This function block uses the built-in function `BYTE_AS_WSTRING` to convert the input byte value to a WSTRING. The conversion is triggered by the event `REQ`, and the result is returned via `CNF`.

Technical Features

- The conversion is performed directly without additional parameters.
- The block is optimized for use in IEC 61131-3 compliant environments.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Completed**: Sends the `CNF` event with the result.

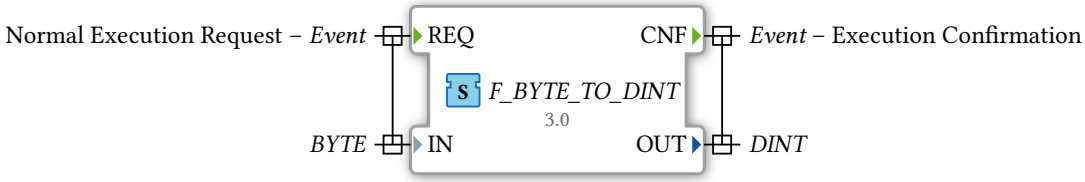
Application Scenarios

- Converting byte data for display in user interfaces.
- Processing byte streams in Unicode-compatible systems.

⚖️ Comparison with Similar Blocks

- Unlike `F_BYTE_AS_STRING`, this block generates a Unicode string (WSTRING) instead of an ASCII string (STRING).
- Similar to `F_WORD_AS_WSTRING`, but optimized for 8-bit data.

Conclusion



The `F_BYTE_AS_WSTRING` block is a simple and efficient way to convert byte data into Unicode strings. Its clear interface and direct functionality make it ideal for numerous applications in automation technology.

F_BYTE_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_DINT` converts a `BYTE` value to a `DINT` value. It is part of the `iec61131::conversion` library and enables simple and efficient type conversion between these two data types.

Interface Structure

Event Inputs

- **REQ**: This input triggers the execution of the function block. It is linked to the data input `IN`.

Event Outputs

- **CNF**: This output signals the successful execution of the function block. It is linked to the data output `OUT`.

Data Inputs

- **IN**: The input expects a `BYTE` value, which is to be converted to a `DINT` value.

Data Outputs

- **OUT**: The output provides the converted `DINT` value.

Adapters

This function block does not have any adapters.

Functionality

The function block performs the conversion from `BYTE` to `DINT` as soon as the event `REQ` is received. The conversion is carried out using the function `BYTE_TO_DINT(IN)`, which converts the value of the input `IN` to the corresponding `DINT` value and outputs it as `OUT`. After successful conversion, the event `CNF` is triggered.

Technical Features

- The function block has a simple structure and contains only one algorithm for the conversion.
- The conversion is performed directly without any additional processing steps.

State Overview

The function block has no internal states. The execution occurs once each time the `REQ` event is received.

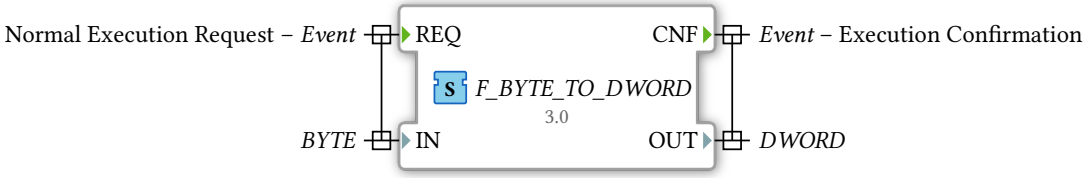
Application Scenarios

- Type conversion in control applications where `BYTE` data needs to be converted to `DINT` data.
- Integration into larger systems that require type compatibility between different data formats.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks such as `F_WORD_TO_DINT` or `F_INT_TO_DINT`, this function block is specifically designed for converting `BYTE` to `DINT`.
- It offers a simple and direct solution for this specific conversion.

Conclusion



The `F_BYTE_TO_DINT` function block is a useful tool for type conversion in IEC 61131-3-based control systems. Its simple and efficient operation makes it a reliable solution for applications requiring conversion from `BYTE` to `DINT`.

F_BYTE_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_DWORD` converts a `BYTE` value to a `DWORD` value. This block is particularly useful in scenarios where an extension of the data width is required, for example, when processing sensor data or communicating between systems with different data formats.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is coupled to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is coupled to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `BYTE` to be converted to a `DWORD` value.

Data Outputs

- **OUT**: The output value of type `DWORD`, containing the result of the conversion.

Adapters

This function block does not use any adapters.

Functionality

When the event input `REQ` is triggered, the algorithm is executed. This algorithm converts the `BYTE` value at input `IN` into a `DWORD` value and outputs the result at output `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Features

- The function block is simple and efficient because it directly utilizes the built-in function `BYTE_TO_DWORD`.
- No additional states or complex logic are required.

State Overview

Because it is a simple function block, there are no state transitions or internal states. The operation is performed atomically upon triggering `REQ`.

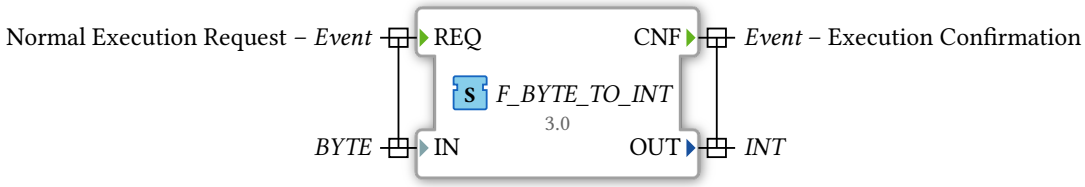
Application Scenarios

- Extending data widths in communication protocols.
- Processing sensor data that is in `BYTE` but needs to be further processed in `DWORD`.
- Compatibility adjustments between different system components.

⚖️ Comparison with similar function blocks

- **F_WORD_TO_DWORD**: Converts `WORD` to `DWORD`, similar in functionality, but with a different input data size.
- **F_BYTE_TO_WORD**: Converts `BYTE` to `WORD`, offering a smaller output data size compared to `F_BYTE_TO_DWORD`.

Conclusion



The `F_BYTE_TO_DWORD` function block is a simple and efficient tool for converting `BYTE` to `DWORD` values. Its clear interface and direct functionality make it ideal for applications requiring data width expansion.

F_BYTE_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_INT` converts a `BYTE` value to a `INT` value. It is part of the `iec61131::conversion` package and enables simple and efficient type conversion between these two data types.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input of type `BYTE`, containing the value to be converted.

Data Outputs

- **OUT**: The output of type `INT`, containing the result of the conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion from `BYTE` to `INT` as soon as the event `REQ` is received. The conversion is performed using the integrated function `BYTE_TO_INT`. After successful conversion, the result is output via output `OUT`, and the event `CNF` is triggered.

Technical Features

- The function block is a simple FB without internal state management.
- The conversion is performed directly and without delay.

State Overview

Since it is a simple function block, there are no state transitions or complex state logic.

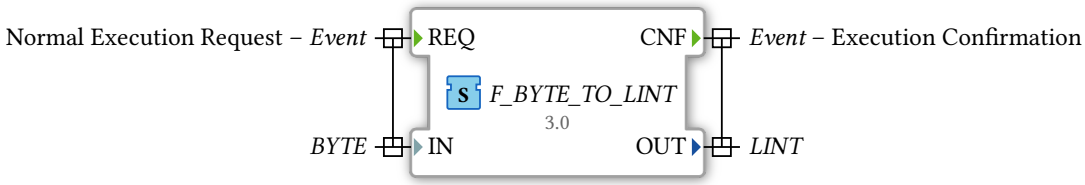
Application Scenarios

- Type conversion in control applications where `BYTE` values need to be converted to `INT` values.
- Integration into larger control systems that need to process different data types.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_WORD_TO_INT` or `F_DWORD_TO_INT` offer conversions for other data types, but with the same basic principle.
- Unlike more complex conversion blocks, `F_BYTE_TO_INT` provides a simple and direct solution for the specific conversion of `BYTE` to `INT`.

Conclusion



The `F_BYTE_TO_INT` function block is an efficient and easy-to-use tool for converting `BYTE` values to `INT` values. Its simplicity and direct operation make it ideal for applications that require fast and reliable type conversions.

F_BYTE_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_LINT` converts a `BYTE` value to a `LINT` value. This block is particularly useful in scenarios where a type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (`BYTE`): The input value to be converted to the `LINT` type.

Data Outputs

- **OUT** (`LINT`): The converted output value.

Adapters

This function block has no adapters.

Functionality

When the `REQ` event is triggered, the value at input `IN` of type `BYTE` is converted to type `LINT` and output `OUT`. The `CNF` event signals the successful completion of the conversion.

Technical Features

- The function block uses the built-in function `BYTE_TO_LINT` for the conversion.
- It is a simple function block without state machines or complex algorithms.

State Overview

Since it is a simple function block, there are no state transitions or complex state logic.

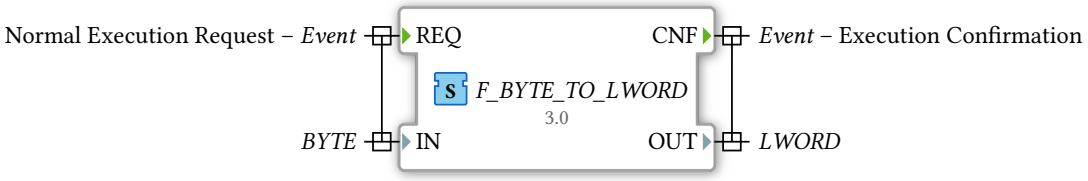
Application Scenarios

- Type conversion in control applications where `BYTE` values need to be converted to `LINT` values.
- Use in data processing chains where different data types are processed.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_WORD_TO_LINT` or `F_DWORD_TO_LINT` offer similar functionality, but for different input types.
- Compared to generic conversion blocks, `F_BYTE_TO_LINT` is specialized and optimized for converting `BYTE` to `LINT`.

Conclusion



The `F_BYTE_TO_LINT` function block is an efficient and specialized tool for converting `BYTE` values to `LINT` values. Its simplicity and direct functionality make it a reliable choice for relevant use cases.

F_BYTE_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_LWORD` converts a `BYTE` value to a `LWORD` value. It is part of the `iec61131::conversion` library and enables simple and efficient type conversion.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `BYTE` to be converted.

Data Outputs

- **OUT**: The output value of type `LWORD`, containing the result of the conversion.

Adapters

- No adapters are available.

Functionality

Upon receiving an incoming `REQ` event, the function block converts the `BYTE` value at input `IN` to a `LWORD` value. The result is output at `OUT` and confirmed by a `CNF` event.

Technical Features

- The function block uses the `BYTE_TO_LWORD` function for conversion.
- It is a simple function block without a state machine.

State Overview

Since it is a simple function block, there are no state transitions. The conversion occurs directly upon a `REQ` event.

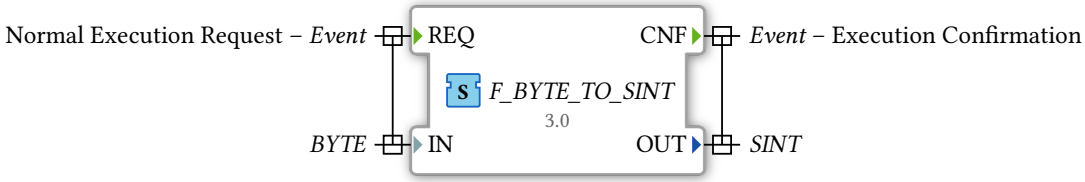
Application Scenarios

- Type conversion in control applications where `BYTE` values need to be converted to `LWORD` values.
- Use in data processing chains where different data types are processed.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks are `F_WORD_TO_LWORD` or `F_DWORD_TO_LWORD`, which convert other data types.
- Unlike more complex conversion blocks, `F_BYTE_TO_LWORD` offers a simple and direct solution for the specific conversion of `BYTE` to `LWORD`.

Conclusion



The `F_BYTE_TO_LWORD` function block is an efficient and simple solution for converting `BYTE` to `LWORD` values. Its clear interface structure and direct functionality make it ideal for use in control applications.

F_BYTE_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_SINT` converts a data type `BYTE` to the data type `SINT`. This block is particularly useful in scenarios where a direct type conversion without additional calculations is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: Expects an input value of type `BYTE`, which is to be converted to `SINT`.

Data Outputs

- **OUT**: Outputs the converted value of type `SINT`.

Adapters

This function block has no adapters.

Functionality

Upon receiving an incoming `REQ` event, the function block converts the `BYTE` value at input `IN` to a `SINT` value and outputs the result via output `OUT`. Subsequently, the `CNF` event is triggered to signal the successful completion of the operation.

Technical Features

- The conversion is performed directly without any additional parameters or settings.
- The block is implemented as a simple function block (SimpleFB), which guarantees efficient execution.

State Overview

The function block has no internal states. Execution is purely event-driven and occurs with each `REQ` event.

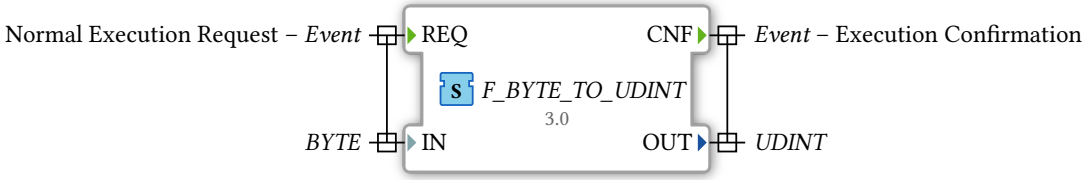
Application Scenarios

- Type conversion in control applications, where `BYTE` data needs to be converted to `SINT`.
- Integration into larger function block networks where different data types are processed.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_BYTE_TO_SINT` is specialized and therefore offers greater efficiency for this specific conversion.
- Other blocks might offer additional features such as range checks or scaling, which is not the case here.

Conclusion



The `F_BYTE_TO_SINT` function block is an efficient tool for the direct conversion of `BYTE` to `SINT`. Its simplicity and specialization make it ideal for applications where fast and uncomplicated type conversion is required.

F_BYTE_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_UDINT` is used to convert a BYTE value to a UDINT value. This function block is particularly useful in scenarios where a type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: This event input triggers the conversion. The input is linked to the data input `IN`.

Event Outputs

- **CNF**: This event output signals the successful completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `BYTE`, containing the value to be converted.

Data Outputs

- **OUT**: The output of type `UDINT`, containing the result of the conversion.

Adapters

This function block has no adapters.

Functionality

When the event input `REQ` is triggered, the algorithm is executed, converting the value at input `IN` (of type `BYTE`) into a `UDINT` value and outputting the result at output `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Features

- The function block uses the built-in function `BYTE_TO_UDINT` for the conversion.
- The conversion is performed without additional parameters or configuration.

State Overview

The function block has no internal states. Execution occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Type conversion in control applications where BYTE values need to be converted to UDINT values.
- Integration into larger control systems that require uniform data processing.

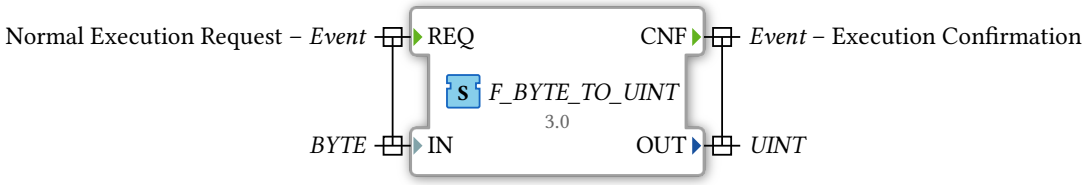
⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks such as `F_WORD_TO_UDINT` or `F_DWORD_TO_UDINT`, this block is specifically optimized for converting `BYTE` to `UDINT`.
- Similar blocks can process different input data types but are otherwise comparable in their functionality.

🛠️ Related Exercises

- Exercise_011a

Conclusion



The `F_BYTE_TO_UDINT` function block offers a simple and efficient way to convert BYTE values to UDINT values. Its clear interface structure and direct functionality make it ideal for applications requiring fast and reliable type conversion.

F_BYTE_TO_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_UINT` converts a `BYTE` value to a `UINT` value. This is particularly useful when data of different types needs to be processed in a system and type conversion is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Confirms the successful execution of the function block. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `BYTE`, which is to be converted to a `UINT` value.

Data Outputs

- **OUT**: The output of type `UINT`, which contains the result of the conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion of the `BYTE` value at the input `IN` to a `UINT` value as soon as the event `REQ` is triggered. The result is output at `OUT`, and the event `CNF` signals successful execution.

Technical Features

- The function block has a simple structure and contains only one algorithm that performs the conversion.
- The conversion is performed using the function `BYTE_TO_UINT`, which converts the `BYTE` value into a `UINT` value.

State Overview

The function block has no internal state. Execution occurs immediately upon receiving the `REQ` event.

Application Scenarios

- Type conversion in control and automation systems.
- Data processing in systems that use different data types.

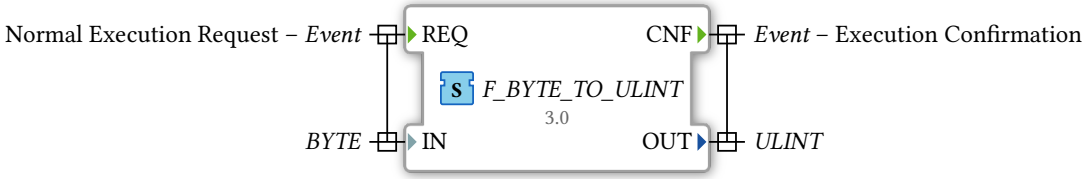
⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_WORD_TO_UINT` or `F_DWORD_TO_UINT` perform similar conversions, but with different input types.
- `F_BYTE_TO_UINT` specializes in converting `BYTE` to `UINT` and is therefore more efficient for this specific use case.

🛠️ Related Exercises

- Exercise_006c

Conclusion



The function block `F_BYTE_TO_UINT` is a simple and efficient tool for converting `BYTE` values to `UINT` values. Its clear interface structure and direct functionality make it ideal for applications requiring such type conversions.

F_BYTE_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_BYTE_TO_ULINT converts a BYTE value to a ULINT value. This conversion is particularly useful in scenarios where data of varying sizes needs to be processed or transferred.

Interface Structure

Event Inputs

- **REQ**: This input triggers the execution of the function block. The input is linked to the data input IN.

Event Outputs

- **CNF**: This output signals the successful execution of the function block. The output is linked to the data output OUT.

Data Inputs

- **IN**: The input expects a BYTE value, which is to be converted to a ULINT value.

Data Outputs

- **OUT**: The output provides the converted ULINT value.

Adapters

No adapters are present.

Functionality

The function block performs the conversion from BYTE to ULINT as soon as the event REQ is received. The conversion is performed using the function BYTE_TO_ULINT, which converts the input value IN into the corresponding value ULINT. After successful conversion, the event CNF is triggered, and the converted value is available at the output OUT.

Technical Features

- The function block has a simple structure and contains only one conversion algorithm.
- The conversion is performed without additional parameters or complex logic.

State Overview

The function block has no internal states. Execution occurs immediately upon receiving the REQ event.

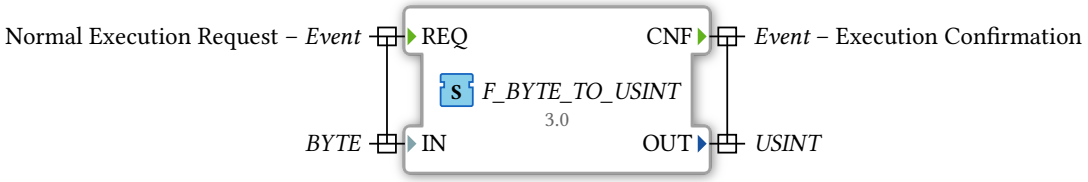
Application Scenarios

- Data conversion in control applications where BYTE values need to be converted to larger data types such as ULINT.
- Integration into larger systems that require uniform data processing in ULINT.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as F_WORD_TO_ULINT or F_DWORD_TO_ULINT perform conversions from other data types to ULINT. F_BYTE_TO_ULINT is specifically for converting BYTE.

Conclusion



The F_BYTE_TO_ULINT function block offers a simple and efficient way to convert BYTE values into ULINT values. Its clear interface and direct functionality make it a useful component in automation technology.

F_BYTE_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_USINT` converts a `BYTE` value to a `USINT` value (Unsigned Short Integer). This function block is particularly useful in scenarios where type conversion between these two data types is required, for example, in communication between different systems or in data processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `BYTE` to be converted.

Data Outputs

- **OUT**: The output value of type `USINT`, containing the result of the conversion.

Adapters

No adapters are available.

Functionality

The function block performs the conversion by transforming the `BYTE` value at input `IN` into a `USINT` value and providing the result at output `OUT`. The conversion occurs synchronously with the triggering of the `REQ` event and is confirmed by the `CNF` event.

Technical Features

- The function block uses the built-in function `BYTE_TO_USINT` for the conversion.
- It is a simple function block without a state machine or complex logic.

State Overview

Because it is a simple function block, there are no state transitions or state management. The operation is atomic and is executed on every `REQ` event.

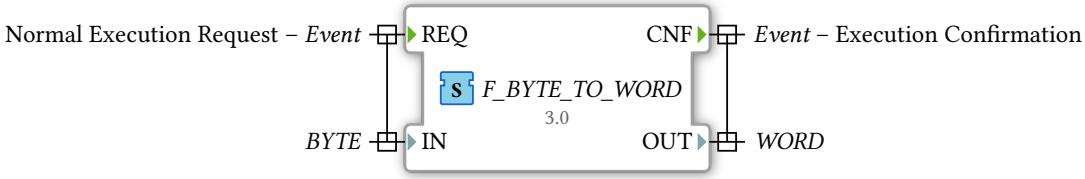
Application Scenarios

- Type conversion in communication protocols where different systems use different data types.
- Data processing in control systems where conversion between `BYTE` and `USINT` is required.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_WORD_TO_UINT` or `F_DWORD_TO_UDINT` perform similar conversions, but with different data types.
- `F_BYTE_TO_USINT` is specifically optimized for converting `BYTE` to `USINT` and is therefore more efficient for this use case.

Conclusion



The `F_BYTE_TO_USINT` function block is a simple yet effective building block for converting between `BYTE` and `USINT`. Its simplicity and efficiency make it ideal for applications requiring fast and reliable type conversion.

F_BYTE_TO_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_BYTE_TO_WORD` converts a `BYTE` data type to a `WORD` data type. This conversion is useful when data of different sizes needs to be processed or transferred.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `BYTE` to be converted.

Data Outputs

- **OUT**: The output of type `WORD`, containing the result of the conversion.

Adapters

No adapters are present.

Functionality

The function block performs the conversion from `BYTE` to `WORD` as soon as the event `REQ` is received. The conversion is performed using the function `BYTE_TO_WORD(IN)`, which converts the input value `IN` into the corresponding value `WORD`. The result is output at `OUT`, and the event `CNF` signals the completion of the operation.

Technical Features

- The function block has a simple structure and contains only one conversion algorithm.
- The conversion is performed directly and without any additional delay.

State Overview

The function block has no internal states. The conversion is performed on each `REQ` event, and the result is output immediately.

Application Scenarios

- **Data Conversion**: When a `BYTE` value needs to be processed in a system that expects `WORD` values.
- **Interface Adaptation**: For communication between systems that use different data types.

⚖️ Comparison with Similar Building Blocks

- **F_WORD_TO_BYTE**: Performs the reverse conversion, from `WORD` to `BYTE`.
- **F_BYTE_TO_INT**: Converts `BYTE` to `INT`, which is another type of data type conversion.

Conclusion

The `F_BYTE_TO_WORD` function block is a simple and efficient tool for converting `BYTE` values to `WORD` values. Its clear interface structure and direct functionality make it ideal for applications requiring fast and straightforward data type conversions.

DINT

F_DINT_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_AS_STRING` converts a 32-bit integer value (DINT) into a string (STRING). This functionality is particularly useful when numeric values are needed for display or logging in a human-readable format.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is activated along with the converted value at data output `OUT`.

Data Inputs

- **IN**: Expects a 32-bit integer value (DINT) to be converted into a string.

Data Outputs

- **OUT**: Returns the converted value as a string (STRING).

Adapters

This function block has no adapter interfaces.

Operation

When the `REQ` event is triggered, the algorithm is started that converts the value of `IN` (DINT type) into a STRING. The result is output to `OUT`, and the `CNF` event signals successful conversion.

Technical Features

- The conversion is performed directly without additional parameters.
- The function block is part of the `iec61131::conversion` package.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

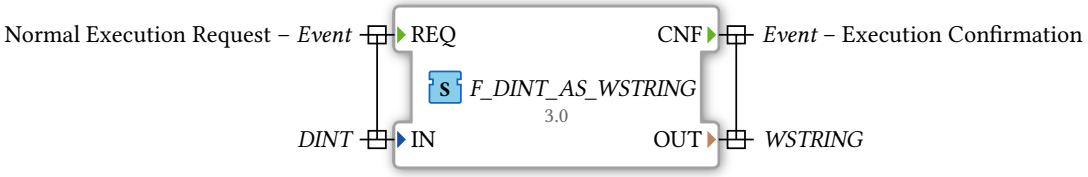
Application Scenarios

- Displaying numeric values in user interfaces.
- Logging measured values to text files or databases.
- Preparing data for communication with systems that can only process strings.

⚖️ Comparison with Similar Blocks

Compared to other conversion blocks, `F_DINT_AS_STRING` offers a specialized and efficient solution for converting DINT to STRING. Other blocks might offer additional features such as formatting or locale settings, but are often more complex to use.

Conclusion



The `F_DINT_AS_STRING` function block is a simple and effective solution for converting integers to strings. Its clear interface and direct functionality make it ideal for applications requiring fast and straightforward conversion.

F_DINT_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_AS_WSTRING` converts a 32-bit integer value (DINT) into a Unicode string (WSTRING). This functionality is particularly useful when numeric values are needed as text for display or further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the input value. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (DINT): The 32-bit integer value to be converted.

Data Outputs

- **OUT** (WSTRING): The resulting Unicode string after conversion.

Adapters

No adapters available.

Functionality

When the `REQ` event is triggered, the value at input `IN` is read and converted into a Unicode string using the function `DINT_AS_WSTRING`. The result is output at `OUT`, and the `CNF` event signals successful execution.

Technical Features

- The function block is a simple algorithm without state machines.
- Conversion is performed directly without additional parameters.

State Overview

Since it is a simple function block, there are no state transitions or management.

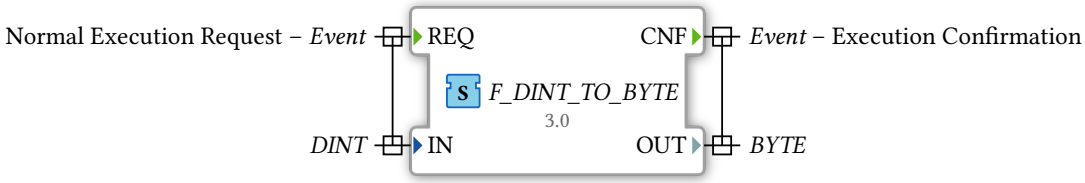
Application Scenarios

- Displaying numeric values in user interfaces.
- Logging numeric data in text format.
- Preparing data for text-based communication protocols.

⚖️ Comparison with Similar Blocks

- Compared to `F_INT_AS_WSTRING`, this block processes 32-bit integers instead of 16-bit integers.
- Similar blocks like `F_DINT_AS_STRING` convert to ASCII instead of Unicode strings.

Conclusion



The `F_DINT_AS_WSTRING` function block offers a simple and efficient way to convert 32-bit integers to Unicode strings. Its clear interface and direct functionality make it ideal for applications that require numerical data in text format.

F_DINT_TO_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_BYTE` converts a 32-bit integer value (DINT) to an 8-bit integer value (BYTE). This conversion is particularly useful when data needs to be exchanged or processed between systems with different word lengths.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs

- **IN**: The input value of type `DINT` (32-bit integer) to be converted.

Data Outputs

- **OUT**: The output value of type `BYTE` (8-bit integer) containing the result of the conversion.

Adapters

This function block does not have any adapter interfaces.

Functionality

When the event input `REQ` is triggered, the algorithm is executed, converting the value at input `IN` (of type `DINT`) into a value of `BYTE`. The result is output at `OUT`, and the event `CNF` signals the completion of the operation.

