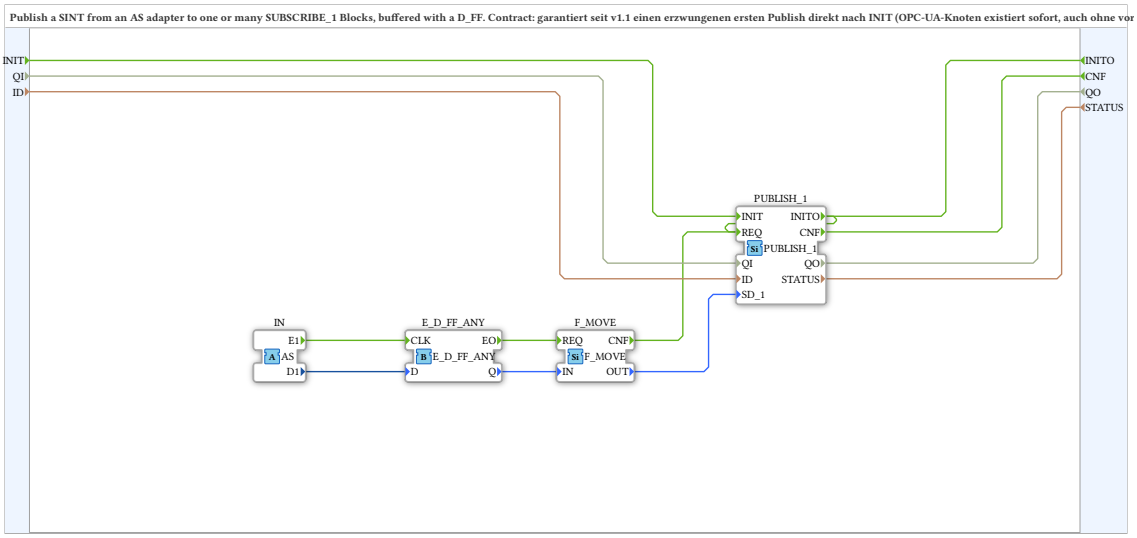
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: Both connections are established, the block is ready to trigger Set or Reset calls.
3. **Send Active**: A Set or Reset event arriving at the ASR socket triggers the corresponding remote method call.

Application Scenarios

- Remotely triggering two independent remote actions (Set/Reset) through a single adapter, e.g. to switch a remote actuator
- Network coupling in ASR-adapter-based applications



Comparison with Similar Function Blocks



- **AE_CLIENT_0**: The same base structure with only one trigger instead of two.
- **ASRT_CLIENT_0**: Extends the same pattern with a third trigger (Toggle).
- **ASR_AX_CLIENT_0_SUBSCRIBE_1**: Combines the same two `CLIENT_0` triggers with an additional `SUBSCRIBE_1` state channel behind a bidirectional adapter.

Conclusion

ASR_CLIENT_0 bundles two independent remote method calls (Set/Reset) behind a single ASR adapter socket, making it suitable for applications where a remote actuator is switched via two separate OPC UA methods.

AS_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AS adapter**. A **SINT** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AS	Socket (Input)	SINT value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AS socket `IN` delivers an event to `IN.E1`, the SINT value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block acknowledges with `CNF`, which is then transmitted externally.

Technical Features

- **Buffering with D-Flip-Flop**: The SINT value to be transmitted is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AS adapter interface is visible externally.

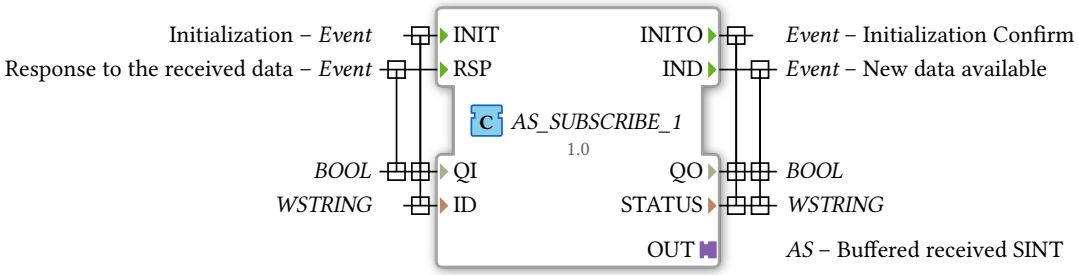
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AS socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

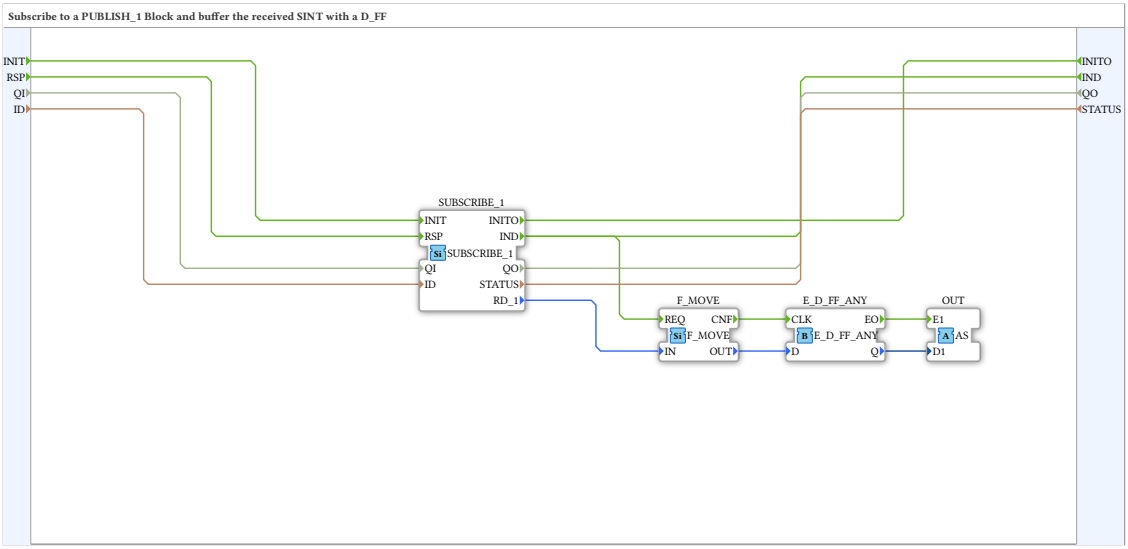
Application Scenarios

- **Network Coupling in AS Applications**: Sending SINT signals (e.g., switching commands or status bits) from adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AS adapters.

Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AS_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AS adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a SINT value at the adapter level but lacks network functionality. **AS_PUBLISH_1** combines buffering and publishing in a single block.



Conclusion

AS_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based SINT processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AS interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AS_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based SINT processing.

AS_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AS adapter**. It subscribes to a publish channel configured via `ID` and provides the received **SINT** value, buffered via a D flip-flop (E_D_FF_ANY), at the adapter plug `OUT`. This allows for clean integration of network communication and SINT signal processing in the AS adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AS	Plug (Output)	Buffered received SINT value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.

5. The event EO of the flip-flop is transferred to the event output OUT.E1, so that downstream components are notified of the new information.

Technical Features

- **Buffering with D flip-flop**: The received SINT value is buffered via an internal iec61499::events::E_D_FF_ANY and remains stable at the output until the next value is received. EO only fires when Q changes.
- **RSP is a no-op for subscribers**: According to source code analysis of 4diac-forte (CCommFB::sendData()), the RSP event in SUBSCRIBE_1 (service type subscriber) does not execute any action – the branch != e_Subscriber is skipped. The event input pair INIT/RSP is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of SUBSCRIBE_1 (including IND/RD_1) is moved internally; only the AS adapter interface is visible externally.

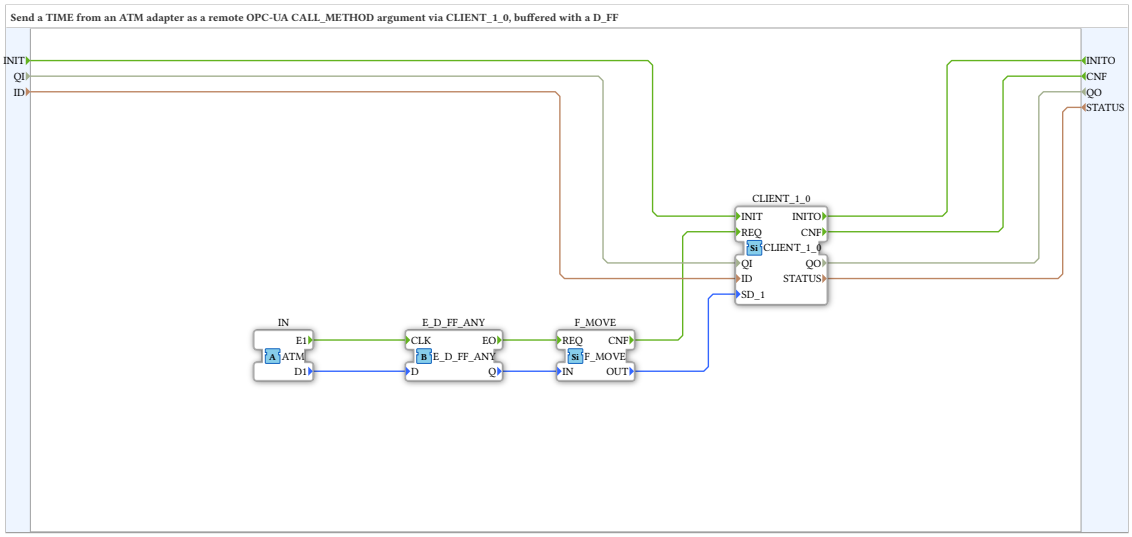
State Overview

1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Receipt**: At IND, the received SINT value is transferred to the internal D flip-flop and output via OUT.

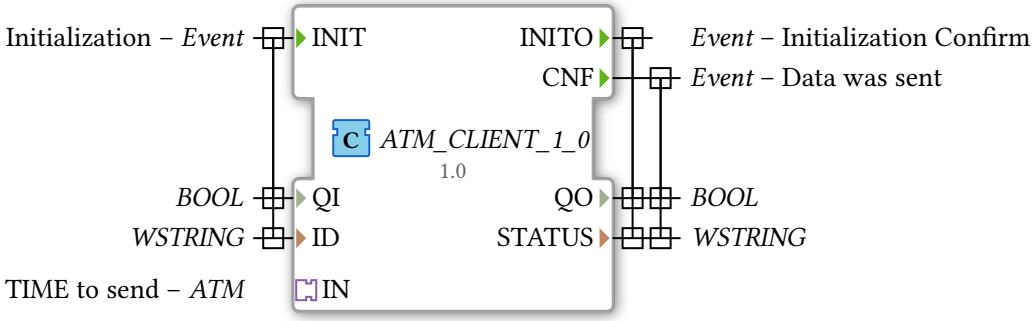
Application Scenarios

- **Network Coupling in AS Applications**: Receiving SINT signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AS adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with AX_PUBLISH_1 and a true event-based E_D_FF_ANY, the feedback between SUBSCRIBE_1 and PUBLISH_1 can be decoupled (a clean fix compared to the interim fix with AX_D_FF).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on AS adapters.

Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (IND, RD_1, …). **AS_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (E_D_FF_ANY), and only provides the AS adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a SINT value at the adapter level but lacks network functionality. **AS_SUBSCRIBE_1** combines subscribing and buffering in a single function block.



Conclusion

AS_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block SUBSCRIBE_1 with adapter-based SINT processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AS interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AS_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block SUBSCRIBE_1 with adapter-based SINT processing.

ATM_CLIENT_1_0

• – ◦ • – ◦ • – ◦ •

Introduction

The **ATM_CLIENT_1_0** function block is a composite function block that encapsulates the network-based `CLIENT_1_0` function block from the IEC 61499 standard library and maps its interface to a unidirectional **ATM adapter** (`TIME` data type). A **TIME** duration value present at adapter socket `IN` is buffered via an internal `E_D_FF_ANY` flip-flop and then sent via `CLIENT_1_0` as an OPC UA **Write** or `CALL_METHOD` invocation to the remote node configured under `ID`.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, connected to `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, connected to `QO` and `STATUS`
- **CNF** (Event): Confirmation that data was sent, connected to `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Input qualifier, opens (TRUE) or closes (FALSE) the connection to the server
- **ID** (WSTRING): Connection identifier (OPC UA address of the target node, e.g., `opc_ua[WRITE;opc.tcp://192.168.1.12:4840#;...]`)

Data Outputs

- **QO** (BOOL): Output qualifier, connection status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapters

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::ATM	Socket (Input)	TIME value to be sent

Functionality

1. The `INIT` event initializes the internal `CLIENT_1_0` block with `QI` and `ID`, establishing connection to the remote server and acknowledging with `INITO`.
2. When the ATM socket `IN` receives an event on `IN.E1`, the TIME value at `IN.D1` is latched into the internal `E_D_FF_ANY` flip-flop.
3. The flip-flop holds the value stable and generates event `EO`.
4. `EO` triggers `F_MOVE` (`TIME` data type) to supply `CLIENT_1_0.SD_1` and fire the send event `REQ` on `CLIENT_1_0`.
5. After successful transmission, `CLIENT_1_0` confirms with `CNF`.

Technical Features

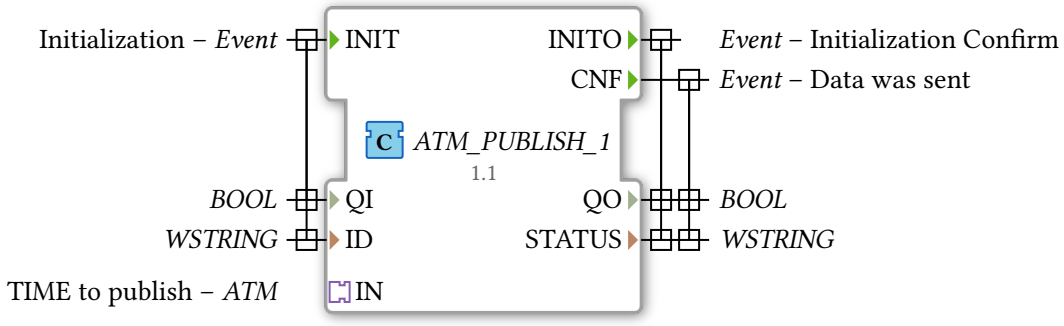
- **Buffering with E_D_FF_ANY**: The TIME value to be sent is buffered using an internal `E_D_FF_ANY`, preventing value instability during transmission.
- **Remote Write / Call Method**: `CLIENT_1_0` directly addresses a remote OPC UA server to transfer time duration parameters.
- **Encapsulation**: The raw `CLIENT_1_0` event/data interface is kept internal; only the clean ATM adapter interface is exposed.

State Overview

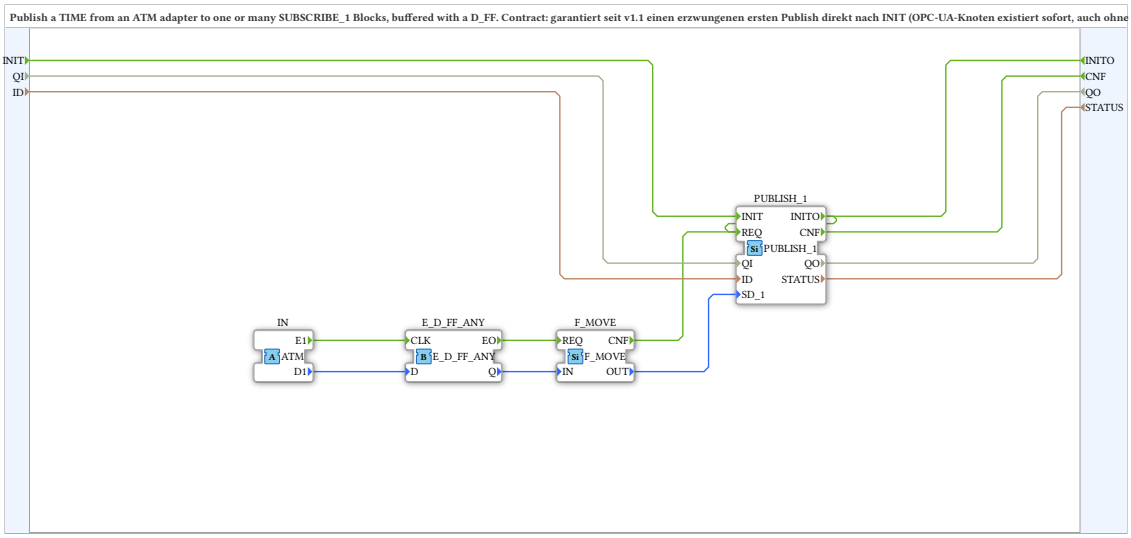
1. **Uninitialized**: The block waits for the `INIT` event.
2. **Initialized**: Connection to the remote server is established; ready to send.
3. **Send Active**: An event on the ATM socket buffers the TIME value and triggers the remote write.

Application Scenarios

- **Remote Time Parameter Transmission**: Sending time duration values (e.g., valve pulse durations, flushing times) to a remote controller via OPC UA.
- **Modular Control Architectures**: Integrating distributed TIME values into libraries built on ATM adapters.



Comparison with Similar Blocks



- **AX_CLIENT_1_0**: Handles BOOL values via an AX adapter.
- **AR_CLIENT_1_0**: Handles REAL values via an AR adapter.
- **ATM_PUBLISH_1**: Encapsulates `PUBLISH_1` for local publish/subscribe.

Conclusion

ATM_CLIENT_1_0 allows direct writing of TIME values to a remote OPC UA server over a clean ATM adapter interface.

ATM_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **ATM adapter**. A **TIME** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::ATM	Socket (Input)	TIME value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the ATM socket `IN` delivers an event to `IN.E1`, the TIME value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then sent externally.

Technical Features

- **Buffering with D-Flip-Flop**: The TIME value to be sent is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the ATM adapter interface is visible externally.

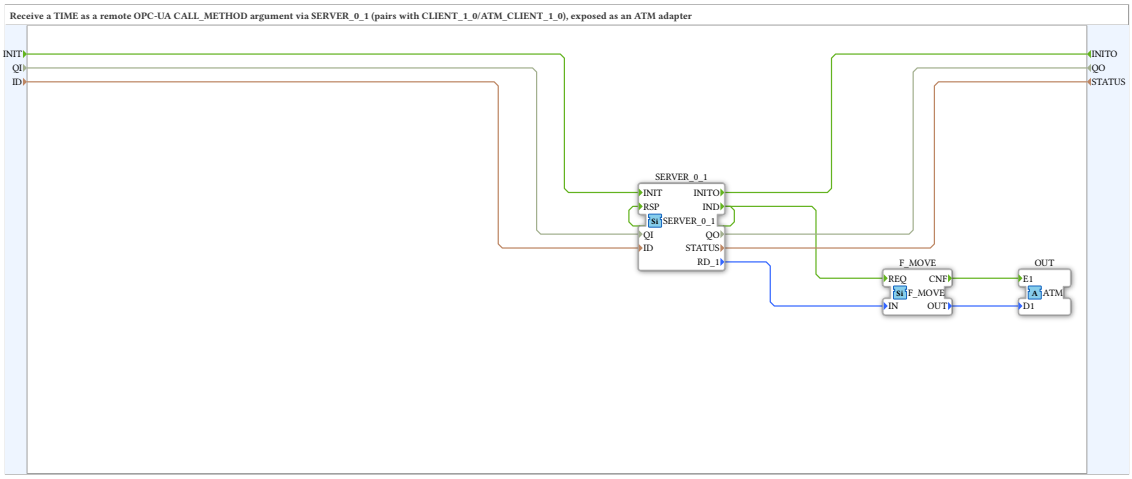
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the ATM socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

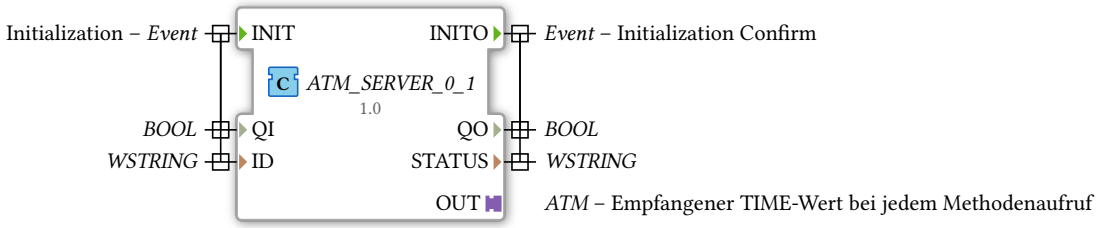
Application Scenarios

- **Network Coupling in ATM Applications**: Sending TIME signals (e.g., switching commands or status bits) from the adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between the user's own publications and subscriptions is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on ATM adapters.

Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **ATM_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the ATM adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a TIME value at the adapter level but lacks network functionality. **ATM_PUBLISH_1** combines buffering and publishing in a single block.



Conclusion

ATM_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based TIME processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the reduced ATM interface makes the function block ideal for fully adapter-based IEC 61499 applications.

ATM_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based TIME processing.

ATM_SERVER_0_1

• – ◦ • – ◦ • – ◦ •

Introduction

The **ATM_SERVER_0_1** function block is a composite function block from the `adapter::net` package. It encapsulates the network server block `iec61499::net::SERVER_0_1` and exposes incoming OPC UA method calls (`CALL_METHOD`) for **TIME** arguments as a unidirectional **ATM adapter** (`OUT`). It serves as the receiving counterpart to **ATM_CLIENT_1_0** (or `CLIENT_1_0`).

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, connected to `QI` and `ID` (forwards to `SERVER_0_1.INIT`)

Event Outputs

- **INITO** (EInit): Initialization confirmation (`SERVER_0_1.INITO`), connected to `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Input qualifier, enables (TRUE) or disables (FALSE) the server
- **ID** (WSTRING): Server identifier (OPC UA server address and method specification)

Data Outputs

- **QO** (BOOL): Output qualifier, server operational status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapters

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::ATM	Plug (Output)	Received TIME value on each method invocation

Functionality

1. An `INIT` event at `ATM_SERVER_0_1` is forwarded to the internal `SERVER_0_1.INIT` input. The server starts the OPC UA endpoint and acknowledges with `INITO` upon success.
2. Upon an incoming method call from a remote client (`CLIENT_1_0`/`ATM_CLIENT_1_0`), `SERVER_0_1` emits indication event `IND` and presents the received TIME value at `RD_1`.
3. To prevent response-latency lockups (RSP latency bug), `SERVER_0_1.IND` is directly looped back to `SERVER_0_1.RSP` within the internal network, causing the server to acknowledge the method immediately.
4. Simultaneously, `IND` passes the received value through `F_MOVE` (`TIME` data type) to ATM plug `OUT.D1` and fires output event `OUT.E1`.

Technical Features

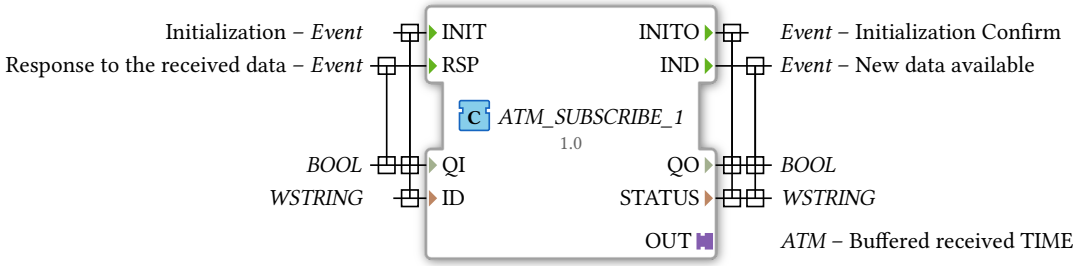
- **Direct RSP Loopback**: To eliminate 4-second server lockups caused by delayed responses, `SERVER_0_1.IND` is internally tied back to `SERVER_0_1.RSP`.
- **Seamless Adapter Integration**: The raw `RD_1` output of `SERVER_0_1` is mapped via `F_MOVE` (TIME) directly onto the ATM adapter structure (`OUT.D1` / `OUT.E1`).
- **Receiving Counterpart to `ATM_CLIENT_1_0`**: In IEC 61499, a `CLIENT_1_0` block (“Connect to a SERVER_0_1 block”) pairs with a `SERVER_0_1` block.

State Overview

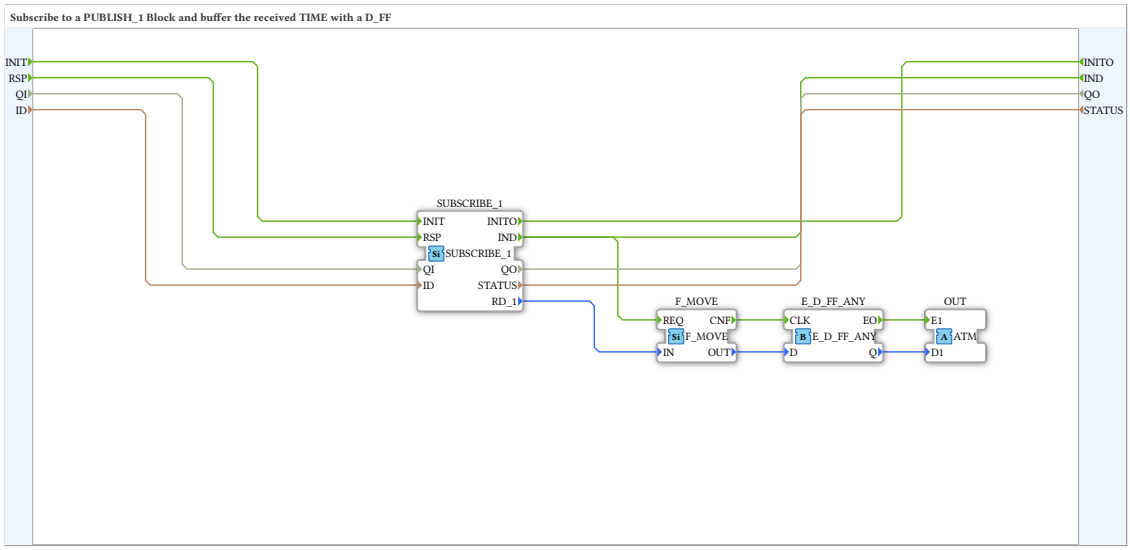
1. **Uninitialized**: The server is inactive and waiting for the `INIT` event.
2. **Listening**: The OPC UA server is active and waiting for method calls from remote clients.
3. **Indication**: A method call arrives; the TIME value is passed to the `OUT` adapter and the response is sent immediately.

Application Scenarios

- **Receiving Remote Time Parameters**: Receiving pulse durations or delay times (e.g. valve open duration, flush duration) from a remote module via OPC UA `CALL_METHOD`.
- **Modular Server Architectures**: Providing OPC UA method endpoints for time duration signals in adapter-based applications.



Comparison with Similar Blocks



- **AR_SERVER_0_1**: Receives REAL values via an AR adapter.
- **AX_SERVER_0_1**: Receives BOOL values via an AX adapter.
- **ATM_SUBSCRIBE_1**: Encapsulates `SUBSCRIBE_1` for local publish/subscribe rather than method invocations.

Conclusion

ATM_SERVER_0_1 delivers received OPC UA method invocations for TIME values over a clean ATM adapter while preventing server response locks.

ATM_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **ATM adapter**. It subscribes to a publish channel configured via `ID` and provides the received **TIME** value, buffered via a D flip-flop (E_D_FF_ANY), at the adapter plug `OUT`. This allows

for the clean integration of network communication and TIME signal processing in the ATM adapter environment.

Interface Structure

Event Inputs
- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs
- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs
- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs
- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::ATM	Plug (Output)	Buffered received TIME value

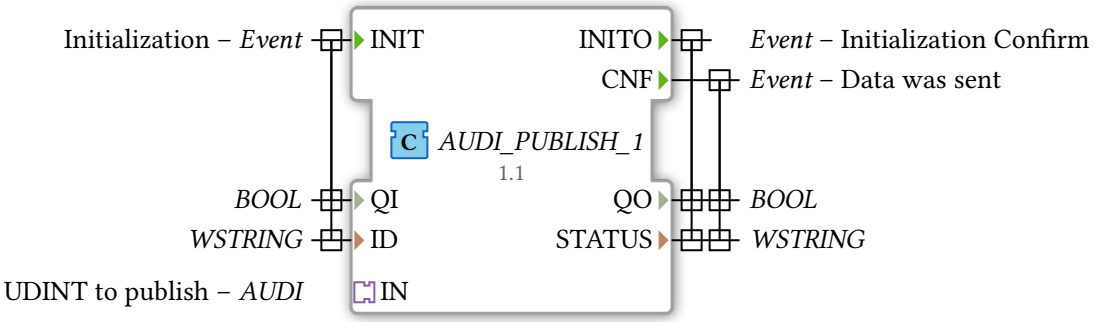
Functionality
1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features
- **Buffering with D flip-flop**: The received TIME value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the ATM adapter interface is visible externally.

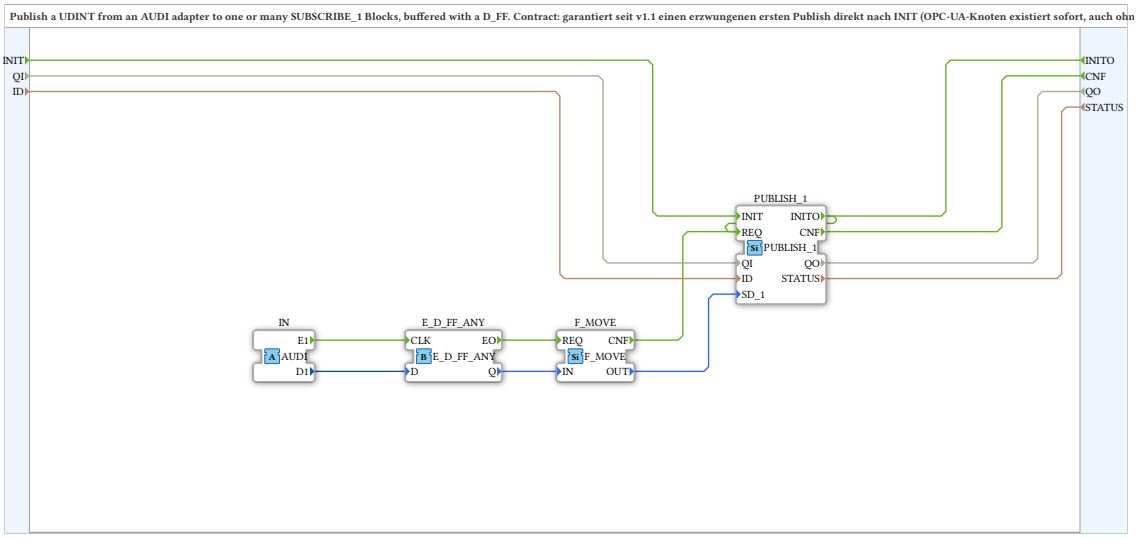
State Overview
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Received**: At `IND`, the received TIME value is transferred to the internal D flip-flop and output via `OUT`.

Application Scenarios
- **Network Coupling in ATM Applications**: Receiving TIME signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via ATM adapters to the adapter-based logic.

- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a clean fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integrating distributed communication into libraries that rely entirely on ATM adapters.



Comparison with Similar Components



- **SUBSCRIBE_1**: The standard component exposes its interface as events/variables (`IND`, `RD_1`, ...). **ATM_SUBSCRIBE_1** encapsulates this component, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the ATM adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a TIME value at the adapter level but lacks network functionality. **ATM_SUBSCRIBE_1** combines subscribing and buffering in a single component.

Conclusion

ATM_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based TIME processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the reduced ATM interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AUDI_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AUDI adapter**. A **UDINT** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AUDI	Socket (Input)	UDINT value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AUDI socket `IN` sends an event to `IN.E1`, the UDINT value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then transmitted externally.

Technical Features

- **Buffering with D-Flip-Flop**: The UDINT value to be transmitted is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AUDI adapter interface remains visible externally.

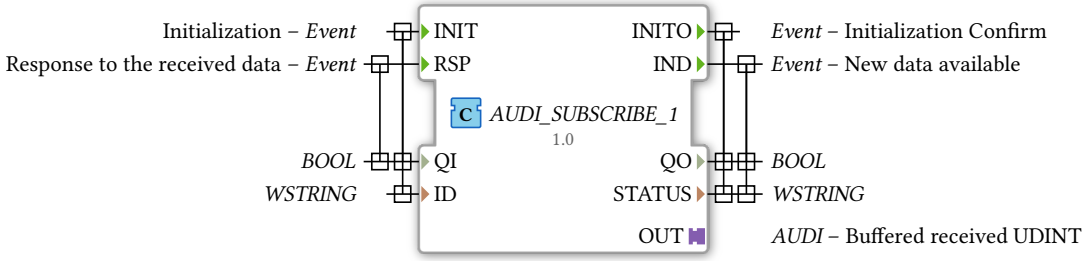
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AUDI socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

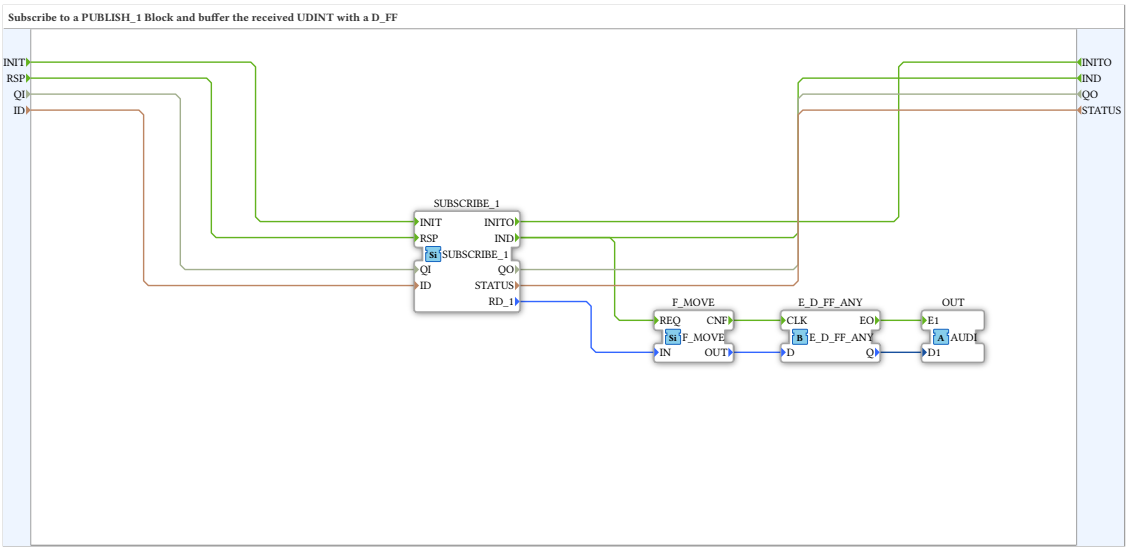
Application Scenarios

- **Network Coupling in AUDI Applications**: Sending UDINT signals (e.g., switching commands or status bits) from adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AUDI adapters.

Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AUDI_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AUDI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a UDINT value at the adapter level but lacks network functionality. **AUDI_PUBLISH_1** combines buffering and publishing in a single block.



Conclusion

AUDI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based UDINT processing. Internal D flip-flop buffering stabilizes the transmit value and decouples feedback loops; the simplified AUDI interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AUDI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based UDINT processing.

AUDI_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AUDI adapter**. It subscribes to a publish channel configured via `ID` and makes the received **UDINT** value buffered via a D flip-flop (E_D_FF_ANY) available at the adapter plug `OUT`. This allows for the clean integration of network communication and UDINT signal processing in the AUDI adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

- **RSP** (Event): Response event, associated with QI

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with QO and STATUS

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AUDI	Plug (Output)	Buffered received UDINT value

Functionality

1. The internal INIT event initializes the internal SUBSCRIBE_1 block with QI and ID. Upon success, it returns INITO.
2. The internal SUBSCRIBE_1 block monitors the configured channel. As soon as the associated PUBLISH_1 block publishes data, it generates the indication event IND and places the received value at RD_1.
3. IND clocks the internal **E_D_FF_ANY** flip-flop (CLK), which receives the value from RD_1 at its data input D.
4. The stored value appears stably at output Q and is transferred via the data connection to OUT.D1 of the AX plug.
5. The event EO of the flip-flop is transferred to the event output OUT.E1, so that downstream components are notified of the new information.

Technical Features

- **Buffering with D flip-flop**: The received UDINT value is buffered via an internal iec61499::events::E_D_FF_ANY and remains stable at the output until the next value is received. EO only fires when Q changes.
- **RSP is a no-op for subscribers**: According to source code analysis of 4diac-forte (CCommFB::sendData()), the RSP event in SUBSCRIBE_1 (service type subscriber) does not execute any action – the branch != e_Subscriber is skipped. The event input pair INIT/RSP is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of SUBSCRIBE_1 (including IND/RD_1) is moved internally; only the AUDI adapter interface is visible externally.

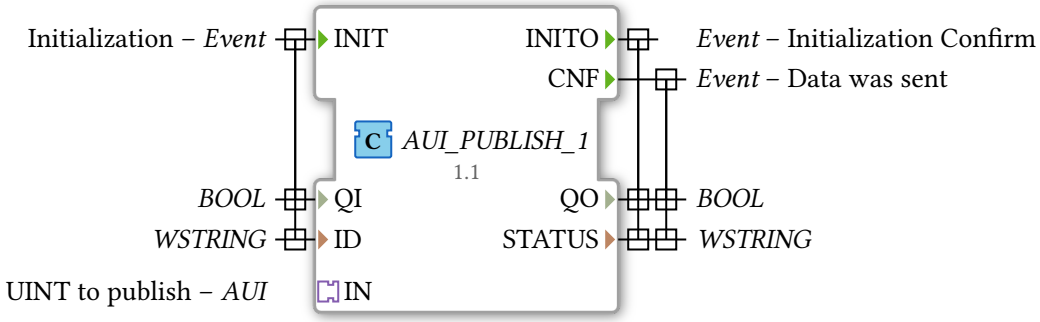
State Overview

1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Reception**: At IND, the received UDINT value is transferred to the internal D flip-flop and output via OUT.

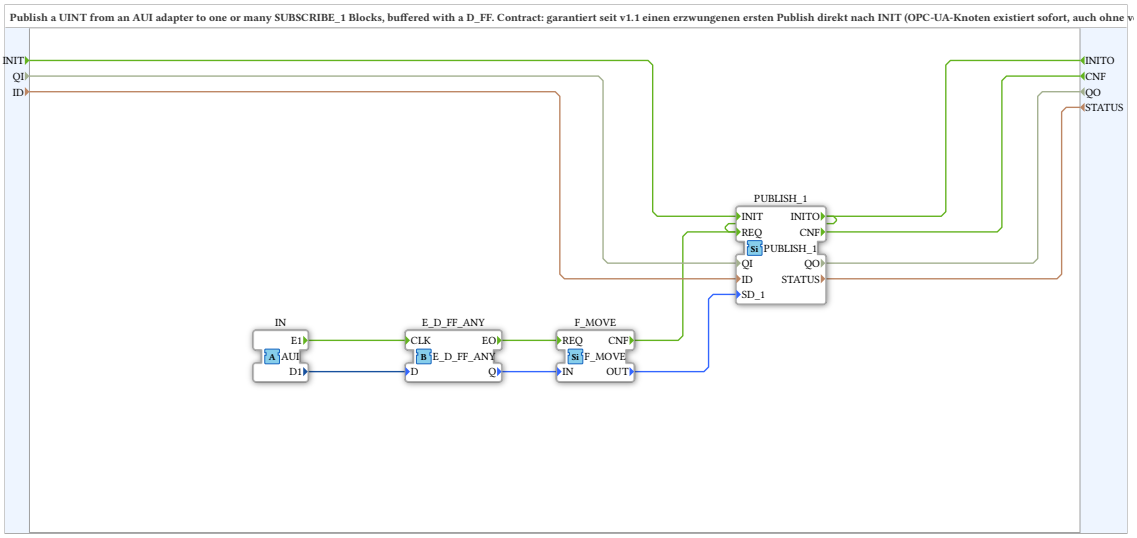
Application Scenarios

- **Network Coupling in AUDI Applications**: Receiving UDINT signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AUDI adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with AX_PUBLISH_1 and a true event-based E_D_FF_ANY, the feedback between SUBSCRIBE_1 and PUBLISH_1 can be decoupled (a clean fix compared to the interim fix with AX_D_FF).
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AUDI adapters.

Comparison with Similar Components



- **SUBSCRIBE_1**: The standard component exposes its interface as events/variables (`IND`, `RD_1`, ...). **AUDI_SUBSCRIBE_1** encapsulates this component, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AUDI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a UDINT value at the adapter level but lacks network functionality. **AUDI_SUBSCRIBE_1** combines subscribing and buffering in a single component.



Conclusion

AUDI_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based UDINT processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AUDI interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AUDI_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based UDINT processing.

• – ○ • – ○ • – ○ •

Introduction

The function block **AUI_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AUI adapter**. A **UINT** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AUI	Socket (Input)	UINT value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AUI socket `IN` sends an event to `IN.E1`, the UINT value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then transmitted externally.

Technical Features

- **Buffering with D-Flip-Flop**: The UINT value to be transmitted is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AUI adapter interface is visible externally.

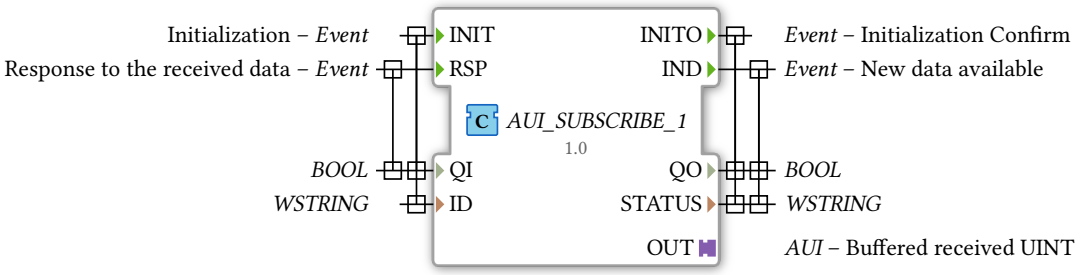
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AUI socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

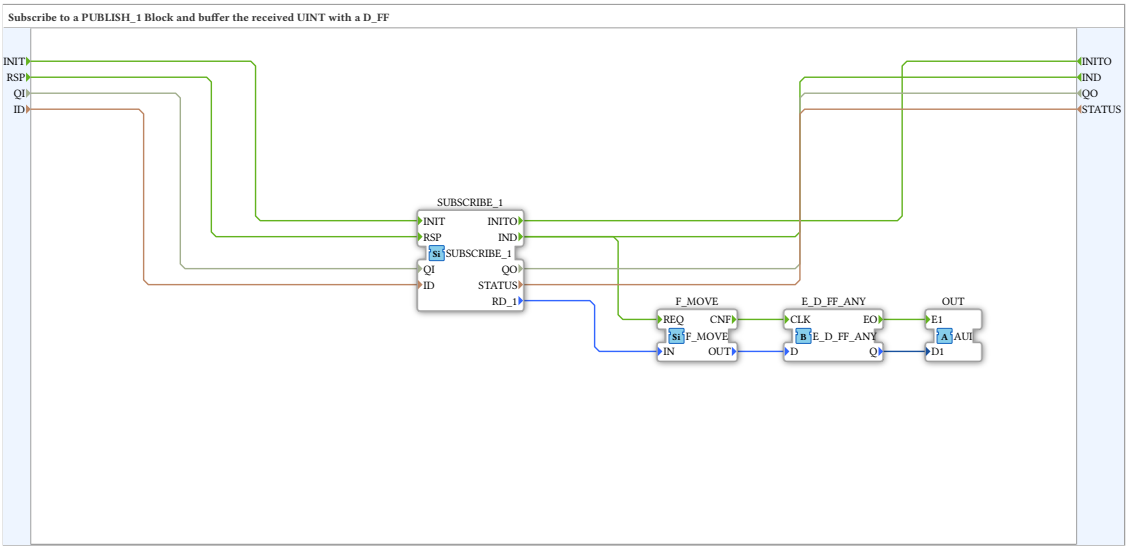
Application Scenarios

- **Network Coupling in AUI Applications**: Sending UINT signals (e.g., switching commands or status bits) from adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AUI adapters.

Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AUI_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AUI adapter – making the interface significantly more compact and integrable into adapter networks.



- **AX_D_FF**: Bufferes a UINT value at the adapter level but lacks network functionality. **AUI_PUBLISH_1** combines buffering and publishing in a single block.

Conclusion

AUI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based UINT processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AUI interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AUI_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AUI_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AUI adapter**. It subscribes to a publish channel configured via `ID` and makes the received **UINT** value buffered via a D flip-flop (E_D_FF_ANY) available on the adapter plug `OUT`. This allows for clean integration of network communication and UINT signal processing in the AUI adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AUI	Plug (Output)	Buffered received UINT value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

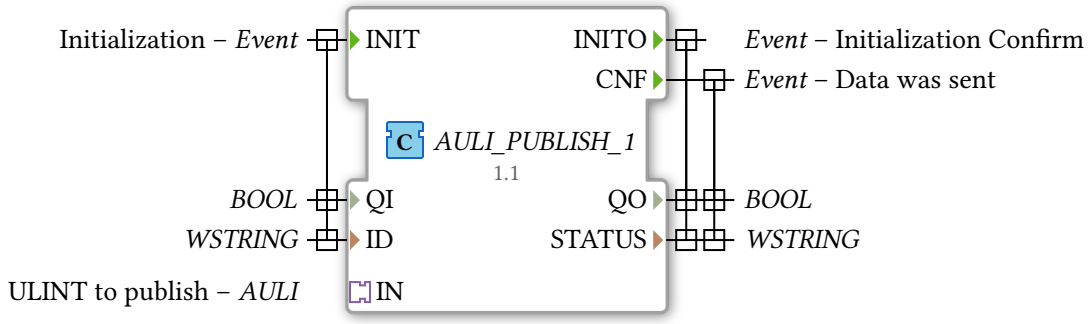
- **Buffering with D flip-flop**: The received UINT value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AUI adapter interface is visible externally.

State Overview

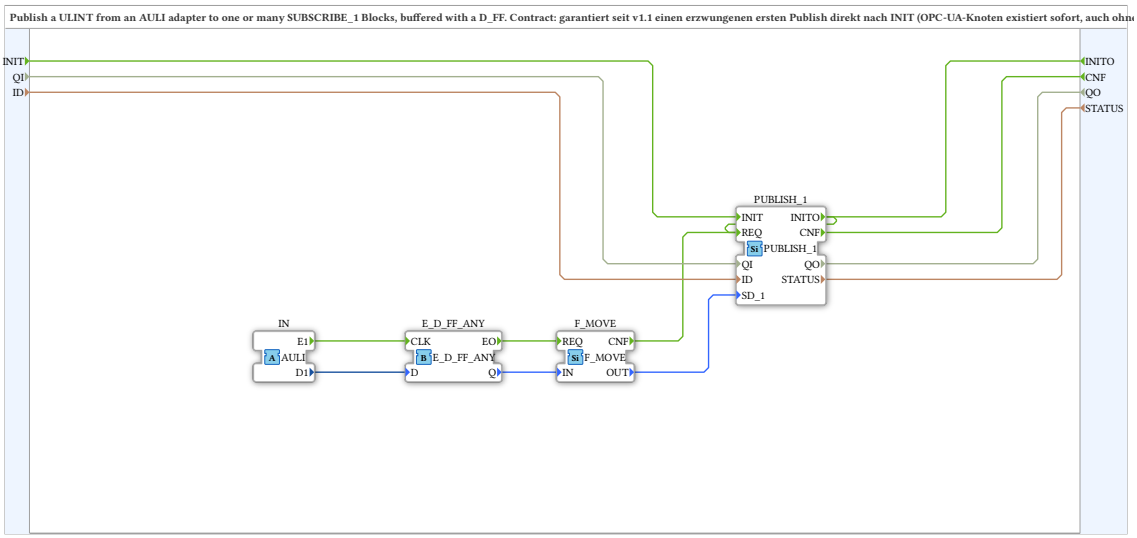
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Receipt**: At `IND`, the received UINT value is transferred to the internal D flip-flop and output via `OUT`.

Application Scenarios

- **Network Coupling in AUI Applications**: Receiving UINT signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AUI adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a clean fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AUI adapters.



Comparison with Similar Building Blocks



- **SUBSCRIBE_1**: The standard building block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AUI_SUBSCRIBE_1** encapsulates this building block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AUI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a UINT value at the adapter level but lacks network functionality. **AUI_SUBSCRIBE_1** combines subscribing and buffering in a single building block.

Conclusion

AUI_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based UINT processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AUI interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AULI_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AULI adapter**. A **ULINT** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AULI	Socket (Input)	ULINT value to be published

Functionality

1. The internal `PUBLISH_1` block is initialized with `QI` and `ID` via the `INIT` event. Upon success, it returns `INITO`.
2. As soon as the AULI socket `IN` delivers an event to `IN.E1`, the ULINT value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF_ANY** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `PUBLISH_1` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and published on the configured channel.
5. After successful transmission, the `PUBLISH_1` block confirms with `CNF`, which is then transmitted externally.

Technical Features

- **Buffering with D-Flip-Flop**: The ULINT value to be transmitted is buffered via an internal `iec61499::events::E_D_FF_ANY`. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based `E_D_FF_ANY` decouples immediate feedback loops between `PUBLISH_1` and `SUBSCRIBE_1` (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with `AX_D_FF`.
- **Encapsulation**: The original event/data interface of `PUBLISH_1` (including `REQ`/`SD_1`) is moved internally; only the AULI adapter interface is visible externally.

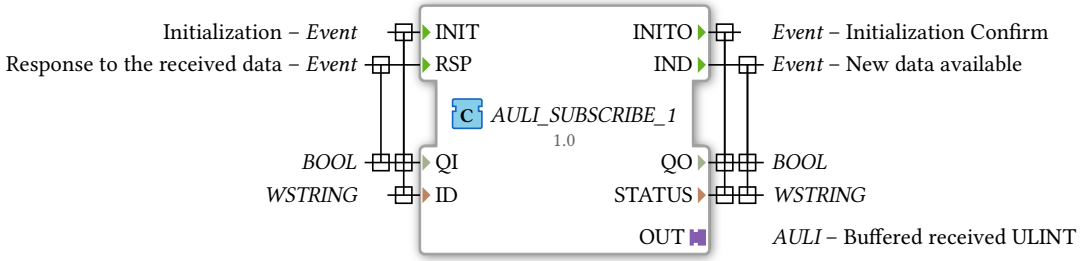
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AULI socket buffers the value and triggers transmission via the internal `PUBLISH_1` block.

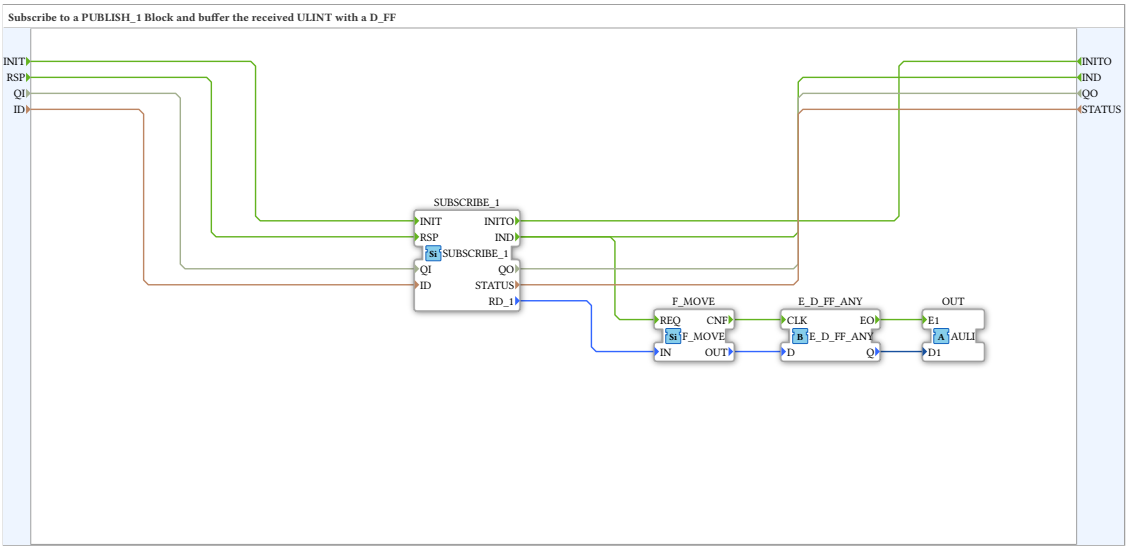
Application Scenarios

- **Network Coupling in AULI Applications**: Sending ULINT signals (e.g., switching commands or status bits) from adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with `AX_SUBSCRIBE_1`, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AULI adapters.

Comparison with Similar Blocks



- **PUBLISH_1**: The standard block exposes its interface as events/variables (`REQ`, `SD_1`, ...). **AULI_PUBLISH_1** encapsulates this block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AULI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a ULINT value at the adapter level but lacks network functionality. **AULI_PUBLISH_1** combines buffering and publishing in a single block.



Conclusion

AULI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based ULINT processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AULI interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AULI_PUBLISH_1 combines the publish/subscribe communication of the standard function block `PUBLISH_1` with adapter-based ULINT processing.

AULI_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AULI adapter**. It subscribes to a publish channel configured via `ID` and makes the received **ULINT** value buffered via a D flip-flop (E_D_FF_ANY) available on the adapter plug `OUT`. This allows for the clean integration of network communication and ULINT signal processing in the AULI adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AULI	Plug (Output)	Buffered received ULINT value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

- **Buffering with D flip-flop**: The received ULINT value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AULI adapter interface is visible externally.

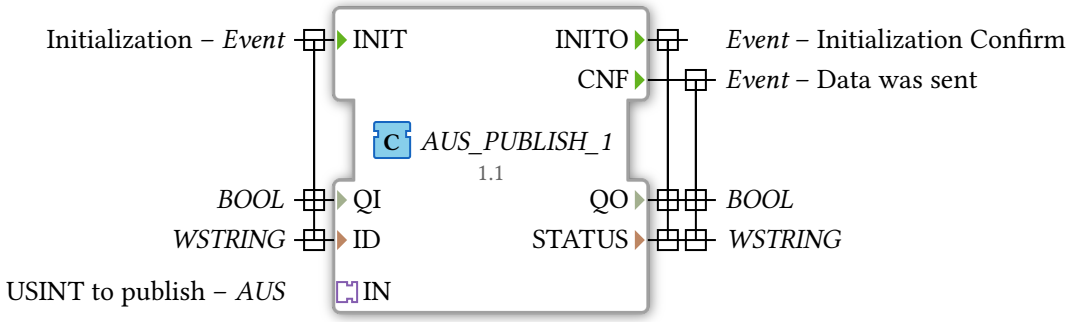
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Receipt**: At `IND`, the received ULINT value is transferred to the internal D flip-flop and output via `OUT`.

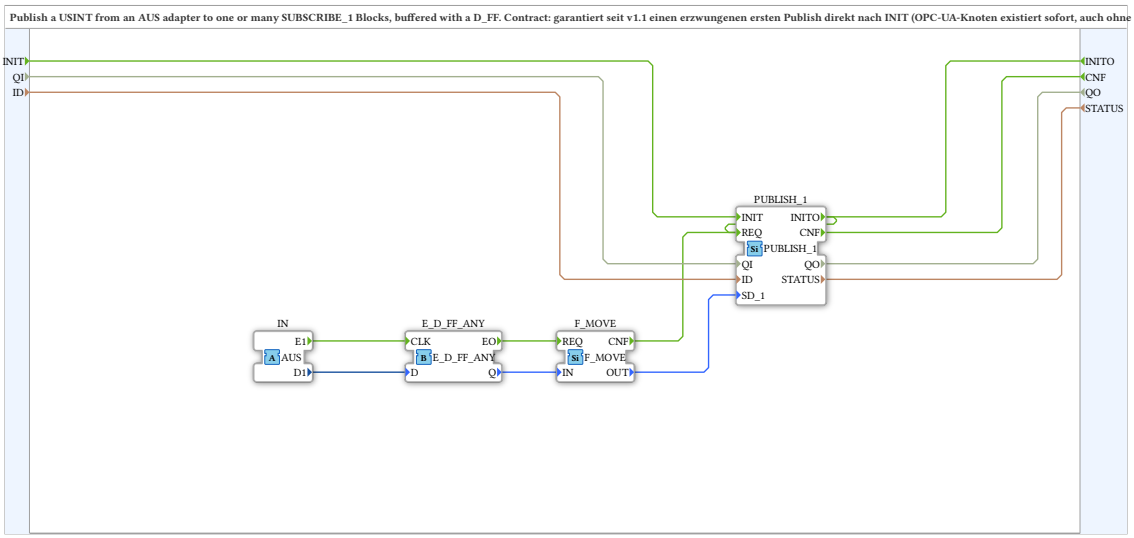
Application Scenarios

- **Network Coupling in AULI Applications**: Receiving ULINT signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AULI adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a clean fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on AULI adapters.

Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AULI_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AULI adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a ULINT value at the adapter level but lacks network functionality. **AULI_SUBSCRIBE_1** combines subscribing and buffering in a single function block.



Conclusion

AULI_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based ULINT processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AULI interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AULI_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based ULINT processing.

AUS_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_PUBLISH_1** is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AUS adapter**. A **USINT** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::OFF	Socket (Input)	USINT value to be published

Functionality

1. The internal PUBLISH_1 block is initialized with QI and ID via the INIT event. Upon success, it returns INITO.
2. As soon as the OFF socket IN delivers an event to IN.E1, the USINT value simultaneously present at IN.D1 is transferred to the internal **E_D_FF_ANY** flip-flop (CLK or D).
3. The flip-flop holds the value stably at its output Q and generates the event EO when the value changes.
4. EO triggers the send event REQ of the internal PUBLISH_1 block. The buffered value Q is transmitted over the data connection as SD_1 and published on the configured channel.
5. After successful transmission, the PUBLISH_1 block acknowledges with CNF, which is then transmitted externally.

Technical Features

- **Buffering with D-Flip-Flop**: The USINT value to be transmitted is buffered via an internal iec61499::events::E_D_FF_ANY. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based E_D_FF_ANY decouples immediate feedback loops between PUBLISH_1 and SUBSCRIBE_1 (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with AX_D_FF.
- **Encapsulation**: The original event/data interface of PUBLISH_1 (including REQ/SD_1) is moved internally; only the OFF adapter interface is visible externally.

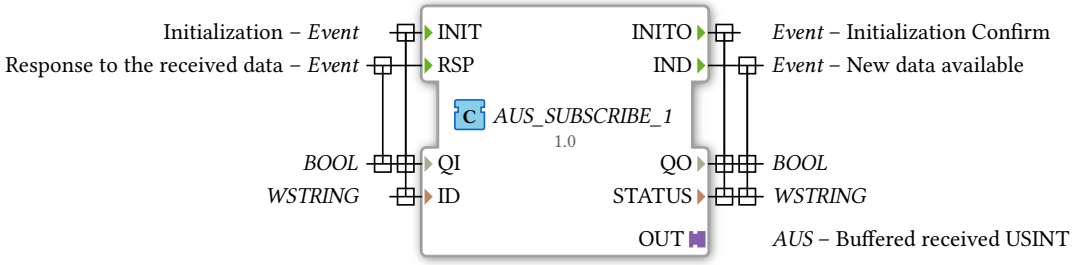
State Overview

1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AUS socket buffers the value and triggers transmission via the internal PUBLISH_1 block.

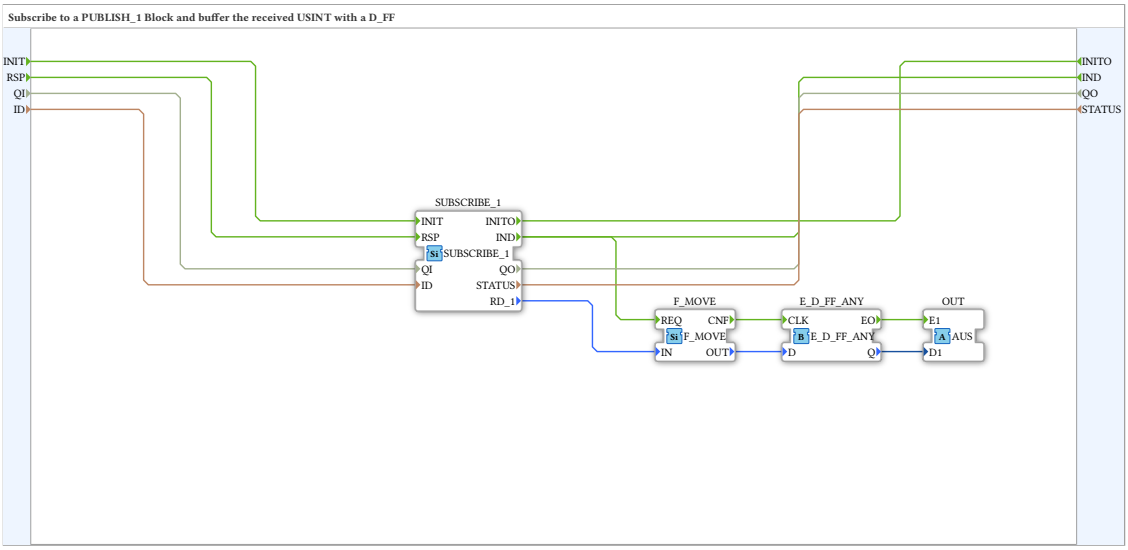
Application Scenarios

- **Network Coupling in AUS Applications**: Sending USINT signals (e.g., switching commands or status bits) from the adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with AX_SUBSCRIBE_1, feedback between the user's own publications and subscriptions is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AUS adapters.

Comparison with Similar Function Blocks



- **PUBLISH_1**: The standard function block exposes its interface as events/variables (REQ, SD_1, ...). **AUS_PUBLISH_1** encapsulates this function block, buffers the value with a D flip-flop (E_D_FF_ANY), and only provides the AUS adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a USINT value at the adapter level but lacks network functionality. **AUS_PUBLISH_1** combines buffering and publishing in a single function block.



Conclusion

AUS_PUBLISH_1 combines the publish/subscribe communication of the standard function block PUBLISH_1 with adapter-based USINT processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AUS interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AUS_PUBLISH_1 combines the publish/subscribe communication of the standard function block PUBLISH_1 with adapter-based USINT processing.

AUS_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AUS adapter**. It subscribes to a publish channel configured via `ID` and makes the received **USINT** value buffered via a D flip-flop (E_D_FF_ANY) available on the adapter plug `OUT`. This allows for clean integration of network communication and USINT signal processing in the AUS adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description

OUT	adapter::types::unidirectional::AUS	Plug (Output)	Buffered received USINT value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

- **Buffering with D flip-flop**: The received USINT value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the OFF adapter interface is visible externally.

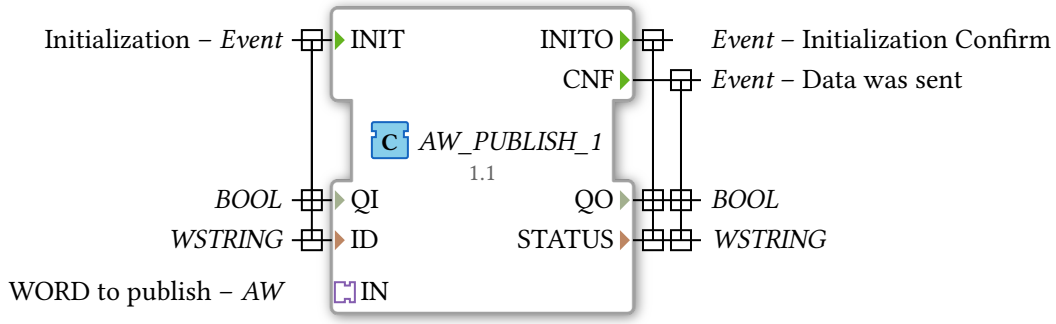
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Reception**: At `IND`, the received USINT value is transferred to the internal D flip-flop and output via `OUT`.

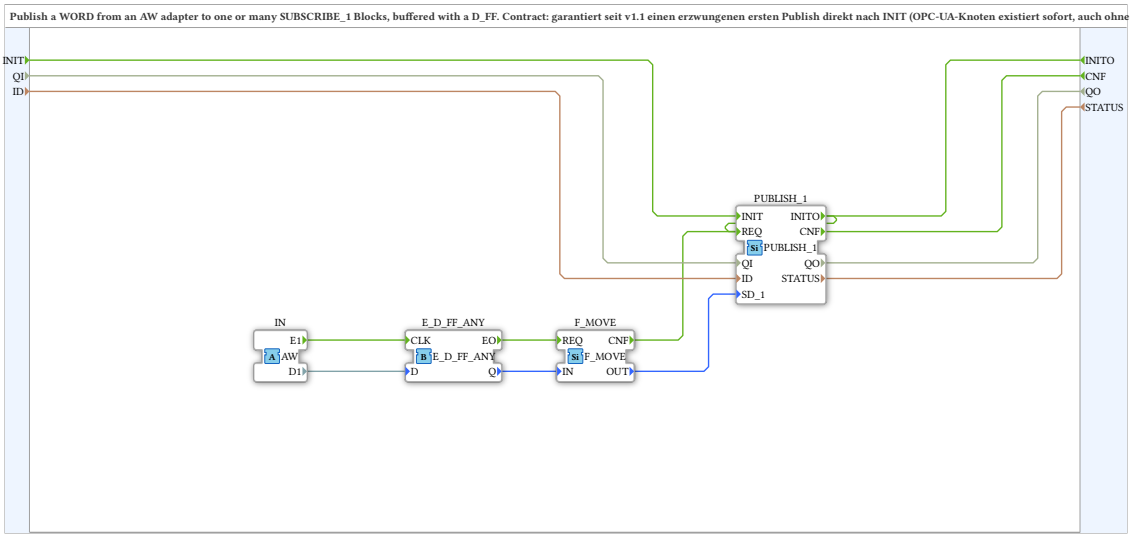
Application Scenarios

- **Network Coupling in AUS Applications**: Receiving USINT signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AUS adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a cleaner fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integrating distributed communication into libraries that rely entirely on AUS adapters.

Comparison with Similar Function Blocks



- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AUS_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the OFF adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a USINT value at the adapter level but lacks network functionality. **AUS_SUBSCRIBE_1** combines subscribing and buffering in a single function block.



Conclusion

AUS_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based USINT processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the reduced AUS interface makes the function block ideal for end-to-end adapter-based IEC 61499 applications.

AUS_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based USINT processing.

AW_PUBLISH_1

• – ○ • – ○ • – ○ •

Introduction

The **AW_PUBLISH_1** function block is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AW adapter**. A **WORD** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF_ANY) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description

IN	adapter::types::unidirectional::AW	Socket (Input)	WORD value to be published

Functionality

1. The internal PUBLISH_1 block is initialized with QI and ID via the INIT event. Upon success, it returns INITO.
2. As soon as the AW socket IN sends an event to IN.E1, the WORD value simultaneously present at IN.D1 is transferred to the internal **E_D_FF_ANY** flip-flop (CLK or D).
3. The flip-flop holds the value stably at its output Q and generates the event EO when the value changes.
4. EO triggers the send event REQ of the internal PUBLISH_1 block. The buffered value Q is transmitted over the data connection as SD_1 and published on the configured channel.
5. After successful transmission, the PUBLISH_1 block confirms with CNF, which is then sent externally.

Technical Features

- **Buffering with D-Flip-Flop**: The WORD value to be sent is buffered via an internal iec61499::events::E_D_FF_ANY. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based E_D_FF_ANY decouples immediate feedback loops between PUBLISH_1 and SUBSCRIBE_1 (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with AX_D_FF.
- **Encapsulation**: The original event/data interface of PUBLISH_1 (including REQ/SD_1) is moved internally; only the AW adapter interface is visible externally.

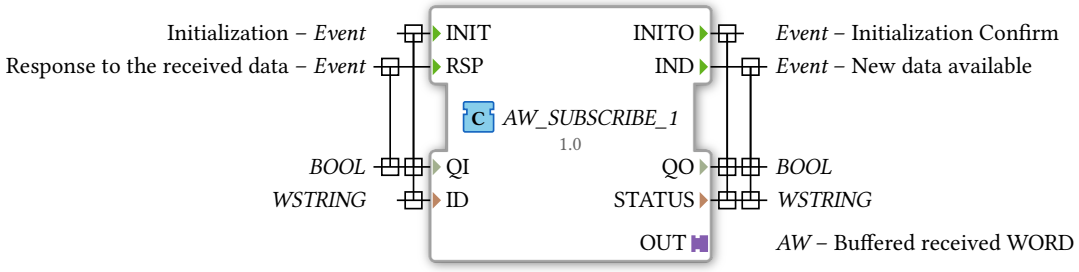
State Overview

1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AW socket buffers the value and triggers transmission via the internal PUBLISH_1 block.

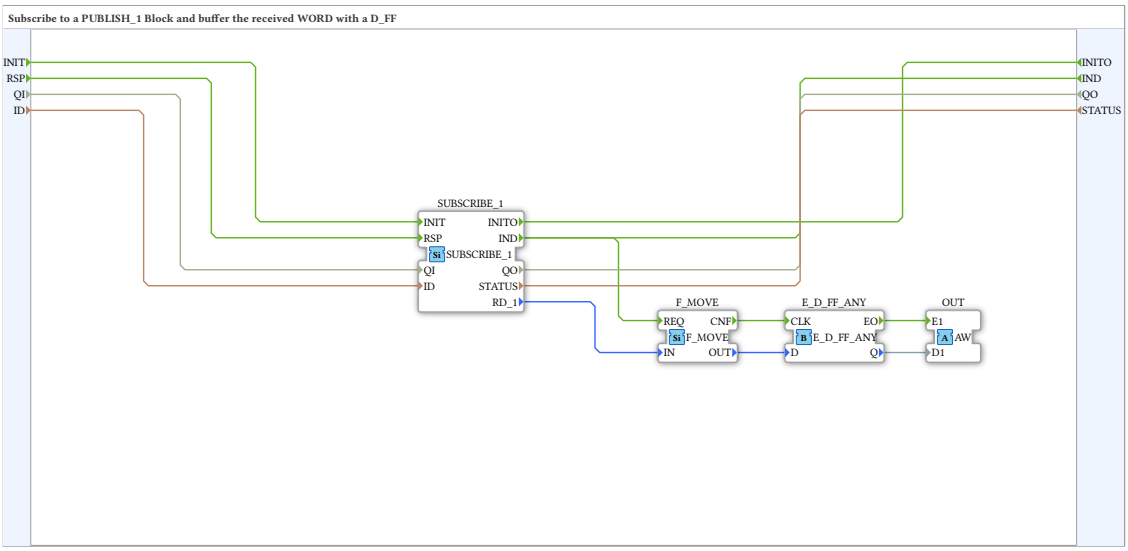
Application Scenarios

- **Network Coupling in AW Applications**: Sending WORD signals (e.g., switching commands or status bits) from the adapter-based logic to remote receivers via Publish/Subscribe.
- **Event Storm Avoidance**: Together with AX_SUBSCRIBE_1, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AW adapters.

Comparison with Similar Function Blocks



- **PUBLISH_1**: The standard function block exposes its interface as events/variables (REQ, SD_1, ...). **AW_PUBLISH_1** encapsulates this function block, buffers the value with a D flip-flop (E_D_FF_ANY), and only provides the AW adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a WORD value at the adapter level but lacks network functionality. **AW_PUBLISH_1** combines buffering and publishing in a single function block.



Conclusion

AW_PUBLISH_1 combines the publish/subscribe communication of the standard function block PUBLISH_1 with adapter-based WORD processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AW interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AW_PUBLISH_1 combines the publish/subscribe communication of the standard function block PUBLISH_1 with adapter-based WORD processing.

AW_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AW adapter**. It subscribes to a publish channel configured via `ID` and makes the received **WORD** value buffered via a D flip-flop (E_D_FF_ANY) available at the adapter plug `OUT`. This allows for clean integration of network communication and WORD signal processing in the AW adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description

OUT	adapter::types::unidirectional::AW	Plug (Output)	Buffered received WORD value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF_ANY** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.
5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

- **Buffering with D flip-flop**: The received WORD value is buffered via an internal `iec61499::events::E_D_FF_ANY` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AW adapter interface is visible externally.

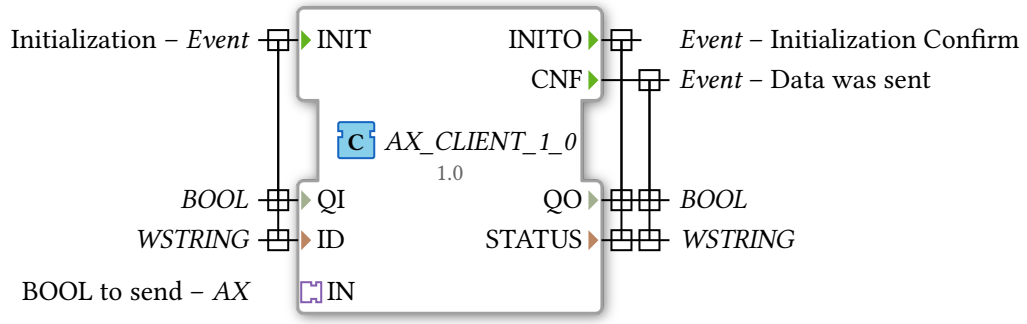
State Overview

1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Received**: At `IND`, the received WORD value is transferred to the internal D flip-flop and output via `OUT`.

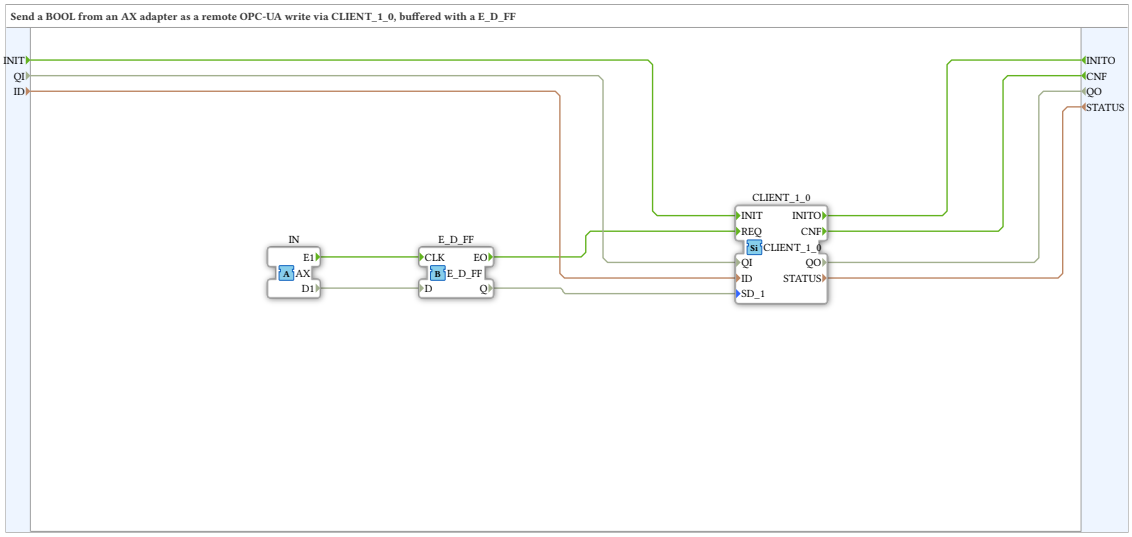
Application Scenarios

- **Network Coupling in AW Applications**: Receiving WORD signals (e.g., switching commands or status bits) via Publish/Subscribe and forwarding them via AW adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF_ANY`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a cleaner fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on AW adapters.

Comparison with Similar Building Blocks



- **SUBSCRIBE_1**: The standard building block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AW_SUBSCRIBE_1** encapsulates this building block, buffers the value with a D flip-flop (`E_D_FF_ANY`), and only provides the AW adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a WORD value at the adapter level but lacks network functionality. **AW_SUBSCRIBE_1** combines subscribing and buffering in a single building block.



Conclusion

AW_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based WORD processing. Internal D flip-flop buffering keeps the received value stable until new data arrives, and the simplified AW interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AW_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based WORD processing.

AX_CLIENT_1_0

• – ◦ • – ◦ • – ◦ •

Introduction

The **AX_CLIENT_1_0** function block is a composite function block that encapsulates the network-based `CLIENT_1_0` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AX adapter**. A **BOOL** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF) and then sent via `CLIENT_1_0` as an OPC UA **write** to the remote node configured in `ID`.

The generic `CLIENT_1_0` network client writes to a **remote** server identified by an `ID` that corresponds to a connection on the server block. For OPC UA, an `ID` such as `opc_ua[WRITE;opc.tcp://192.168.1.12:4840#;...]` is a transport-specific example, not a requirement; unlike **AX_PUBLISH_1** (local publish/subscribe), `CLIENT_1_0` can write to a remote server.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, opens (TRUE) or closes (FALSE) the connection to the server
- **ID** (WSTRING): Connection identifier (OPC UA address of the target node, e.g. `opc_ua[WRITE;opc.tcp://192.168.1.12:4840#;...]`)

Data Outputs

- **QO** (BOOL): Qualifier output, connection status

- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AX	Socket (Input)	BOOL value to be sent

Functionality

1. The internal `CLIENT_1_0` block is initialized with `QI` and `ID` via the `INIT` event; it establishes the connection to the remote server. Upon success, it returns `INITO`.
2. As soon as the AX socket `IN` sends an event to `IN.E1`, the BOOL value simultaneously present at `IN.D1` is transferred to the internal **E_D_FF** flip-flop (`CLK` or `D`).
3. The flip-flop holds the value stably at its output `Q` and generates the event `EO` when the value changes.
4. `EO` triggers the send event `REQ` of the internal `CLIENT_1_0` block. The buffered value `Q` is transmitted over the data connection as `SD_1` and sent to the server as an OPC UA write.
5. After successful transmission, the `CLIENT_1_0` block confirms with `CNF`, which is then sent out.

Technical Features

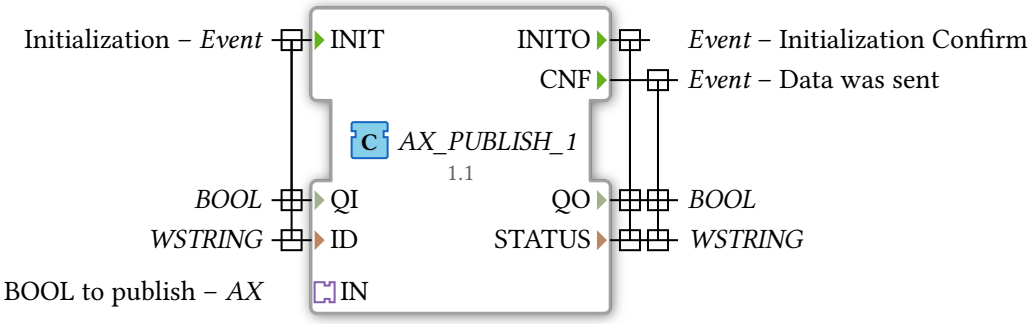
- **Buffering with D-Flip-Flop**: The BOOL value to be sent is buffered via an internal `iec61499::events::E_D_FF`. This prevents a changing input value during processing from interfering with the transmission.
- **Remote write instead of local publish**: `CLIENT_1_0` addresses a remote OPC UA server directly (ACTION=WRITE with a full ENDPOINT in `ID`), unlike `PUBLISH_1`/`SUBSCRIBE_1`, which only work locally on the same FORTE node.
- **Encapsulation**: The original event/data interface of `CLIENT_1_0` (including `REQ`/`SD_1`) is moved internally; only the AX adapter interface is visible externally.

State Overview

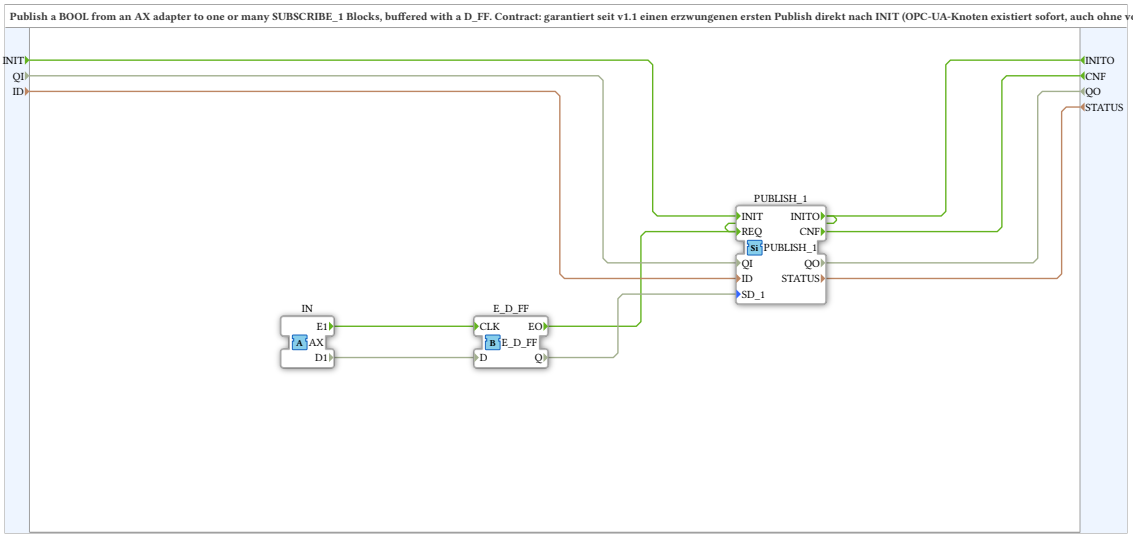
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The connection to the remote server is established, the block is ready to send.
3. **Send Active**: An event arriving at the AX socket buffers the value and triggers the remote write via the internal `CLIENT_1_0` block.

Application Scenarios

- **Remote control of other modules**: A VT button press on a module with its own ISOBUS/VT connection triggers an OPC UA write to a different, remote control module (e.g. STG1 switches an output on STG2–STG5).
- **Network coupling in AX applications**: Sending Boolean signals (switching commands) from adapter-based logic directly to a remote OPC UA server.
- **Modular control architectures**: Integration of distributed remote control into libraries that consistently rely on AX adapters.



Comparison with Similar Function Blocks



- **CLIENT_1_0**: The standard function block exposes its interface as events/variables (`REQ`, `SD_1`, …). **AX_CLIENT_1_0** encapsulates this function block, buffers the value with a D flip-flop, and only provides the AX adapter.
- **AX_PUBLISH_1**: Structurally identical (same events/variables/adapter), but encapsulates `PUBLISH_1` instead of `CLIENT_1_0` – so it only publishes locally instead of actively writing to a remote node.

Conclusion

AX_CLIENT_1_0 combines the connection-oriented remote-write communication of the standard function block `CLIENT_1_0` with adapter-based Boolean processing. Internal D flip-flop buffering stabilizes the transmitted value; the simplified AX interface makes the function block ideal for writing directly to a remote OPC UA server in fully adapter-based IEC 61499 applications.

AX_PUBLISH_1

• – ◦ • – ◦ • – ◦ •

Introduction

The **AX_PUBLISH_1** function block is a composite function block that encapsulates the network-based `PUBLISH_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AX adapter**. A **BOOL** value present at the adapter socket `IN` is buffered via an internal D flip-flop (E_D_FF) and then sent to all associated `SUBSCRIBE_1` receivers via the configured publish channel.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`
- **CNF** (Event): Confirmation that data has been sent, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the publish service
- **ID** (WSTRING): Publish channel identifier

Data Outputs

- **QO** (BOOL): Qualifier output, block execution status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description

IN	adapter::types::unidirectional::AX	Socket (Input)	BOOL value to be published

Functionality

1. The internal PUBLISH_1 block is initialized with QI and ID via the INIT event. Upon success, it returns INITO.
2. As soon as the AX socket IN sends an event to IN.E1, the BOOL value simultaneously present at IN.D1 is transferred to the internal **E_D_FF** flip-flop (CLK or D).
3. The flip-flop holds the value stably at its output Q and generates the event EO when the value changes.
4. EO triggers the send event REQ of the internal PUBLISH_1 block. The buffered value Q is transmitted over the data connection as SD_1 and published on the configured channel.
5. After successful transmission, the PUBLISH_1 block confirms with CNF, which is then sent out.

Technical Features

- **Buffering with D-Flip-Flop**: The BOOL value to be sent is buffered via an internal iec61499::events::E_D_FF. This prevents a changing input value during processing from interfering with the transmission.
- **Event-based decoupling**: The true event-based E_D_FF decouples immediate feedback loops between PUBLISH_1 and SUBSCRIBE_1 (e.g., on the same OPC UA node) – a clean fix compared to the interim fix with AX_D_FF.
- **Encapsulation**: The original event/data interface of PUBLISH_1 (including REQ/SD_1) is moved internally; only the AX adapter interface is visible externally.

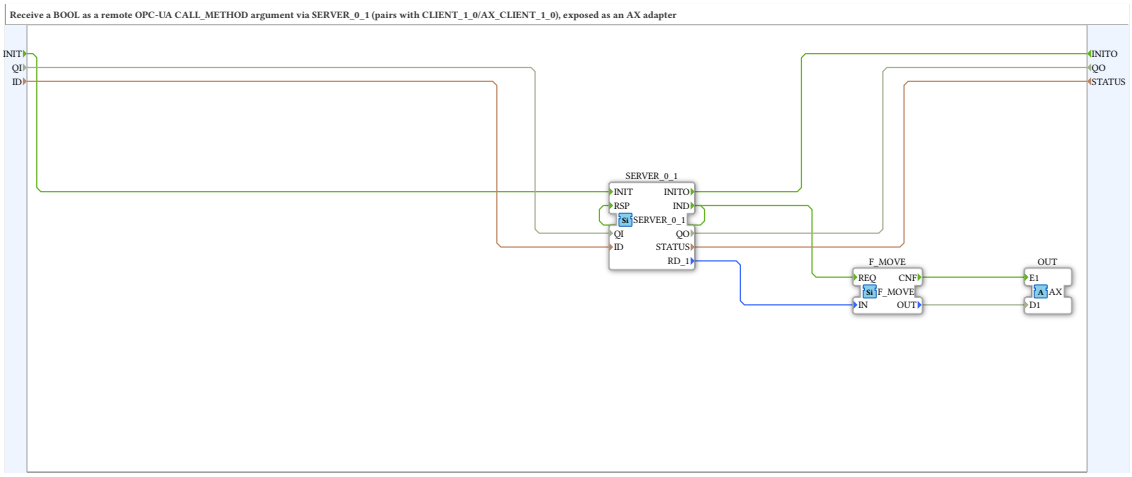
State Overview

1. **Not Initialized**: The block is waiting for the INIT event.
2. **Initialized**: The block is ready to publish data via the configured channel.
3. **Send Active**: An event arriving at the AX socket buffers the value and triggers transmission via the internal PUBLISH_1 block.

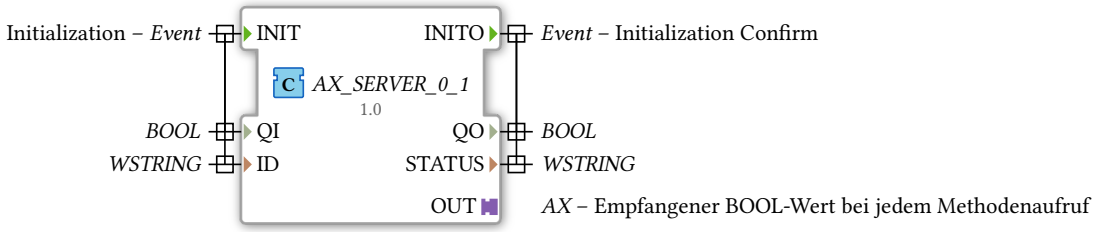
Application Scenarios

- **Network Coupling in AX Applications**: Sending Boolean signals (e.g., switching commands or status bits) from adapter-based logic to remote receivers via publish/subscribe.
- **Event Storm Avoidance**: Together with AX_SUBSCRIBE_1, feedback between your own publications and your own subscription is decoupled.
- **Modular Control Architectures**: Integration of distributed communication into libraries that consistently rely on AX adapters.

Comparison with Similar Function Blocks



- **PUBLISH_1**: The standard function block exposes its interface as events/variables (REQ, SD_1, ...). **AX_PUBLISH_1** encapsulates this function block, buffers the value with a D flip-flop, and only provides the AX adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a Boolean value at the adapter level but lacks network functionality. **AX_PUBLISH_1** combines buffering and publishing in a single function block.



Conclusion

AX_PUBLISH_1 combines the publish/subscribe communication of the standard function block PUBLISH_1 with adapter-based Boolean processing. Internal D flip-flop buffering stabilizes the transmitted value and decouples feedback loops; the simplified AX interface makes the function block ideal for fully adapter-based IEC 61499 applications.

AX_PUBLISH_1 combines the publish/subscribe communication of the standard function block PUBLISH_1 with adapter-based Boolean processing.

AX_SERVER_0_1

• – ◦ • – ◦ • – ◦ •

Introduction

The **AX_SERVER_0_1** function block is a composite function block from the `adapter::net` package. It encapsulates the network server block `iec61499::net::SERVER_0_1` and exposes incoming OPC UA method calls (`CALL_METHOD`) for **BOOL** arguments as a unidirectional **AX adapter** (`OUT`). It serves as the receiving counterpart to **AX_CLIENT_1_0** (or `CLIENT_1_0`).

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, connected to `QI` and `ID` (forwards to `SERVER_0_1.INIT`)

Event Outputs

- **INITO** (EInit): Initialization confirmation (`SERVER_0_1.INITO`), connected to `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Input qualifier, enables (TRUE) or disables (FALSE) the server
- **ID** (WSTRING): Server identifier (OPC UA server address and method specification)

Data Outputs

- **QO** (BOOL): Output qualifier, server operational status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapters

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AX	Plug (Output)	Received BOOL value on each method invocation

Functionality

1. An `INIT` event at `AX_SERVER_0_1` is forwarded to the internal `SERVER_0_1.INIT` input. The server starts the OPC UA endpoint and acknowledges with `INITO` upon success.

2. Upon an incoming method call from a remote client (`CLIENT_1_0`/`AX_CLIENT_1_0`), `SERVER_0_1` emits indication event `IND` and presents the received BOOL value at `RD_1`.
3. To prevent response-latency lockups (RSP latency bug), `SERVER_0_1.IND` is directly looped back to `SERVER_0_1.RSP` within the internal network, causing the server to acknowledge the method immediately.
4. Simultaneously, `IND` passes the received value through `F_MOVE` (`BOOL` data type) to AX plug `OUT.D1` and fires output event `OUT.E1`.

Technical Features

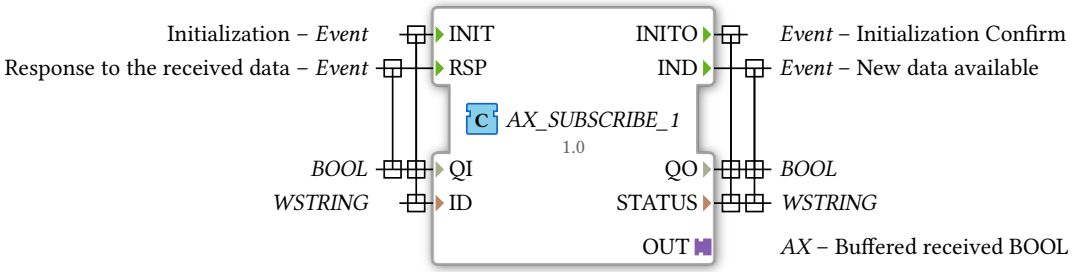
- **Direct RSP Loopback**: To eliminate 4-second server lockups caused by delayed responses, `SERVER_0_1.IND` is internally tied back to `SERVER_0_1.RSP`.
- **Seamless Adapter Integration**: The raw `RD_1` output of `SERVER_0_1` is mapped via `F_MOVE` (BOOL) directly onto the AX adapter structure (`OUT.D1` / `OUT.E1`).
- **Receiving Counterpart to `AX_CLIENT_1_0`**: In IEC 61499, a `CLIENT_1_0` block (“Connect to a SERVER_0_1 block”) pairs with a `SERVER_0_1` block.

State Overview

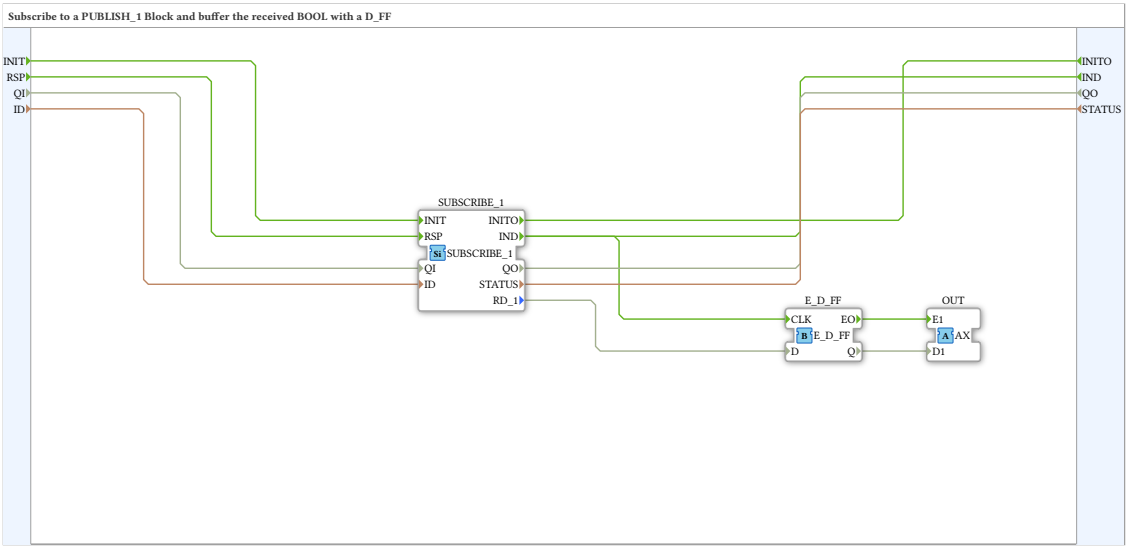
1. **Uninitialized**: The server is inactive and waiting for the `INIT` event.
2. **Listening**: The OPC UA server is active and waiting for method calls from remote clients.
3. **Indication**: A method call arrives; the BOOL value is passed to the `OUT` adapter and the response is sent immediately.

Application Scenarios

- **Receiving Remote Control Commands**: Receiving discrete switching commands (e.g. start/stop, enable signals) from a remote module via OPC UA `CALL_METHOD`.
- **Modular Server Architectures**: Providing OPC UA method endpoints for Boolean signals in adapter-based applications.



Comparison with Similar Blocks



- **AR_SERVER_0_1**: Receives REAL values via an AR adapter.
- **ATM_SERVER_0_1**: Receives TIME values via an ATM adapter.
- **AX_SUBSCRIBE_1**: Encapsulates `SUBSCRIBE_1` for local publish/subscribe rather than method invocations.

Conclusion

AX_SERVER_0_1 delivers received OPC UA method invocations for BOOL values over a clean AX adapter while preventing server response locks.

AX_SUBSCRIBE_1

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_SUBSCRIBE_1** is a composite function block that encapsulates the network-based `SUBSCRIBE_1` function block from the IEC 61499 standard library and maps its interface to a unidirectional **AX adapter**. It subscribes to a publish channel configured via `ID` and provides the received **BOOL** value, buffered via a D flip-flop (E_D_FF), on the adapter plug `OUT`. This allows for clean integration of network communication and Bool signal processing in the AX adapter environment.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization event, associated with `QI` and `ID`
- **RSP** (Event): Response event, associated with `QI`

Event Outputs

- **INITO** (EInit): Initialization confirmation, associated with `QO` and `STATUS`

Data Inputs

- **QI** (BOOL): Qualifier input, activates the subscription service
- **ID** (WSTRING): Identifier of the publish channel to be subscribed to

Data Outputs

- **QO** (BOOL): Qualifier output, status of the Block Execution
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AX	Plug (Output)	Buffered received BOOL value

Functionality

1. The internal `INIT` event initializes the internal `SUBSCRIBE_1` block with `QI` and `ID`. Upon success, it returns `INITO`.
2. The internal `SUBSCRIBE_1` block monitors the configured channel. As soon as the associated `PUBLISH_1` block publishes data, it generates the indication event `IND` and places the received value at `RD_1`.
3. `IND` clocks the internal **E_D_FF** flip-flop (`CLK`), which receives the value from `RD_1` at its data input `D`.
4. The stored value appears stably at output `Q` and is transferred via the data connection to `OUT.D1` of the AX plug.

5. The event `EO` of the flip-flop is transferred to the event output `OUT.E1`, so that downstream components are notified of the new information.

Technical Features

- **Buffering with D flip-flop**: The received BOOL value is buffered via an internal `iec61499::events::E_D_FF` and remains stable at the output until the next value is received. `EO` only fires when `Q` changes.
- **RSP is a no-op for subscribers**: According to source code analysis of `4diac-forte` (`CCommFB::sendData()`), the `RSP` event in `SUBSCRIBE_1` (service type subscriber) does not execute any action – the branch `!= e_Subscriber` is skipped. The event input pair `INIT`/`RSP` is only executed for acknowledgment and is non-functional for acknowledgment in the subscriber case. It is nevertheless routed externally to maintain a configurable connection.
- **Encapsulation**: The original event/data interface of `SUBSCRIBE_1` (including `IND`/`RD_1`) is moved internally; only the AX adapter interface is visible externally.

State Overview

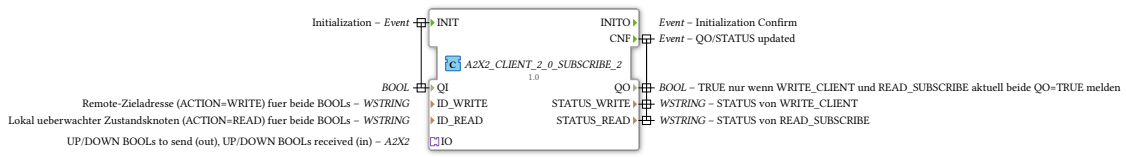
1. **Not Initialized**: The block is waiting for the `INIT` event.
2. **Initialized**: The subscription is active; the block is waiting for data from the publisher.
3. **Data Received**: At `IND`, the received BOOL value is transferred to the internal D flip-flop and output via `OUT`.

Application Scenarios

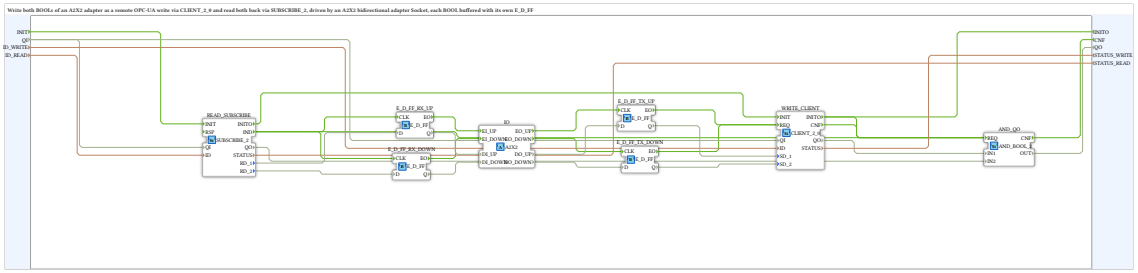
- **Network Coupling in AX Applications**: Receiving Boolean signals (e.g., switching commands or status bits) via publish/subscribe and forwarding them via AX adapters to the adapter-based logic.
- **Event Storm Avoidance**: Together with `AX_PUBLISH_1` and a true event-based `E_D_FF`, the feedback between `SUBSCRIBE_1` and `PUBLISH_1` can be decoupled (a cleaner fix compared to the interim fix with `AX_D_FF`).
- **Modular Control Architectures**: Integration of distributed communication into libraries that rely entirely on AX adapters.

Comparison with Similar Function Blocks

- **SUBSCRIBE_1**: The standard function block exposes its interface as events/variables (`IND`, `RD_1`, ...). **AX_SUBSCRIBE_1** encapsulates this function block, buffers the value with a D flip-flop, and only provides the AX adapter – making the interface significantly more compact and integrable into adapter networks.
- **AX_D_FF**: Bufferes a Boolean value at the adapter level but lacks network functionality. **AX_SUBSCRIBE_1** combines subscribing and buffering in a single function block.



Conclusion



AX_SUBSCRIBE_1 combines the publish/subscribe communication of the standard function block `SUBSCRIBE_1` with adapter-based Boolean processing. The internal D-flip-flop buffer keeps the received value stable until new data arrives, and the reduced AX interface makes the device ideal for end-to-end adapter-based IEC 61499 applications.

The internal D-flip-flop buffer keeps the received value stable until new data arrives, and the reduced AX interface makes the device ideal for end-to-end adapter-based IEC 61499 applications.

BOOL

A2X2_CLIENT_2_0_SUBSCRIBE_2

• — ○ • — ○ • — ○ •

Introduction

The function block **A2X2_CLIENT_2_0_SUBSCRIBE_2** is a composite FB that bridges between a bidirectional A2X2 adapter (with two BOOL channels, UP and DOWN) and an OPC-UA server. It uses the standard `CLIENT_2_0` and `SUBSCRIBE_2` function blocks to write two BOOL values to a remote OPC-UA node and read two BOOL values from a local state node. Each input/output BOOL is individually buffered using `E_D_FF` flip-flops to ensure stable signal transfer and to decouple event sequences.

Interface Structure

Event Inputs

Event	Type	Comment
`INIT`	EInit	Initialization event. Resets the FB and starts the data flow.

Event Outputs

Event	Type	Comment
`INITO`	EInit	Initialization confirm. Emitted after both internal FB initializations complete.
`CNF`	Event	Confirmation event. Emitted when `QO`, `STATUS_WRITE`, and `STATUS_READ` are updated.

Data Inputs

Name	Type	Comment
`QI`	BOOL	Enable input. When `FALSE`, the FB is inactive and outputs are reset.
`ID_WRITE`	WSTRING	Remote target address for the write operation (both BOOLs).
`ID_READ`	WSTRING	Local state node address to monitor (both BOOLs).

Data Outputs

Name	Type	Comment
`QO`	BOOL	`TRUE` only when both the write client and the read subscriber report `QO = TRUE`.
`STATUS_WRITE`	WSTRING	Status string from the internal `WRITE_CLIENT` FB.
`STATUS_READ`	WSTRING	Status string from the internal `READ_SUBSCRIBE` FB.

Adapters

Adapter	Type	Comment
`IO`	`adapter::types::bidirectional::A2X2`	Bidirectional BOOL channels: `DO_UP`/`DO_DOWN` (send) and `DI_UP`/`DI_DOWN` (receive).

Functionality

The FB operates in two independent data paths:

1. **Write Path**: BOOL values received from the adapter (`IO.DO_UP`, `IO.DO_DOWN`) are captured in the corresponding `E_D_FF_TX_UP` and `E_D_FF_TX_DOWN` flip-flops. Each event at `IO.EO_UP` or `IO.EO_DOWN` triggers a `REQ` on the `WRITE_CLIENT` FB, which sends the buffered values to the remote OPC-UA node via `SD_1` and `SD_2`.
2. **Read Path**: The `READ_SUBSCRIBE` FB continuously monitors the configured `ID_READ` node. Upon each `IND` event, its `RD_1` and `RD_2` data outputs are fed into the `E_D_FF_RX_UP` and `E_D_FF_RX_DOWN` flip-flops. Their stored values are then presented on `IO.DI_UP` and `IO.DI_DOWN` and emitted via the corresponding event outputs (`IO.EI_UP`, `IO.EI_DOWN`).

The internal `AND_QO` block combines the `QO` signals from both the write client and the read subscriber, producing the overall `QO` output. The `CNF` event is generated whenever either the write client finishes a write operation (`WRITE_CLIENT.CNF`) or the read subscriber receives new data (`READ_SUBSCRIBE.IND`), ensuring that the status outputs are always current.

Technical Features

- Uses standard IEC 61499 `CLIENT_2_0` and `SUBSCRIBE_2` blocks for OPC-UA communication.
- Four `E_D_FF` flip-flops provide edge-triggered buffering, preventing data loss when events occur faster than the communication cycle.
- Initialization is chained: `INIT` ⟶ `READ_SUBSCRIBE.INIT` ⟶ `WRITE_CLIENT.INIT` ⟶ `INITO`.
- The output `QO` is only `TRUE` when both write and read sides are operational, giving a combined health indicator.
- Status strings are propagated separately for write and read operations, aiding diagnostics.

State Overview

The FB does not maintain a complex internal state machine. Its behaviour is driven by the internal FB instances:

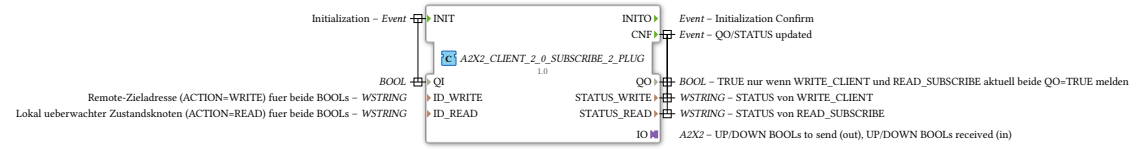
- **`READ_SUBSCRIBE`** operates in the standard subscribe-mode, generating `IND` events whenever subscribed data changes.
- **`WRITE_CLIENT`** operates in client mode, generating `REQ` events to send data and `CNF` events to confirm completion.
- The `E_D_FF` flip-flops act as single-bit storage elements, toggling their `Q` outputs on each clock edge from the corresponding event inputs.
- The `AND_QO` block simply performs a logical AND of the two `QO` signals.

Overall, the FB is in an active state only when `QI = TRUE`. When `QI` is `FALSE`, all internal blocks are disabled and outputs become `FALSE`/empty strings.

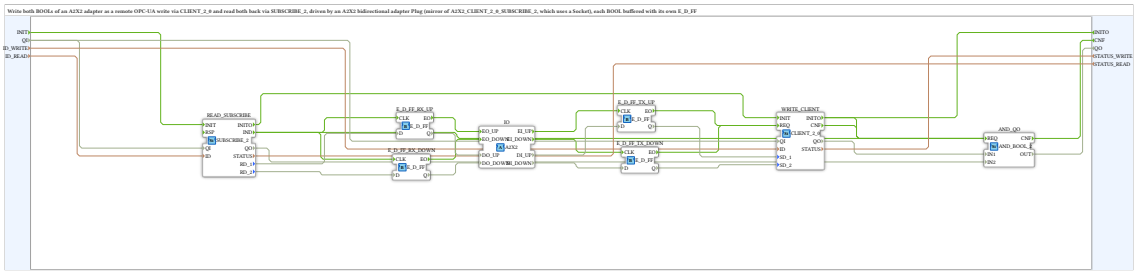
Application Scenarios

This FB is suitable for applications requiring:

- Reliable bidirectional exchange of two BOOL values between an industrial controller and an OPC-UA server.
- Separation of write and read data paths with individual status reporting.
- Edge-triggered buffering to handle high-frequency updates without loss.
- Use cases where an A2X2 adapter is present, such as connecting to remote I/O, interlocking logic, or display of single-bit state information.



Comparison with Similar Blocks



- **A2X2_CLIENT_2_0_SUBSCRIBE_1** (hypothetical) might handle only one BOOL channel; this FB processes two channels (UP and DOWN) with independent buffering.
- Using two separate `CLIENT_2_0` and `SUBSCRIBE_2` blocks for each channel would double the network connections and complicate status aggregation; this FB encapsulates both in one unit.
- Compared to a simple direct coupling without flip-flops, the `E_D_FF` buffers prevent race conditions and ensure that only stable, latched values are transmitted or displayed.

Conclusion

A2X2_CLIENT_2_0_SUBSCRIBE_2 provides a compact, reliable solution for bidirectional BOOL exchange with an OPC-UA server. It combines standard communication blocks with local buffering, yielding clear status outputs and a robust initialization sequence. Its interface is tailored to the A2X2 adapter, making it a ready-to-use component in distributed automation systems.

A2X2_CLIENT_2_0_SUBSCRIBE_2_PLUG

• – ○ • – ○ • – ○ •

Introduction

The `A2X2_CLIENT_2_0_SUBSCRIBE_2_PLUG` is a composite function block that bridges a bidirectional A2X2 adapter plug with an OPC-UA server. It writes two Boolean values (UP and DOWN) to a remote node via the `CLIENT_2_0` write service and continuously reads two Boolean values from another remote node via the `SUBSCRIBE_2` subscription service. Each Boolean direction is individually buffered using its own `E_D_FF` flip-flop, ensuring reliable edge-triggered data transfer between the adapter interface and the network services.

This block is the plug-side mirror of `A2X2_CLIENT_2_0_SUBSCRIBE_2`, which uses a socket. It is designed for applications where an OPC-UA server must be remotely controlled and monitored through a bidirectional adapter interface, such as in industrial automation and IoT gateways.

Interface Structure

Event Inputs

Event	Type	Comment	With
`INIT`	`EInit`	Initialization	`QI`

Event Outputs

Event	Type	Comment	With
`INITO`	`EInit`	Initialization Confirm	–
`CNF`	`Event`	`QO` / `STATUS` updated	`QO`, `STATUS_WRITE`, `STATUS_READ`

Data Inputs

Name	Type	Comment
`QI`	`BOOL`	Enable the block. `TRUE` starts the client and subscribe services.
`ID_WRITE`	`WSTRING`	Remote target address (ACTION=WRITE) for both Boolean values.
`ID_READ`	`WSTRING`	Locally monitored state node (ACTION=READ) for both Boolean values.

Data Outputs

Name	Type	Comment
QO	BOOL	TRUE only if both WRITE_CLIENT.QO and READ_SUBSCRIBE.QO are TRUE.
STATUS_WRITE	WSTRING	Status of the WRITE_CLIENT instance.
STATUS_READ	WSTRING	Status of the READ_SUBSCRIBE instance.

Adapters

Name	Type	Comment
IO	adapter::types::bidirectional::A2X2	UP/DOWN BOOLs to send (out), UP/DOWN BOOLs received (in).

Functionality

The block operates as a bidirectional data bridge between the A2X2 adapter plug and an OPC-UA server. Two independent paths handle the write and read directions:

Write Path (PLC → OPC-UA):

The adapter plug provides two input Booleans, DI_UP and DI_DOWN. When the plug raises the corresponding event (EI_UP or EI_DOWN), the associated E_D_FF latch captures the current value on its D input and triggers its output event (EO). This event activates WRITE_CLIENT.REQ, causing the client to send the latched value(s) (SD_1 for UP, SD_2 for DOWN) to the remote OPC-UA node specified by ID_WRITE. The client's CNF event indicates completion or error.

Read Path (OPC-UA → PLC):

The SUBSCRIBE_2 FB continuously listens to the remote node given by ID_READ. When new data arrives (event IND), the two received Booleans (RD_1 and RD_2) are latched into the corresponding E_D_FF flip-flops. The outputs of these flip-flops (Q) are placed on DO_UP and DO_DOWN, and the respective output events (EO_UP, EO_DOWN) are triggered on the adapter plug, notifying the consumer that new values are available.

Initialization and Monitoring:

- The INIT event starts the READ_SUBSCRIBE first; after its INITO, the WRITE_CLIENT is initialized. The overall INITO is emitted when both are ready.
- The AND_QO logic combines the QO outputs of both network blocks. QO is TRUE only when both the client and the subscriber report operational health. The CNF event is triggered by the AND_QO block whenever any of the two blocks updates its status. This allows external logic to monitor the combined service status.

Technical Features

- **Composite type** – Built from standard 4diac FBs (CLIENT_2_0, SUBSCRIBE_2, E_D_FF, AND_BOOL_2).
- **Edge-triggered buffering** – Each Boolean direction uses a dedicated E_D_FF to reliably capture data changes on the adapter side and on the subscription side.
- **Independent addressing** – The write and read targets are configured separately via ID_WRITE and ID_READ, allowing different OPC-UA nodes for command and feedback.
- **Combined status** – The QO output reflects the overall health of both communication channels.
- **Event-driven** – No continuous polling; all transfers are event-based, minimizing network traffic.
- **Initialization sequence** – Ensures subscribe becomes active before client writes are attempted.

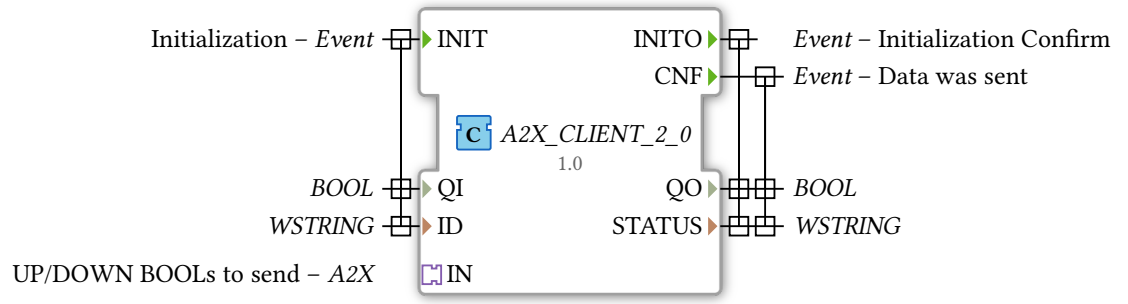
State Overview

There is no explicit state machine; the block's behaviour is event-driven. However, the following operational states can be inferred:

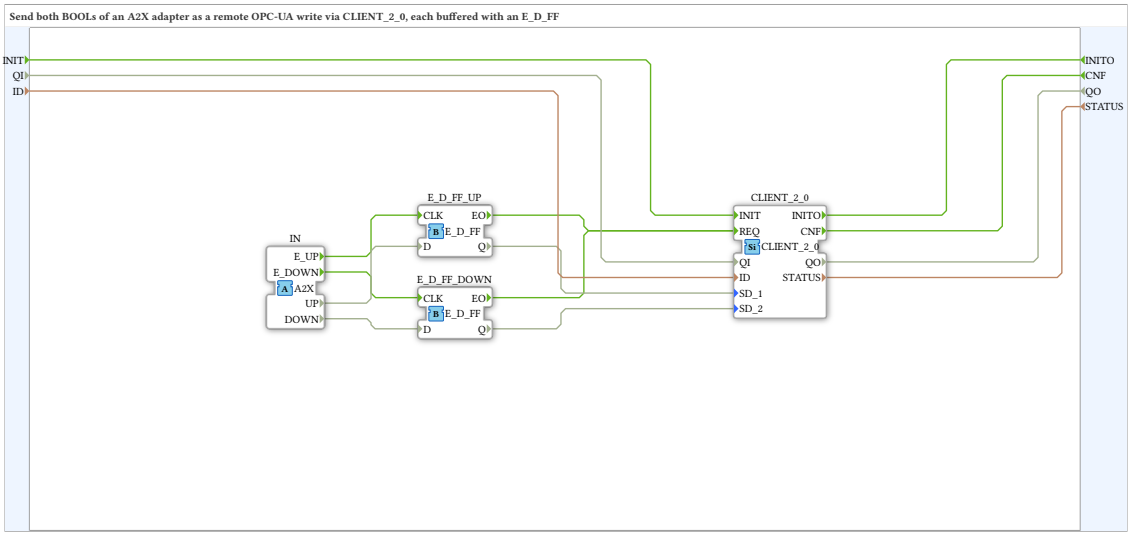
- **Idle** – QI = FALSE or initialization not completed. No network activity.
- **Initializing** – After INIT, the subscribe service is being started, followed by the client. QO is FALSE.
- **Active** – Both WRITE_CLIENT and READ_SUBSCRIBE have QO = TRUE. The block is writing and reading data as events arrive.
- **Degraded / Error** – Either the client or subscriber reports a failed QO (FALSE). The combined QO becomes FALSE, and the corresponding STATUS output contains diagnostic information.

Application Scenarios

- **Remote I/O control** – Controlling two output bits on a remote PLC or device via OPC-UA while simultaneously monitoring two input bits.
- **HMI / SCADA integration** – Bridging an A2X2 adapter to an OPC-UA server for supervisory control and data acquisition.
- **Gateway between protocols** – Using the adapter to interface with proprietary fieldbus systems while exposing the same signals through OPC-UA.
- **Redundant monitoring** – The combined status (`QO`) can be used to trigger alarms if either the write or read channel fails.



Comparison with Similar Blocks



- **`A2X2_CLIENT_2_0_SUBSCRIBE_2` (Socket version)** – Operates identically but uses an A2X2 socket instead of a plug. The choice depends on the direction of data flow in the surrounding network; this block is intended for use in a system that provides the adapter (plug side).
- **Simple write/read blocks** – Standalone `CLIENT_2_0` and `SUBSCRIBE_2` blocks require manual management of events and data. This composite block encapsulates the necessary buffering and event linking, simplifying integration.
- **Alternative adapter types** – Blocks for other adapter types (e.g., single Boolean or analog) would have different interfaces but follow a similar pattern.

Conclusion

The `A2X2_CLIENT_2_0_SUBSCRIBE_2_PLUG` provides a clean, reusable solution for bridging two Boolean values from an adapter plug to an OPC-UA server and back. Its event-driven design, combined with flip-flop buffering and a unified status output, makes it well suited for real-time industrial applications where reliable and responsive data exchange is required. The block is fully self-contained and can be integrated directly into any 4diac application.

A2X_CLIENT_2_0

• – ○ • – ○ • – ○ •

Introduction

A2X_CLIENT_2_0 is a composite function block that takes two Boolean values (UP and DOWN) from an A2X adapter socket and performs a remote OPC-UA write via an embedded CLIENT_2_0 client. Each incoming value change is captured by its own edge-triggered D flip-flop (E_D_FF) before the write request is issued. This buffering ensures that only the most recent state changes are sent to the remote server, while the rest of the network remains decoupled from the exact timing of the write operation.

Interface Structure

Event Inputs

Name	Type	Comment	With Variables
INIT	EInit	Initialization	QI, ID

Event Outputs

Name	Type	Comment	With Variables
INITO	EInit	Initialization Confirm	QO, STATUS
CNF	Event	Data was sent	QO, STATUS

Data Inputs

Name	Type	Comment
QI	BOOL	Initialization qualifier, passed directly to the embedded CLIENT_2_0
ID	WSTRING	Connection identifier / endpoint address for the OPC-UA server

Data Outputs

Name	Type	Comment
QO	BOOL	Quality / state output of the embedded CLIENT_2_0
STATUS	WSTRING	Status message, holding the last operation result

Adapters

Name	Type	Direction	Comment
IN	adapter::types::unidirectional::A2X	Socket	Provides UP/DOWN Boolean values and their change events (E_UP / E_DOWN)

Functionality

The block is initialized via the INIT event. On INIT, the QI and ID input values are forwarded to the internal CLIENT_2_0, and the client establishes the connection to the configured OPC-UA server. The INITO event confirms successful completion and reports the resulting QO and STATUS.

At runtime, the adapter socket IN delivers the two Boolean values UP and DOWN. Each value is connected to the data input D of its own edge-triggered D flip-flop:

- IN.UP ⟶ E_D_FF_UP.D
- IN.DOWN ⟶ E_D_FF_DOWN.D

The corresponding adapter events (IN.E_UP and IN.E_DOWN) act as clock signals (CLK) for the respective flip-flops. When either event occurs, the current value on its data input is latched into the flip-flop output (Q). At the same time, the flip-flop's event output (EO) triggers a REQ event on the embedded CLIENT_2_0.

The latched values are connected to the client's data inputs:

- E_D_FF_UP.Q ⟶ CLIENT_2_0.SD_1
- E_D_FF_DOWN.Q ⟶ CLIENT_2_0.SD_2

All other values (the unchanged one) remain at their previous latched state. The REQ event therefore causes a single OPC-UA write operation, transmitting both SD_1 and SD_2 to the remote server. Upon completion, the client outputs the CNF event together with the current QO and STATUS values.

Technical Features

- **Edge-triggered buffering**: Two independent E_D_FF instances capture UP and DOWN changes, guaranteeing that only actual state transitions cause a write operation.
- **Shared write channel**: Both flip-flop outputs lead to a single CLIENT_2_0 REQ input, ensuring that one event produces exactly one write request.
- **Direct initialization pass-through**: QI and ID are forwarded unchanged to the CLIENT_2_0, keeping the configuration interface minimal.
- **Combined result reporting**: Both INITO and CNF events deliver the same QO and STATUS data, giving a consistent view of the connection and operation state.

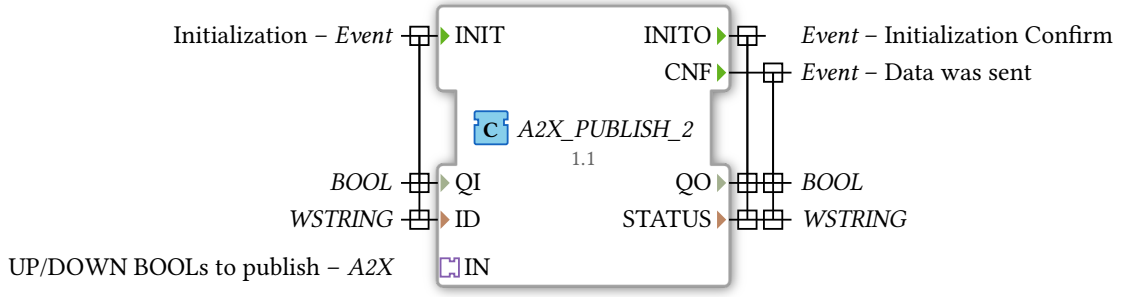
State Overview

The block behaves as follows:

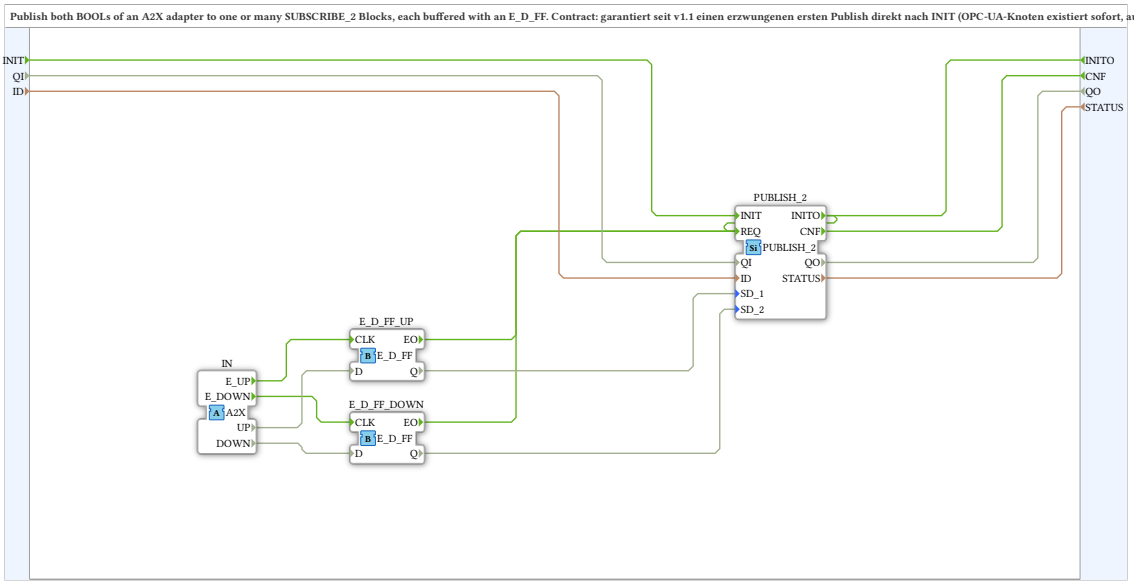
- **Uninitialized**: Before INIT, the internal CLIENT_2_0 is inactive. No events are processed and no writes occur.
- **Initializing**: After INIT arrives, the client is configured with QI and ID. Successful completion is signalled by INITO; the client is then ready for REQ.
- **Idle / Waiting**: Between REQ events, the flip-flops wait for new adapter events (E_UP or E_DOWN). Their outputs hold the last written values.
- **Write in progress**: When E_UP or E_DOWN fires, the corresponding flip-flop updates its output and triggers REQ. The write operation is performed by the client; its completion is signalled by CNF.

Application Scenarios

- **Remote up/down control**: Sending two binary command states (e.g., raise/lower) from a local adapter to an OPC-UA server, where each state change must be individually acknowledged.
- **Binary state mirroring**: Continuously synchronizing two Boolean process variables to a remote controller, while avoiding continuous polling or redundant writes.
- **Distributed automation**: In a system where the A2X adapter provides field-level signals, this block forwards them to a central OPC-UA data hub, independent of the client's polling cycles.



Comparison with Similar Blocks



- **Without buffering (direct connection)**: A straightforward CLIENT_2_0 with direct adapter connections would only write when a client-internal trigger occurs; it would not automatically react to every value change. A2X_CLIENT_2_0 ensures a write is issued for every transition.
- **Single E_D_FF variant**: A version using only one flip-flop would concatenate both values into a single data point, losing independence of the two signals. Here, each signal has its own flip-flop, preserving individual change events.
- **Manual REQ triggering**: Some designs require an external block to generate REQ every time new data arrives. In A2X_CLIENT_2_0, this trigger is generated internally by the flip-flops, reducing the external wiring and keeping the interface compact.

Conclusion

A2X_CLIENT_2_0 provides a clean, self-contained solution for forwarding two Boolean signals from an A2X adapter to a remote OPC-UA server. By integrating two edge-triggered flip-flops with a standard OPC-UA client, it combines reliable change detection with efficient write operations. Its simple interface —only an INIT event, an adapter socket, and the standard QI/ID/QO/STATUS data—makes it easy to integrate into larger automation networks while ensuring that each state change is transmitted exactly once.

A2X_PUBLISH_2

• – ○ • – ○ • – ○ •

Introduction

The **A2X_PUBLISH_2** function block is a network publishing component that takes the two Boolean values (`UP` and `DOWN`) from an A2X adapter socket and publishes them via a standard `PUBLISH_2` block to one or more `SUBSCRIBE_2` counterparts. Each published value is buffered internally with an edge-triggered `E_D_FF` flip-flop, ensuring that only state changes trigger a network transmission, reducing unnecessary network traffic. The block is designed for scenarios where a single publisher must distribute a pair of Boolean signals (e.g., up/down commands) to multiple subscribers over Ethernet.

Interface Structure

Event Inputs

Event	Type	With Variables	Comment
`INIT`	`EInit`	`QI`, `ID`	Initialization of the publish connection.

Event Outputs

Event	Type	With Variables	Comment
`INITO`	`EInit`	`QO`, `STATUS`	Initialization confirmation.
`CNF`	`Event`	`QO`, `STATUS`	Confirmation that data was sent.

Data Inputs

Variable	Type	Comment

QI	BOOL	Quality / enable input. When TRUE, the block is active.
ID	WSTRING	Remote endpoint identifier (e.g., IP address and port) for the publish channel.

Data Outputs

Variable	Type	Comment
QO	BOOL	Quality / confirmed output. Reflects the active state after initialization.
STATUS	WSTRING	Status information of the last operation (e.g., error or success message).

Adapters

Direction	Name	Type	Comment
Socket	IN	adapter::types::unidirectional::A2X	Provides the two BOOL values UP and DOWN to be published.

Functionality

The A2X_PUBLISH_2 block combines an A2X adapter with an internal PUBLISH_2 network block and two edge-triggered D-flip-flops (E_D_FF_UP and E_D_FF_DOWN).

1. **Data capture**: The Boolean values IN.UP and IN.DOWN are continuously wired to the D inputs of two flip-flops.
2. **Edge detection**: When an event IN.E_UP occurs, the flip-flop E_D_FF_UP latches the current UP value onto its output Q. The same applies to E_D_FF_DOWN when IN.E_DOWN occurs.
3. **Trigger publishing**: On every rising edge at either flip-flop (the EO output), the internal PUBLISH_2 block receives a REQ event, capturing the latched values into its SD_1 and SD_2 data inputs.
4. **Network transmission**: The PUBLISH_2 block sends the two values to the configured endpoint (ID). When successful, it emits the CNF event and updates QO and STATUS.
5. **Initialization**: The INIT event initializes the underlying PUBLISH_2 connection. The result is reported via INITO, QO, and STATUS.

The internal buffering ensures that repeated identical values do not trigger unnecessary transmissions. Only actual changes of the UP or DOWN signals cause the publish operation.

Technical Features

- **Edge-triggered buffering**: Both input signals are latched in E_D_FF elements, ensuring that the last state is retained until a new edge appears.
- **Single publish channel**: The two buffered values are transmitted together in one PUBLISH_2 operation, minimizing network overhead.
- **Standard 61499-compliant**: Built from standard iec61499 function blocks (E_D_FF, PUBLISH_2).
- **Unidirectional adapter**: Designed for one-way communication from the publisher to subscribers.
- **Status feedback**: QO and STATUS provide clear reporting of initialization and transmission results.

State Overview

The block behaves as follows with respect to its internal flip-flops:

State	Condition	Behavior
Initial	After INIT, no event received	Flip-flops hold their default (FALSE). No publish trigger occurs.
Idle	No edge on E_UP or E_DOWN	Flip-flop outputs unchanged; no publication triggered.
Up-edge	IN.E_UP rises	UP value latched; E_D_FF_UP.EO triggers PUBLISH_2.REQ.
Down-edge	IN.E_DOWN rises	DOWN value latched; E_D_FF_DOWN.EO triggers PUBLISH_2.REQ.
Publishing	REQ emitted	PUBLISH_2 sends SD_1 and SD_2 to the network.

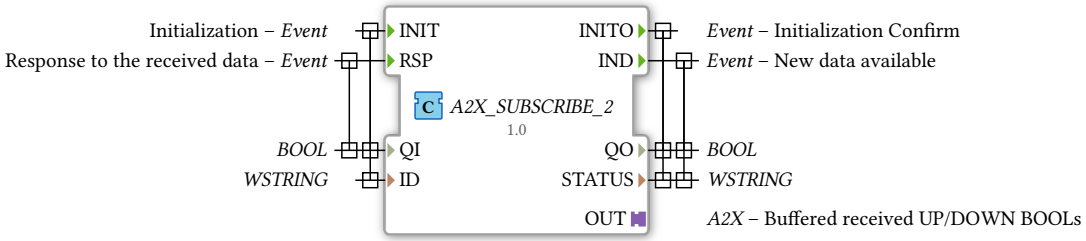
Confirmed	CNF emitted	Outputs QO and STATUS are updated; the block returns to idle.

The flip-flops retain their last value indefinitely until the next relevant edge, meaning the last published state is always remembered.

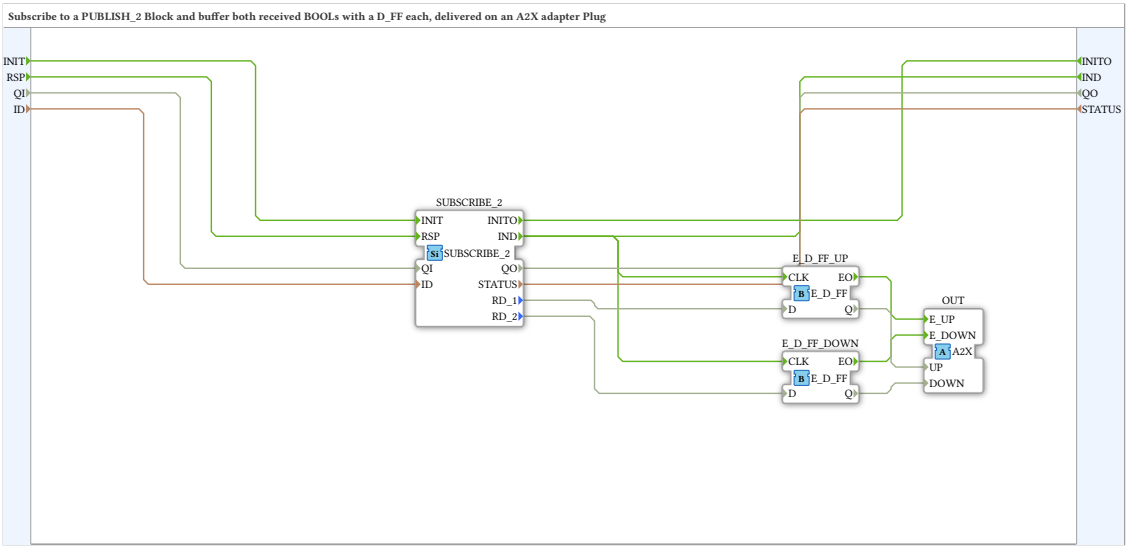
Application Scenarios

- **Machine control**: Publishing two limit-switch states (up/down) from one controller to several HMIs or PLCs.
- **Remote I/O**: Distributing two Boolean sensor values to all subscribers in a multicast group.
- **Building automation**: Broadcasting window open/close or door up/down commands to multiple control panels.
- **Rapid status distribution**: Any application where a single source must notify several consumers of a Boolean pair, with network efficiency achieved by transmitting only on state changes.