The algorithm used is:
OUT := DINT_TO_BYTE(IN);

Technical Features

- Converting `DINT` to `BYTE` can result in data loss if the original value is outside the representable range of `BYTE` (0 to 255).
- The function block is simple and deterministic, without internal states or complex logic.

State Overview

The function block has no internal state. Execution occurs exclusively upon triggering the `REQ` event.

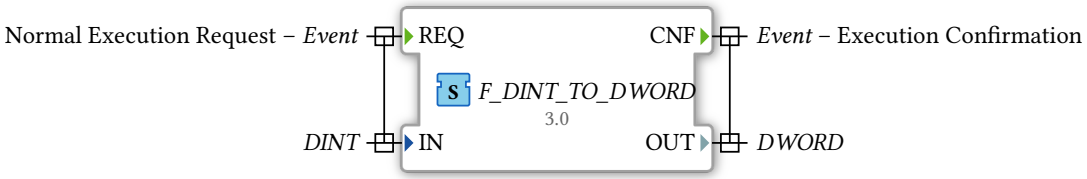
Application Scenarios

- Reducing data width for communication with peripheral devices that can only process BYTE data.
- Preprocessing data for systems with limited storage capacity.
- Integration into larger control systems where different data types need to be converted.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_DINT_TO_BYTE` is specialized and optimized for the specific conversion of `DINT` to `BYTE`.
- Similar blocks like `F_INT_TO_BYTE` or `F_WORD_TO_BYTE` offer conversions between other data types, but with similar functionality.

Conclusion



The `F_DINT_TO_BYTE` function block is a simple and efficient tool for converting 32-bit integers to 8-bit values. Its simplicity and determinism make it reliable, but users should consider potential data loss with large input values. Ideal for applications where space-saving data representation is required.

F_DINT_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_DWORD` converts a 32-bit integer value (DINT) into a 32-bit unsigned value (DWORD). This conversion is particularly necessary when signed values need to be converted to unsigned values, for example, for further processing in certain control algorithms or for communication with other systems.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the input value `IN` from DINT to DWORD.

Event Outputs

- **CNF**: Signals successful completion of the conversion and provides the converted value `OUT`.

Data Inputs

- **IN** (DINT): The signed 32-bit input value to be converted.

Data Outputs

- **OUT** (DWORD): The unsigned 32-bit output value after the conversion.

Adapters

- No adapters are available.

Functionality

This function block performs the DINT to DWORD conversion when the event `REQ` is triggered. The value of input `IN` is converted using the function `DINT_TO_DWORD` and made available at output `OUT`. After the conversion is complete, the event `CNF` is triggered.

Technical Features

- The conversion is performed directly and without any additional delay.
- The function block is optimized for use in real-time control systems.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Conversion State**: Performs the conversion and sets the output `OUT`.
3. **Acknowledgement State**: Triggers the `CNF` event and returns to the idle state.

Application Scenarios

- Conversion of signed sensor data to unsigned values for further processing.
- Preparation of data for communication with systems that expect unsigned values.

⚖️ Comparison with Similar Blocks

- Unlike generic conversion blocks, `F_DINT_TO_DWORD` specializes in DINT to DWORD conversion and therefore offers optimized and error-free conversion for this specific use case.

Conclusion

The `F_DINT_TO_DWORD` function block is an efficient and reliable tool for converting signed to unsigned 32-bit values. Its ease of use and direct integration into the 4diac IDE make it an ideal solution for relevant applications.

F_DINT_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_INT` converts a 32-bit DINT value to a 16-bit INT value. This conversion is particularly necessary in scenarios where data needs to be exchanged between systems with different word lengths.

Interface Structure

Event Inputs

- `REQ` (Normal Execution Request): Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- `CNF` (Execution Confirmation): Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- `IN` (DINT): The 32-bit DINT value to be converted.

Data Outputs

- `OUT` (INT): The resulting 16-bit INT value after conversion.

Adapters

No adapters available.

Functionality

This function block performs the conversion of a 32-bit DINT value (`IN`) to a 16-bit INT value (`OUT`) as soon as the event `REQ` is triggered. The conversion is carried out by the function `DINT_TO_INT`. After the conversion is complete, the event `CNF` is triggered.

Technical Details

- Data loss can occur if the original DINT value is outside the representable range of an INT value (-32768 to 32767).
- This function block is part of the package `iec61131::conversion`.

State Overview

This function block has no internal state. The conversion occurs immediately upon triggering the `REQ` event.

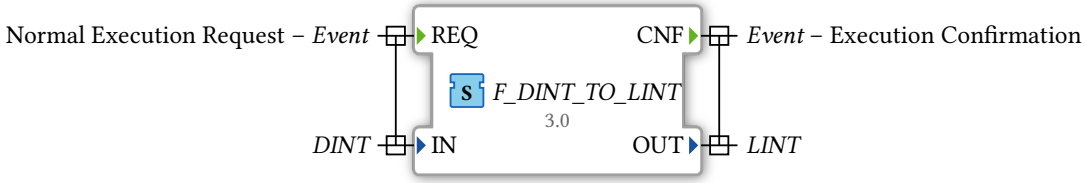
Application Scenarios

- Data conversion in control systems with different word widths.
- Integration of systems that use different data types.
- Reduction of memory usage when the higher precision of DINT is not required.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_DINT_TO_INT` specializes in converting DINT to INT and therefore offers a simple and direct solution for this specific use case.
- Other conversion blocks, such as `F_INT_TO_DINT`, perform the opposite conversion.

Conclusion



The function block `F_DINT_TO_INT` is an efficient tool for converting 32-bit DINT values to 16-bit INT values. Its simple and specialized functionality makes it ideal for applications where such conversions are required regularly. However, when using it, the potential for data loss with large values must be taken into account.

F_DINT_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_LINT` converts a 32-bit integer value (DINT) to a 64-bit integer value (LINT). This block is particularly useful in scenarios where extending the value range or changing the type is required for subsequent processing steps.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals successful completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN** (DINT): The 32-bit integer value to be converted.

Data Outputs

- **OUT** (LINT): The resulting 64-bit integer value after conversion.

Adapters

This function block does not use any adapters.

Operation

When the `REQ` event is triggered, the value of the `IN` input is copied to the `OUT` output. An automatic type conversion from DINT to LINT occurs, preserving the numeric value.

Technical Features

- The conversion is performed without data loss, as the LINT type supports a larger range of values than DINT.
- The algorithm is implemented in Structured Text (ST) and consists of a simple assignment.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

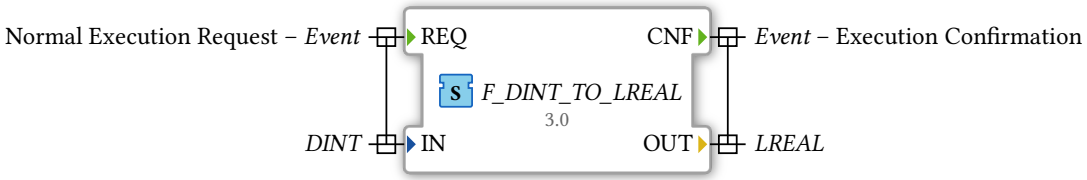
Application Scenarios

- Extending the value range for subsequent calculations
- Type adaptation in heterogeneous systems
- Data preparation for interfaces with varying requirements

⚖️ Comparison with Similar Function Blocks

Compared to generic conversion blocks, `F_DINT_TO_LINT` offers a specialized and type-safe solution for the specific conversion between DINT and LINT. Other blocks might offer more general conversion options, but may be less efficient or require additional configuration.

Conclusion



The `F_DINT_TO_LINT` function block provides a simple and efficient solution for converting 32-bit to 64-bit integers. Its clear interface and direct functionality make it a reliable component in control systems where such type conversions are required.

F_DINT_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_LREAL` converts a 32-bit integer value (DINT) into a 64-bit floating-point value (LREAL). This conversion is particularly necessary in control systems where different data types need to be processed in various parts of the application.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs

- **IN**: The input value of type `DINT`, which is to be converted to a `LREAL` value.

Data Outputs

- **OUT**: The output value of type `LREAL`, which represents the result of the conversion.

Adapters

This function block does not use any adapters.

Functionality

The function block performs a direct type conversion. When the event `REQ` is triggered, the value of `IN` is read and converted to the data type `LREAL`. The result is output to `OUT`, and the event `CNF` signals successful conversion.

Technical Features

- The conversion is performed without additional scaling or offset adjustment.
- The function block is deterministic and has no internal states.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

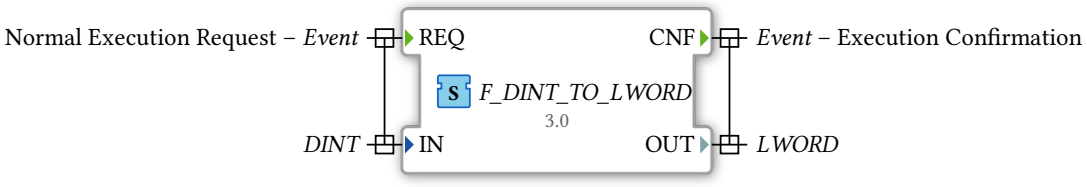
Application Scenarios

- Conversion of integers to floating-point numbers for mathematical calculations.
- Integration into control systems where different data types need to be processed.
- Use in control engineering where precise floating-point calculations are required.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_DINT_TO_LREAL` specializes in converting `DINT` to `LREAL`, thus offering greater efficiency and code readability.
- Other building blocks might offer additional features such as scaling or limiting, which is not the case here.

Conclusion



The `F_DINT_TO_LREAL` function block is a simple and efficient building block for converting integers to floating-point numbers. Its clear interface and deterministic operation make it ideal for use in control systems.

F_DINT_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_LWORD` converts a 32-bit integer value (DINT) to a 64-bit unsigned integer value (LWORD). This block is particularly useful in scenarios where extending the value range or changing the type is required for subsequent processing steps.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the function block reads the value at the data input `IN` and performs the conversion.

Event Outputs

- **CNF**: Signals the completion of the conversion. Simultaneously, the converted value is output at data output `OUT`.

Data Inputs

- **IN** (DINT): The 32-bit integer value to be converted to a 64-bit unsigned integer value.

Data Outputs

- **OUT** (LWORD): The resulting 64-bit unsigned integer value after the conversion.

Adapters

This function block does not have any adapter interfaces.

Operation

When event input `REQ` is triggered, the function block's algorithm is activated. This function reads the value at input `IN`, converts it from DINT to LWORD, and stores the result at output `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Features

- The conversion is performed by directly assigning the DINT value to an LWORD, with the value being extended accordingly.
- The function block is deterministic and performs no additional calculations or checks.

State Overview

The function block has no internal states. The operation is re-executed with each `REQ` event.

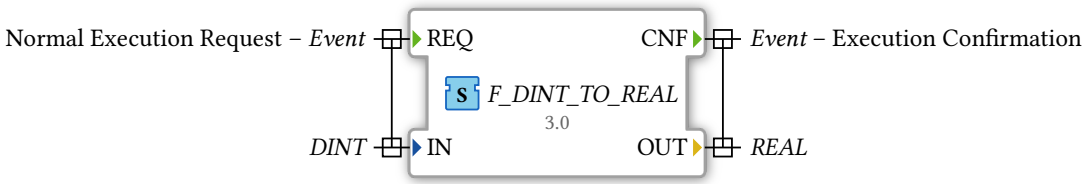
Application Scenarios

- Extending the value range for subsequent operations that require 64-bit values.
- Type conversion in heterogeneous systems where different data types need to be processed.
- Use in control systems where higher precision or a larger value range is required.

⚖️ Comparison with similar function blocks

- Unlike generic conversion function blocks, `F_DINT_TO_LWORD` specializes in converting DINT to LWORD.
- Similar function blocks such as `F_INT_TO_DINT` or `F_LINT_TO_LWORD` offer conversions between other integer types.

Conclusion



The `F_DINT_TO_LWORD` function block is a simple yet effective function block for converting 32-bit to 64-bit integer values. Its deterministic operation and clear interface make it a reliable component in control and automation solutions.

F_DINT_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_REAL` converts an integer value of type `DINT` into a floating-point value of type `REAL`. This conversion is necessary in many control and automation applications when data needs to be exchanged between different systems or components.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `DINT`, which is to be converted to a `REAL` value.

Data Outputs

- **OUT**: The converted output value of type `REAL`.

Adapters

No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The algorithm `REQ` converts the input value `IN` of type `DINT` into a `REAL` value and stores the result in `OUT`. The event `CNF` is then triggered to signal the completion of the conversion.

Technical Features

- The function block is implemented simply and efficiently, without additional states or complex logic.
- The conversion is performed directly by the function `DINT_TO_REAL`.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

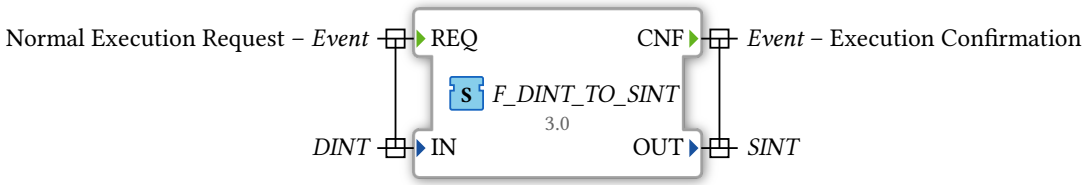
Application Scenarios

- Conversion of integer sensor values to floating-point values for further calculations.
- Data conversion between systems that use different data types.
- Integration into control algorithms that require floating-point values.

⚖️ Comparison with Similar Function Blocks

- **F_INT_TO_REAL**: Converts `INT` to `REAL`, but has a smaller input range compared to `DINT`.
- **F_LINT_TO_REAL**: Converts `LINT` to `REAL`, has a larger input range, but is unnecessary in most cases if `DINT` is sufficient.

Conclusion



The function block `F_DINT_TO_REAL` is a simple and efficient tool for converting `DINT` values to `REAL` values. It is particularly useful in applications where data with different data types needs to be exchanged between different systems or components. Its direct and stateless implementation makes it reliable and easy to integrate.

F_DINT_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_SINT` converts a 32-bit integer value (DINT) to an 8-bit integer value (SINT). This block is particularly useful in scenarios where type conversion between integer data types of different sizes is required.

Interface Structure

Event Inputs
- **REQ**: Triggers the conversion. It is associated with the input value `IN`.

Event Outputs
- **CNF**: Signals the completion of the conversion. Returns the converted value via `OUT`.

Data Inputs
- **IN** (DINT): The 32-bit integer value to be converted.

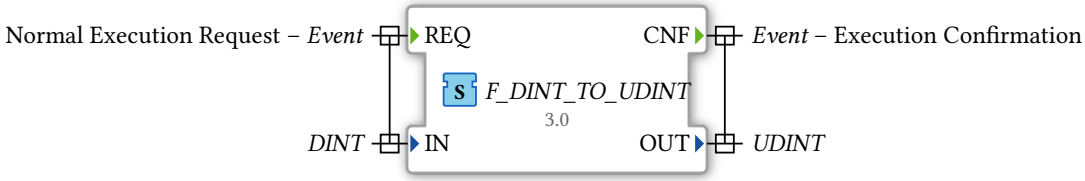
Data Outputs
- **OUT** (SINT): The resulting 8-bit integer value after conversion.

Adapters
- No adapters available.

Functionality
This function block performs the conversion from `DINT` to `SINT` as soon as the event `REQ` is triggered. The algorithm uses the built-in function `DINT_TO_SINT` to perform the conversion. After successful conversion, the event `CNF` is output with the result `OUT`.

Technical Features
- **Type Conversion**: Conversion can lead to data loss if the original `DINT` value is outside the representable range of `SINT` (-128 to 127).
- **Simple Implementation**: The function block is implemented as a simple function block (SimpleFB) without internal states.

State Overview
The function block has no internal states. Execution occurs immediately upon receiving the `REQ` event.



Application Scenarios
- **Data Reduction**: When only the lower 8 bits of a 32-bit value are relevant.
- **Compatibility**: Adapting values for systems or components that can only process `SINT`.
- **Logging**: Memory-optimized storage of values where the higher bits are not needed.

⚖️ Comparison with similar function blocks
- **F_INT_TO_SINT**: Similar function block, but for 16-bit to 8-bit conversion.
- **F_ANY_TO_**: Generic conversion function blocks that are more flexible but potentially less efficient.

Conclusion
The `F_DINT_TO_SINT` function block provides a simple and efficient way to convert 32-bit integers to 8-bit integers. Its use is particularly useful in resource-constrained environments or when adapting data types between different system components. However, be aware of the potential for data loss with large input values.

F_DINT_TO_UDINT
• − ◦ • − ◦ • − ◦ •

Introduction
The function block `F_DINT_TO_UDINT` converts a 32-bit signed integer value (DINT) to a 32-bit unsigned integer value (UDINT). This conversion is useful when exchanging data between systems that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs

- **IN**: The DINT value to be converted (32-bit signed integer).

Data Outputs

- **OUT**: The converted UDINT value (32-bit unsigned integer).

Adapters

No adapters are supported.

Functionality

When the event input `REQ` is triggered, the function block's algorithm is executed. The value at input `IN`, of type `DINT`, is converted to a `UDINT` value and output at `OUT`. The event `CNF` is then triggered to signal the successful completion of the conversion.

Technical Features

- The conversion is performed directly by the function `DINT_TO_UDINT`.
- There is no additional error handling for overflows or invalid values.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering `REQ`.

Application Scenarios

- Conversion of sensor values that are in the form of signed integers for systems that expect unsigned values.
- Data preparation for communication protocols that use unsigned integers.

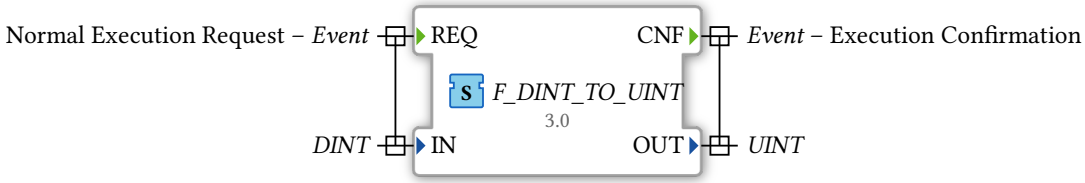
⚖️ Comparison with Similar Function Blocks

- **F_INT_TO_UINT**: Converts 16-bit signed integers to unsigned integers.
- **F_LINT_TO_ULINT**: Converts 64-bit signed integers to unsigned integers.
- **F_SINT_TO_USINT**: Converts 8-bit signed integers to unsigned integers.

🛠️ Related Exercises

- Exercise_009a

Conclusion



The function block `F_DINT_TO_UDINT` provides a simple and efficient way to convert signed 32-bit integers to unsigned 32-bit integers. It is particularly useful in scenarios where data needs to be exchanged between systems with different data type requirements.

F_DINT_TO_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_UINT` converts a 32-bit integer value (DINT) to an unsigned 32-bit integer value (UINT). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals successful completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `DINT` to be converted.

Data Outputs

- **OUT**: The output value of type `UINT`, representing the result of the conversion.

Adapters

No adapters are defined for this function block.

Functionality

This function block performs the conversion from `DINT` to `UINT` when the event `REQ` is received. The conversion is performed using the built-in function `DINT_TO_UINT`. After successful conversion, the event `CNF` is triggered, and the converted value is output via the output `OUT`.

Technical Features

- The conversion is performed directly without any additional delay.
- The block does not support error handling for invalid input values.

State Overview

1. **Idle**: Waits for the event `REQ`.
2. **Conversion**: Performs the conversion and outputs the result via `OUT`, followed by an event `CNF`.

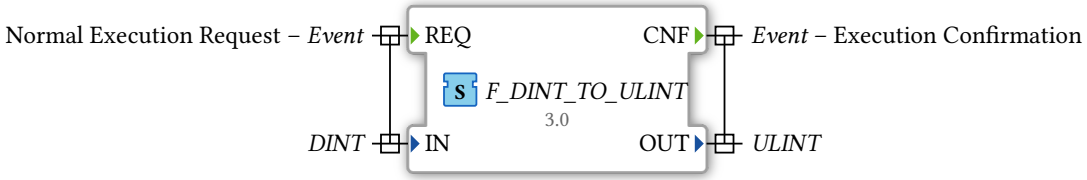
Application Scenarios

- Type conversion in control applications where signed values need to be converted to unsigned values.
- Data processing in industrial automation systems.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_DINT_TO_UINT` specializes in converting between `DINT` and `UINT`, thus offering a simpler and more direct solution for this specific use case.

Conclusion



The `F_DINT_TO_UINT` function block is an efficient tool for the specific conversion between `DINT` and `UINT` data types. Its simplicity and direct functionality make it ideal for applications requiring fast and reliable type conversion.

F_DINT_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DINT_TO_ULINT` converts a 32-bit signed integer value (`DINT`) into a 64-bit unsigned integer value (`ULINT`). This block is particularly useful when data needs to be exchanged between systems with different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event, along with the converted value, is output at data output `OUT`.

Data Inputs

- **IN** (`DINT`): The signed 32-bit integer value to be converted.

Data Outputs

- **OUT** (`ULINT`): The unsigned 64-bit integer value containing the result of the conversion.

Adapters

- No adapters are available.

Functionality

The function block performs the conversion of `DINT` to `ULINT` as soon as the event `REQ` is received. The algorithm `REQ` is executed, converting the value of `IN` using the function `DINT_TO_ULINT` and outputting it to `OUT`. Finally, the event `CNF` is triggered to signal the successful completion of the operation.

Technical Features

- The function block supports direct conversion without additional parameters.
- The conversion is performed without data loss because the `ULINT` type covers a larger value range than `DINT`.

State Overview

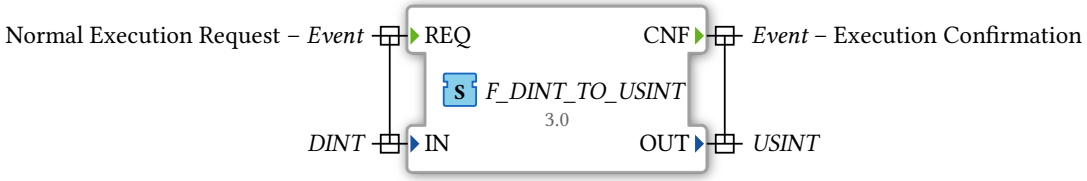
1. **Idle State**: Waits for the `REQ` event.
2. **Conversion State**: Performs the conversion and sets the output `OUT`.
3. **Acknowledgement State**: Triggers the `CNF` event and returns to the idle state.

Application Scenarios

- Data conversion in control systems that use different data types.
- Integration of components that require unsigned 64-bit values.
- Increased compatibility between different systems.

⚖️ Comparison with similar function blocks

- **F_INT_TO_ULINT**: Converts a smaller signed integer (`INT`) to `ULINT`.
- **F_LINT_TO_ULINT**: Converts a 64-bit signed integer (`LINT`) to `ULINT`.
- **F_DINT_TO_LINT**: Converts `DINT` to a signed 64-bit integer (`LINT`).



Conclusion

The F_DINT_TO_ULINT function block provides a simple and efficient way to convert signed 32-bit integer values to unsigned 64-bit integer values. Its clear interface and reliable operation make it ideal for applications requiring safe and lossless data type conversion.

F_DINT_TO_USINT

• – ◦ • – ◦ • – ◦ •

The function block F_DINT_TO_USINT converts a 32-bit integer value (DINT) to an 8-bit unsigned integer value (USINT). This conversion is useful when data needs to be exchanged between systems or components that use different data types.

- **REQ**: Starts the conversion. This event input is linked to the data input IN.
- **CNF**: Signals the completion of the conversion. This event output is linked to the data output OUT.
- **IN**: The input value of type DINT (32-bit integer) to be converted.
- **OUT**: The output value of type USINT (8-bit unsigned integer) containing the result of the conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapters.

When the event input REQ is triggered, the algorithm is executed. This algorithm converts the value at input IN (of type DINT) into a value of type USINT and outputs the result at output OUT. The event output CNF is then activated to signal the successful completion of the conversion.

- The conversion is performed by the built-in function DINT_TO_USINT.
- Please note that data loss may occur during the conversion from DINT to USINT, as the value range of USINT (0 to 255) is smaller than that of DINT (-2,147,483,648 to 2,147,483,647).

1. **Idle State**: The function block is waiting for the event REQ.
2. **Active State**: Upon receiving REQ, the conversion is performed and CNF is triggered.

- Data conversion in control systems when different data types are used.
- Reduction of memory usage when only small unsigned values are required.
- Interface adaptation between different system components.
- **F_INT_TO_USINT**: Converts a 16-bit integer value (INT) to an 8-bit unsigned integer value (USINT). In comparison, F_DINT_TO_USINT processes larger input values.
- **F_LINT_TO_USINT**: Converts a 64-bit integer value (LINT) to an 8-bit unsigned integer value (USINT). F_DINT_TO_USINT is designed for smaller input ranges.

The function block F_DINT_TO_USINT offers a simple and efficient way to convert 32-bit integers to 8-bit unsigned integers. It is particularly useful in scenarios where memory space needs to be optimized or data needs to be exchanged between systems with different data types. However, due to the potential for data loss, it should be ensured that the input values are within the valid range of USINT.

Conclusion

F_DINT_TO_WORD

• – ◦ • – ◦ • – ◦ •

The function block `F_DINT_TO_WORD` converts a 32-bit integer value (DINT) into a 16-bit word value (WORD). This conversion is particularly useful when data needs to be exchanged between systems with different word widths.

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is read and converted.
- **CNF**: Signals the successful completion of the conversion. The converted value is available at data output `OUT`.
- **IN**: The 32-bit integer value (DINT) to be converted.
- **OUT**: The converted 16-bit word value (WORD).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block has no adapters.

When the event input `REQ` is triggered, the algorithm is executed, converting the value of `IN` from DINT to WORD and outputting the result to `OUT`. The event `CNF` is then triggered to signal the completion of the operation.

- The conversion truncates the upper 16 bits of the DINT value, as a WORD can only store 16 bits. It is therefore important to ensure that the original DINT value is within the representable range of a WORD (0 to 65535) to avoid data loss.
- The function block is deterministic and has no internal states.

Since this is a simple function block without internal states, there are no state transitions. The block performs the conversion on each `REQ` event and signals completion with `CNF`.

- Communication between systems that use different word widths.
- Adapting data for peripheral devices that can only process WORD data.
- Use in control systems where memory optimization is required.
- Compared to generic conversion blocks like `F_ANY_TO_ANY`, `F_DINT_TO_WORD` is specialized and therefore more efficient when precisely this type of conversion is required.

- Similar blocks like `F_INT_TO_WORD` work with smaller integer types, while `F_DINT_TO_WORD` handles the larger DINT type.

The `F_DINT_TO_WORD` function block is a specialized and efficient tool for converting 32-bit integers to 16-bit words. Its simplicity and determinism make it a reliable component in control applications, especially for data adaptation between different systems.

F_DT_TO_DATE

• – ◦ • – ◦ • – ◦ •

The function block `F_DT_TO_DATE` converts a date-time value (DT) into a date (DATE). This functionality is particularly useful when control applications only require the date without time information.

- `REQ`: Starts the conversion process. Connected to the data input `IN`.
- `CNF`: Signals the completion of the conversion. Connected to the data output `OUT`.
- `IN` (DT): The input for the date-time value to be converted.
- `OUT` (DATE): The output for the converted date.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapters.

Upon receiving a `REQ` event, the DT value at input `IN` is converted to a DATE value and output at `OUT`. Simultaneously, the `CNF` event is triggered to signal the completion of the operation.

- The function block implements the conversion using the function `DT_TO_DATE`.
- The conversion is atomic and occurs in a single execution step.

The function block has no internal states. Each `REQ` request is processed independently.

- Extracting the date from timestamps in logging systems
- Preprocessing date information for reports or visualizations
- Interfaces to systems that can only process DATE data types
- Compared to `F_DT_TO_TIME`, this function block only converts the date portion
- Similar to `F_DT_TO_TOD`, but focusing on the date instead of the time of day

The `F_DT_TO_DATE` function block offers a simple and efficient way to convert DT values into pure dates. Its lean implementation makes it particularly suitable for real-time applications where performance is critical.

F_DT_TO_TOD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DT_TO_TOD` converts a date and time value (DT) into a pure time value (TOD - Time of Day). This function is particularly useful when only the time of day needs to be extracted from a combined date and time stamp.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the function block performs the conversion.

Event Outputs

- **CNF**: Signals the successful completion of the conversion.

Data Inputs

- **IN**: The input of type `DT`, containing the date and time value to be converted.

Data Outputs

- **OUT**: The output of type `TOD`, providing the converted time value (without the date).

Adapters

This function block does not use any adapters.

Operation

When the `REQ` event is triggered, the algorithm is executed, converting the input value `IN` of type `DT` into a `TOD` value. The result is output at `OUT`, and the `CNF` event signals the successful completion of the operation.

Technical Features

- The function block is implemented as a simple FB (SimpleFB), ensuring fast and efficient execution.
- The conversion is performed using the built-in function `DT_TO_TOD`.

State Overview

The function block has no internal states. The conversion is performed anew with each `REQ` event.

Application Scenarios

- Extracting the time of day from timestamps for time-based control systems.
- Preprocessing data for systems that only require the time of day.

⚖️ Comparison with Similar Function Blocks

- Unlike `F_TOD_TO_DT`, this function block converts in the opposite direction.
- Similar function blocks like `F_DT_TO_DATE` or `F_DT_TO_TIME` extract other parts of a date and time value.

Conclusion

The `F_DT_TO_TOD` function block provides a simple and efficient way to extract the time of day from a combined date and time value. Its clear interface and simple functionality make it a useful tool in control applications.

F_DWORD_AS_STRING

• − ◦ • − ◦ • − ◦ •

The function block `F_DWORD_AS_STRING` is used to convert a DWORD value into a STRING. This function block is particularly useful when numeric values need to be converted into a human-readable format or prepared for text output.

- **REQ**: Starts the conversion of the DWORD value to a STRING. This input is connected to the data input `IN`.
- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.
- **IN**: The DWORD value to be converted to a STRING.
- **OUT**: The resulting STRING after the DWORD value has been converted.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The value at input `IN` (DWORD) is converted to a STRING and output at `OUT`. Successful conversion is indicated by the event `CNF`.

- The function block uses the function `DWORD_AS_STRING` for conversion.
- The conversion occurs synchronously with the triggering of the `REQ` event.

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Complete**: Signals completion with `CNF` and outputs the result to `OUT`.

- Conversion of numeric IDs or status values into readable text format.
- Preparation of data for logging or user display.
- Integration into systems that require string-based communication.
- Compared to generic conversion blocks, `F_DWORD_AS_STRING` specializes in converting DWORD to STRING and therefore offers a simple and direct solution for this specific use case.
- Other blocks might offer additional conversion options or parameters, but may be more complex to use.

The `F_DWORD_AS_STRING` function block is an efficient and easy-to-use tool for converting DWORD values to strings. Its clear interface structure and direct functionality make it ideal for applications requiring fast and reliable conversion.

Technical Features

F_DWORD_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_AS_WSTRING` is used to convert a DWORD value to a WSTRING value. This function block is particularly useful in scenarios where numeric values need to be converted into a string, for example, for display or logging.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This input triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. This output signals the completion of the conversion.

Data Inputs

- **IN**: Input for the DWORD value to be converted.

Data Outputs

- **OUT**: Output for the resulting WSTRING value after conversion.

Adapters

- No adapters available.

Functionality

The function block performs the conversion from DWORD to WSTRING as soon as the event `REQ` is received. The conversion is carried out using the function `DWORD_AS_WSTRING`. After successful conversion, the event `CNF` is triggered, and the converted value is available at output `OUT`.

Technical Features

- The function block is implemented simply and efficiently, without additional state management.
- The conversion is performed directly and without delay.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

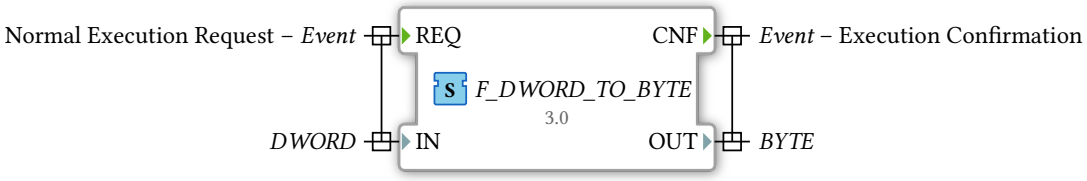
Application Scenarios

- Displaying numeric values in a user interface.
- Logging numeric data in text format.
- Communicating with systems that require strings.

⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion blocks, `F_DWORD_AS_WSTRING` specializes in converting DWORD to WSTRING and is therefore more efficient in this specific use case.
- Other blocks might have additional parameters or states, which is not necessary here.

Conclusion



The `F_DWORD_AS_WSTRING` function block is a simple and efficient block for converting DWORD values to WSTRING. Its simplicity makes it particularly suitable for applications where fast and direct conversion is required.

F_DWORD_TO_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_TO_BYTE` converts a 32-bit value (DWORD) to an 8-bit value (BYTE). This conversion is useful in scenarios where data reduction or type conversion is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `DWORD` (32-bit) to be converted to `BYTE`.

Data Outputs

- **OUT**: The output value of type `BYTE` (8-bit) containing the result of the conversion.

Adapters

- No adapters are available.

Functionality

This function block performs the conversion from `DWORD` to `BYTE` as soon as the event `REQ` is received. The conversion is performed using the function `DWORD_TO_BYTE`. After successful conversion, the event `CNF` is triggered.

Technical Details

- Data loss can occur if the original `DWORD` value is outside the representable range of `BYTE` (0-255).
- The function block is implemented as a simple FB (SimpleFB) and uses an ST algorithm for the conversion.

State Overview

1. **Idle**: Waits for the event `REQ`.
2. **Processing**: Performs the conversion.
3. **Completed**: Sends the event `CNF` and returns to the idle state.

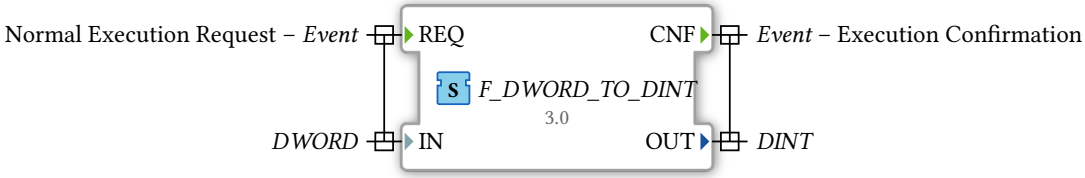
Application Scenarios

- Data reduction in control systems.
- Type conversion in communication protocols.
- Adapting data for specific hardware interfaces.

⚖️ Comparison with similar function blocks

- **F_WORD_TO_BYTE**: Converts a 16-bit value (WORD) to a BYTE.
- **F_DWORD_TO_WORD**: Converts a 32-bit value (DWORD) to a 16-bit value (WORD).
- **F_BYTE_TO_DWORD**: Performs the reverse conversion (BYTE to DWORD).

Conclusion



The function block `F_DWORD_TO_BYTE` provides a simple and efficient way to convert 32-bit values to 8-bit values. However, due to the potential for data loss with large values, its use should be carefully considered.

F_DWORD_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_TO_DINT` converts a `DWORD` value to a `DINT` value. This conversion is particularly necessary when exchanging data between systems that use different data types. The block is part of the `iec61131::conversion` package and conforms to standard 61499-1.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input expects a `DWORD` value to be converted.

Data Outputs

- **OUT**: The output provides the converted `DINT` value.

Adapters

No adapters are present.

Functionality

The function block performs the conversion from `DWORD` to `DINT` as soon as the event `REQ` is received. The conversion is performed using the function `DWORD_TO_DINT(IN)`. After successful conversion, the event `CNF` is triggered, and the converted value is output via the output `OUT`.

Technical Features

- The block is implemented as a simple function block (`SimpleFB`).
- The conversion is performed directly without additional state management.

State Overview

Since it is a simple function block, there are no explicit states. The conversion is performed with each `REQ` event.

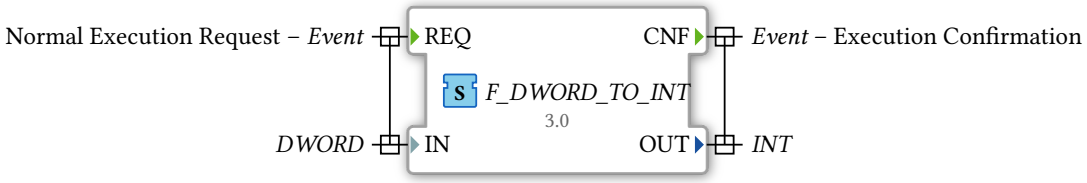
Application Scenarios

- Conversion of `DWORD` data supplied by one system into `DINT` data for another system.
- Use in control systems where data types need to be harmonized.

⚖️ Comparison with similar blocks

- Similar blocks could be `F_WORD_TO_INT` or `F_LWORD_TO_LINT`, but these convert different data types.
- Unlike more complex conversion blocks, `F_DWORD_TO_DINT` offers a direct and simple solution for this specific conversion.

Conclusion



The `F_DWORD_TO_DINT` function block provides an efficient and simple way to convert `DWORD` values to `DINT` values. Its clear interface and direct operation make it ideal for applications requiring fast and reliable type conversion.

F_DWORD_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_TO_INT` converts a DWORD value to an INT value. It is part of the package `iec61131::conversion` and enables easy conversion between these two data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion process. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `DWORD`, containing the value to be converted.

Data Outputs

- **OUT**: The output of type `INT`, providing the result of the conversion.

Adapters

This function block has no adapters.

Operation

When an event is received at input `REQ`, the algorithm is executed, converting the value of `IN` (of type `DWORD`) to a value of type `INT`. The result is output at `OUT` and confirmed by the event `CNF`.

Technical Features

- The function block uses the standard function `DWORD_TO_INT` for conversion.
- It is a simple function block without internal states or complex logic.

State Overview

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

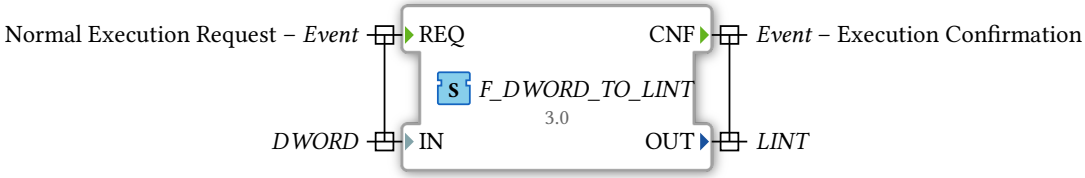
Application Scenarios

- Conversion of DWORD values supplied by hardware or other systems into INT values for further processing.
- Integration into control systems that need to process different data types.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks such as `F_WORD_TO_INT` or `F_BYTE_TO_INT`, this function block is specifically optimized for converting DWORD to INT.
- It offers a simple and direct solution without additional functions or parameters.

Conclusion



The `F_DWORD_TO_INT` function block is a useful tool for converting between DWORD and INT data types. Its simplicity and direct functionality make it a reliable solution for various use cases.

F_DWORD_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_TO_LINT` converts a `DWORD` value to a `LINT` value. This conversion is particularly useful when data needs to be exchanged between systems or components that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `DWORD`, which is to be converted to a `LINT` value.

Data Outputs

- **OUT**: The output value of type `LINT`, which contains the result of the conversion.

Adapters

This function block does not use any adapters.

Functionality

When an event is received at input `REQ`, the algorithm is executed. This algorithm converts the `DWORD` value at input `IN` into a `LINT` value and outputs the result at output `OUT`. The event `CNF` is then triggered to signal the completion of the conversion.

Technical Features

- The function block has a simple structure and contains only one algorithm that performs the conversion.
- The conversion is performed directly without any additional processing steps.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

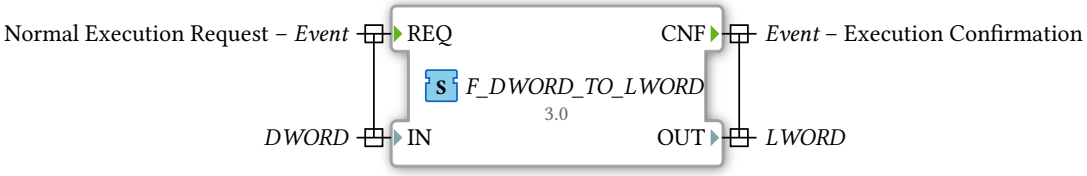
Application Scenarios

- Converting data between systems that use different data types.
- Use in control systems where type conversion is required.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion function blocks, `F_DWORD_TO_LINT` specializes in converting `DWORD` to `LINT`.
- Other function blocks could perform similar conversions for other data types, such as `F_WORD_TO_INT`.

Conclusion



The `F_DWORD_TO_LINT` function block is a simple and efficient tool for converting `DWORD` values to `LINT` values. Its clear interface structure and direct functionality make it a reliable solution for type conversions in control systems.

F_DWORD_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_DWORD_TO_LWORD converts a 32-bit data value (DWORD) to a 64-bit data value (LWORD). This conversion is particularly useful in scenarios where an increase in data width is required to ensure compatibility with subsequent processing steps.

Interface Structure

Event Inputs

- **REQ** (Type: Event): Starts the execution of the function block. This input is linked to the data input IN.

Event Outputs

- **CNF** (Type: Event): Signals the successful completion of the conversion. The output is linked to the data output OUT.

Data Inputs

- **IN** (Type: DWORD): The 32-bit input value to be converted to a 64-bit value.

Data Outputs

- **OUT** (Type: LWORD): The resulting 64-bit output value after conversion.

Adapters

This function block does not have any adapters.

Functionality

This function block performs the DWORD to LWORD conversion by converting the 32-bit input value (IN) to a 64-bit value (OUT). The conversion occurs automatically upon receiving an event at input REQ. After successful conversion, the event CNF is triggered.

Technical Features

- The function block is implemented as a simple FB (SimpleFB) and uses an ST algorithm for the conversion.
- The conversion is performed without data loss, as the 32-bit value is embedded into the 64-bit value.

State Overview

The function block has no internal state. The conversion occurs immediately upon receiving the REQ event.

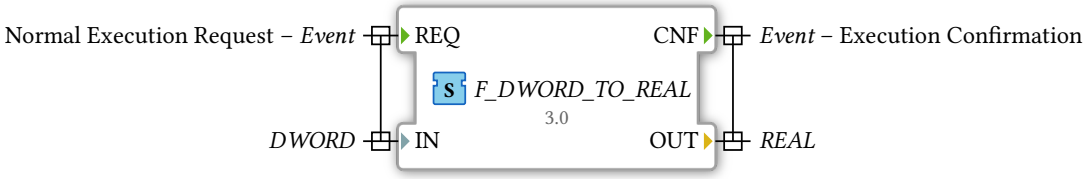
Application Scenarios

- Extending the data width for subsequent processing steps.
- Ensuring compatibility between systems that use different data widths.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks (e.g., F_WORD_TO_DWORD), this function block is specifically optimized for converting 32-bit to 64-bit values.
- Similar blocks might offer additional features such as scaling or offset adjustment, which is not the case here.

Conclusion



The F_DWORD_TO_LWORD function block is a simple and efficient tool for converting 32-bit to 64-bit values. Its clear interface structure and direct functionality make it ideal for applications that only require data width extension.

F_DWORD_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_TO_REAL` converts a DWORD value (32-bit unsigned integer) to a REAL value (32-bit floating-point number). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is activated as soon as the conversion is complete and the result value is available at data output `OUT`.

Data Inputs

- **IN**: DWORD value to be converted to a REAL value.

Data Outputs

- **OUT**: The converted REAL value.

Adapters

No adapters available.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The value at input `IN` is converted to a REAL value using the function `DWORD_TO_REAL` and output at output `OUT`. Finally, the event `CNF` is triggered to signal the successful completion of the operation.

Technical Features

- The conversion is performed directly and without any additional delay.
- No special error handling is performed, e.g., for invalid input values.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Conversion State**: Performs the conversion and sets the output `OUT`.
3. **Confirmation State**: Enables `CNF` and returns to the idle state.

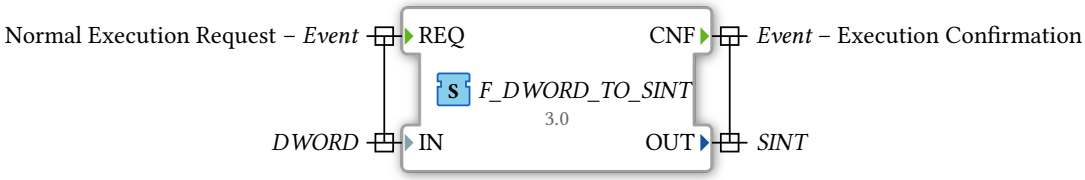
Application Scenarios

- Type conversion in control applications where DWORD data needs to be converted to floating-point numbers.
- Integration into larger function blocks that require type conversion.

⚖️ Comparison with similar function blocks

- Similar function blocks such as `F_WORD_TO_REAL` or `F_INT_TO_REAL` offer similar functionality, but for different input types.
- `F_DWORD_TO_REAL` is specifically optimized for converting DWORD to REAL.

Conclusion



The `F_DWORD_TO_REAL` function block is a simple and efficient building block for converting DWORD to REAL values. Its clear interface and direct functionality make it a reliable component in control applications.

F_DWORD_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_TO_SINT` converts a 32-bit DWORD value to an 8-bit SINT value (signed integer). This block is part of the IEC 61131 conversion library and enables simple type conversion between these data types.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion process. This input is linked to the data input `IN`.

Event Outputs

- `CNF`: Signals successful completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- `IN` (DWORD): The 32-bit input value to be converted to a SINT value.

Data Outputs

- `OUT` (SINT): The converted 8-bit SINT value.

Adapters

This function block does not have any adapter interfaces.

Functionality

When the `REQ` event is triggered, the algorithm that converts the `IN` value of type DWORD into a SINT value is executed. The conversion is performed by the built-in function `DWORD_TO_SINT`. After the conversion is complete, the `CNF` event is triggered, and the converted value is available at the `OUT` output.

Technical Features

- Data loss can occur during the conversion if the DWORD value is outside the representable range of a SINT (-128 to 127).
- The function block is a simple block without internal state management.

State Overview

The function block has no internal states. Execution occurs immediately upon receiving the `REQ` event.

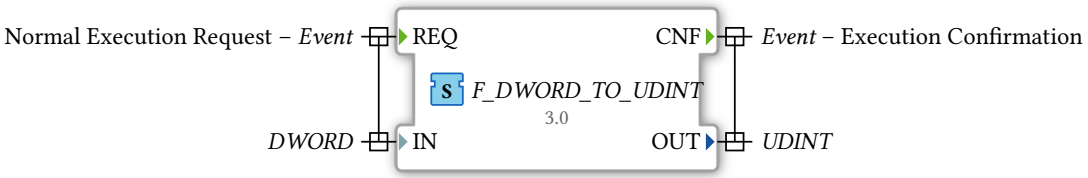
Application Scenarios

- Type conversion in control applications where DWORD values need to be converted to more compact SINT values.
- Data reduction when only the least significant part of a DWORD value is required.

⚖️ Comparison with Similar Function Blocks

- Compared to `F_DWORD_TO_INT` or `F_DWORD_TO_USINT`, this function block converts to a signed 8-bit value.
- Similar function blocks for other target types are available in the IEC 61131 conversion library.

Conclusion



The `F_DWORD_TO_SINT` function block provides a simple and efficient way to convert DWORD values to SINT values. It is particularly useful in applications where storage space or data bandwidth needs to be optimized. When using it, the possible value range of the SINT data type must be considered to avoid unwanted data loss.

F_DWORD_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_TO_UDINT` converts a `DWORD` value to a `UDINT` value. This block is part of the `iec61131::conversion` package and enables simple and efficient type conversion.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `DWORD`, containing the value to be converted.

Data Outputs

- **OUT**: The output of type `UDINT`, providing the result of the conversion.

Adapters

- This function block does not use any adapters.

Functionality

The function block performs the conversion from `DWORD` to `UDINT` as soon as the `REQ` event is triggered. The conversion is performed using the built-in function `DWORD_TO_UDINT`. After the conversion is complete, the `CNF` event is triggered, and the converted value is available at output `OUT`.

Technical Features

- The function block has a simple structure and contains only one algorithm (`REQ`) that performs the conversion.
- The conversion is performed directly and without any additional delay.

State Overview

The function block has no internal state. The conversion is re-executed with each `REQ` event.

Application Scenarios

- Type conversion in control applications where `DWORD` values need to be converted to `UDINT` values.
- Integration into larger control systems that require type compatibility between different data formats.

⚖️ Comparison with similar blocks

- Similar function blocks such as `F_WORD_TO_UINT` or `F_BYTE_TO_USINT` perform similar type conversions, but for different data types.
- Unlike generic conversion blocks, `F_DWORD_TO_UDINT` is specialized and optimized for converting `DWORD` to `UDINT`.

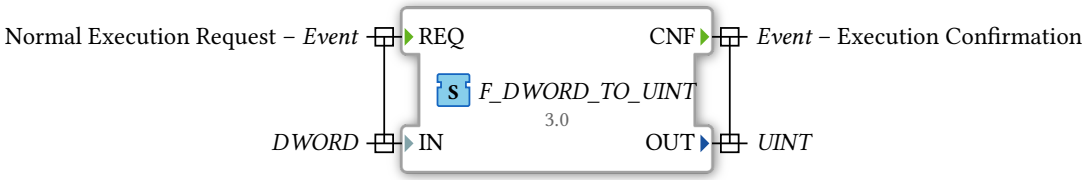
- Uebung_153



Conclusion

The `F_DWORD_TO_UDINT` function block provides a simple and efficient solution for converting `DWORD` values to `UDINT` values. Its clear interface structure and direct functionality make it a reliable component in control applications.

F_DWORD_TO_UINT

• – ◦ • – ◦ • – ◦ •

The function block `F_DWORD_TO_UINT` converts a `DWORD` value to a `UINT` value. This function block is particularly useful in scenarios where type conversion between these two data types is required, for example, in communication between different systems or when processing data from different sources.

- **REQ**: This input triggers the execution of the function block. The associated data value `IN` is processed upon this event.
- **CNF**: This output is activated after successful conversion and confirms execution. The converted value `OUT` is output with this event.
- **IN** (`DWORD`): The input value to be converted from `DWORD` to `UINT`.
- **OUT** (`UINT`): The output value after conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use adapters.

The function block performs the conversion from `DWORD` to `UINT` as soon as the event `REQ` is received. The conversion is performed using the function `DWORD_TO_UINT`, which converts the input value `IN` and outputs the result to `OUT`. After successful conversion, the event `CNF` is triggered.

- The function block is a simple algorithm (`SimpleFB`) and does not perform any complex state transitions.
- The conversion occurs directly and without delay.

Since it is a simple function block, there are no complex state transitions. The block responds exclusively to the `REQ` event, outputting the converted value, and to the `CNF` event.

- Type conversion in communication interfaces where different systems use different data types.
- Data processing in control systems where conversion between `DWORD` and `UINT` is required.
- Compared to other conversion blocks such as `F_WORD_TO_UINT` or `F_BYTE_TO_UINT`, this one is specifically optimized for converting `DWORD` to `UINT`.
- Compared to other conversion blocks like `F_WORD_TO_UINT` or `F_BYTE_TO_UINT`, this one is specifically optimized for converting `DWORD` to `UINT`.

Similar function blocks might offer additional features such as range checks or error handling, which this function block does not.

The `F_DWORD_TO_UINT` function block is a simple and efficient tool for converting `DWORD` values to `UINT` values. Its simplicity makes it particularly suitable for applications where fast and direct type conversion is required.

F_DWORD_TO_ULINT

• – ◦ • – ◦ • – ◦ •

The function block `F_DWORD_TO_ULINT` converts a `DWORD` value to a `ULINT` value. It is part of the `iec61131::conversion` package and is typically used in automation applications where type conversion between these two data types is required.

- **REQ**: This input triggers the execution of the function block. It is linked to the data input `IN`.
- **CNF**: This output signals the successful execution of the function block. It is linked to the data output `OUT`.
- **IN**: The input expects a `DWORD` value, which is to be converted to a `ULINT` value.
- **OUT**: The output provides the converted `ULINT` value.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapters.

The function block performs the conversion from `DWORD` to `ULINT` as soon as the `REQ` event arrives. The algorithm within the function block uses the function `DWORD_TO_ULINT` to carry out the conversion. After successful conversion, the `CNF` event is triggered, and the converted value is available at the `OUT` output.

- The function block is implemented as a simple function block (`SimpleFB`).

- The conversion occurs directly and without any additional delay.
- The function block is licensed under the Eclipse Public License 2.0.

This function block has no internal state. Execution occurs exclusively upon the occurrence of the `REQ` event.

- Type conversion in automation applications where `DWORD` values need to be converted to `ULINT` values.
- Integration into larger control systems that process different data types.
- Similar function blocks such as `F_WORD_TO_UINT` or `F_BYTE_TO_USINT` perform similar conversions, but for different data types.
- `F_DWORD_TO_ULINT` specializes in converting `DWORD` to `ULINT` and offers no additional functionality.

The `F_DWORD_TO_ULINT` function block is a simple and efficient tool for type conversion in IEC 61131-3-based control systems. Its clear interface and direct operation make it a reliable component in automation projects.

Conclusion

F_DWORD_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_TO_USINT` converts a 32-bit value (DWORD) to an 8-bit unsigned integer (USINT). This conversion is particularly useful when data needs to be exchanged between systems with different word lengths.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs

- **IN** (DWORD): The 32-bit value to be converted to an 8-bit unsigned integer.

Data Outputs

- **OUT** (USINT): The resulting 8-bit unsigned integer after conversion.

Adapters

This function block does not have any adapter interfaces.

Operation

The function block performs the conversion by transforming the 32-bit value at input `IN` into an 8-bit unsigned integer. The conversion is performed by the function `DWORD_TO_USINT`, which converts the value accordingly. During the conversion, only the least significant byte of the DWORD value is considered, while the higher-order bytes are ignored.

Technical Features

- The conversion truncates the higher-order bytes, which can lead to data loss if the original DWORD value is greater than 255.
- The function block is deterministic and performs the conversion in a single execution step.

State Overview

The function block has no internal state. The conversion is performed anew each time the `REQ` event is triggered.

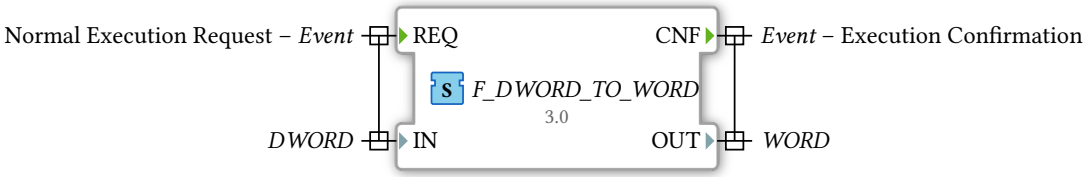
Application Scenarios

- Data reduction in communication protocols where only 8-bit values can be transmitted.
- Adapting data formats between different system components.
- Use in controllers where specific hardware can only process 8-bit data.

⚖️ Comparison with Similar Function Blocks

- **F_WORD_TO_USINT**: Converts a 16-bit value (WORD) to an 8-bit unsigned integer. In contrast, `F_DWORD_TO_USINT` processes 32-bit values.
- **F_DWORD_TO_BYTE**: Similar in functionality, but the output type is BYTE, which is also 8 bits, but unsigned.

Conclusion



The function block `F_DWORD_TO_USINT` is a simple and efficient tool for converting 32-bit values to 8-bit unsigned integers. It is particularly suitable for applications where data needs to be reduced to a smaller word width. However, due to the potential for data loss with large input values, its use should be carefully planned.

F_DWORD_TO_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_DWORD_TO_WORD` converts a 32-bit DWORD value to a 16-bit WORD value. This conversion is useful when data needs to be exchanged between systems with different word lengths or when memory space needs to be optimized.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN** (DWORD): The 32-bit input value to be converted.

Data Outputs

- **OUT** (WORD): The converted 16-bit output value.

Adapters

This function block does not use adapters.

Operation

When the `REQ` event is triggered, the algorithm is executed that converts the DWORD value at the input `IN` to a WORD value and outputs the result to `OUT`. The `CNF` event is then triggered to signal the completion of the conversion.