Comparison with Similar Blocks



Block	Key Difference
A2X_PUBLISH_2	Buffers adapter BOOLs in E_D_FF and publishes only on change.
Plain PUBLISH_2	Publishes directly from data inputs with no internal edge detection; every REQ sends data.
A2X_SUBSCRIBE_2	Receives instead of sends, no buffering of edge events.
A2X_PUBLISH_2 with manual buffering	Requires external E_D_FF instances; this block encapsulates them for convenience.



The main advantage over a direct PUBLISH_2 usage is the automatic edge-triggered buffering, which reduces network load and simplifies application logic.

Conclusion

The **A2X_PUBLISH_2** function block provides a compact, efficient solution for publishing a pair of Boolean signals from an A2X adapter to multiple subscribers. By integrating edge-triggered buffers with a standard publish block, it ensures that only meaningful state changes are transmitted, reducing network traffic and simplifying the application design. It is well suited for distributed automation systems where reliable and efficient status dissemination is required.

A2X_SUBSCRIBE_2

• – ○ • – ○ • – ○ •

Introduction

The **A2X_SUBSCRIBE_2** function block is a composite network subscriber designed to receive two Boolean values from a remote **PUBLISH_2** block via an Ethernet-based publish/subscribe mechanism. It internally buffers the two received BOOL values using dedicated D flip-flops (E_D_FF) and delivers them — together with corresponding event signals — through a unidirectional A2X adapter plug for further processing in the application logic.

This block is particularly useful in distributed IEC 61499 systems where two independent Boolean state variables (e.g., UP and DOWN commands) must be reliably received, synchronized, and made available to a local consumer in a structured and event-driven manner.

Interface Structure

Event Inputs

Event Name	Type	Associated Data	Description
`INIT`	EInit	`QI`, `ID`	Initialization event that configures the underlying subscription with the quality indicator and the communication identifier.
`RSP`	Event	`QI`	Response event used to acknowledge or re-trigger the subscription process after a previous request.

Event Outputs

Event Name	Type	Associated Data	Description
`INITO`	EInit	`QO`, `STATUS`	Initialization confirmation, indicating whether the subscription was successfully established.
`IND`	Event	`QO`, `STATUS`	Indicates that new data has been received from the publisher and is available at the adapter outputs.

Data Inputs

Data Name	Type	Description
`QI`	BOOL	Quality indicator enabling (`TRUE`) or disabling (`FALSE`) the subscription operation.

ID	WSTRING	Communication identifier (e.g., multicast address or group ID) used to bind the subscriber to the correct publisher.

Data Outputs

Data Name	Type	Description
QO	BOOL	Quality output confirming that the subscription is active and operational.
STATUS	WSTRING	Status information string providing runtime diagnostics or error messages.

Adapters

Adapter Name	Direction	Type	Description
OUT	Plug	adapter::types::unidirectional::A2X	Buffered output adapter delivering the two received Boolean values (UP, DOWN) together with their associated event indicators (E_UP, E_DOWN).

Functionality

The **A2X_SUBSCRIBE_2** block operates as follows:

1. **Initialization**: Upon receiving the INIT event, the internal SUBSCRIBE_2 network subscriber is configured using the QI enable flag and the ID communication identifier. The INITO event confirms successful initialization with updated QO and STATUS values.
2. **Data Reception**: When the underlying SUBSCRIBE_2 network service receives data from a matching publisher, it raises the IND event. This event triggers three parallel actions:
   - The newly received RD_1 value is latched into the E_D_FF_UP D flip-flop.
   - The newly received RD_2 value is latched into the E_D_FF_DOWN D flip-flop.
   - The IND event is propagated to the block's external event output to signal that fresh data is available.
3. **Buffered Output**: The latched values from both flip-flops are continuously driven onto the adapter outputs (OUT.UP and OUT.DOWN). Correspondingly, the flip-flop event outputs (EO) are connected to OUT.E_UP and OUT.E_DOWN, providing event-driven notifications for each data change.
4. **Response Handling**: The RSP event input allows the application to explicitly trigger a new subscription request or acknowledgement cycle through the internal subscriber, with the QI value supplied for re-evaluation.

Technical Features

- **Composite implementation**: Built as a network of three internal function blocks (SUBSCRIBE_2, E_D_FF_UP, E_D_FF_DOWN), demonstrating reusable modular design.
- **Ethernet-based communication**: Uses the standard IEC 61499 network SUBSCRIBE_2 service type for reliable remote data exchange.
- **Data buffering**: Each incoming Boolean value is latched into an edge-triggered D flip-flop, ensuring stable output values between publication cycles.
- **Event-driven architecture**: Both the external IND event and the internal adapter events (E_UP, E_DOWN) are generated based on the reception trigger, allowing downstream logic to react immediately.
- **Standardized status reporting**: QO and STATUS provide consistent quality and diagnostic information for monitoring and error handling.
- **Unidirectional data flow**: The A2X adapter plug strictly follows a publisher-to-subscriber direction, simplifying data flow analysis.

State Overview

The block does not maintain an explicit internal state machine in the composite network, but its behaviour can be described in terms of operational phases:

Phase	Description	Trigger

Idle	Subscription is inactive; `QO = FALSE`.	Before `INIT` or after failed initialization
Initializing	`INIT` received; internal subscriber is being configured.	`INIT` event edge
Active / Subscribed	Subscription established; `QO = TRUE`; waiting for data.	Successful `INITO` with valid status
Data Received	New publication arrived; flip-flop latches are updated; `IND` raised.	Internal `SUBSCRIBE_2.IND`
Re-Trigger	Application requested a new subscription cycle via `RSP`.	`RSP` event edge

Application Scenarios

Typical use cases for **A2X_SUBSCRIBE_2** include:

- **Distributed control systems**: Receiving two independent Boolean control commands (e.g., UP/DOWN, START/STOP) from a central controller over Ethernet and forwarding them to local actuator logic.
- **Remote status monitoring**: Acquiring two-status-bit telemetry (e.g., valve open/closed, sensor alarm/normal) from a remote field device and presenting them to a local HMI or processing unit.
- **Command buffering in safety-related applications**: Latching incoming commands to guarantee stable output levels even if network interruptions occur between publication cycles.
- **Multi-node coordination**: Acting as a reception front-end in a star or multicast network where one publisher serves multiple subscribers.

Comparison with Similar Blocks

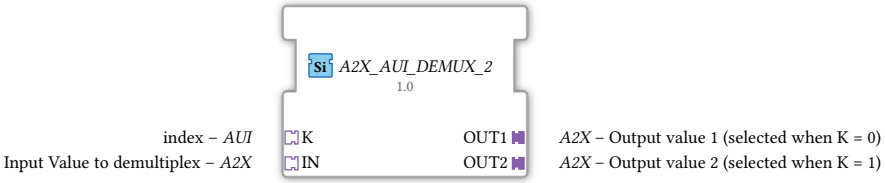
Feature	A2X_SUBSCRIBE_2	Standard SUBSCRIBE_2	SUBSCRIBE_1
Data capacity	2 BOOL values	2 BOOL values (`RD_1`, `RD_2`)	1 value (any type)
Output format	Buffered via D flip-flops, delivered through A2X adapter	Raw output variables	Raw output variable
Event granularity	Separate events per buffered channel (`E_UP`, `E_DOWN`) plus common `IND`	Single `IND` event	Single `IND` event
Integration convenience	Direct plug connection to A2X adapter sockets	Requires manual connection of data/events	Requires manual connection
Data stability	Continues to hold last values after reception	Outputs follow last received values (no explicit latching)	Outputs follow last received values
Use case fit	Application-oriented ready-to-connect subscriber	Low-level network service	Generic single-value network reception

Compared to the raw `SUBSCRIBE_2` network FB, **A2X_SUBSCRIBE_2** adds buffering, structured event distribution, and an adapter-based interface that simplifies integration into higher-level application designs.

Conclusion

The **A2X_SUBSCRIBE_2** function block provides a clean, ready-to-use solution for receiving two Boolean values over an Ethernet-based publish/subscribe network and delivering them to the application layer through a standardized A2X adapter interface. By combining network subscription with D flip-

flop buffering and dedicated per-channel events, it significantly reduces the design effort for distributed control applications while enhancing data stability and clarity. Its modular composite implementation follows best practices of IEC 61499, making it a valuable building block in industrial automation and decentralized control scenarios.



2.8.0.3 selection

unidirectional

Numerical Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace in ascending order.

A2X_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

A2X_AUI_DEMUX_2 is a generic, unidirectional demultiplexer function block for 4diac-ide. It receives one value through an A2X adapter socket and forwards it to one of two A2X output adapters. The selected output is controlled by an index value received through the AUI adapter socket K.

The block is designed as a generic FB: the actual behavior is provided by the generic implementation class `GEN_A2X_AUI_DEMUX`. The adapter outputs are only updated when the routed value actually changes.

Interface Structure

The interface is adapter-centric. There are no direct data inputs or data outputs. All values are transported via the unidirectional adapter sockets and plugs.

Event Inputs

There are no top-level event inputs. The FB is activated through data changes arriving on its adapter sockets.

Event Outputs

No event outputs.

Data Inputs

There are no direct data inputs. The input value is supplied through the `IN` adapter socket.

Data Outputs

There are no direct data outputs. The demultiplexed values are provided through the `OUT1` and `OUT2` adapter plugs.

Adapters

Adapter	Direction	Type	Description
`OUT1`	Plug / output	`A2X`	Output value 1, selected when K = 0
`OUT2`	Plug / output	`A2X`	Output value 2, selected when K = 1
`K`	Socket / input	`AUI`	Index input used to select the active output
`IN`	Socket / input	`A2X`	Input value to be demultiplexed

Functionality

The FB behaves as a 1-to-2 demultiplexer:

1. It receives an index value on the K socket.
2. If K = 0, the value from IN is routed to OUT1.
3. If K = 1, the value from IN is routed to OUT2.
4. The selected output adapter is updated only when the new value differs from the previously output value.
5. If the value is unchanged, no output update and no event take place.

This behavior reduces unnecessary communication between adapters and prevents downstream function blocks from reacting to unchanged values.

Technical Features

- Generic FB with generic class name GEN_A2X_AUI_DEMUX.
- Package: adapter::selection::unidirectional.
- Fully adapter-based interface without direct data inputs or outputs.
- Unidirectional A2X and AUI adapter types.
- Two output adapters allow selecting between two destinations.
- Event generation is suppressed when the output value has not changed.
- Suitable for use inside modular IEC 61499 applications with adapter-based communication.

State Overview

The XML type definition does not contain an explicit ECC state machine. The behavior is implemented by the generic backend. Conceptually, the FB can be viewed in the following states:

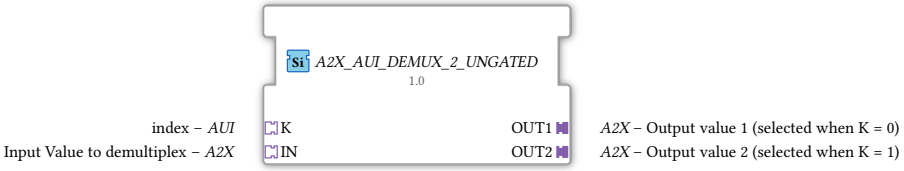
State	Description
WAITING	The FB waits for a new index value on K or a new input value on IN.
ROUTING	The current input value is routed to the output selected by K.
UPDATING	The selected output adapter is updated because the value has changed.
IDLE	The value is unchanged, so no adapter update and no event occur.

Application Scenarios

- **Selection between two values:** A single A2X value source can be forwarded to one of two different consumers based on a selector index.
- **Mode-dependent routing:** In an automation application, the same process value can be sent to different control or monitoring modules depending on the operational mode.
- **Adapter-based signal distribution:** The FB can be used as a compact demultiplexing stage in a modular IEC 61499 system where communication uses unidirectional A2X and AUI adapters.
- **Event reduction:** When values are frequently repeated, the change-only behavior avoids unnecessary event processing in the downstream logic.

Comparison with Similar Blocks

Block Type	Purpose	Difference
A2X_AUI_DEMUX_2	Demultiplexes one A2X input to two A2X outputs using an AUI index.	Adapter-based, generic, event-on-change only.
Typical multiplexer	Combines multiple inputs into one output.	Opposite data flow direction.
AX_AUI_DEMUX_2	Similar demultiplexing function with an alternative adapter type.	This block is the A2X variant and uses A2X for the value channel.



The main distinguishing feature of A2X_AUI_DEMUX_2 compared with non-adapter demultiplexers is its clean adapter-based interface and its ability to suppress events when no value change occurs.

Conclusion

A2X_AUI_DEMUX_2 is a flexible, generic demultiplexer function block for adapter-based 4diac applications. It routes one A2X input value to one of two outputs using an AUI index, while avoiding unnecessary

update events. Its compact adapter interface makes it well suited for modular, event-driven control systems.

A2X_AUI_DEMUX_2_UNGATED

• – ◦ • – ◦ • – ◦ •

Introduction

A2X_AUI_DEMUX_2_UNGATED is an adapter-based generic demultiplexer function block. It routes an incoming value received through the `IN` adapter to one of two output adapters, `OUT1` or `OUT2`, depending on the index received through the `K` adapter.

The "UNGATED" variant does not perform any change detection. Every newly computed value or result is forwarded unconditionally. This makes the block suitable for consumers that require a periodic data cadence, independent of whether the actual payload value has changed, for example in derivative or frequency calculations.

Interface Structure

The block does not use dedicated data inputs or data outputs. All value and index information is exchanged through unidirectional adapters. The block has no event outputs.

Event Inputs

None. Incoming triggers are received through the adapter sockets.

Event Outputs

No event outputs.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket	`K`	`adapter::types::unidirectional::AUI`	Index input used for output selection.
Socket	`IN`	`adapter::types::unidirectional::A2X`	Input value to be demultiplexed.
Plug	`OUT1`	`adapter::types::unidirectional::A2X`	Output value 1, selected when `K = 0`.
Plug	`OUT2`	`adapter::types::unidirectional::A2X`	Output value 2, selected when `K = 1`.

Functionality

The function block operates as a one-to-two demultiplexer:

1. The index adapter `K` provides the selection information.
2. The value adapter `IN` provides the value to be routed.
3. If `K = 0`, the incoming value is forwarded to `OUT1`.
4. If `K = 1`, the incoming value is forwarded to `OUT2`.

Because the block is "ungated", it does not compare the current value against the previous value. Every new calculation result or incoming value is passed through even if the payload is unchanged. This behavior is essential for consumers that rely on a steady event stream or periodic update rate.

Technical Features

- Adapter-based interface without separate data inputs or outputs.
- Unidirectional adapter types are used for both index and data transfer.
- Generic FB implementation via the attribute `eclipse4diac::core::GenericClassName` with value `GEN_A2X_AUI_DEMUX`.
- No event outputs.
- Two socket adapters: `K` and `IN`.
- Two plug adapters: `OUT1` and `OUT2`.
- No change detection or value gating logic.
- Designed for periodic, time-driven consumers.

State Overview

The XML definition does not contain an explicit ECC state machine. The behavior is handled by the generic runtime implementation behind `GEN_A2X_AUI_DEMUX`.

The relevant runtime state is limited to:

- The currently selected output path, determined by the index `K`.
- The forwarding state of the input value `IN`.

Since the block is ungated, there is no state representing “value changed” or “value unchanged”. Every incoming processing cycle leads to unconditional forwarding to the selected output.

Application Scenarios

A2X_AUI_DEMUX_2_UNGATED is useful in all cases where an incoming data stream must be distributed to one of two consumers based on an index, and where every computed result must be delivered.

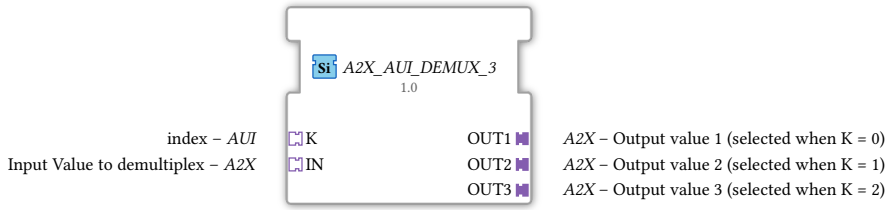
Typical examples:

- Derivative or slope calculations that need to process every sample.
- Frequency or period measurement functions that require a fixed event cadence.
- Adapter-based unidirectional data distribution in a 4diac IEC 61499 application.
- Splitting a continuous value stream into two downstream processing branches.

Comparison with Similar Blocks

The closest comparable block is `A2X_AUI_DEMUX_2`. Both blocks share the same adapter interface and output selection behavior.

The key difference is:



- `A2X_AUI_DEMUX_2` includes change detection and only forwards values when the result has changed.
- `A2X_AUI_DEMUX_2_UNGATED` disables this detection and forwards every newly computed result unconditionally.

This makes the ungated variant preferable for consumers that need a periodic trigger even when the data value is constant, while the gated variant is better suited for event-driven consumers that only want to react to actual value changes.

Conclusion

A2X_AUI_DEMUX_2_UNGATED is a flexible, adapter-based generic demultiplexer for unidirectional data flow. It selects between two outputs using an index adapter and forwards every incoming value without change detection. This unconditional forwarding behavior makes it especially suitable for calculation chains that require a constant update cadence, such as derivative and frequency computations.

A2X_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

A2X_AUI_DEMUX_3 is a generic A2X demultiplexer function block. It receives a value through an A2X input adapter and forwards it to one of three A2X output adapters. The active output is selected by an index value provided through an AUI adapter socket.

The block is designed to reduce unnecessary communication: the adapter output is only updated when the value actually changes, and an event is only generated for a real value change.

Interface Structure

Event Inputs

The FB does not declare dedicated event inputs on its FB interface. Event interaction is expected through the connected A2X/AUI adapters.

Event Outputs

No event outputs.

Data Inputs

None. All incoming data is transferred through the adapter sockets.

Data Outputs

None. All outgoing data is transferred through the adapter plugs.

Adapters

Sockets:

- `K` — Adapter type `adapter::types::unidirectional::AUI` — index input.
- `IN` — Adapter type `adapter::types::unidirectional::A2X` — input value to demultiplex.

Plugs:

- `OUT1` — Adapter type `adapter::types::unidirectional::A2X` — output value 1, selected when `K = 0`.
- `OUT2` — Adapter type `adapter::types::unidirectional::A2X` — output value 2, selected when `K = 1`.
- `OUT3` — Adapter type `adapter::types::unidirectional::A2X` — output value 3, selected when `K = 2`.

Functionality

A2X_AUI_DEMUX_3 acts as a 1-to-3 demultiplexer for A2X adapter values. The index received on the `K` socket selects which of the three output adapters receives the incoming value from the `IN` socket.

The block only forwards an output value if the value has actually changed compared to the last forwarded value. This reduces unnecessary output updates and event traffic.

Technical Features

- Generic FB with the generic class name `GEN_A2X_AUI_DEMUX`.
- No explicit data inputs or data outputs; all payload data is carried by A2X adapters.
- Unidirectional adapter interface.
- 1-of-3 demultiplexing.
- Change detection on the output value.
- Suitable for integration into adapter-based 4diac applications.

State Overview

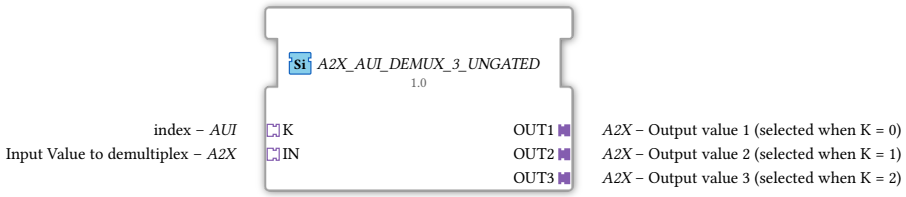
The FB does not expose an internal ECC state machine in its XML definition. Conceptually, the block behaves as follows:

- **Idle state** — No new index or value has arrived. The selected output keeps its last value.
- **Value update** — A new value arrives on `IN`. If it differs from the previously forwarded value, the selected output adapter is updated and an event is generated.
- **Index change** — A new value arrives on `K`. The next value update is redirected to the newly selected output.

Application Scenarios

A2X_AUI_DEMUX_3 can be used wherever one input value must be routed to one of several possible consumers. Typical scenarios include:

- Distributing process values to different visualization or control units.
- Switching between multiple output branches based on an operating mode or index.
- Reducing communication load by suppressing unchanged values.
- Building generic adapter-based routing logic in 4diac applications.



Comparison with Similar Blocks

Block / Variant	Characteristics
`A2X_AUI_DEMUX_3`	Generic A2X-based 1-to-3 demultiplexer with change detection.
`AX_AUI_DEMUX_3`	Closely related variant that does not use the A2X generic adapter backend.
Conventional demultiplexer without change detection	Forwards every input value and event unconditionally, causing higher communication load.

Conclusion

A2X_AUI_DEMUX_3 is a compact generic demultiplexer block for adapter-oriented 4diac applications. It combines selection of one of three outputs with change-based update behavior, making it suitable for efficient and selective value distribution in automation and communication systems.

A2X_AUI_DEMUX_3_UNGATED

• – ◦ • – ◦ • – ◦ •

Introduction

A2X_AUI_DEMUX_3_UNGATED is an adapter-based demultiplexer FB that distributes an incoming value stream from one input adapter to one of three output adapters. The selection is made through an index adapter. In contrast to gated demultiplexers, this FB does not perform any change detection: every newly computed result is forwarded unconditionally. It is therefore suitable for consumers that require a periodic data cadence even when the value itself has not changed, for example derivative or frequency calculations.

The FB uses the unidirectional A2X adapter type for data transport and a unidirectional AUI adapter for the index selection. It is declared as a generic FB with the generic class name `GEN_A2X_AUI_DEMUX`.

Interface Structure

Event Inputs

No event inputs are declared. The FB is driven entirely through its adapter sockets.

Event Outputs

No event outputs.

Data Inputs

No data inputs are declared.

Data Outputs

No data outputs are declared.

Adapters

Direction	Adapter	Type	Description

Socket	K	adapter::types::unidirectional::AUI	Index selector. Determines which output is used.
Socket	IN	adapter::types::unidirectional::A2X	Input value stream to be demultiplexed.
Plug	OUT1	adapter::types::unidirectional::A2X	Output value 1, selected when K = 0.
Plug	OUT2	adapter::types::unidirectional::A2X	Output value 2, selected when K = 1.
Plug	OUT3	adapter::types::unidirectional::A2X	Output value 3, selected when K = 2.

Functionality

A2X_AUI_DEMUX_3_UNGATED forwards data received on the IN adapter to exactly one of the three output adapters. The output is chosen according to the index received on the K adapter:

- K = 0 ⟶ OUT1
- K = 1 ⟶ OUT2
- K = 2 ⟶ OUT3

Each time a new value arrives on IN, the FB passes that value to the currently selected output. No comparison with a previously forwarded value is performed. This is the key difference between this block and a gated demultiplexer: the output is updated as often as new results arrive, regardless of whether the data content has changed.

Because all data and selection information is transported through adapter connections, no separate input events, output events or data inputs are required.

Technical Features

- Three unidirectional output plugs: OUT1, OUT2, OUT3.
- One unidirectional input socket IN for the data stream to be demultiplexed.
- One unidirectional index socket K for output selection.
- No change detection or gating logic.
- No internal storage of the last forwarded value.
- Generic FB implementation using the class name GEN_A2X_AUI_DEMUX.
- Intended for use in adapter-based selection and distribution scenarios.
- The adapter package is adapter::selection::unidirectional.

State Overview

The FB does not define a complex state machine. Because no change detection is required, there is no state that stores and compares previous values. The operational behavior can be summarized as:

- Awaiting index selection through K.
- Awaiting a new value on IN.
- Forwarding the received value to the output selected by K.

This simple structure makes the FB deterministic and easy to use in periodic processing chains.

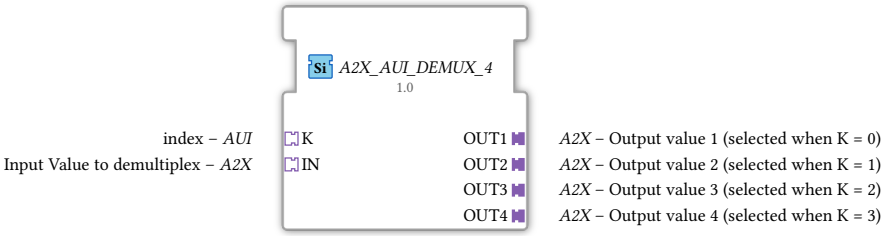
Application Scenarios

A2X_AUI_DEMUX_3_UNGATED is useful wherever a data source must be routed to one of several consumers on every computation cycle. Typical scenarios include:

- Periodic derivative or frequency calculation where the consumer needs a fixed update rate even if the source value remains constant.
- Distribution of a process value to different functional modules depending on an operating mode.
- Adapter-based stream switching in automation applications.
- Demultiplexing of a single data stream into three alternative processing paths without requiring the source to detect value changes.

Because the block is un-gated, it is especially suitable for time-driven applications where the timing of the output event is more important than the value difference between two consecutive samples.

Comparison with Similar Blocks



Compared with `A2X_AUI_DEMUX_3`, the `_UNGATED` variant differs in its forwarding behavior. The gated variant only forwards a value when the input value has changed. The un-gated variant forwards every newly computed value unconditionally. This makes `A2X_AUI_DEMUX_3_UNGATED` the preferred choice for consumers that need a continuous periodic stream of events.

Compared with the `AX_AUI_DEMUX_3_UNGATED` variant, this FB uses the `A2X` adapter type instead of `AX`. It is therefore suitable for systems built on the newer or different `A2X` unidirectional adapter family while preserving the same demultiplexing behavior.

Conclusion

A2X_AUI_DEMUX_3_UNGATED is a simple and flexible adapter-based demultiplexer for three output paths. Its main advantage is the unconditional forwarding of every incoming value, which guarantees a regular output cadence. The use of adapter sockets for both index selection and data input makes it well suited for modern adapter-oriented IEC 61499 applications, especially where periodic downstream processing is required.

A2X_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

A2X_AUI_DEMUX_4 is a generic IEC 61499-2 function block that implements a 1-to-4 demultiplexer for unidirectional adapter connections. It receives a value through an `IN` socket and forwards it to one of four output adapters `OUT1` … `OUT4`. The active output is selected by the index value received through the `K` socket.

The block is designed as a generic FB. Its runtime behavior is provided by the referenced generic implementation class `GEN_A2X_AUI_DEMUX`. The adapter outputs are only updated when the value actually changes, so unnecessary update events are suppressed.

Interface Structure

Event Inputs

There are no event inputs.

Event Outputs

No event outputs.

Data Inputs

There are no direct data inputs. All data is exchanged through adapter sockets and plugs.

Data Outputs

There are no direct data outputs. All data is exchanged through adapter sockets and plugs.

Adapters

Interface Role	Adapter Name	Type	Comment
Socket / Input	`K`	`adapter::types::unidirectional::AUI`	Index
Socket / Input	`IN`	`adapter::types::unidirectional::A2X`	Input Value to demultiplex

Plug / Output	OUT1	adapter::types::unidirectional::A2X	Output value 1, selected when K = 0
Plug / Output	OUT2	adapter::types::unidirectional::A2X	Output value 2, selected when K = 1
Plug / Output	OUT3	adapter::types::unidirectional::A2X	Output value 3, selected when K = 2
Plug / Output	OUT4	adapter::types::unidirectional::A2X	Output value 4, selected when K = 3

Functionality

A2X_AUI_DEMUX_4 acts as a unidirectional adapter-based demultiplexer:

1. The index K is received through the K socket.
2. The value to be routed is received through the IN socket.
3. Depending on K, one of the four output adapters OUT1 … OUT4 is selected.
4. The selected output is updated with the incoming value.

According to the FB type comment, the adapter output is only updated when the value changes. If the new value is identical to the previous value, no unnecessary output update or event is generated.

Because the FB is a generic FB, the detailed internal processing is delegated to the runtime backend GEN_A2X_AUI_DEMUX. The type definition itself mainly describes the adapter interface and the generic class binding.

Technical Features

- Generic FB implementation: GEN_A2X_AUI_DEMUX
- Package: adapter::selection::unidirectional
- 1-to-4 demultiplexing using unidirectional adapters
- Four A2X output plugs: OUT1, OUT2, OUT3, OUT4
- One AUI index socket: K
- One A2X input socket: IN
- No direct data inputs or data outputs
- No event inputs or outputs
- Output updates and events are suppressed when the value has not actually changed
- Suitable for IEC 61499-2 adapter-based applications

State Overview

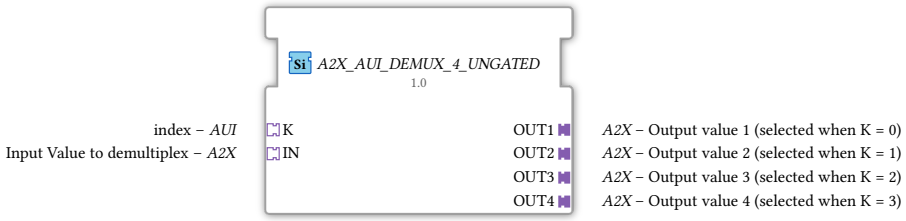
The XML type definition does not contain an explicit ECC. The behavior is therefore controlled by the generic implementation. The following states describe the logical behavior of the FB:

State	Description
Idle	The FB waits for a new index or input value.
Select	The index K is read and one of the four outputs is selected.
Update	The selected output adapter is updated with the value from IN. If the value has not changed, this step is skipped.

Application Scenarios

A2X_AUI_DEMUX_4 is useful in IEC 61499 applications where a single unidirectional adapter value must be routed to one of four consumers. Typical scenarios include:

- Distributing a measured value to one of several processing blocks.
- Selecting one of four control destinations based on an index.
- Building adapter-based routing structures without using direct data connections.
- Reducing unnecessary communication traffic when the routed value changes infrequently.



Comparison with Similar Blocks

- A standard demultiplexer typically uses direct data inputs and outputs. A2X_AUI_DEMUX_4 instead uses unidirectional adapters, which allows flexible adapter-based connections.
- It is the A2X adapter variant of the `AX_AUI_DEMUX_4` demultiplexer concept.
- Unlike a simple selector, this FB has one input and four possible output destinations.
- Unlike blocks that always forward data, this FB only updates an output when the value actually changes, reducing unnecessary events.

Conclusion

A2X_AUI_DEMUX_4 is a compact, generic, adapter-based 1-to-4 demultiplexer. It combines index-based output selection with unidirectional A2X/AUI adapter communication and change-only update behavior. This makes it suitable for efficient and flexible routing in IEC 61499-2 applications.

A2X_AUI_DEMUX_4_UNGATED

• – ◦ • – ◦ • – ◦ •

Introduction

The `A2X_AUI_DEMUX_4_UNGATED` function block is a generic one-to-four demultiplexer based on Eclipse 4diac adapters. It receives a value via the `IN` adapter and an index via the `K` adapter, and forwards the input value to one of four output adapters (`OUT1`…`OUT4`).

It is the ungated version of `A2X_AUI_DEMUX_4`: it performs no change detection and forwards every newly computed result unconditionally. This makes it suitable for downstream consumers that require a periodic data cadence independent of whether the sampled value has changed, e.g. derivative or frequency calculations.

Interface Structure

Event Inputs

None.

Event Outputs

No event outputs.

Data Inputs

None. All data is transferred through adapters.

Data Outputs

None. All data is transferred through adapters.

Adapters

Adapter	Direction	Type	Comment
`IN`	Socket	`adapter::types::unidirectional::A2X`	Input value to demultiplex.
`K`	Socket	`adapter::types::unidirectional::AUI`	Index; selects the active output.
`OUT1`	Plug	`adapter::types::unidirectional::A2X`	Output value 1, selected when `K = 0`.
`OUT2`	Plug	`adapter::types::unidirectional::A2X`	Output value 2, selected when `K = 1`.
`OUT3`	Plug	`adapter::types::unidirectional::A2X`	Output value 3, selected when `K = 2`.

OUT4	Plug	adapter::types::unidirectional::A2X	Output value 4, selected when K = 3.

Functionality

A2X_AUI_DEMUX_4_UNGATED implements a 1-to-4 demultiplexing routing logic:

1. The value to distribute is available on the IN adapter.
2. The selection index is available on the K adapter.
3. Depending on K, the value is routed to OUT1, OUT2, OUT3, or OUT4.

The term UNGATED indicates that the FB does not suppress repeated values. While a normal gated demultiplexer would compare the current value with the previous one and only forward a result when a change is detected, this variant always passes the newly calculated/received value through. Therefore, each input update triggers an output update, and the output cadence follows the input cadence.

Technical Features

- IEC 61499-2 compliant generic function block.
- Generic class name: GEN_A2X_AUI_DEMUX.
- Adapter package: adapter::selection::unidirectional.
- Four unidirectional A2X output plugs.
- Unidirectional A2X input socket for the value to demultiplex.
- Unidirectional AUI input socket for the selection index.
- No explicit data inputs or data outputs; all payload data crosses the adapter interface.
- No change-detection state or old-value storage.

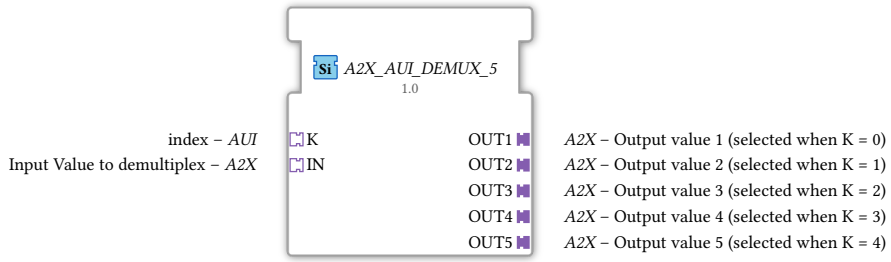
State Overview

The FB type itself does not define an internal ECC state machine. Since it is ungated, it does not keep a memory of the last forwarded value and does not compare values. The only relevant selection state is the current index K. Once a new index is applied, subsequent input values are forwarded to the newly selected output. With respect to data content, the FB behaves statelessly.

Application Scenarios

- **Periodic derivative calculation:** A derivative or rate-of-change consumer needs an update in every scan/cycle, even if the measured value stayed constant. The ungated demultiplexer ensures the required cadence.
- **Frequency measurement:** Frequency calculations often rely on time stamps and event counts. Dropping unchanged values would break the calculation; unconditional forwarding prevents this.
- **Value distribution:** One sensor/calculation result can be routed to one of four consumers, selected by a controller or configuration index.
- **Streaming and telemetry:** When a periodic output stream must be maintained towards a selected sub-system, this FB can provide the required steady flow.

Comparison with Similar Blocks



Block	Behavior
A2X_AUI_DEMUX_4	Gated demultiplexer. It performs change detection and only forwards new/changed values.
A2X_AUI_DEMUX_4_UNGATED	Ungated demultiplexer. It forwards every newly available value regardless of whether the content changed.

The main difference is therefore the presence or absence of value-change filtering. The ungated variant is preferred when downstream processing cannot miss an update cycle. The gated variant is preferred when output bandwidth should be minimized and consumers only need to react to actual value changes.

Conclusion

A2X_AUI_DEMUX_4_UNGATED is a flexible generic 1-to-4 demultiplexer built on unidirectional adapters. It combines a simple index-based output selection with an unconditional forwarding policy. By omitting change detection, it guarantees that every newly computed result reaches the selected consumer, making it particularly suitable for time-sensitive and cadence-dependent calculations such as derivatives and frequency measurements.

A2X_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`A2X_AUI_DEMUX_5` is a generic adapter-based demultiplexor. It receives a value through the unidirectional `A2X` socket `IN` and forwards it to one of five unidirectional `A2X` output plugs (`OUT1` … `OUT5`). The output selection is determined by the index value received through the `AUI` socket `K`.

The block is designed as a generic FB: the concrete type name `A2X_AUI_DEMUX_5` represents a five-output configuration of the generic class `GEN_A2X_AUI_DEMUX`. A key property is that the selected adapter output is updated only when the transferred value actually changes; no unnecessary update event is generated for unchanged values.

Interface Structure

The FB uses adapter connections instead of a direct set of data inputs and outputs. It has no direct event inputs and no direct data inputs or outputs. All input and output data is carried by the adapter sockets and plugs.

Event Inputs

The FB does not declare any direct event inputs.

Event Outputs

No event outputs.

Data Inputs

The FB does not declare any direct data inputs.

Data Outputs

The FB does not declare any direct data outputs.

Adapters

Direction	Name	Type	Description
Socket (input)	`K`	`adapter::types::unidirectional::AUI`	Selection index.
Socket (input)	`IN`	`adapter::types::unidirectional::A2X`	Input value to demultiplex.
Plug (output)	`OUT1`	`adapter::types::unidirectional::A2X`	Output selected when `K = 0`.
Plug (output)	`OUT2`	`adapter::types::unidirectional::A2X`	Output selected when `K = 1`.
Plug (output)	`OUT3`	`adapter::types::unidirectional::A2X`	Output selected when `K = 2`.
Plug (output)	`OUT4`	`adapter::types::unidirectional::A2X`	Output selected when `K = 3`.
Plug (output)	`OUT5`	`adapter::types::unidirectional::A2X`	Output selected when `K = 4`.

Functionality

The functional behavior can be summarized as:

1. The FB observes the index adapter `K`.
2. Based on the current index, it activates one of the output plugs:

- `K = 0` selects `OUT1`
- `K = 1` selects `OUT2`
- `K = 2` selects `OUT3`
- `K = 3` selects `OUT4`
- `K = 4` selects `OUT5`

3. The value received on the `IN` socket is forwarded to the selected output plug.
4. The output adapter is updated only when the value has actually changed. This avoids unnecessary adapter update events.

The valid index range is therefore `0` to `4`. Behavior for indices outside this range depends on the concrete generic runtime implementation.

Technical Features

- Generic FB class: `GEN_A2X_AUI_DEMUX`.
- Five unidirectional output adapters of type `A2X`.
- Two unidirectional input adapters: `K` (`AUI`) and `IN` (`A2X`).
- Adapter-based interface: no direct data inputs or outputs.
- Value-change-triggered output update.
- Declared as an IEC 61499-2 FB type.
- Compiler package: `adapter::selection::unidirectional`.

State Overview

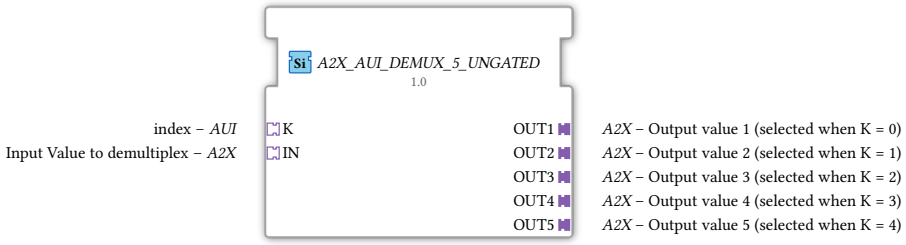
The FB type does not contain an explicit ECC state machine. The behavior is therefore handled by the generic runtime implementation. Logically, the following phases can be distinguished:

Phase	Description
Wait	The FB waits for a new value on `IN` or a new index on `K`.
Select	The current value of `K` determines the active output plug.
Forward	The current `IN` value is written to the selected output if it changed.

These phases are not necessarily separate ECC states; they describe the observable behavior of the demultiplexor.

Application Scenarios

- Routing a single data source to one of five consumers based on an index.
- Dynamic selection of a target station or submodule in an adapter-based automation network.
- Reduction of event load by forwarding only actual value changes.
- Reuse in unidirectional data-flow architectures without direct data wiring.



Comparison with Similar Blocks

- Compared with a conventional demultiplexer that uses direct data inputs and outputs, `A2X_AUI_DEMUX_5` uses adapter sockets and plugs. This makes it suitable for applications that already model communication endpoints as adapters.
- The `_5` variant is a concrete five-output configuration of the generic class `GEN_A2X_AUI_DEMUX`; other variants can provide a different number of outputs.
- In contrast to a multiplexer, which combines multiple input values into one output, this block distributes one input value to one of several outputs.

Conclusion

`A2X_AUI_DEMUX_5` is a compact and reusable generic demultiplexor for adapter-based unidirectional communication. Its index-controlled output selection, five outputs, and value-change-triggered update behavior make it suitable for applications where a single value must be routed to one of several destinations without generating unnecessary events.

A2X_AUI_DEMUX_5_UNGATED

• – ◦ • – ◦ • – ◦ •

Introduction

A2X_AUI_DEMUX_5_UNGATED is a unidirectional 1-to-5 demultiplexer FB. It forwards one input value received through the `A2X` adapter socket to one of five `A2X` output adapters, depending on an index value received through the `AUI` adapter socket.

In contrast to a gated demultiplexer, this block does **not** perform change detection. Every newly computed or received result is forwarded unconditionally. This makes the FB suitable for consumers that require a continuous periodic data cadence, such as derivative or frequency calculations, even when the value itself has not changed.

Interface Structure

Event Inputs

There are no explicit event inputs declared in the interface list. The FB is controlled through its adapter sockets and plugs.

Event Outputs

No event outputs.

Data Inputs

There are no explicit data inputs. The input value is transmitted through the adapter socket `IN`.

Data Outputs

There are no explicit data outputs. The demultiplexed results are transmitted through the adapter plugs `OUT1` to `OUT5`.

Adapters

Adapter	Type	Direction	Description
`K`	`adapter::types::unidirectional::AUI`	Socket	Index input used to select the active output
`IN`	`adapter::types::unidirectional::A2X`	Socket	Input value to demultiplex
`OUT1`	`adapter::types::unidirectional::A2X`	Plug	Output value 1, selected when `K = 0`
`OUT2`	`adapter::types::unidirectional::A2X`	Plug	Output value 2, selected when `K = 1`
`OUT3`	`adapter::types::unidirectional::A2X`	Plug	Output value 3, selected when `K = 2`
`OUT4`	`adapter::types::unidirectional::A2X`	Plug	Output value 4, selected when `K = 3`
`OUT5`	`adapter::types::unidirectional::A2X`	Plug	Output value 5, selected when `K = 4`

Functionality

The FB acts as a demultiplexer between one input adapter and five output adapters. The index supplied through the `K` adapter determines which output receives the current value from `IN`.

The `K` index mapping is fixed:

- `K = 0` ⟶ `OUT1`

- `K = 1` ⟶ `OUT2`
- `K = 2` ⟶ `OUT3`
- `K = 3` ⟶ `OUT4`
- `K = 4` ⟶ `OUT5`

The designation “UNGATED” indicates that no gating mechanism suppresses repeated values. If a new result arrives, it is forwarded to the selected output regardless of whether the value differs from the previous one.

Technical Features

- 1-to-5 unidirectional adapter-based demultiplexing.
- Uses `adapter::types::unidirectional::A2X` for the data path.
- Uses `adapter::types::unidirectional::AUI` for index selection.
- No value-change detection.
- Every delivered result is passed through unconditionally.
- Interface contract is based on a generic implementation class `GEN_A2X_AUI_DEMUX`.
- Suitable for periodic and time-triggered processing chains.
- Licensed under EPL-2.0.

State Overview

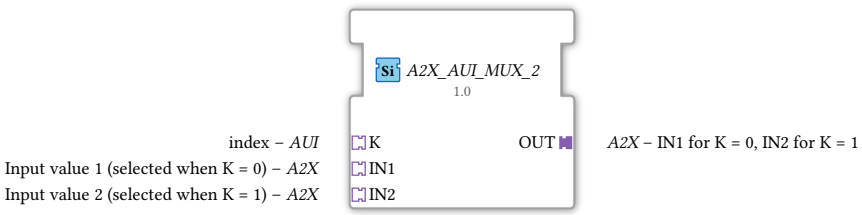
This block does not rely on input value history to make forwarding decisions. Because it is ungated, it does not need to remember the last output value in order to suppress duplicate updates.

The only relevant runtime information is the currently selected index `K`. The observable behavior is therefore essentially stateless with respect to the incoming data values.

Application Scenarios

- Periodic derivative or frequency calculations where a constant input value must still produce a steady output cadence.
- Distribution of one input stream to multiple alternative consumers.
- Test and simulation environments that need deterministic forwarding on every cycle.
- Systems where downstream blocks expect a continuous update signal even when the data has not changed.
- Generic adapter-based selection between five unidirectional output paths.

Comparison with Similar Blocks



The gated variant `A2X_AUI_DEMUX_5` forwards a value only when a change is detected. `A2X_AUI_DEMUX_5_UNGATED` removes this restriction and forwards every newly produced result unconditionally.

This makes the gated variant useful for state-oriented or event-driven consumers that only react to actual changes. The ungated variant is better suited for time-driven calculations, control loops, and signal-processing blocks that require a regular data rhythm.

Conclusion

`A2X_AUI_DEMUX_5_UNGATED` is a simple and predictable adapter-based demultiplexer. It provides a clean mapping from one input adapter to five output adapters using an external index. By omitting change detection, it guarantees that every result cycle is propagated to the selected output. This behavior is ideal for applications that require a constant update flow or periodicity, independent of whether the actual data value has changed.

A2X_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

A2X_AUI_MUX_2 is a generic, adapter-based multiplexer for unidirectional IEC 61499 adapter connections. It selects one of two A2X input adapters using an AUI index adapter and forwards the selected value to an A2X output adapter. The output is only updated when the selected value actually changes, which helps to suppress unnecessary event traffic.

Interface Structure

Event Inputs

The FB does not declare any top-level event inputs. It is triggered through its connected adapter sockets.

Event Outputs

No event outputs.

Data Inputs

There are no direct data inputs. Input data is transported through the adapter sockets.

Data Outputs

There are no direct data outputs. Output data is transported through the output adapter plug.

Adapters

Kind	Name	Adapter Type	Comment
Plug	OUT	`adapter::types::unidirectional::A2X`	IN1 for K = 0, IN2 for K = 1
Socket	K	`adapter::types::unidirectional::AUI`	Index
Socket	IN1	`adapter::types::unidirectional::A2X`	Input value 1 (selected when K = 0)
Socket	IN2	`adapter::types::unidirectional::A2X`	Input value 2 (selected when K = 1)

Functionality

A2X_AUI_MUX_2 selects one of two A2X input streams based on the index supplied by the AUI adapter:

- K = 0 selects IN1.
- K = 1 selects IN2.

The selected value is written to the output adapter OUT. The generic runtime implementation `GEN_A2X_AUI_MUX` compares the newly selected value with the value currently present on OUT. If the values are the same, the output is not updated and no event is emitted. If the value differs, OUT is updated.

Technical Features

- Generic FB using the runtime class `GEN_A2X_AUI_MUX`.
- Fully adapter-based interface, no direct data I/O.
- Unidirectional data flow from the input adapters to the output adapter.
- Value-change detection avoids unnecessary output updates and events.
- Part of the package `adapter::selection::unidirectional`.
- Compliant with the IEC 61499-2 type specification.

State Overview

A2X_AUI_MUX_2 does not define an explicit ECC state machine. Instead, its behavior is implemented by the generic runtime class. Internally, the FB retains the last value written to OUT. When a new index is applied, the generic implementation checks whether the newly selected input differs from the stored value. If a change is detected, the output and internal state are updated. If no change is detected, the FB remains in its current output state.

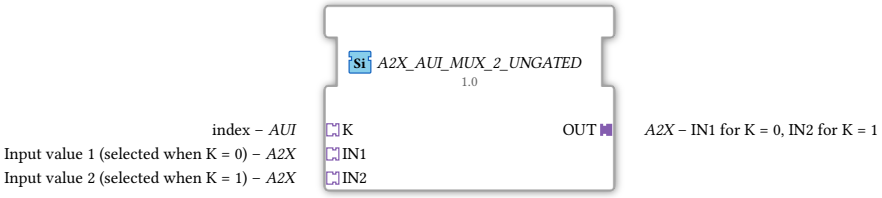
Application Scenarios

- Selecting between two A2X data sources in an adapter-based automation system.
- Redundancy or failover switching based on an AUI index.
- Routing one of two adapter-based signal paths to a downstream consumer.
- Reducing event load by suppressing repeated identical values.

- Reusable selection logic in modular IEC 61499 applications.

Comparison with Similar Blocks

Compared with `AX_AUI_MUX_2`, this FB is the A2X variant. It uses A2X adapter types for the data paths and an AUI adapter for the index.



Compared with a conventional MUX function block, A2X_AUI_MUX_2 has no direct data inputs or outputs. All data exchange is encapsulated in adapters, which improves reusability and type decoupling.

Compared with a simple gate or switch, this FB provides real selection logic and integrated change detection, making it suitable for event-driven selection scenarios without redundant updates.

Conclusion

A2X_AUI_MUX_2 is a compact, generic, unidirectional multiplexer for IEC 61499 applications. It selects one of two A2X input adapters via an AUI index and forwards the selected value to an A2X output. The integrated value-change detection prevents unnecessary output events, making it well suited for event-driven automation and adapter-based system designs.

A2X_AUI_MUX_2_UNGATED

• – ○ • – ○ • – ○ •

Introduction

A2X_AUI_MUX_2_UNGATED is an adapter-based, event-driven multiplexer for selecting one of two unidirectional A2X data streams and forwarding it to a single output. It is an ungated variant of the A2X_AUI_MUX_2 function block. In contrast to a gated multiplexer, it does not perform any change detection. Every newly computed result is forwarded unconditionally, regardless of whether the value has actually changed.

This behavior is intended for consumers that require a periodic cadence or a regular data flow, such as derivative or frequency calculations, where the arrival of each new result is important even if the value remains identical to the previous one.

Interface Structure

The function block has no conventional event inputs or data inputs/outputs. Its interface is entirely built around unidirectional adapters. It has no event outputs.

Event Inputs

None.

Event Outputs

No event outputs.

Data Inputs

None.

Data Outputs

None.

Adapters

Kind	Name	Type	Description
Socket	`K`	`adapter::types::unidirectional::AUI`	Selection index. Selects `IN1` when `K = 0` and `IN2` when `K = 1`.

Socket	IN1	adapter::types::unidirectional::A2X	First value stream, selected when K = 0.
Socket	IN2	adapter::types::unidirectional::A2X	Second value stream, selected when K = 1.
Plug	OUT	adapter::types::unidirectional::A2X	Multiplexed output stream.

Functionality

The block acts as a two-input multiplexer for unidirectional adapter streams. The selection index is received through the AUI adapter socket K. When K = 0, the data arriving via IN1 is passed to OUT. When K = 1, the data arriving via IN2 is passed to OUT.

The "UNGATED" characteristic means that the block does not compare incoming values with previous values. Every incoming result is forwarded immediately to the output. This makes the block well suited for applications in which downstream blocks need each processing cycle to be triggered, even if the underlying value has not changed.

The block is a generic function block realized through the generic class name GEN_A2X_AUI_MUX. It is intended for use in unidirectional, adapter-based selection scenarios.

Technical Features

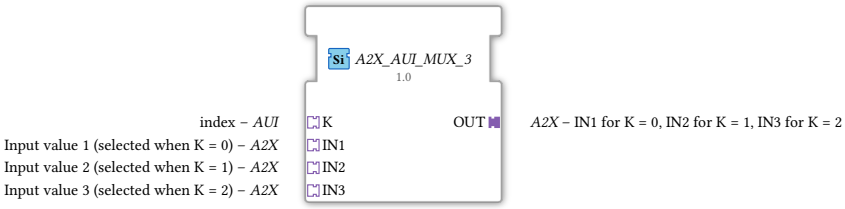
- Adapter-based interface with no direct data inputs or outputs.
- Supports one AUI index socket for selecting one of two A2X input sockets.
- Provides a single unidirectional A2X output plug.
- Forwards all incoming results unconditionally without change detection.
- Generic implementation using GEN_A2X_AUI_MUX.
- Package: adapter::selection::unidirectional.
- Suitable for periodic and cadence-sensitive data flow architectures.

State Overview

The block does not expose an explicit state machine. It behaves as a combinatorial, event-triggered adapter multiplexer. In the ungated variant, no internal state is used to store or compare previous input values. This means there is no hysteresis, no change detection latch, and no suppression of repeated values.

Application Scenarios

- **Derivative/Frequency Calculations**: Downstream blocks that need a new result at every input event, regardless of whether the value changed, benefit from the unconditional forwarding behavior.
- **Periodic Data Distribution**: When a consumer requires a fixed periodic data cadence, the ungated multiplexer ensures that every computed result is delivered.
- **Adapter-Based Selecting**: When two unidirectional data sources must be selected dynamically through an adapter-based index, this block provides a clean and reusable solution.
- **Stream Redirection**: Useful in processing chains where the active input source may switch between two producers without losing event rhythm.



Comparison with Similar Blocks

- **A2X_AUI_MUX_2**: The gated variant performs change detection. It only forwards data when the incoming value differs from the previously forwarded value. This reduces unnecessary downstream activity but can break a periodic cadence.
- **A2X_AUI_MUX_2_UNGATED**: This variant forwards every newly calculated result without compare-and-skip logic. It preserves the event rhythm but may produce repeated identical values on the output.
- **Conventional MUX blocks**: Standard multiplexers typically use direct data inputs and a scalar selector. This block instead uses unidirectional adapters, making it more suitable for structured, event-driven adapter communication.

Conclusion

A2X_AUI_MUX_2_UNGATED is a compact, adapter-based multiplexer that selects between two unidirectional A2X streams using an AUI index. Its key feature is the absence of change detection: every result is forwarded immediately. This makes it ideal for applications that rely on a stable periodic event flow, such as derivative or frequency calculations, where the arrival of each result itself carries information.

A2X_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

A2X_AUI_MUX_3 is a generic adapter-based 3-to-1 multiplexer function block for IEC 61499 applications. It selects one of three A2X input adapters and forwards the selected value to an A2X output adapter. The selection index is supplied through an AUI adapter. The block is implemented as the typed generic variant `GEN_A2X_AUI_MUX` and is designed so that the output adapter is only updated when the selected value actually changes.

Interface Structure

The function block has no direct data inputs or data outputs. All value and control information is exchanged through the adapter interface.

Event Inputs

None.

Event Outputs

No event outputs.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Plug	`OUT`	`adapter::types::unidirectional::A2X`	Selected input value: IN1 for K = 0, IN2 for K = 1, IN3 for K = 2
Socket	`K`	`adapter::types::unidirectional::AUI`	Index used to select the active multiplexer input
Socket	`IN1`	`adapter::types::unidirectional::A2X`	Input value 1, selected when K = 0
Socket	`IN2`	`adapter::types::unidirectional::A2X`	Input value 2, selected when K = 1
Socket	`IN3`	`adapter::types::unidirectional::A2X`	Input value 3, selected when K = 2

Functionality

A2X_AUI_MUX_3 behaves as an adapter-based multiplexer:

1. A new selection index is received through the `K` adapter.
2. The index value determines which input adapter is active:
   - K = 0 selects `IN1`
   - K = 1 selects `IN2`
   - K = 2 selects `IN3`
3. The value of the selected input adapter is compared with the current value on the output adapter `OUT`.

This behavior reduces unnecessary event and data traffic on the adapter connection. The block is therefore especially useful in applications where the index may be set repeatedly to the same value, but only actual value changes should be propagated.

Technical Features

- Generic implementation based on `GEN_A2X_AUI_MUX`
- Three A2X input adapters: `IN1`, `IN2`, `IN3`
- One A2X output adapter: `OUT`
- One AUI index adapter: `K`
- Fully adapter-based interface; no direct data inputs or outputs
- Unidirectional adapter communication
- Change-only output update behavior
- Suitable for distributed IEC 61499 applications
- Licensed under EPL-2.0

State Overview

The block does not declare an explicit state machine in its interface definition. Its observable behavior can be described by the following conceptual states:

- **Idle**: waiting for a new index value on the `K` adapter.
- **Evaluate**: reading the index and selecting the corresponding input adapter.
- **Compare**: checking whether the selected input value differs from the current output value.
- **Publish**: updating the `OUT` adapter if an actual change occurred.

This state behavior ensures that redundant selections do not cause unnecessary output activity.

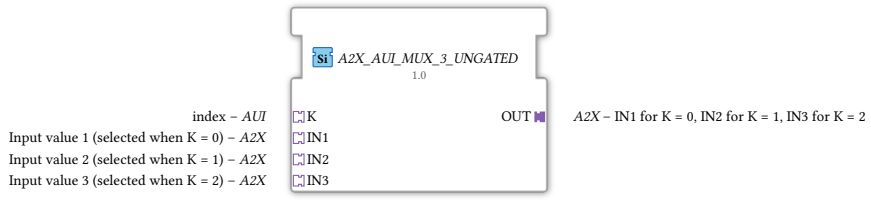
Application Scenarios

A2X_AUI_MUX_3 is suitable for the following use cases:

- Selecting one of three process values or measurement signals connected via adapters.
- Routing different data sources to a single consumer without using direct data connections.
- Building adapter-based signal selection logic in distributed control systems.
- Reducing network or communication load by suppressing output updates when the selected value is unchanged.
- Using as a reusable building block in larger adapter-based multiplexer or routing structures.

Comparison with Similar Blocks

Compared to a conventional data multiplexer, A2X_AUI_MUX_3 does not expose physical data inputs and outputs. Instead, it uses unidirectional adapters for both values and index, making integration in adapter-based system architectures easier.



In contrast to standard multiplexers that always copy the selected input to the output, A2X_AUI_MUX_3 only updates the output when the selected value actually changes. This makes it more efficient in event-driven systems.

The block is an A2X variant of the existing `AX_AUI_MUX_3` concept. The main difference is the use of the `A2X` adapter type for the value interfaces while the index remains on the `AUI` adapter type.

Conclusion

A2X_AUI_MUX_3 is a compact, adapter-based 3-to-1 multiplexer that combines selection logic with change detection. Its unidirectional adapter interface and event-on-change behavior make it well suited for distributed IEC 61499 applications where efficient communication and minimal unnecessary events are important.

A2X_AUI_MUX_3_UNGATED

• – ○ • – ○ • – ○ •

Introduction

A2X_AUI_MUX_3_UNGATED is a multiplexer function block from the A2X family. It selects one of three A2X input streams and forwards it to a single A2X output stream. The selection is controlled through an AUI index adapter.

The key property of this block is described by the "UNGATED" suffix: it does **not** perform any change detection. Every newly calculated result is passed on unconditionally, even if the value itself has not changed. This makes the block suitable for consumers that require a periodic data cadence, for example derivative or frequency calculations.

Interface Structure

The block does not expose direct event inputs, data inputs, or data outputs. All input and output information is exchanged through adapter connections. The following subsets describe the FB interface as visible in the type definition.

Event Inputs

None.

Event Outputs

No event outputs.

Data Inputs

None at the FB boundary. Input data is carried via the adapter sockets.

Data Outputs

None at the FB boundary. Output data is carried via the adapter plug.

Adapters

Role	Name	Type	Direction	Description
Output	OUT	adapter::types::unidirectional::A2X	Plug	Selected value stream. IN1 for K=0, IN2 for K=1, IN3 for K=2.
Selection	K	adapter::types::unidirectional::AUI	Socket	Index input that determines which A2X input is routed to OUT.
Input 1	IN1	adapter::types::unidirectional::A2X	Socket	Input value 1, selected when K = 0.
Input 2	IN2	adapter::types::unidirectional::A2X	Socket	Input value 2, selected when K = 1.
Input 3	IN3	adapter::types::unidirectional::A2X	Socket	Input value 3, selected when K = 2.

Functionality

The function block behaves as a three-way multiplexer:

1. It reads the current index from the K adapter.
2. According to the index value, it selects one of the three A2X input adapters.
3. It forwards the selected input stream to the OUT adapter.

The block is "ungated", meaning there is no internal comparison between the current value and the previously forwarded value. Every new calculation result from the selected input is forwarded without filtering. This is intentional and is the main difference from a change-detecting multiplexer.

Technical Features

- Generic FB implementation based on the attribute eclipse4diac::core::GenericClassName with the value GEN_A2X_AUI_MUX.
- The block supports exactly three A2X input channels.
- The adapter types are defined in the package adapter::types::unidirectional.

- No direct data inputs or outputs; all data transfer occurs through unidirectional adapters.
- No value-change recognition, no gating logic, no event suppression.

State Overview

The block is intentionally stateless with respect to value history. It does not store previous A2X values and does not compare incoming values with earlier ones. Once an index is supplied via `K`, the corresponding input is routed to `OUT` without additional conditions.

The only implicit state is the currently active selection index. After a new index is received and processed, the new selection becomes active.

Application Scenarios

Typical use cases include:

- Periodic distribution of measured or calculated values to downstream blocks that must be triggered on every scan, regardless of whether the value changed.
- Derivative and frequency calculations that need a continuous data stream.
- Data routing in automation systems where multiple A2X sources must be cyclically switched to one consumer.
- Applications that require a steady cadence for timing-sensitive calculations.

Comparison with Similar Blocks

The closest relative is `A2X_AUI_MUX_3`. Both blocks implement the same three-input multiplexer structure. The difference is the presence of change detection:

- `A2X_AUI_MUX_3` suppresses forwarding when the value has not changed.
- `A2X_AUI_MUX_3_UNGATED` forwards every new result unconditionally.

For consumers that only need to react to actual value changes, the gated variant is more efficient. For consumers that require a periodic processing rhythm, the ungated variant is the better choice because it preserves the data cadence.

Conclusion

A2X_AUI_MUX_3_UNGATED is a useful multiplexer block for unidirectional A2X data streams. By omitting change detection, it guarantees that every incoming result is passed through, making it particularly suitable for applications with periodic timing requirements. Its interface is compact and based entirely on adapters, allowing clean integration into 4diac IEC 61499 systems.

A2X_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

A2X_AUI_MUX_4 is a generic, adapter-based 4-to-1 multiplexer for Eclipse 4diac. It connects four unidirectional A2X adapter inputs (`IN1` … `IN4`) to one A2X adapter output (`OUT`). The active input is selected by the value received on the AUI adapter `K`. The output is not simply forwarded from the selected input; it is updated only when the selected value actually changes. This avoids unnecessary downstream events.

Interface Structure

The FB has no ordinary event or data inputs/outputs. All control and data information is exchanged through adapter interfaces. There are no event outputs.

Event Inputs

None.

Event Outputs

No event outputs.

Data Inputs

None. All payload data is supplied via adapter sockets.

Data Outputs

None. All payload data is provided through the `OUT` adapter plug.

Adapters

Port	Name	Type	Direction	Description
Socket	`K`	`adapter::types::unidirectional::AUI`	Input	Carries the selection index.
Socket	`IN1`	`adapter::types::unidirectional::A2X`	Input	Value selected when K = 0.
Socket	`IN2`	`adapter::types::unidirectional::A2X`	Input	Value selected when K = 1.
Socket	`IN3`	`adapter::types::unidirectional::A2X`	Input	Value selected when K = 2.
Socket	`IN4`	`adapter::types::unidirectional::A2X`	Input	Value selected when K = 3.
Plug	`OUT`	`adapter::types::unidirectional::A2X`	Output	Selected value; updated only when the selected value changes.

Functionality

The block continuously receives the selector value `K` and the four A2X input adapter values. It determines which input is active according to the current value of `K`:

- K = 0 selects `IN1`.
- K = 1 selects `IN2`.
- K = 2 selects `IN3`.
- K = 3 selects `IN4`.

When the active index changes, or when the value on the currently active input changes, the block compares the new selected value with the value previously sent to `OUT`. If the values differ, `OUT` is updated with the new value. If the values are equal, the output remains unchanged and no event is generated. This prevents event flooding and ensures that downstream adapter consumers only react to real value changes.

Technical Features

- Generic FB implementation: the `eclipse4diac::core::GenericClassName` attribute is `GEN_A2X_AUI_MUX`, so the concrete behavior is provided by a generic runtime backend with this name.
- Adapter-based interface: uses unidirectional `A2X` and `AUI` adapter types; no elementary data ports are required.
- Change-driven output: `OUT` is only updated on actual selected-value changes.
- Four selectable inputs: enough for 4-to-1 selection scenarios.
- Compiler/package namespace: `adapter::selection::unidirectional`.

State Overview

The XML definition does not contain an explicit ECC state machine; the actual behavior is implemented by the generic backend `GEN_A2X_AUI_MUX`. Conceptually, the block maintains a single internal state: the last value forwarded to `OUT`. The relevant state transition is:

- **No change**: selected value equals the last forwarded value → no output update.
- **Change**: selected value differs from the last forwarded value → `OUT` is updated.

This implicit state allows the block to suppress repeated transmissions of identical values.

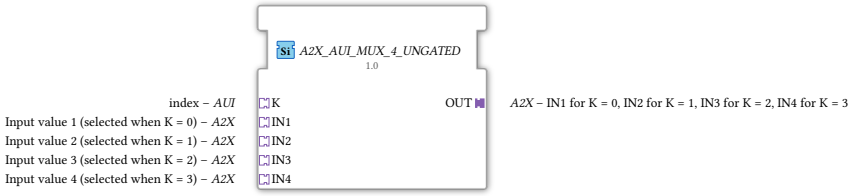
Application Scenarios

- Selecting one of four A2X data sources at runtime, using an AUI adapter as the selector.
- Connecting multiple A2X producer adapters to a single consumer without exposing elementary data types.

- Event-driven systems where downstream components should be triggered only when the selected value actually changes.
- Reducing unnecessary network or adapter communication in distributed 4diac applications.
- Using as an adapter-based alternative to a classic multiplexer in Eclipse 4diac.

Comparison with Similar Blocks

A2X_AUI_MUX_4 is an A2X variant of AX_AUI_MUX_4. Compared with a conventional data-input multiplexer, it uses adapter ports instead of elementary data inputs and outputs. This makes it suitable for structured or adapter-based data exchange.



Block / Approach	Interface	Update behavior
A2X_AUI_MUX_4	4 × A2X sockets, 1 × AUI socket, 1 × A2X plug	Output update only on actual value change.
AX_AUI_MUX_4	Adapter-based, non-A2X variant	Similar selection structure; different adapter type.
Classic MUX	Elementary data inputs and data output	Usually event-triggered; may forward unchanged values and emit an event on every selection.

The change-detection behavior of A2X_AUI_MUX_4 is its main distinction from a standard multiplexer.

Conclusion

A2X_AUI_MUX_4 provides an adapter-oriented, change-driven multiplexing solution for Eclipse 4diac. It selects one of four A2X inputs using an AUI selector and forwards the selected value through an A2X output. Because the output update is suppressed when no actual value change occurs, the block helps keep event chains lean and efficient. It is especially useful in adapter-based automation architectures where only meaningful data changes should propagate to consumers.

A2X_AUI_MUX_4_UNGATED

• – ○ • – ○ • – ○ •

Introduction

A2X_AUI_MUX_4_UNGATED is a unidirectional, adapter-based 4-to-1 multiplexer for A2X adapter streams. It selects one of four A2X input adapters according to an index received through an AUI adapter and forwards the selected stream to an A2X output plug.

In contrast to a change-detecting multiplexer, the “UNGATED” variant does not compare old and new values. Every newly calculated result is forwarded unconditionally. This makes the block especially suitable for consumers that require a periodic or continuous sample flow, such as derivative or frequency calculations.

• – ○ • – ○ • – ○ •

Interface Structure

The FB has no direct data inputs or data outputs. All runtime values are transported through unidirectional adapters. The interface consists of one index socket, four input sockets, and one output plug.

Event Inputs

There are no explicit event inputs. Control and data flow are handled through the adapter connections.

Event Outputs

No event outputs.

Data Inputs

None. All input values are carried by the adapter sockets.

Data Outputs

None. The selected A2X value is provided through the `OUT` adapter plug.

Adapters

Adapter	Type	Direction	Description
`K`	`adapter::types::unidirectional::AUI`	Socket	Selection index.
`IN1`	`adapter::types::unidirectional::A2X`	Socket	Input value 1, selected when `K = 0`.
`IN2`	`adapter::types::unidirectional::A2X`	Socket	Input value 2, selected when `K = 1`.
`IN3`	`adapter::types::unidirectional::A2X`	Socket	Input value 3, selected when `K = 2`.
`IN4`	`adapter::types::unidirectional::A2X`	Socket	Input value 4, selected when `K = 3`.
`OUT`	`adapter::types::unidirectional::A2X`	Plug	Selected A2X output stream.

• – ◦ • – ◦ • – ◦ •

Functionality

A2X_AUI_MUX_4_UNGATED acts as a four-channel multiplexer for A2X adapter data. The `K` socket carries the multiplexer index. This index is interpreted as an integer value in the range `0` to `3`.

The input selection is mapped as follows:

- `K = 0` ⟶ `IN1`
- `K = 1` ⟶ `IN2`
- `K = 2` ⟶ `IN3`
- `K = 3` ⟶ `IN4`

The selected input adapter is connected to the `OUT` plug, and the data is forwarded without any value-change filtering.

The main characteristic of this FB is that it is “ungated”. A normal gated multiplexer may suppress an output update when the selected value has not changed. This block does not do that. Every updated result coming from the selected input is passed through to `OUT`, even if it is identical to the previously forwarded value.

• – ◦ • – ◦ • – ◦ •

Technical Features

- Generic FB implementation class: `GEN_A2X_AUI_MUX`
- Adapter-based interface: no conventional data inputs or outputs
- Unidirectional adapter types from the package `adapter::types::unidirectional`
- Four A2X input channels plus one AUI index channel
- One A2X output plug
- No change detection or value filtering
- Suitable for periodic, time-driven data consumers

• – ◦ • – ◦ • – ◦ •

State Overview

The FB type is declared as a generic FB, so the XML does not contain an explicit execution control chart. The actual behavior is provided by the generic implementation `GEN_A2X_AUI_MUX`. Conceptually, the block operates in the following cycle:

State	Description
Waiting	The FB waits for an update on the `K` index adapter or on the selected A2X input.

Decoding	The index K is evaluated and mapped to IN1, IN2, IN3, or IN4.
Forwarding	The selected input data is passed to the OUT plug.

No state compares current and previous values. Therefore, every processed result is forwarded unconditionally.

• – ○ • – ○ • – ○ •

Application Scenarios

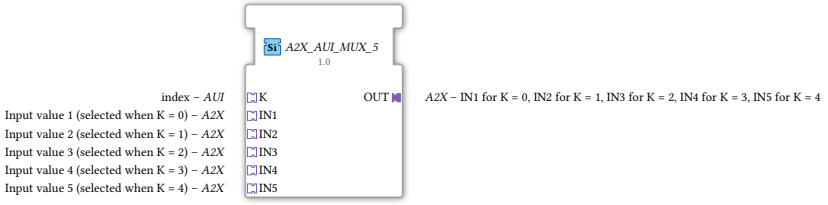
- **Periodic derivative calculations**
  Derivative blocks need a constant sample rhythm. If a value remains unchanged and a change-detecting multiplexer blocks the update, the derivative calculation may miss a sample interval. This UB forwards every new result and preserves the periodic cadence.
- **Frequency or rate measurement**
  Frequency and rate calculations rely on time-based updates rather than value changes. The ungated behavior keeps the downstream calculation active.
- **Selecting among four A2X sources**
  The FB can switch between four independent A2X adapter streams while maintaining a single, continuous output stream.
- **Adapter-based signal routing**
  Because the FB uses only adapters, it can be integrated into unidirectional, adapter-oriented data flows without mixing in conventional data inputs or outputs.

• – ○ • – ○ • – ○ •

Comparison with Similar Blocks

Block	Behavior
A2X_AUI_MUX_4	A four-input A2X multiplexer with change detection. It may suppress forwarding when the selected input value has not changed.
A2X_AUI_MUX_4_UNGATED	Same multiplexing function, but without change detection. Every newly calculated result is forwarded unconditionally.
AX_AUI_MUX_4_UNGATED	A non-A2X variant of the same ungated selection concept. The A2X variant uses dedicated unidirectional A2X adapter types.

The essential difference is the “UNGATED” behavior: downstream blocks that require uniform sample timing should use this variant instead of a change-detecting multiplexer.



• – ○ • – ○ • – ○ •

Conclusion

A2X_AUI_MUX_4_UNGATED is a specialized adapter-based multiplexer that selects one of four A2X inputs and forwards the selected data without change detection. Its strength is deterministic, periodic forwarding of all calculated results, which makes it ideal for time-critical consumers such as derivative and frequency calculations.

By combining a clear four-input structure, and an AUI-based index interface, the block offers a simple yet flexible building block for unidirectional adapter-oriented control and measurement applications.

A2X_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

A2X_AUI_MUX_5 is an adapter-based unidirectional multiplexer for IEC 61499 applications. It selects one of five A2X input adapters, **IN1** to **IN5**, based on the index value supplied by the **K** adapter. The selected value is forwarded to the **OUT** A2X output adapter.

The function block is implemented as a generic FB and uses change detection to minimize unnecessary adapter traffic. The output adapter **OUT** is only updated when the selected value actually changes.

Interface Structure

The block communicates mainly through adapters. There are no conventional event inputs, data inputs, or data outputs. All value data is exchanged through the A2X and AUI adapter connections.

Event Inputs

There are no event inputs defined for this function block.

Event Outputs

No event outputs.

Data Inputs

There are no data inputs defined for this function block.

Data Outputs

There are no data outputs defined for this function block.

Adapters

Direction	Name	Adapter Type	Comment
Socket	K	adapter::types::unidirectional::AUI	Selection index.
Socket	IN1	adapter::types::unidirectional::A2X	Input value 1, selected when K = 0.
Socket	IN2	adapter::types::unidirectional::A2X	Input value 2, selected when K = 1.
Socket	IN3	adapter::types::unidirectional::A2X	Input value 3, selected when K = 2.
Socket	IN4	adapter::types::unidirectional::A2X	Input value 4, selected when K = 3.
Socket	IN5	adapter::types::unidirectional::A2X	Input value 5, selected when K = 4.
Plug	OUT	adapter::types::unidirectional::A2X	Selected A2X value forwarded to the output.

Functionality

A2X_AUI_MUX_5 behaves as a 5-to-1 adapter multiplexer:

1. The index value is received through the **K** AUI adapter.
2. The corresponding input adapter **IN1** to **IN5** is selected.
3. The value of the selected input is forwarded to the **OUT** adapter.

If the index changes to an input that carries the same value as the current output, the output is not updated. This avoids unnecessary event and data propagation in the connected IEC 61499 application.

Since the FB is a generic function block, the actual behavior is delegated to the generic class **GEN_A2X_AUI_MUX**. The runtime environment must provide this generic backend.

Technical Features

- 5-to-1 adapter-based multiplexing.
- Unidirectional data flow through A2X and AUI adapters.
- Change-triggered output update.
- No scalar data inputs or outputs are required.
- Generic FB design using `eclipse4diac::core::GenericClassName`.
- Generic backend: `GEN_A2X_AUI_MUX`.
- Located in the adapter package `adapter::selection::unidirectional`.
- Designed according to the IEC 61499-2 FB type identification structure.

State Overview

The FBType XML does not define an explicit ECC. Instead, the behavior is provided by the generic backend. Conceptually, the function block can be described using two states:

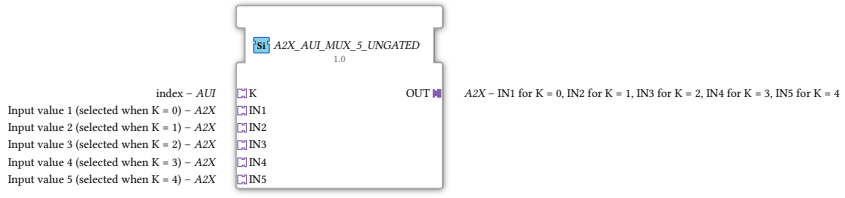
State	Description
Idle	Waiting for a change on the K index or on the currently selected input adapter.
Updating	The selected value has changed; OUT is updated.

After an update, the block returns to the idle state. If an incoming value or a new index selection does not produce a different output value, no state transition to updating occurs and no event is emitted.

Application Scenarios

- **Source selection:** Connect up to five A2X data sources and dynamically select the active source using an AUI index.
- **Event-efficient data forwarding:** Downstream logic is triggered only when the output value really changes.
- **Redundancy handling:** Switch between redundant input channels without propagating duplicate values.
- **Adapter-based system integration:** Integrate the block into unidirectional adapter chains where typed adapter connections are preferred over scalar data wiring.

Comparison with Similar Blocks



Compared to the **AX_AUI_MUX_5** block, this FB is the A2X variant and uses the A2X adapter type for its data interfaces. The main improvement is the change-detection behavior: the output update is suppressed when the selected value has not actually changed.

Compared to a conventional multiplexer FB with scalar data inputs and a numeric selector, A2X_AUI_MUX_5 uses typed adapters and provides a unidirectional connection style. This makes it more suitable for modular, adapter-oriented IEC 61499 architectures.

Conclusion

A2X_AUI_MUX_5 is a compact and event-efficient adapter multiplexer for selecting one of five A2X input channels. Its unidirectional adapter interface, generic implementation, and change-triggered output update make it suitable for modern IEC 61499 applications where adapter-based communication and reduced event traffic are important.

A2X_AUI_MUX_5_UNGATED

• – ○ • – ○ • – ○ •

Introduction

The **A2X_AUI_MUX_5_UNGATED** is an adapter-based, unidirectional 5-to-1 multiplexer. It selects one of five `A2X` input adapters through an `AUI` index adapter and forwards the selected value to an `A2X` output adapter.

The `_UNGATED` variant does **not** perform change detection: every newly computed result is forwarded unconditionally. This makes it suitable for consumers that require a periodic output cadence independent of whether the actual value has changed, for example derivative or frequency calculations.

Interface Structure

Event Inputs

None.

The FB is triggered through its adapter sockets rather than through explicit event inputs.

Event Outputs

No event outputs.

Data Inputs

None.

All data is transported through the adapter sockets.

Data Outputs

None.

All data is transported through the adapter plug.

Adapters

Name	Type	Direction	Comment
`OUT`	`adapter::types::unidirectional::A2X`	Plug	Selected input value: `IN1` for `K = 0`, `IN2` for `K = 1`, `IN3` for `K = 2`, `IN4` for `K = 3`, `IN5` for `K = 4`.
`K`	`adapter::types::unidirectional::AUI`	Socket	Index selector.
`IN1`	`adapter::types::unidirectional::A2X`	Socket	Input value 1, selected when `K = 0`.
`IN2`	`adapter::types::unidirectional::A2X`	Socket	Input value 2, selected when `K = 1`.
`IN3`	`adapter::types::unidirectional::A2X`	Socket	Input value 3, selected when `K = 2`.
`IN4`	`adapter::types::unidirectional::A2X`	Socket	Input value 4, selected when `K = 3`.
`IN5`	`adapter::types::unidirectional::A2X`	Socket	Input value 5, selected when `K = 4`.

Functionality

The FB works as a unidirectional adapter multiplexer:

1. The index adapter `K` determines which of the five input adapters is currently selected.
2. The selected input adapter is connected through to the output adapter `OUT`.
3. Every newly available result on the selected input is forwarded immediately and unconditionally.

The selection mapping is zero-based:

`K`	Selected Input
`0`	`IN1`
`1`	`IN2`
`2`	`IN3`
`3`	`IN4`
`4`	`IN5`

Because the FB is **ungated**, it does not compare old and new values and does not suppress repeated or unchanged data. Any refresh of the selected input results in an output update.

Technical Features

- Adapter-only interface with no direct data inputs or outputs.
- Unidirectional data flow from input sockets to the output plug.
- 5 input channels and 1 output channel.
- Zero-based channel selection via the `AUI` index adapter.
- No change detection, no value filtering, no hysteresis.
- Configured as a generic FB type using `GEN_A2X_AUI_MUX`.
- Belongs to the compiler package `adapter::selection::unidirectional`.

State Overview

The FB does not define an explicit internal state machine. Its behavior is essentially stateless and transparent:

Aspect	Description
Current selection	Determined by the current value delivered through the `K` adapter.
Forwarding	The selected `INx` adapter is continuously passed through to `OUT`.
Change detection	Not present. Every newly computed result is forwarded.

There is no stored “last value” and no internal comparison logic.

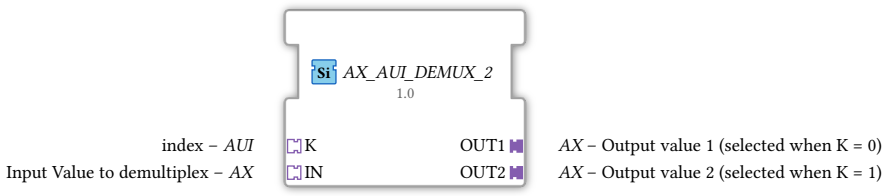
Application Scenarios

Typical use cases for `A2X_AUI_MUX_5_UNGATED` include:

- Periodic derivative calculations that require an input sample on every cycle, even if the value is unchanged.
- Frequency or rate-of-change computations that depend on a constant time base.
- Data acquisition systems selecting between multiple sensors while maintaining a regular output rhythm.
- Pipelines where downstream blocks expect a fixed update cadence rather than change-triggered events.
- Adapter-based unidirectional communication paths that need a simple 5-to-1 selection mechanism.

Comparison with Similar Blocks

The closest counterpart is the change-detecting `A2X_AUI_MUX_5` variant.



Feature	`A2X_AUI_MUX_5`	`A2X_AUI_MUX_5_UNGATED`
Change detection	Yes	No
Forwarding behavior	Only forwards when the value has changed	Forwards every newly computed result
Output cadence	Event-driven / aperiodic	Periodic cadence possible
Best suited for	Consumers that react only to value changes	Consumers that need a continuous or periodic stream of results
CPU load on unchanged data	Lower	Higher, because every result is passed through

Thus, the ungated variant is not a replacement for the gated variant, but a complementary block for time-oriented applications.

Conclusion

`A2X_AUI_MUX_5_UNGATED` is a compact, adapter-only multiplexer for selecting one of five unidirectional `A2X` inputs via an `AUI` index. Its main characteristic is the unconditional forwarding of every newly computed result, independent of value changes. This behavior makes it well suited for periodic, time-sensitive consumers, especially derivative and frequency calculations, while still providing the familiar multiplexer structure.

AX_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

AX_AUI_DEMUX_2 is the adapter-based variant of the generic demultiplexer for data type BOOL. Unlike AX_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AX_AUI_DEMUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the Boolean value to forward, routed to exactly one of the outputs (AX adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AX adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 2 output adapters (OUT1 … OUT2) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AX_AUI_DEMUX) – shared across all port counts of this block family (AX_AUI_DEMUX_2 … AX_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) ⟶ determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

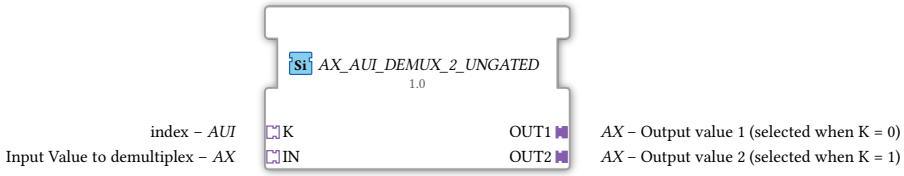
- Distributing a Boolean value to up to 2 downstream consumers, selected via an adapter-carried index

- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AX_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AX_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AX_AUI_DEMUX_2` carries the demultiplexer logic of the `AX_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AX_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `BOOL`. Unlike `AX_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AX_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the Boolean value to forward, routed to exactly one of the outputs (AX adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AX adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_DEMUX`) – shared across all port counts of this block family (AX_AUI_DEMUX_2_UNGATED … AX_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

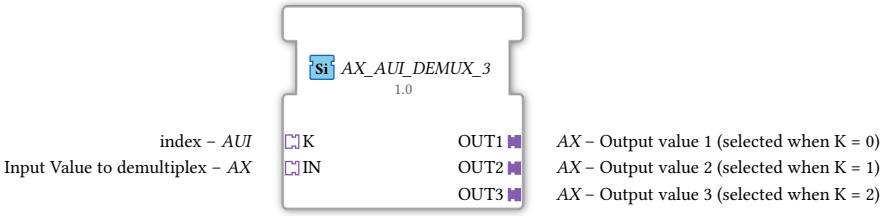
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a Boolean value to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AX_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AX_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AX_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AX_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AX_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `BOOL`. Unlike `AX_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AX_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the Boolean value to forward, routed to exactly one of the outputs (AX adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AX adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AX adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_DEMUX`) – shared across all port counts of this block family (AX_AUI_DEMUX_2 … AX_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

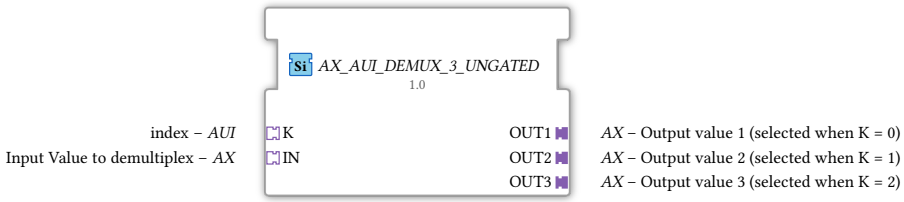
Application Scenarios

- Distributing a Boolean value to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AX_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AX_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AX_AUI_DEMUX_3` carries the demultiplexer logic of the `AX_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AX_AUI_DEMUX_3_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `BOOL`. Unlike `AX_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AX_AUI_DEMUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the Boolean value to forward, routed to exactly one of the outputs (AX adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AX adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AX adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_DEMUX`) – shared across all port counts of this block family (AX_AUI_DEMUX_2 … AX_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

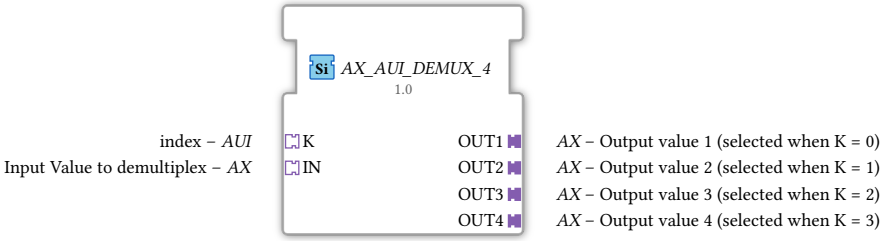
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a Boolean value to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AX_DEMUX_3 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **AX_AUI_DEMUX_3**: The gated variant – updates the output only on an actual value change.

Conclusion

AX_AUI_DEMUX_3_UNGATED carries the demultiplexer logic of the AX_DEMUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

AX_AUI_DEMUX_4 is the adapter-based variant of the generic demultiplexer for data type BOOL. Unlike AX_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AX_AUI_DEMUX_4 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the Boolean value to forward, routed to exactly one of the outputs (AX adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AX adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AX adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AX adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_DEMUX`) – shared across all port counts of this block family (AX_AUI_DEMUX_2 … AX_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

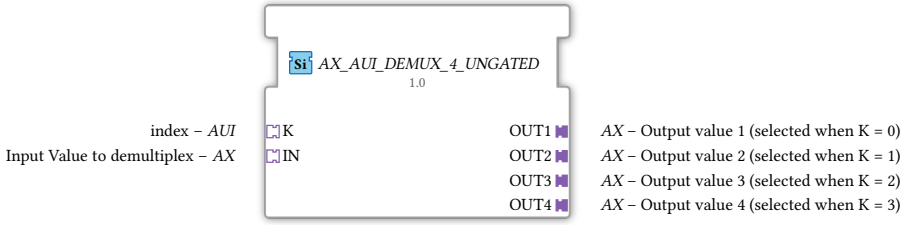
Application Scenarios

- Distributing a Boolean value to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖ Comparison with Similar Blocks

Compare with `AX_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AX_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AX_AUI_DEMUX_4` carries the demultiplexer logic of the `AX_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AX_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `BOOL`. Unlike `AX_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AX_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the Boolean value to forward, routed to exactly one of the outputs (AX adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AX adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AX adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AX adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_DEMUX`) – shared across all port counts of this block family (AX_AUI_DEMUX_2 … AX_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

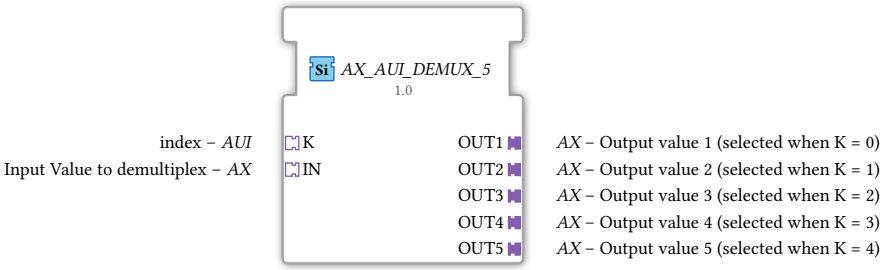
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a Boolean value to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AX_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AX_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AX_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AX_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AX_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `BOOL`. Unlike `AX_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AX_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the Boolean value to forward, routed to exactly one of the outputs (AX adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AX adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AX adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AX adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AX adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_DEMUX`) – shared across all port counts of this block family (AX_AUI_DEMUX_2 … AX_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

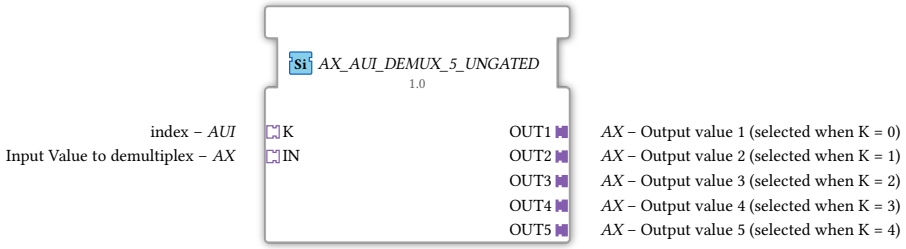
Application Scenarios

- Distributing a Boolean value to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AX_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AX_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AX_AUI_DEMUX_5 carries the demultiplexer logic of the AX_DEMUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AX_AUI_DEMUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AX_AUI_DEMUX_5_UNGATED is the adapter-based variant of the generic demultiplexer for data type BOOL. Unlike AX_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AX_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the Boolean value to forward, routed to exactly one of the outputs (AX adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AX adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AX adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AX adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AX adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_DEMUX`) – shared across all port counts of this block family (AX_AUI_DEMUX_2 … AX_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

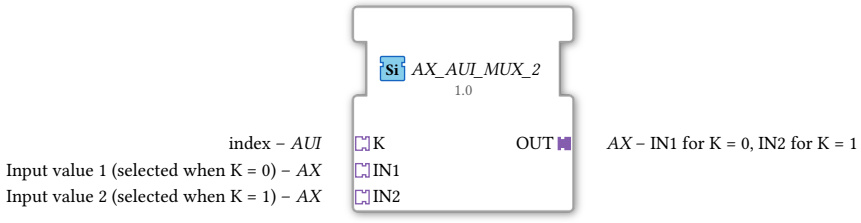
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a Boolean value to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AX_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AX_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AX_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AX_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_MUX_2

• – ○ • – ○ • – ○ •

Introduction

`AX_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `BOOL`. Unlike `AX_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its

own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AX_AUI_MUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 2, passed through to OUT when the index is K = 0 (AX adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to OUT when the index is K = 1 (AX adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN2:

1. The current value of K.D1 determines which of the 2 input adapters (IN1 … IN2) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AX_AUI_MUX) – shared across all port counts of this block family (AX_AUI_MUX_2 … AX_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN2) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

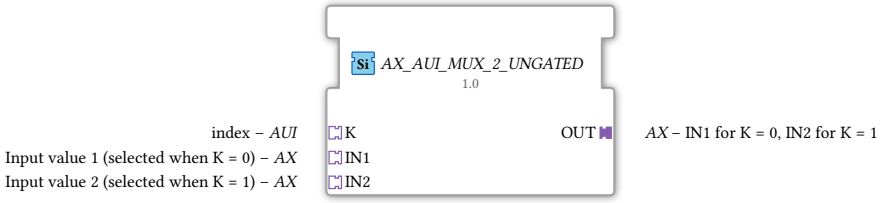
Application Scenarios

- Choosing between up to 2 Boolean value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AX_MUX_2 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **AX_AUI_MUX_2_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AX_AUI_MUX_2 carries the multiplexer logic of the AX_MUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AX_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AX_AUI_MUX_2_UNGATED is the adapter-based variant of the generic multiplexer for data type BOOL. Unlike AX_MUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AX_AUI_MUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AX adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AX adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` ... `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_MUX`) – shared across all port counts of this block family (AX_AUI_MUX_2_UNGATED ... AX_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

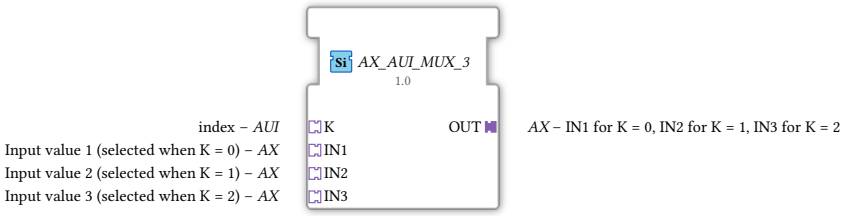
- **Any event** (selector adapter `K` or `IN1`...`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 Boolean value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AX_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AX_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AX_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AX_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

AX_AUI_MUX_3 is the adapter-based variant of the generic multiplexer for data type BOOL. Unlike AX_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AX_AUI_MUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (AX adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (AX adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (AX adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AX_AUI_MUX) – shared across all port counts of this block family (AX_AUI_MUX_2 … AX_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN3) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

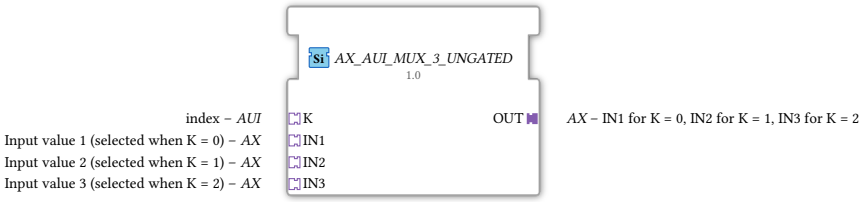
- Choosing between up to 3 Boolean value sources through a centrally managed adapter index

- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AX_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **`AX_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AX_AUI_MUX_3` carries the multiplexer logic of the `AX_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_AUI_MUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AX_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `BOOL`. Unlike `AX_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AX_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AX adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AX adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AX adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_MUX`) – shared across all port counts of this block family (AX_AUI_MUX_2 … AX_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

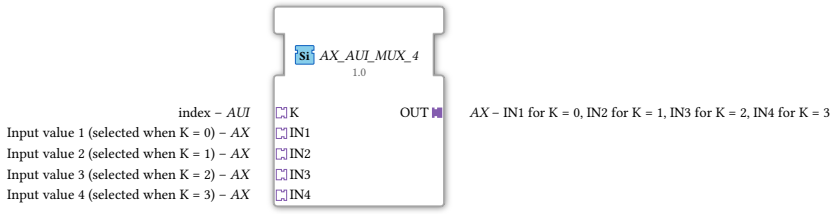
- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 Boolean value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AX_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AX_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AX_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AX_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AX_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `BOOL`. Unlike `AX_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AX_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AX adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AX adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AX adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AX adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_MUX`) – shared across all port counts of this block family (AX_AUI_MUX_2 … AX_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

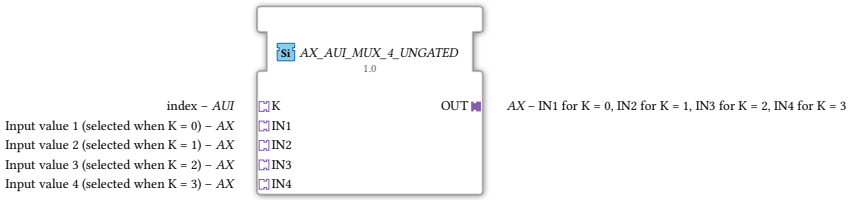
Application Scenarios

- Choosing between up to 4 Boolean value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AX_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AX_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AX_AUI_MUX_4` carries the multiplexer logic of the `AX_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AX_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• — ○ • — ○ • — ○ •

Introduction

`AX_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `BOOL`. Unlike `AX_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AX_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AX adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AX adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AX adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AX adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_MUX`) – shared across all port counts of this block family (AX_AUI_MUX_2 … AX_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

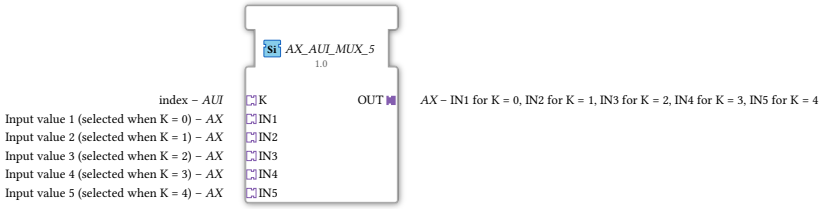
- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 Boolean value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AX_MUX_4 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **AX_AUI_MUX_4**: The gated variant – updates the output only on an actual value change.

Conclusion

AX_AUI_MUX_4_UNGATED carries the multiplexer logic of the AX_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

AX_AUI_MUX_5 is the adapter-based variant of the generic multiplexer for data type BOOL. Unlike AX_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AX_AUI_MUX_5 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AX adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AX adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AX adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AX adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AX adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1...IN5:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AX_AUI_MUX`) – shared across all port counts of this block family (AX_AUI_MUX_2 … AX_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

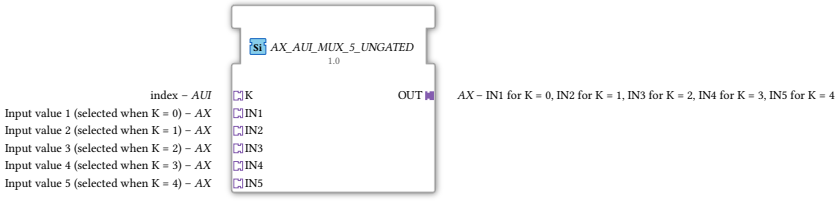
Application Scenarios

- Choosing between up to 5 Boolean value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AX_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AX_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AX_AUI_MUX_5` carries the multiplexer logic of the `AX_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AX_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AX_AUI_MUX_5_UNGATED is the adapter-based variant of the generic multiplexer for data type BOOL. Unlike AX_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AX_AUI_MUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AX adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AX adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AX adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AX adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AX adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AX adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN5:

1. The current value of K.D1 determines which of the 5 input adapters (IN1 … IN5) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AX_AUI_MUX) – shared across all port counts of this block family (AX_AUI_MUX_2 … AX_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN5) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 5 Boolean value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AX_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AX_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AX_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AX_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_DEMUX_2

• – ○ • – ○ • – ○ •

Introduction

`AB_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AB_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index

be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AB_AUI_DEMUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AB adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AB adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 2 output adapters (OUT1 … OUT2) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AB_AUI_DEMUX) – shared across all port counts of this block family (AB_AUI_DEMUX_2 … AB_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

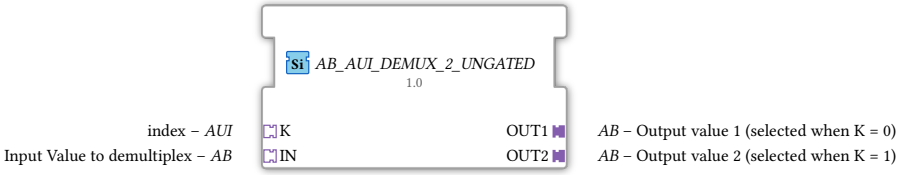
- Distributing a byte value (8-bit bit pattern) to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)

- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AB_DEMUX_2 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **AB_AUI_DEMUX_2_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AB_AUI_DEMUX_2 carries the demultiplexer logic of the AB_DEMUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AB_AUI_DEMUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AB_AUI_DEMUX_2_UNGATED is the adapter-based variant of the generic demultiplexer for data type BYTE. Unlike AB_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AB_AUI_DEMUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AB adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AB adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_DEMUX`) – shared across all port counts of this block family (AB_AUI_DEMUX_2_UNGATED … AB_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

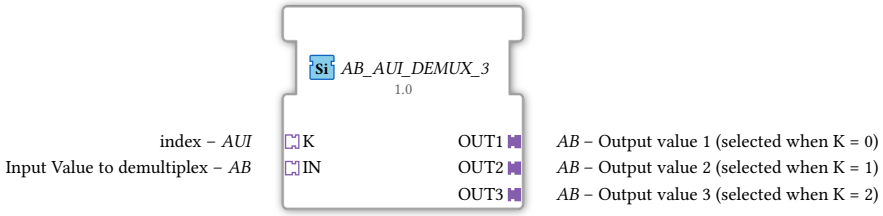
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AB_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AB_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AB_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AB_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AB_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AB_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AB_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AB adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AB adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AB adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_DEMUX`) – shared across all port counts of this block family (AB_AUI_DEMUX_2 … AB_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

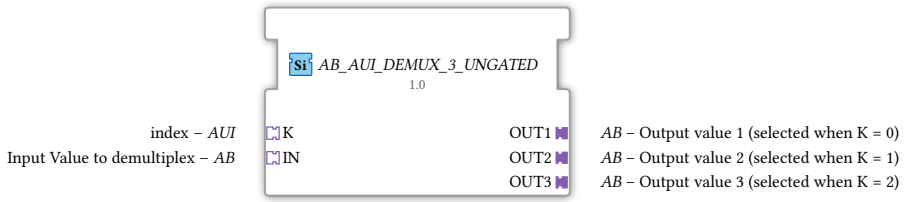
Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AB_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AB_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AB_AUI_DEMUX_3` carries the demultiplexer logic of the `AB_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AB_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AB_AUI_DEMUX_3_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AB_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AB_AUI_DEMUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AB adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AB adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AB adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_DEMUX`) – shared across all port counts of this block family (AB_AUI_DEMUX_2 … AB_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

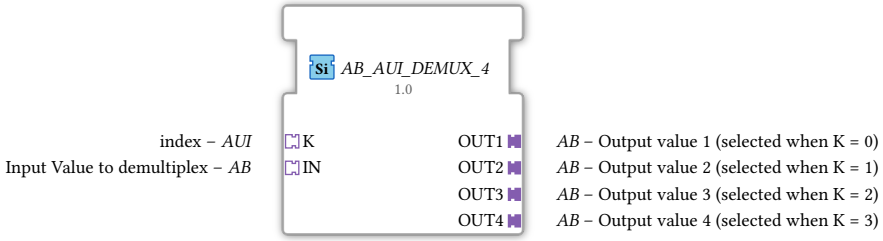
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AB_DEMUX_3 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **AB_AUI_DEMUX_3**: The gated variant – updates the output only on an actual value change.

Conclusion

AB_AUI_DEMUX_3_UNGATED carries the demultiplexer logic of the AB_DEMUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

AB_AUI_DEMUX_4 is the adapter-based variant of the generic demultiplexer for data type BYTE. Unlike AB_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AB_AUI_DEMUX_4 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AB adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AB adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AB adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AB adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_DEMUX`) – shared across all port counts of this block family (AB_AUI_DEMUX_2 … AB_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

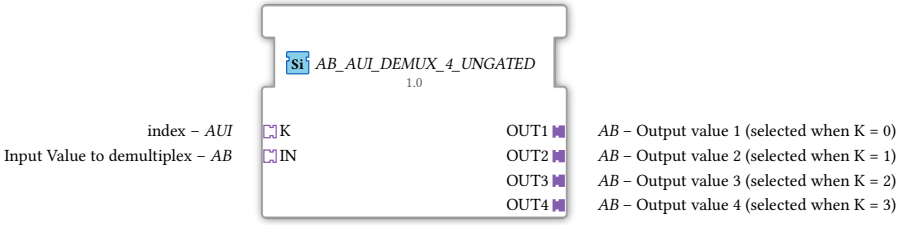
Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AB_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AB_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AB_AUI_DEMUX_4` carries the demultiplexer logic of the `AB_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AB_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AB adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AB adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AB adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AB adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see “Change Detection” below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn’t changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_DEMUX`) – shared across all port counts of this block family (AB_AUI_DEMUX_2 … AB_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

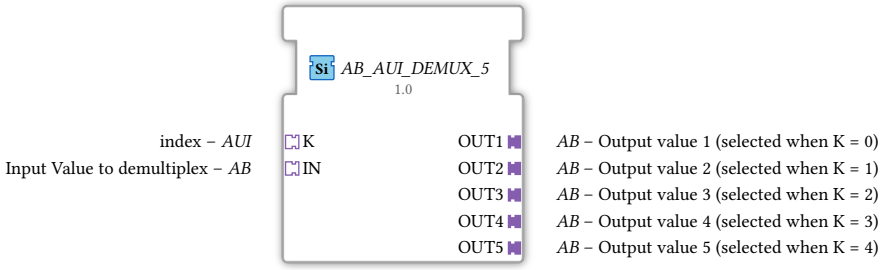
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AB_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AB_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AB_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AB_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AB_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AB_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AB_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AB adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AB adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AB adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AB adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AB adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_DEMUX`) – shared across all port counts of this block family (AB_AUI_DEMUX_2 … AB_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

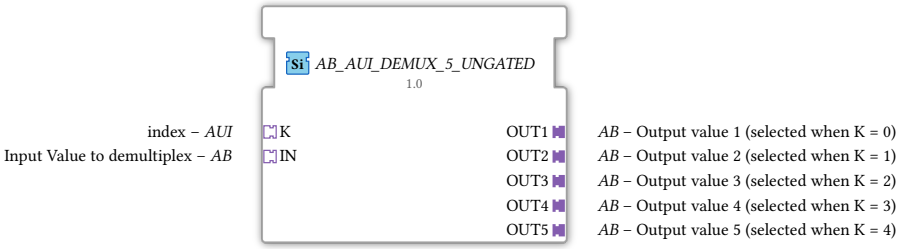
Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AB_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AB_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AB_AUI_DEMUX_5 carries the demultiplexer logic of the AB_DEMUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AB_AUI_DEMUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AB_AUI_DEMUX_5_UNGATED is the adapter-based variant of the generic demultiplexer for data type BYTE. Unlike AB_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AB_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AB adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AB adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AB adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AB adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AB adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_DEMUX`) – shared across all port counts of this block family (AB_AUI_DEMUX_2 … AB_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

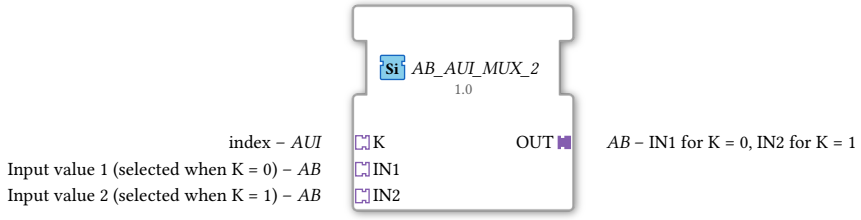
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AB_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AB_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AB_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AB_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AB_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AB_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its

own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AB_AUI_MUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 2, passed through to OUT when the index is K = 0 (AB adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to OUT when the index is K = 1 (AB adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN2:

1. The current value of K.D1 determines which of the 2 input adapters (IN1 … IN2) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AB_AUI_MUX) – shared across all port counts of this block family (AB_AUI_MUX_2 … AB_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN2) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

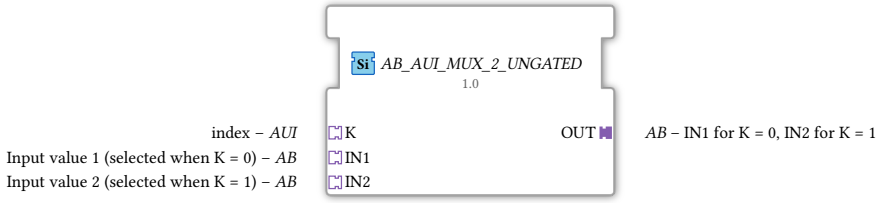
Application Scenarios

- Choosing between up to 2 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AB_MUX_2 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **AB_AUI_MUX_2_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AB_AUI_MUX_2 carries the multiplexer logic of the AB_MUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AB_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AB_AUI_MUX_2_UNGATED is the adapter-based variant of the generic multiplexer for data type BYTE. Unlike AB_MUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AB_AUI_MUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AB adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AB adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_MUX`) – shared across all port counts of this block family (AB_AUI_MUX_2_UNGATED … AB_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AB_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AB_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AB_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AB_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

AB_AUI_MUX_3 is the adapter-based variant of the generic multiplexer for data type BYTE. Unlike AB_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AB_AUI_MUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (AB adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (AB adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (AB adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AB_AUI_MUX) – shared across all port counts of this block family (AB_AUI_MUX_2 … AB_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN3) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

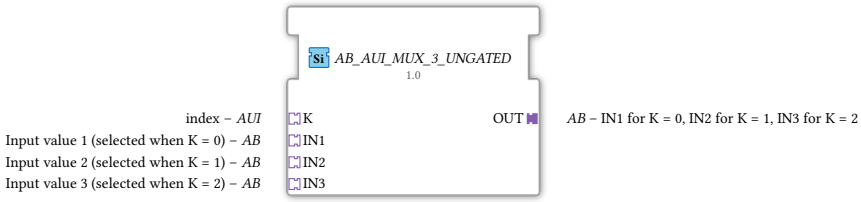
- Choosing between up to 3 byte value (8-bit bit pattern) sources through a centrally managed adapter index

- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AB_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **`AB_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AB_AUI_MUX_3` carries the multiplexer logic of the `AB_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AB_AUI_MUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AB_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AB_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AB_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AB adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AB adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AB adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_MUX`) – shared across all port counts of this block family (AB_AUI_MUX_2 … AB_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

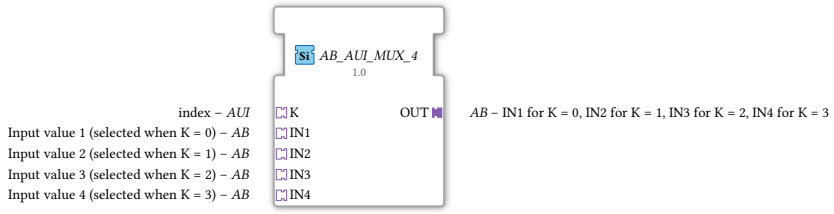
- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AB_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AB_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AB_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AB_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AB_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AB_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AB_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AB adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AB adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AB adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AB adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_MUX`) – shared across all port counts of this block family (AB_AUI_MUX_2 … AB_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

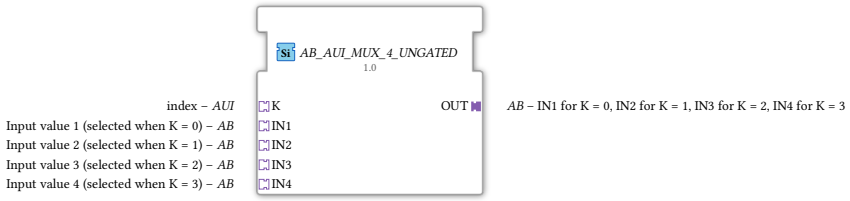
Application Scenarios

- Choosing between up to 4 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AB_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AB_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AB_AUI_MUX_4` carries the multiplexer logic of the `AB_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AB_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AB_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AB_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AB_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AB adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AB adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AB adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AB adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_MUX`) – shared across all port counts of this block family (AB_AUI_MUX_2 … AB_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

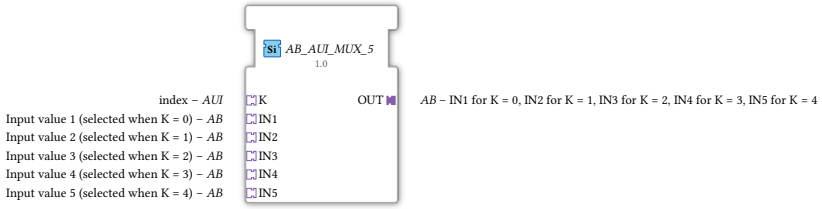
- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AB_MUX_4 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **AB_AUI_MUX_4**: The gated variant – updates the output only on an actual value change.

Conclusion

AB_AUI_MUX_4_UNGATED carries the multiplexer logic of the AB_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

AB_AUI_MUX_5 is the adapter-based variant of the generic multiplexer for data type BYTE. Unlike AB_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AB_AUI_MUX_5 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AB adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AB adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AB adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AB adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AB adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1...IN5:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AB_AUI_MUX`) – shared across all port counts of this block family (AB_AUI_MUX_2 … AB_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

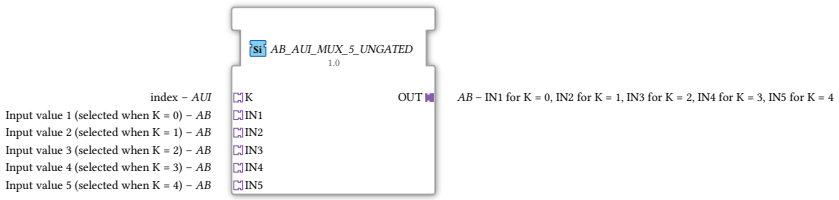
Application Scenarios

- Choosing between up to 5 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AB_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AB_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AB_AUI_MUX_5` carries the multiplexer logic of the `AB_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AB_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AB_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AB_AUI_MUX_5_UNGATED is the adapter-based variant of the generic multiplexer for data type BYTE. Unlike AB_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AB_AUI_MUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AB adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AB adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AB adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AB adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AB adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AB adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN5:

1. The current value of K.D1 determines which of the 5 input adapters (IN1 … IN5) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AB_AUI_MUX) – shared across all port counts of this block family (AB_AUI_MUX_2 … AB_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN5) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 5 byte value (8-bit bit pattern) sources through a centrally managed adapter index

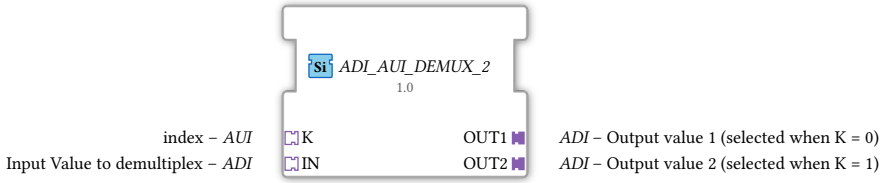
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AB_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AB_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.



Conclusion

`AB_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AB_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ADI_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`ADI_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `DINT`. Unlike `ADI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the 32-bit signed integer to forward, routed to exactly one of the outputs (ADI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (ADI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_DEMUX`) – shared across all port counts of this block family (ADI_AUI_DEMUX_2 … ADI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

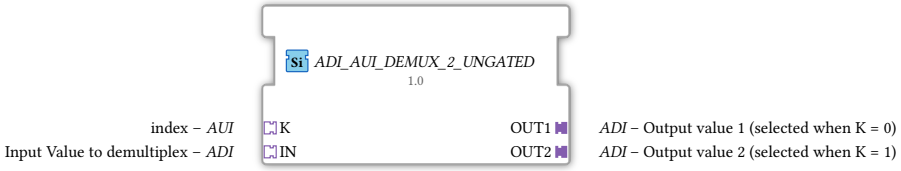
Application Scenarios

- Distributing a 32-bit signed integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ADI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ADI_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ADI_AUI_DEMUX_2` carries the demultiplexer logic of the `ADI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ADI_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `DINT`. Unlike `ADI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit signed integer to forward, routed to exactly one of the outputs (ADI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (ADI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_DEMUX`) – shared across all port counts of this block family (ADI_AUI_DEMUX_2_UNGATED … ADI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit signed integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ADI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ADI_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ADI_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `ADI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_DEMUX_3

• – ○ • – ○ • – ○ •

Introduction

`ADI_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `DINT`. Unlike `ADI_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit signed integer to forward, routed to exactly one of the outputs (ADI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (ADI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (ADI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_DEMUX`) – shared across all port counts of this block family (ADI_AUI_DEMUX_2 … ADI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

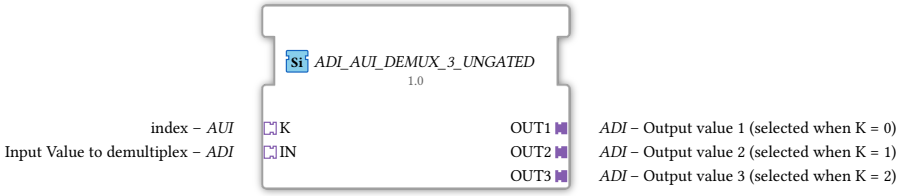
Application Scenarios

- Distributing a 32-bit signed integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ADI_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ADI_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ADI_AUI_DEMUX_3` carries the demultiplexer logic of the `ADI_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_DEMUX_3_UNGATED

i UNGATED variant: This block is the ungated version of ADI_AUI_DEMUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

ADI_AUI_DEMUX_3_UNGATED is the adapter-based variant of the generic demultiplexer for data type DINT. Unlike ADI_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ADI_AUI_DEMUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 32-bit signed integer to forward, routed to exactly one of the outputs (ADI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (ADI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (ADI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 3 output adapters (OUT1 … OUT3) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_ADI_AUI_DEMUX) – shared across all port counts of this block family (ADI_AUI_DEMUX_2 … ADI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

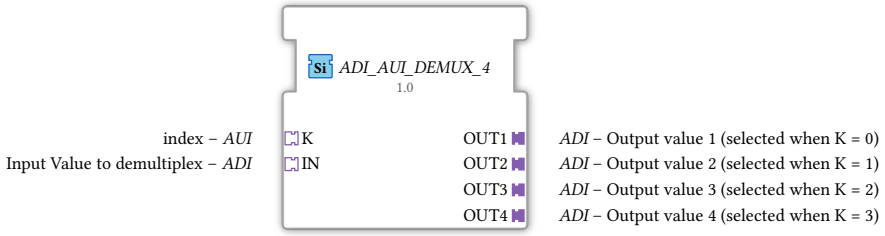
- **Any event** (selector adapter K or IN) ⟶ determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit signed integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with ADI_DEMUX_3 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **ADI_AUI_DEMUX_3**: The gated variant – updates the output only on an actual value change.

Conclusion

ADI_AUI_DEMUX_3_UNGATED carries the demultiplexer logic of the ADI_DEMUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_DEMUX_4

• – ○ • – ○ • – ○ •

Introduction

ADI_AUI_DEMUX_4 is the adapter-based variant of the generic demultiplexer for data type DINT. Unlike ADI_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit signed integer to forward, routed to exactly one of the outputs (ADI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (ADI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (ADI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (ADI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_DEMUX`) – shared across all port counts of this block family (ADI_AUI_DEMUX_2 … ADI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

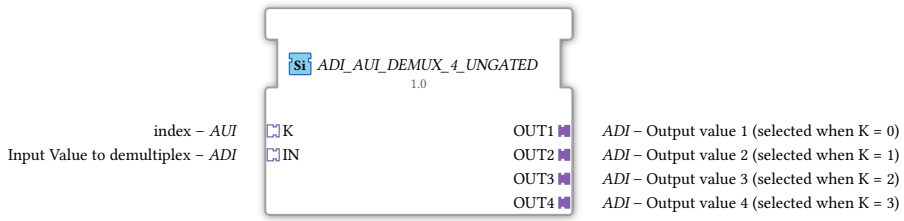
Application Scenarios

- Distributing a 32-bit signed integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ADI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ADI_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ADI_AUI_DEMUX_4` carries the demultiplexer logic of the `ADI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ADI_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `DINT`. Unlike `ADI_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the 32-bit signed integer to forward, routed to exactly one of the outputs (ADI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (ADI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (ADI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (ADI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_DEMUX`) – shared across all port counts of this block family (ADI_AUI_DEMUX_2 … ADI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit signed integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ADI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ADI_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ADI_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `ADI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`ADI_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `DINT`. Unlike `ADI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit signed integer to forward, routed to exactly one of the outputs (ADI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (ADI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (ADI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (ADI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (ADI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_DEMUX`) – shared across all port counts of this block family (ADI_AUI_DEMUX_2 … ADI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

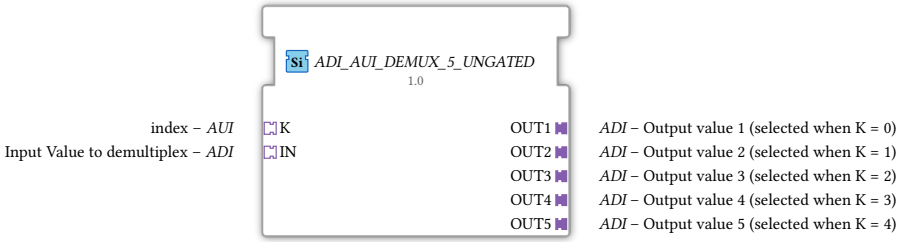
Application Scenarios

- Distributing a 32-bit signed integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ADI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ADI_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ADI_AUI_DEMUX_5` carries the demultiplexer logic of the `ADI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_AUI_DEMUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`ADI_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `DINT`. Unlike `ADI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K

data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_DEMUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit signed integer to forward, routed to exactly one of the outputs (ADI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (ADI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (ADI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (ADI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (ADI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_DEMUX`) – shared across all port counts of this block family (ADI_AUI_DEMUX_2 … ADI_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

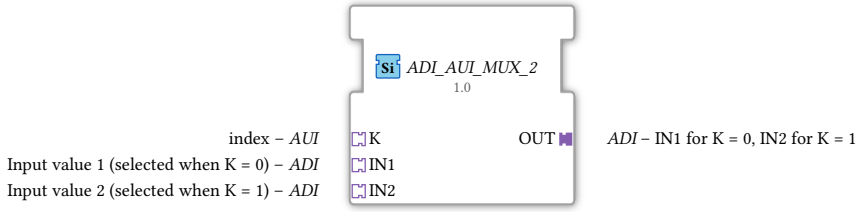
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit signed integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ADI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ADI_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ADI_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `ADI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_MUX_2

• – ○ • – ○ • – ○ •

Introduction

`ADI_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `DINT`. Unlike `ADI_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (ADI adapter type).

- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (ADI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_MUX`) – shared across all port counts of this block family (ADI_AUI_MUX_2 … ADI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

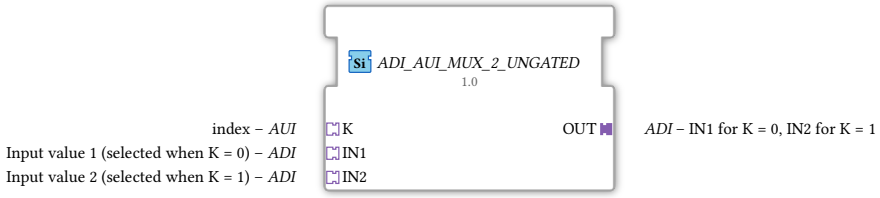
Application Scenarios

- Choosing between up to 2 32-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ADI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`ADI_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ADI_AUI_MUX_2` carries the multiplexer logic of the `ADI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of ADI_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ADI_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `DINT`. Unlike `ADI_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_MUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (ADI adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (ADI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_MUX`) – shared across all port counts of this block family (ADI_AUI_MUX_2_UNGATED … ADI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

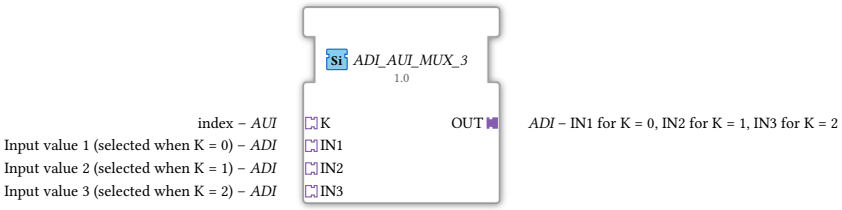
- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 32-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ADI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`ADI_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ADI_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `ADI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`ADI_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `DINT`. Unlike `ADI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (ADI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (ADI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (ADI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_MUX`) – shared across all port counts of this block family (ADI_AUI_MUX_2 … ADI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

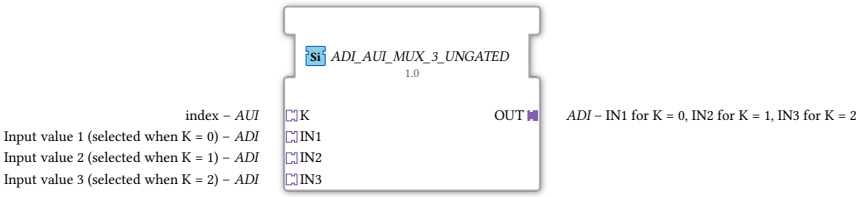
- Choosing between up to 3 32-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ADI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`ADI_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.



Conclusion

`ADI_AUI_MUX_3` carries the multiplexer logic of the `ADI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of ADI_AUI_MUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change

(e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ADI_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `DINT`. Unlike `ADI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (ADI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (ADI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (ADI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_MUX`) – shared across all port counts of this block family (ADI_AUI_MUX_2 … ADI_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 32-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ADI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`ADI_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ADI_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `ADI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`ADI_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `DINT`. Unlike `ADI_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (ADI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (ADI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (ADI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (ADI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_MUX`) – shared across all port counts of this block family (ADI_AUI_MUX_2 … ADI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

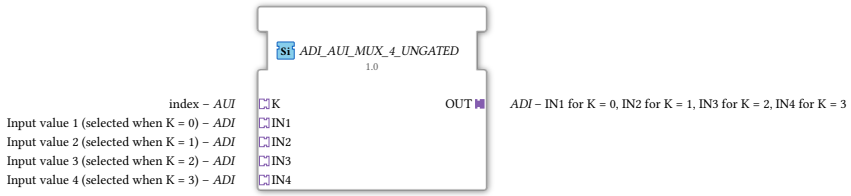
Application Scenarios

- Choosing between up to 4 32-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ADI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`ADI_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ADI_AUI_MUX_4` carries the multiplexer logic of the `ADI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_AUI_MUX_4`. - **`ADI_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ADI_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `ADI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`ADI_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `DINT`. Unlike `ADI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (ADI adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (ADI adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (ADI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (ADI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (ADI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_MUX`) – shared across all port counts of this block family (ADI_AUI_MUX_2 … ADI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

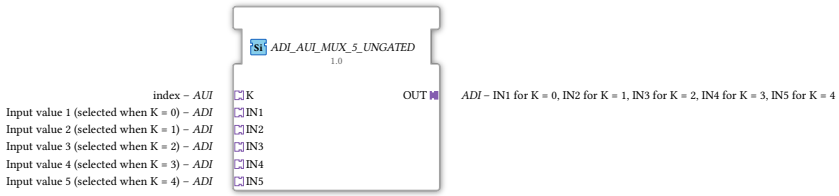
Application Scenarios

- Choosing between up to 5 32-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ADI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- **`ADI_AUI_MUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ADI_AUI_MUX_5` carries the multiplexer logic of the `ADI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ADI_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`ADI_AUI_MUX_5_UNGATED` is the adapter-based variant of the generic multiplexer for data type `DINT`. Unlike `ADI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ADI_AUI_MUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (ADI adapter type).

- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (ADI adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (ADI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (ADI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (ADI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ADI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ADI_AUI_MUX`) – shared across all port counts of this block family (ADI_AUI_MUX_2 … ADI_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

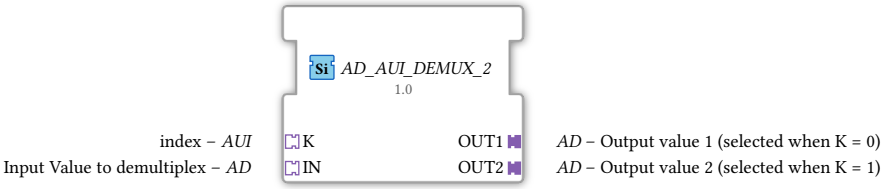
- Choosing between up to 5 32-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ADI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- `ADI_AUI_MUX_5`: The gated variant – updates the output only on an actual value change.



Conclusion

`ADI_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `ADI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AD_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AD_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `DWORD`. Unlike `AD_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AD_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit bit pattern to forward, routed to exactly one of the outputs (AD adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AD adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_DEMUX`) – shared across all port counts of this block family (AD_AUI_DEMUX_2 … AD_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

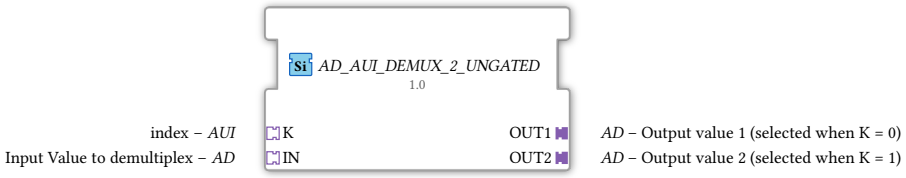
Application Scenarios

- Distributing a 32-bit bit pattern to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AD_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AD_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AD_AUI_DEMUX_2` carries the demultiplexer logic of the `AD_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AD_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `DWORD`. Unlike `AD_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AD_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit bit pattern to forward, routed to exactly one of the outputs (AD adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AD adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_DEMUX`) – shared across all port counts of this block family (AD_AUI_DEMUX_2_UNGATED … AD_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

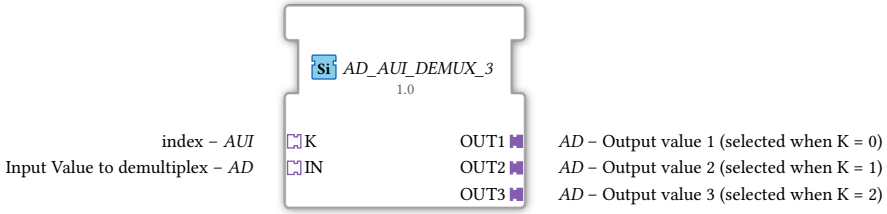
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit bit pattern to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AD_DEMUX_2 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **AD_AUI_DEMUX_2**: The gated variant – updates the output only on an actual value change.