Technical Features

- The conversion is performed by truncating the 16 most significant bits of the DWORD value.
- No check is performed to prevent potential data loss during this conversion.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

Application Scenarios

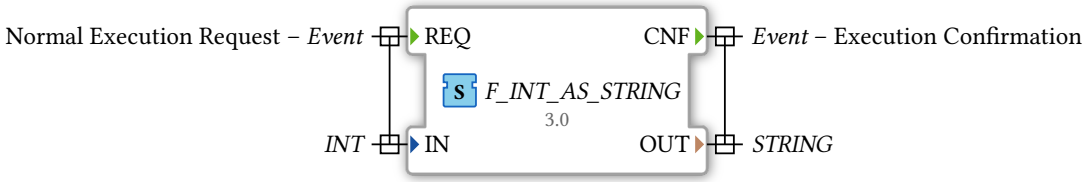
- Communication between systems with different word widths
- Memory optimization in embedded systems
- Data preprocessing in control systems

⚖️ Comparison with Similar Function Blocks

- Unlike `F_DWORD_TO_BYTE`, this function block converts to a WORD value instead of a BYTE.
- Similar to `F_WORD_TO_BYTE`, but with different data types.

Conclusion

The `F_DWORD_TO_WORD` function block offers a simple and efficient way to convert DWORD values to WORD values. It is particularly useful in systems that need to handle different word widths. However, be aware of the potential for data loss during the conversion.



INT

F_INT_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_AS_STRING` converts an integer value (`INT`) into a string (`STRING`). This functionality is particularly useful when numeric values need to be output in a user-readable format or further processed in a word processor.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the input value. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN** (`INT`): The integer value to be converted to a string.

Data Outputs

- **OUT** (`STRING`): The resulting string after the input value has been converted.

Adapters

- This function block has no adapters.

Functionality

When the event `REQ` is triggered, the algorithm is executed that converts the integer value `IN` to a string and outputs the result to `OUT`. The event `CNF` is then triggered to signal the successful completion of the conversion.

Technical Features

- The conversion is performed using the function `INT_AS_STRING`, which directly converts the `INT` value into a `STRING` value.
- The function block is simple and efficient because it does not require complex state machines or additional processing steps.

State Overview

Because it is a simple function block, there are no explicit states. The functionality is executed directly upon triggering the `REQ` event.

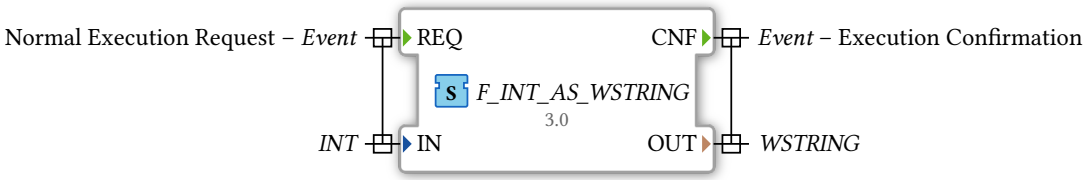
Application Scenarios

- Displaying numeric values in user interfaces or logs.
- Preparing data for output in text formats (e.g., CSV, JSON).
- Integration into systems that require strings for further processing.

⚖️ Comparison with similar building blocks

- Compared to generic conversion blocks, `F_INT_AS_STRING` specializes in converting `INT` to `STRING` and is therefore more efficient and easier to use.
- Other blocks might support additional parameters such as formatting or locale settings, which is not the case here.

Conclusion



The `F_INT_AS_STRING` function block offers a simple and effective way to convert integer values to strings. Its simplicity and direct functionality make it ideal for applications that require fast and straightforward conversion.

F_INT_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_AS_WSTRING` converts an integer value (`INT`) into a wide string (`WSTRING`). This functionality is particularly useful when numeric values are needed as text for display or further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs

- **IN**: The integer value (`INT`) to be converted into a wide string.

Data Outputs

- **OUT**: The resulting wide string (`WSTRING`) after conversion.

Adapters

- No adapters are available.

Functionality

The function block uses the built-in function `INT_AS_WSTRING` to convert the integer input value into a wide string. The conversion is initiated by the event `REQ` and confirmed by the event `CNF`.

Technical Features

- The function block has a simple structure and performs only basic data type conversion.
- No additional parameters or complex algorithms are required.

State Overview

1. **Ready**: Waits for the event `REQ`.
2. **Active**: Performs the conversion and sets the output `OUT`.
3. **Confirmed**: Sends the event `CNF` and returns to the ready state.

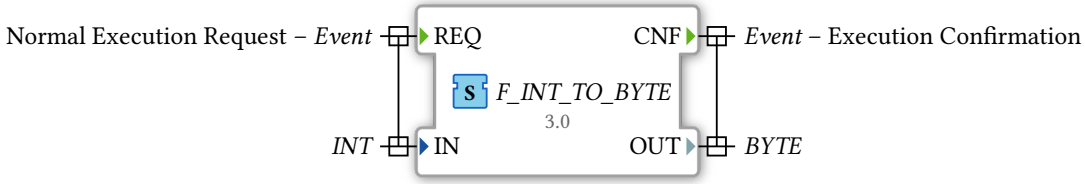
Application Scenarios

- Displaying numeric values in user interfaces.
- Logging numeric data in text format.
- Preparing data for communication with systems that expect text formats.

⚖️ Comparison with Similar Function Blocks

- **F_DINT_AS_WSTRING**: Converts a long integer value (`DINT`) to a wide string.
- **F_REAL_AS_WSTRING**: Converts a floating-point value (`REAL`) to a wide string.
- **F_STRING_AS_INT**: Performs the reverse conversion (string to integer).

Conclusion



The `F_INT_AS_WSTRING` function block is a simple and efficient tool for converting integers to wide strings. Its clear interface and direct functionality make it a reliable solution for basic data type conversions.

F_INT_TO_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_BYTE` is used to convert an integer value (`INT`) to a byte value (`BYTE`). It is part of the package `iec61131::conversion` and provides a simple and efficient way to convert data types within IEC 61499 systems.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: The integer value (`INT`) to be converted to a byte value.

Data Outputs

- **OUT**: The resulting byte value (`BYTE`) after the conversion.

Adapters

This function block does not use any adapters.

Functionality

When an event is received at input `REQ`, the algorithm is executed, converting the value of `IN` from `INT` to `BYTE` and outputting the result to `OUT`. The event `CNF` is then triggered to signal the successful completion of the conversion.

The algorithm is defined as follows:
ALGORITHM REQ OUT := INT_TO_BYTE(IN); END_ALGORITHM

Technical Features

- The function block is implemented simply and efficiently, without additional states or complex logic.
- The conversion is performed directly and without delay.

State Overview

Since it is a simple function block, there are no explicit states. Execution occurs immediately upon receiving the `REQ` event.

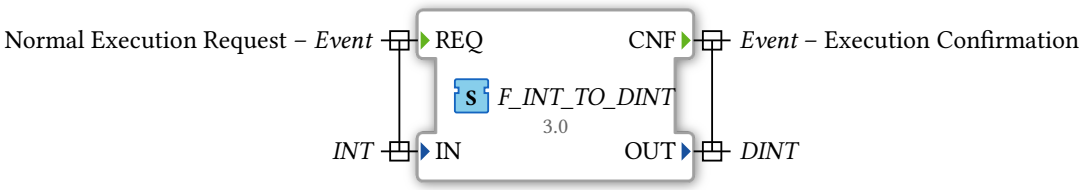
Application Scenarios

- Type conversion in control applications where integer values need to be converted to byte values.
- Integration into larger systems that require strict type control.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_DINT_TO_BYTE` or `F_WORD_TO_BYTE` offer conversions between other data types but are designed for different source types.
- `F_INT_TO_BYTE` is specifically optimized for converting `INT` to `BYTE`.

Conclusion



The function block `F_INT_TO_BYTE` is a useful tool for type conversion in IEC 61499-based systems. Its simple and efficient implementation makes it ideal for applications requiring fast and reliable conversions.

F_INT_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_DINT` is used to convert a 16-bit integer value (`INT`) to a 32-bit integer value (`DINT`). This conversion is useful when exchanging data between systems or components that use different integer formats.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (`INT`): The 16-bit integer value to be converted.

Data Outputs

- **OUT** (`DINT`): The resulting 32-bit integer value after the conversion.

Adapters

This function block does not use adapters.

Operation

The function block performs a direct type conversion. When the `REQ` event occurs, the value of `IN` is copied to `OUT`. The 16-bit `INT` value is automatically expanded to a 32-bit `DINT` value. After the conversion is complete, the `CNF` event is triggered.

Technical Features

- The conversion is lossless, as a `INT` value can be converted to a `DINT` value without any issues.
- The function block is deterministic and has no internal states.

State Overview

The function block has no internal states. It reacts exclusively to the `REQ` event with an immediate conversion and output of the `CNF` event.

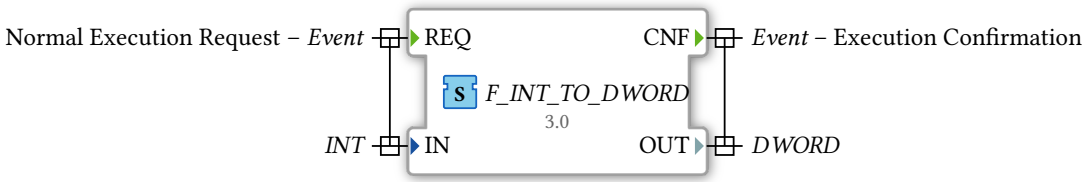
Application Scenarios

- Data communication between systems that use different integer formats.
- Extending integer values for further calculations or storage.
- Compatibility with libraries or functions that require `DINT` values.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_INT_TO_DINT` is specialized and optimized for converting `INT` to `DINT`.
- Other conversion blocks might offer additional features such as overflow checks or scaling, which are not necessary here.

Conclusion



The `F_INT_TO_DINT` function block is a simple and efficient building block for lossless conversion of 16-bit to 32-bit integer values. It is particularly useful in scenarios where type conversion without additional calculations is required.

F_INT_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_DWORD` converts an integer value (INT) to a double-word value (DWORD). This conversion is particularly useful when exchanging data between systems that use different data types.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs
- **CNF**: Confirms the successful execution of the conversion. This output is linked to the data output `OUT`.

Data Inputs
- **IN** (INT): The integer value to be converted to a DWORD value.

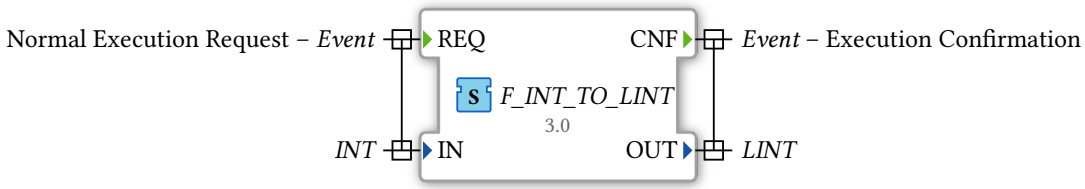
Data Outputs
- **OUT** (DWORD): The resulting DWORD value after conversion.

Adapters
This function block does not use any adapters.

Functionality
The function block performs the INT to DWORD conversion as soon as the event `REQ` is triggered. The conversion is carried out using the function `INT_TO_DWORD`, which converts the input value `IN` to the output value `OUT`. After successful conversion, the event `CNF` is triggered.

Technical Features
- This function block is a simple function block (SimpleFB) and uses an ST algorithm for conversion.
- The conversion is performed directly and without any additional delay.

State Overview
The function block has no internal states. The conversion occurs immediately after the `REQ` event is triggered.



Application Scenarios
- Data conversion in control systems that use different data types.
- Integration of systems that generate INT values but require DWORD values.

⚖️ Comparison with Similar Function Blocks
- Compared to other conversion blocks such as `F_INT_TO_REAL` or `F_DWORD_TO_INT`, this function block specializes in converting INT to DWORD.
- Simpler and more direct than universal conversion blocks that support multiple data types.

Conclusion
The `F_INT_TO_DWORD` function block is an efficient and simple tool for converting integer to double-word values. Its clear interface and direct functionality make it ideal for applications requiring fast and reliable data type conversion.

F_INT_TO_LINT
• – ◦ • – ◦ • – ◦ •

Introduction
The function block `F_INT_TO_LINT` converts a 16-bit integer value (`INT`) into a 64-bit long integer value (`LINT`). This block is particularly useful in scenarios where extending the value range or changing the type is required for subsequent processing steps.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs
- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs
- **IN** (`INT`): The 16-bit integer value to be converted.

Data Outputs
- **OUT** (`LINT`): The resulting 64-bit long integer value after the conversion.

Adapters
No adapters are present.

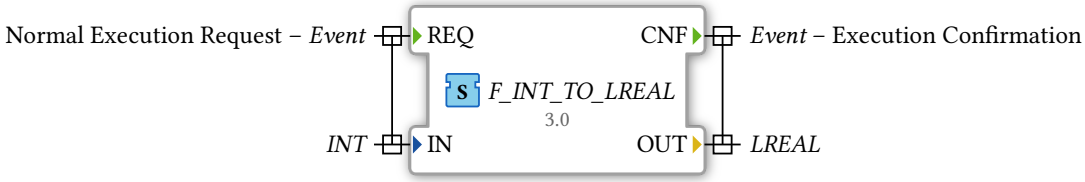
Functionality
The function block performs a direct assignment of the input value `IN` of type `INT` to the output value `OUT` of type `LINT`. The conversion is performed implicitly through type conversion, preserving the numeric value.

Technical Features
- **Simple Implementation**: The algorithm consists of a single assignment.
- **No Data Loss**: Since `LINT` has a larger range of values than `INT`, there are no overflow problems.
- **Deterministic Behavior**: Execution is predictable and fast.

State Overview
The function block has no internal state. Every call to `REQ` results in immediate execution and output via `CNF`.

Application Scenarios
- **Data Processing**: Extending integer values for subsequent calculations with a larger value range.
- **Interface Adaptation**: Adapting data for components that expect `LINT`.
- **Logging**: Storing `INT` values in systems that use `LINT`.

⚖️ Comparison with Similar Function Blocks
- **F_INT_TO_DINT**: Converts `INT` to `DINT` (32-bit), offering a smaller value range than `LINT`.
- **F_DINT_TO_LINT**: Converts `DINT` to `LINT`, similar but with a different input type.
- **F_LINT_TO_INT**: Reverse conversion, potentially resulting in data loss.



Conclusion
The `F_INT_TO_LINT` function block is a simple and efficient tool for type conversion in the 4diac IDE. Its strength lies in its direct and lossless conversion, making it ideal for applications with extended value requirements.

F_INT_TO_LREAL
• – ◦ • – ◦ • – ◦ •

Introduction
The function block `F_INT_TO_LREAL` converts an integer value (INT) into a 64-bit floating-point number (LREAL). This block is particularly useful in applications where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `INT`, which is to be converted to a value of `LREAL`.

Data Outputs

- **OUT**: The output value of type `LREAL`, which contains the result of the conversion.

Adapters

- No adapters are available.

Functionality

The function block performs the conversion by directly assigning the integer input value `IN` to the floating-point output value `OUT`. The conversion occurs automatically when an event arrives at the `REQ` input. After the conversion is complete, the `CNF` event is triggered.

Technical Features

- The conversion is performed without additional parameters or configuration.
- The function block is optimized for use in the 4diac IDE and supports real-time processing.

State Overview

1. **Idle State**: Waits for a `REQ` event.
2. **Conversion State**: Performs the type conversion.
3. **Acknowledge State**: Sends the `CNF` event and returns to the idle state.

Application Scenarios

- Type conversion in control applications requiring floating-point operations.
- Integration into larger control systems that process mixed data types.

⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion blocks, `F_INT_TO_LREAL` specializes in converting `INT` to `LREAL` and is therefore more efficient at this specific task.
- Other function blocks might offer additional features such as scaling or range checking, which is not the case here.

Conclusion

The `F_INT_TO_LREAL` function block is a simple and efficient building block for converting integer values to floating-point numbers. Its simplicity and direct operation make it a reliable choice for basic type conversions in automation technology.

F_INT_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_LWORD` converts an integer value (`INT`) into a 64-bit unsigned integer value (`LWORD`). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Triggers the execution of the function block. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals successful execution of the function block. This output is connected to the data output `OUT`.

Data Inputs

- **IN** (`INT`): The input value to be converted to a `LWORD` value.

Data Outputs

- **OUT** (`LWORD`): The converted output value.

Adapters

No adapters available.

Functionality

Upon receiving an incoming `REQ` event, the function block converts the `INT` value at the input `IN` to a `LWORD` value. The result is output at `OUT`, and the `CNF` event signals successful execution.

The algorithm is defined as follows:
ALGORITHM REQ OUT := INT_TO_LWORD(IN); END_ALGORITHM

Technical Features

- The function block is simple and efficient because it directly utilizes the built-in `INT_TO_LWORD` function.
- No additional states or complex logic are required.

State Overview

The function block has no internal states. Execution occurs immediately upon receiving the `REQ` event.

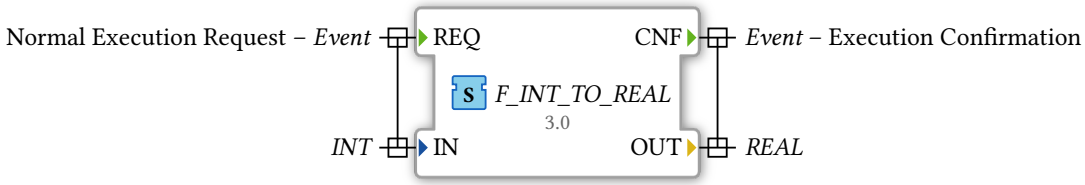
Application Scenarios

- Type conversion in control applications where `INT` values need to be converted to `LWORD` values.
- Integration into larger systems that process different data types.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_DINT_TO_LWORD` or `F_SINT_TO_LWORD` offer conversions from other integer types to `LWORD`.
- `F_INT_TO_LWORD` is specifically optimized for converting `INT` to `LWORD`.

Conclusion



The `F_INT_TO_LWORD` function block provides a simple and efficient solution for converting `INT` values to `LWORD` values. Its clear interface and direct functionality make it ideal for use in control applications.

F_INT_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_REAL` converts an integer value (`INT`) into a floating-point number (`REAL`). This functionality is particularly useful when data needs to be converted between different numerical representations in control applications.

Interface Structure

Event Inputs

- **REQ**: This input triggers the execution of the conversion. It is linked to the data input `IN`.

Event Outputs

- **CNF**: This output signals the completion of the conversion. It is linked to the data output `OUT`.

Data Inputs

- **IN** (`INT`): The integer value to be converted to a floating-point number.

Data Outputs

- **OUT** (`REAL`): The resulting floating-point value after conversion.

Adapters

This function block does not use any adapters.

Functionality

When the event `REQ` is triggered, the value of the data input `IN` is read and converted to the type `REAL`. The result is output at data output `OUT`, and the event `CNF` signals the successful completion of the operation.

Technical Features

- The conversion is performed directly without additional parameters or settings.
- The function block is implemented simply and efficiently, ensuring fast execution.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

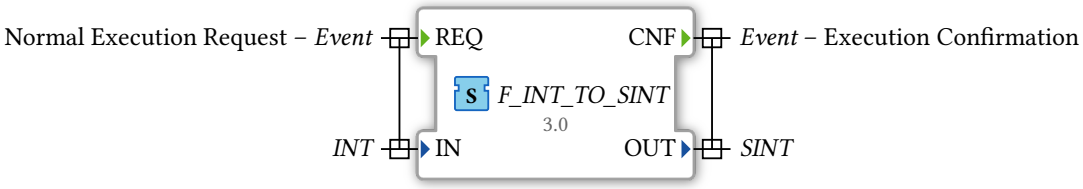
Application Scenarios

- Conversion of sensor values (e.g., acquired as `INT`) into floating-point numbers for further calculations.
- Integration into control logic that needs to process mixed data types.

⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion blocks, `F_INT_TO_REAL` is specialized and therefore more efficient for this specific use case.
- Other blocks might offer additional features such as range checks or scaling, which are not required here.

Conclusion



The `F_INT_TO_REAL` function block is a simple and effective tool for converting integer values to floating-point numbers. Its clear interface and direct functionality make it ideal for applications requiring fast and reliable type conversion.

F_INT_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_SINT` converts an integer value of type `INT` into a signed 8-bit integer value of type `SINT`. This conversion is useful when data needs to be exchanged or processed between systems with different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `INT` to be converted.

Data Outputs

- **OUT**: The converted output value of type `SINT`.

Adapters

No adapters are present.

Functionality

This function block performs the conversion from `INT` to `SINT` as soon as the event `REQ` is triggered. The algorithm within the block uses the function `INT_TO_SINT` to perform the conversion. After the conversion is complete, the event `CNF` is triggered, and the converted value is available at the output `OUT`.

Technical Features

- The function block has a simple structure and contains only one algorithm for the conversion.
- There is no additional error handling for overflow or underflow conditions. The user must ensure that the input value is within the valid range for `SINT` (-128 to 127).

State Overview

The function block has no internal states. The conversion occurs immediately after the `REQ` event is triggered.

Application Scenarios

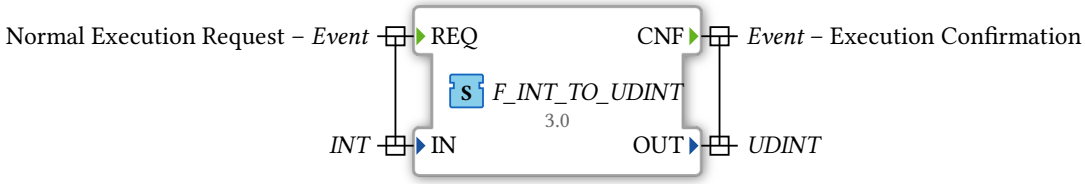
- Data conversion in control systems where different data types need to be processed.
- Communication between systems that use different data types.
- Reducing memory usage when a smaller data type is sufficient.

⚖️ Comparison with Similar Function Blocks

- **F_INT_TO_USINT**: Converts `INT` to `USINT` (unsigned 8-bit integer).
- **F_INT_TO_DINT**: Converts `INT` to `DINT` (32-bit integer), which does not involve data reduction.
- **F_INT_TO_REAL**: Converts `INT` to `REAL` (floating-point number).

Conclusion

The `F_INT_TO_SINT` function block is a simple and efficient tool for converting `INT` to `SINT` values. It is particularly suitable for applications that need to optimize storage space or exchange data between



systems with different data types. However, users should ensure that the input values are within the valid range for `SINT` to avoid unexpected results.

F_INT_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_UDINT` converts a signed 16-bit integer value (`INT`) into an unsigned 32-bit integer value (`UDINT`). This conversion is particularly necessary in scenarios where data needs to be exchanged between systems with different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The signed 16-bit integer value (`INT`) to be converted.

Data Outputs

- **OUT**: The resulting unsigned 32-bit integer value (`UDINT`).

Adapters

- No adapters are present.

Functionality

This function block performs the conversion from `INT` to `UDINT` as soon as the event `REQ` is received. The conversion is performed using the function `INT_TO_UDINT(IN)`, which converts the input value `IN` into the corresponding value `UDINT`. After successful conversion, the event `CNF` is triggered, and the converted value is available at the output `OUT`.

Technical Features

- The conversion is performed without additional parameters or configuration.
- The function block is suitable for use in real-time systems because it operates deterministically.

State Overview

1. **Idle State**: Waits for the event `REQ`.
2. **Conversion State**: Performs the conversion and sets the output `OUT`.
3. **Acknowledgement State**: Triggers the event `CNF` and returns to the idle state.

Application Scenarios

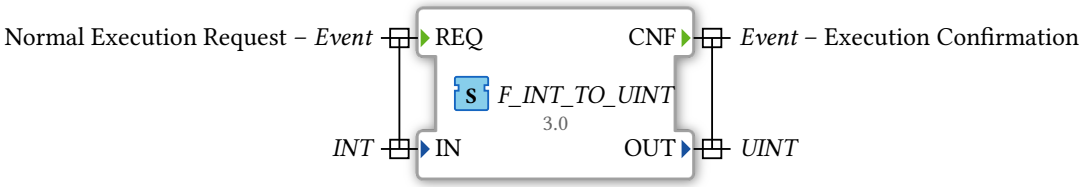
- Data conversion in control systems that use different data types.
- Integration of sensor data in `INT` format into systems requiring `UDINT` format.
- Compatibility layer between different hardware or software components.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_DINT_TO_UDINT` or `F_SINT_TO_UDINT` offer conversions between other data types, but not specifically for `INT` to `UDINT`.

Unlike generic conversion blocks, `F_INT_TO_UDINT` is optimized for a specific conversion.

Conclusion



The function block `F_INT_TO_UDINT` is a specialized and efficient tool for converting signed 16-bit integer values to unsigned 32-bit integer values. Its simple interface and deterministic operation make it ideal for use in real-time applications.

F_INT_TO_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_UINT` converts a signed integer value (`INT`) to an unsigned integer value (`UINT`). This conversion is useful when exchanging data between systems that use different data types, or when unsigned processing is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN** (`INT`): The signed integer value to be converted.

Data Outputs

- **OUT** (`UINT`): The resulting unsigned integer value after the conversion.

Adapters

No adapters are used.

Functionality

The function block performs the conversion from `INT` to `UINT` when the event `REQ` is triggered. The conversion is performed using the function `INT_TO_UINT(IN)`. After successful conversion, the event `CNF` is triggered, and the converted value is available at output `OUT`.

Technical Features

- The conversion is performed without additional parameters or configuration.
- The block is implemented as a simple function block (`SimpleFB`) and uses an ST algorithm for the conversion.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Conversion State**: Performs the conversion and sets the output `OUT`.
3. **Acknowledgement State**: Triggers the `CNF` event and returns to the idle state.

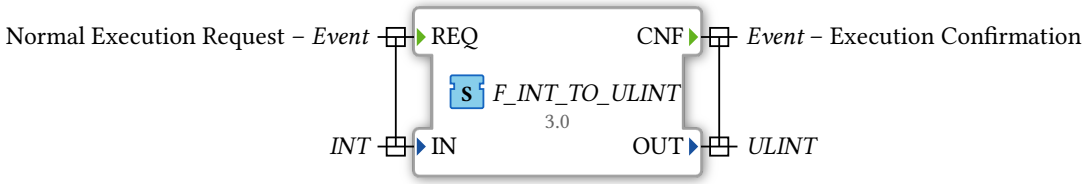
Application Scenarios

- **Data Processing**: Converts sensor values or control data in `INT` format for systems that expect `UINT`.
- **Communication**: Prepares data for transmission between systems with different data type requirements.

⚖️ Comparison with Similar Blocks

- **F_UINT_TO_INT**: Performs the reverse conversion from `UINT` to `INT`.
- **Generic Conversion Blocks**: May offer more flexibility but are also more complex to use.

Conclusion



The `F_INT_TO_UINT` function block is a simple and efficient tool for converting signed to unsigned integer values. Its clear interface and simple functionality make it ideal for applications requiring fast and reliable type conversion.

F_INT_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_ULINT` converts an integer value of data type `INT` into an unsigned 64-bit integer value of data type `ULINT`. This conversion is particularly useful when values need to be exchanged between different systems or components that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the input value. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion and outputs the converted value via the data output `OUT`.

Data Inputs

- **IN**: The input value of data type `INT` to be converted.

Data Outputs

- **OUT**: The converted output value of data type `ULINT`.

Adapters

This function block does not use any adapters.

Operation

The function block performs the conversion as soon as the event `REQ` is received. The algorithm within the function block converts the `INT` value at input `IN` into a `ULINT` value and outputs the result at `OUT`. Successful conversion is signaled by triggering the `CNF` event.

Technical Features

- The conversion is performed directly and without any additional delay.
- The function block is suitable for use in real-time systems.
- The implementation complies with the IEC 61131-3 standard.

State Overview

The function block has no internal states. The conversion is performed each time the `REQ` event is received.