Conclusion

AD_AUI_DEMUX_2_UNGATED carries the demultiplexer logic of the AD_DEMUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

AD_AUI_DEMUX_3 is the adapter-based variant of the generic demultiplexer for data type DWORD. Unlike AD_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AD_AUI_DEMUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 32-bit bit pattern to forward, routed to exactly one of the outputs (AD adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AD adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AD adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_DEMUX`) – shared across all port counts of this block family (AD_AUI_DEMUX_2 … AD_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

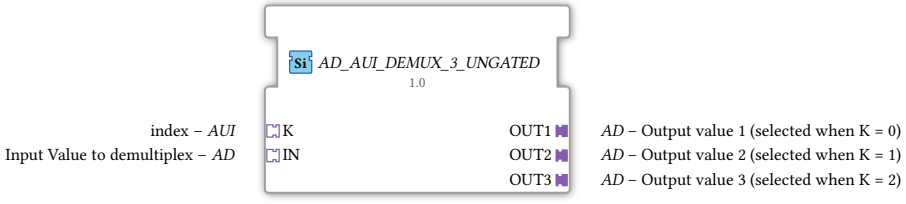
Application Scenarios

- Distributing a 32-bit bit pattern to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖ Comparison with Similar Blocks

Compare with `AD_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AD_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AD_AUI_DEMUX_3` carries the demultiplexer logic of the `AD_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AD_AUI_DEMUX_3_UNGATED is the adapter-based variant of the generic demultiplexer for data type DWORD. Unlike AD_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AD_AUI_DEMUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 32-bit bit pattern to forward, routed to exactly one of the outputs (AD adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AD adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AD adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 3 output adapters (OUT1 … OUT3) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AD_AUI_DEMUX) – shared across all port counts of this block family (AD_AUI_DEMUX_2 … AD_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

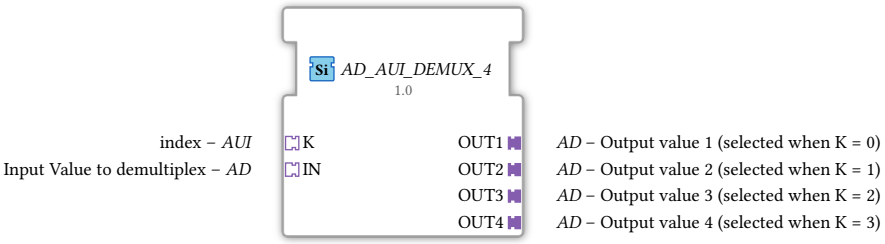
- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit bit pattern to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖ Comparison with Similar Blocks

Compare with `AD_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AD_AUI_DEMUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AD_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AD_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AD_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `DWORD`. Unlike `AD_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AD_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the 32-bit bit pattern to forward, routed to exactly one of the outputs (AD adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AD adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AD adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AD adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_DEMUX`) – shared across all port counts of this block family (AD_AUI_DEMUX_2 … AD_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

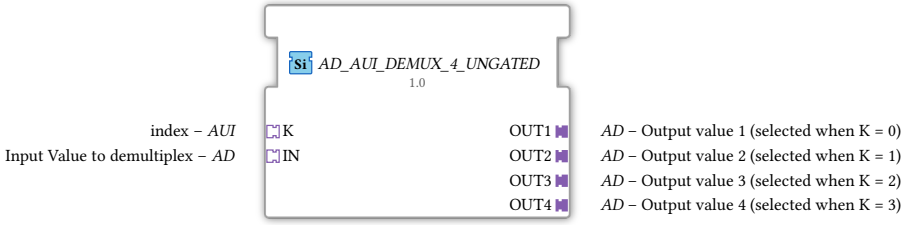
Application Scenarios

- Distributing a 32-bit bit pattern to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AD_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- `AD_AUI_DEMUX_4_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AD_AUI_DEMUX_4` carries the demultiplexer logic of the `AD_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). • – ◦ • – ◦ • – ◦ •

Introduction

`AD_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `DWORD`. Unlike `AD_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AD_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit bit pattern to forward, routed to exactly one of the outputs (AD adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AD adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AD adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AD adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_DEMUX`) – shared across all port counts of this block family (AD_AUI_DEMUX_2 … AD_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

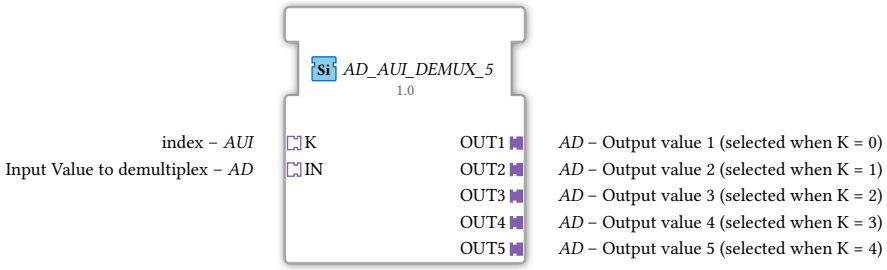
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit bit pattern to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AD_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AD_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AD_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AD_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AD_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `DWORD`. Unlike `AD_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AD_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit bit pattern to forward, routed to exactly one of the outputs (AD adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AD adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AD adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AD adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AD adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_DEMUX`) – shared across all port counts of this block family (AD_AUI_DEMUX_2 … AD_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

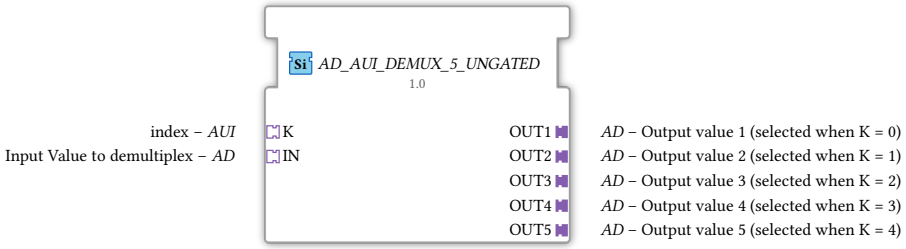
Application Scenarios

- Distributing a 32-bit bit pattern to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AD_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AD_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AD_AUI_DEMUX_5 carries the demultiplexer logic of the AD_DEMUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AD_AUI_DEMUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AD_AUI_DEMUX_5_UNGATED is the adapter-based variant of the generic demultiplexer for data type DWORD. Unlike AD_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AD_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 32-bit bit pattern to forward, routed to exactly one of the outputs (AD adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AD adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AD adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AD adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AD adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_DEMUX`) – shared across all port counts of this block family (AD_AUI_DEMUX_2 … AD_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

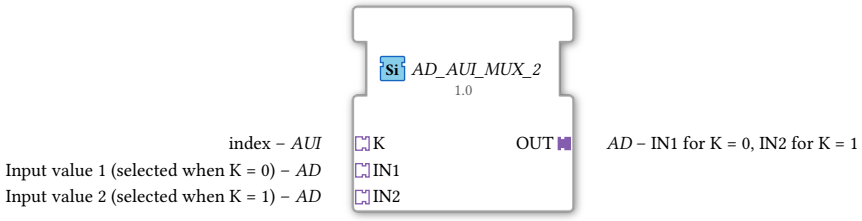
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit bit pattern to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖ Comparison with Similar Blocks

Compare with `AD_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AD_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AD_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AD_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AD_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `DWORD`. Unlike `AD_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index

be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AD_AUI_MUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 2, passed through to OUT when the index is K = 0 (AD adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to OUT when the index is K = 1 (AD adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN2:

1. The current value of K.D1 determines which of the 2 input adapters (IN1 … IN2) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AD_AUI_MUX) – shared across all port counts of this block family (AD_AUI_MUX_2 … AD_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN2) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

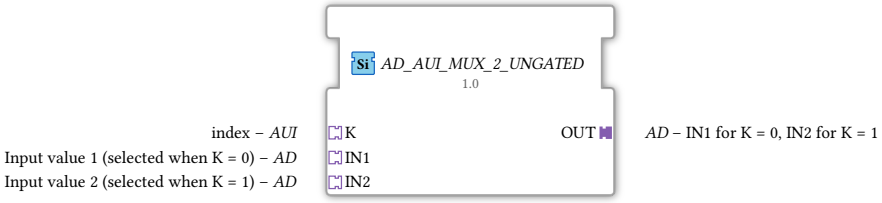
Application Scenarios

- Choosing between up to 2 32-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AD_MUX_2 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **AD_AUI_MUX_2_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AD_AUI_MUX_2 carries the multiplexer logic of the AD_MUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AD_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AD_AUI_MUX_2_UNGATED is the adapter-based variant of the generic multiplexer for data type DWORD. Unlike AD_MUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AD_AUI_MUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AD adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AD adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` ... `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_MUX`) – shared across all port counts of this block family (AD_AUI_MUX_2_UNGATED ... AD_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

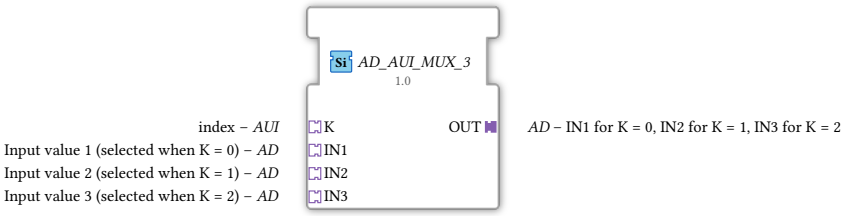
- **Any event** (selector adapter `K` or `IN1`...`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 32-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AD_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AD_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AD_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AD_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

AD_AUI_MUX_3 is the adapter-based variant of the generic multiplexer for data type DWORD. Unlike AD_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AD_AUI_MUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (AD adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (AD adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (AD adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AD_AUI_MUX) – shared across all port counts of this block family (AD_AUI_MUX_2 … AD_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN3) → read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

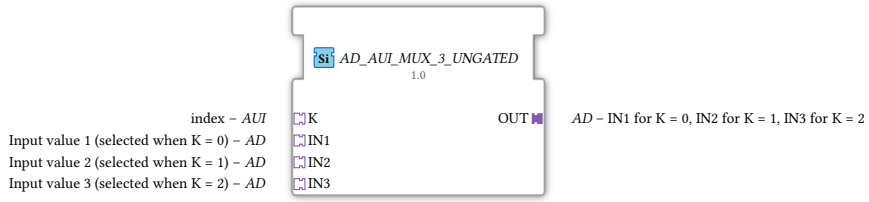
- Choosing between up to 3 32-bit bit pattern sources through a centrally managed adapter index

- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AD_MUX_3 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **AD_AUI_MUX_3_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AD_AUI_MUX_3 carries the multiplexer logic of the AD_MUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AD_AUI_MUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AD_AUI_MUX_3_UNGATED is the adapter-based variant of the generic multiplexer for data type DWORD. Unlike AD_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AD_AUI_MUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AD adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AD adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AD adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_MUX`) – shared across all port counts of this block family (AD_AUI_MUX_2 … AD_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

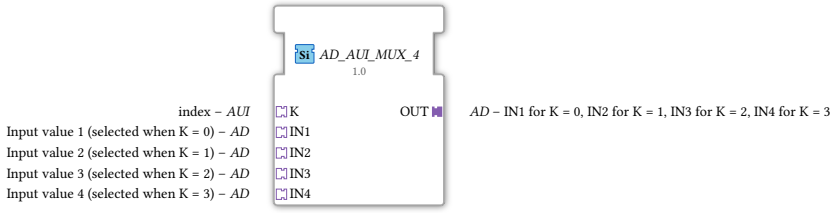
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AD_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AD_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AD_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AD_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AD_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `DWORD`. Unlike `AD_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AD_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AD adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AD adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AD adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AD adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_MUX`) – shared across all port counts of this block family (AD_AUI_MUX_2 … AD_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

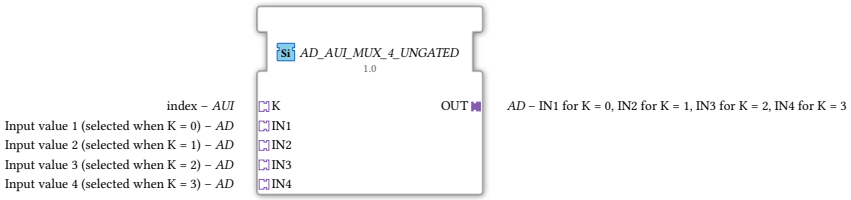
Application Scenarios

- Choosing between up to 4 32-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AD_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AD_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AD_AUI_MUX_4` carries the multiplexer logic of the `AD_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AD_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AD_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `DWORD`. Unlike `AD_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AD_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AD adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AD adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AD adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AD adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_MUX`) – shared across all port counts of this block family (AD_AUI_MUX_2 … AD_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

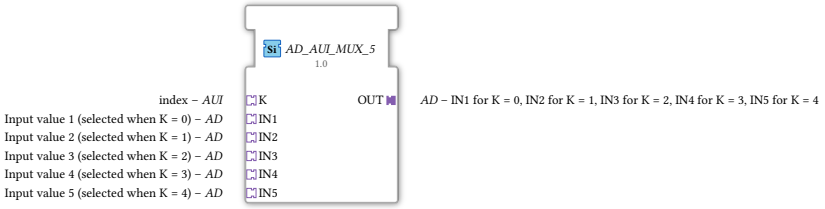
- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 32-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AD_MUX_4 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **AD_AUI_MUX_4**: The gated variant – updates the output only on an actual value change.

Conclusion

AD_AUI_MUX_4_UNGATED carries the multiplexer logic of the AD_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

AD_AUI_MUX_5 is the adapter-based variant of the generic multiplexer for data type DWORD. Unlike AD_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AD_AUI_MUX_5 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AD adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AD adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AD adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AD adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AD adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_MUX`) – shared across all port counts of this block family (AD_AUI_MUX_2 … AD_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

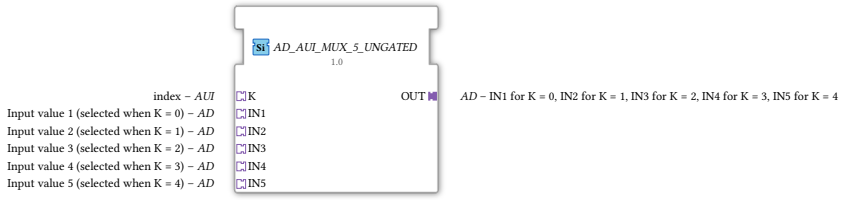
Application Scenarios

- Choosing between up to 5 32-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AD_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AD_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AD_AUI_MUX_5` carries the multiplexer logic of the `AD_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AD_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AD_AUI_MUX_5_UNGATED` is the adapter-based variant of the generic multiplexer for data type `DWORD`. Unlike `AD_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AD_AUI_MUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AD adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AD adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AD adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AD adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AD adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AD adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AD_AUI_MUX`) – shared across all port counts of this block family (AD_AUI_MUX_2 … AD_AUI_MUX_5_UNGATED).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

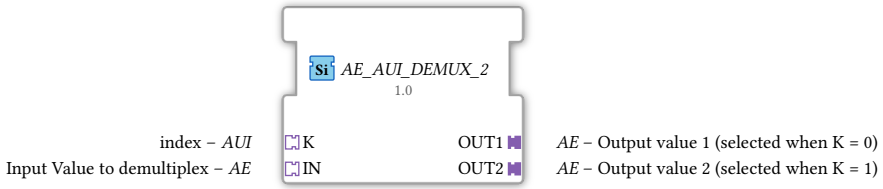
- Choosing between up to 5 32-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AD_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- `AD_AUI_MUX_5`: The gated variant – updates the output only on an actual value change.



Conclusion

`AD_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AD_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AE_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AE_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `EVENT`. Unlike `AE_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AE_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the event to forward, routed to exactly one of the outputs (AE adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AE adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AE adapter type).

Functionality

`AE_AUI_DEMUX_2` receives an event on socket **IN** and forwards it to exactly one of the 2 output plugs `OUT1` … `OUT2`. Which output is written is decided by the index arriving on the adapter socket **K** (type `AUI`): as soon as the `AUI` plug connected to K fires its internal `E1` event carrying the data value `D1`, `AE_AUI_DEMUX_2` interprets that value as a 0-based index (`0` … `1`), writes the forwarded event to the corresponding `OUT` plug and triggers that plug's adapter event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AE_AUI_DEMUX`) – shared across all port counts of this block family (AE_AUI_DEMUX_2 … AE_AUI_DEMUX_5).
- The `AE` adapter carries only an event, no data value – `AE_AUI_DEMUX_2` therefore switches pure event pulses, not payload data.

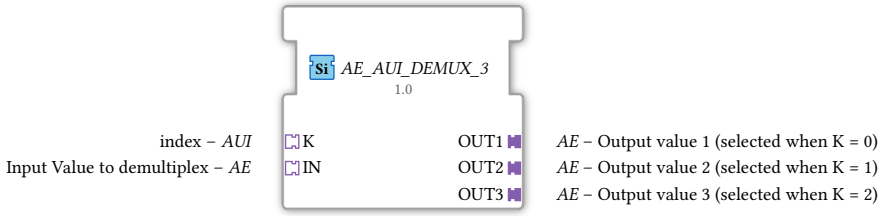
State Overview

The block is stateless with respect to any sequencing logic: it waits for the `E1` event on socket **K**, evaluates the index carried with it once it arrives and updates the affected adapter plug. No state beyond the most recently written adapter value is kept between calls.

Application Scenarios

- Distributing a control event to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks



Compare with `AE_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

Conclusion

`AE_AUI_DEMUX_2` carries the demultiplexer logic of the `AE_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AE_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AE_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `EVENT`. Unlike `AE_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AE_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the event to forward, routed to exactly one of the outputs (AE adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AE adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AE adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AE adapter type).

Functionality

`AE_AUI_DEMUX_3` receives an event on socket **IN** and forwards it to exactly one of the 3 output plugs `OUT1` … `OUT3`. Which output is written is decided by the index arriving on the adapter socket **K** (type `AUI`): as soon as the `AUI` plug connected to K fires its internal `E1` event carrying the data value `D1`, `AE_AUI_DEMUX_3` interprets that value as a 0-based index (`0` … `2`), writes the forwarded event to the corresponding `OUT` plug and triggers that plug's adapter event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AE_AUI_DEMUX`) – shared across all port counts of this block family (AE_AUI_DEMUX_2 … AE_AUI_DEMUX_5).
- The `AE` adapter carries only an event, no data value – `AE_AUI_DEMUX_3` therefore switches pure event pulses, not payload data.

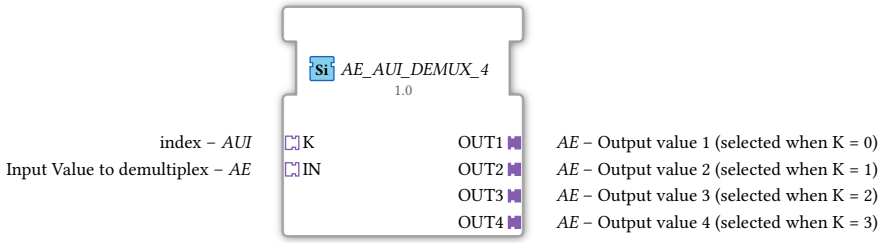
State Overview

The block is stateless with respect to any sequencing logic: it waits for the `E1` event on socket **K**, evaluates the index carried with it once it arrives and updates the affected adapter plug. No state beyond the most recently written adapter value is kept between calls.

Application Scenarios

- Distributing a control event to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks



Compare with `AE_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

Conclusion

`AE_AUI_DEMUX_3` carries the demultiplexer logic of the `AE_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AE_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AE_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `EVENT`. Unlike `AE_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AE_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the event to forward, routed to exactly one of the outputs (AE adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AE adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AE adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AE adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AE adapter type).

Functionality

`AE_AUI_DEMUX_4` receives an event on socket **IN** and forwards it to exactly one of the 4 output plugs `OUT1` … `OUT4`. Which output is written is decided by the index arriving on the adapter socket **K** (type `AUI`): as soon as the `AUI` plug connected to K fires its internal `E1` event carrying the data value `D1`, `AE_AUI_DEMUX_4` interprets that value as a 0-based index (`0` … `3`), writes the forwarded event to the corresponding `OUT` plug and triggers that plug's adapter event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AE_AUI_DEMUX`) – shared across all port counts of this block family (AE_AUI_DEMUX_2 … AE_AUI_DEMUX_5).
- The `AE` adapter carries only an event, no data value – `AE_AUI_DEMUX_4` therefore switches pure event pulses, not payload data.

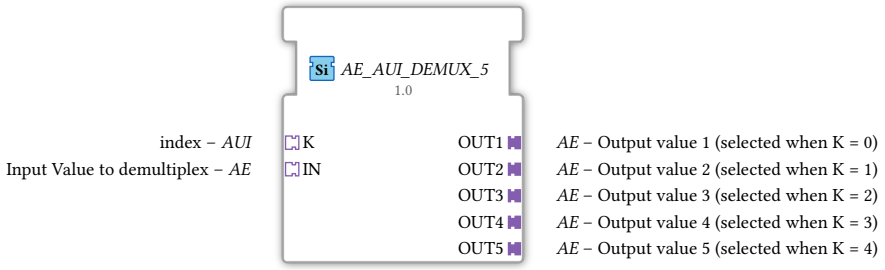
State Overview

The block is stateless with respect to any sequencing logic: it waits for the `E1` event on socket **K**, evaluates the index carried with it once it arrives and updates the affected adapter plug. No state beyond the most recently written adapter value is kept between calls.

Application Scenarios

- Distributing a control event to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks



Compare with `AE_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

Conclusion

`AE_AUI_DEMUX_4` carries the demultiplexer logic of the `AE_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AE_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

AE_AUI_DEMUX_5 is the adapter-based variant of the generic demultiplexer for data type EVENT. Unlike AE_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AE_AUI_DEMUX_5 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the event to forward, routed to exactly one of the outputs (AE adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AE adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AE adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AE adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AE adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AE adapter type).

Functionality

AE_AUI_DEMUX_5 receives an event on socket **IN** and forwards it to exactly one of the 5 output plugs OUT1 … OUT5. Which output is written is decided by the index arriving on the adapter socket **K** (type AUI): as soon as the AUI plug connected to K fires its internal E1 event carrying the data value D1, AE_AUI_DEMUX_5 interprets that value as a 0-based index (0 … 4), writes the forwarded event to the corresponding OUT plug and triggers that plug's adapter event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AE_AUI_DEMUX) – shared across all port counts of this block family (AE_AUI_DEMUX_2 … AE_AUI_DEMUX_5).
- The AE adapter carries only an event, no data value – AE_AUI_DEMUX_5 therefore switches pure event pulses, not payload data.

State Overview

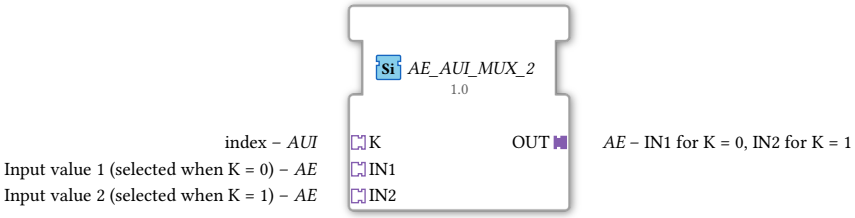
The block is stateless with respect to any sequencing logic: it waits for the E1 event on socket **K**, evaluates the index carried with it once it arrives and updates the affected adapter plug. No state beyond the most recently written adapter value is kept between calls.

Application Scenarios

- Distributing a control event to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)

- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks



Compare with `AE_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

Conclusion

`AE_AUI_DEMUX_5` carries the demultiplexer logic of the `AE_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AE_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AE_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `EVENT`. Unlike `AE_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AE_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AE adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AE adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AE adapter type).

Functionality

`AE_AUI_MUX_2` selects one of the 2 input sockets `IN1` … `IN2` via the adapter socket **K** (type `AUI`) and forwards its value to the single output plug `OUT`. As soon as the `AUI` plug connected to K fires its internal

E1 event carrying the data value D1, AE_AUI_MUX_2 interprets that value as a 0-based index (0 … 1), copies the selected event to OUT and triggers its adapter event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AE_AUI_MUX) – shared across all port counts of this block family (AE_AUI_MUX_2 … AE_AUI_MUX_5).
- The AE adapter carries only an event, no data value – AE_AUI_MUX_2 therefore switches pure event pulses, not payload data.

State Overview

The block is stateless with respect to any sequencing logic: it waits for the E1 event on socket **K**, evaluates the index carried with it once it arrives and updates the affected adapter plug. No state beyond the most recently written adapter value is kept between calls.

Application Scenarios

- Choosing between up to 2 event sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AE_MUX_2 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

Conclusion

AE_AUI_MUX_2 carries the multiplexer logic of the AE_MUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AE_AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

AE_AUI_MUX_3 is the adapter-based variant of the generic multiplexer for data type EVENT. Unlike AE_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AE_AUI_MUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AE adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AE adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AE adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AE adapter type).

Functionality

`AE_AUI_MUX_3` selects one of the 3 input sockets `IN1` … `IN3` via the adapter socket **K** (type `AUI`) and forwards its value to the single output plug `OUT`. As soon as the `AUI` plug connected to K fires its internal `E1` event carrying the data value `D1`, `AE_AUI_MUX_3` interprets that value as a 0-based index (`0` … `2`), copies the selected event to `OUT` and triggers its adapter event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AE_AUI_MUX`) – shared across all port counts of this block family (AE_AUI_MUX_2 … AE_AUI_MUX_5).
- The `AE` adapter carries only an event, no data value – `AE_AUI_MUX_3` therefore switches pure event pulses, not payload data.

State Overview

The block is stateless with respect to any sequencing logic: it waits for the `E1` event on socket **K**, evaluates the index carried with it once it arrives and updates the affected adapter plug. No state beyond the most recently written adapter value is kept between calls.

Application Scenarios

- Choosing between up to 3 event sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AE_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

Conclusion

`AE_AUI_MUX_3` carries the multiplexer logic of the `AE_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AE_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AE_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `EVENT`. Unlike `AE_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AE_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AE adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AE adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AE adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AE adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AE adapter type).

Functionality

`AE_AUI_MUX_4` selects one of the 4 input sockets `IN1` … `IN4` via the adapter socket **K** (type `AUI`) and forwards its value to the single output plug `OUT`. As soon as the `AUI` plug connected to K fires its internal `E1` event carrying the data value `D1`, `AE_AUI_MUX_4` interprets that value as a 0-based index (`0` … `3`), copies the selected event to `OUT` and triggers its adapter event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AE_AUI_MUX`) – shared across all port counts of this block family (AE_AUI_MUX_2 … AE_AUI_MUX_5).
- The `AE` adapter carries only an event, no data value – `AE_AUI_MUX_4` therefore switches pure event pulses, not payload data.

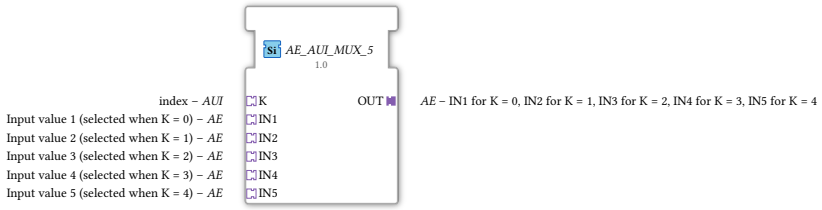
State Overview

The block is stateless with respect to any sequencing logic: it waits for the `E1` event on socket **K**, evaluates the index carried with it once it arrives and updates the affected adapter plug. No state beyond the most recently written adapter value is kept between calls.

Application Scenarios

- Choosing between up to 4 event sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks



Compare with `AE_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

Conclusion

`AE_AUI_MUX_4` carries the multiplexer logic of the `AE_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AE_AUI_MUX_5

• — ○ • — ○ • — ○ •

Introduction

`AE_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `EVENT`. Unlike `AE_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AE_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AE adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AE adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AE adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AE adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AE adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AE adapter type).

Functionality

`AE_AUI_MUX_5` selects one of the 5 input sockets `IN1` … `IN5` via the adapter socket **K** (type `AUI`) and forwards its value to the single output plug `OUT`. As soon as the `AUI` plug connected to K fires its internal `E1` event carrying the data value `D1`, `AE_AUI_MUX_5` interprets that value as a 0-based index (`0` … `4`), copies the selected event to `OUT` and triggers its adapter event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AE_AUI_MUX`) – shared across all port counts of this block family (AE_AUI_MUX_2 … AE_AUI_MUX_5).
- The `AE` adapter carries only an event, no data value – `AE_AUI_MUX_5` therefore switches pure event pulses, not payload data.

State Overview

The block is stateless with respect to any sequencing logic: it waits for the `E1` event on socket **K**, evaluates the index carried with it once it arrives and updates the affected adapter plug. No state beyond the most recently written adapter value is kept between calls.

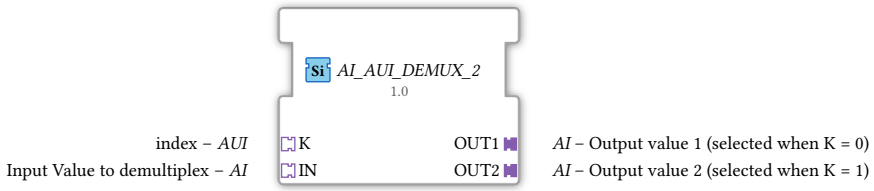
Application Scenarios

- Choosing between up to 5 event sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AE_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



Conclusion

`AE_AUI_MUX_5` carries the multiplexer logic of the `AE_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AI_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

AI_AUI_DEMUX_2 is the adapter-based variant of the generic demultiplexer for data type INT. Unlike AI_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AI_AUI_DEMUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 16-bit signed integer to forward, routed to exactly one of the outputs (AI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 2 output adapters (OUT1 … OUT2) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AI_AUI_DEMUX) – shared across all port counts of this block family (AI_AUI_DEMUX_2 … AI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

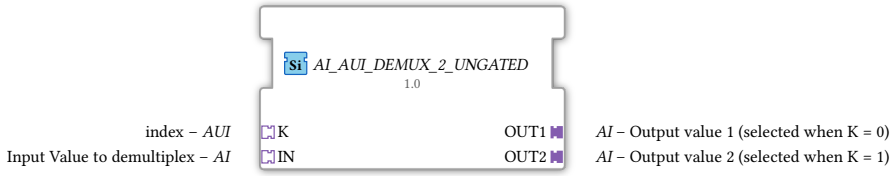
Application Scenarios

- Distributing a 16-bit signed integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AI_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AI_AUI_DEMUX_2` carries the demultiplexer logic of the `AI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AI_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `INT`. Unlike `AI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit signed integer to forward, routed to exactly one of the outputs (AI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_DEMUX`) – shared across all port counts of this block family (AI_AUI_DEMUX_2_UNGATED … AI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

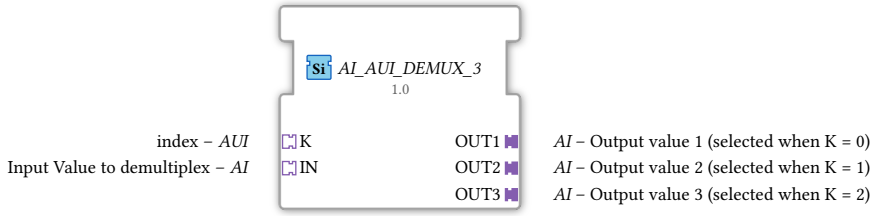
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 16-bit signed integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AI_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AI_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AI_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `INT`. Unlike `AI_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit signed integer to forward, routed to exactly one of the outputs (AI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_DEMUX`) – shared across all port counts of this block family (AI_AUI_DEMUX_2 … AI_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

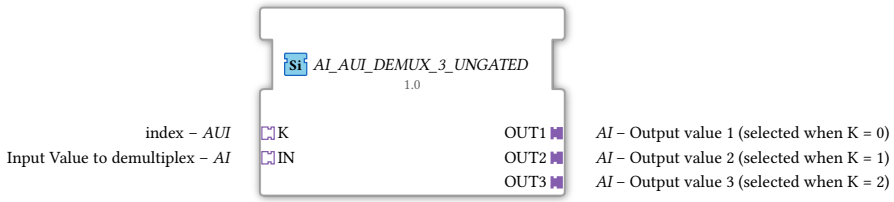
Application Scenarios

- Distributing a 16-bit signed integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AI_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AI_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AI_AUI_DEMUX_3` carries the demultiplexer logic of the `AI_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). - **`AI_AUI_DEMUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AI_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AI_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AI_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `INT`. Unlike `AI_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit signed integer to forward, routed to exactly one of the outputs (AI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_DEMUX`) – shared across all port counts of this block family (AI_AUI_DEMUX_2 … AI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

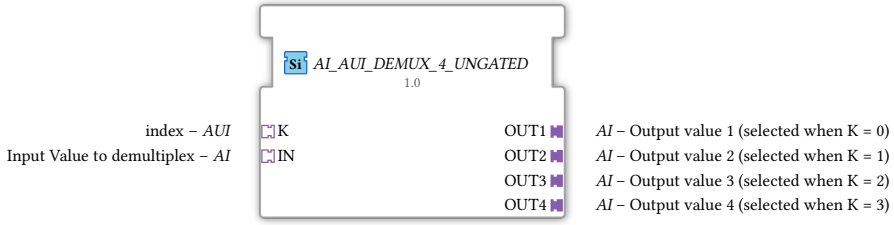
Application Scenarios

- Distributing a 16-bit signed integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AI_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AI_AUI_DEMUX_4` carries the demultiplexer logic of the `AI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AI_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `INT`. Unlike `AI_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit signed integer to forward, routed to exactly one of the outputs (AI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see “Change Detection” below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn’t changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_DEMUX`) – shared across all port counts of this block family (AI_AUI_DEMUX_2 … AI_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

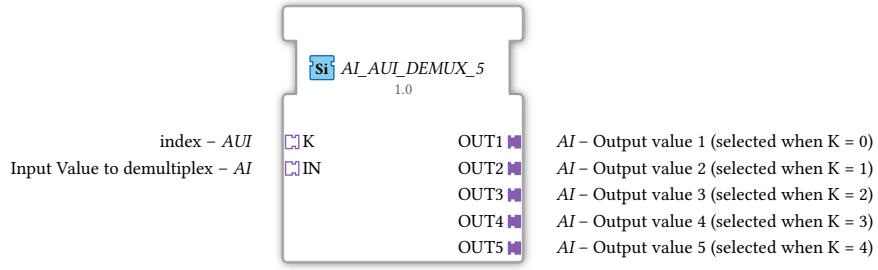
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 16-bit signed integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AI_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AI_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AI_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `INT`. Unlike `AI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit signed integer to forward, routed to exactly one of the outputs (AI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_DEMUX`) – shared across all port counts of this block family (AI_AUI_DEMUX_2 … AI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

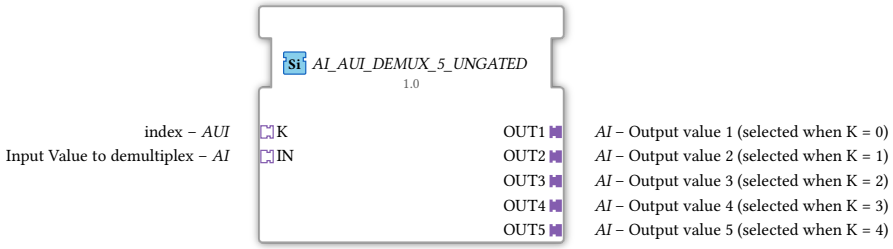
Application Scenarios

- Distributing a 16-bit signed integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AI_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AI_AUI_DEMUX_5` carries the demultiplexer logic of the `AI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_AUI_DEMUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AI_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `INT`. Unlike `AI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_DEMUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit signed integer to forward, routed to exactly one of the outputs (AI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_DEMUX`) – shared across all port counts of this block family (AI_AUI_DEMUX_2 … AI_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

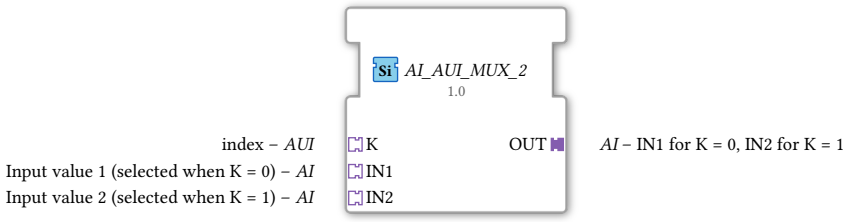
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 16-bit signed integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AI_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AI_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AI_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `INT`. Unlike `AI_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its

own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AI_AUI_MUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 2, passed through to OUT when the index is K = 0 (AI adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to OUT when the index is K = 1 (AI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN2:

1. The current value of K.D1 determines which of the 2 input adapters (IN1 … IN2) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AI_AUI_MUX) – shared across all port counts of this block family (AI_AUI_MUX_2 … AI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN2) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

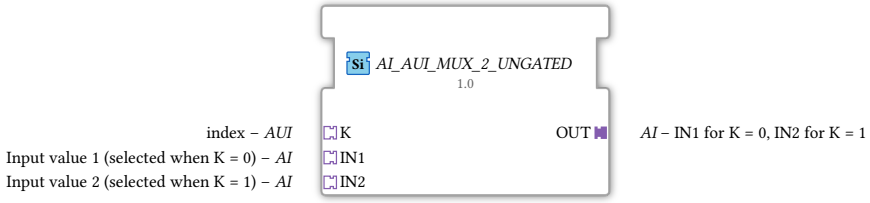
Application Scenarios

- Choosing between up to 2 16-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AI_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AI_AUI_MUX_2` carries the multiplexer logic of the `AI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_AUI_MUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AI_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `INT`. Unlike `AI_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Conclusion

`AI_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

AI_AUI_MUX_3 is the adapter-based variant of the generic multiplexer for data type INT. Unlike AI_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AI_AUI_MUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (AI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (AI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (AI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AI_AUI_MUX) – shared across all port counts of this block family (AI_AUI_MUX_2 … AI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN3) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

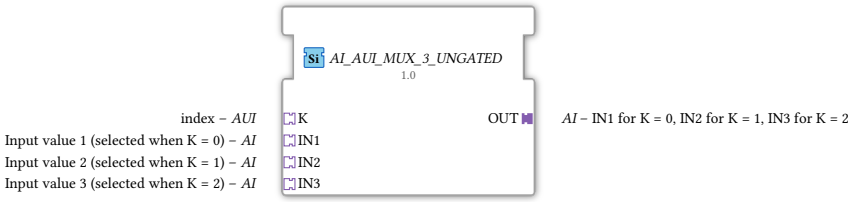
- Choosing between up to 3 16-bit signed integer sources through a centrally managed adapter index

- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **`AI_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AI_AUI_MUX_3` carries the multiplexer logic of the `AI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_AUI_MUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AI_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `INT`. Unlike `AI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_MUX`) – shared across all port counts of this block family (AI_AUI_MUX_2 … AI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

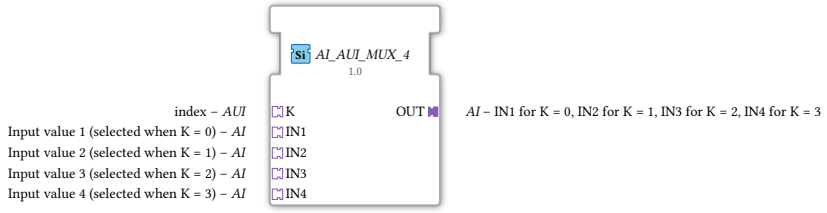
- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 16-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AI_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AI_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_MUX_4

• — ○ • — ○ • — ○ •

Introduction

`AI_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `INT`. Unlike `AI_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_MUX`) – shared across all port counts of this block family (AI_AUI_MUX_2 … AI_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

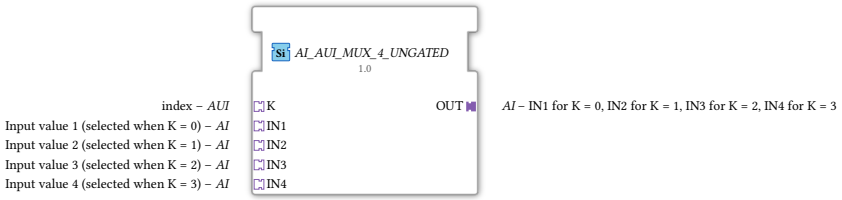
Application Scenarios

- Choosing between up to 4 16-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AI_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AI_AUI_MUX_4` carries the multiplexer logic of the `AI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_AUI_MUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• — ○ • — ○ • — ○ •

Introduction

`AI_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `INT`. Unlike `AI_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_MUX`) – shared across all port counts of this block family (AI_AUI_MUX_2 … AI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

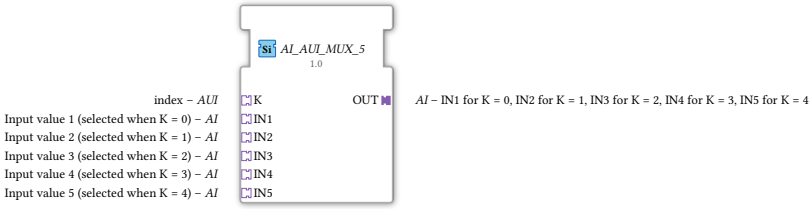
- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 16-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AI_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AI_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `AI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`AI_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `INT`. Unlike `AI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AI_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AI adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AI adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AI_AUI_MUX`) – shared across all port counts of this block family (AI_AUI_MUX_2 … AI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

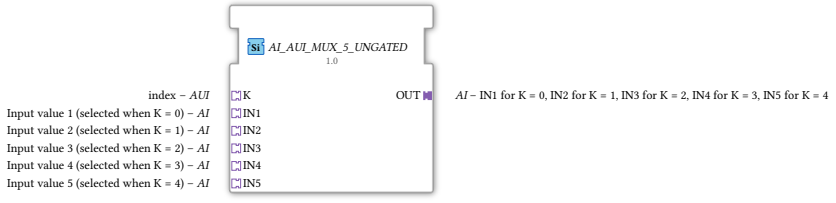
Application Scenarios

- Choosing between up to 5 16-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AI_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AI_AUI_MUX_5` carries the multiplexer logic of the `AI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AI_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AI_AUI_MUX_5_UNGATED is the adapter-based variant of the generic multiplexer for data type INT. Unlike AI_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AI_AUI_MUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AI adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AI adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN5:

1. The current value of K.D1 determines which of the 5 input adapters (IN1 … IN5) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AI_AUI_MUX) – shared across all port counts of this block family (AI_AUI_MUX_2 … AI_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN5) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

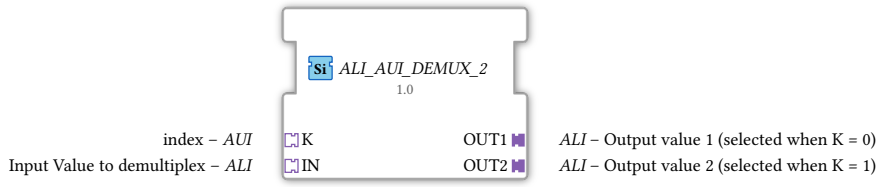
- Choosing between up to 5 16-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AI_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.



Conclusion

`AI_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALI_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`ALI_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `LINT`. Unlike `ALI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the 64-bit signed integer to forward, routed to exactly one of the outputs (ALI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (ALI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_DEMUX`) – shared across all port counts of this block family (ALI_AUI_DEMUX_2 … ALI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

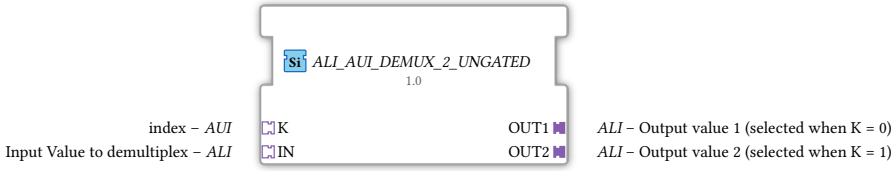
Application Scenarios

- Distributing a 64-bit signed integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ALI_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALI_AUI_DEMUX_2` carries the demultiplexer logic of the `ALI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ALI_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `LINT`. Unlike `ALI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit signed integer to forward, routed to exactly one of the outputs (ALI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (ALI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_DEMUX`) – shared across all port counts of this block family (ALI_AUI_DEMUX_2_UNGATED … ALI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit signed integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ALI_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALI_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `ALI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_DEMUX_3

• – ○ • – ○ • – ○ •

Introduction

`ALI_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `LINT`. Unlike `ALI_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN** (Socket): input adapter carrying the 64-bit signed integer to forward, routed to exactly one of the outputs (ALI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (ALI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (ALI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_DEMUX`) – shared across all port counts of this block family (ALI_AUI_DEMUX_2 … ALI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

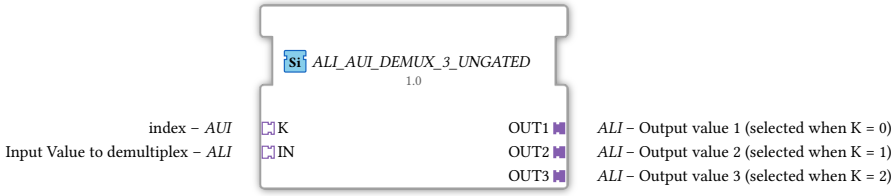
Application Scenarios

- Distributing a 64-bit signed integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALI_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ALI_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALI_AUI_DEMUX_3` carries the demultiplexer logic of the `ALI_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_DEMUX_3_UNGATED

i UNGATED variant: This block is the ungated version of ALI_AUI_DEMUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

ALI_AUI_DEMUX_3_UNGATED is the adapter-based variant of the generic demultiplexer for data type LINT. Unlike ALI_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ALI_AUI_DEMUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 64-bit signed integer to forward, routed to exactly one of the outputs (ALI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (ALI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (ALI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 3 output adapters (OUT1 … OUT3) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_ALI_AUI_DEMUX) – shared across all port counts of this block family (ALI_AUI_DEMUX_2 … ALI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

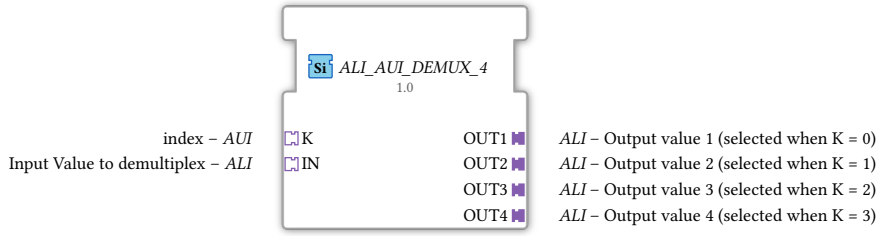
- **Any event** (selector adapter K or IN) ⟶ determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit signed integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with ALI_DEMUX_3 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **ALI_AUI_DEMUX_3**: The gated variant – updates the output only on an actual value change.

Conclusion

ALI_AUI_DEMUX_3_UNGATED carries the demultiplexer logic of the ALI_DEMUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_DEMUX_4

• – ○ • – ○ • – ○ •

Introduction

ALI_AUI_DEMUX_4 is the adapter-based variant of the generic demultiplexer for data type LINT. Unlike ALI_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit signed integer to forward, routed to exactly one of the outputs (ALI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (ALI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (ALI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (ALI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_DEMUX`) – shared across all port counts of this block family (ALI_AUI_DEMUX_2 … ALI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

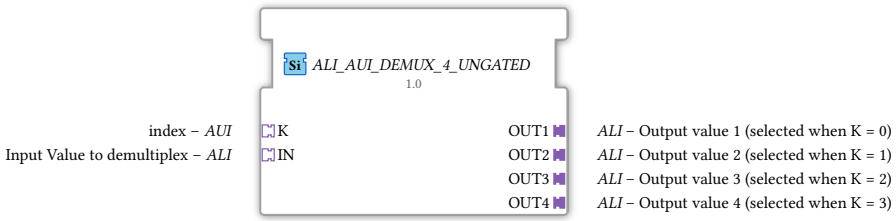
Application Scenarios

- Distributing a 64-bit signed integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ALI_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALI_AUI_DEMUX_4` carries the demultiplexer logic of the `ALI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ALI_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `LINT`. Unlike `ALI_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the 64-bit signed integer to forward, routed to exactly one of the outputs (ALI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (ALI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (ALI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (ALI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_DEMUX`) – shared across all port counts of this block family (ALI_AUI_DEMUX_2 … ALI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

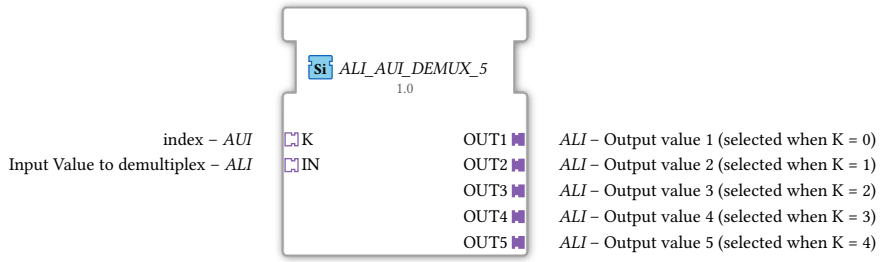
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit signed integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ALI_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALI_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `ALI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`ALI_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `LINT`. Unlike `ALI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit signed integer to forward, routed to exactly one of the outputs (ALI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (ALI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (ALI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (ALI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (ALI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_DEMUX`) – shared across all port counts of this block family (ALI_AUI_DEMUX_2 … ALI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

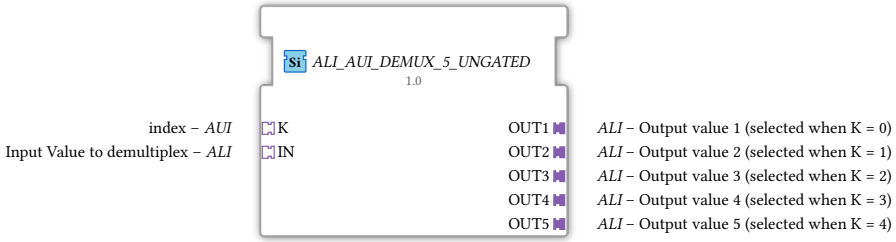
Application Scenarios

- Distributing a 64-bit signed integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ALI_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALI_AUI_DEMUX_5` carries the demultiplexer logic of the `ALI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_AUI_DEMUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ALI_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `LINT`. Unlike `ALI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K

data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ALI_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 64-bit signed integer to forward, routed to exactly one of the outputs (ALI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (ALI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (ALI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (ALI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (ALI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 5 output adapters (OUT1 … OUT5) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_ALI_AUI_DEMUX) – shared across all port counts of this block family (ALI_AUI_DEMUX_2 … ALI_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

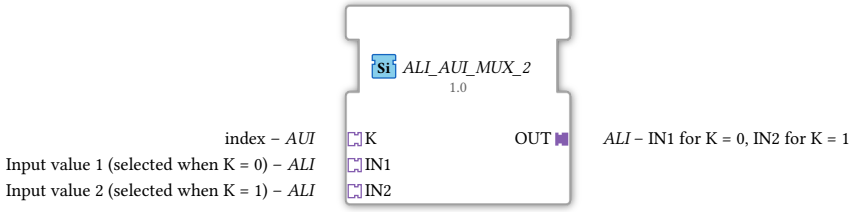
- **Any event** (selector adapter K or IN) ⟶ determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit signed integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ALI_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALI_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `ALI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`ALI_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `LINT`. Unlike `ALI_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (ALI adapter type).

- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (ALI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_MUX`) – shared across all port counts of this block family (ALI_AUI_MUX_2 … ALI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

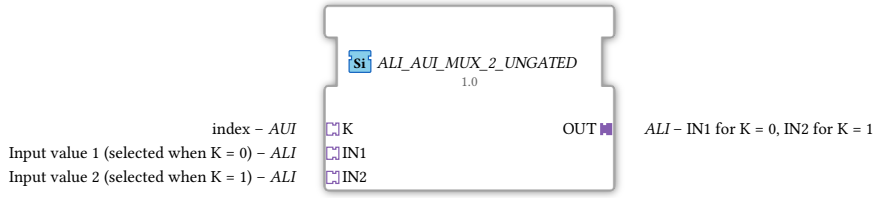
Application Scenarios

- Choosing between up to 2 64-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`ALI_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALI_AUI_MUX_2` carries the multiplexer logic of the `ALI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_AUI_MUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ALI_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `LINT`. This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_MUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (ALI adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (ALI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_MUX`) – shared across all port counts of this block family (ALI_AUI_MUX_2_UNGATED … ALI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

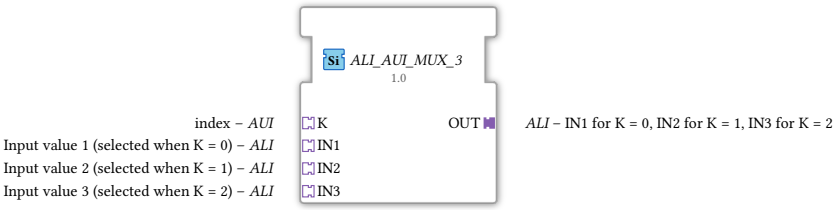
- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 64-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`ALI_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALI_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `ALI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`ALI_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `LINT`. Unlike `ALI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (ALI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (ALI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (ALI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_MUX`) – shared across all port counts of this block family (ALI_AUI_MUX_2 … ALI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

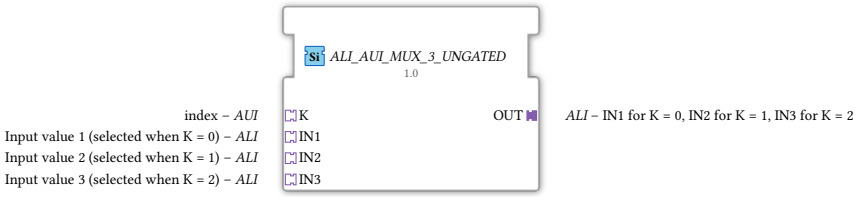
- Choosing between up to 3 64-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`ALI_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.



Conclusion

`ALI_AUI_MUX_3` carries the multiplexer logic of the `ALI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_AUI_MUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change

(e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ALI_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `LINT`. Unlike `ALI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (ALI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (ALI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (ALI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_MUX`) – shared across all port counts of this block family (ALI_AUI_MUX_2 … ALI_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 64-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`ALI_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALI_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `ALI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`ALI_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `LINT`. Unlike `ALI_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (ALI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (ALI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (ALI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (ALI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_MUX`) – shared across all port counts of this block family (ALI_AUI_MUX_2 … ALI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 64-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`ALI_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

ALI_AUI_MUX_4 carries the multiplexer logic of the ALI_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of ALI_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

ALI_AUI_MUX_4_UNGATED is the adapter-based variant of the generic multiplexer for data type LINT. Unlike ALI_MUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ALI_AUI_MUX_4_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 4, passed through to OUT when the index is K = 0 (ALI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to OUT when the index is K = 1 (ALI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to OUT when the index is K = 2 (ALI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to OUT when the index is K = 3 (ALI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN4:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_MUX`) – shared across all port counts of this block family (ALI_AUI_MUX_2 … ALI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

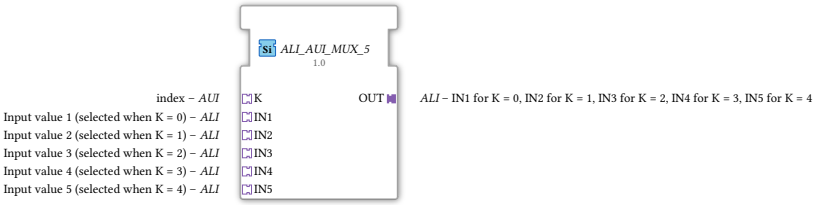
- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 64-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`ALI_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALI_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `ALI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`ALI_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `LINT`. Unlike `ALI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (ALI adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (ALI adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (ALI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (ALI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (ALI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_MUX`) – shared across all port counts of this block family (ALI_AUI_MUX_2 … ALI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

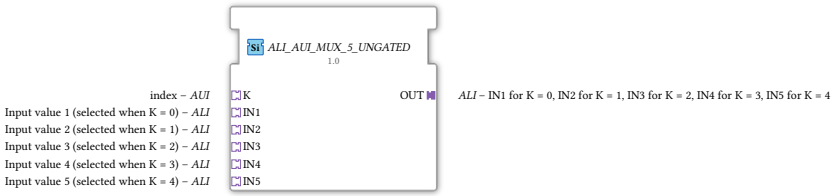
Application Scenarios

- Choosing between up to 5 64-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- **`ALI_AUI_MUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALI_AUI_MUX_5` carries the multiplexer logic of the `ALI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALI_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`ALI_AUI_MUX_5_UNGATED` is the adapter-based variant of the generic multiplexer for data type `LINT`. Unlike `ALI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALI_AUI_MUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (ALI adapter type).

- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (ALI adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (ALI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (ALI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (ALI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALI_AUI_MUX`) – shared across all port counts of this block family (ALI_AUI_MUX_2 … ALI_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

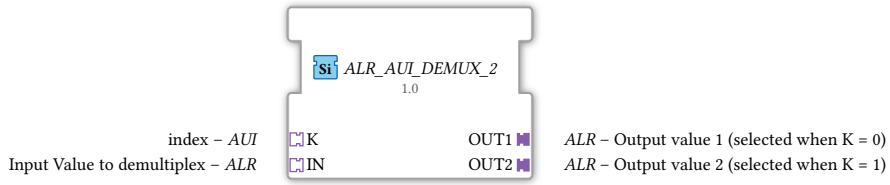
- Choosing between up to 5 64-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`ALI_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.



Conclusion

`ALI_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `ALI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALR_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`ALR_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `LREAL`. Unlike `ALR_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit floating-point value to forward, routed to exactly one of the outputs (ALR adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (ALR adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_DEMUX`) – shared across all port counts of this block family (ALR_AUI_DEMUX_2 … ALR_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

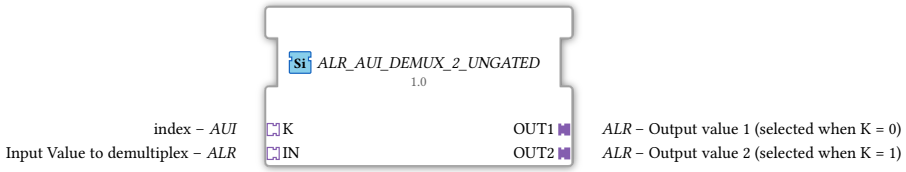
Application Scenarios

- Distributing a 64-bit floating-point value to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALR_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ALR_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALR_AUI_DEMUX_2` carries the demultiplexer logic of the `ALR_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ALR_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `LREAL`. Unlike `ALR_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit floating-point value to forward, routed to exactly one of the outputs (ALR adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (ALR adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_DEMUX`) – shared across all port counts of this block family (ALR_AUI_DEMUX_2_UNGATED … ALR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

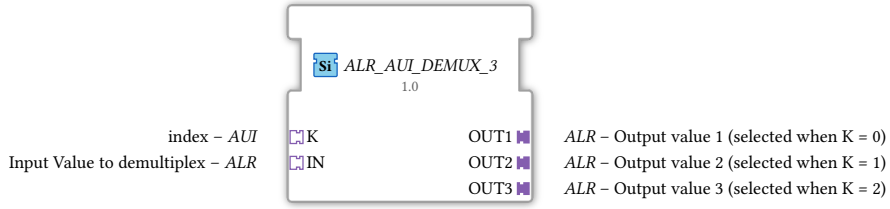
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit floating-point value to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with ALR_DEMUX_2 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **ALR_AUI_DEMUX_2**: The gated variant – updates the output only on an actual value change.

Conclusion

ALR_AUI_DEMUX_2_UNGATED carries the demultiplexer logic of the ALR_DEMUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

ALR_AUI_DEMUX_3 is the adapter-based variant of the generic demultiplexer for data type LREAL. Unlike ALR_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ALR_AUI_DEMUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 64-bit floating-point value to forward, routed to exactly one of the outputs (ALR adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (ALR adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (ALR adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_DEMUX`) – shared across all port counts of this block family (ALR_AUI_DEMUX_2 … ALR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

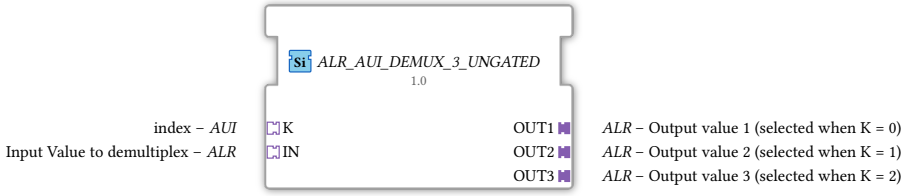
Application Scenarios

- Distributing a 64-bit floating-point value to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALR_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ALR_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALR_AUI_DEMUX_3` carries the demultiplexer logic of the `ALR_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

ALR_AUI_DEMUX_3_UNGATED is the adapter-based variant of the generic demultiplexer for data type LREAL. Unlike ALR_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ALR_AUI_DEMUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 64-bit floating-point value to forward, routed to exactly one of the outputs (ALR adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (ALR adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (ALR adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 3 output adapters (OUT1 … OUT3) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_ALR_AUI_DEMUX) – shared across all port counts of this block family (ALR_AUI_DEMUX_2 … ALR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

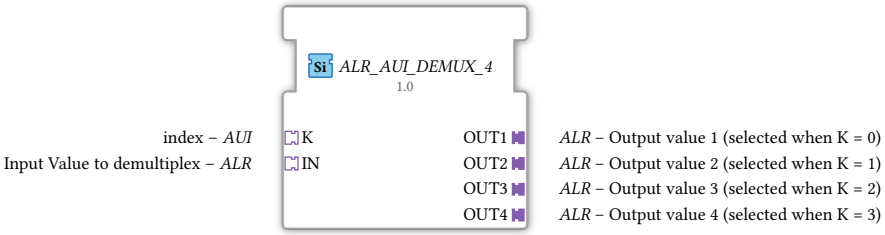
- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit floating-point value to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALR_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ALR_AUI_DEMUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALR_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `ALR_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`ALR_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `LREAL`. Unlike `ALR_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the 64-bit floating-point value to forward, routed to exactly one of the outputs (ALR adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (ALR adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (ALR adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (ALR adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_DEMUX`) – shared across all port counts of this block family (ALR_AUI_DEMUX_2 … ALR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

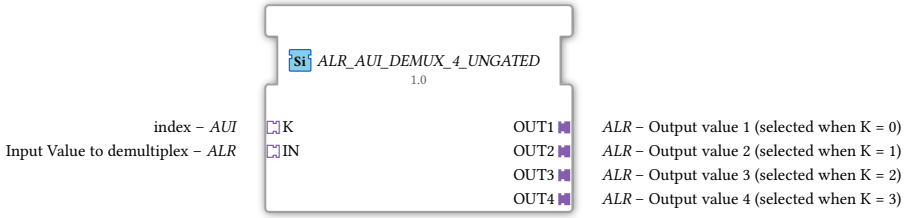
- Distributing a 64-bit floating-point value to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALR_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ALR_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.



Conclusion

`ALR_AUI_DEMUX_4` carries the demultiplexer logic of the `ALR_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change

(e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`ALR_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `LREAL`. - **`ALR_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALR_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `ALR_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`ALR_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `LREAL`. Unlike `ALR_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit floating-point value to forward, routed to exactly one of the outputs (ALR adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (ALR adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (ALR adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (ALR adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (ALR adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_DEMUX`) – shared across all port counts of this block family (ALR_AUI_DEMUX_2 … ALR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

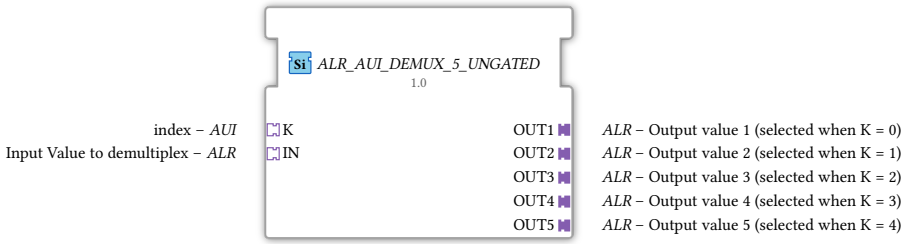
- Distributing a 64-bit floating-point value to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)

- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with ALR_DEMUX_5 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **ALR_AUI_DEMUX_5_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

ALR_AUI_DEMUX_5 carries the demultiplexer logic of the ALR_DEMUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of ALR_AUI_DEMUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

ALR_AUI_DEMUX_5_UNGATED is the adapter-based variant of the generic demultiplexer for data type LREAL. Unlike ALR_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ALR_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN** (Socket): input adapter carrying the 64-bit floating-point value to forward, routed to exactly one of the outputs (ALR adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (ALR adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (ALR adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (ALR adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (ALR adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_DEMUX`) – shared across all port counts of this block family (ALR_AUI_DEMUX_2 … ALR_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

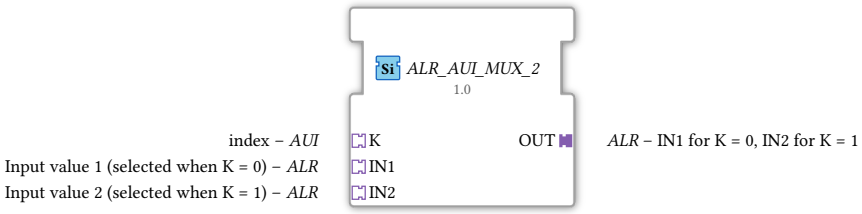
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit floating-point value to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ALR_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ALR_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALR_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `ALR_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`ALR_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `LREAL`. Unlike `ALR_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (ALR adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (ALR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_MUX`) – shared across all port counts of this block family (ALR_AUI_MUX_2 … ALR_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

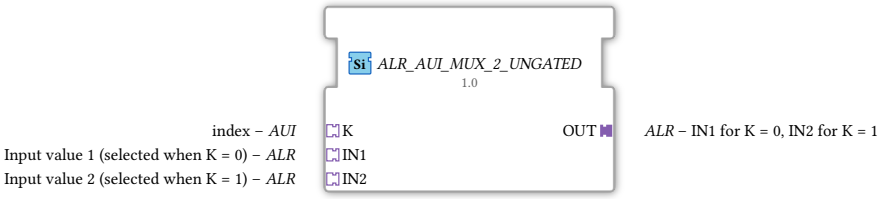
Application Scenarios

- Choosing between up to 2 64-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALR_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`ALR_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALR_AUI_MUX_2` carries the multiplexer logic of the `ALR_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_AUI_MUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`ALR_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `LREAL`. Unlike `ALR_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_MUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (ALR adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (ALR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_MUX`) – shared across all port counts of this block family (ALR_AUI_MUX_2_UNGATED … ALR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

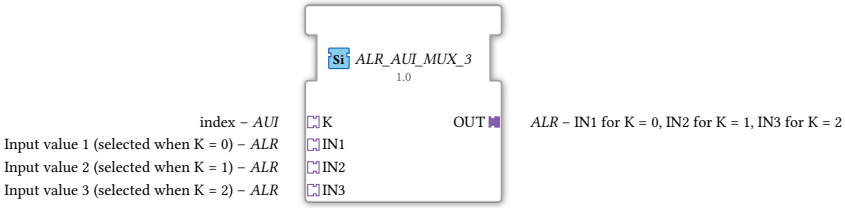
- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 64-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALR_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`ALR_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALR_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `ALR_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

`ALR_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `LREAL`. Unlike `ALR_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (ALR adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (ALR adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (ALR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_MUX`) – shared across all port counts of this block family (ALR_AUI_MUX_2 … ALR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 64-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALR_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`ALR_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALR_AUI_MUX_3` carries the multiplexer logic of the `ALR_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_MUX_3_UNGATED

i UNGATED variant: This block is the ungated version of `ALR_AUI_MUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

ALR_AUI_MUX_3_UNGATED is the adapter-based variant of the generic multiplexer for data type LREAL. Unlike ALR_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ALR_AUI_MUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (ALR adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (ALR adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (ALR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_ALR_AUI_MUX) – shared across all port counts of this block family (ALR_AUI_MUX_2 … ALR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

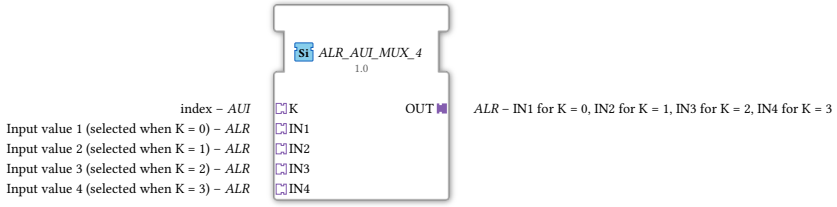
- **Any event** (selector adapter K or IN1…IN3) → read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 64-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALR_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`ALR_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALR_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `ALR_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`ALR_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `LREAL`. Unlike `ALR_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (ALR adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (ALR adapter type).

- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (ALR adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (ALR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_MUX`) – shared across all port counts of this block family (ALR_AUI_MUX_2 … ALR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 64-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALR_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`ALR_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ALR_AUI_MUX_4` carries the multiplexer logic of the `ALR_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of ALR_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• — ○ • — ○ • — ○ •

Introduction

`ALR_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `LREAL`. Unlike `ALR_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (ALR adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (ALR adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (ALR adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (ALR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see “Change Detection” below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn’t changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_MUX`) – shared across all port counts of this block family (ALR_AUI_MUX_2 … ALR_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

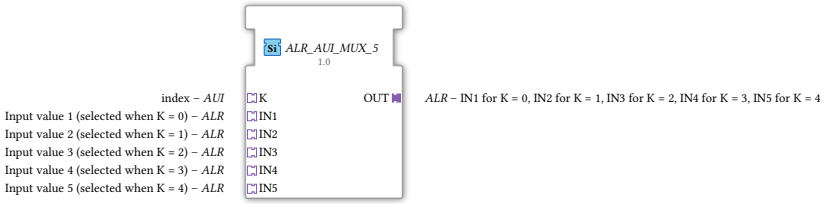
- **Any event** (selector adapter `K` or `IN1`...`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 64-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALR_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`ALR_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ALR_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `ALR_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`ALR_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `LREAL`. Unlike `ALR_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ALR_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (ALR adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (ALR adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (ALR adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (ALR adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (ALR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_MUX`) – shared across all port counts of this block family (ALR_AUI_MUX_2 … ALR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

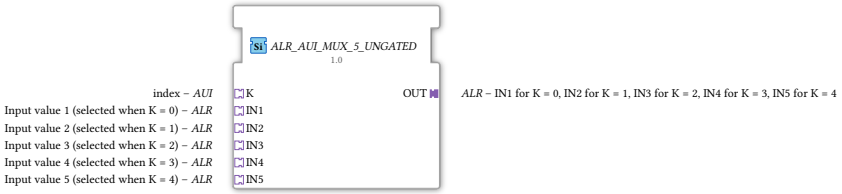
Application Scenarios

- Choosing between up to 5 64-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALR_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `ALR_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

ALR_AUI_MUX_5 carries the multiplexer logic of the ALR_MUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ALR_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of ALR_AUI_MUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

ALR_AUI_MUX_5_UNGATED is the adapter-based variant of the generic multiplexer for data type LREAL. Unlike ALR_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ALR_AUI_MUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (ALR adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (ALR adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (ALR adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (ALR adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (ALR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ALR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` ... `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ALR_AUI_MUX`) – shared across all port counts of this block family (ALR_AUI_MUX_2 ... ALR_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

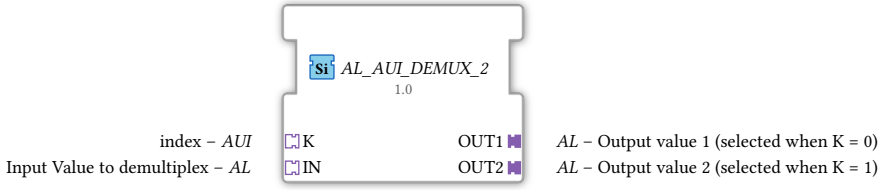
- Choosing between up to 5 64-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ALR_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- `ALR_AUI_MUX_5`: The gated variant – updates the output only on an actual value change.



Conclusion

`ALR_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `ALR_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AL_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

AL_AUI_DEMUX_2 is the adapter-based variant of the generic demultiplexer for data type LWORD. Unlike AL_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AL_AUI_DEMUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 64-bit bit pattern to forward, routed to exactly one of the outputs (AL adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AL adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 2 output adapters (OUT1 … OUT2) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AL_AUI_DEMUX) – shared across all port counts of this block family (AL_AUI_DEMUX_2 … AL_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

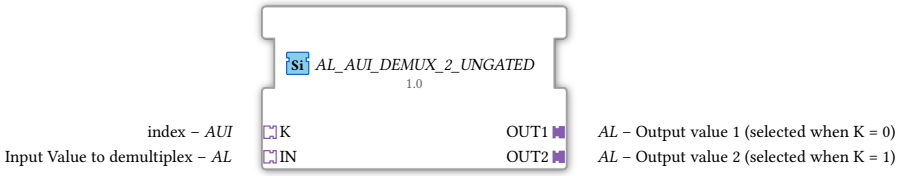
- Distributing a 64-bit bit pattern to up to 2 downstream consumers, selected via an adapter-carried index

- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AL_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AL_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AL_AUI_DEMUX_2` carries the demultiplexer logic of the `AL_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AL_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AL_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `LWORD`. Unlike `AL_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN** (Socket): input adapter carrying the 64-bit bit pattern to forward, routed to exactly one of the outputs (AL adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AL adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_DEMUX`) – shared across all port counts of this block family (AL_AUI_DEMUX_2_UNGATED … AL_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

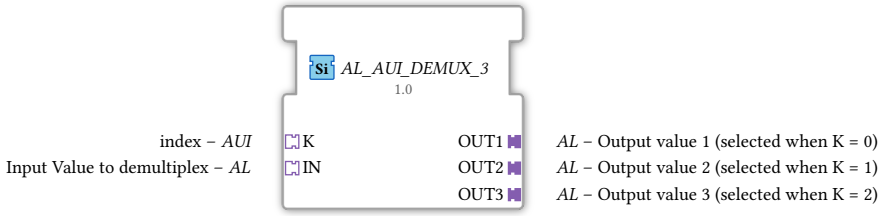
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit bit pattern to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AL_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

Conclusion

`AL_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AL_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AL_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `LWORD`. Unlike `AL_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit bit pattern to forward, routed to exactly one of the outputs (AL adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AL adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AL adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_DEMUX`) – shared across all port counts of this block family (AL_AUI_DEMUX_2 … AL_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

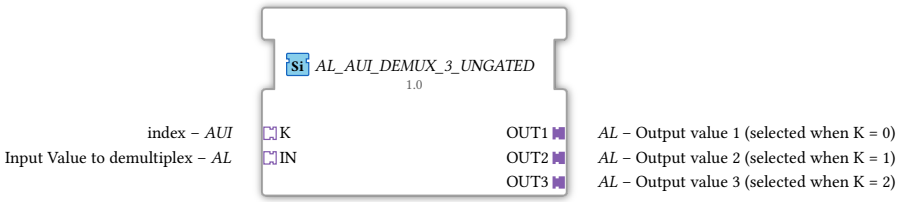
Application Scenarios

- Distributing a 64-bit bit pattern to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AL_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AL_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AL_AUI_DEMUX_3` carries the demultiplexer logic of the `AL_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

`AL_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AL_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AL_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `LWORD`. Unlike `AL_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit bit pattern to forward, routed to exactly one of the outputs (AL adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AL adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AL adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AL adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_DEMUX`) – shared across all port counts of this block family (AL_AUI_DEMUX_2 … AL_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

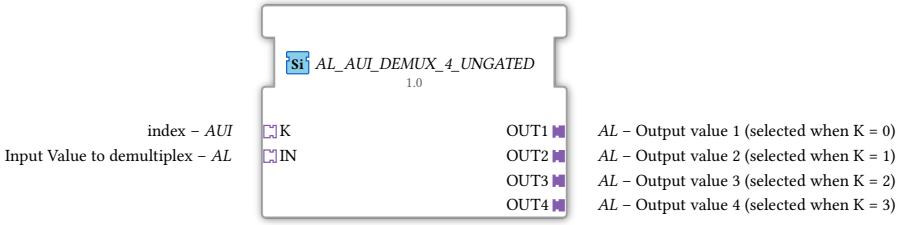
Application Scenarios

- Distributing a 64-bit bit pattern to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AL_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AL_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AL_AUI_DEMUX_4` carries the demultiplexer logic of the `AL_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AL_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AL_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `LWORD`. Unlike `AL_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit bit pattern to forward, routed to exactly one of the outputs (AL adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AL adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AL adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AL adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_DEMUX`) – shared across all port counts of this block family (AL_AUI_DEMUX_2 … AL_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

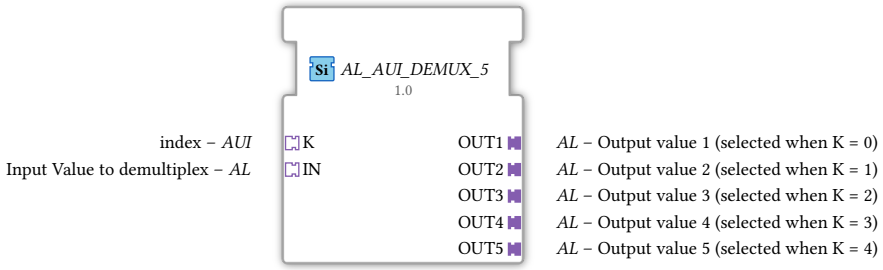
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit bit pattern to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AL_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AL_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AL_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AL_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AL_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `LWORD`. Unlike `AL_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit bit pattern to forward, routed to exactly one of the outputs (AL adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AL adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AL adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AL adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AL adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_DEMUX`) – shared across all port counts of this block family (AL_AUI_DEMUX_2 … AL_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

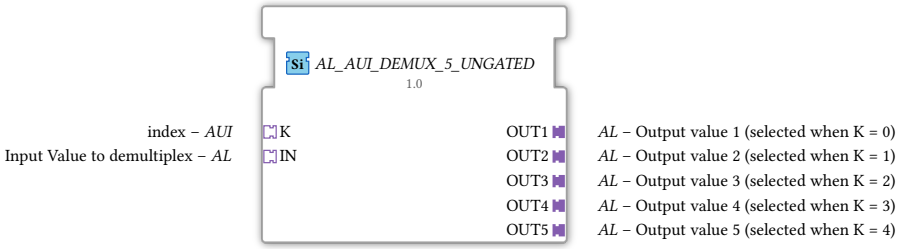
Application Scenarios

- Distributing a 64-bit bit pattern to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AL_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AL_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AL_AUI_DEMUX_5 carries the demultiplexer logic of the AL_DEMUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AL_AUI_DEMUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AL_AUI_DEMUX_5_UNGATED is the adapter-based variant of the generic demultiplexer for data type LWORD. Unlike AL_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AL_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter’s own E1/D1 event.
- **IN** (Socket): input adapter carrying the 64-bit bit pattern to forward, routed to exactly one of the outputs (AL adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AL adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AL adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AL adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AL adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_DEMUX`) – shared across all port counts of this block family (AL_AUI_DEMUX_2 … AL_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

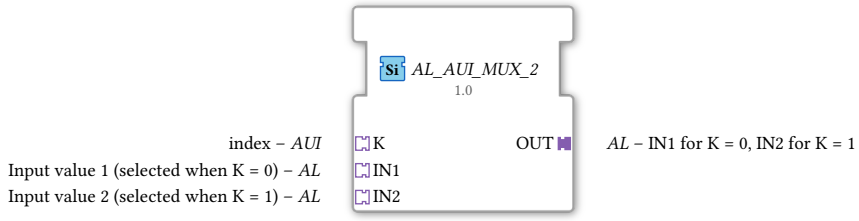
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit bit pattern to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖ Comparison with Similar Blocks

Compare with `AL_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AL_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AL_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AL_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AL_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `LWORD`. Unlike `AL_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index

be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AL_AUI_MUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 2, passed through to OUT when the index is K = 0 (AL adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to OUT when the index is K = 1 (AL adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN2:

1. The current value of K.D1 determines which of the 2 input adapters (IN1 … IN2) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AL_AUI_MUX) – shared across all port counts of this block family (AL_AUI_MUX_2 … AL_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN2) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

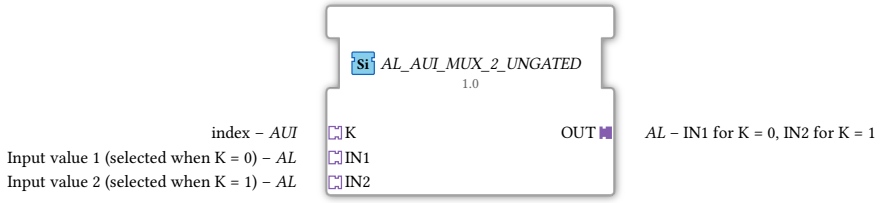
Application Scenarios

- Choosing between up to 2 64-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AL_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AL_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AL_AUI_MUX_2` carries the multiplexer logic of the `AL_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AL_AUI_MUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AL_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `LWORD`. Unlike `AL_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_MUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.

- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AL adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AL adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` ... `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_MUX`) – shared across all port counts of this block family (AL_AUI_MUX_2_UNGATED ... AL_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 64-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AL_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AL_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AL_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AL_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

AL_AUI_MUX_3 is the adapter-based variant of the generic multiplexer for data type LWORD. Unlike AL_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AL_AUI_MUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (AL adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (AL adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (AL adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AL_AUI_MUX) – shared across all port counts of this block family (AL_AUI_MUX_2 … AL_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN3) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

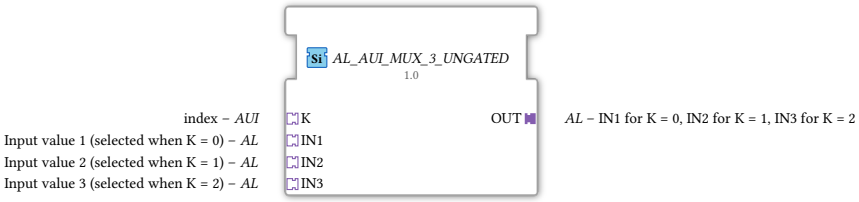
- Choosing between up to 3 64-bit bit pattern sources through a centrally managed adapter index

- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AL_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **`AL_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AL_AUI_MUX_3` carries the multiplexer logic of the `AL_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AL_AUI_MUX_3. • – ○ • – ○ • – ○ •

Introduction

`AL_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `LWORD`. Unlike `AL_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AL adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AL adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AL adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_MUX`) – shared across all port counts of this block family (AL_AUI_MUX_2 … AL_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

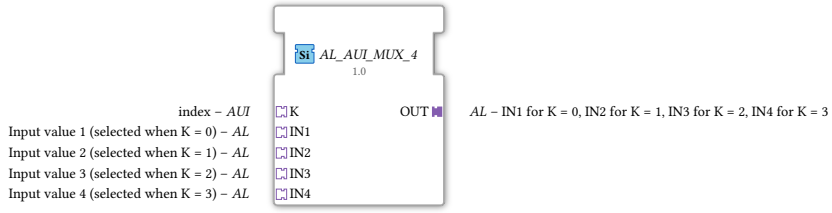
- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 64-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AL_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AL_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AL_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AL_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_MUX_4

• — ○ • — ○ • — ○ •

Introduction

`AL_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `LWORD`. Unlike `AL_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AL adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AL adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AL adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AL adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_MUX`) – shared across all port counts of this block family (AL_AUI_MUX_2 … AL_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

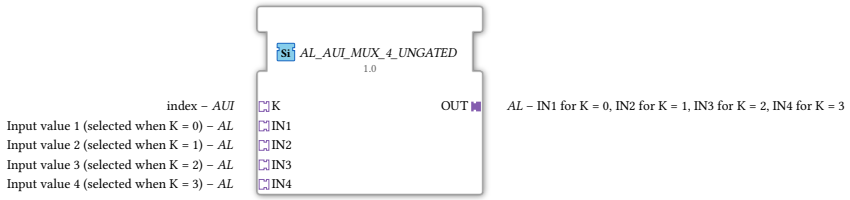
Application Scenarios

- Choosing between up to 4 64-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AL_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AL_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AL_AUI_MUX_4` carries the multiplexer logic of the `AL_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AL_AUI_MUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AL_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `LWORD`. Unlike `AL_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AL adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AL adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AL adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AL adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_MUX`) – shared across all port counts of this block family (AL_AUI_MUX_2 … AL_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

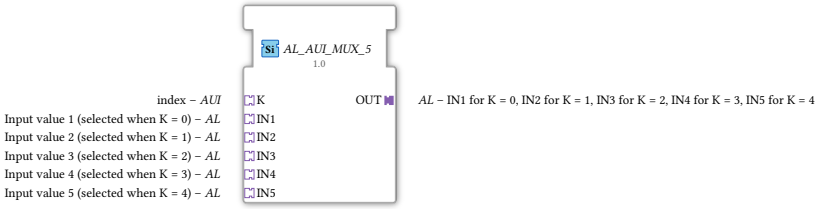
- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 64-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AL_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AL_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AL_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `AL_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`AL_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `LWORD`. Unlike `AL_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AL_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AL adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AL adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AL adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AL adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AL adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AL adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AL_AUI_MUX`) – shared across all port counts of this block family (AL_AUI_MUX_2 … AL_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

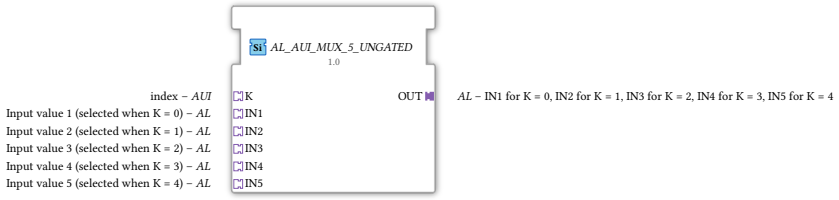
Application Scenarios

- Choosing between up to 5 64-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AL_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AL_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AL_AUI_MUX_5` carries the multiplexer logic of the `AL_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AL_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AL_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Compare with `AL_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

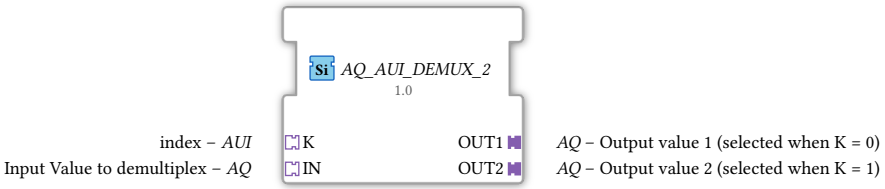
No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- `AL_AUI_MUX_5`: The gated variant – updates the output only on an actual value change.



Conclusion

`AL_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AL_MUX_5` family over to a purely adapter-based index supply. This makes the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AQ_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AQ_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AQ adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AQ adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_DEMUX`) – shared across all port counts of this block family (AQ_AUI_DEMUX_2 … AQ_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

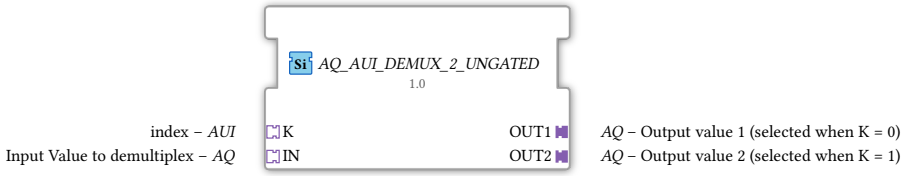
Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AQ_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AQ_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AQ_AUI_DEMUX_2` carries the demultiplexer logic of the `AQ_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AQ_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AQ adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AQ adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.

2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_DEMUX`) – shared across all port counts of this block family (AQ_AUI_DEMUX_2_UNGATED … AQ_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

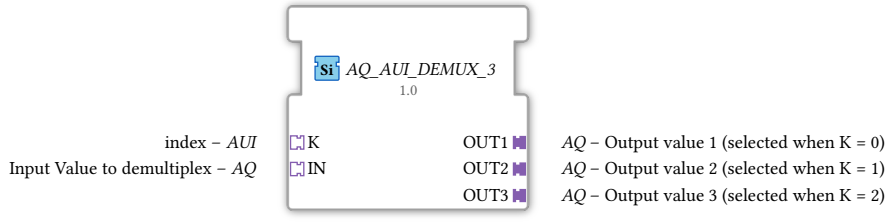
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AQ_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AQ_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AQ_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AQ_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AQ_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index

be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AQ_AUI_DEMUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AQ adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AQ adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AQ adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 3 output adapters (OUT1 … OUT3) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AQ_AUI_DEMUX) – shared across all port counts of this block family (AQ_AUI_DEMUX_2 … AQ_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The QUARTER value is technically transferred as a BYTE with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

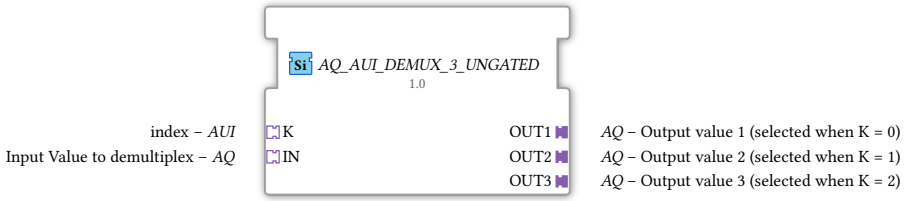
- Distributing a byte value (8-bit bit pattern) to up to 3 downstream consumers, selected via an adapter-carried index

- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AQ_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AQ_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AQ_AUI_DEMUX_3` carries the demultiplexer logic of the `AQ_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_DEMUX_3_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AQ_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_DEMUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AQ adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AQ adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AQ adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_DEMUX`) – shared across all port counts of this block family (AQ_AUI_DEMUX_2 … AQ_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

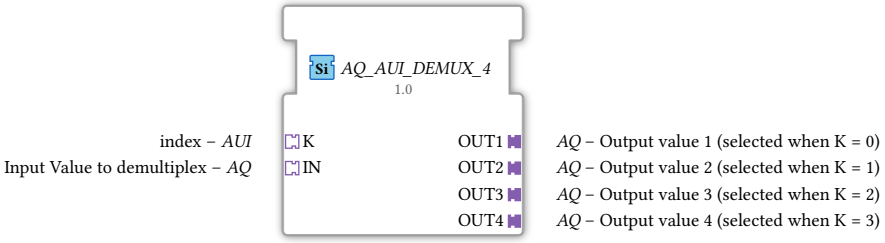
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AQ_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AQ_AUI_DEMUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AQ_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AQ_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AQ_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AQ adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AQ adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AQ adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AQ adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.

- Generic implementation (`GEN_AQ_AUI_DEMUX`) – shared across all port counts of this block family (AQ_AUI_DEMUX_2 … AQ_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

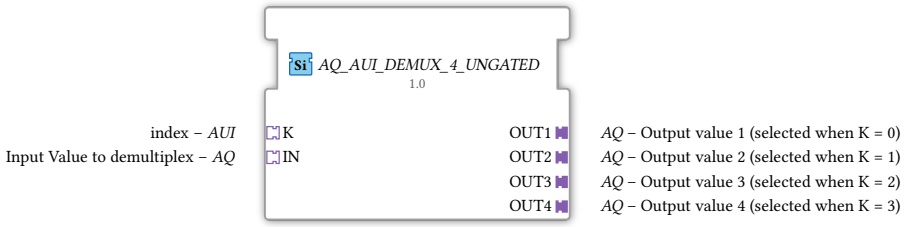
Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AQ_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AQ_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AQ_AUI_DEMUX_4` carries the demultiplexer logic of the `AQ_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AQ_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the

index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AQ_AUI_DEMUX_4_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AQ adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AQ adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AQ adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AQ adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 4 output adapters (OUT1 … OUT4) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AQ_AUI_DEMUX) – shared across all port counts of this block family (AQ_AUI_DEMUX_2 … AQ_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The QUARTER value is technically transferred as a BYTE with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

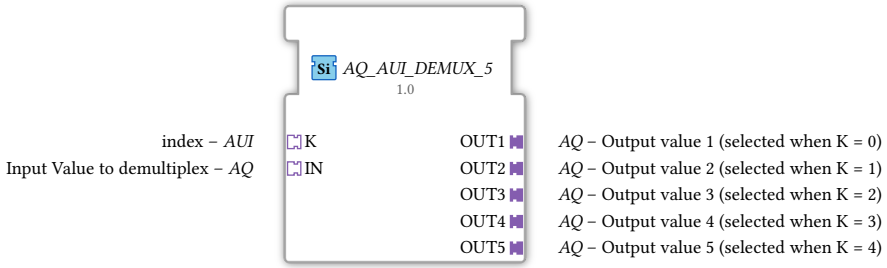
- **Any event** (selector adapter K or IN) ⟶ determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AQ_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AQ_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AQ_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AQ_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `BYTE`. Unlike `AQ_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AQ adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AQ adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AQ adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AQ adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AQ adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_DEMUX`) – shared across all port counts of this block family (AQ_AUI_DEMUX_2 … AQ_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

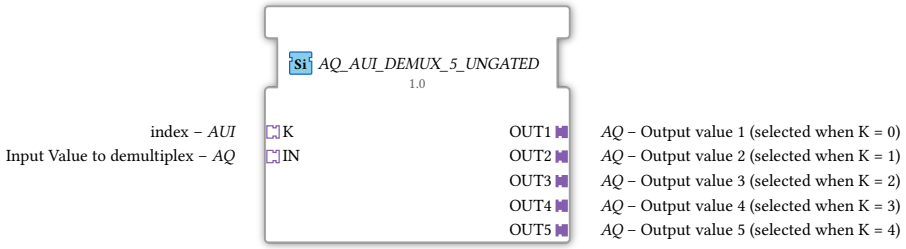
Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AQ_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AQ_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AQ_AUI_DEMUX_5` carries the demultiplexer logic of the `AQ_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_DEMUX_5_UNGATED

i UNGATED variant: This block is the ungated version of AQ_AUI_DEMUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AQ_AUI_DEMUX_5_UNGATED is the adapter-based variant of the generic demultiplexer for data type BYTE. Unlike AQ_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AQ_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the byte value (8-bit bit pattern) to forward, routed to exactly one of the outputs (AQ adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AQ adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AQ adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AQ adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AQ adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 5 output adapters (OUT1 … OUT5) is currently selected.

2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_DEMUX`) – shared across all port counts of this block family (AQ_AUI_DEMUX_2 … AQ_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

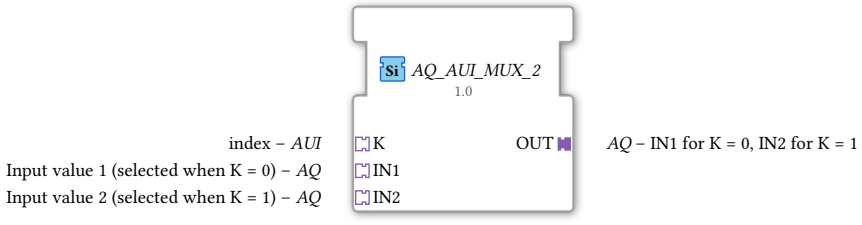
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a byte value (8-bit bit pattern) to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AQ_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AQ_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AQ_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AQ_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AQ_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AQ adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AQ adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_MUX`) – shared across all port counts of this block family (AQ_AUI_MUX_2 … AQ_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

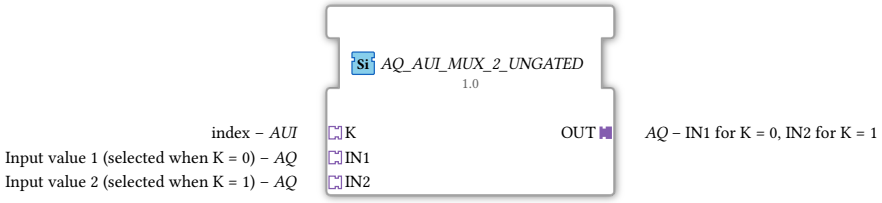
Application Scenarios

- Choosing between up to 2 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AQ_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AQ_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AQ_AUI_MUX_2` carries the multiplexer logic of the `AQ_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_AUI_MUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AQ_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_MUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.

- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AQ adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AQ adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_MUX`) – shared across all port counts of this block family (AQ_AUI_MUX_2_UNGATED … AQ_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AQ_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AQ_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AQ_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AQ_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AQ_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AQ adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AQ adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AQ adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_MUX`) – shared across all port counts of this block family (AQ_AUI_MUX_2 … AQ_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

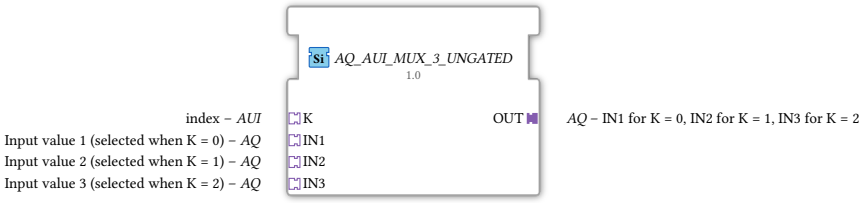
Application Scenarios

- Choosing between up to 3 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AQ_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **`AQ_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AQ_AUI_MUX_3` carries the multiplexer logic of the `AQ_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AQ_AUI_MUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AQ_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AQ_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AQ adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AQ adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AQ adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_MUX`) – shared across all port counts of this block family (AQ_AUI_MUX_2 … AQ_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AQ_MUX_3 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **AQ_AUI_MUX_3**: The gated variant – updates the output only on an actual value change.

Conclusion

AQ_AUI_MUX_3_UNGATED carries the multiplexer logic of the AQ_MUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

AQ_AUI_MUX_4 is the adapter-based variant of the generic multiplexer for data type BYTE. Unlike AQ_MUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AQ_AUI_MUX_4 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 4, passed through to OUT when the index is K = 0 (AQ adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to OUT when the index is K = 1 (AQ adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to OUT when the index is K = 2 (AQ adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to OUT when the index is K = 3 (AQ adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1...IN4:

1. The current value of K.D1 determines which of the 4 input adapters (IN1 … IN4) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AQ_AUI_MUX) – shared across all port counts of this block family (AQ_AUI_MUX_2 … AQ_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The QUARTER value is technically transferred as a BYTE with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN4) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

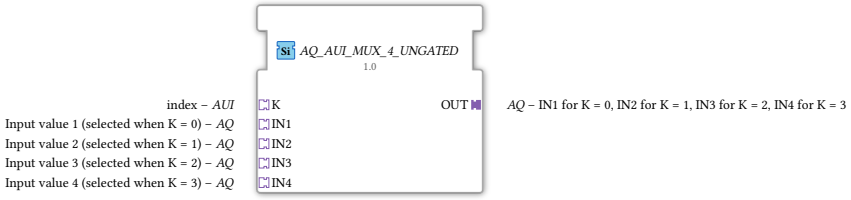
Application Scenarios

- Choosing between up to 4 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AQ_MUX_4 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **AQ_AUI_MUX_4_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AQ_AUI_MUX_4 carries the multiplexer logic of the AQ_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AQ_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AQ_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AQ_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AQ adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AQ adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AQ adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AQ adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_MUX`) – shared across all port counts of this block family (AQ_AUI_MUX_2 … AQ_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

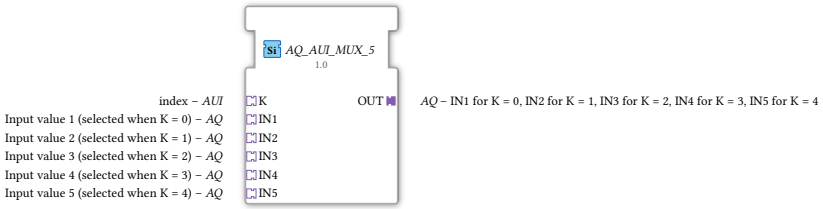
- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AQ_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AQ_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AQ_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `AQ_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`AQ_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `BYTE`. Unlike `AQ_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AQ_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AQ adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AQ adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AQ adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AQ adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AQ adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_MUX`) – shared across all port counts of this block family (AQ_AUI_MUX_2 … AQ_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

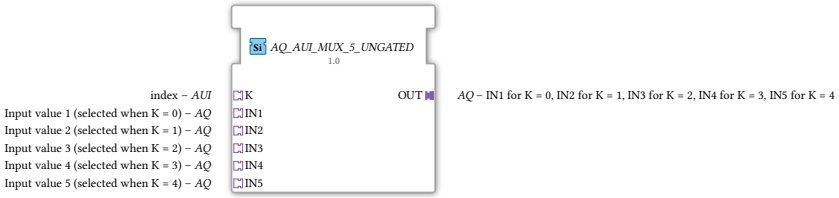
Application Scenarios

- Choosing between up to 5 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AQ_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- **`AQ_AUI_MUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AQ_AUI_MUX_5 carries the multiplexer logic of the AQ_MUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AQ_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AQ_AUI_MUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AQ_AUI_MUX_5_UNGATED is the adapter-based variant of the generic multiplexer for data type BYTE. Unlike AQ_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AQ_AUI_MUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AQ adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AQ adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AQ adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AQ adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AQ adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AQ adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` ... `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AQ_AUI_MUX`) – shared across all port counts of this block family (AQ_AUI_MUX_2 ... AQ_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- The `QUARTER` value is technically transferred as a `BYTE` with 2 significant bits; interpretation as a quadrant/quarter value happens in the calling context.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

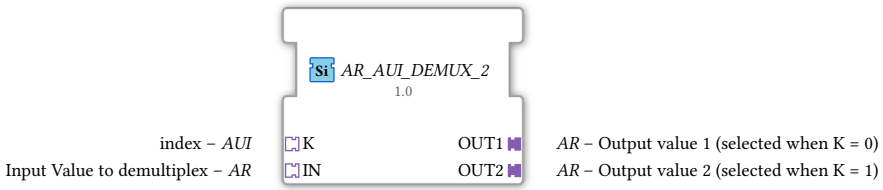
- Choosing between up to 5 byte value (8-bit bit pattern) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AQ_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- `AQ_AUI_MUX_5`: The gated variant – updates the output only on an actual value change.



Conclusion

`AQ_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AQ_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AR_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

AR_AUI_DEMUX_2 is the adapter-based variant of the generic demultiplexer for data type REAL. Unlike AR_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AR_AUI_DEMUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 32-bit floating-point value to forward, routed to exactly one of the outputs (AR adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AR adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 2 output adapters (OUT1 … OUT2) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AR_AUI_DEMUX) – shared across all port counts of this block family (AR_AUI_DEMUX_2 … AR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

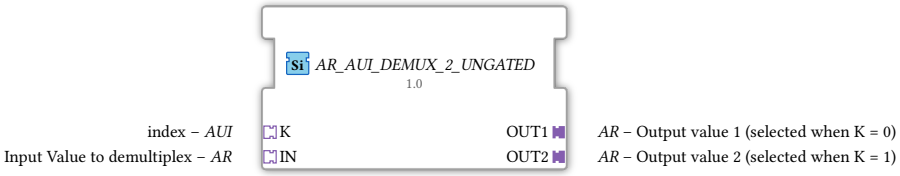
Application Scenarios

- Distributing a 32-bit floating-point value to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AR_DEMUX_2 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **AR_AUI_DEMUX_2_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AR_AUI_DEMUX_2 carries the demultiplexer logic of the AR_DEMUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AR_AUI_DEMUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AR_AUI_DEMUX_2_UNGATED is the adapter-based variant of the generic demultiplexer for data type REAL. Unlike AR_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AR_AUI_DEMUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit floating-point value to forward, routed to exactly one of the outputs (AR adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AR adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_DEMUX`) – shared across all port counts of this block family (AR_AUI_DEMUX_2_UNGATED … AR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

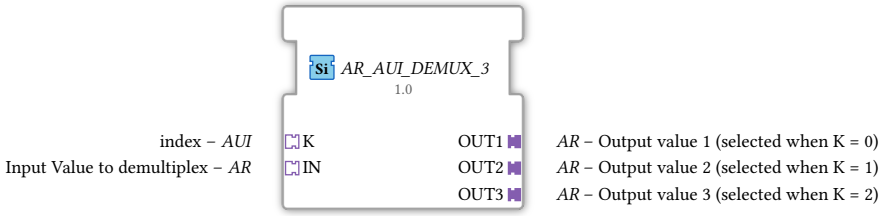
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit floating-point value to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AR_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AR_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AR_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AR_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AR_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `REAL`. Unlike `AR_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AR_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit floating-point value to forward, routed to exactly one of the outputs (AR adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AR adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AR adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_DEMUX`) – shared across all port counts of this block family (AR_AUI_DEMUX_2 … AR_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

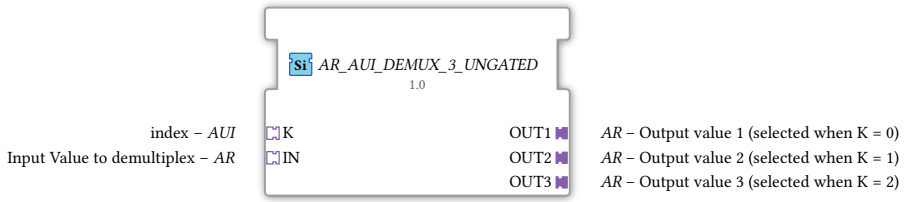
Application Scenarios

- Distributing a 32-bit floating-point value to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AR_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AR_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AR_AUI_DEMUX_3` carries the demultiplexer logic of the `AR_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AR_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AR_AUI_DEMUX_3_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `REAL`. Unlike `AR_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AR_AUI_DEMUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit floating-point value to forward, routed to exactly one of the outputs (AR adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AR adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AR adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_DEMUX`) – shared across all port counts of this block family (AR_AUI_DEMUX_2 … AR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

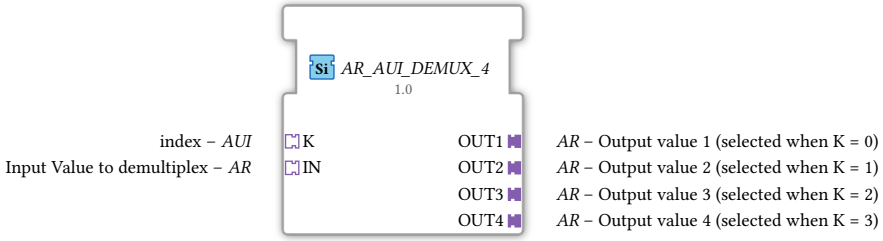
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit floating-point value to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AR_DEMUX_3 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **AR_AUI_DEMUX_3**: The gated variant – updates the output only on an actual value change.

Conclusion

AR_AUI_DEMUX_3_UNGATED carries the demultiplexer logic of the AR_DEMUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

AR_AUI_DEMUX_4 is the adapter-based variant of the generic demultiplexer for data type REAL. Unlike AR_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AR_AUI_DEMUX_4 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 32-bit floating-point value to forward, routed to exactly one of the outputs (AR adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AR adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AR adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AR adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_DEMUX`) – shared across all port counts of this block family (AR_AUI_DEMUX_2 … AR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

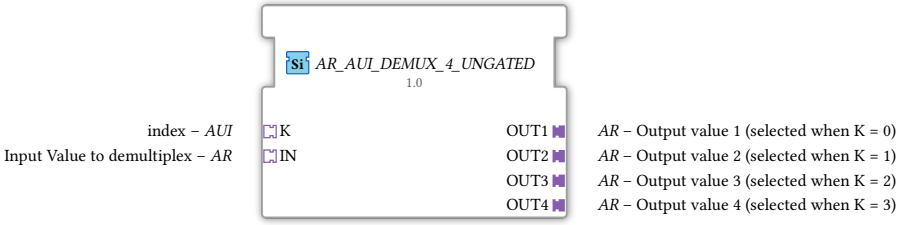
Application Scenarios

- Distributing a 32-bit floating-point value to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AR_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AR_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AR_AUI_DEMUX_4` carries the demultiplexer logic of the `AR_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_DEMUX_4_UNGATED

`AR_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AR_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AR_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `REAL`. Unlike `AR_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AR_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit floating-point value to forward, routed to exactly one of the outputs (AR adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AR adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AR adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AR adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AR adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_DEMUX`) – shared across all port counts of this block family (AR_AUI_DEMUX_2 … AR_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

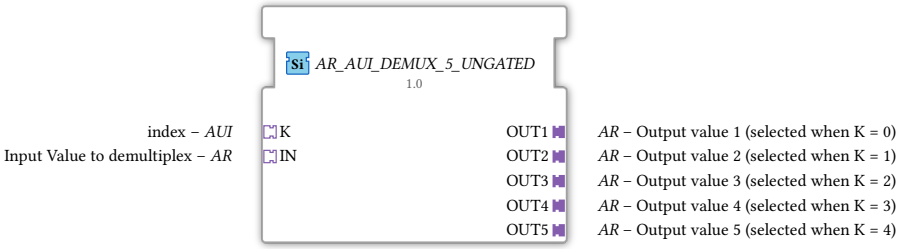
Application Scenarios

- Distributing a 32-bit floating-point value to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AR_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AR_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AR_AUI_DEMUX_5 carries the demultiplexer logic of the AR_DEMUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AR_AUI_DEMUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AR_AUI_DEMUX_5_UNGATED is the adapter-based variant of the generic demultiplexer for data type REAL. Unlike AR_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AR_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 32-bit floating-point value to forward, routed to exactly one of the outputs (AR adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AR adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AR adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AR adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AR adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_DEMUX`) – shared across all port counts of this block family (AR_AUI_DEMUX_2 … AR_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

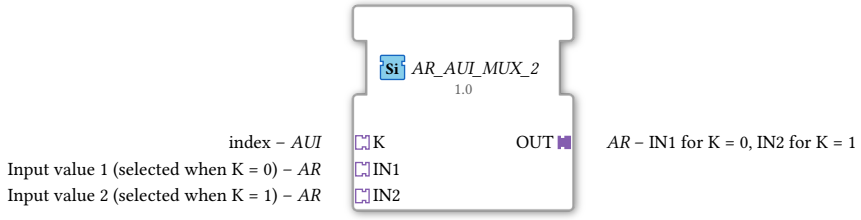
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit floating-point value to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AR_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AR_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AR_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AR_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_MUX_2

• – ○ • – ○ • – ○ •

Introduction

`AR_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `REAL`. Unlike `AR_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its

own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AR_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AR adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_MUX`) – shared across all port counts of this block family (AR_AUI_MUX_2 … AR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

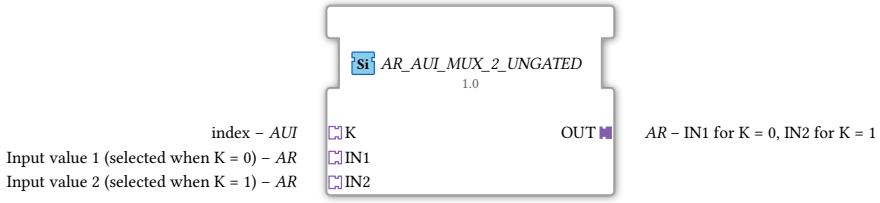
Application Scenarios

- Choosing between up to 2 32-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AR_MUX_2 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **AR_AUI_MUX_2_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AR_AUI_MUX_2 carries the multiplexer logic of the AR_MUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AR_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AR_AUI_MUX_2_UNGATED is the adapter-based variant of the generic multiplexer for data type REAL. Unlike AR_MUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AR_AUI_MUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AR adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` ... `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_MUX`) – shared across all port counts of this block family (AR_AUI_MUX_2_UNGATED ... AR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 32-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AR_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AR_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AR_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AR_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

AR_AUI_MUX_3 is the adapter-based variant of the generic multiplexer for data type REAL. Unlike AR_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AR_AUI_MUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (AR adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (AR adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (AR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AR_AUI_MUX) – shared across all port counts of this block family (AR_AUI_MUX_2 … AR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN3) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

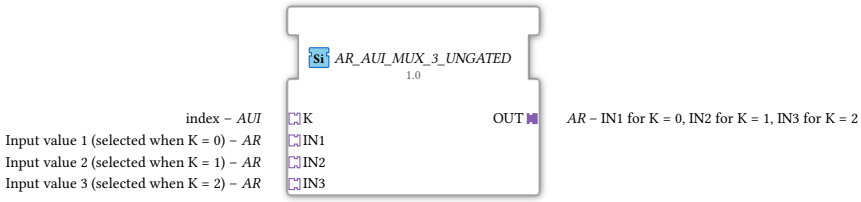
- Choosing between up to 3 32-bit floating-point value sources through a centrally managed adapter index

- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AR_MUX_3 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **AR_AUI_MUX_3_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AR_AUI_MUX_3 carries the multiplexer logic of the AR_MUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AR_AUI_MUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). • – ○ • – ○ • – ○ •

Introduction

AR_AUI_MUX_3_UNGATED is the adapter-based variant of the generic multiplexer for data type REAL. Unlike AR_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AR_AUI_MUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AR adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AR adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_MUX`) – shared across all port counts of this block family (AR_AUI_MUX_2 … AR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 32-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AR_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AR_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AR_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AR_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_MUX_4

• — ○ • — ○ • — ○ •

Introduction

`AR_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `REAL`. Unlike `AR_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AR_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AR adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AR adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AR adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_MUX`) – shared across all port counts of this block family (AR_AUI_MUX_2 … AR_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

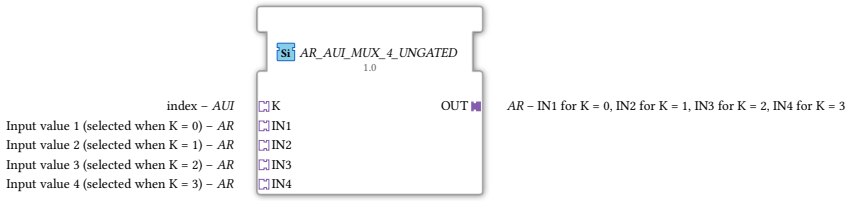
Application Scenarios

- Choosing between up to 4 32-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AR_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AR_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AR_AUI_MUX_4` carries the multiplexer logic of the `AR_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AR_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AR_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `REAL`. Unlike `AR_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AR_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AR adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AR adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AR adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_MUX`) – shared across all port counts of this block family (AR_AUI_MUX_2 … AR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

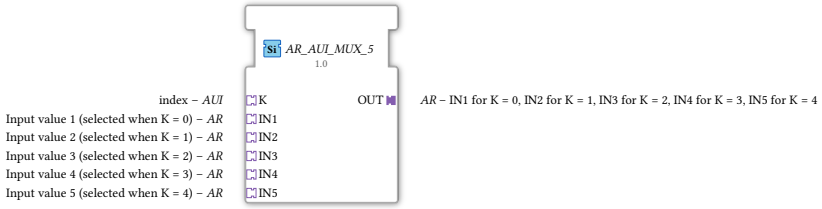
- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 32-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AR_MUX_4 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **AR_AUI_MUX_4**: The gated variant – updates the output only on an actual value change.

Conclusion

AR_AUI_MUX_4_UNGATED carries the multiplexer logic of the AR_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

AR_AUI_MUX_5 is the adapter-based variant of the generic multiplexer for data type REAL. Unlike AR_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AR_AUI_MUX_5 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AR adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AR adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AR adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AR adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN5:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AR_AUI_MUX`) – shared across all port counts of this block family (AR_AUI_MUX_2 … AR_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

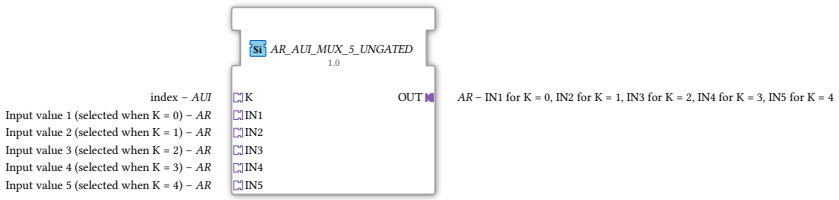
Application Scenarios

- Choosing between up to 5 32-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AR_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AR_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AR_AUI_MUX_5` carries the multiplexer logic of the `AR_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AR_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AR_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AR_AUI_MUX_5_UNGATED is the adapter-based variant of the generic multiplexer for data type REAL. Unlike AR_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AR_AUI_MUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AR adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AR adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AR adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AR adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AR adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AR adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN5:

1. The current value of K.D1 determines which of the 5 input adapters (IN1 … IN5) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AR_AUI_MUX) – shared across all port counts of this block family (AR_AUI_MUX_2 … AR_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN5) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

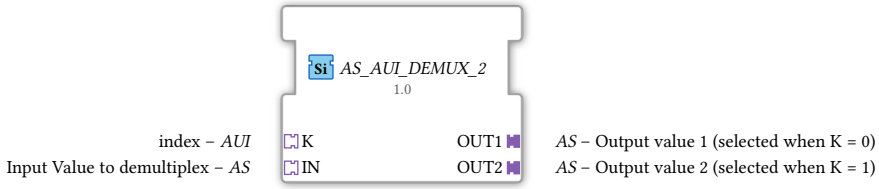
- Choosing between up to 5 32-bit floating-point value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AR_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AR_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.



Conclusion

`AR_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AR_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AS_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AS_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `SINT`. Unlike `AS_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the 8-bit signed integer to forward, routed to exactly one of the outputs (AS adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AS adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_DEMUX`) – shared across all port counts of this block family (AS_AUI_DEMUX_2 … AS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

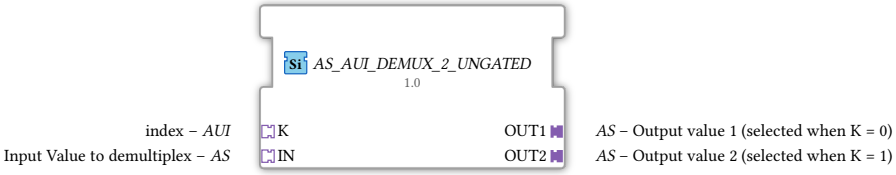
Application Scenarios

- Distributing a 8-bit signed integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AS_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AS_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AS_AUI_DEMUX_2` carries the demultiplexer logic of the `AS_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AS_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AS_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `SINT`. Unlike `AS_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit signed integer to forward, routed to exactly one of the outputs (AS adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AS adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see “Change Detection” below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn’t changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_DEMUX`) – shared across all port counts of this block family (AS_AUI_DEMUX_2_UNGATED … AS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 8-bit signed integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

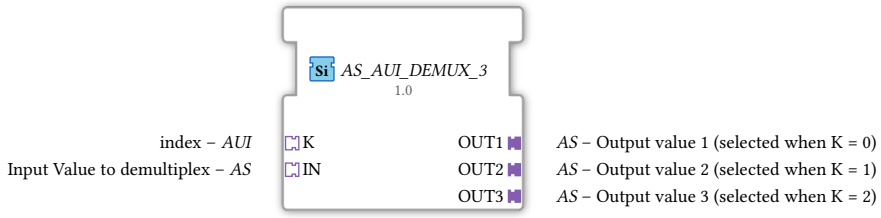
Compare with `AS_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AS_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AS_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AS_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AS_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `SINT`. Unlike `AS_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN** (Socket): input adapter carrying the 8-bit signed integer to forward, routed to exactly one of the outputs (AS adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AS adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AS adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_DEMUX`) – shared across all port counts of this block family (AS_AUI_DEMUX_2 … AS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

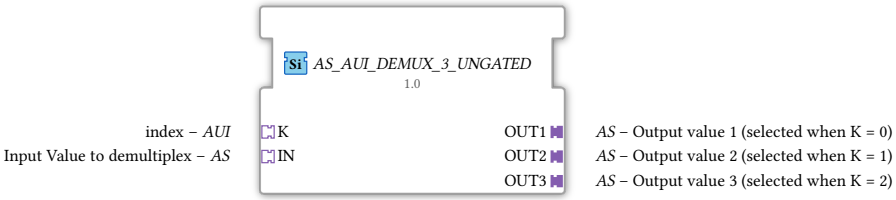
Application Scenarios

- Distributing a 8-bit signed integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AS_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AS_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AS_AUI_DEMUX_3` carries the demultiplexer logic of the `AS_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_DEMUX_3_UNGATED

• – ◦ • – ◦ • – ◦ •

Introduction

AS_AUI_DEMUX_3_UNGATED is the adapter-based variant of the generic demultiplexer for data type SINT. Unlike AS_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AS_AUI_DEMUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 8-bit signed integer to forward, routed to exactly one of the outputs (AS adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AS adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AS adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 3 output adapters (OUT1 … OUT3) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AS_AUI_DEMUX) – shared across all port counts of this block family (AS_AUI_DEMUX_2 … AS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

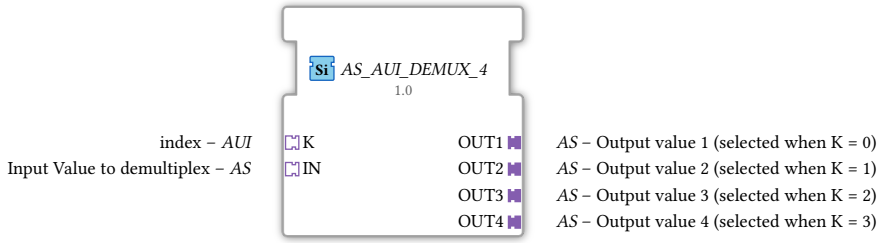
- **Any event** (selector adapter K or IN) ⟶ determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a 8-bit signed integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AS_DEMUX_3 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **AS_AUI_DEMUX_3**: The gated variant – updates the output only on an actual value change.

Conclusion

AS_AUI_DEMUX_3_UNGATED carries the demultiplexer logic of the AS_DEMUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

AS_AUI_DEMUX_4 is the adapter-based variant of the generic demultiplexer for data type SINT. Unlike AS_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit signed integer to forward, routed to exactly one of the outputs (AS adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AS adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AS adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AS adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_DEMUX`) – shared across all port counts of this block family (AS_AUI_DEMUX_2 … AS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

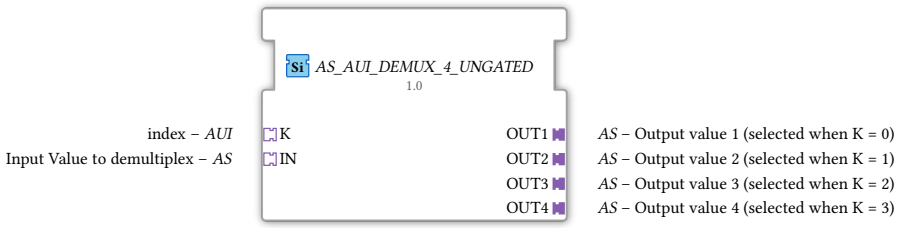
Application Scenarios

- Distributing a 8-bit signed integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AS_DEMUX_4 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **AS_AUI_DEMUX_4_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AS_AUI_DEMUX_4 carries the demultiplexer logic of the AS_DEMUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AS_AUI_DEMUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AS_AUI_DEMUX_4_UNGATED is the adapter-based variant of the generic demultiplexer for data type SINT. Unlike AS_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AS_AUI_DEMUX_4_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN** (Socket): input adapter carrying the 8-bit signed integer to forward, routed to exactly one of the outputs (AS adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AS adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AS adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AS adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_DEMUX`) – shared across all port counts of this block family (AS_AUI_DEMUX_2 … AS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

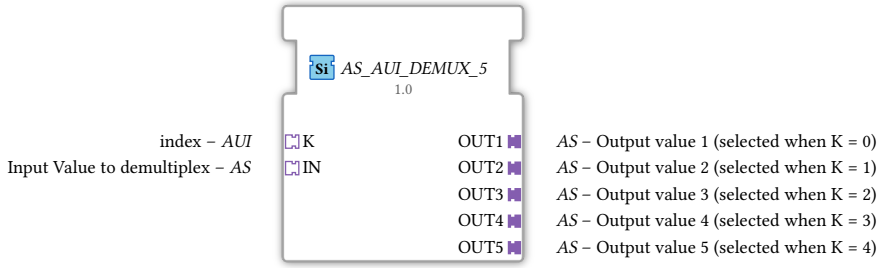
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 8-bit signed integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AS_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AS_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AS_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AS_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AS_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `SINT`. Unlike `AS_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit signed integer to forward, routed to exactly one of the outputs (AS adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AS adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AS adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AS adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AS adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see “Change Detection” below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn’t changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_DEMUX`) – shared across all port counts of this block family (AS_AUI_DEMUX_2 … AS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

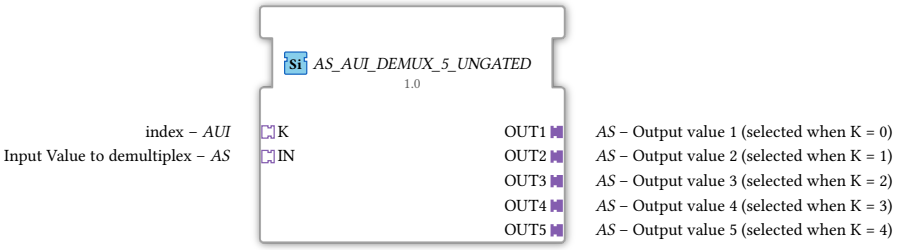
Application Scenarios

- Distributing a 8-bit signed integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AS_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AS_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AS_AUI_DEMUX_5` carries the demultiplexer logic of the `AS_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AS_AUI_DEMUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AS_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `SINT`. Unlike `AS_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data

input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_DEMUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit signed integer to forward, routed to exactly one of the outputs (AS adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AS adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AS adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AS adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AS adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_DEMUX`) – shared across all port counts of this block family (AS_AUI_DEMUX_2 … AS_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

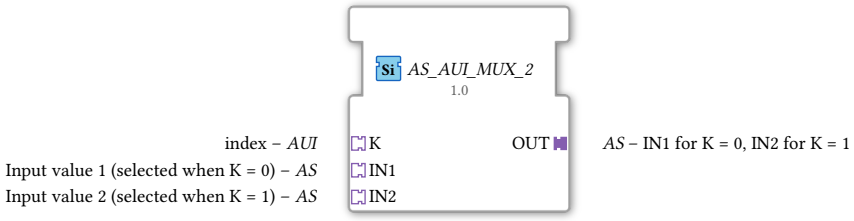
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 8-bit signed integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AS_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AS_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AS_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AS_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AS_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `SINT`. Unlike `AS_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AS adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AS adapter type).

- **OUT** (Plug): output adapter, forwards whichever input the index selected (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_MUX`) – shared across all port counts of this block family (AS_AUI_MUX_2 … AS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

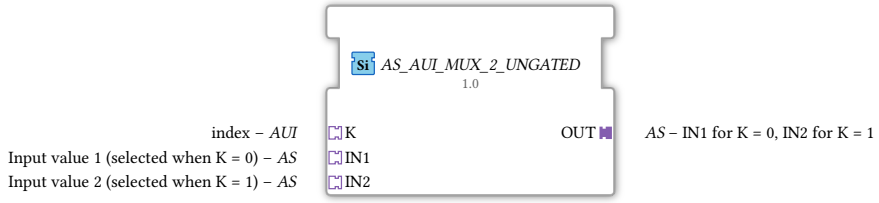
Application Scenarios

- Choosing between up to 2 8-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AS_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AS_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AS_AUI_MUX_2` carries the multiplexer logic of the `AS_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AS_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AS_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `SINT`. Conclusion

`AS_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AS_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_MUX_3

• — ○ • — ○ • — ○ •

Introduction

`AS_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `SINT`. Unlike `AS_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AS adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AS adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_MUX`) – shared across all port counts of this block family (AS_AUI_MUX_2 … AS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 8-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AS_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AS_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AS_AUI_MUX_3` carries the multiplexer logic of the `AS_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AS_AUI_MUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change

(e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AS_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `SINT`. Unlike `AS_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AS adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AS adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_MUX`) – shared across all port counts of this block family (AS_AUI_MUX_2 … AS_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

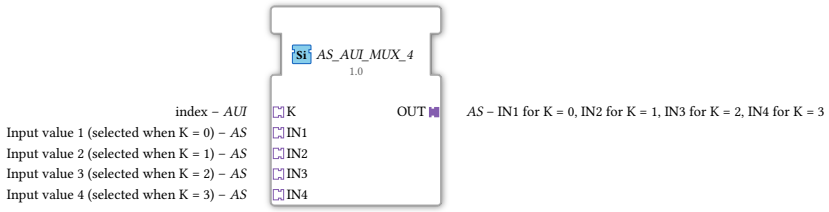
- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 8-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AS_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AS_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AS_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AS_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AS_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `SINT`. Unlike `AS_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AS adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AS adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AS adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_MUX`) – shared across all port counts of this block family (AS_AUI_MUX_2 … AS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

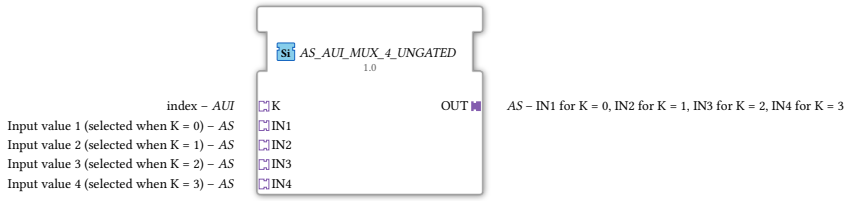
Application Scenarios

- Choosing between up to 4 8-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AS_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AS_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AS_AUI_MUX_4` carries the multiplexer logic of the `AS_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AS_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AS_AUI_MUX_4_UNGATED is the adapter-based variant of the generic multiplexer for data type SINT. Unlike AS_MUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AS_AUI_MUX_4_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 4, passed through to OUT when the index is K = 0 (AS adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to OUT when the index is K = 1 (AS adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to OUT when the index is K = 2 (AS adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to OUT when the index is K = 3 (AS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN4:

1. The current value of K.D1 determines which of the 4 input adapters (IN1 … IN4) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AS_AUI_MUX) – shared across all port counts of this block family (AS_AUI_MUX_2 … AS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

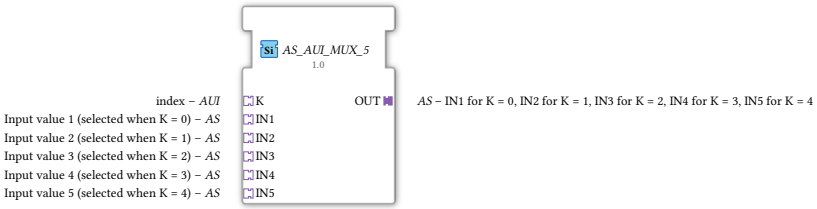
- **Any event** (selector adapter K or IN1…IN4) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 8-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AS_MUX_4 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **AS_AUI_MUX_4**: The gated variant – updates the output only on an actual value change.

Conclusion

AS_AUI_MUX_4_UNGATED carries the multiplexer logic of the AS_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

AS_AUI_MUX_5 is the adapter-based variant of the generic multiplexer for data type SINT. Unlike AS_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AS_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AS adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AS adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AS adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AS adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AS_AUI_MUX`) – shared across all port counts of this block family (AS_AUI_MUX_2 … AS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

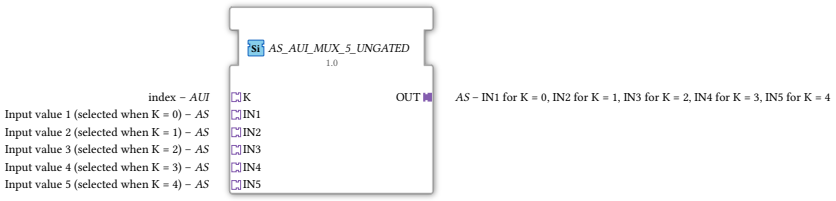
Application Scenarios

- Choosing between up to 5 8-bit signed integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AS_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AS_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AS_AUI_MUX_5` carries the multiplexer logic of the `AS_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AS_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AS_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

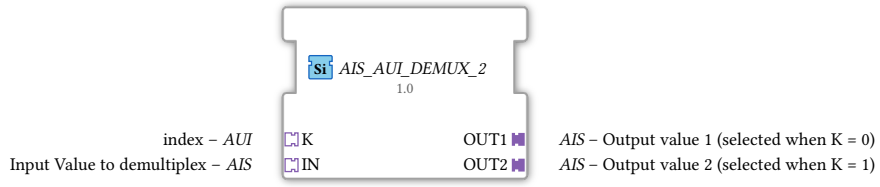
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AS_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- `AS_AUI_MUX_5`: The gated variant – updates the output only on an actual value change.