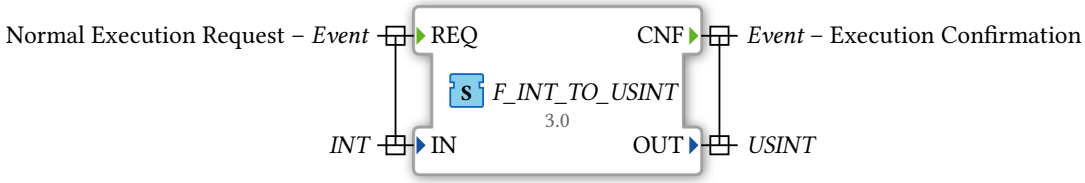
Application Scenarios

- Conversion of sensor values for processing in systems that require `ULINT` values.
- Integration of components that use different data types.
- Use in control systems that require type conversion.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks such as `F_DINT_TO_ULINT` or `F_SINT_TO_ULINT`, this function block is specifically optimized for converting `INT` to `ULINT`.
- Similar function blocks might offer additional features such as range checks or error handling, which this function block does not.

Conclusion



The function block `F_INT_TO_ULINT` is a simple and efficient building block for converting `INT` values to `ULINT` values. It is particularly useful in scenarios where direct and fast type conversion is required. Its clear interface structure and simple functionality make it a reliable tool in automation technology.

F_INT_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_USINT` converts an integer value of data type `INT` (16-bit signed integer) to data type `USINT` (8-bit unsigned integer). This block is particularly useful in scenarios where type conversion between numeric values of different sizes is required.

Interface Structure

Event Inputs

- **REQ** (Type: `Event`): Starts the execution of the conversion. The input is linked to the data input `IN`.

Event Outputs

- **CNF** (Type: `Event`): Signals successful completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (Type: `INT`): The input value to be converted.

Data Outputs

- **OUT** (Type: `USINT`): The result of the conversion from `INT` to `USINT`.

Adapters

This function block does not have any adapter interfaces.

Adapters ... ## Functionality

When the event input `REQ` is triggered, the algorithm of the function block is executed. This converts the value at the data input `IN` from type `INT` to type `USINT` and stores the result in the data output `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Details

- The conversion is performed by the function `INT_TO_USINT`, which converts the `INT` value into a `USINT` value. Data loss can occur if the original `INT` value is outside the representable range of `USINT` (0 to 255).
- This function block is part of the `iec61131::conversion` package, which provides various type conversions.

State Overview

The function block has no internal state. Execution occurs immediately upon receiving the `REQ` event.

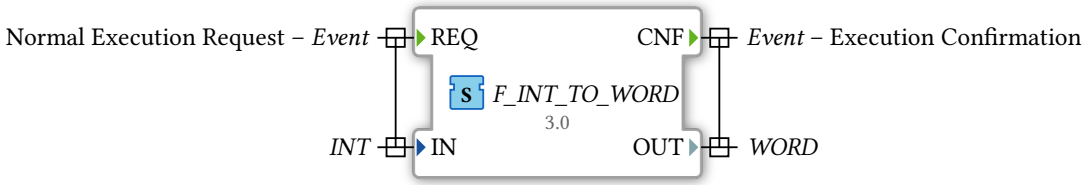
Application Scenarios

- Type conversion in control applications where different data types need to be processed.
- Reducing memory usage by converting to smaller data types where possible.
- Preparing data for communication with systems that can only process `USINT` values.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_DINT_TO_USINT` or `F_SINT_TO_USINT` offer conversions from other integer types to `USINT`. `F_INT_TO_USINT` is specifically optimized for converting `INT` to `USINT`.
- Unlike generic conversion blocks, this function block provides a direct and efficient solution for specific type conversion.

Conclusion



The `F_INT_TO_USINT` function block is a simple and efficient function block for converting `INT` to `USINT` values. It is ideally suited for applications that require precise and specific type conversion, especially in environments with limited resources or specific data type requirements.

F_INT_TO_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_INT_TO_WORD` converts an integer value (INT) into a 16-bit word value (WORD). This conversion is particularly useful in scenarios where data needs to be exchanged between systems with different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. Simultaneously, the converted value is output at data output `OUT`.

Data Inputs

- **IN**: The input for the integer value (INT) to be converted.

Data Outputs

- **OUT**: The output for the converted 16-bit word value (WORD).

Adapters

No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The value at input `IN` is read and converted into a WORD value using the function `INT_TO_WORD`. The result is output at `OUT`, and simultaneously the event `CNF` is triggered to signal the successful completion of the operation.

Technical Features

- The function block is implemented simply and efficiently, without additional states or complex logic.
- The conversion occurs directly and without delay.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Data conversion in control systems where different data types need to be processed.
- Interfaces between systems that use different data types.
- Logging and monitoring where data in uniform formats is required.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_INT_TO_WORD` specializes in converting INT to WORD and is therefore more efficient at this specific task.
- Other blocks, such as `F_DINT_TO_WORD` or `F_SINT_TO_WORD`, offer similar functionality but for different source data types.

Conclusion

The `F_INT_TO_WORD` function block is a simple and effective tool for converting integer values to 16-bit word values. Its clear interface and straightforward operation make it a reliable component in control and automation systems.

LINT

F_LINT_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_AS_STRING` converts a LINT data type (64-bit integer) to a STRING data type (character string). This block is particularly useful when numeric values are needed as text for output or further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event is triggered, the value at the data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event, along with the converted value, is output at data output `OUT`.

Data Inputs

- **IN** (LINT): The input for the LINT value to be converted.

Data Outputs

- **OUT** (STRING): The output for the converted STRING value.

Adapters

- No adapters are present.

Functionality

When the `REQ` event is triggered, the function block converts the LINT value at input `IN` into a STRING value. The result is output at `OUT` and confirmed by the `CNF` event.

Technical Features

- The function block is a simple function block (SimpleFB) and uses an ST algorithm for conversion.
- The conversion is performed directly by the function `LINT_AS_STRING(IN)`.

State Overview

1. **Initialization**: The function block waits for the `REQ` event.
2. **Conversion**: The LINT value is converted upon `REQ`.
3. **Acknowledgement**: The `CNF` event is triggered, and the converted value is output.

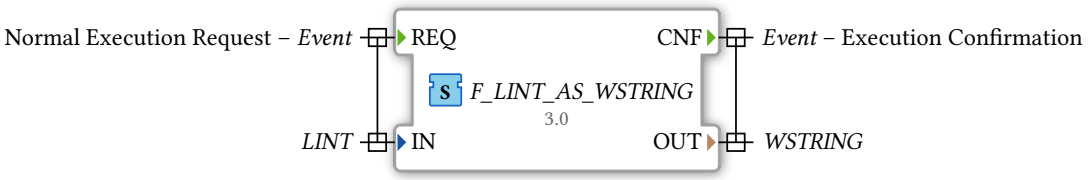
Application Scenarios

- Displaying numeric values in user interfaces.
- Logging numeric data to text files.
- Preparing data for communication via text-based protocols.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks like `F_INT_AS_STRING` or `F_DINT_AS_STRING`, this block supports the larger LINT data type (64-bit).

Conclusion



The `F_LINT_AS_STRING` function block offers a simple and efficient way to convert large integers into readable strings. Its clear interface and straightforward operation make it ideal for applications requiring conversion between these data types.

F_LINT_AS_WSTRING

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_LINT_AS_WSTRING` is used to convert a LINT value (64-bit integer) into a WSTRING (wide string). This block is particularly useful in scenarios where numeric values need to be output as strings or processed further.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion of the LINT value to a WSTRING. This input is connected to the data input `IN`.

Event Outputs
- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs
- **IN** (LINT): The LINT value to be converted to a WSTRING.

Data Outputs
- **OUT** (WSTRING): The resulting WSTRING after conversion.

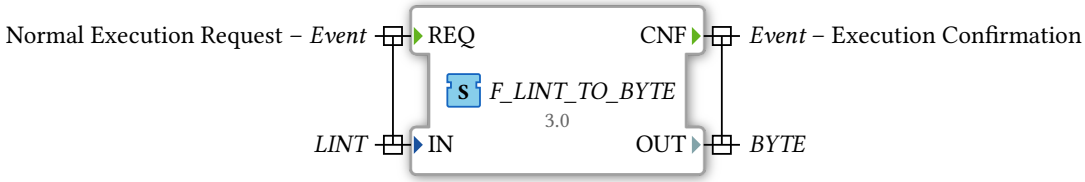
Adapters
No adapters are present.

Functionality
The function block performs the conversion as soon as the `REQ` event occurs. The LINT value from `IN` is converted to a WSTRING and output to `OUT`. The conversion is confirmed by the `CNF` event.

Technical Features
- The function block uses the `LINT_AS_WSTRING` function for conversion.
- The conversion is performed directly without additional parameters.

State Overview
1. **Idle State**: Waits for the `REQ` event.
2. **Conversion State**: Performs the conversion and outputs the result.
3. **Confirmation State**: Sends the `CNF` event to confirm the conversion.

Application Scenarios
- Displaying numeric values in user interfaces.
- Logging numeric data to text files.
- Communicating with systems that expect string data.



⚖️ Comparison with Similar Function Blocks
- **F_INT_AS_WSTRING**: Converts INT (16-bit) to WSTRING.
- **F_DINT_AS_WSTRING**: Converts DINT (32-bit) to WSTRING.
- **F_LINT_AS_STRING**: Converts LINT to STRING (not Wide String).

Conclusion
The `F_LINT_AS_WSTRING` function block provides a simple and efficient way to convert 64-bit integers to wide strings. Its clear interface and direct functionality make it ideal for applications that require conversion between these data types.

F_LINT_TO_BYTE

• − ◦ • − ◦ • − ◦ •

Introduction
The function block `F_LINT_TO_BYTE` converts a LINT data type (64-bit integer) to a BYTE data type (8-bit integer). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Triggers the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals successful completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: Input for the LINT value to be converted.

Data Outputs

- **OUT**: Output for the converted BYTE value.

Adapters

- No adapters available.

Functionality

This function block performs the conversion from LINT to BYTE as soon as the event `REQ` is triggered. The conversion is carried out using the function `LINT_TO_BYTE(IN)`, where the value from `IN` is converted to the BYTE type and output to `OUT`. After successful conversion, the event `CNF` is triggered.

Technical Features

- The function block is a simple algorithm (SimpleFB) and does not perform any complex state transitions.
- Data loss can occur during conversion if the LINT value is outside the representable range of a BYTE (0 to 255).

State Overview

Since this is a simple function block, there are no state transitions. Execution occurs directly upon triggering `REQ`.

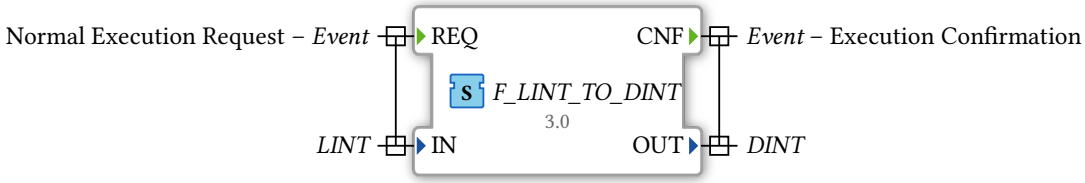
Application Scenarios

- Type conversion in control applications where LINT data needs to be converted to BYTE data.
- Use in data processing chains where different data types need to be made compatible.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_INT_TO_BYTE` or `F_DINT_TO_BYTE` perform similar conversions, but with different output data types.
- `F_LINT_TO_BYTE` is specifically for converting 64-bit to 8-bit integers.

Conclusion



The `F_LINT_TO_BYTE` function block provides a simple and efficient way to convert LINT data to BYTE data. Its use is essential in type conversion scenarios; however, potential data loss with large values should be considered.

F_LINT_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_TO_DINT` converts a 64-bit integer value (LINT) to a 32-bit integer value (DINT). This conversion is useful when data needs to be exchanged between systems with different word widths or when memory space needs to be optimized.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (LINT): The 64-bit integer value to be converted.

Data Outputs

- **OUT** (DINT): The resulting 32-bit integer value after conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion by calling the algorithm `REQ` as soon as the event `REQ` occurs. The algorithm uses the function `LINT_TO_DINT` to convert the value from `IN` to `OUT`. After successful conversion, the event `CNF` is triggered.

Technical Features

- The function block is part of the package `iec61131::conversion`.
- It is a simple function block without internal states or complex logic.
- The conversion can result in data loss if the original LINT value is outside the representable range of a DINT.

State Overview

Because it is a simple function block, there are no state transitions or internal states. The logic is executed directly upon the arrival of the `REQ` event.

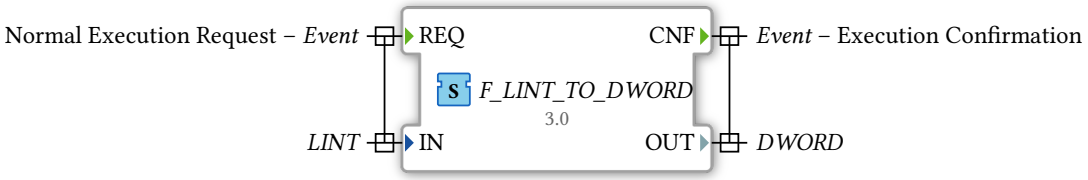
Application Scenarios

- Data compatibility between systems with different word widths.
- Memory optimization when 64-bit values are not required.
- Integration into larger control systems that require DINT values.

⚖️ Comparison with Similar Blocks

- Unlike generic conversion blocks, `F_LINT_TO_DINT` specializes in converting LINT to DINT.
- Other blocks might offer additional features such as range checks or error handling, which is not the case here.

Conclusion



The `F_LINT_TO_DINT` function block provides a simple and efficient way to convert 64-bit integer values to 32-bit integer values. Its simplicity makes it reliable and easy to integrate; however, users should be aware of potential data loss when converting large values.

F_LINT_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_TO_DWORD` converts a LINT value (64-bit integer) to a DWORD value (32-bit unsigned integer). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `LINT`, containing the value to be converted.

Data Outputs

- **OUT**: The output of type `DWORD`, containing the result of the conversion.

Adapters

- No adapters are available.

Functionality

The function block performs the conversion by transforming the `LINT` value at input `IN` into a `LINT_TO_DWORD` value. The result is output at `OUT`. The conversion is started by the event `REQ` and confirmed by `CNF`.

Technical Features

- The conversion truncates the 32 most significant bits of the `LINT` value, as `DWORD` can only store 32 bits.
- No overflow check is performed, which can lead to data loss with large `LINT` values.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Complete**: Sends the `CNF` event and outputs the result.

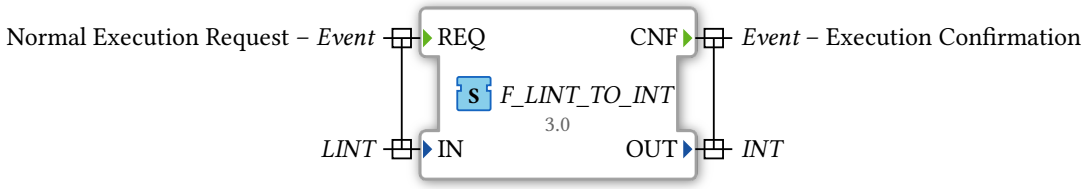
Application Scenarios

- Type conversion in control applications where different data types need to be processed.
- Data reduction when only the lower 32 bits of a `LINT` value are relevant.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_INT_TO_DINT` or `F_DINT_TO_LINT` perform similar type conversions, but between different data types.
- `F_LINT_TO_DWORD` is specifically for converting `LINT` to `DWORD`.

Conclusion



The `F_LINT_TO_DWORD` function block offers a simple and efficient way to convert `LINT` values to `DWORD` values. Its use is recommended in scenarios requiring type conversion between these specific data types, although potential data loss with large values should be considered.

F_LINT_TO_INT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_LINT_TO_INT` is used to convert a 64-bit integer value (LINT) to a 16-bit integer value (INT). This conversion is useful when data needs to be exchanged or processed between systems with different word lengths.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (LINT): The 64-bit integer value to be converted.

Data Outputs

- **OUT** (INT): The resulting 16-bit integer value after conversion.

Adapters

- No adapters are present.

Functionality

This function block performs the conversion from a LINT to an INT value as soon as the event `REQ` is received. The conversion is carried out by the function `LINT_TO_INT(IN)`, which converts the value of `IN` to an INT value and outputs the result to `OUT`. The event `CNF` is then triggered to signal successful conversion.

Technical Details

- Data loss can occur during conversion if the original LINT value is outside the representable range of an INT value (-32,768 to 32,767).
- The function block has a simple structure and contains only one conversion algorithm.

State Overview

1. **Idle State**: Waits for the event `REQ`.
2. **Conversion State**: Performs the conversion and outputs the result.
3. **Acknowledge State**: Sends the event `CNF` and returns to the idle state.

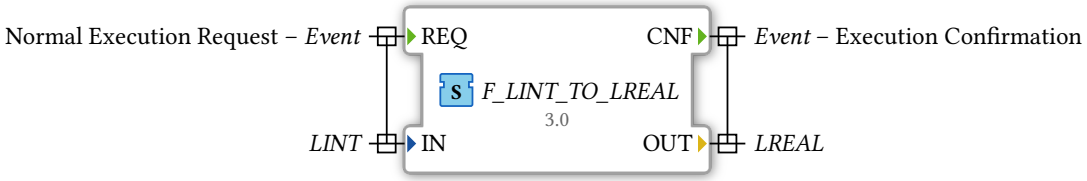
Application Scenarios

- Data communication between systems with different word widths.
- Reduced memory usage when full 64-bit precision is not required.
- Integration into control systems that can only process 16-bit integers.

⚖️ Comparison with similar function blocks

- **F_LINT_TO_DINT**: Converts LINT to DINT (32-bit integer).
- **F_LINT_TO_UDINT**: Converts LINT to UDINT (32-bit unsigned integer).
- **F_LINT_TO_ULINT**: Converts LINT to ULINT (64-bit unsigned integer).

Conclusion



The `F_LINT_TO_INT` function block provides a simple and efficient way to convert 64-bit integer values to 16-bit integer values. It is particularly useful in scenarios where reducing data width is necessary, however, the possibility of data loss during conversion should be considered.

F_LINT_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_TO_LREAL` converts an integer value of type `LINT` (64-bit integer) to a floating-point value of type `LREAL` (64-bit floating-point). This conversion is particularly necessary when integer values are to be used in calculations with floating-point numbers.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `LINT` to be converted to a `LREAL` value.

Data Outputs

- **OUT**: The converted output value of type `LREAL`.

Adapters

This function block does not use adapters.

Functionality

When the event `REQ` is triggered, the algorithm is executed, converting the value of `IN` of type `LINT` to type `LREAL` and outputting the result to `OUT`. The event `CNF` is then triggered to signal the completion of the conversion.

Technical Features

- The conversion is performed directly without additional parameters.
- The function block is suitable for use in real-time systems because it operates deterministically.

State Overview

The function block has no internal states. The conversion occurs immediately upon the triggering of `REQ`.

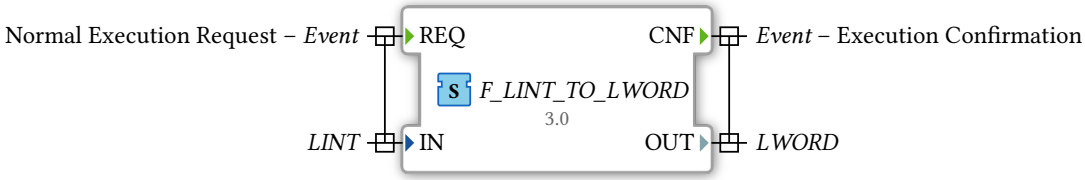
Application Scenarios

- Conversion of large integers to floating-point numbers for mathematical calculations.
- Integration into control systems that need to process mixed data types.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks such as `F_INT_TO_REAL` or `F_DINT_TO_REAL`, `F_LINT_TO_LREAL` handles larger number ranges (64-bit).

Conclusion



The `F_LINT_TO_LREAL` function block provides an efficient and reliable method for converting 64-bit integers to 64-bit floating-point numbers. Its simple interface and deterministic operation make it ideal for use in industrial control systems.

F_LINT_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_TO_LWORD` converts a LINT data type (64-bit signed integer) to an LWORD data type (64-bit bit string). This block is particularly useful in scenarios where numeric values need to be converted to their binary representation.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event input is triggered, the function block reads the value at the data input `IN` and performs the conversion.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. This event, along with the converted value, is output at the data output `OUT`.

Data Inputs

- **IN**: Expects a value of type `LINT` (64-bit signed integer) to be converted.

Data Outputs

- **OUT**: Outputs the converted value of type `LWORD` (64-bit bit string).

Adapters

This function block has no adapter interfaces.

Functionality

When the `REQ` event is triggered, the value at input `IN` is read and converted into a `LWORD` value using the function `LINT_TO_LWORD`. The result is provided at output `OUT`, and simultaneously, the `CNF` event is triggered.

Technical Features

- The conversion occurs directly and without any additional delay.
- The function block is deterministic and has no internal states.

State Overview

Since this is a simple function block, there are no state transitions or state machines. The conversion occurs immediately upon triggering the `REQ` event.

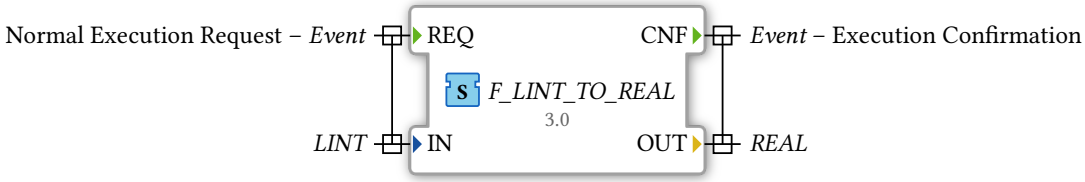
Application Scenarios

- Conversion of numeric values into their binary representation for bitwise operations.
- Use in protocol implementations where numeric values must be transmitted as bit strings.
- Integration into systems that perform low-level bit manipulation.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_LINT_TO_LWORD` specializes in converting `LINT` to `LWORD` and therefore offers an optimized and type-safe solution.
- Similar blocks such as `INT_TO_WORD` or `DINT_TO_DWORD` work with smaller data types.

Conclusion



The `F_LINT_TO_LWORD` function block provides an efficient and reliable method for converting 64-bit integers to 64-bit bit strings. Its simplicity and determinism make it ideal for real-time applications where fast and precise type conversions are required.

F_LINT_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_TO_REAL` converts an integer value of type `LINT` (64-bit integer) to a floating-point value of type `REAL`. This conversion is useful when data needs to be transformed from an integer format to a floating-point format, for example, for further calculations or display.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event, along with the converted value, is output at data output `OUT`.

Data Inputs

- **IN**: The input of type `LINT`, which provides the integer value to be converted.

Data Outputs

- **OUT**: The output of type `REAL`, which provides the result of the conversion.

Adapters

- This function block does not use any adapters.

Operation

The function block performs the conversion as soon as the event `REQ` is received. The algorithm reads the value of `IN`, converts it using the function `LINT_TO_REAL`, and writes the result to `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Features

- The conversion is performed without rounding or scaling, as it is a direct type conversion.
- The function block is suitable for use in real-time systems because it does not involve any delays or complex calculations.

State Overview

The function block has no internal state. The operation is re-executed with each `REQ` event.

Application Scenarios

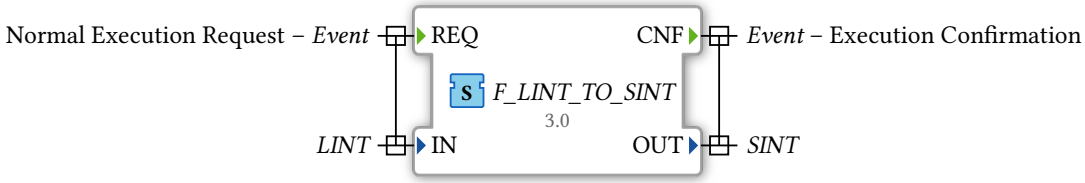
- Conversion of sensor values stored as `LINT` to `REAL` for further processing.

- Integration into systems that require floating-point operations but receive input data as integers.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_INT_TO_REAL` or `F_DINT_TO_REAL` perform similar conversions, but with smaller integer types (`INT` or `DINT`).
- `F_LINT_TO_REAL` is specifically optimized for 64-bit integers (`LINT`).

Conclusion



The `F_LINT_TO_REAL` function block offers a simple and efficient way to convert 64-bit integer values to floating-point numbers. Its clear interface and direct functionality make it ideal for applications requiring type conversion without additional processing.

F_LINT_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_TO_SINT` converts a 64-bit integer value (`LINT`) into an 8-bit integer value (`SINT`). This conversion is useful when data needs to be exchanged or processed between systems with different word lengths.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is connected to data output `OUT`.

Data Inputs

- **IN** (`LINT`): The 64-bit integer value to be converted.

Data Outputs

- **OUT** (`SINT`): The resulting 8-bit integer value after conversion.

Adapters

No adapters are available.

Functionality

When the event `REQ` is triggered, the algorithm is executed, converting the value of `IN` (of type `LINT`) to a `SINT` value and outputting the result to `OUT`. The event `CNF` is then triggered to signal the completion of the conversion.

Technical Features

- Data loss can occur if the original `LINT` value is outside the representable range of `SINT` (-128 to 127).
- The function block is simple and deterministic, without internal states or complex logic.

State Overview

This function block has no internal states. Execution occurs solely in response to the `REQ` event.

Application Scenarios

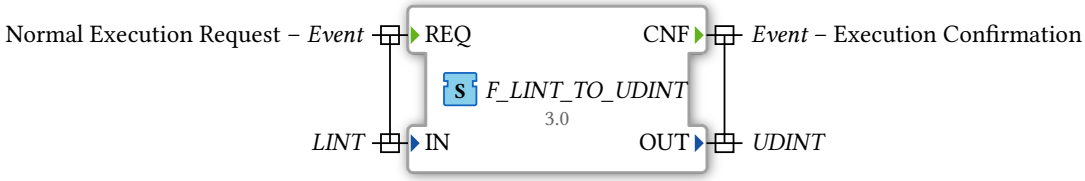
- Data reduction during transmission between systems with different word widths.
- Processing of sensor data where only the lower 8 bits are relevant.

- Compatibility with older systems that can only process 8-bit data.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_LINT_TO_SINT` is specialized and optimized for converting `LINT` to `SINT`.
- Other conversion blocks might offer additional features such as overflow handling or scaling, which is not the case here.

Conclusion



The `F_LINT_TO_SINT` function block is a simple and efficient tool for converting 64-bit to 8-bit integers. Its simplicity makes it robust and easy to understand, although it lacks advanced features such as overflow control. It is ideal for applications requiring direct and fast conversion.

F_LINT_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_TO_UDINT` converts a 64-bit signed integer value (`LINT`) to a 32-bit unsigned integer value (`UDINT`). This block is part of the `iec61131::conversion` library and is suitable for applications requiring type conversion.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (`LINT`): The 64-bit signed integer value to be converted.

Data Outputs

- **OUT** (`UDINT`): The resulting 32-bit unsigned integer value after the conversion.

Adapters

No adapters available.

Functionality

When the event `REQ` is triggered, the algorithm is executed, converting the value of `IN` from `LINT` to `UDINT` and outputting the result to `OUT`. The event `CNF` is then triggered to signal the completion of the operation.

Technical Features

- The block uses the built-in function `LINT_TO_UDINT` for the conversion.
- It is a simple function block without state machines or complex logic.

State Overview

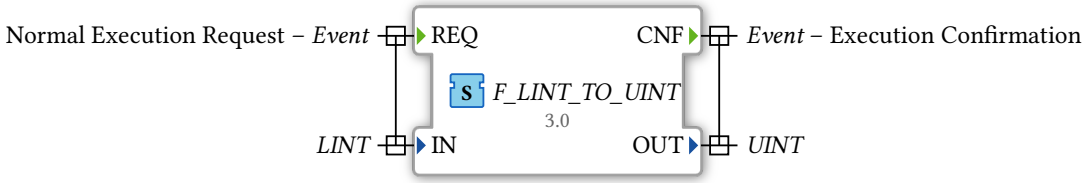
The block has no internal states. The conversion occurs immediately upon triggering `REQ`.

Application Scenarios

- Type conversion in control applications where 64-bit values need to be converted to 32-bit values.
- Use in data processing chains where different data types need to be made compatible.

⚖️ Comparison with Similar Blocks

- Similar blocks like `F_DINT_TO_UDINT` or `F_INT_TO_UINT` offer conversions between other integer types, but not for `LINT` to `UDINT`.
- Unlike generic conversion blocks, `F_LINT_TO_UDINT` is specialized and optimized for this specific conversion.