Conclusion

`AS_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AS_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AIS_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AIS_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `STRING`. Unlike `AIS_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the character string (8-bit characters) to forward, routed to exactly one of the outputs (AIS adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AIS adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_DEMUX`) – shared across all port counts of this block family (AIS_AUI_DEMUX_2 … AIS_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

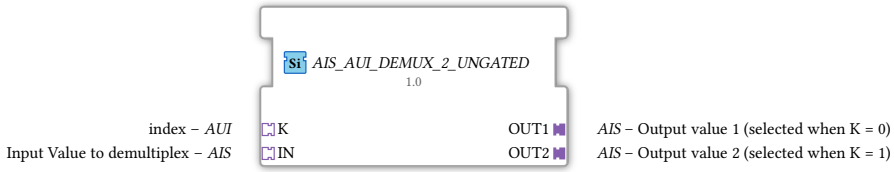
Application Scenarios

- Distributing a character string (8-bit characters) to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIS_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AIS_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIS_AUI_DEMUX_2` carries the demultiplexer logic of the `AIS_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AIS_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `STRING`. Unlike `AIS_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the character string (8-bit characters) to forward, routed to exactly one of the outputs (AIS adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AIS adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_DEMUX`) – shared across all port counts of this block family (AIS_AUI_DEMUX_2_UNGATED … AIS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

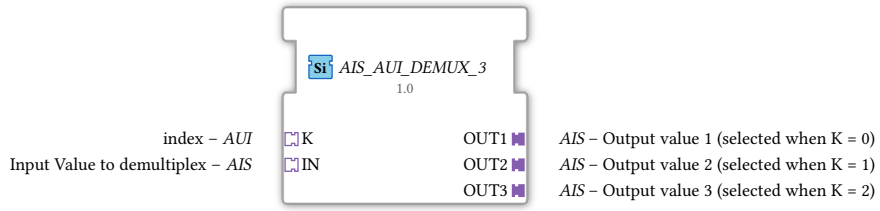
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a character string (8-bit characters) to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIS_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AIS_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIS_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AIS_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AIS_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `STRING`. Unlike `AIS_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the character string (8-bit characters) to forward, routed to exactly one of the outputs (AIS adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AIS adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AIS adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_DEMUX`) – shared across all port counts of this block family (AIS_AUI_DEMUX_2 … AIS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

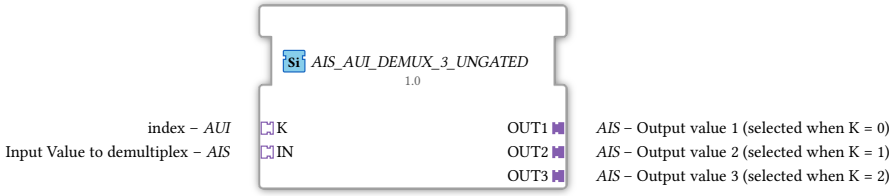
Application Scenarios

- Distributing a character string (8-bit characters) to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIS_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AIS_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIS_AUI_DEMUX_3` carries the demultiplexer logic of the `AIS_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AIS_AUI_DEMUX_3_UNGATED is the adapter-based variant of the generic demultiplexer for data type STRING. Unlike AIS_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AIS_AUI_DEMUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the character string (8-bit characters) to forward, routed to exactly one of the outputs (AIS adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AIS adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AIS adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 3 output adapters (OUT1 … OUT3) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AIS_AUI_DEMUX) – shared across all port counts of this block family (AIS_AUI_DEMUX_2 … AIS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

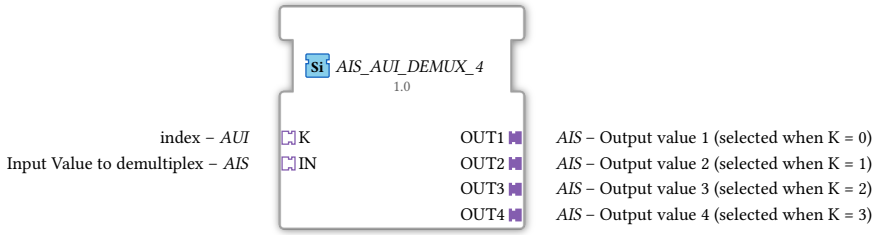
- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a character string (8-bit characters) to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIS_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AIS_AUI_DEMUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIS_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AIS_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AIS_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `STRING`. Unlike `AIS_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the character string (8-bit characters) to forward, routed to exactly one of the outputs (AIS adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AIS adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AIS adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AIS adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_DEMUX`) – shared across all port counts of this block family (AIS_AUI_DEMUX_2 … AIS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

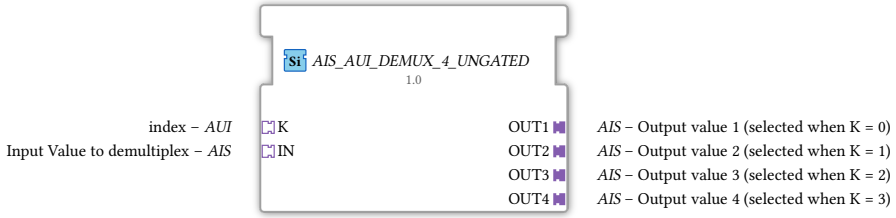
- Distributing a character string (8-bit characters) to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIS_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AIS_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.



Conclusion

`AIS_AUI_DEMUX_4` carries the demultiplexer logic of the `AIS_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change

(e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AIS_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `STRING`. Unlike `AIS_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the character string (8-bit characters) to forward, routed to exactly one of the outputs (AIS adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AIS adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AIS adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AIS adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_DEMUX`) – shared across all port counts of this block family (AIS_AUI_DEMUX_2 … AIS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

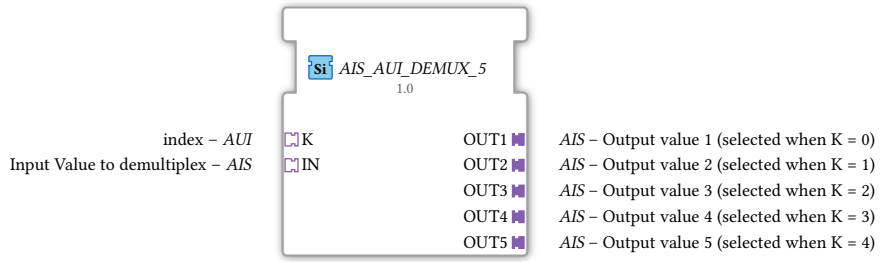
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a character string (8-bit characters) to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIS_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AIS_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIS_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AIS_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AIS_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `STRING`. Unlike `AIS_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the character string (8-bit characters) to forward, routed to exactly one of the outputs (AIS adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AIS adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AIS adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AIS adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AIS adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_DEMUX`) – shared across all port counts of this block family (AIS_AUI_DEMUX_2 … AIS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

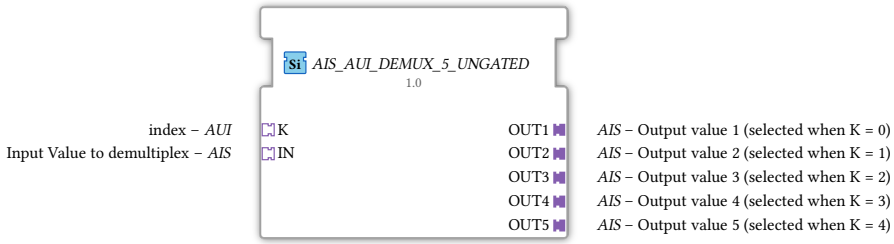
- Distributing a character string (8-bit characters) to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)

- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIS_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AIS_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIS_AUI_DEMUX_5` carries the demultiplexer logic of the `AIS_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_AUI_DEMUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AIS_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `STRING`. Unlike `AIS_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

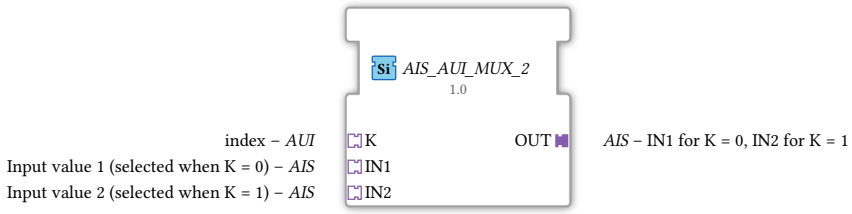
⚖️ Comparison with Similar Blocks

Compare with `AIS_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AIS_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIS_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AIS_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AIS_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `STRING`. Unlike `AIS_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AIS adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AIS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_MUX`) – shared across all port counts of this block family (AIS_AUI_MUX_2 … AIS_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

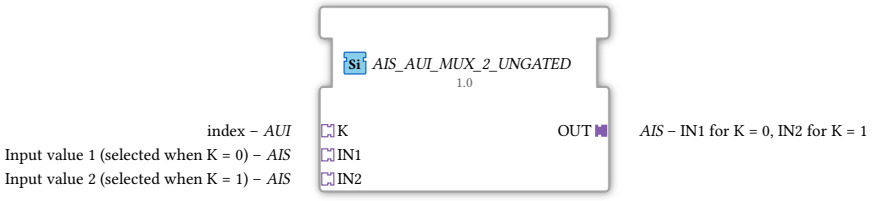
Application Scenarios

- Choosing between up to 2 character string (8-bit characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIS_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AIS_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIS_AUI_MUX_2` carries the multiplexer logic of the `AIS_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_AUI_MUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AIS_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `STRING`. Unlike `AIS_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_MUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AIS adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AIS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_MUX`) – shared across all port counts of this block family (AIS_AUI_MUX_2_UNGATED … AIS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

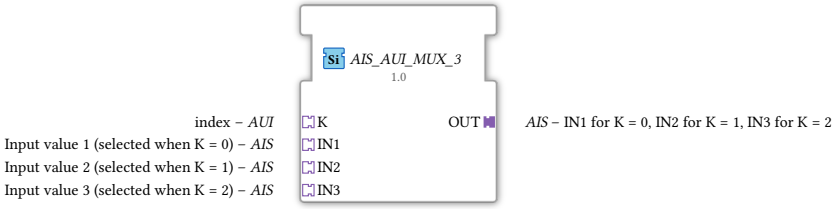
- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 character string (8-bit characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIS_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AIS_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIS_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AIS_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

`AIS_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `STRING`. Unlike `AIS_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AIS adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AIS adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AIS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_MUX`) – shared across all port counts of this block family (AIS_AUI_MUX_2 … AIS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

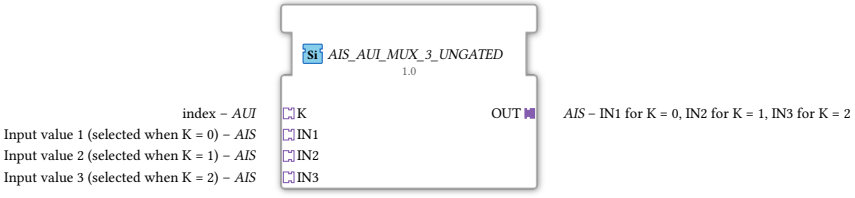
Application Scenarios

- Choosing between up to 3 character string (8-bit characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIS_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **`AIS_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIS_AUI_MUX_3` carries the multiplexer logic of the `AIS_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_AUI_MUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AIS_AUI_MUX_3_UNGATED is the adapter-based variant of the generic multiplexer for data type STRING. Unlike AIS_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AIS_AUI_MUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (AIS adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (AIS adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (AIS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AIS_AUI_MUX) – shared across all port counts of this block family (AIS_AUI_MUX_2 … AIS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN3) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 character string (8-bit characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖ Comparison with Similar Blocks

Compare with `AIS_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AIS_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIS_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AIS_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AIS_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `STRING`. Unlike `AIS_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AIS adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AIS adapter type).

- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AIS adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AIS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_MUX`) – shared across all port counts of this block family (AIS_AUI_MUX_2 … AIS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

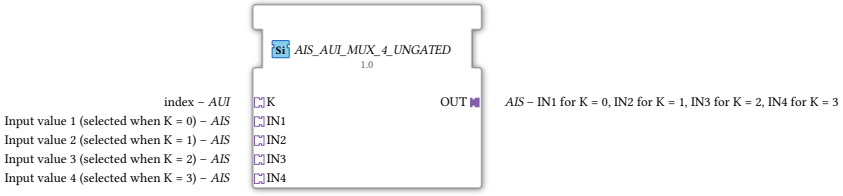
Application Scenarios

- Choosing between up to 4 character string (8-bit characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIS_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AIS_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIS_AUI_MUX_4` carries the multiplexer logic of the `AIS_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_AUI_MUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• — ○ • — ○ • — ○ •

Introduction

`AIS_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `STRING`. Unlike `AIS_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AIS adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AIS adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AIS adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AIS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_MUX`) – shared across all port counts of this block family (AIS_AUI_MUX_2 … AIS_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

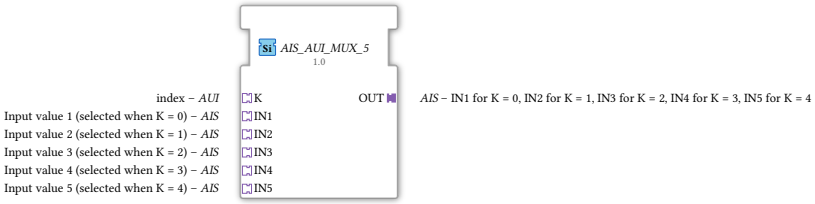
Compare with `AIS_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AIS_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIS_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `AIS_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`AIS_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `STRING`. Unlike `AIS_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIS_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AIS adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AIS adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AIS adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AIS adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AIS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_MUX`) – shared across all port counts of this block family (AIS_AUI_MUX_2 … AIS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

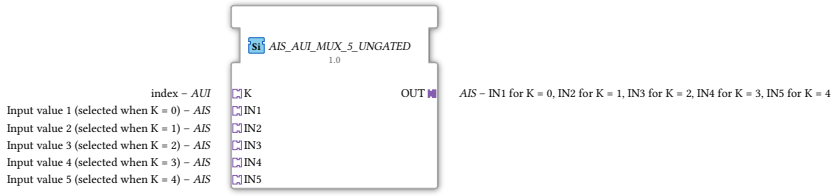
Application Scenarios

- Choosing between up to 5 character string (8-bit characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIS_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AIS_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AIS_AUI_MUX_5 carries the multiplexer logic of the AIS_MUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AIS_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AIS_AUI_MUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AIS_AUI_MUX_5_UNGATED is the adapter-based variant of the generic multiplexer for data type STRING. Unlike AIS_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AIS_AUI_MUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (AIS adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (AIS adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (AIS adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (AIS adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (AIS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIS_AUI_MUX`) – shared across all port counts of this block family (AIS_AUI_MUX_2 … AIS_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

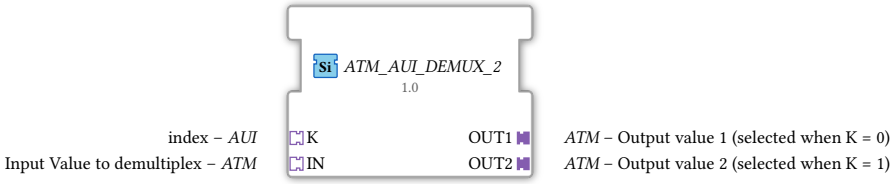
- Choosing between up to 5 character string (8-bit characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIS_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AIS_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.



Conclusion

`AIS_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AIS_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ATM_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

ATM_AUI_DEMUX_2 is the adapter-based variant of the generic demultiplexer for data type TIME. Unlike ATM_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ATM_AUI_DEMUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the duration value to forward, routed to exactly one of the outputs (ATM adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (ATM adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 2 output adapters (OUT1 … OUT2) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_ATM_AUI_DEMUX) – shared across all port counts of this block family (ATM_AUI_DEMUX_2 … ATM_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) ⟶ determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

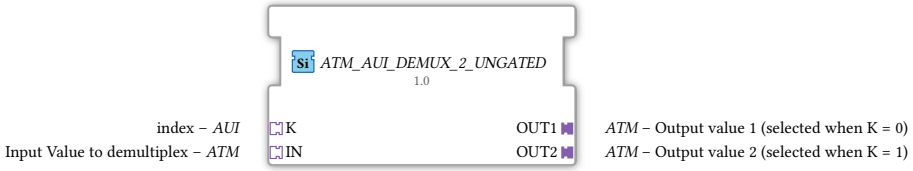
- Distributing a duration value to up to 2 downstream consumers, selected via an adapter-carried index

- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with ATM_DEMUX_2 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **ATM_AUI_DEMUX_2_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

ATM_AUI_DEMUX_2 carries the demultiplexer logic of the ATM_DEMUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of ATM_AUI_DEMUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

ATM_AUI_DEMUX_2_UNGATED is the adapter-based variant of the generic demultiplexer for data type TIME. Unlike ATM_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ATM_AUI_DEMUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the duration value to forward, routed to exactly one of the outputs (ATM adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (ATM adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_DEMUX`) – shared across all port counts of this block family (ATM_AUI_DEMUX_2_UNGATED … ATM_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

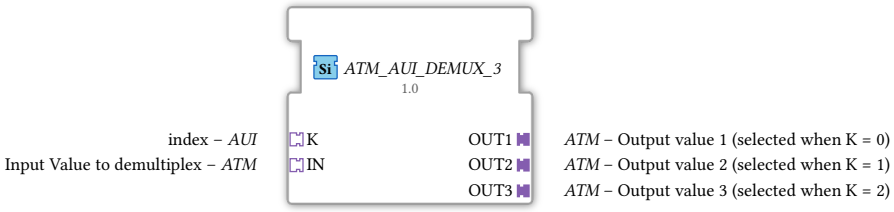
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a duration value to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ATM_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ATM_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ATM_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `ATM_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`ATM_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `TIME`. Unlike `ATM_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ATM_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the duration value to forward, routed to exactly one of the outputs (ATM adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (ATM adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (ATM adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_DEMUX`) – shared across all port counts of this block family (ATM_AUI_DEMUX_2 … ATM_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

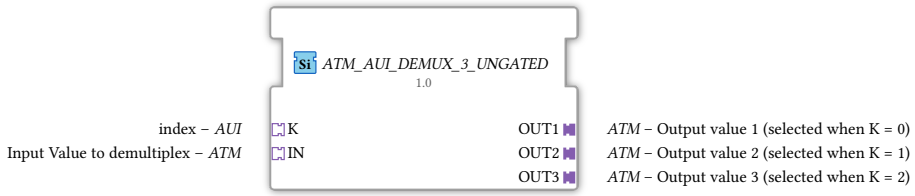
Application Scenarios

- Distributing a duration value to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ATM_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ATM_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ATM_AUI_DEMUX_3` carries the demultiplexer logic of the `ATM_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ATM_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`ATM_AUI_DEMUX_3_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `TIME`. Unlike `ATM_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ATM_AUI_DEMUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

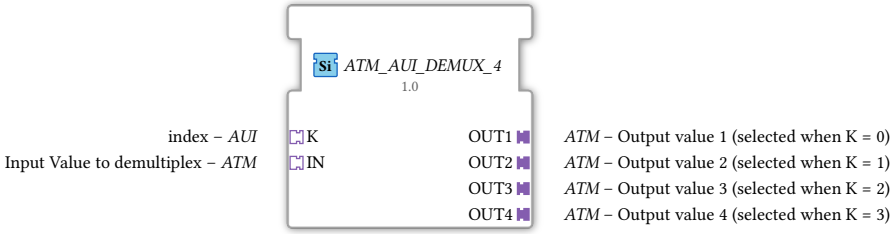
Compare with ATM_DEMUX_3 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **ATM_AUI_DEMUX_3**: The gated variant – updates the output only on an actual value change.

Conclusion

ATM_AUI_DEMUX_3_UNGATED carries the demultiplexer logic of the ATM_DEMUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

ATM_AUI_DEMUX_4 is the adapter-based variant of the generic demultiplexer for data type TIME. Unlike ATM_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ATM_AUI_DEMUX_4 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the duration value to forward, routed to exactly one of the outputs (ATM adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (ATM adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (ATM adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (ATM adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_DEMUX`) – shared across all port counts of this block family (ATM_AUI_DEMUX_2 … ATM_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

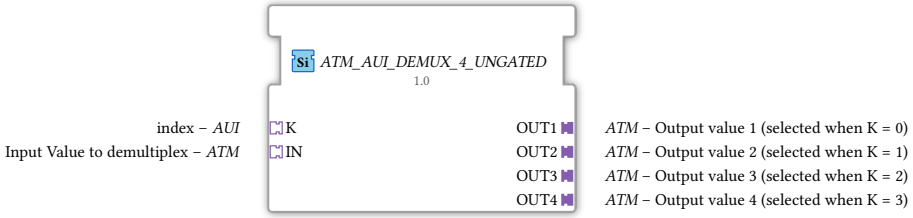
Application Scenarios

- Distributing a duration value to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖ Comparison with Similar Blocks

Compare with `ATM_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`ATM_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ATM_AUI_DEMUX_4` carries the demultiplexer logic of the `ATM_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ATM_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). • – ◦ • – ◦ • – ◦ •

Introduction

`ATM_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `TIME`. Unlike `ATM_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ATM_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the duration value to forward, routed to exactly one of the outputs (ATM adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (ATM adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (ATM adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (ATM adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see “Change Detection” below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn’t changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_DEMUX`) – shared across all port counts of this block family (ATM_AUI_DEMUX_2 … ATM_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

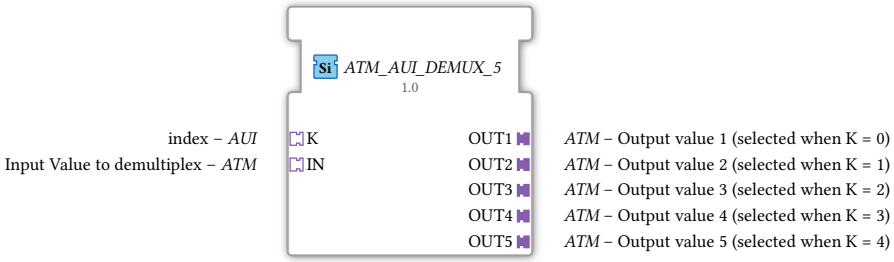
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a duration value to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ATM_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ATM_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ATM_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `ATM_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_DEMUX_5

• – ○ • – ○ • – ○ •

Introduction

`ATM_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `TIME`. Unlike `ATM_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ATM_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the duration value to forward, routed to exactly one of the outputs (ATM adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (ATM adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (ATM adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (ATM adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (ATM adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_DEMUX`) – shared across all port counts of this block family (ATM_AUI_DEMUX_2 … ATM_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

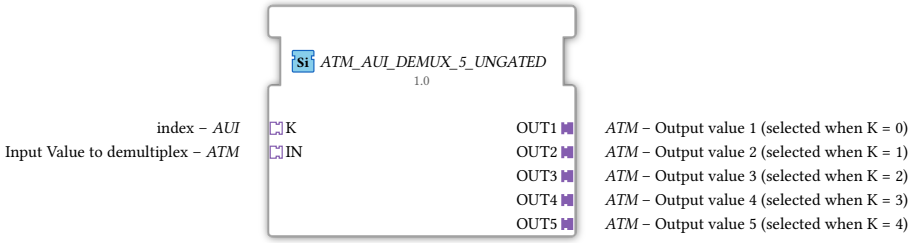
Application Scenarios

- Distributing a duration value to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ATM_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- `ATM_AUI_DEMUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

ATM_AUI_DEMUX_5 carries the demultiplexer logic of the ATM_DEMUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of ATM_AUI_DEMUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

ATM_AUI_DEMUX_5_UNGATED is the adapter-based variant of the generic demultiplexer for data type TIME. Unlike ATM_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ATM_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the duration value to forward, routed to exactly one of the outputs (ATM adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (ATM adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (ATM adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (ATM adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (ATM adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_DEMUX`) – shared across all port counts of this block family (ATM_AUI_DEMUX_2 … ATM_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

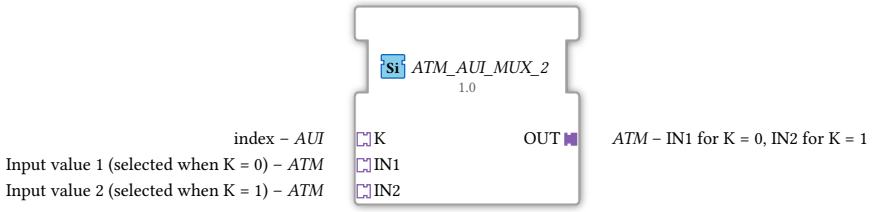
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a duration value to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `ATM_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`ATM_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ATM_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `ATM_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`ATM_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `TIME`. Unlike `ATM_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index

be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ATM_AUI_MUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 2, passed through to OUT when the index is K = 0 (ATM adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to OUT when the index is K = 1 (ATM adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN2:

1. The current value of K.D1 determines which of the 2 input adapters (IN1 … IN2) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_ATM_AUI_MUX) – shared across all port counts of this block family (ATM_AUI_MUX_2 … ATM_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN2) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

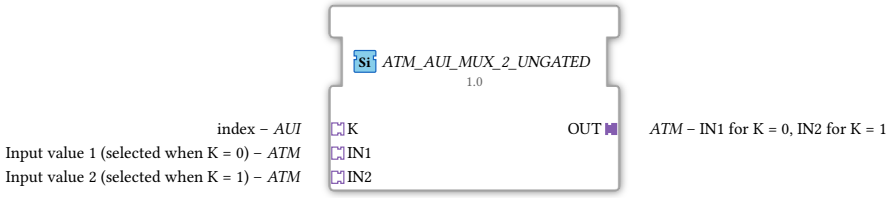
Application Scenarios

- Choosing between up to 2 duration value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with ATM_MUX_2 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **ATM_AUI_MUX_2_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

ATM_AUI_MUX_2 carries the multiplexer logic of the ATM_MUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of ATM_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

ATM_AUI_MUX_2_UNGATED is the adapter-based variant of the generic multiplexer for data type TIME. Unlike ATM_MUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ATM_AUI_MUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (ATM adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (ATM adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_MUX`) – shared across all port counts of this block family (ATM_AUI_MUX_2_UNGATED … ATM_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

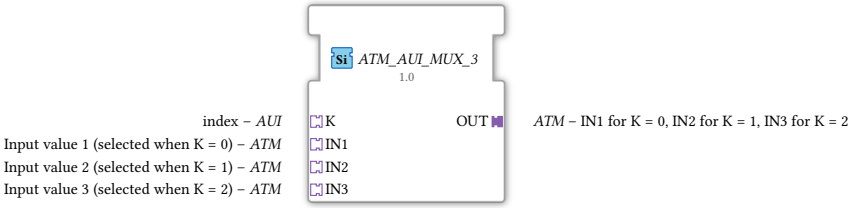
- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 duration value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ATM_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`ATM_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ATM_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `ATM_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

ATM_AUI_MUX_3 is the adapter-based variant of the generic multiplexer for data type TIME. Unlike ATM_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ATM_AUI_MUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (ATM adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (ATM adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (ATM adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_ATM_AUI_MUX) – shared across all port counts of this block family (ATM_AUI_MUX_2 … ATM_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN3) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

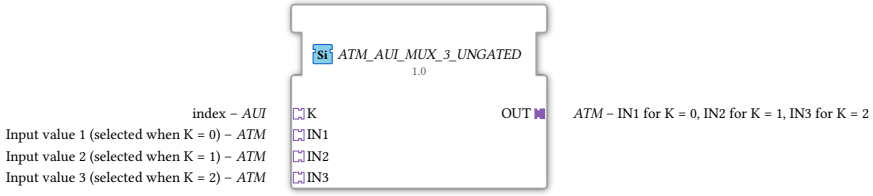
- Choosing between up to 3 duration value sources through a centrally managed adapter index

- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ATM_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **`ATM_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ATM_AUI_MUX_3` carries the multiplexer logic of the `ATM_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ATM_AUI_MUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`ATM_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `TIME`. Unlike `ATM_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ATM_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (ATM adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (ATM adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (ATM adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_MUX`) – shared across all port counts of this block family (ATM_AUI_MUX_2 … ATM_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

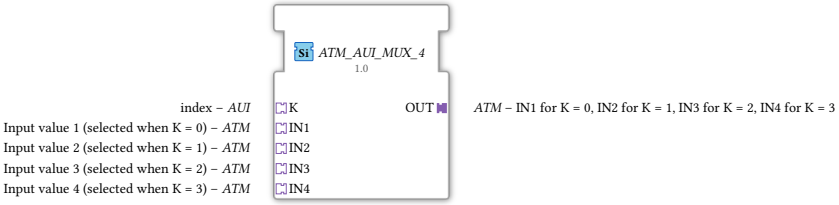
- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 duration value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ATM_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`ATM_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`ATM_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `ATM_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_MUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`ATM_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `TIME`. Unlike `ATM_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ATM_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (ATM adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (ATM adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (ATM adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (ATM adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_MUX`) – shared across all port counts of this block family (ATM_AUI_MUX_2 … ATM_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 duration value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ATM_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`ATM_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ATM_AUI_MUX_4` carries the multiplexer logic of the `ATM_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ATM_AUI_MUX_4`. Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`ATM_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `TIME`. Unlike `ATM_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ATM_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (ATM adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (ATM adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (ATM adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (ATM adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_MUX`) – shared across all port counts of this block family (ATM_AUI_MUX_2 … ATM_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

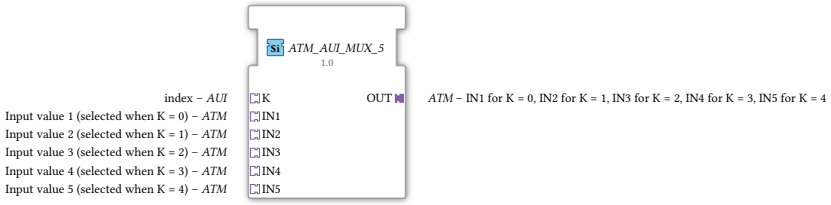
- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 duration value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with ATM_MUX_4 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **ATM_AUI_MUX_4**: The gated variant – updates the output only on an actual value change.

Conclusion

ATM_AUI_MUX_4_UNGATED carries the multiplexer logic of the ATM_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

ATM_AUI_MUX_5 is the adapter-based variant of the generic multiplexer for data type TIME. Unlike ATM_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, ATM_AUI_MUX_5 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 5, passed through to OUT when the index is K = 0 (ATM adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to OUT when the index is K = 1 (ATM adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to OUT when the index is K = 2 (ATM adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to OUT when the index is K = 3 (ATM adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to OUT when the index is K = 4 (ATM adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_MUX`) – shared across all port counts of this block family (ATM_AUI_MUX_2 … ATM_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

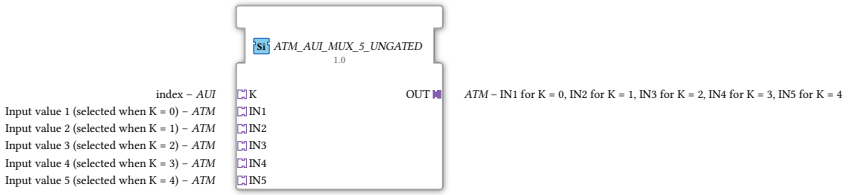
Application Scenarios

- Choosing between up to 5 duration value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ATM_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `ATM_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`ATM_AUI_MUX_5` carries the multiplexer logic of the `ATM_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

ATM_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ATM_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• — ○ • — ○ • — ○ •

Introduction

`ATM_AUI_MUX_5_UNGATED` is the adapter-based variant of the generic multiplexer for data type `TIME`. Unlike `ATM_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `ATM_AUI_MUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (ATM adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (ATM adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (ATM adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (ATM adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (ATM adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (ATM adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_ATM_AUI_MUX`) – shared across all port counts of this block family (ATM_AUI_MUX_2 … ATM_AUI_MUX_5_UNGATED).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

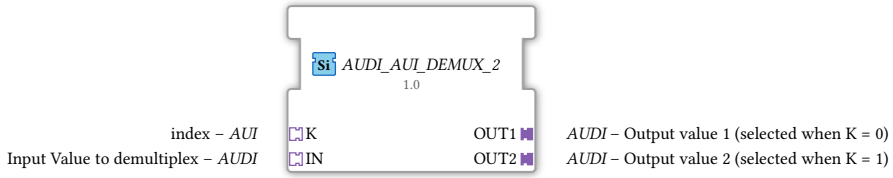
- Choosing between up to 5 duration value sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `ATM_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- `ATM_AUI_MUX_5`: The gated variant – updates the output only on an actual value change.



Conclusion

`ATM_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `ATM_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AUDI_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AUDI_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `UDINT`. Unlike `AUDI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit unsigned integer to forward, routed to exactly one of the outputs (AUDI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AUDI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_DEMUX`) – shared across all port counts of this block family (AUDI_AUI_DEMUX_2 … AUDI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

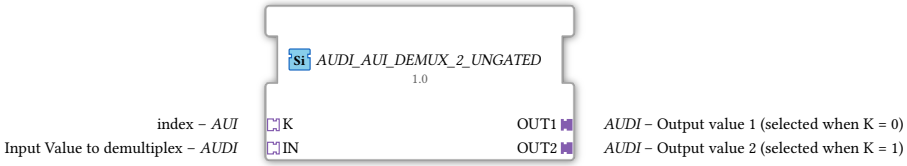
Application Scenarios

- Distributing a 32-bit unsigned integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUDI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUDI_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AUDI_AUI_DEMUX_2 carries the demultiplexer logic of the AUDI_DEMUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUDI_AUI_DEMUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AUDI_AUI_DEMUX_2_UNGATED is the adapter-based variant of the generic demultiplexer for data type UDINT. Unlike AUDI_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUDI_AUI_DEMUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 32-bit unsigned integer to forward, routed to exactly one of the outputs (AUDI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AUDI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 2 output adapters (OUT1 … OUT2) is currently selected.

2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_DEMUX`) – shared across all port counts of this block family (AUDI_AUI_DEMUX_2_UNGATED … AUDI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

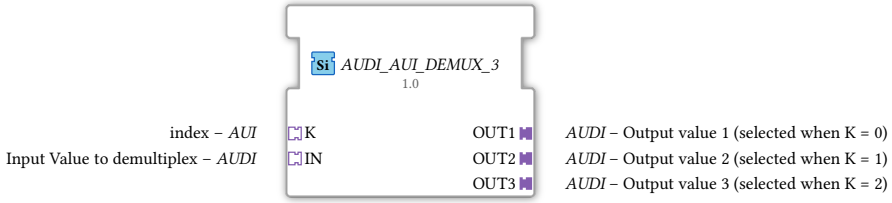
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit unsigned integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUDI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUDI_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUDI_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AUDI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_DEMUX_3

• – ○ • – ○ • – ○ •

Introduction

`AUDI_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `UDINT`. Unlike `AUDI_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit unsigned integer to forward, routed to exactly one of the outputs (AUDI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AUDI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AUDI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_DEMUX`) – shared across all port counts of this block family (AUDI_AUI_DEMUX_2 … AUDI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

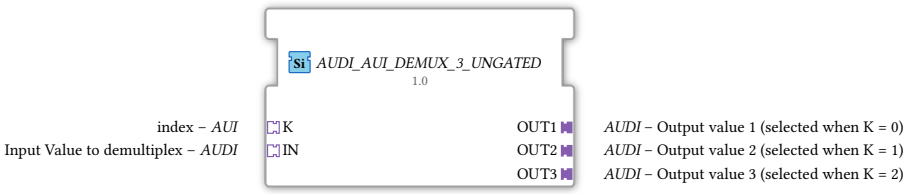
Application Scenarios

- Distributing a 32-bit unsigned integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AUDI_DEMUX_3 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **AUDI_AUI_DEMUX_3_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AUDI_AUI_DEMUX_3 carries the demultiplexer logic of the AUDI_DEMUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUDI_AUI_DEMUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AUDI_AUI_DEMUX_3_UNGATED is the adapter-based variant of the generic demultiplexer for data type UDINT. Unlike AUDI_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUDI_AUI_DEMUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN** (Socket): input adapter carrying the 32-bit unsigned integer to forward, routed to exactly one of the outputs (AUDI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AUDI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AUDI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_DEMUX`) – shared across all port counts of this block family (AUDI_AUI_DEMUX_2 … AUDI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit unsigned integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUDI_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUDI_AUI_DEMUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUDI_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AUDI_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AUDI_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `UDINT`. Unlike `AUDI_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit unsigned integer to forward, routed to exactly one of the outputs (AUDI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AUDI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AUDI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AUDI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.

- Generic implementation (`GEN_AUDI_AUI_DEMUX`) – shared across all port counts of this block family (AUDI_AUI_DEMUX_2 … AUDI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

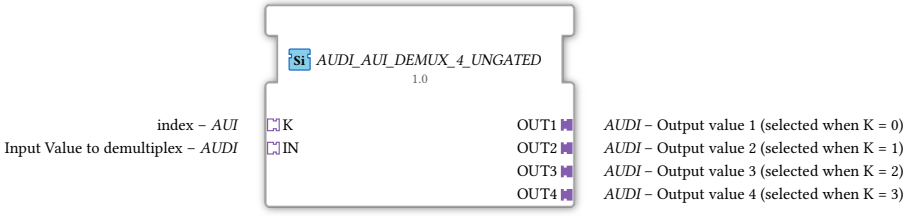
Application Scenarios

- Distributing a 32-bit unsigned integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUDI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUDI_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUDI_AUI_DEMUX_4` carries the demultiplexer logic of the `AUDI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUDI_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AUDI_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `UDINT`. Unlike `AUDI_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit unsigned integer to forward, routed to exactly one of the outputs (AUDI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AUDI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AUDI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AUDI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_DEMUX`) – shared across all port counts of this block family (AUDI_AUI_DEMUX_2 … AUDI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

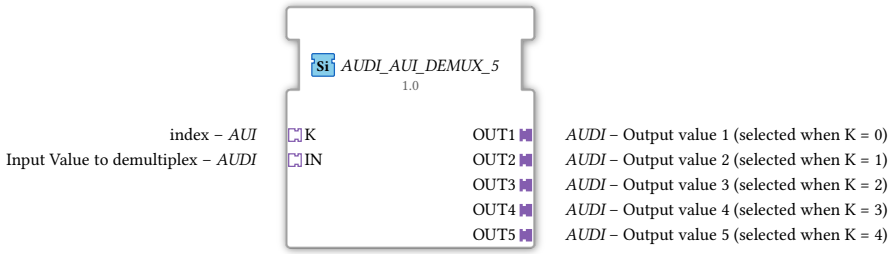
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit unsigned integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUDI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUDI_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUDI_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AUDI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AUDI_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `UDINT`. Unlike `AUDI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit unsigned integer to forward, routed to exactly one of the outputs (AUDI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AUDI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AUDI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AUDI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AUDI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_DEMUX`) – shared across all port counts of this block family (AUDI_AUI_DEMUX_2 … AUDI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

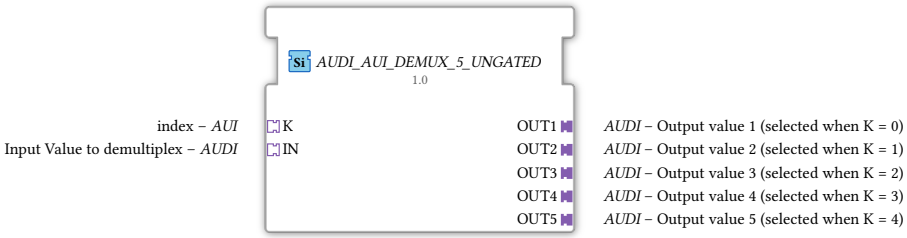
Application Scenarios

- Distributing a 32-bit unsigned integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUDI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUDI_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUDI_AUI_DEMUX_5` carries the demultiplexer logic of the `AUDI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUDI_AUI_DEMUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AUDI_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `UDINT`. Unlike `AUDI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_DEMUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 32-bit unsigned integer to forward, routed to exactly one of the outputs (AUDI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AUDI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AUDI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AUDI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AUDI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.

- Generic implementation (`GEN_AUDI_AUI_DEMUX`) – shared across all port counts of this block family (AUDI_AUI_DEMUX_2 … AUDI_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

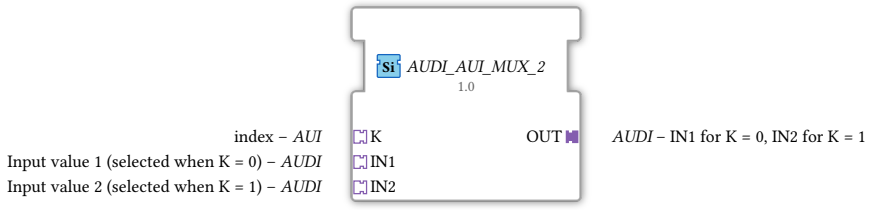
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 32-bit unsigned integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUDI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUDI_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUDI_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AUDI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AUDI_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `UDINT`. Unlike `AUDI_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AUDI adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AUDI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_MUX`) – shared across all port counts of this block family (AUDI_AUI_MUX_2 … AUDI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

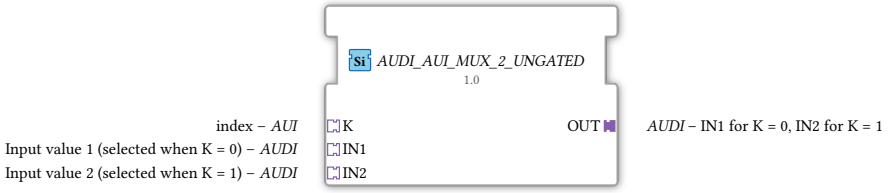
Application Scenarios

- Choosing between up to 2 32-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUDI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AUDI_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUDI_AUI_MUX_2` carries the multiplexer logic of the `AUDI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_MUX_2_UNGATED

i UNGATED variant: This block is the ungated version of AUDI_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AUDI_AUI_MUX_2_UNGATED is the adapter-based variant of the generic multiplexer for data type UDINT. Unlike AUDI_MUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUDI_AUI_MUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 2, passed through to OUT when the index is K = 0 (AUDI adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to OUT when the index is K = 1 (AUDI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1...IN2:

1. The current value of K.D1 determines which of the 2 input adapters (IN1 ... IN2) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_MUX`) – shared across all port counts of this block family (AUDI_AUI_MUX_2_UNGATED … AUDI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

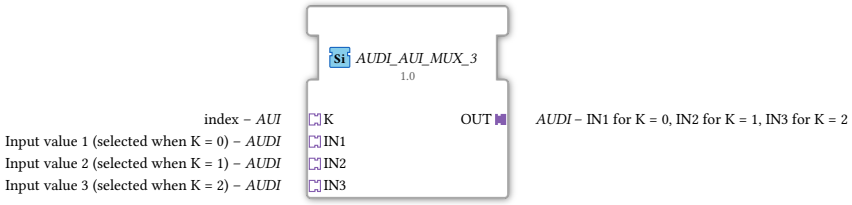
- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 32-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUDI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AUDI_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUDI_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AUDI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

`AUDI_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `UDINT`. Unlike `AUDI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AUDI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AUDI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AUDI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_MUX`) – shared across all port counts of this block family (AUDI_AUI_MUX_2 … AUDI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

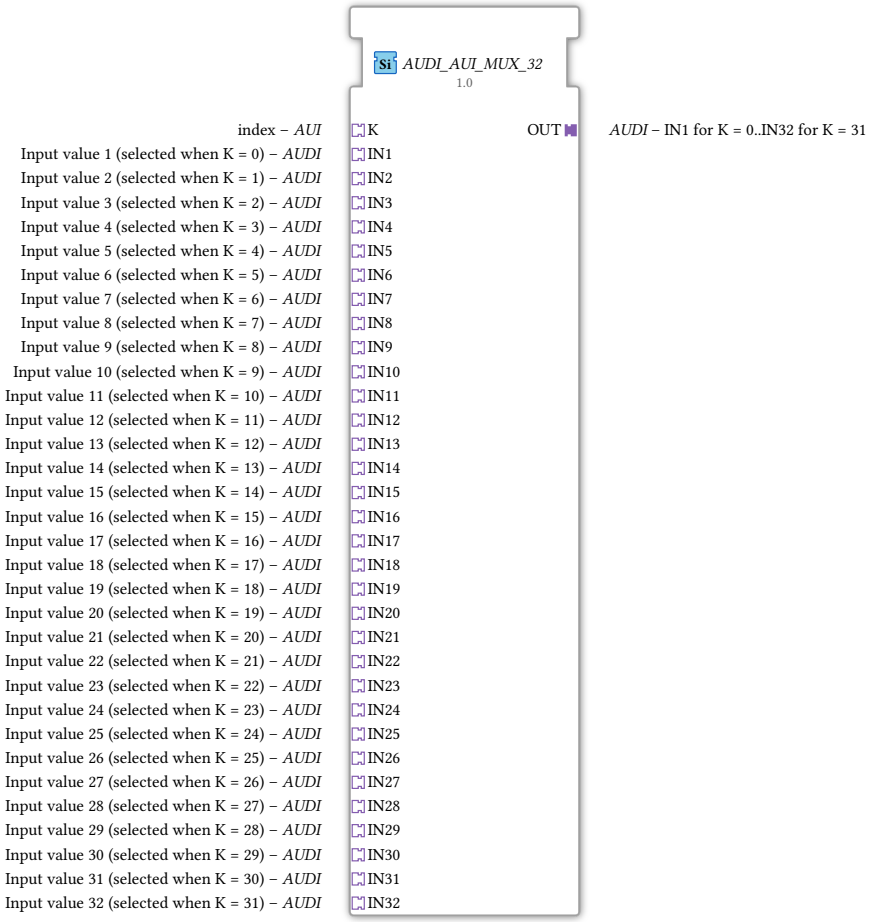
- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 32-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUDI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AUDI_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUDI_AUI_MUX_3` carries the multiplexer logic of the `AUDI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_MUX_32

• – ○ • – ○ • – ○ •

Introduction

AUDI_AUI_MUX_32 is a generic function block that implements a 32-channel adapter multiplexer. It selects one of 32 unidirectional AUDI adapter inputs (IN1 to IN32) based on an index value received via a dedicated AUI adapter input (K) and forwards the selected data to the unidirectional AUDI adapter output (OUT). The output is only updated when the value actually changes, avoiding unnecessary retransmissions.

This block is part of the adapter-based selection pattern and is designed for applications where multiple data sources must be routed to a single consumer under dynamic index control.

Interface Structure

Event Inputs

The function block has **no event inputs**. All data transfer is handled through adapter connections.

Event Outputs

The function block has **no event outputs**.

Data Inputs

There are **no direct data inputs**. All input data is provided through the socket adapters.

Data Outputs

There are **no direct data outputs**. All output data is provided through the plug adapter.

Adapters

Adapter	Direction	Type	Description
`OUT`	Plug	`adapter::types::unidirectional::AUDI`	Output adapter carrying the selected input value.
`K`	Socket	`adapter::types::unidirectional::AUI`	Index input (0 to 31) selecting which of the 32 inputs is routed to the output.
`IN1`	Socket	`adapter::types::unidirectional::AUDI`	Input value 1 (selected when K = 0).
`IN2`	Socket	`adapter::types::unidirectional::AUDI`	Input value 2 (selected when K = 1).
`IN3`	Socket	`adapter::types::unidirectional::AUDI`	Input value 3 (selected when K = 2).
`IN4`	Socket	`adapter::types::unidirectional::AUDI`	Input value 4 (selected when K = 3).
`IN5`	Socket	`adapter::types::unidirectional::AUDI`	Input value 5 (selected when K = 4).
`IN6`	Socket	`adapter::types::unidirectional::AUDI`	Input value 6 (selected when K = 5).
`IN7`	Socket	`adapter::types::unidirectional::AUDI`	Input value 7 (selected when K = 6).
`IN8`	Socket	`adapter::types::unidirectional::AUDI`	Input value 8 (selected when K = 7).
`IN9`	Socket	`adapter::types::unidirectional::AUDI`	Input value 9 (selected when K = 8).
`IN10`	Socket	`adapter::types::unidirectional::AUDI`	Input value 10 (selected when K = 9).
`IN11`	Socket	`adapter::types::unidirectional::AUDI`	Input value 11 (selected when K = 10).
`IN12`	Socket	`adapter::types::unidirectional::AUDI`	Input value 12 (selected when K = 11).
`IN13`	Socket	`adapter::types::unidirectional::AUDI`	Input value 13 (selected when K = 12).
`IN14`	Socket	`adapter::types::unidirectional::AUDI`	Input value 14 (selected when K = 13).
`IN15`	Socket	`adapter::types::unidirectional::AUDI`	Input value 15 (selected when K = 14).
`IN16`	Socket	`adapter::types::unidirectional::AUDI`	Input value 16 (selected when K = 15).
`IN17`	Socket	`adapter::types::unidirectional::AUDI`	Input value 17 (selected when K = 16).
`IN18`	Socket	`adapter::types::unidirectional::AUDI`	Input value 18 (selected when K = 17).
`IN19`	Socket	`adapter::types::unidirectional::AUDI`	Input value 19 (selected when K = 18).
`IN20`	Socket	`adapter::types::unidirectional::AUDI`	Input value 20 (selected when K = 19).
`IN21`	Socket	`adapter::types::unidirectional::AUDI`	Input value 21 (selected when K = 20).
`IN22`	Socket	`adapter::types::unidirectional::AUDI`	Input value 22 (selected when K = 21).
`IN23`	Socket	`adapter::types::unidirectional::AUDI`	Input value 23 (selected when K = 22).
`IN24`	Socket	`adapter::types::unidirectional::AUDI`	Input value 24 (selected when K = 23).
`IN25`	Socket	`adapter::types::unidirectional::AUDI`	Input value 25 (selected when K = 24).
`IN26`	Socket	`adapter::types::unidirectional::AUDI`	Input value 26 (selected when K = 25).
`IN27`	Socket	`adapter::types::unidirectional::AUDI`	Input value 27 (selected when K = 26).
`IN28`	Socket	`adapter::types::unidirectional::AUDI`	Input value 28 (selected when K = 27).
`IN29`	Socket	`adapter::types::unidirectional::AUDI`	Input value 29 (selected when K = 28).

IN30	Socket	adapter::types::unidirectional::AUDI	Input value 30 (selected when K = 29).
IN31	Socket	adapter::types::unidirectional::AUDI	Input value 31 (selected when K = 30).
IN32	Socket	adapter::types::unidirectional::AUDI	Input value 32 (selected when K = 31).

Functionality

The block continuously monitors the index value received on the K socket. When the index changes (or a new value arrives), the corresponding input adapter data (IN1 to IN32) is routed to the OUT adapter. The output value is compared with the previously forwarded value; if a difference is detected, the output is updated. If the value remains identical, no update is performed, preventing unnecessary load on downstream components.

The multiplexing logic is generic – the block is marked as a generic function block (GEN_AUDI_AUI_MUX), meaning the actual adapter types and internal behavior are resolved at deployment time.

Technical Features

- **32-to-1 multiplexing** with unidirectional adapter interfaces.
- **Change-detection** on the output: the output is only updated when the selected value actually changes.
- **No event inputs** required – the block operates autonomously on incoming adapter data.
- **Index range**: 0 to 31, corresponding to IN1 to IN32.
- **Unidirectional data flow** – all adapters are unidirectional, simplifying the interface.
- **Generic FB type** – uses the eclipse 4diac generic mechanism for late type resolution.

State Overview

The block does not expose explicit internal states. It can be conceptually described by two implicit operating phases:

1. **Idle / Monitoring** – Waiting for a new index or input value change.

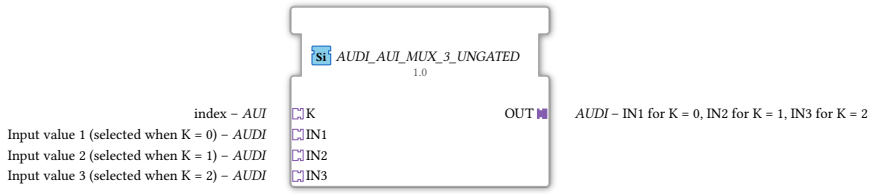
No persistent state or mode beyond the current selected value and its cached copy is maintained.

Application Scenarios

- **Signal routing in agricultural machinery** (as indicated by the source context) where one of many sensors must be connected to a display or controller.
- **Dynamic sensor selection** – choosing between 32 measurement channels based on a control index.
- **Data consolidation** – merging multiple producer adapters into a single consumer path.
- **Event-driven communication** – where downstream components should only be notified when a value really changes, to reduce bus traffic.

Comparison with Similar Blocks

Feature	AUDI_AUI_MUX_32	Conventional Data MUX
Interface	Fully adapter-based (AUDI/AUI)	Direct data inputs (ANY)
Change detection	Yes, only on real change	Typically always raises event
Number of channels	32	Variable (often 2, 4, 8)
Generic type	Yes (generic FB)	Usually typed
Event inputs	None (autonomous)	Often explicit trigger event



Compared to a classic IEC 61499 multiplexer FB (e.g., using data inputs and a selector input), this block is oriented towards adapter-based communication and provides inherent change filtering, making it better suited for distributed, event-driven systems.

Conclusion

AUDI_AUI_MUX_32 is a powerful and flexible adapter multiplexer for up to 32 unidirectional data sources. Its generic nature and change-detection behavior reduce unnecessary event traffic, while the adapter-based interface integrates seamlessly with modern 4diac IEC 61499 applications. It is especially useful in scenarios where a single consumer must be dynamically connected to a large number of producers.

AUDI_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUDI_AUI_MUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AUDI_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `UDINT`. Unlike `AUDI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AUDI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AUDI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AUDI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` ... `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_MUX`) – shared across all port counts of this block family (AUDI_AUI_MUX_2 … AUDI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 32-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUDI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AUDI_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUDI_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AUDI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AUDI_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `UDINT`. Unlike `AUDI_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AUDI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AUDI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AUDI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AUDI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_MUX`) – shared across all port counts of this block family (AUDI_AUI_MUX_2 … AUDI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 32-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUDI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AUDI_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUDI_AUI_MUX_4` carries the multiplexer logic of the `AUDI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUDI_AUI_MUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AUDI_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `UDINT`. Unlike `AUDI_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AUDI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AUDI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AUDI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AUDI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_MUX`) – shared across all port counts of this block family (AUDI_AUI_MUX_2 … AUDI_AUI_MUX_5).

Application Scenarios

- Choosing between up to 4 32-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUDI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AUDI_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUDI_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `AUDI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`AUDI_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `UDINT`. Unlike `AUDI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AUDI adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AUDI adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AUDI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AUDI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AUDI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_MUX`) – shared across all port counts of this block family (AUDI_AUI_MUX_2 … AUDI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 5 32-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUDI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AUDI_AUI_MUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUDI_AUI_MUX_5` carries the multiplexer logic of the `AUDI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUDI_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AUDI_AUI_MUX_5_UNGATED` is the adapter-based variant of the generic multiplexer for data type `UDINT`. Unlike `AUDI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUDI_AUI_MUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AUDI adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AUDI adapter type).

- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AUDI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AUDI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AUDI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUDI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUDI_AUI_MUX`) – shared across all port counts of this block family (AUDI_AUI_MUX_2 … AUDI_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

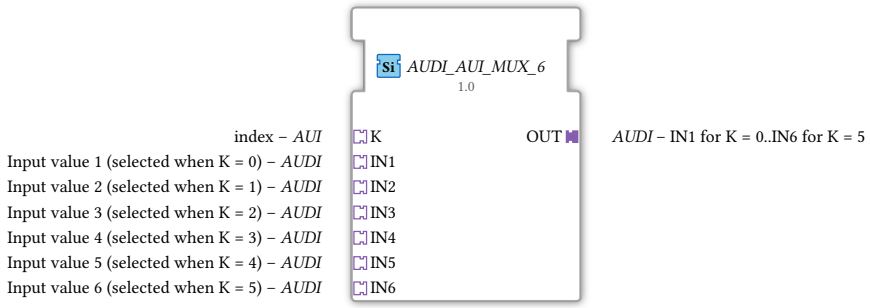
The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 5 32-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks



Compare with `AUDI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).
No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AUDI_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUDI_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AUDI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUDI_AUI_MUX_6

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUDI_AUI_MUX_6** function block is a generic 6-to-1 multiplexer specifically designed for use with unidirectional AUDI/AUI adapter types. It selects one of six input adapters (IN1…IN6) based on an index value provided via the K adapter, and forwards the selected data to a single output adapter (OUT). The block optimises communication by updating the output only when the value on the selected input actually changes, thus reducing unnecessary network traffic and processing overhead.

The block belongs to the 4diac IDE environment and follows the IEC 61499 standard. It is intended for scenarios where multiple data sources need to be routed to a common destination, with a dynamic selection mechanism.

Interface Structure

Event Inputs

None.

Event Outputs

- No event outputs.

Data Inputs

None.

Data Outputs

None.

Adapters

The block uses exclusively adapter interfaces to exchange data and control signals.

Plugs (Output):

- **OUT** (Type: `adapter::types::unidirectional::AUDI`) – The output adapter that carries the selected value. The value on this adapter is updated only when a change occurs on the currently selected input.

Sockets (Input):

- **K** (Type: `adapter::types::unidirectional::AUI`) – The index adapter. It supplies the selection index (0 to 5) that determines which of the six input adapters is routed to the output.
- **IN1** (Type: `adapter::types::unidirectional::AUDI`) – Input value 1, selected when K = 0.
- **IN2** (Type: `adapter::types::unidirectional::AUDI`) – Input value 2, selected when K = 1.
- **IN3** (Type: `adapter::types::unidirectional::AUDI`) – Input value 3, selected when K = 2.
- **IN4** (Type: `adapter::types::unidirectional::AUDI`) – Input value 4, selected when K = 3.
- **IN5** (Type: `adapter::types::unidirectional::AUDI`) – Input value 5, selected when K = 4.
- **IN6** (Type: `adapter::types::unidirectional::AUDI`) – Input value 6, selected when K = 5.

All adapters are unidirectional, meaning data flows in one direction: from the input sockets to the output plug.

Functionality

The AUDI_AUI_MUX_6 acts as a data selector. It continuously reads the value from the input adapter selected by the current index K. If the value on that input differs from the last value forwarded to the output, the block updates the output adapter. If the value remains unchanged, no output update or event is generated, thereby avoiding unnecessary communication.

The selection index K is provided through a dedicated adapter, allowing the selection to be changed dynamically during operation. The block is designed for use with adapters that carry both data and control information, but the multiplexing logic focuses solely on the data part of the adapter.

Technical Features

- **Generic Implementation** – The block is defined as a generic FB with the class name `GEN_AUDI_AUI_MUX`. This allows it to be instantiated with different underlying data types while preserving the same multiplexing behaviour.
- **Change-driven Output** – The output adapter is updated only when the value on the currently selected input changes. This reduces network load and improves efficiency in distributed automation systems.
- **Index-based Selection** – The selection index K is provided via an adapter interface, facilitating easy integration with other function blocks that can supply an AUI value.
- **No Data I/O** – The block has no dedicated data inputs or outputs; all data exchange occurs through the adapter interfaces.
- **Six Inputs, One Output** – Supports up to six different data sources, which can be selected arbitrarily.

State Overview

The block does not expose complex internal states. Its behaviour can be described by two main conditions:

1. **Value unchanged** – The value on the selected input matches the value previously forwarded to the output. In this state, no update is performed.
2. **Value changed** – The value on the selected input differs from the previously forwarded value. The output adapter is updated with the new value.

The selection index K can change at any time, and the block immediately re-evaluates the appropriate input.

Application Scenarios

- **Data Aggregation** – Combining multiple sensor readings (e.g., temperature, pressure, humidity) into a single data stream, where the current sensor is chosen via an index.
- **Mode Switching** – Switching between different parameter sets or control modes in an automation process, where the active set is determined by a selection signal.
- **Output Multiplexing** – Routing different data sources to a common display, communication module, or control output.
- **Redundancy Handling** – Selecting between redundant sensors or data paths based on a health or prioritisation index.

Comparison with Similar Blocks

Unlike a conventional multiplexer (e.g., a multi-input FB with an integer index), the AUDI_AUI_MUX_6 uses adapter interfaces for both the selection and the data. This makes it particularly suitable for distributed systems where data exchange occurs over network connections following the AUDI/AUI protocol. The key difference from a simple value multiplexer is the change-detection mechanism: most standard multiplexers unconditionally copy the selected input to the output, whereas this block suppresses redundant updates and only emits an event on actual change. This behaviour can significantly reduce network traffic in time-critical or bandwidth-limited environments.

Conclusion

The AUDI_AUI_MUX_6 is a specialised function block for multiplexing up to six unidirectional AUDI data streams to a single output, with an index-based selection via an AUI adapter. Its change-driven output update mechanism and generic design make it a valuable component in IEC 61499-based distributed automation systems where efficient data routing and minimal communication overhead are required. The block simplifies the integration of multiple data sources into a single sink, while maintaining high responsiveness.

AUDI_AUI_MUX_7

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUDI_AUI_MUX_7** is a generic multiplexer function block designed for unidirectional adapter-based selection of analog data values. It accepts up to **seven input adapters** (IN1 through IN7) and routes one of them to a single output adapter (OUT) based on an index value provided via the K adapter. The block is implemented as a generic FB with the class name `GEN_AUDI_AUI_MUX`, allowing flexible reuse in various IEC 61499 applications.

A distinctive feature of this block is its **change-driven output behavior**: the output adapter is only refreshed when the selected value actually changes. This minimizes unnecessary data traffic and event propagation in the system.

Interface Structure

Event Inputs

The block defines **no event inputs**. Activation and data flow are handled entirely through the adapter connections.

Event Outputs

The block defines **no event outputs**.

Data Inputs

The block has **no direct data inputs**. All input data is transported through adapter sockets.

Data Outputs

The block has **no direct data outputs**. All output data is transported through the adapter plug.

Adapters

Direction	Name	Type	Comment
Plug (Output)	OUT	adapter::types::unidirectional::AUDI	Delivers the selected input value.
Socket	K	adapter::types::unidirectional::AUI	Provides the index selection (0 to 6).
Socket	IN1	adapter::types::unidirectional::AUDI	Input value 1 (selected when K = 0).
Socket	IN2	adapter::types::unidirectional::AUDI	Input value 2 (selected when K = 1).
Socket	IN3	adapter::types::unidirectional::AUDI	Input value 3 (selected when K = 2).
Socket	IN4	adapter::types::unidirectional::AUDI	Input value 4 (selected when K = 3).
Socket	IN5	adapter::types::unidirectional::AUDI	Input value 5 (selected when K = 4).
Socket	IN6	adapter::types::unidirectional::AUDI	Input value 6 (selected when K = 5).
Socket	IN7	adapter::types::unidirectional::AUDI	Input value 7 (selected when K = 6).

Functionality

The AUDI_AUI_MUX_7 acts as a **7-to-1 multiplexer** operating on unidirectional adapter data. The index adapter **K** determines which of the seven input adapters (IN1…IN7) is forwarded to the output adapter **OUT**. The mapping is straightforward:

- K = 0 ⟶ OUT receives the value from IN1
- K = 1 ⟶ OUT receives the value from IN2
- …
- K = 6 ⟶ OUT receives the value from IN7

The core logic of the block performs a continuous comparison between the last transmitted output value and the newly selected input value. If the selected value differs from the previously output value, the output adapter is updated. If the value is identical to the last one, no update occurs, regardless of whether the index changed or the input data was refreshed.

This behavior ensures that downstream components only react to genuine value changes, avoiding redundant processing and reducing communication overhead.

Technical Features

- **Generic implementation** – The underlying generic FB (`GEN_AUDI_AUI_MUX`) can be instantiated for different adapter types or multiplexer widths by binding the appropriate adapter declarations.
- **Change detection** – Output update is suppressed when the selected value equals the last transmitted value.
- **Unidirectional adapters** – All adapter interfaces are of the `unidirectional` type, making the block suitable for one-way data flow scenarios without handshake or acknowledgment logic at the adapter level.
- **Seven input channels** – Specifically tailored for applications requiring up to seven selectable data sources.
- **Index range** – The K adapter must provide a value in the range 0 to 6; values outside this range are not defined and should be avoided.

State Overview

The block does not expose an explicit state machine, but its internal behavior can be modeled as follows:

State	Condition	Action
Idle	No index change and selected input value unchanged	No output update.
Update	Index changed **or** selected input value changed	New value written to OUT.

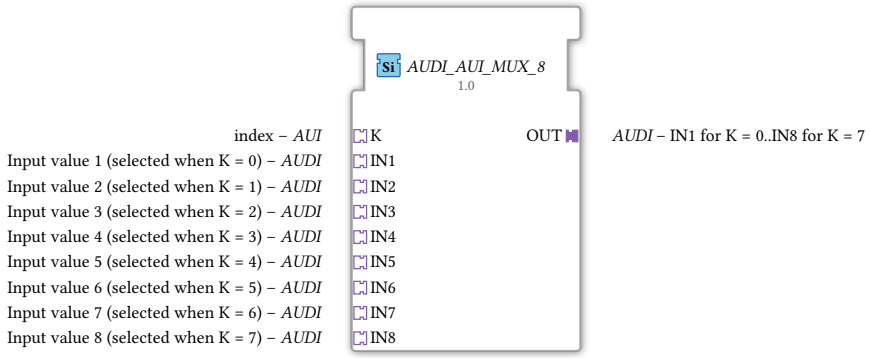
The block remains in the Idle state until one of the two trigger conditions occurs. After updating OUT, it returns to Idle until the next change is detected.

Application Scenarios

- **Sensor selection** – In agricultural or industrial machinery, the block can select between multiple analog sensors (e.g., temperature, pressure, fill level) based on a mode or channel selector.
- **Redundant measurement systems** – When several redundant sensors measure the same physical quantity, the mux can choose the active channel and only propagate the value when it actually differs from the last one.
- **Calibration and commissioning** – A service tool can switch between different test points or calibration inputs without generating unnecessary downstream events.
- **Multi-zone control** – In HVAC or process control, the block can route zone-specific values to a central controller, with event-driven updates only on real changes.

Comparison with Similar Blocks

Feature	AUDI_AUI_MUX_7	Conventional Data MUX	Event-driven MUX
Input channels	7 (adapter-based)	Typically 2/4/8 (data pins)	Variable
Interface type	Unidirectional adapters	Direct data I/O	Direct data + event I/O
Output update	Only on value change	Always on selection	On request event



Generic capability	Yes (generic class)	No (fixed type)	Often fixed

Compared to a conventional multiplexer, AUDI_AUI_MUX_7 adds intelligent change detection and adapter-based connectivity, making it more suitable for distributed, event-driven IEC 61499 systems. Unlike a simple event-triggered mux, it suppresses unnecessary output updates, which can significantly reduce network load in cyclic communication environments.

Conclusion

The **AUDI_AUI_MUX_7** is a robust and efficient adapter-based multiplexer that combines the flexibility of a generic FB with a smart change-detection mechanism. Its unidirectional adapter interface and seven input channels make it an ideal building block for modern automation systems where data consistency and communication efficiency are critical. By updating the output only when the value actually changes, it helps to keep downstream logic simple and to minimize unnecessary processing overhead.