Conclusion

The `F_LINT_TO_UDINT` block is an efficient tool for converting 64-bit signed integer values to 32-bit unsigned integer values. Its simplicity and direct operation make it a reliable component in control applications.

F_LINT_TO_UINT

• – ◦ • – ◦ • – ◦ •

The function block `F_LINT_TO_UINT` is used to convert a 64-bit integer value (`LINT`) into a 16-bit unsigned integer value (`UINT`). This block is particularly useful in scenarios where type conversion between numeric data types of different sizes is required.

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.
- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.
- **IN**: This input expects a value of type `LINT` (64-bit integer) to be converted.
- **OUT**: This output returns the converted value of type `UINT` (16-bit unsigned integer).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters are defined.

The function block performs the conversion from `LINT` to `UINT` as soon as the event `REQ` is triggered. The algorithm `REQ` uses the function `LINT_TO_UINT` to convert the input value. The result is output via `OUT`, and the event `CNF` signals successful execution.

- **Type Conversion**: It is important to note that data loss can occur when converting from a larger to a smaller data type if the original value is outside the representable range of `UINT`.

The function block has no internal states. The conversion is re-executed with each `REQ` event.

- **Data Processing**: In control systems where different data types need to be harmonized.
- **Interface Compatibility**: For communication between systems that use different data types.
- **F_LINT_TO_INT**: Converts `LINT` to `INT`, while preserving the sign.
- **F_LINT_TO_ULINT**: Converts `LINT` to `ULINT` without reducing the bit width.

The `F_LINT_TO_UINT` function block is a simple yet effective tool for type conversion in IEC 61499-based systems. Its clear interface and direct operation make it a reliable solution for conversion tasks. However, be aware of potential data loss during the conversion process.

Conclusion

F_LINT_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_TO_ULINT` converts a signed 64-bit integer value (`LINT`) to an unsigned 64-bit integer value (`ULINT`). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: This input triggers the conversion. It is linked to the data input `IN`.

Event Outputs

- **CNF**: This output signals the completion of the conversion. It is linked to the data output `OUT`.

Data Inputs

- **IN** (`LINT`): The signed 64-bit integer value to be converted.

Data Outputs

- **OUT** (`ULINT`): The unsigned 64-bit integer value output as the result of the conversion.

Adapters

This function block has no adapters.

Functionality

The function block performs the conversion from `LINT` to `ULINT` as soon as the event `REQ` is triggered. The conversion is carried out using the function `LINT_TO_ULINT(IN)`, which converts the value of `IN` into the corresponding unsigned type. After successful conversion, the event `CNF` is triggered, and the converted value is available at output `OUT`.

Technical Features

- The function block is a simple block without internal state management.
- The conversion occurs directly and without delay.

State Overview

Since it is a simple function block, there are no state transitions or complex state logic.

Application Scenarios

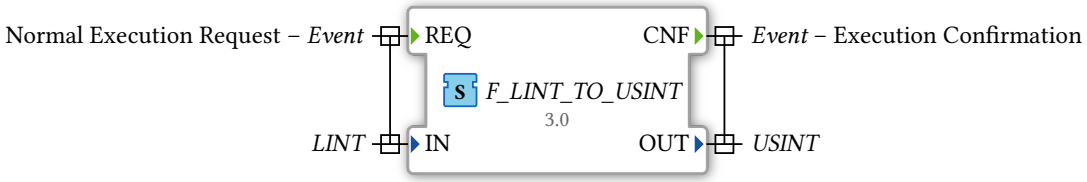
- Type conversion in control applications where signed and unsigned values need to be processed.

- Data processing in industrial automation systems where different data types need to be made compatible.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks could be `F_INT_TO_UINT` or `F_DINT_TO_UDINT`, but these are designed for smaller integer types.
- Unlike generic conversion function blocks, `F_LINT_TO_ULINT` is specialized for the 64-bit variants of the data types.

Conclusion



The `F_LINT_TO_ULINT` function block provides a simple and efficient way to convert signed 64-bit integer values to unsigned values. Its clear interface structure and direct functionality make it a reliable tool in industrial automation.

F_LINT_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LINT_TO_USINT` converts a 64-bit integer value (`LINT`) into an 8-bit unsigned integer value (`USINT`). This block is part of the IEC 61131 conversion library and is typically used in automation applications where data types of different sizes need to be processed.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (`LINT`): The 64-bit integer value to be converted.

Data Outputs

- **OUT** (`USINT`): The resulting 8-bit unsigned integer value after the conversion.

Adapters

No adapters are present.

Operation

The function block performs the conversion when the event `REQ` is triggered. The value of `IN` of type `LINT` is converted to type `USINT`, and the result is output to `OUT`. The conversion is confirmed by the event `CNF`.

Technical Features

- The conversion truncates higher-order bits if the value of `LINT` is outside the representable range of `USINT` (0 to 255).
- The block is deterministic and has no internal state.

State Overview

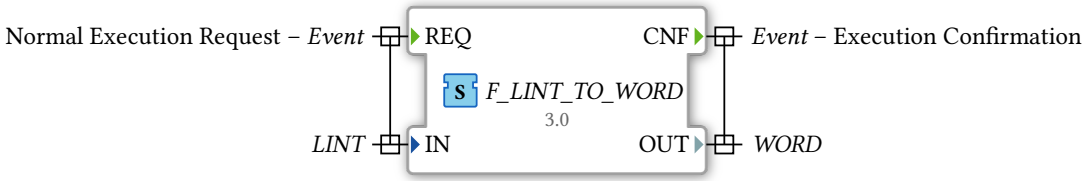
The function block has no internal state. Execution occurs immediately after receiving the `REQ` event.

Application Scenarios

- Conversion of sensor values or counters stored as `LINT` for processing in systems that only support `USINT`.
- Use in control systems where memory optimization is crucial.

⚖️ Comparison with Similar Blocks

- Similar conversion blocks like `F_INT_TO_USINT` or `F_DINT_TO_USINT` operate with smaller input data types (`INT` and `DINT`, respectively).
- Unlike generic conversion blocks, `F_LINT_TO_USINT` specializes in converting `LINT` to `USINT`.



Conclusion

The `F_LINT_TO_USINT` function block is a specialized and efficient tool for converting 64-bit integers to 8-bit unsigned values. Its simple and deterministic operation makes it reliable in automation applications.

F_LINT_TO_WORD

• – ◦ • – ◦ • – ◦ •

The function block `F_LINT_TO_WORD` converts a LINT data type (64-bit integer) to a WORD data type (16-bit word count). This conversion is useful when data needs to be exchanged between systems with different word widths or when an explicit type conversion is required.

- `REQ` (Normal Execution Request): Starts the execution of the conversion. Linked to the data input `IN`.
- `CNF` (Execution Confirmation): Signals successful completion of the conversion. Linked to the data output `OUT`.
- `IN` (LINT): The input value to be converted from LINT to WORD.
- `OUT` (WORD): The converted output value in WORD format.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use adapters.

Functionality

The function block performs the conversion from LINT to WORD when the event `REQ` is triggered. The conversion is performed using the built-in function `LINT_TO_WORD`, which takes the value of the input `IN` and converts it to the WORD data type. The result is output at `OUT`, and the event `CNF` signals successful execution.

- The conversion truncates the higher-order bits of the LINT value because WORD can only store 16 bits.
- There is no overflow or underflow check during the conversion.

The function block is stateless and re-executes the conversion with each `REQ` event.

- Data communication between systems with different word lengths.
- Similar function blocks such as `F_DINT_TO_WORD` or `F_INT_TO_WORD` perform similar conversions, but with different output data types.

- `F_LINT_TO_WORD` is specific to converting 64-bit to 16-bit and does not offer additional functionality such as overflow checking.

The `F_LINT_TO_WORD` function block is a simple yet effective tool for converting LINT to WORD data. It is particularly useful in scenarios where data width reduction is required without the need for additional validation.

LREAL

F_LREAL_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_AS_STRING` is used to convert an LREAL value (64-bit floating-point number) into a STRING. This functionality is particularly useful when numeric values are needed as strings for display, logging, or communication.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs

- `IN` (LREAL): The input value to be converted to a STRING.

Data Outputs

- `OUT` (STRING): The resulting STRING after conversion.

Adapters

This function block does not use any adapters.

Operation

When the `REQ` event is triggered, the algorithm is executed, which converts the LREAL value `IN` to a STRING and outputs the result via `OUT`. The `CNF` event signals the successful completion of the conversion.

Technical Features

- The conversion is performed using the function `LREAL_AS_STRING`.
- The function block is simple and has no internal states or complex logic.

State Overview

Since it is a simple function block, there are no state transitions or machines.

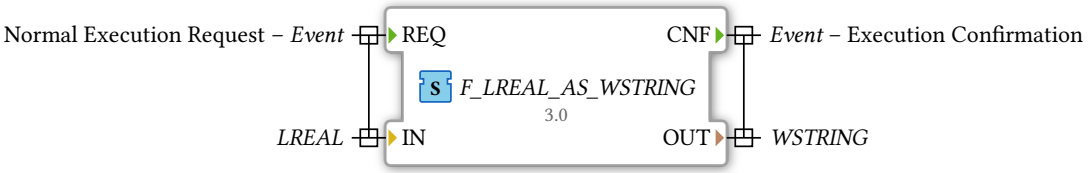
Application Scenarios

- Displaying floating-point numbers in user interfaces.
- Logging measured values to text files or databases.
- Preparing data for communication via text protocols.

⚖️ Comparison with Similar Function Blocks

- Unlike `F_STRING_TO_LREAL`, this function block performs the reverse conversion.
- Compared to generic conversion function blocks, this one specializes in LREAL-to-STRING conversions.

Conclusion



The `F_LREAL_AS_STRING` function block offers a simple and efficient way to convert floating-point numbers into strings. Its clear interface and straightforward functionality make it a useful component in many automation applications.

F_LREAL_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_AS_WSTRING` converts an LREAL value (64-bit floating-point number) into a WSTRING (wide string). This is particularly useful when numeric values are needed for display or further processing as text.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the input value. The input value `IN` is associated with this event.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output value `OUT` is output with this event.

Data Inputs

- **IN** (LREAL): The input value to be converted to a WSTRING.

Data Outputs

- **OUT** (WSTRING): The result string after conversion.

Adapters

This function block does not use any adapters.

Functionality

When the `REQ` event is triggered, the input value `IN` of type LREAL is converted to a WSTRING using the function `LREAL_AS_WSTRING` and made available at output `OUT`. The `CNF` event signals successful conversion.

Technical Features

- The conversion is performed directly without additional parameters.
- This function block is suitable for use in real-time systems.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Converts the input value.
3. **Done**: Sends the `CNF` event with the converted value.

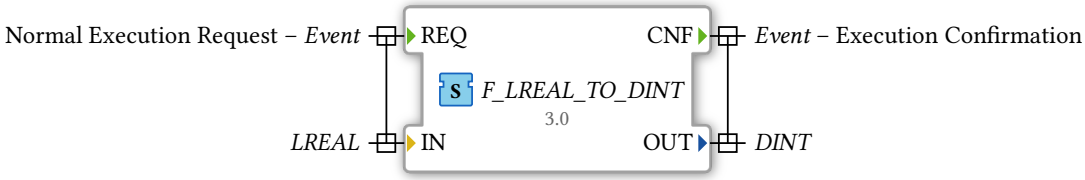
Application Scenarios

- Displaying floating-point values on user interfaces.
- Logging measured values to text files.
- Preparing data for communication with systems that expect string data.

⚖️ Comparison with Similar Function Blocks

- Compared to `F_REAL_AS_WSTRING`, this function block processes 64-bit floating-point numbers instead of 32-bit.
- Similar to `F_DINT_AS_WSTRING`, but for floating-point numbers instead of integers.

Conclusion



The `F_LREAL_AS_WSTRING` function block offers a simple and efficient way to convert LREAL values to WSTRINGs. Its clear interface and direct functionality make it a useful tool in various use cases.

F_LREAL_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_TO_DINT` converts an LREAL value (64-bit floating-point number) to a DINT value (32-bit integer). This block is part of the `iec61131::conversion` package and implements a simple type conversion.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion process. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (LREAL): The input value to be converted from LREAL to DINT.

Data Outputs

- **OUT** (DINT): The result of the conversion as a DINT value.

Adapters

This function block does not have any adapters.

Operation

When the `REQ` event is triggered, the algorithm is executed that converts the `IN` value from LREAL to DINT and outputs the result to `OUT`. The `CNF` event is then triggered to signal the successful completion of the operation.

Technical Features

- The conversion is performed by the built-in function `LREAL_TO_DINT`.
- This is a simple function block without state management or complex logic.

State Overview

The function block has no internal states. Execution is purely event-driven and occurs with each `REQ` event.

Application Scenarios

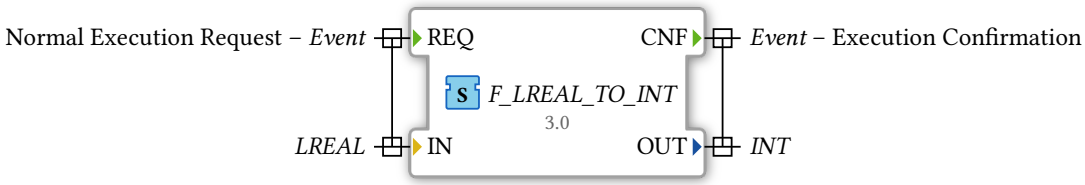
- Type conversion in control applications where floating-point numbers need to be converted to integers.
- Use in calculations where an integer representation is required.

⚖️ Comparison with Similar Blocks

- Compared to other conversion blocks such as `F_REAL_TO_INT` or `F_LREAL_TO_LINT`, this block offers a specific conversion from LREAL to DINT.

Similar blocks can have different source or target types, such as `F_DINT_TO_LREAL` for reverse conversion.

Conclusion



The `F_LREAL_TO_DINT` function block is a simple and efficient tool for type conversion in IEC 61499-based control systems. Its clear interface and direct operation make it ideal for applications requiring fast conversion of floating-point numbers to integers.

F_LREAL_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_TO_INT` converts an LREAL value (64-bit floating-point number) into an INT value (16-bit integer). This conversion is performed by rounding the LREAL value down to the nearest integer value.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion of the input value. The input value is passed with this event.

Event Outputs

- `CNF`: Signals the completion of the conversion and outputs the converted value.

Data Inputs

- `IN` (LREAL): The input value to be converted to an INT value.

Data Outputs

- `OUT` (INT): The converted integer value.

Adapters

This function block does not use any adapters.

Functionality

Upon receiving the `REQ` event, the algorithm that converts the `IN` value from LREAL to INT is executed. The conversion is performed by the function `LREAL_TO_INT`, which rounds the LREAL value down to the nearest integer value. The result is output to `OUT`, and the `CNF` event is triggered.

Technical Features

- The conversion truncates decimal places (not rounding, but rounding down).
- Overflow problems may occur with values outside the integer range.

State Overview

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

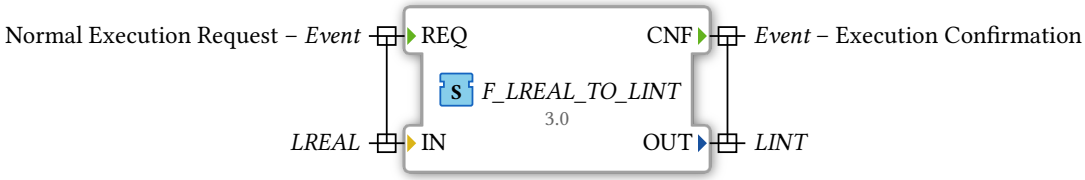
Application Scenarios

- Conversion of sensor values (e.g., temperature measurements) for processing in integer-based systems.
- Preparation of floating-point values for output on integer displays or interfaces.

⚖️ Comparison with Similar Function Blocks

- `F_REAL_TO_INT`: Converts REAL (32-bit floating-point number) to INT.
- `F_LREAL_TO_DINT`: Converts LREAL to DINT (32-bit integer) for a wider range of values.

Conclusion



The `F_LREAL_TO_INT` function block is a simple yet effective tool for converting floating-point numbers to integers. It is particularly well-suited for applications requiring fast and direct conversion without additional logic. However, for values exceeding the INT range, alternative function blocks such as `F_LREAL_TO_DINT` should be considered.

F_LREAL_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_TO_LINT` is used to convert an LREAL value (64-bit floating-point number) to a LINT value (64-bit integer). This conversion is particularly necessary in scenarios where floating-point numbers need to be converted to integers, for example, when processing sensor values or controlling actuators.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This input triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. This output signals the completion of the conversion.

Data Inputs

- **IN**: LREAL (64-bit floating-point number). The input value to be converted.

Data Outputs

- **OUT**: LINT (64-bit integer). The converted output value.

Adapters

No adapters available.

Functionality

This function block performs the conversion from LREAL to LINT as soon as the event `REQ` is received. The conversion is carried out using the function `LREAL_TO_LINT`, which converts the input value `IN` to the output value `OUT`. After the conversion is complete, the event `CNF` is triggered.

Technical Features

- The conversion truncates the decimal part of the floating-point number.
- The value is not rounded.
- Values outside the representable range of LINT may result in overflow problems.

State Overview

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

Application Scenarios

- Conversion of sensor values (e.g., temperature measurements) into integers for further processing.
- Control of actuators that expect integer values.
- Data preprocessing in control systems.

⚖️ Comparison with Similar Function Blocks

- `F_REAL_TO_INT`: Converts REAL (32-bit floating-point number) to INT (16-bit integer).
- `F_LREAL_TO_DINT`: Converts LREAL (64-bit floating-point number) to DINT (32-bit integer).
- `F_LREAL_TO_LINT` offers higher accuracy through the use of 64-bit integers.

Conclusion

The function block `F_LREAL_TO_LINT` is a simple and efficient building block for converting 64-bit floating-point numbers to 64-bit integers. It is particularly suitable for applications requiring high accuracy and a large value range. Its simple interface and direct operation make it easy to integrate into existing control systems.

F_LREAL_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_TO_LWORD` converts an LREAL value (64-bit floating-point number) to an LWORD value (64-bit unsigned integer). This conversion is particularly necessary in scenarios where floating-point numbers need to be converted to a binary representation.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs

- **IN** (LREAL): The input value to be converted.

Data Outputs

- **OUT** (LWORD): The converted output value.

Adapters

This function block does not use any adapters.

Functionality

The function block performs the conversion by transforming the LREAL value at input `IN` into an LWORD value. The conversion is performed directly without additional parameters. When event `REQ` is triggered, the algorithm that converts the value and outputs event `CNF` is executed.

Technical Features

- The conversion is performed using the function `LREAL_TO_LWORD`, which is implemented in the function block's algorithm.
- The function block is simple and has no internal states or complex logic.

State Overview

Since it is a simple function block, there are no state transitions or internal states. The conversion occurs immediately upon triggering the `REQ` event.

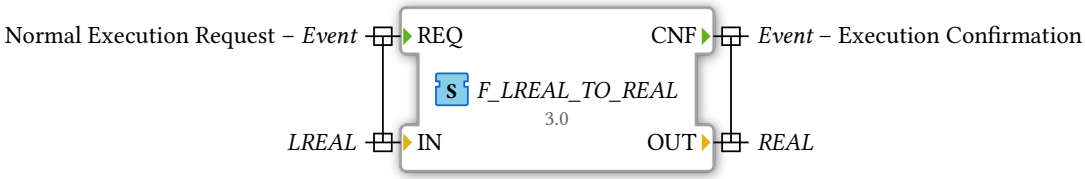
Application Scenarios

- Conversion of floating-point numbers into a binary representation for further processing in other systems.
- Use in control systems where floating-point values need to be converted into a format understandable to the hardware.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_REAL_TO_WORD` or `F_DINT_TO_DWORD` perform similar conversions, but with different data types.
- `F_LREAL_TO_LWORD` is specifically for converting 64-bit floating-point numbers to 64-bit unsigned integers.

Conclusion



The `F_LREAL_TO_LWORD` function block provides a simple and efficient way to convert floating-point numbers to a binary representation. Its clear interface and direct functionality make it ideal for applications requiring such conversions.

F_LREAL_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_TO_REAL` converts an LREAL value (64-bit floating-point number) to a REAL value (32-bit floating-point number). This block is particularly useful in scenarios where type conversion between these two numeric data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The LREAL input value to be converted.

Data Outputs

- **OUT**: The REAL output value containing the conversion result.

Adapters

This function block has no adapters.

Operation

When the event input `REQ` is triggered, the algorithm is executed, converting the LREAL value of `IN` to a REAL value and outputting the result to `OUT`. The event `CNF` is then triggered to signal the completion of the operation.

Technical Features

- The function block performs a direct type conversion, taking into account potential accuracy losses due to the different bit widths of the data types.
- The conversion is performed using the built-in function `LREAL_TO_REAL`.

State Overview

The function block is stateless and performs the conversion on every `REQ` event.

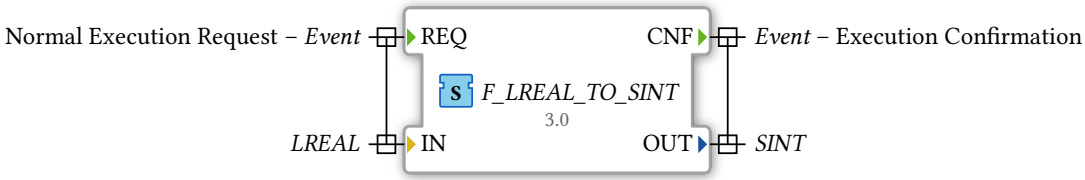
Application Scenarios

- Type conversion in control applications where LREAL values from high-precision calculations need to be converted into REAL values for further processing.
- Compatibility with systems or function blocks that can only process REAL data types.

⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion blocks, `F_LREAL_TO_REAL` specializes in converting between LREAL and REAL, thus offering a clearly defined and efficient solution for this specific use case.

Conclusion



The `F_LREAL_TO_REAL` function block is a simple yet effective building block for converting between LREAL and REAL data types. Its clear interface and direct functionality make it a reliable component in control applications where such type conversions are required.

F_LREAL_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_TO_SINT` converts a `LREAL` value (64-bit floating-point number) to a `SINT` value (8-bit integer count). This conversion is useful when floating-point numbers need to be converted into a compact integer representation, for example, for storage or transmission in systems with limited bandwidth.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (`LREAL`): The input value to be converted.

Data Outputs

- **OUT** (`SINT`): The converted output value.

Adapters

No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is received. The `LREAL` value at input `IN` is converted into a `SINT` value and output as `OUT`. The `CNF` event signals the completion of the conversion.

Technical Features

- The conversion is performed by the function `LREAL_TO_SINT`, which converts the `LREAL` value into a `SINT` value.
- This is a simple function block without state management or complex logic.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

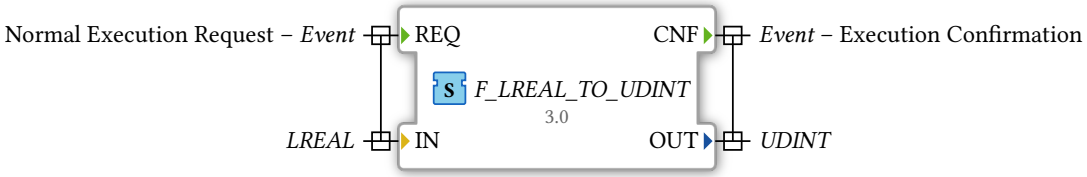
Application Scenarios

- Conversion of floating-point numbers to integers for storage in limited memory areas.
- Use in control systems where floating-point numbers need to be converted into compact integer formats.
- Integration into data processing chains where data width reduction is required.

⚖️ Comparison with Similar Function Blocks

- **F_REAL_TO_SINT**: Converts `REAL` (32-bit floating-point number) to `SINT`. Compared to `F_LREAL_TO_SINT`, this method processes input data with lower precision.
- **F_LREAL_TO_INT**: Converts `LREAL` to `INT` (16-bit integer). Offers a wider output width compared to `F_LREAL_TO_SINT`.

Conclusion



The `F_LREAL_TO_SINT` function block is a simple and efficient tool for converting 64-bit floating-point numbers to 8-bit integers. Its simple interface and direct operation make it ideal for applications where space or bandwidth limitations are a concern.

F_LREAL_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_TO_UDINT` is used to convert a 64-bit floating-point value (LREAL) into a 32-bit unsigned integer value (UDINT). This conversion is useful when floating-point numbers need to be converted into unsigned integers, for example, for specific control or communication applications.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN** (LREAL): The input value to be converted.

Data Outputs

- **OUT** (UDINT): The converted output value.

Adapters

This function block does not use any adapters.

Functionality

The function block performs the conversion from an LREAL value to a UDINT value as soon as the `REQ` event is received. The conversion is performed using the built-in function `LREAL_TO_UDINT`. After the conversion is complete, the `CNF` event is triggered, and the converted value is available at the output `OUT`.

Technical Features

- The conversion truncates the floating-point value to the nearest integer.
- There is no overflow or underflow check. Values outside the UDINT range (0 to 4,294,967,295) result in undefined behavior.

State Overview

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

Application Scenarios

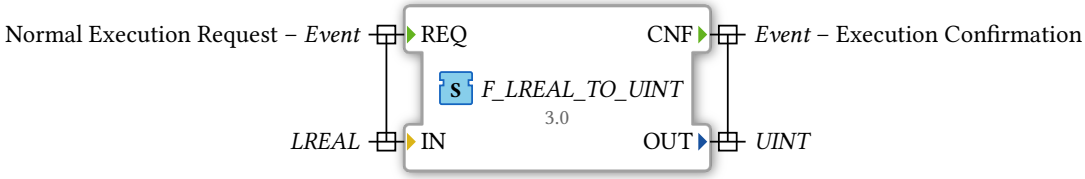
- Conversion of sensor data (e.g., temperature measurements) into unsigned integer values for further processing.
- Preparation of floating-point values for communication with systems that only support unsigned integers.

⚖️ Comparison with similar components

- **F_REAL_TO_UINT**: Converts 32-bit floating-point values (REAL) to 16-bit unsigned integer values (UINT).
- **F_LREAL_TO_DINT**: Converts 64-bit floating-point values (LREAL) to 32-bit signed integer values (DINT).
- **F_LREAL_TO_UDINT** is specific for converting to unsigned 32-bit integers.

🛠️ Related Exercises

- Exercise_152
- Exercise_153



Conclusion

The function block `F_LREAL_TO_UDINT` offers a simple and efficient way to convert floating-point values into unsigned integers. However, due to the lack of overflow checking, it should only be used in scenarios where the input values are known and within the valid range.

F_LREAL_TO_UINT

• – ◦ • – ◦ • – ◦ •

The function block `F_LREAL_TO_UINT` converts an LREAL value (64-bit floating-point number) to a UINT value (unsigned 16-bit integer). This block is part of the `iec61131::conversion` library and enables simple and efficient type conversion in automation applications.

- **REQ**: Starts the conversion. When this event occurs, the algorithm for converting the input value is executed.
- **CNF**: Signals the completion of the conversion. This event is output after successful conversion of the value.

- **IN**: The input expects an LREAL number (64-bit floating-point number) to be converted into a UINT value.
- **OUT**: Outputs the result of the conversion as a UINT value (unsigned 16-bit integer).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block has no adapters.

When the `REQ` event occurs, the algorithm for converting the LREAL value at input `IN` into a UINT value is executed. The result is output at `OUT`, and the `CNF` event signals the successful completion of the operation.

- **Data Types**: The function block processes 64-bit floating-point numbers (LREAL) and outputs 16-bit unsigned integers (UINT).
- **Algorithm**: The conversion is performed directly by the built-in `LREAL_TO_UINT` function.
- **Error Handling**: The function block does not have built-in error handling for overflow or invalid input values.

1. **Wait State**: The function block waits for the `REQ` event.
2. **Execution State**: The conversion is performed at `REQ`.
3. **Confirmation State**: After successful conversion, `CNF` is output, and the function block returns to the wait state.

- Conversion of sensor values (e.g., temperature measurements) into integer values for further processing.
- Type conversion in control applications where floating-point numbers are required to integers for specific operations.
- Interface adaptation between system components with different data types.
- Compared to generic conversion blocks, `F_LREAL_TO_UINT` is specialized for converting LREAL to UINT.
- Other conversion blocks might offer additional functions such as range checking or error handling, but are more complex to use.

The `F_LREAL_TO_UINT` function block offers a simple and efficient solution for the specific conversion of 64-bit floating-point numbers to 16-bit unsigned integers. Its simple interface and direct operation make it ideal for applications where fast type conversion without additional functions is required. However, for applications with critical values, additional checks should be implemented.

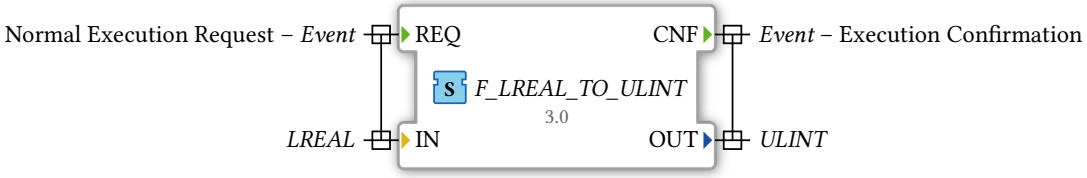
Conclusion



F_LREAL_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_TO_ULINT` converts an LREAL value (64-bit floating-point number) to a ULINT value (64-bit unsigned integer). This conversion is particularly necessary in scenarios where

floating-point numbers need to be converted to unsigned integers, for example, for certain calculations or for storage in specific data formats.

Interface Structure

Event Inputs

- `REQ` (Normal Execution Request): Starts the conversion of the input value. It is linked to the data input `IN`.

Event Outputs

- `CNF` (Execution Confirmation): Signals the completion of the conversion. Linked to the data output `OUT`.

Data Inputs

- `IN` (LREAL): The input value to be converted.

Data Outputs

- `OUT` (ULINT): The converted output value.

Adapters

No adapters available.

Functionality

The function block performs the conversion as soon as the event `REQ` is received. The algorithm `REQ` converts the LREAL value `IN` into a ULINT value using the function `LREAL_TO_ULINT` and stores the result in `OUT`. The event `CNF` is then triggered to signal the completion of the conversion.

Technical Features

- The conversion is performed without rounding; that is, the decimal portion is truncated.
- Values outside the representable range of ULINT (0 to 2^64-1) may result in overflow or unexpected results.

State Overview

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

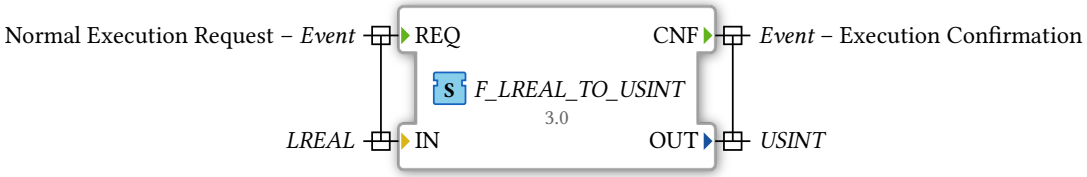
Application Scenarios

- Conversion of sensor values (e.g., temperature measurements) into unsigned integers for further processing.
- Conversion of floating-point numbers for storage in databases or protocols that only support integers.
- Use in control algorithms that require unsigned integers.

⚖️ Comparison with Similar Components

- `F_REAL_TO_UINT`: Converts REAL (32-bit floating-point number) to UINT (16-bit unsigned integer).
- `F_LREAL_TO_LINT`: Converts LREAL to LINT (64-bit signed integer).
- `F_LREAL_TO_ULINT` is specific to 64-bit unsigned conversions and therefore offers higher accuracy and a wider range of values compared to 16- or 32-bit versions.

Conclusion



The function block `F_LREAL_TO_ULINT` offers a simple and efficient way to convert floating-point numbers to unsigned integers. Its clear interface and direct functionality make it ideal for applications requiring precise conversion without rounding.

F_LREAL_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LREAL_TO_USINT` converts an LREAL value (64-bit floating-point number) to a USINT value (8-bit unsigned integer). This conversion is particularly useful when floating-point numbers need to be converted to unsigned integers, for example, for controlling hardware registers or communicating with systems that can only process integers.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: LREAL (64-bit floating-point number) – The input value to be converted.

Data Outputs

- **OUT**: USINT (8-bit unsigned integer) – The result of the conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion by executing the algorithm `REQ` as soon as the event `REQ` occurs. The algorithm converts the LREAL value `IN` to a USINT value using the function `LREAL_TO_USINT` and stores the result in `OUT`. The event `CNF` is then triggered to signal the completion of the conversion.

Technical Details

- The conversion truncates the floating-point value to an 8-bit unsigned integer. Note that values outside the range of 0 to 255 can lead to unexpected results (overflow/underflow).
- The block is implemented as a simple function block (SimpleFB) and uses an ST algorithm for the conversion.

State Overview

The function block has no internal state. The conversion occurs immediately upon receiving the `REQ` event.

Application Scenarios

- Conversion of sensor values (e.g., temperature, voltage) into unsigned integers for controlling hardware.
- Communication with systems that can only process integers (e.g., older controllers or protocols).
- Data reduction when high precision is not required.

⚖️ Comparison with Similar Blocks

- Compared to `F_REAL_TO_USINT` (conversion of 32-bit floating-point numbers), this block offers higher input precision through the use of 64-bit floating-point numbers.
- Similar blocks such as `F_LREAL_TO_INT` or `F_LREAL_TO_UINT` offer conversions to other integer types with different value ranges.

🛠️ Related Exercises

- Exercise_126b_sub

Conclusion

The `F_LREAL_TO_USINT` function block is a simple yet effective tool for converting 64-bit floating-point numbers to 8-bit unsigned integers. It is particularly suitable for applications requiring a limited output size; however, the input signal's range should be considered to avoid overflows.

LWORD

F_LWORD_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LWORD_AS_STRING` converts a `LWORD` data type to a `STRING` data type. This block is particularly useful when large binary data (64-bit) needs to be converted into a readable string.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- `IN` (LWORD): The input value to be converted.

Data Outputs

- `OUT` (STRING): The result of the conversion.

Adapters

No adapters are present.

Functionality

The function block performs the conversion as soon as the `REQ` event is triggered. The `LWORD` value at input `IN` is converted to `STRING` and output `OUT`. Successful conversion is signaled by the `CNF` event.

Technical Features

- The function block uses the standard algorithm `LWORD_AS_STRING` for conversion.
- The block is part of the `iec61131::conversion` package.

State Overview

1. **Idle State**: The function block waits for the `REQ` event.
2. **Conversion State**: Upon receiving `REQ`, the conversion is performed.
3. **Completion State**: After successful conversion, the `CNF` event is triggered.

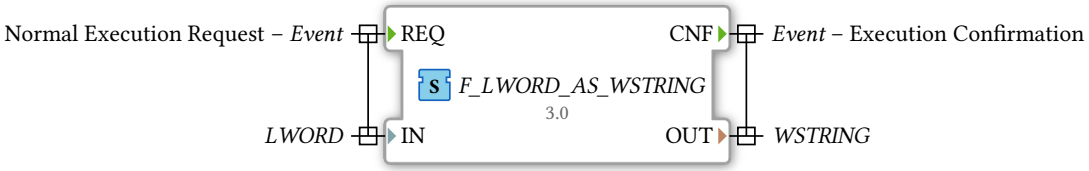
Application Scenarios

- Conversion of large binary data into readable strings.
- Use in systems that need to work with binary and textual data.

⚖️ Comparison with Similar Function Blocks

- Unlike other conversion blocks that may process different data types, this one is specifically optimized for converting `LWORD` to `STRING`.

Conclusion



The `F_LWORD_AS_STRING` function block provides a simple and efficient way to convert large binary data into strings. Its clear interface structure and simple functionality make it a valuable component in automation technology.

F_LWORD_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LWORD_AS_WSTRING` is used to convert an LWORD data type to a WSTRING data type. This functionality is particularly useful when data needs to be exchanged between systems that use different data types.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This event input triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. This event is output once the conversion is complete.

Data Inputs

- **IN**: Input variable of type LWORD containing the value to be converted.

Data Outputs

- **OUT**: Output variable of type WSTRING containing the converted value.

Adapters

No adapters are present.

Functionality

The function block performs the conversion from LWORD to WSTRING as soon as the event `REQ` is received. The conversion is carried out using the integrated function `LWORD_AS_WSTRING`. After successful conversion, the event `CNF` is output.

Technical Features

- The function block is a simple FB (SimpleFB) and contains a single algorithm.
- The conversion occurs directly and without any additional delay.

State Overview

The function block has no internal states. Execution occurs immediately upon receipt of the `REQ` event.

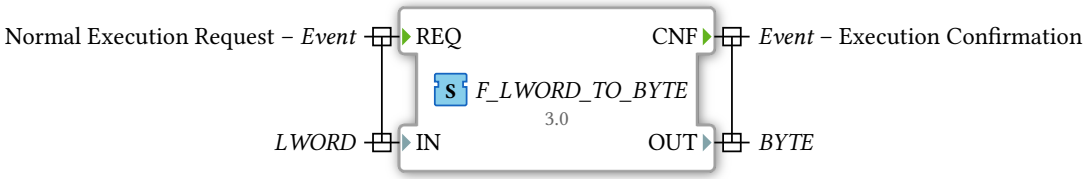
Application Scenarios

- Data conversion in industrial control systems.
- Exchange of data between systems that use different data types.
- Integration into larger control applications where type conversion is required.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks, `F_LWORD_AS_WSTRING` specializes in converting LWORD to WSTRING.
- Other blocks might support more general conversions, but may be less efficient for this specific use case.

Conclusion



The `F_LWORD_AS_WSTRING` function block offers an efficient and direct method for converting LWORD to WSTRING. Its simple structure and clear functionality make it a reliable tool in control applications.

F_LWORD_TO_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LWORD_TO_BYTE` converts a 64-bit value (LWORD) to an 8-bit value (BYTE). This conversion is particularly useful when data needs to be exchanged or processed between systems with different word lengths.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs

- **IN**: The input for the 64-bit value (LWORD) to be converted.

Data Outputs

- **OUT**: The output for the converted 8-bit value (BYTE).

Adapters

- No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The value at input `IN` is read and converted into a BYTE value using the function `LWORD_TO_BYTE`. The result is output at `OUT`, and the event `CNF` signals the completion of the operation.

Technical Details

- The conversion can result in data loss because a 64-bit value is converted to an 8-bit value. It is important to ensure that the original value is within the representable range of a byte (0 to 255).

- The function block is implemented as a simple function block (SimpleFB) and uses an ST algorithm for the conversion.

State Overview

1. **Idle State**: Waits for the event `REQ`.
2. **Active State**: Performs the conversion and outputs the result.
3. **Completion State**: Signals completion with `CNF` and returns to the idle state.

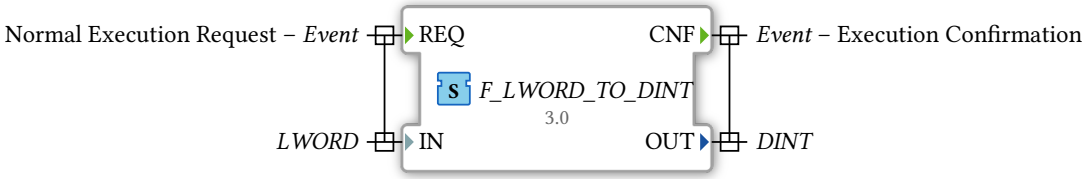
Application Scenarios

- Data Reduction: When only the lower 8 bits of a 64-bit value are relevant.
- Communication with devices that can only process BYTE data.
- Memory optimization in systems with limited resources.

⚖️ Comparison with Similar Components

- **F_WORD_TO_BYTE**: Converts a 16-bit value (WORD) to a BYTE.
- **F_DWORD_TO_BYTE**: Converts a 32-bit value (DWORD) to a BYTE.
- **F_LWORD_TO_WORD**: Converts a 64-bit value to a 16-bit value.

Conclusion



The function block `F_LWORD_TO_BYTE` offers a simple and efficient way to convert 64-bit data to 8-bit data. It is particularly useful in scenarios where only a portion of the data is needed or the target platform supports limited data types. However, be aware of the potential data loss during the conversion.

F_LWORD_TO_DINT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_LWORD_TO_DINT` converts a `LWORD` data type to a `DINT` data type. This block is particularly useful in scenarios where type conversion between these two data types is required, for example, when processing large binary datasets or when communicating between systems with different data type requirements.

Interface Structure

Event Inputs

- **REQ**: This event input triggers the execution of the function block. It is connected to the data input `IN`.

Event Outputs

- **CNF**: This event output signals the successful execution of the function block. It is connected to the data output `OUT`.

Data Inputs

- **IN** (LWORD): The input for the `LWORD` value to be converted.

Data Outputs

- **OUT** (DINT): The output for the converted `DINT` value.

Adapters

This function block does not use any adapters.

Functionality

The function block converts the incoming `LWORD` value (`IN`) into a `DINT` value (`OUT`) as soon as the `REQ` event is triggered. The conversion is performed using the built-in function `LWORD_TO_DINT`. After successful conversion, the `CNF` event is triggered to indicate completion of the operation.

Technical Features

- The function block has a simple structure and consists of a single algorithm that performs the conversion.
- There is no state machine or complex logic, as the conversion is performed directly without intermediate steps.

State Overview

Since this is a simple function block, there are no state transitions or complex state logic. The block performs the conversion on each `REQ` event and signals completion with `CNF`.

Application Scenarios

- **Data Conversion**: In systems where `LWORD` data needs to be converted to `DINT`, e.g., in communication between different hardware components.
- **Data Processing**: When processing large binary data sets that need to be further processed in a smaller format.

⚖️ Comparison with Similar Blocks

- **F_LWORD_TO_INT**: Similar function block, but converts to the smaller `INT` data type.
- **F_LWORD_TO_UDINT**: Converts to an unsigned `DINT` data type (`UDINT`).

Conclusion

The `F_LWORD_TO_DINT` function block is a simple and efficient tool for converting `LWORD` to `DINT` data. Its simplicity and direct functionality make it a reliable solution for type conversions in 4diac IDE-based systems.

F_LWORD_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LWORD_TO_DWORD` is used to convert an LWORD data type to a DWORD data type. This conversion is useful when data needs to be exchanged between systems or components that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN**: Input for the LWORD value to be converted.

Data Outputs

- **OUT**: Output for the converted DWORD value.

Adapters

- No adapters available.

Functionality

The function block performs the conversion from LWORD to DWORD when the event `REQ` is triggered. The algorithm within the function block uses the function `LWORD_TO_DWORD` to perform the conversion. After successful conversion, the event `CNF` is triggered to signal the completion of the operation.

Technical Features

- The function block is a simple function block (SimpleFB) and performs a direct conversion.
- There are no additional states or complex logic, as the conversion occurs in a single step.

State Overview

Since this is a simple function block, there are no state transitions or state machines. The function block reacts directly to the `REQ` event and outputs the result via `CNF`.

Application Scenarios

- **Data Compatibility**: When one system creates LWORD data, but another system can only process DWORD data.
- **Protocol Conversion**: For communication between different protocols or interfaces that use different data types.

⚖️ Comparison with Similar Function Blocks

- **F_DWORD_TO_LWORD**: Performs the reverse conversion (DWORD to LWORD).
- **F_WORD_TO_DWORD**: Converts WORD to DWORD, but has a smaller input size compared to LWORD.

Conclusion

The `F_LWORD_TO_DWORD` function block is a simple and efficient tool for converting LWORD to DWORD data. Its simplicity and direct functionality make it a reliable solution for data conversion tasks in 4diac IDE-based systems.

F_LWORD_TO_INT

• – ◦ • – ◦ • – ◦ •

The function block `F_LWORD_TO_INT` converts a `LWORD` value (64-bit unsigned integer) to a `INT` value (16-bit signed integer). This conversion is useful when data needs to be exchanged or processed between systems with different word lengths.

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.
- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.
- **IN**: The input value of type `LWORD` (64-bit unsigned integer) to be converted.
- **OUT**: The output value of type `INT` (16-bit signed integer) containing the result of the conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- No adapters are available.

The function block performs the conversion by transforming the `LWORD` value at input `IN` into a `INT` value and outputting it at output `OUT`. The conversion occurs upon an event at input `REQ` and is confirmed by an event at output `CNF`.

- Converting a 64-bit value to a 16-bit value can result in data loss if the original value is outside the representable range of `INT`.
- Converting from a 64-bit value to a 16-bit value can lead to data loss if the original value is outside the representable range of `INT`.
- The function block is implemented as a simple function block (`SimpleFB`) and uses an ST algorithm for conversion.

The function block has no internal states. The conversion occurs immediately upon an event at the input `REQ`.

- Conversion of 64-bit data values for systems that can only process 16-bit data.
- Data reduction when only the lower 16-bit portion of a 64-bit value is relevant.
- `F_DWORD_TO_INT`: Converts a 32-bit value to a 16-bit value.
- `F_LWORD_TO_DINT`: Converts a 64-bit value to a 32-bit value.
- `F_LWORD_TO_SINT`: Converts a 64-bit value to an 8-bit value.

The function block `F_LWORD_TO_INT` provides a simple and efficient way to convert 64-bit data values to 16-bit data values. However, when using it, be aware of the potential data loss if the original value is outside the representable range of `INT`.

Conclusion

F_LWORD_TO_LINT

• – ○ • – ○ • – ○ •

The function block `F_LWORD_TO_LINT` converts a `LWORD` value (64-bit unsigned) to a `LINT` value (64-bit signed). This block is particularly useful in scenarios where type conversion between these two data types is required.

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.
- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.
- **IN**: Input for the `LWORD` value to be converted.
- **OUT**: Output for the converted `LINT` value.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- No adapters are present.

Functionality

The function block performs the conversion from `LWORD` to `LINT` as soon as the event `REQ` is triggered. The conversion is performed using the function `LWORD_TO_LINT(IN)`. Upon successful conversion, the event `CNF` is triggered.

- The function block is a simple FB (SimpleFB) and uses an ST algorithm for the conversion.
- The conversion is performed directly without additional state management.

Since it is a simple function block, there are no complex state transitions. The block responds to `REQ` by executing the algorithm and signals completion with `CNF`.

- Type conversion in control applications where `LWORD` data needs to be converted to `LINT`.
- Similar blocks could be `F_DWORD_TO_DINT` or `F_WORD_TO_INT`, but these are designed for smaller data types.
- Unlike generic conversion blocks, this one is specifically optimized for converting `LWORD` to `LINT`.

The `F_LWORD_TO_LINT` function block offers an efficient and direct method for converting `LWORD` to `LINT`. Its simplicity and specialization make it a reliable component in control applications.

Conclusion

F_LWORD_TO_LREAL

• – ○ • – ○ • – ○ •

Introduction

The function block `F_LWORD_TO_LREAL` converts an LWORD data value (64-bit unsigned integer) to an LREAL data value (64-bit floating-point number according to IEEE 754). This block is particularly useful in applications where direct type conversion between these two data types is required.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. The input value `IN` is processed upon this event.

Event Outputs
- **CNF**: Signals the completion of the conversion and outputs the converted value `OUT`.

Data Inputs
- **IN** (LWORD): The input value to be converted.

Data Outputs
- **OUT** (LREAL): The result of the conversion.

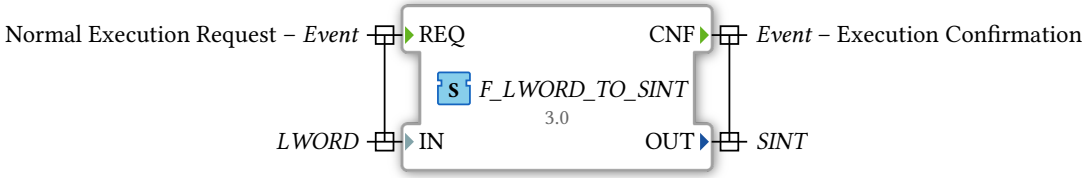
Adapters
This function block has no adapters.

Operation
When the `REQ` event is triggered, the algorithm that converts the `IN` value of type LWORD to an LREAL value is executed. The result is output via the `OUT` output, and the `CNF` event signals successful conversion.

Technical Features
- The conversion is performed directly without additional parameters.
- The function block is optimized for use in real-time systems.

State Overview
The function block has a simple state machine:

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Complete**: Sends the `CNF` event with the result.



Application Scenarios
- Data processing in control systems where LWORD values need to be converted to floating-point numbers.
- Integration into larger function block networks that process mixed data types.

⚖️ Comparison with similar blocks
- Similar blocks such as `F_DWORD_TO_REAL` or `F_WORD_TO_REAL` offer conversions for smaller data types.
- `F_LWORD_TO_LREAL` is specifically optimized for 64-bit conversions.

Conclusion
The `F_LWORD_TO_LREAL` function block is an efficient tool for directly converting 64-bit integers to floating-point numbers. Its simple interface and reliable operation make it ideal for use in complex automation solutions.

F_LWORD_TO_SINT
• – ◦ • – ◦ • – ◦ •

Introduction
The function block `F_LWORD_TO_SINT` converts a `LWORD` value (64-bit unsigned integer) to a `SINT` value (8-bit signed integer). This conversion is useful when data needs to be transferred from a larger range of values to a smaller, more specific range.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. When activated, the input value `IN` is processed.

Event Outputs

- **CNF**: Signals successful completion of the conversion and provides the result value `OUT`.

Data Inputs

- **IN** (`LWORD`): The input value that is converted from `LWORD` to `SINT`.

Data Outputs

- **OUT** (`SINT`): The result of the conversion.

Adapters

This function block does not use adapters.

Functionality

The function block performs a direct type conversion of the input value `IN` from type `LWORD` to type `SINT`. The conversion is carried out by the function `LWORD_TO_SINT(IN)`, which is implemented in the algorithm `REQ`. Upon successful conversion, the event `CNF` is triggered.

Technical Features

- **Type Conversion**: Since `LWORD` covers a larger range of values than `SINT`, data loss can occur if the input value is outside the representable range of `SINT` (-128 to 127).
- **Algorithm**: The algorithm is implemented in Structured Text (ST) and performs a direct conversion.

State Overview

1. **Idle State**: Waits for the event `REQ`.
2. **Execution State**: The conversion is performed upon `REQ`.
3. **Acknowledgement State**: After successful conversion, `CNF` is triggered, and the block returns to the idle state.

Application Scenarios

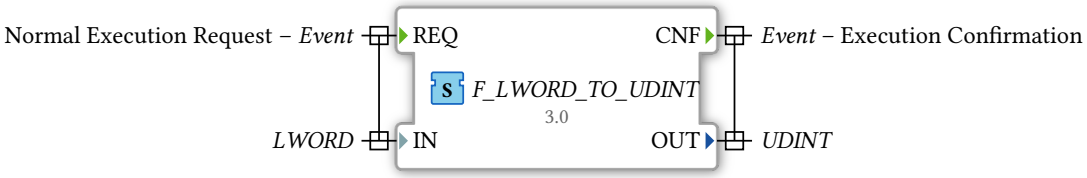
- **Data Reduction**: When only the lower 8 bits of a 64-bit value are relevant.
- **Communication**: When transferring data between systems with different word sizes.
- **Memory Optimization**: When memory space is limited and smaller data types are preferred.

⚖️ Comparison with similar building blocks

- **F_LWORD_TO_INT**: Converts `LWORD` to `INT` (16-bit signed integer).
- **F_LWORD_TO_DINT**: Converts `LWORD` to `DINT` (32-bit signed integer).
- **F_LWORD_TO_USINT**: Converts `LWORD` to `USINT` (8-bit unsigned integer).

Unlike these blocks, `F_LWORD_TO_SINT` is specifically for conversion to an 8-bit signed integer.

Conclusion



The function block `F_LWORD_TO_SINT` provides a simple and efficient way to convert 64-bit values to 8-bit signed integers. It is particularly useful in scenarios where memory efficiency or the processing of portions of a larger data type is required. However, when using it, care must be taken to avoid potential data loss with values outside the `SINT` range.

F_LWORD_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LWORD_TO_UDINT` converts a `LWORD` value (64-bit unsigned integer) to a `UDINT` value (32-bit unsigned integer). This conversion is useful when data needs to be transferred or processed between systems with different word lengths.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- `IN` (LWORD): The 64-bit unsigned integer value to be converted.

Data Outputs

- `OUT` (UDINT): The resulting 32-bit unsigned integer value after the conversion.

Adapters

This function block does not use any adapters.

Functionality

When the `REQ` event is triggered, the value of `IN` is converted from `LWORD` to `UDINT`, and the result is output to `OUT`. The `CNF` event signals the successful completion of the conversion.

The conversion is performed by the function `LWORD_TO_UDINT`, which returns the lower 32 bits of the `LWORD` value as `UDINT`.

Technical Features

- The function block is suitable for use in real-time systems.
- The conversion is deterministic and has a constant execution time.
- Values greater than the maximum `UDINT` value (2^32 - 1) are truncated.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

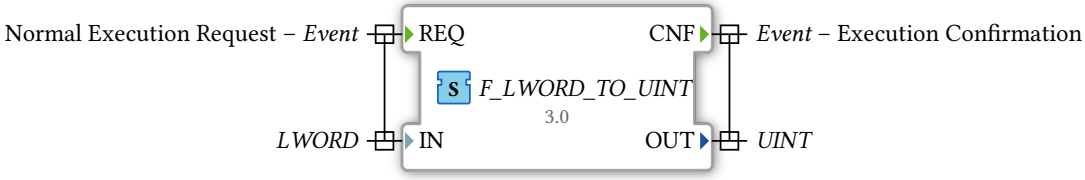
Application Scenarios

- Communication between systems with different word widths.
- Processing data from external sources that provide 64-bit values, but only 32-bit values are required.
- Reducing memory usage when dealing with known small value ranges.

⚖️ Comparison with Similar Function Blocks

- `F_LWORD_TO_DINT`: Converts to a 32-bit signed integer.
- `F_LWORD_TO_UINT`: Converts to a 16-bit unsigned integer.
- `F_LWORD_TO_WORD`: Converts to a 16-bit unsigned value.

Conclusion



The F_LWORD_TO_UDINT function block provides a simple and efficient way to convert 64-bit values to 32-bit values. It is particularly useful in systems that need to handle different word lengths.

F_LWORD_TO_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_LWORD_TO_UINT converts a LWORD data type to a UINT data type. This function block is particularly useful in scenarios where type conversion between these two data types is required, for example, in communication between systems with different data formats.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This event input triggers the conversion. It is linked to the data input IN.

Event Outputs

- **CNF**: Execution Confirmation. This event is triggered after successful conversion and is associated with the data output OUT.

Data Inputs

- **IN**: Input data of type LWORD to be converted to the UINT data type.

Data Outputs

- **OUT**: Output data of type UINT containing the result of the conversion.

Adapters

No adapters available.

Functionality

The function block performs the conversion from LWORD to UINT when the event REQ is received. The conversion is performed using the function LWORD_TO_UINT(IN), which converts the value of IN and passes the result to OUT. After successful conversion, the event CNF is triggered.

Technical Features

- The function block is a simple algorithm (SimpleFB) and does not perform any complex state transitions.
- The conversion occurs directly without additional conditions or delays.

State Overview

Since it is a simple function block, there are no explicit states. The functionality is limited to directly responding to the REQ event, subsequently outputting the converted value, and triggering the CNF event.

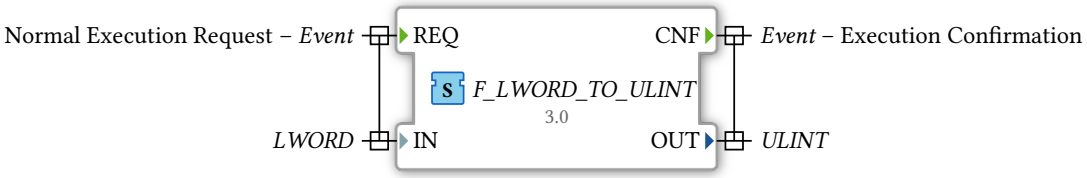
Application Scenarios

- Type conversion in communication interfaces between systems that use different data types.
- Data processing in control systems where conversion from LWORD to UINT is required.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks could be F_DWORD_TO_UINT or F_WORD_TO_UINT, which, however, process different input data types.
- The main difference lies in the input data type (LWORD), which has a larger bit width than DWORD or WORD.