AUDI_AUI_MUX_8

• – ◦ • – ◦ • – ◦ •

Introduction

The AUDI_AUI_MUX_8 is a generic multiplexer function block designed to select one of eight input adapters (IN1 to IN8) and forward its value to a single output adapter (OUT). The selection is controlled by a dedicated index adapter (K). This FB is implemented as a generic type (GEN_AUDI_AUI_MUX), allowing flexible adaptation across different data types. A key feature is that the output adapter is only updated when the actual value changes.

Interface Structure

Event Inputs

None.

Event Outputs

No event outputs.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Plug (Output)	OUT	adapter::types::unidirectional::AUDI	Selected input value is forwarded to this output adapter.

Socket (Input)	K	adapter::types::unidirectional::AUI	Index selection adapter. Determines which input (IN1..IN8) is routed to OUT.
Socket (Input)	IN1	adapter::types::unidirectional::AUDI	Input value 1, selected when K = 0.
Socket (Input)	IN2	adapter::types::unidirectional::AUDI	Input value 2, selected when K = 1.
Socket (Input)	IN3	adapter::types::unidirectional::AUDI	Input value 3, selected when K = 2.
Socket (Input)	IN4	adapter::types::unidirectional::AUDI	Input value 4, selected when K = 3.
Socket (Input)	IN5	adapter::types::unidirectional::AUDI	Input value 5, selected when K = 4.
Socket (Input)	IN6	adapter::types::unidirectional::AUDI	Input value 6, selected when K = 5.
Socket (Input)	IN7	adapter::types::unidirectional::AUDI	Input value 7, selected when K = 6.
Socket (Input)	IN8	adapter::types::unidirectional::AUDI	Input value 8, selected when K = 7.

Functionality

The AUDI_AUI_MUX_8 function block acts as an 8-to-1 multiplexer for adapter-based data. It reads the index value from the K adapter and selects the corresponding input adapter (IN1 to IN8). The value of the selected input is then copied to the output adapter OUT. The selection follows a direct mapping:

- K = 0 ⟶ IN1
- K = 1 ⟶ IN2
- K = 2 ⟶ IN3
- K = 3 ⟶ IN4
- K = 4 ⟶ IN5
- K = 5 ⟶ IN6
- K = 6 ⟶ IN7
- K = 7 ⟶ IN8

The output is updated only when the value of the selected input differs from the current output value. If no change is detected, the OUT adapter remains unchanged and no update is performed. This behavior reduces unnecessary communication and processing overhead in the system.

Technical Features

- **Generic implementation**: The FB is based on the generic class GEN_AUDI_AUI_MUX, making it adaptable for different data types.
- **Adapter-based connectivity**: All inputs and the output use unidirectional adapter interfaces, ensuring clean and type-safe connections.
- **Eight selectable channels**: Supports up to 8 distinct input sources.
- **Single index input**: The selection is performed via a dedicated index adapter (K), simplifying control logic.

State Overview

The FB does not maintain a complex state machine. It operates in a purely combinatorial manner from the perspective of value selection. However, an internal state holds the last output value to enable change detection. When a new selection is made or an input value changes:

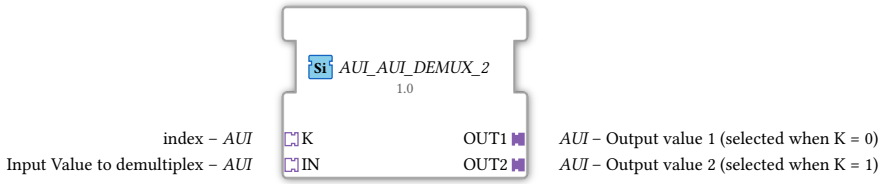
1. The index K is evaluated.
2. The corresponding input is read.
3. The new value is compared with the stored output value.
4. If different, the OUT adapter is updated.

Application Scenarios

- **Data source selection**: Switching between multiple sensor signals in automation systems.
- **Redundancy handling**: Selecting among redundant data sources based on availability or quality criteria.
- **Configuration switches**: Routing different parameter sets to a common processing unit.
- **Multi-zone monitoring**: Selecting zone-specific data for a central controller.

Comparison with Similar Blocks

Compared to standard multiplexer FBs (e.g., those with discrete data inputs), the AUDI_AUI_MUX_8 uses adapter interfaces instead of plain data pins. This allows it to connect to complex datatype structures and unidirectional communication channels. Unlike many other multiplexers, this FB only updates the output when the value actually changes, making it more efficient for event-driven systems. It also provides a generic implementation, which reduces the need for multiple specific FB types.



Conclusion

The AUDI_AUI_MUX_8 function block provides a flexible and efficient multiplexing solution for adapter-based data in 4diac IDE applications. Its generic nature, combined with change-detection logic, makes it well-suited for modern, event-driven industrial automation systems where bandwidth and processing efficiency are important. The clear mapping of index to input simplifies configuration and integration.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AUI_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AUI_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `UINT`. Unlike `AUI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUI_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit unsigned integer to forward, routed to exactly one of the outputs (AUI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AUI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_DEMUX`) – shared across all port counts of this block family (AUI_AUI_DEMUX_2 … AUI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is `UINT`, `AUI_AUI_DEMUX_2` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

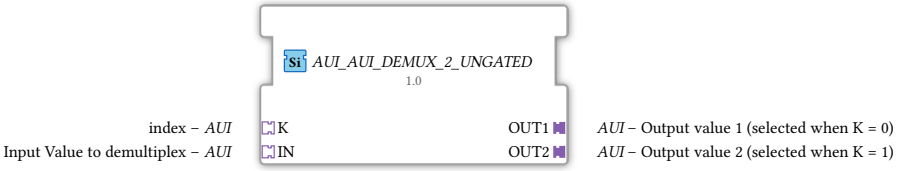
Application Scenarios

- Distributing a 16-bit unsigned integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUI_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUI_AUI_DEMUX_2` carries the demultiplexer logic of the `AUI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AUI_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `UINT`. Unlike `AUI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUI_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit unsigned integer to forward, routed to exactly one of the outputs (AUI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AUI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_DEMUX`) – shared across all port counts of this block family (AUI_AUI_DEMUX_2_UNGATED … AUI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

- Because this block's own payload type is `UINT`, `AUI_AUI_DEMUX_2_UNGATED` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

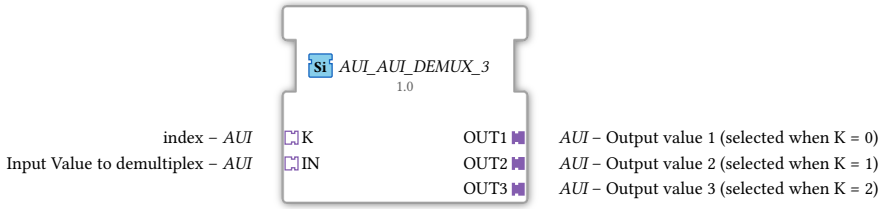
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 16-bit unsigned integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUI_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUI_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AUI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AUI_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `UINT`. Unlike `AUI_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUI_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit unsigned integer to forward, routed to exactly one of the outputs (AUI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AUI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AUI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

`AUI_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AUI_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AUI_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `UINT`. Unlike `AUI_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input,

but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUI_AUI_DEMUX_4 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 16-bit unsigned integer to forward, routed to exactly one of the outputs (AUI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AUI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AUI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AUI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 4 output adapters (OUT1 … OUT4) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AUI_AUI_DEMUX) – shared across all port counts of this block family (AUI_AUI_DEMUX_2 … AUI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is UINT, AUI_AUI_DEMUX_4 uses the same adapter type (AUI) for both the payload (IN/OUT) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

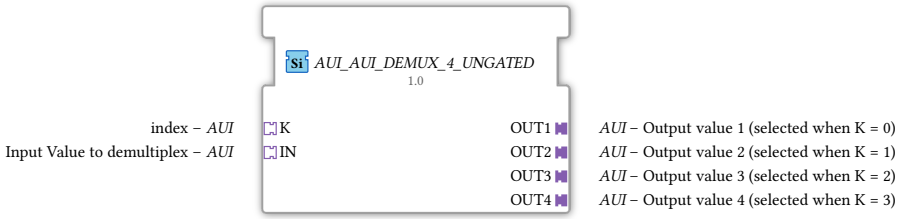
Application Scenarios

- Distributing a 16-bit unsigned integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUI_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUI_AUI_DEMUX_4` carries the demultiplexer logic of the `AUI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). • – ◦ • – ◦ • – ◦ •

Introduction

`AUI_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `UINT`. Unlike `AUI_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUI_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN** (Socket): input adapter carrying the 16-bit unsigned integer to forward, routed to exactly one of the outputs (AUI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AUI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AUI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AUI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_DEMUX`) – shared across all port counts of this block family (AUI_AUI_DEMUX_2 … AUI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is `UINT`, `AUI_AUI_DEMUX_4_UNGATED` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

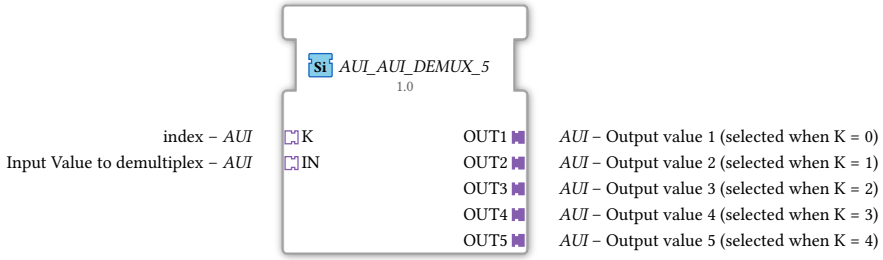
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 16-bit unsigned integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUI_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

AUI_AUI_DEMUX_4_UNGATED carries the demultiplexer logic of the AUI_DEMUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_DEMUX_5

• – ○ • – ○ • – ○ •

Introduction

AUI_AUI_DEMUX_5 is the adapter-based variant of the generic demultiplexer for data type UINT. Unlike AUI_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUI_AUI_DEMUX_5 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 16-bit unsigned integer to forward, routed to exactly one of the outputs (AUI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AUI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AUI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AUI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AUI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 5 output adapters (OUT1 … OUT5) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_DEMUX`) – shared across all port counts of this block family (AUI_AUI_DEMUX_2 … AUI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is `UINT`, `AUI_AUI_DEMUX_5` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

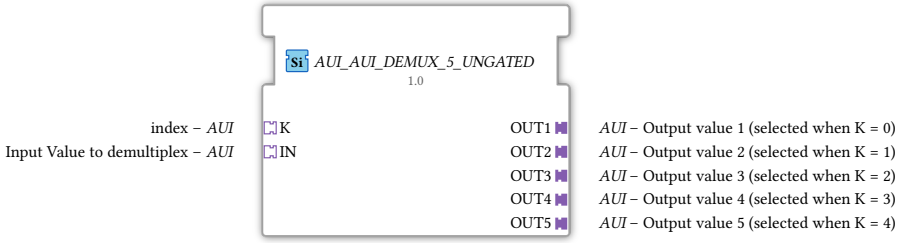
Application Scenarios

- Distributing a 16-bit unsigned integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUI_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUI_AUI_DEMUX_5` carries the demultiplexer logic of the `AUI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_DEMUX_5_UNGATED

i UNGATED variant: This block is the ungated version of AUI_AUI_DEMUX_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AUI_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `UINT`. Unlike `AUI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUI_AUI_DEMUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit unsigned integer to forward, routed to exactly one of the outputs (AUI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AUI adapter type).

- Because this block's own payload type is `UINT`, `AUI_AUI_DEMUX_5_UNGATED` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

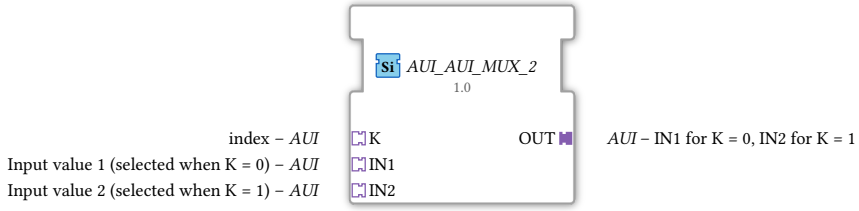
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 16-bit unsigned integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUI_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUI_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AUI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AUI_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `UINT`. Unlike `AUI_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUI_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AUI adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AUI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_MUX`) – shared across all port counts of this block family (AUI_AUI_MUX_2 … AUI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is `UINT`, `AUI_AUI_MUX_2` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

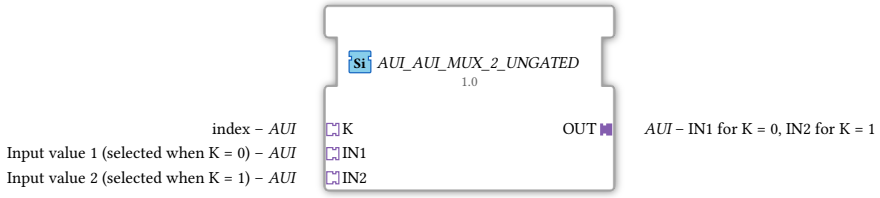
Application Scenarios

- Choosing between up to 2 16-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AUI_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUI_AUI_MUX_2` carries the multiplexer logic of the `AUI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_MUX_2_UNGATED

• – ○ • – ○ • – ○ •

Introduction

AUI_AUI_MUX_2_UNGATED is the adapter-based variant of the generic multiplexer for data type UINT. Unlike AUI_MUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUI_AUI_MUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 2, passed through to OUT when the index is K = 0 (AUI adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to OUT when the index is K = 1 (AUI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN2:

1. The current value of K.D1 determines which of the 2 input adapters (IN1 … IN2) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_MUX`) – shared across all port counts of this block family (AUI_AUI_MUX_2_UNGATED … AUI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is `UINT`, `AUI_AUI_MUX_2_UNGATED` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

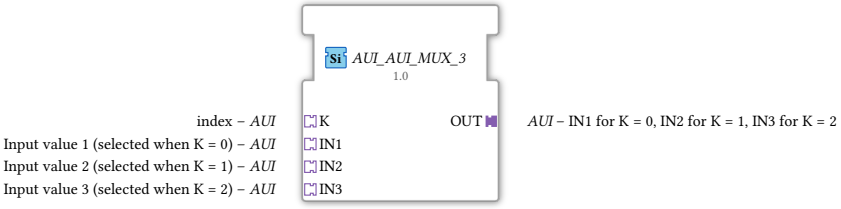
- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 16-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AUI_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUI_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AUI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

`AUI_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `UINT`. Unlike `AUI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUI_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AUI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AUI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AUI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_MUX`) – shared across all port counts of this block family (AUI_AUI_MUX_2 … AUI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is `UINT`, `AUI_AUI_MUX_3` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) → read the currently selected input, update `OUT` on a value change and send its adapter event.

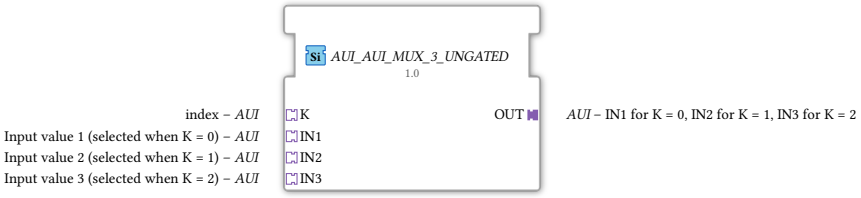
Application Scenarios

- Choosing between up to 3 16-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AUI_MUX_3 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **AUI_AUI_MUX_3_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AUI_AUI_MUX_3 carries the multiplexer logic of the AUI_MUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUI_AUI_MUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AUI_AUI_MUX_3_UNGATED is the adapter-based variant of the generic multiplexer for data type UINT. Unlike AUI_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUI_AUI_MUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AUI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AUI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AUI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_MUX`) – shared across all port counts of this block family (AUI_AUI_MUX_2 … AUI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is `UINT`, `AUI_AUI_MUX_3_UNGATED` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 16-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖ Comparison with Similar Blocks

Compare with `AUI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AUI_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUI_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AUI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AUI_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `UINT`. Unlike `AUI_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUI_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AUI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AUI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AUI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AUI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_MUX`) – shared across all port counts of this block family (AUI_AUI_MUX_2 … AUI_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is `UINT`, `AUI_AUI_MUX_4` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

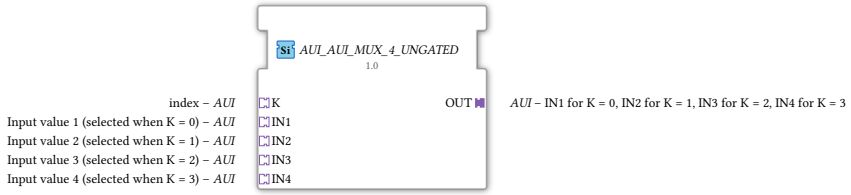
Application Scenarios

- Choosing between up to 4 16-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AUI_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUI_AUI_MUX_4` carries the multiplexer logic of the `AUI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_AUI_MUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AUI_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `UINT`. Unlike `AUI_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). Conclusion

`AUI_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `AUI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`AUI_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `UINT`. Unlike `AUI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUI_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AUI adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AUI adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AUI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AUI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AUI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` ... `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUI_AUI_MUX`) – shared across all port counts of this block family (AUI_AUI_MUX_2 ... AUI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.
- Because this block's own payload type is `UINT`, `AUI_AUI_MUX_5` uses the same adapter type (`AUI`) for both the payload (`IN`/`OUT`) and the index socket **K** – the two roles are wired independently even though they share an adapter type.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

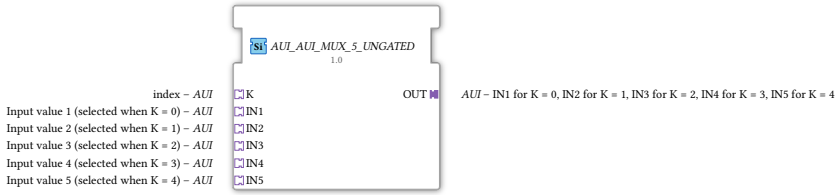
Application Scenarios

- Choosing between up to 5 16-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AUI_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUI_AUI_MUX_5` carries the multiplexer logic of the `AUI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUI_AUI_MUX_5`. Application Scenarios

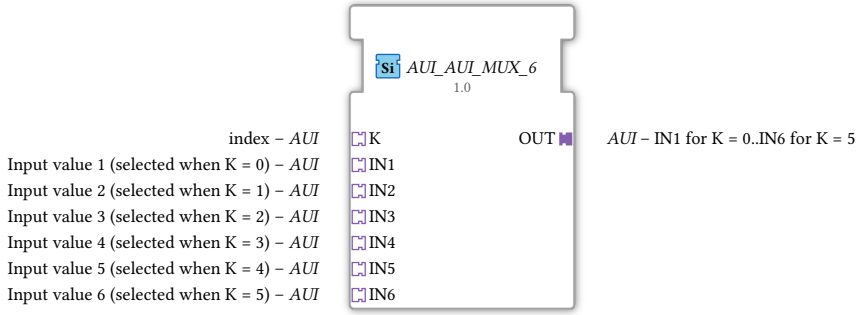
- Choosing between up to 5 16-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- `AUI_AUI_MUX_5`: The gated variant – updates the output only on an actual value change.

Conclusion

`AUI_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AUI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUI_AUI_MUX_6

• – ○ • – ○ • – ○ •

Introduction

AUI_AUI_MUX_6 is an adapter-based multiplexer function block. It selects one of six unidirectional AUI adapter inputs, `IN1` through `IN6`, based on the index value received through the `K` adapter. The selected value is forwarded to the `OUT` adapter plug. The output is updated only when the actual value changes.

Interface Structure

Event Inputs

None. The FB does not expose dedicated event inputs. Its operation is triggered through the connected adapter interfaces, in particular through changes on the `K` index adapter.

Event Outputs

No event outputs.

Data Inputs

None. Data is transferred through the AUI adapter connections instead of dedicated data inputs.

Data Outputs

None. The selected value is made available through the `OUT` adapter plug.

Adapters

Direction	Name	Adapter Type	Description
Socket	`K`	`adapter::types::unidirectional::AUI`	Index adapter. Determines which input is selected.
Socket	`IN1`	`adapter::types::unidirectional::AUI`	Input value 1, selected when `K = 0`.
Socket	`IN2`	`adapter::types::unidirectional::AUI`	Input value 2, selected when `K = 1`.
Socket	`IN3`	`adapter::types::unidirectional::AUI`	Input value 3, selected when `K = 2`.
Socket	`IN4`	`adapter::types::unidirectional::AUI`	Input value 4, selected when `K = 3`.
Socket	`IN5`	`adapter::types::unidirectional::AUI`	Input value 5, selected when `K = 4`.
Socket	`IN6`	`adapter::types::unidirectional::AUI`	Input value 6, selected when `K = 5`.
Plug	`OUT`	`adapter::types::unidirectional::AUI`	Selected AUI output. Represents `IN1` for `K = 0` up to `IN6` for `K = 5`.

Functionality

AUI_AUI_MUX_6 behaves as a multiplexer for AUI adapter connections. It reads the value provided through the `K` socket and interprets it as an integer index between `0` and `5`. Based on this index, one of the six input adapters is routed to the `OUT` adapter.

The FB is designed to avoid unnecessary communication. If a new index value is received but the selected output value has not actually changed, the output is not rewritten and no event is generated. Only when a real value change occurs is the `OUT` adapter updated.

Because `K` is itself an AUI adapter, the index can be supplied by another adapter-compatible block, making the FB suitable for use in adapter-oriented IEC 61499 architectures.

Technical Features

- Six unidirectional AUI input sockets and one unidirectional AUI output plug.
- No direct event inputs or data pins; all communication is performed via adapter interfaces.
- Index range `0` to `5` selects `IN1` to `IN6`.
- Output update is suppressed when the value has not changed.
- The FB is defined as a generic block with the generic class name `GEN_AUI_AUI_MUX`.
- The block is distributed under the Eclipse Public License 2.0.

State Overview

The FB does not contain an explicit ECC state machine in its type definition. Its behavior can therefore be described conceptually:

State	Description
Idle	Waiting for a new index value or value change on the selected input.
Evaluating	The `K` adapter value is read and interpreted as the selection index.
Updating	The selected input value is transferred to the `OUT` adapter.
Returning	The FB then returns to the idle state.

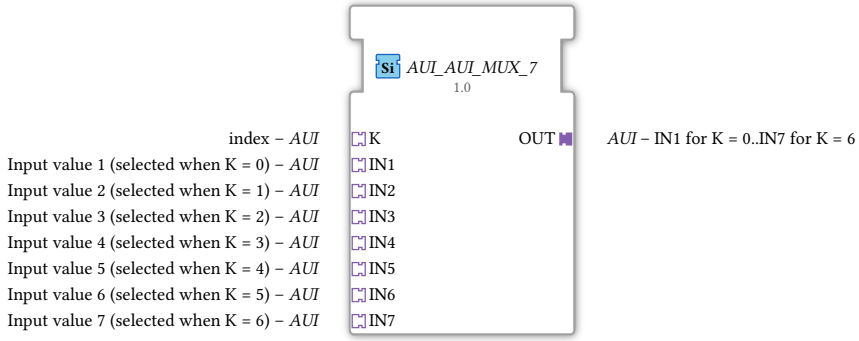
Application Scenarios

- Selecting one of six AUI data sources based on a dynamic index.
- Routing adapter-based signals in modular automation systems.
- Switching between measurement or configuration values without generating redundant events.

- Use in applications where event-on-change behavior is required to reduce communication load.

Comparison with Similar Blocks

Compared to a conventional IEC 61499 MUX block, AUI_AUI_MUX_6 does not use individual data inputs and a `REQ` event input. Instead, it uses unidirectional AUI adapter sockets, which allows a more structured and reusable connection style.



In contrast to a standard multiplexer, this FB updates its output only when the output value actually changes. This makes it particularly useful in event-driven systems where unnecessary events should be avoided.

As a generic FB, it can be instantiated through the generic class name `GEN_AUI_AUI_MUX`, providing flexible tool support while keeping the adapter-based interface consistent.

Conclusion

AUI_AUI_MUX_6 is a compact and useful building block for adapter-based selection and routing tasks. It combines multiplexing functionality with event-on-change behavior, reducing unnecessary output updates. Its six AUI inputs make it well suited for systems that need to choose among multiple unidirectional adapter connections.

AUI_AUI_MUX_7

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_AUI_MUX_7** is a generic, adapter-based multiplexer function block designed to select one of seven input channels and forward its value to a single output. The selection is performed via a dedicated index adapter (`K`). The block is part of the unidirectional adapter type system and is characterized by an event-driven output update mechanism: the output adapter is only refreshed when the selected value actually changes, thereby suppressing redundant events and data transmissions.

Interface Structure

Event Inputs

The function block does not declare any explicit event inputs. Its operation is purely data-driven through the adapter sockets; changes on the selected input adapter trigger the internal processing and subsequent output update.

Event Outputs

No event outputs.

Data Inputs

The block does not expose any direct data inputs. All input data is carried through the adapter sockets listed below.

Data Outputs

The block does not expose any direct data outputs. All output data is carried through the adapter plug `OUT`.

Adapters

Plugs (Outputs):

Name	Type	Comment
OUT	adapter::types::unidirectional::AUI	Selected input value; IN1 for K=0 ... IN7 for K=6

Sockets (Inputs):

Name	Type	Comment
K	adapter::types::unidirectional::AUI	Index; selects one of the 7 input channels (0...6)
IN1	adapter::types::unidirectional::AUI	Input value 1 (selected when K = 0)
IN2	adapter::types::unidirectional::AUI	Input value 2 (selected when K = 1)
IN3	adapter::types::unidirectional::AUI	Input value 3 (selected when K = 2)
IN4	adapter::types::unidirectional::AUI	Input value 4 (selected when K = 3)
IN5	adapter::types::unidirectional::AUI	Input value 5 (selected when K = 4)
IN6	adapter::types::unidirectional::AUI	Input value 6 (selected when K = 5)
IN7	adapter::types::unidirectional::AUI	Input value 7 (selected when K = 6)

Functionality

The block operates as a 7-to-1 multiplexer on the AUI adapter level. The index adapter `K` determines which of the seven input adapters (`IN1` ... `IN7`) is routed to the output adapter `OUT`. The mapping is straightforward:

- `K = 0` ⟶ `IN1`
- `K = 1` ⟶ `IN2`
- `K = 2` ⟶ `IN3`
- `K = 3` ⟶ `IN4`
- `K = 4` ⟶ `IN5`
- `K = 5` ⟶ `IN6`
- `K = 6` ⟶ `IN7`

The output is **not** updated on every input change. Instead, the output adapter is refreshed only when the value of the currently selected input channel deviates from the previously forwarded value. If the selected input value remains unchanged, no output update is performed and no event is generated. This behavior minimizes unnecessary data traffic on the output adapter connection.

Technical Features

- **Generic FB Implementation:** The block is defined as a generic type (`GEN_AUI_AUI_MUX`) and instantiated for the 7-input variant.
- **Unidirectional Adapter Interface:** All adapters (input and output) use the `adapter::types::unidirectional::AUI` type, ensuring a one-way data flow.
- **Event-Driven Output Update:** Output refresh occurs solely on actual value change, reducing communication overhead.
- **No Direct Data I/O:** All data exchange is encapsulated within the adapter interface, promoting modular and reusable design.

State Overview

The block does not exhibit a complex state machine. Its behavior can be described as:

1. **Idle / Monitoring State:** The block monitors the index adapter `K` and the selected input channel.
2. **Change Detection State:** When the index changes or the value of the selected input changes, the block compares the new value with the previously forwarded value.

Application Scenarios

- **Sensor Selection:** Selecting between multiple sensors or measurement sources connected via AUI adapters, forwarding only the active channel's data.
- **Data Source Routing:** Routing data from multiple production lines or machines to a single monitoring or control interface.

- **Mode Switching:** Switching between different operational parameter sets (e.g., configuration profiles) in an IEC 61499-based automation system.
- **Reducing Bus Load:** In distributed systems, using the change-detection mechanism to avoid unnecessary network traffic when values remain stable.

Feature	AUI_AUI_MUX_7	Typical data MUX (ANSI/IEC)
Interface	Adapter-based (AUI)	Direct data pins
Number of inputs	7	Typically 2, 4, 8 (binary select)
Selection	Via adapter `K`	Via binary select lines
Output update	Only on value change	Always on new input/select
Generic instantiation	Yes (`GEN_AUI_AUI_MUX`)	Usually fixed type

Compared to conventional data multiplexers, this block offers a cleaner adapter abstraction, supports a larger number of inputs, and incorporates an event-based change detection that can significantly reduce communication and processing overhead in event-driven 4diac applications.

Conclusion

The **AUI_AUI_MUX_7** provides a robust and efficient solution for adapter-level multiplexing in IEC 61499 environments. Its key strengths lie in the unidirectional adapter interface, the generic instantiation pattern, and the intelligent change-detection mechanism that only updates the output when actual value differences occur. This makes it particularly suitable for distributed automation scenarios where bandwidth and processing efficiency are critical.

AUI_AUI_MUX_8

• – ◦ • – ◦ • – ◦ •

Introduction

The **AUI_AUI_MUX_8** is a generic unidirectional multiplexer function block designed for selecting one of eight input adapters and forwarding its value to a single output adapter. It is part of the AUI (Agrartechnik Universal Interface) adapter family and provides a compact, event-driven solution for dynamic signal routing in automation applications.

This block acts as a selector: based on the index value provided on the **K** adapter, exactly one of the eight input channels (**IN1** to **IN8**) is connected to the output adapter **OUT**. The output is only refreshed when the selected index actually changes, reducing unnecessary network traffic and event load in distributed control systems.

The block is implemented as a generic function block (generic class name `GEN_AUI_AUI_MUX`), allowing reuse across different data types supported by the underlying AUI adapter type.

Interface Structure

Event Inputs

The block has **no event inputs**. All triggering is performed implicitly through value changes on the **K** index adapter.

Event Outputs

No event outputs.

Data Inputs

The block has **no direct data inputs**. All input values are carried via adapter sockets.

Data Outputs

The block has **no direct data outputs**. All output values are carried via the adapter plug.

Adapters

Output Plug (Plugs)

Adapter	Type	Description
OUT	`adapter::types::unidirectional::AUI`	Active output carrying the value of the selected input channel (IN1 for K = 0 … IN8 for K = 7).

Input Sockets (Sockets)

Adapter	Type	Description
K	`adapter::types::unidirectional::AUI`	Index selector. Determines which input channel is forwarded to **OUT** (valid range: 0–7).
IN1	`adapter::types::unidirectional::AUI`	Input value 1, selected when K = 0.
IN2	`adapter::types::unidirectional::AUI`	Input value 2, selected when K = 1.
IN3	`adapter::types::unidirectional::AUI`	Input value 3, selected when K = 2.
IN4	`adapter::types::unidirectional::AUI`	Input value 4, selected when K = 3.
IN5	`adapter::types::unidirectional::AUI`	Input value 5, selected when K = 4.
IN6	`adapter::types::unidirectional::AUI`	Input value 6, selected when K = 5.
IN7	`adapter::types::unidirectional::AUI`	Input value 7, selected when K = 6.
IN8	`adapter::types::unidirectional::AUI`	Input value 8, selected when K = 7.

Functionality

The multiplexer operates on an event-driven basis:

1. The index value **K** is continuously monitored through its adapter socket.
2. Whenever **K** changes to a new value within the valid range (0–7), the block connects the corresponding input adapter (**IN1** through **IN8**) to the output adapter **OUT**.
3. The connected input's current value is copied to **OUT**.

Key design characteristic: **the output is only updated when the index value actually changes**. If **K** is set repeatedly to the same index, no update occurs. This behavior minimizes unnecessary communication on the output adapter and reduces processing overhead in the connected downstream logic.

The block is declared as a generic FB (`eclipse4diac::core::GenericClassName = 'GEN_AUI_AUI_MUX'`), meaning it can be instantiated with type parameters to match the concrete AUI adapter variant required by the application.

Technical Features

- **Eight-to-one multiplexing** with unidirectional AUI adapter type.
- **Change-only update strategy** – output is refreshed exclusively when the selected index changes, avoiding redundant transmissions.
- **Generic implementation** – can be specialized via the generic class name for different adapter data types.
- **Adapter-based interface** – no direct data pins; all data traffic flows through standardised AUI adapters, enabling easy connection to other AUI-compatible blocks.
- **Standard compliance** – conforms to IEC 61499-2 for distributed automation function blocks.
- **License** – distributed under the Eclipse Public License 2.0.

State Overview

The block maintains an internal state representing the currently active index. The following state transitions occur:

Current State	Trigger Condition	Action	New State
Idle	No change on **K**	None (no output update, no event)	Idle
Idle	**K** changes to valid index n	Select **IN_(n+1)**, copy value to **OUT**	Active (index n)
Active	**K** changes to a different valid index m	Select **IN_(m+1)**, copy value to **OUT**	Active (index m)
Active	**K** set to same value again	No action (no update, no event)	Active (unchanged)
Any	**K** out of valid range (0–7)	No valid selection; output remains unchanged	Last valid state

The internal state is only the last applied index; no additional sequencing or timeout logic is required.

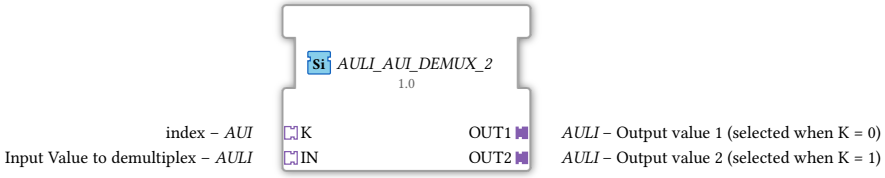
Application Scenarios

- **Sensor selection in agricultural machinery**: Switch between multiple sensors (e.g., temperature, pressure, fill level) connected to a single processing unit, using an index signal to select the active measurement source.
- **Mode-dependent data routing**: Redirect different data sources to a common consumer depending on the current operating mode (e.g., automatic, manual, service).
- **Redundant channel handling**: Select between redundant or alternative data paths (e.g., primary vs. backup sensor) based on a health-check index.
- **Parameter multiplexing in distributed control**: Combine multiple configuration values arriving on separate AUI adapters into one output stream for a downstream controller.
- **Test and commissioning**: Dynamically switch between different test signal generators feeding a single measurement or logging unit.

Comparison with Similar Blocks

Block	Type	Number of Inputs	Update Behaviour	Output Event
AUI_AUI_MUX_8	Adapter-based	8	Only on index change	None
Typical MUX (data pin)	Direct data	2–16	On every input change or on selector event	Usually none
AUI_AUI_MUX_2	Adapter-based	2	Only on index change	None
DEMUX variants	Adapter-based	1 input, multiple outputs	Selects one of several outputs	Optional confirmation

Compared to classic data-pin multiplexers, this block offers the advantage of a fully adapter-based interface, making it seamlessly interoperable with other AUI blocks in the 4diac environment. Its change-only update strategy distinguishes it from conventional multiplexers that propagate updates on every input variation, which can be beneficial in bandwidth-constrained or event-intensive systems.



Conclusion

The **AUI_AUI_MUX_8** is a versatile, generic multiplexer block for the AUI adapter family, providing reliable eight-channel selection with a change-detection mechanism. Its adapter-only interface and change-detection logic make it well suited for modern distributed automation applications where communication efficiency and modularity are essential. By integrating seamlessly with the Eclipse 4diac suite and adhering to the IEC 61499 standard, it offers a robust solution for signal routing tasks in agricultural, industrial, and process automation environments.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AULI_AUI_DEMUX_2

• – ○ • – ○ • – ○ •

Introduction

`AULI_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `ULINT`. Unlike `AULI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit unsigned integer to forward, routed to exactly one of the outputs (AULI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AULI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_DEMUX`) – shared across all port counts of this block family (AULI_AUI_DEMUX_2 … AULI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

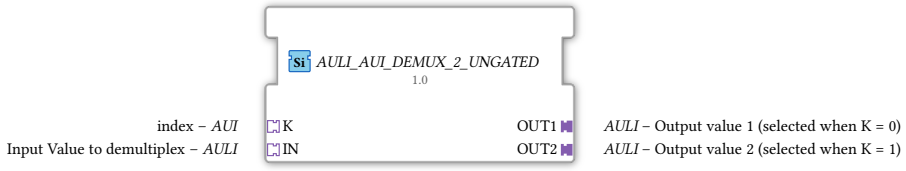
Application Scenarios

- Distributing a 64-bit unsigned integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AULI_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AULI_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AULI_AUI_DEMUX_2` carries the demultiplexer logic of the `AULI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AULI_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `ULINT`. Unlike `AULI_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit unsigned integer to forward, routed to exactly one of the outputs (AULI adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AULI adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_DEMUX`) – shared across all port counts of this block family (AULI_AUI_DEMUX_2_UNGATED … AULI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AULI_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AULI_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AULI_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AULI_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `ULINT`. Unlike `AULI_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN** (Socket): input adapter carrying the 64-bit unsigned integer to forward, routed to exactly one of the outputs (AULI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AULI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AULI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_DEMUX`) – shared across all port counts of this block family (AULI_AUI_DEMUX_2 … AULI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

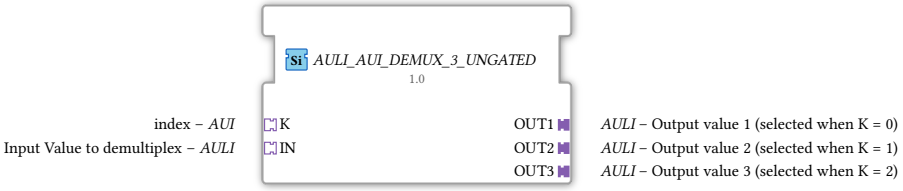
Application Scenarios

- Distributing a 64-bit unsigned integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AULI_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AULI_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AULI_AUI_DEMUX_3` carries the demultiplexer logic of the `AULI_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_DEMUX_3_UNGATED

i UNGATED variant: This block is the ungated version of AULI_AUI_DEMUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AULI_AUI_DEMUX_3_UNGATED is the adapter-based variant of the generic demultiplexer for data type ULINT. Unlike AULI_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AULI_AUI_DEMUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 64-bit unsigned integer to forward, routed to exactly one of the outputs (AULI adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AULI adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AULI adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 3 output adapters (OUT1 … OUT3) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AULI_AUI_DEMUX) – shared across all port counts of this block family (AULI_AUI_DEMUX_2 … AULI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

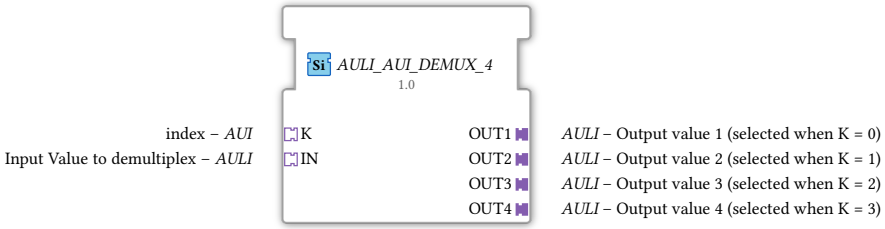
- **Any event** (selector adapter K or IN) ⟶ determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit unsigned integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AULI_DEMUX_3 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **AULI_AUI_DEMUX_3**: The gated variant – updates the output only on an actual value change.

Conclusion

AULI_AUI_DEMUX_3_UNGATED carries the demultiplexer logic of the AULI_DEMUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

AULI_AUI_DEMUX_4 is the adapter-based variant of the generic demultiplexer for data type ULINT. Unlike AULI_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit unsigned integer to forward, routed to exactly one of the outputs (AULI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AULI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AULI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AULI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_DEMUX`) – shared across all port counts of this block family (AULI_AUI_DEMUX_2 … AULI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

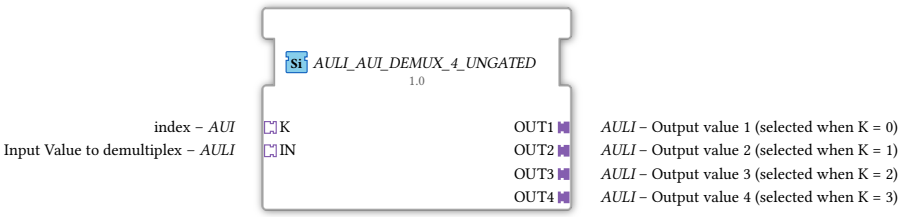
Application Scenarios

- Distributing a 64-bit unsigned integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AULI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AULI_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AULI_AUI_DEMUX_4` carries the demultiplexer logic of the `AULI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AULI_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `ULINT`. Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the 64-bit unsigned integer to forward, routed to exactly one of the outputs (AULI adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AULI adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AULI adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AULI adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_DEMUX`) – shared across all port counts of this block family (AULI_AUI_DEMUX_2 … AULI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

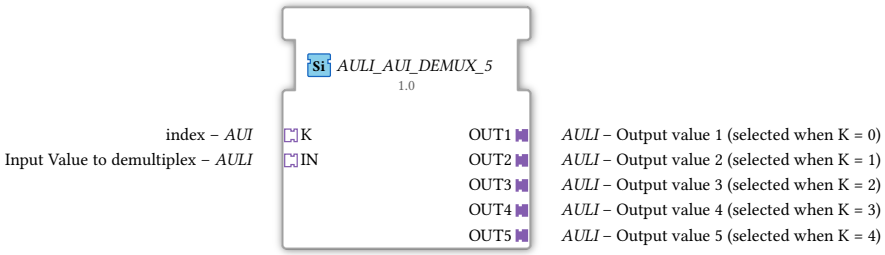
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit unsigned integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AULI_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AULI_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AULI_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AULI_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AULI_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `ULINT`. Unlike `AULI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit unsigned integer to forward, routed to exactly one of the outputs (AULI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AULI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AULI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AULI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AULI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_DEMUX`) – shared across all port counts of this block family (AULI_AUI_DEMUX_2 … AULI_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

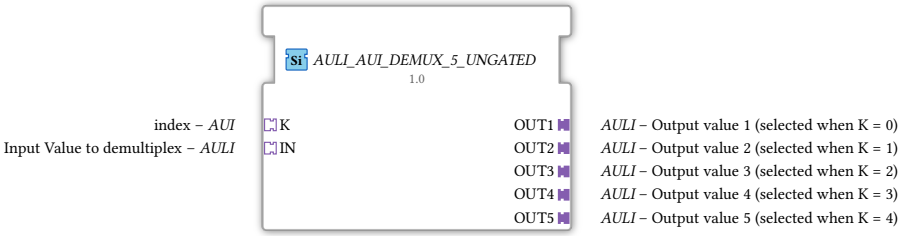
Application Scenarios

- Distributing a 64-bit unsigned integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AULI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AULI_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AULI_AUI_DEMUX_5` carries the demultiplexer logic of the `AULI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_AUI_DEMUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AULI_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `ULINT`. Unlike `AULI_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K

data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_DEMUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 64-bit unsigned integer to forward, routed to exactly one of the outputs (AULI adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AULI adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AULI adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AULI adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AULI adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_DEMUX`) – shared across all port counts of this block family (AULI_AUI_DEMUX_2 … AULI_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

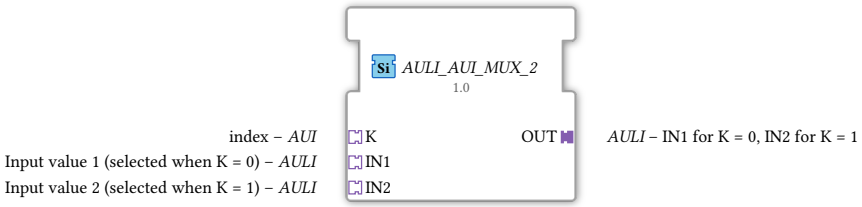
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 64-bit unsigned integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AULI_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AULI_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AULI_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AULI_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AULI_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `ULINT`. Unlike `AULI_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AULI adapter type).

- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AULI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_MUX`) – shared across all port counts of this block family (AULI_AUI_MUX_2 … AULI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

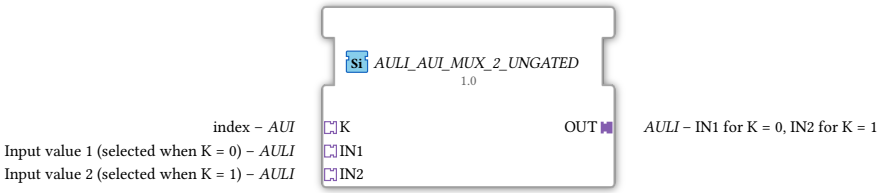
Application Scenarios

- Choosing between up to 2 64-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AULI_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AULI_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AULI_AUI_MUX_2` carries the multiplexer logic of the `AULI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_MUX_2_UNGATED

Conclusion

`AULI_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AULI_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_MUX_3

• – ∘ • – ∘ • – ∘ •

Introduction

`AULI_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `ULINT`. Unlike `AULI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AULI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AULI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AULI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_MUX`) – shared across all port counts of this block family (AULI_AUI_MUX_2 … AULI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

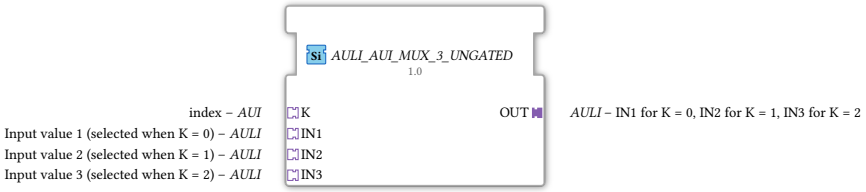
- Choosing between up to 3 64-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AULI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AULI_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.



Conclusion

`AULI_AUI_MUX_3` carries the multiplexer logic of the `AULI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_AUI_MUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change

(e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• — ○ • — ○ • — ○ •

Introduction

`AULI_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `ULINT`. Unlike `AULI_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AULI adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AULI adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AULI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_MUX`) – shared across all port counts of this block family (AULI_AUI_MUX_2 … AULI_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 64-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AULI_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AULI_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AULI_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AULI_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AULI_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `ULINT`. Unlike `AULI_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AULI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AULI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AULI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AULI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_MUX`) – shared across all port counts of this block family (AULI_AUI_MUX_2 … AULI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 64-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AULI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AULI_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AULI_AUI_MUX_4 carries the multiplexer logic of the AULI_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AULI_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AULI_AUI_MUX_4_UNGATED is the adapter-based variant of the generic multiplexer for data type ULINT. Unlike AULI_MUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AULI_AUI_MUX_4_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 4, passed through to OUT when the index is K = 0 (AULI adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to OUT when the index is K = 1 (AULI adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to OUT when the index is K = 2 (AULI adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to OUT when the index is K = 3 (AULI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN4:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_MUX`) – shared across all port counts of this block family (AULI_AUI_MUX_2 … AULI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 64-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AULI_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AULI_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AULI_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `AULI_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`AULI_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `ULINT`. Unlike `AULI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AULI adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AULI adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AULI adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AULI adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AULI adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AULI adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AULI_AUI_MUX`) – shared across all port counts of this block family (AULI_AUI_MUX_2 … AULI_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 5 64-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AULI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AULI_AUI_MUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AULI_AUI_MUX_5` carries the multiplexer logic of the `AULI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AULI_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AULI_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AULI_AUI_MUX_5_UNGATED` is the adapter-based variant of the generic multiplexer for data type `ULINT`. Unlike `AULI_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AULI_AUI_MUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

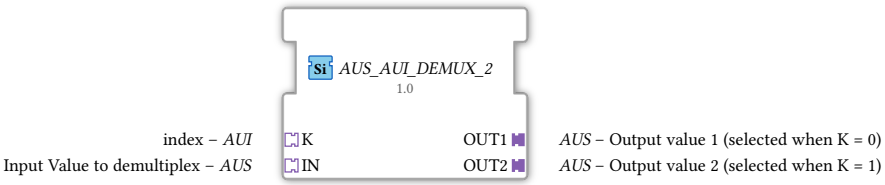
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AULI_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).
No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AULI_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.



Conclusion

`AULI_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AULI_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AUS_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

AUS_AUI_DEMUX_2 is the adapter-based variant of the generic demultiplexer for data type USINT. Unlike AUS_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUS_AUI_DEMUX_2 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 8-bit unsigned integer to forward, routed to exactly one of the outputs (AUS adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AUS adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 2 output adapters (OUT1 … OUT2) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AUS_AUI_DEMUX) – shared across all port counts of this block family (AUS_AUI_DEMUX_2 … AUS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

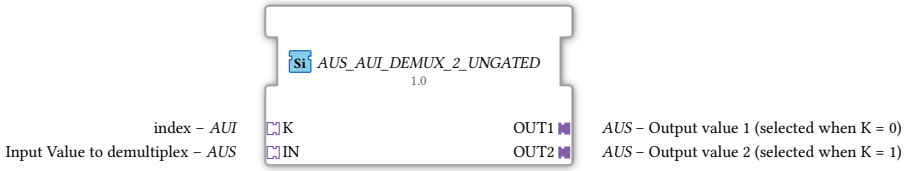
Application Scenarios

- Distributing a 8-bit unsigned integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUS_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUS_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUS_AUI_DEMUX_2` carries the demultiplexer logic of the `AUS_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AUS_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `USINT`. Unlike `AUS_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit unsigned integer to forward, routed to exactly one of the outputs (AUS adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AUS adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_DEMUX`) – shared across all port counts of this block family (AUS_AUI_DEMUX_2_UNGATED … AUS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

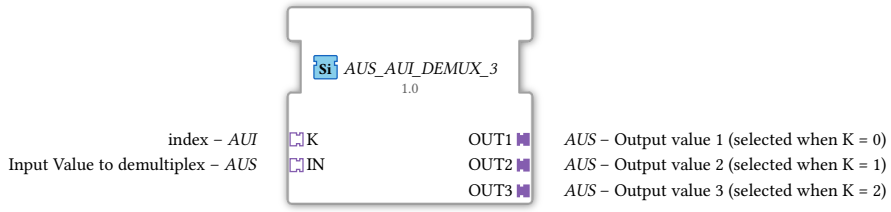
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 8-bit unsigned integer to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUS_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUS_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUS_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AUS_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AUS_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `USINT`. Unlike `AUS_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit unsigned integer to forward, routed to exactly one of the outputs (AUS adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AUS adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AUS adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_DEMUX`) – shared across all port counts of this block family (AUS_AUI_DEMUX_2 … AUS_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

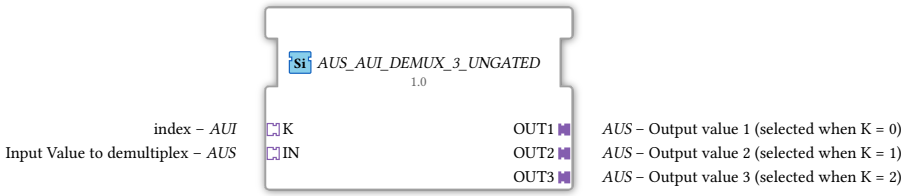
Application Scenarios

- Distributing a 8-bit unsigned integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUS_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUS_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUS_AUI_DEMUX_3` carries the demultiplexer logic of the `AUS_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AUS_AUI_DEMUX_3_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `USINT`. Unlike `AUS_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_DEMUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit unsigned integer to forward, routed to exactly one of the outputs (AUS adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AUS adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AUS adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_DEMUX`) – shared across all port counts of this block family (AUS_AUI_DEMUX_2 … AUS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

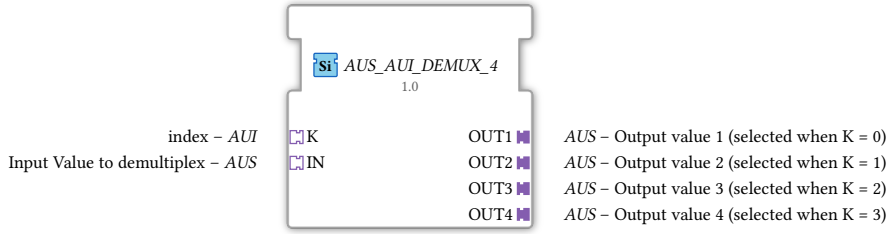
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 8-bit unsigned integer to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUS_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUS_AUI_DEMUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUS_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AUS_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AUS_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `USINT`. Unlike `AUS_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit unsigned integer to forward, routed to exactly one of the outputs (AUS adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AUS adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AUS adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AUS adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_DEMUX`) – shared across all port counts of this block family (AUS_AUI_DEMUX_2 … AUS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

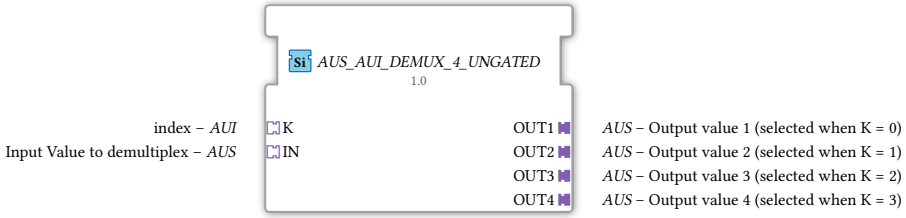
Application Scenarios

- Distributing a 8-bit unsigned integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUS_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUS_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUS_AUI_DEMUX_4` carries the demultiplexer logic of the `AUS_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AUS_AUI_DEMUX_4_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `USINT`. Unlike `AUS_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_DEMUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit unsigned integer to forward, routed to exactly one of the outputs (AUS adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AUS adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AUS adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AUS adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_DEMUX`) – shared across all port counts of this block family (AUS_AUI_DEMUX_2 … AUS_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

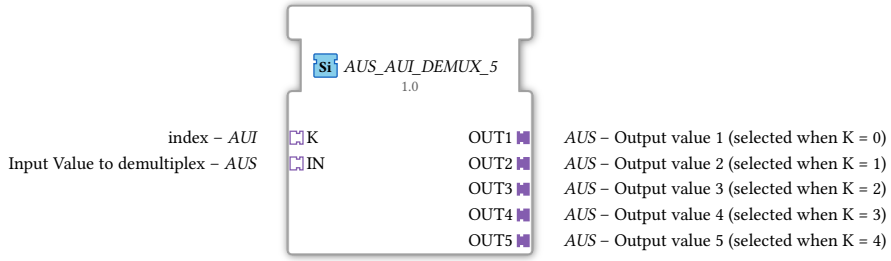
- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 8-bit unsigned integer to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUS_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUS_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUS_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AUS_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AUS_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `USINT`. Unlike `AUS_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 8-bit unsigned integer to forward, routed to exactly one of the outputs (AUS adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AUS adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AUS adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AUS adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AUS adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_DEMUX`) – shared across all port counts of this block family (AUS_AUI_DEMUX_2 … AUS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

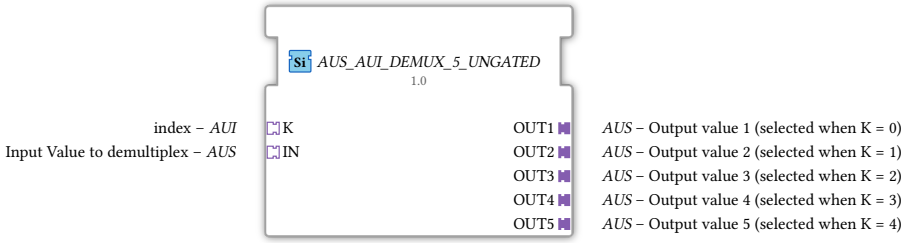
Application Scenarios

- Distributing a 8-bit unsigned integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUS_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AUS_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AUS_AUI_DEMUX_5 carries the demultiplexer logic of the AUS_DEMUX_5 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUS_AUI_DEMUX_5. • – ○ • – ○ • – ○ •

Introduction

AUS_AUI_DEMUX_5_UNGATED is the adapter-based variant of the generic demultiplexer for data type USINT. Unlike AUS_DEMUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUS_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 8-bit unsigned integer to forward, routed to exactly one of the outputs (AUS adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AUS adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AUS adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AUS adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AUS adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_DEMUX`) – shared across all port counts of this block family (AUS_AUI_DEMUX_2 … AUS_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

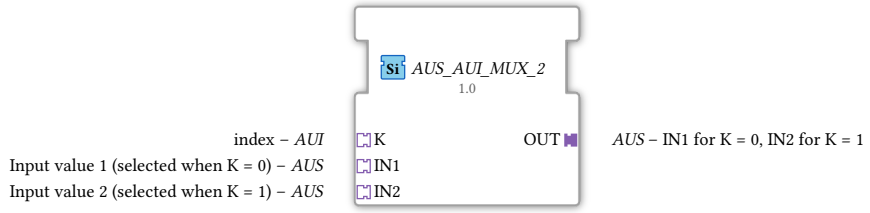
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 8-bit unsigned integer to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AUS_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AUS_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUS_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AUS_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_MUX_2

• – ○ • – ○ • – ○ •

Introduction

`AUS_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `USINT`. Unlike `AUS_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input,

but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AUS adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AUS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_MUX`) – shared across all port counts of this block family (AUS_AUI_MUX_2 … AUS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

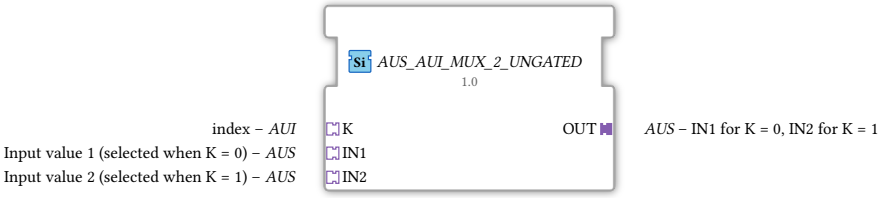
Application Scenarios

- Choosing between up to 2 8-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AUS_MUX_2 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **AUS_AUI_MUX_2_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AUS_AUI_MUX_2 carries the multiplexer logic of the AUS_MUX_2 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUS_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AUS_AUI_MUX_2_UNGATED is the adapter-based variant of the generic multiplexer for data type USINT. Unlike AUS_MUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUS_AUI_MUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AUS adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AUS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` ... `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_MUX`) – shared across all port counts of this block family (AUS_AUI_MUX_2_UNGATED ... AUS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

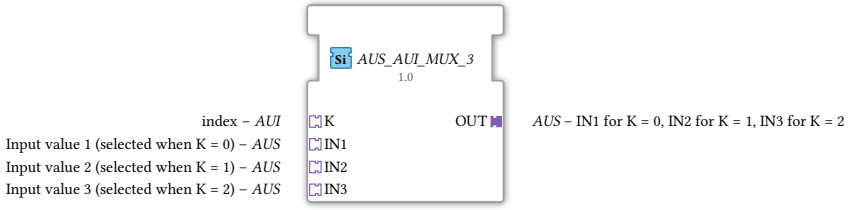
- **Any event** (selector adapter `K` or `IN1`...`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 8-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUS_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AUS_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUS_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AUS_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

AUS_AUI_MUX_3 is the adapter-based variant of the generic multiplexer for data type USINT. Unlike AUS_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUS_AUI_MUX_3 evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (AUS adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (AUS adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (AUS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AUS_AUI_MUX) – shared across all port counts of this block family (AUS_AUI_MUX_2 … AUS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN3) → read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

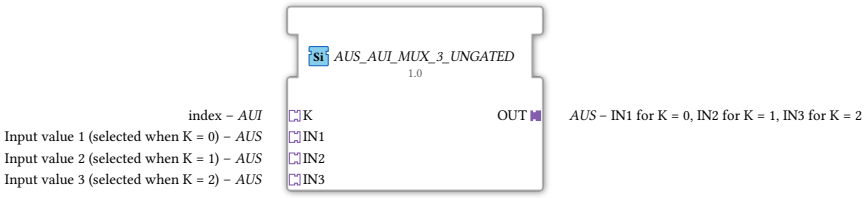
- Choosing between up to 3 8-bit unsigned integer sources through a centrally managed adapter index

- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AUS_MUX_3 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **AUS_AUI_MUX_3_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AUS_AUI_MUX_3 carries the multiplexer logic of the AUS_MUX_3 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AUS_AUI_MUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AUS_AUI_MUX_3_UNGATED is the adapter-based variant of the generic multiplexer for data type USINT. Unlike AUS_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AUS_AUI_MUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AUS adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AUS adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AUS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_MUX`) – shared across all port counts of this block family (AUS_AUI_MUX_2 … AUS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 8-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUS_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AUS_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AUS_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AUS_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AUS_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `USINT`. Unlike `AUS_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AUS adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AUS adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AUS adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AUS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_MUX`) – shared across all port counts of this block family (AUS_AUI_MUX_2 … AUS_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 8-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUS_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AUS_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUS_AUI_MUX_4` carries the multiplexer logic of the `AUS_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_MUX_4_UNGATED

Conclusion

`AUS_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `AUS_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`AUS_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `USINT`. Unlike `AUS_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AUS adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AUS adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AUS adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AUS adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AUS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_MUX`) – shared across all port counts of this block family (AUS_AUI_MUX_2 … AUS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

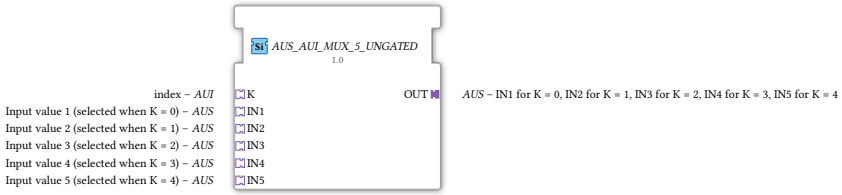
Application Scenarios

- Choosing between up to 5 8-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUS_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AUS_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AUS_AUI_MUX_5` carries the multiplexer logic of the `AUS_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AUS_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AUS_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• — ○ • — ○ • — ○ •

Introduction

`AUS_AUI_MUX_5_UNGATED` is the adapter-based variant of the generic multiplexer for data type `USINT`. Unlike `AUS_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AUS_AUI_MUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AUS adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AUS adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AUS adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AUS adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AUS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AUS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AUS_AUI_MUX`) – shared across all port counts of this block family (AUS_AUI_MUX_2 … AUS_AUI_MUX_5_UNGATED).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

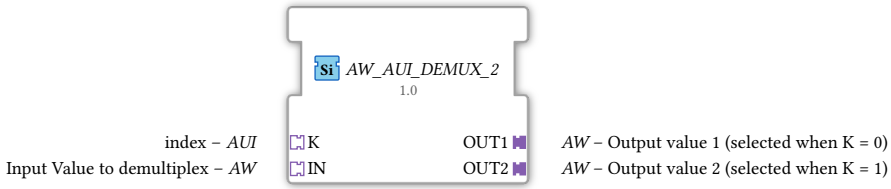
- Choosing between up to 5 8-bit unsigned integer sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AUS_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- `AUS_AUI_MUX_5`: The gated variant – updates the output only on an actual value change.



Conclusion

`AUS_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AUS_MUX_5` family over to a purely adapter-based index supply. This makes the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AW_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AW_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `WORD`. Unlike `AW_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit bit pattern to forward, routed to exactly one of the outputs (AW adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AW adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_DEMUX`) – shared across all port counts of this block family (AW_AUI_DEMUX_2 … AW_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

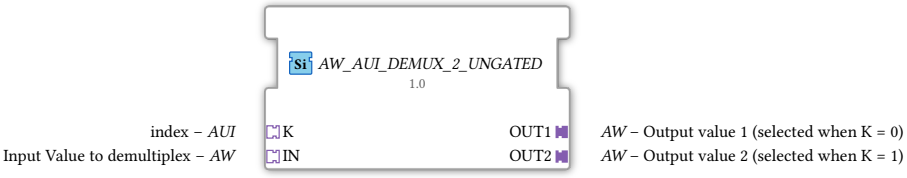
Application Scenarios

- Distributing a 16-bit bit pattern to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AW_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AW_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AW_AUI_DEMUX_2` carries the demultiplexer logic of the `AW_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AW_AUI_DEMUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AW_AUI_DEMUX_2_UNGATED is the adapter-based variant of the generic demultiplexer for data type WORD. Unlike AW_DEMUX_2, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AW_AUI_DEMUX_2_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 16-bit bit pattern to forward, routed to exactly one of the outputs (AW adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AW adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 2 output adapters (OUT1 … OUT2) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_DEMUX`) – shared across all port counts of this block family (AW_AUI_DEMUX_2_UNGATED … AW_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

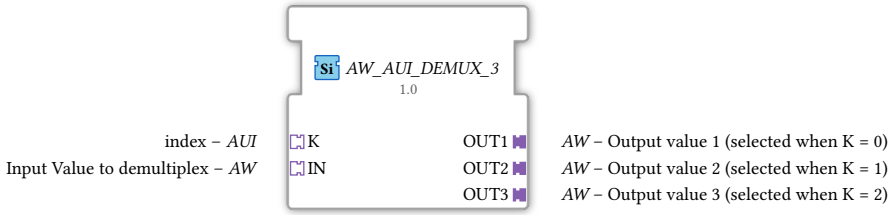
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 16-bit bit pattern to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AW_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AW_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AW_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AW_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_DEMUX_3

• – ○ • – ○ • – ○ •

Introduction

`AW_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `WORD`. Unlike `AW_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit bit pattern to forward, routed to exactly one of the outputs (AW adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AW adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AW adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_DEMUX`) – shared across all port counts of this block family (AW_AUI_DEMUX_2 … AW_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

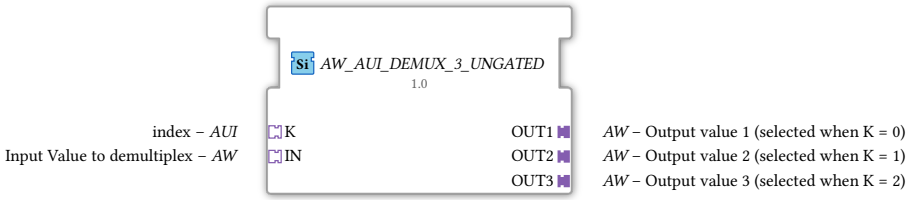
Application Scenarios

- Distributing a 16-bit bit pattern to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AW_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AW_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AW_AUI_DEMUX_3` carries the demultiplexer logic of the `AW_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_AUI_DEMUX_3`.