Conclusion



The F_LWORD_TO_UINT function block provides a simple and efficient way to convert LWORD data to the UINT data type. Its clear interface structure and direct functionality make it a useful component in various use cases, especially where type conversions between these data types are required.

F_LWORD_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_LWORD_TO_ULINT is used to convert an LWORD data type to a ULINT data type. This conversion is particularly necessary in scenarios where data of different bit lengths needs to be processed or transmitted.

Interface Structure

Event Inputs

- **REQ**: This event input triggers the conversion. It is linked to the data input IN.

Event Outputs

- **CNF**: This event output signals the successful completion of the conversion. It is linked to the data output OUT.

Data Inputs

- **IN**: The input expects a variable of type LWORD, which is to be converted.

Data Outputs

- **OUT**: The output returns the result of the conversion as ULINT.

Adapters

This function block has no adapters.

Functionality

When the event input REQ is triggered, the algorithm is started, which converts the value of IN of type LWORD to type ULINT and outputs the result as OUT. The event CNF is then triggered to signal the successful conversion.

Technical Features

- This function block is particularly efficient because it directly utilizes the built-in function LWORD_TO_ULINT.
- There are no special constraints or limitations when using this function block.

State Overview

This function block has no internal states. The conversion occurs immediately upon triggering the REQ event.

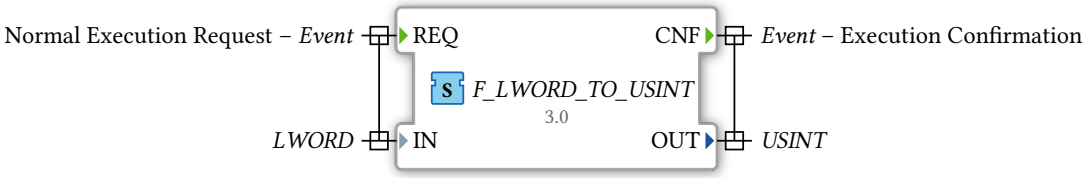
Application Scenarios

- Data conversion in control systems where different data types need to be processed.
- Integration into larger systems that require type conversion between LWORD and ULINT.

⚖️ Comparison with Similar Function Blocks

Compared to other conversion blocks, F_LWORD_TO_ULINT specializes in converting LWORD to ULINT and therefore offers an optimized solution for this specific use case.

Conclusion



The `F_LWORD_TO_ULINT` function block is a simple and efficient building block for converting between the data types `LWORD` and `ULINT`. Its clear interface structure and direct functionality make it a reliable component in control applications.

F_LWORD_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LWORD_TO_USINT` converts a 64-bit value (LWORD) to an 8-bit unsigned integer (USINT). This conversion is particularly useful when data from a larger range of values needs to be transformed into a smaller, more specific range.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion and outputs the result via the data output `OUT`.

Data Inputs

- **IN (LWORD)**: The 64-bit value to be converted to a USINT value.

Data Outputs

- **OUT (USINT)**: The resulting 8-bit unsigned integer value after the conversion.

Adapters

No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The algorithm converts the 64-bit input value `IN` into an 8-bit unsigned integer value and stores the result in `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Details

- The conversion is performed by the built-in function `LWORD_TO_USINT`.
- Note that when converting from a larger to a smaller data type, data loss may occur if the original value is outside the representable range of the target type.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Conversion State**: Performs the conversion. 3. **Acknowledge State**: Sends the `CNF` event and returns to the idle state.

Application Scenarios

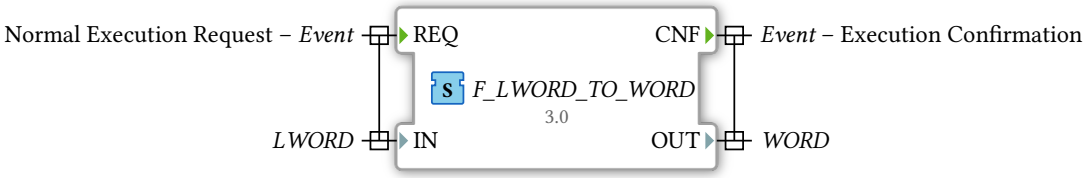
- Processing 64-bit data that needs to be reduced to 8 bits.
- Communication between systems with different data widths.
- Memory optimization in embedded systems.

⚖️ Comparison with Similar Components

- **F_LWORD_TO_BYTE**: Also converts LWORD to an 8-bit value, but without a sign (BYTE).

- **F_LWORD_TO_INT**: Converts to a 16-bit signed integer, offering a larger value range, but with a sign.

Conclusion



The `F_LWORD_TO_USINT` function block is a simple and efficient tool for converting 64-bit data to 8-bit unsigned integer values. It is particularly useful in scenarios where storage space or data bandwidth is limited. However, it should be ensured that the original data is within the representable range of the target type to avoid data loss.

F_LWORD_TO_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_LWORD_TO_WORD` is used to convert a 64-bit value (LWORD) to a 16-bit value (WORD). This conversion is particularly necessary in scenarios where data needs to be exchanged or processed between systems with different word widths.

Interface Structure

Event Inputs

- **REQ**: Signals the start of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: LWORD (64-bit) – The input value to be converted.

Data Outputs

- **OUT**: WORD (16-bit) – The converted output value.

Adapters

No adapters available.

Functionality

This function block performs the conversion from a 64-bit value (LWORD) to a 16-bit value (WORD). During the conversion, the lower 16 bits of the input value are retained, while the upper 48 bits are discarded. The conversion occurs synchronously with the `REQ` event, and the result is confirmed with the `CNF` event.

Technical Features

- The conversion is performed without rounding or scaling, as it is a direct bit conversion.
- No check is performed to prevent potential data loss due to word width reduction. The user must ensure that the input value is within the permissible range.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

Application Scenarios

- Communication between systems with different word widths.
- Processing data originating from 64-bit sources but intended for use in 16-bit systems.
- Reducing the data width to optimize storage space when the higher-order bits are not required.

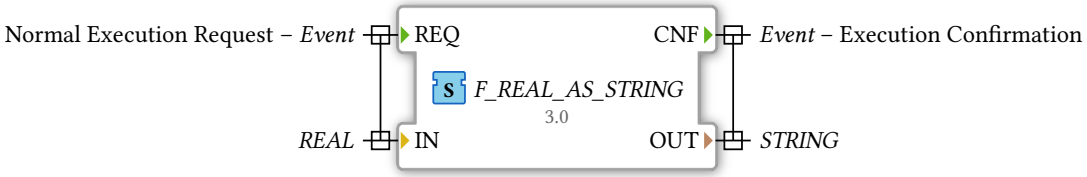
⚖️ Comparison with Similar Function Blocks

- **F_LWORD_TO_DWORD**: Converts LWORD to DWORD (32-bit), retaining more data bits.
- **F_LWORD_TO_BYTE**: Converts LWORD to BYTE (8-bit), reducing the data width even further.
- **F_LWORD_TO_**: Similar function blocks for other target data types, each with a different bit width as a result.

Conclusion

The `F_LWORD_TO_WORD` function block offers a simple and efficient way to reduce 64-bit data to 16-bit data. It is particularly useful in heterogeneous system environments where data needs to be exchanged between components with different word widths. However, due to the lack of data loss checks, users should ensure that the conversion is appropriate and safe.

LWORD Conversions



Here you will find functions for converting the LWORD data type.

REAL

F_REAL_AS_STRING

• – ◦ • – ◦ • – ◦ •

The function block `F_REAL_AS_STRING` converts a REAL value to a STRING value. It is part of the package `iec61131::conversion` and enables the easy conversion of numeric values to a string.

- **REQ**: Starts the conversion of the REAL value to a STRING. This input is linked to the data input `IN`.
- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.
- **IN**: The REAL value to be converted to a STRING.
- **OUT**: The converted STRING value of input `IN`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block has no adapters.

Functionality

When an event is present at input `REQ`, the algorithm is executed, converting the REAL value of `IN` to a STRING and outputting the result to `OUT`. The event `CNF` is then triggered to signal the successful completion of the conversion.

- The function block uses the function `REAL_AS_STRING` for conversion.
- It is a simple function block without a state machine.

Since it is a simple function block, there are no state transitions. The conversion occurs directly upon triggering the `REQ` event.

- Conversion of sensor values for display on an HMI.
- Conversion of numerical values for logging in text files.

- Integration into systems that require string-based communication.
- Compared to other conversion blocks such as `F_INT_AS_STRING` or `F_BOOL_AS_STRING`, this one is specifically designed for real values.
- Simpler and more direct than universal conversion blocks, which may require additional parameters.

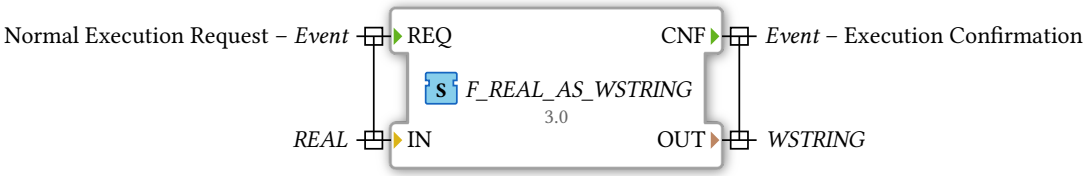
The `F_REAL_AS_STRING` function block offers an efficient and straightforward way to convert REAL values to STRINGs. Its simple interface and direct functionality make it ideal for applications where numeric values need to be processed as strings.

Technical Features

State Overview

Application Scenarios

⚖️ Vergleich mit ähnlichen Bausteinen



Conclusion

F_REAL_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_AS_WSTRING` converts a `REAL` value into a `WSTRING` value. This block is particularly useful when numeric values need to be converted into a string suitable for output or further processing.

Interface Structure

Event Inputs

- **REQ**: This input triggers the conversion. Upon receiving an event, the algorithm for converting the `REAL` value into a `WSTRING` value is started.

Event Outputs

- **CNF**: This event signals the successful completion of the conversion and returns the result as a `WSTRING` value.

Data Inputs

- **IN**: The input expects a `REAL` value, which is to be converted to a `WSTRING` value.

Data Outputs

- **OUT**: The output returns the converted `WSTRING` value after the conversion is complete.

Adapters

This function block does not have any adapter interfaces.

Functionality

The function block `F_REAL_AS_WSTRING` converts the `REAL` value at input `IN` to a `WSTRING` value upon receiving an incoming `REQ` event. The result is provided at output `OUT` and confirmed by a `CNF` event.

The conversion algorithm is implemented as a simple ST (Structured Text) statement:
ALGORITHM REQ OUT := REAL_AS_WSTRING(IN); END_ALGORITHM

Technical Features

- The function block is part of the `iec61131::conversion` package.

- The conversion is performed directly without additional parameters or settings.

Status Overview

1. **Idle**: Waits for a `REQ` event.
2. **Processing**: Performs the conversion.
3. **Completed**: Sends the `CNF` event with the result.

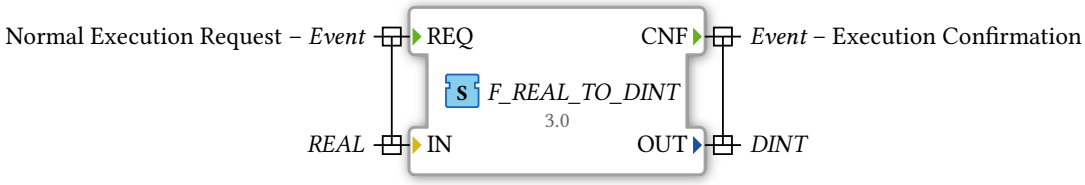
Application Scenarios

- **Data Output**: Converts numeric values for display on a control panel or in a log file.
- **Data Communication**: Prepares numeric values for transmission as strings in network protocols.

⚖️ Comparison with Similar Function Blocks

- **F_REAL_TO_STRING**: Similar function block, but it converts to `STRING` instead of `WSTRING`. `F_REAL_AS_WSTRING` is better suited for Unicode-enabled environments.
- **F_WSTRING_AS_REAL**: Performs the reverse conversion (from `WSTRING` to `REAL`).

Conclusion



The function block `F_REAL_AS_WSTRING` provides a simple and efficient way to convert `REAL` values to `WSTRING` values. Its clear interface and direct functionality make it ideal for applications that require a Unicode-compatible string representation of floating-point numbers.

F_REAL_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_TO_DINT` converts a REAL value (floating-point number) into a DINT value (32-bit integer). This conversion is performed by rounding the REAL value down to the nearest integer.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. Triggered after successful conversion.

Data Inputs

- **IN**: Input for the REAL value to be converted.

Data Outputs

- **OUT**: Output for the converted DINT value.

Adapters

No adapters available.

Functionality

When the `REQ` event is triggered, the algorithm that converts the `IN` value from REAL to DINT is executed. The result is output at `OUT`, and the `CNF` event is triggered.

Technical Features

- The conversion is performed by rounding down the REAL value.
- The function block is simple and has no internal states.

State Overview

No states are present, as the block is stateless.

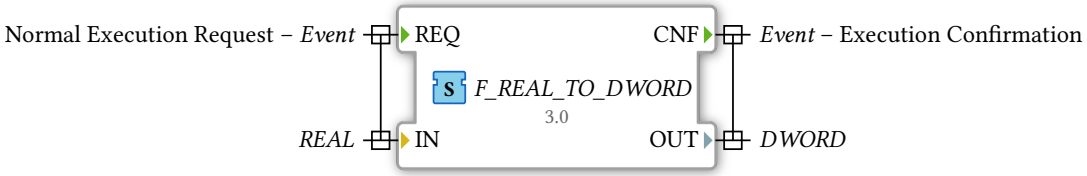
Application Scenarios

- Conversion of sensor values (floating-point) to integer values for control logic.
- Data processing in control systems where integer values are required.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks might offer other conversion methods, e.g., rounding or rounding up.
- Compared to generic conversion blocks, this one specializes in REAL-to-DINT conversion.

Conclusion



The `F_REAL_TO_DINT` function block is a simple and efficient building block for converting floating-point numbers to integers. It is particularly useful in scenarios where fast and direct conversion is required.

F_REAL_TO_DWORD

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_REAL_TO_DWORD` converts a REAL value (floating-point number) to a DWORD value (32-bit unsigned integer). This conversion is particularly useful when floating-point values need to be processed in systems that only support integer operations.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. The value to be converted is provided via the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is output via the data output `OUT`.

Data Inputs

- **IN**: REAL value to be converted to a DWORD value.

Data Outputs

- **OUT**: The resulting DWORD value after conversion.

Adapters

This function block does not use any adapters.

Operation

When an event is received at input `REQ`, the algorithm is executed, converting the REAL value of `IN` to a DWORD value and outputting the result to `OUT`. The event `CNF` is then triggered to signal the completion of the operation.

Technical Features

- The conversion is performed by the function `REAL_TO_DWORD`, which directly converts the REAL value into a DWORD value. The floating-point value is rounded to the nearest integer.
- Note that data loss can occur with very large or small values, as the DWORD type offers only limited precision.

State Overview

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

Application Scenarios

- Processing sensor data that is in floating-point form but needs to be further processed in integer form.
- Integration into control systems that only support integer operations.
- Data conversion for communication protocols that require DWORD values.

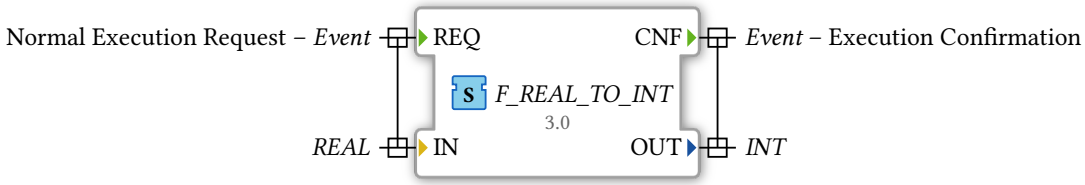
⚖️ Comparison with Similar Function Blocks

- **F_REAL_TO_INT**: Converts REAL to INT (signed integer). In contrast, `F_REAL_TO_DWORD` returns an unsigned value.
- **F_REAL_TO_LREAL**: Converts REAL to LREAL (higher precision), while `F_REAL_TO_DWORD` converts the value to an integer type.

🛠️ Related Exercises

- Exercise_126b2_sub

Conclusion



The function block `F_REAL_TO_DWORD` provides a simple and efficient way to convert floating-point values to unsigned integers. It is particularly useful in environments that only support integer operations or when data needs to be processed further in a specific format. However, when using this method, care must be taken to avoid potential data loss during the conversion process.

F_REAL_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_TO_INT` converts a REAL value (floating-point number) to an INT value (integer). This conversion is particularly useful when data needs to be exchanged between systems that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input for the REAL value to be converted.

Data Outputs

- **OUT**: The output for the converted INT value.

Adapters

- No adapters are available.

Functionality

The function block performs the conversion by converting the REAL value at input `IN` into an INT value and outputting the result at output `OUT`. The conversion is triggered by the event `REQ` and confirmed by the event `CNF`.

Technical Details

- The conversion is performed using the function `REAL_TO_INT`, which converts the REAL value into an INT value.
- The function block is simple and efficient because it does not use complex algorithms or state machines.

State Overview

The function block has no internal states. The conversion occurs immediately after the `REQ` event is triggered.

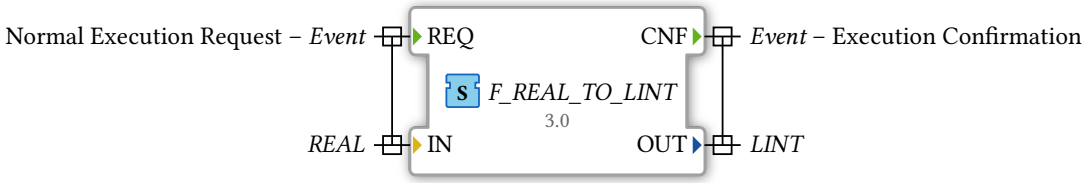
Application Scenarios

- **Data Conversion**: Converting sensor values (floating-point numbers) to integers for further processing.
- **Interface Compatibility**: Adapting data between systems that expect different data types.

⚖️ Comparison with Similar Blocks

- **F_TRUNC**: Converts REAL to INT by truncating the decimal places, while `F_REAL_TO_INT` performs standard rounding.
- **F_ROUND**: Rounds REAL to INT, similar to `F_REAL_TO_INT`, but with specific rounding rules.

Conclusion



The `F_REAL_TO_INT` function block is a simple and effective tool for converting floating-point numbers to integers. Its simplicity and direct functionality make it ideal for applications requiring fast and straightforward data type conversion.

F_REAL_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_TO_LINT` converts a REAL value (floating-point number) to a LINT value (64-bit integer). This conversion is particularly useful when numerical calculations need to be performed with different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event input is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event, along with the converted value, is output at data output `OUT`.

Data Inputs

- **IN**: The input for the REAL value to be converted to a LINT value.

Data Outputs

- **OUT**: The output where the converted LINT value is displayed.

Adapters

This function block has no adapters.

Operation

When the `REQ` event is triggered, the algorithm `REQ` is executed. This function converts the REAL value at input `IN` into a LINT value using the function `REAL_TO_LINT` and writes the result to output `OUT`. The `CNF` event is then triggered to signal the successful completion of the conversion.

Technical Details

- Converting REAL to LINT can result in data loss if the REAL value has decimal places, as these are truncated during the conversion.
- This function block is part of the `iec61131::conversion` package.

State Overview

This function block has no internal states. The conversion occurs immediately after the `REQ` event is triggered.

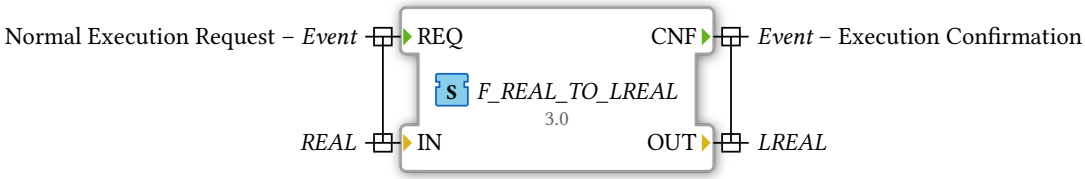
Application Scenarios

- Conversion of sensor values (e.g., temperature measurements) for further processing into integer operations.
- Integration into control systems that need to process mixed data types.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks (e.g., `F_REAL_TO_INT`), `F_REAL_TO_LINT` offers higher precision through the use of the 64-bit LINT data type.
- Similar blocks, such as `F_LINT_TO_REAL`, perform the reverse conversion.

Conclusion



The `F_REAL_TO_LINT` function block is a simple and efficient block for converting floating-point numbers to 64-bit integers. Its use is particularly recommended in scenarios with high precision requirements, although potential data loss during conversion must be taken into account.

F_REAL_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_TO_LREAL` is used to convert a REAL value to an LREAL value. This block is part of the `iec61131::conversion` package and enables simple type conversion between the two numeric data types.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion. Linked to the data input `IN`.

Event Outputs

- **CNF**: Execution confirmation. Triggered after successful conversion. Linked to the data output `OUT`.

Data Inputs

- **IN**: Input value of type `REAL` to be converted.

Data Outputs

- **OUT**: Output value of type `LREAL` containing the result of the conversion.

Adapters

This function block does not use any adapters.

Functionality

Upon receiving the event `REQ`, the function block converts the REAL value `IN` to an LREAL value and assigns the result to the output `OUT`. The event `CNF` is then triggered to confirm successful execution.

Technical Features

- The function block is a simple building block without internal states or complex logic.
- Conversion is performed directly by assignment, as `LREAL` offers higher accuracy than `REAL` and can therefore represent all values without loss.

State Overview

Since it is a simple function block, there are no state transitions or management. Execution occurs atomically upon receiving the `REQ` event.

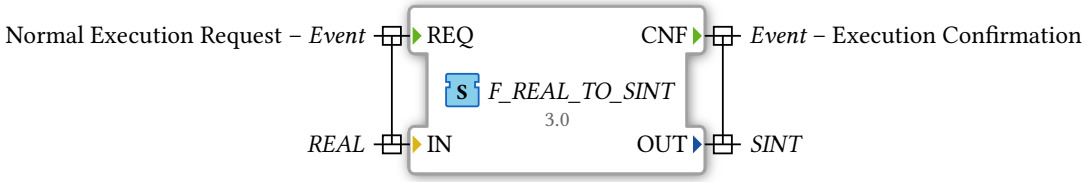
Application Scenarios

- Type conversion in control applications where higher accuracy is required.
- Integration into existing systems that use different data types.
- Use in mathematical calculations that require higher precision.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_INT_TO_REAL` or `F_DINT_TO_LINT` also perform type conversions, but between different data types.
- Unlike complex conversion blocks, `F_REAL_TO_LREAL` offers a simple and direct conversion without additional parameters or logic.

Conclusion



The `F_REAL_TO_LREAL` function block is a useful tool for the simple and efficient conversion of REAL to LREAL values. Its simplicity and direct functionality make it ideal for applications that require fast type conversion without added complexity.

F_REAL_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_TO_SINT` converts a `REAL` value (floating-point number) to a `SINT` value (8-bit signed integer). This block is particularly useful in control applications where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. The value at input `IN` is processed upon this event.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event, along with the converted value, is output at `OUT`.

Data Inputs

- **IN**: Input for the `REAL` value to be converted to a `SINT` value.

Data Outputs

- **OUT**: Output for the converted `SINT` value.

Adapters

- This function block does not have any adapters.

Functionality

The function block performs the conversion by transforming the `REAL` value at input `IN` into a `SINT` value using the function `REAL_TO_SINT`. The conversion occurs when the event `REQ` is triggered, and the result is output with the event `CNF`.

Technical Features

- The function block is implemented as a simple function block (`SimpleFB`) containing only one algorithm.
- The conversion truncates the `REAL` value to the value range of `SINT` (-128 to 127). Values outside this range result in an overflow.

State Overview

The function block has no internal state. The conversion occurs immediately upon the occurrence of the `REQ` event.

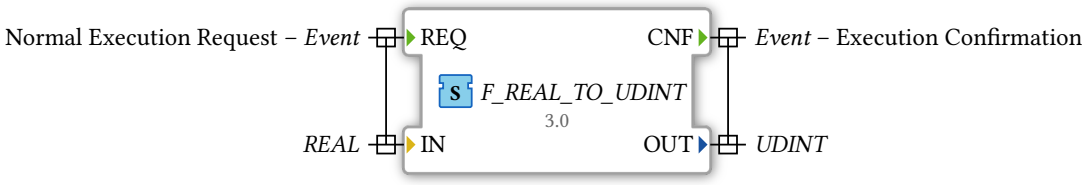
Application Scenarios

- Type conversion in control algorithms where floating-point values need to be converted to integers.
- Signal processing where `REAL` sensor data needs to be reduced to `SINT`.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_REAL_TO_INT` or `F_REAL_TO_USINT` offer conversions to other integer types. `F_REAL_TO_SINT` is specific to 8-bit signed integers.

Conclusion



The `F_REAL_TO_SINT` function block is a simple and efficient building block for converting floating-point numbers to 8-bit signed integers. Its use is advantageous in scenarios where such type conversion is required, particularly in control and signal processing applications.

F_REAL_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_TO_UDINT` converts a REAL value to a UDINT value. This block is part of the `iec61131::conversion` package and implements a simple but important type conversion for use in control applications.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (REAL): The input value to be converted from REAL to UDINT.

Data Outputs

- **OUT** (UDINT): The result of the conversion.

Adapters

This function block does not use any adapters.

Operation

When an event is received at input `REQ`, the algorithm is executed, which converts the REAL value at input `IN` into a UDINT value and outputs the result at output `OUT`. The event `CNF` is then triggered to signal the successful completion of the conversion.

Technical Features

- The conversion is performed using the built-in function `REAL_TO_UDINT`.
- The function block is deterministic and has no internal states.

State Overview

Since this is a simple function block, there are no state transitions or machines. The block performs the conversion on each `REQ` event and signals completion with `CNF`.

Application Scenarios

- Type conversion in control applications where REAL values need to be processed as UDINT.
- Integration into larger function block networks that process different data types.

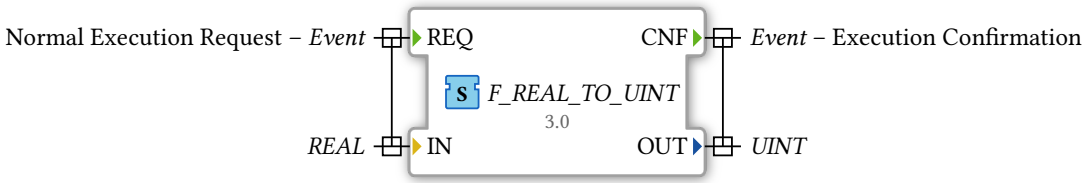
⚖️ Comparison with Similar Function Blocks

- Similar conversion blocks like `F_REAL_TO_INT` or `F_REAL_TO_LREAL` offer conversions to other data types, but not specifically to UDINT.
- Unlike more complex blocks, `F_REAL_TO_UDINT` provides a simple and direct solution for this specific conversion.

🛠️ Related Exercises

- Exercise_072c

Conclusion



The `F_REAL_TO_UDINT` function block is a simple yet essential building block for type conversion in IEC 61499-based control applications. Its deterministic and stateless nature makes it reliable and easily integrated into various applications.

F_REAL_TO_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_TO_UINT` converts a REAL value (floating-point number) to a UINT value (unsigned integer). This conversion is particularly useful when exchanging data between systems that use different data types or when an explicit type conversion is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event input is triggered, the algorithm for converting the REAL value to a UINT value is executed.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event is triggered as soon as the algorithm has been successfully executed.

Data Inputs

- **IN**: The REAL input value to be converted to a UINT value.

Data Outputs

- **OUT**: The UINT output value representing the result of the conversion.

Adapters

This function block has no adapter interfaces.

Functionality

When the `F_REAL_TO_UINT` event is triggered, the function block `F_REAL_TO_UINT` converts the REAL value at input `IN` to a UINT value. The result is output at `OUT`, and the `CNF` event signals the successful completion of the operation.

The underlying algorithm is:
ALGORITHM REQ OUT := REAL_TO_UINT(IN); END_ALGORITHM

Technical Features

- The conversion is performed using the standard function `REAL_TO_UINT`, which rounds the REAL value to the nearest UINT value.
- Note that undefined behavior may occur with values outside the representable range of UINT (0 to 65535).

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

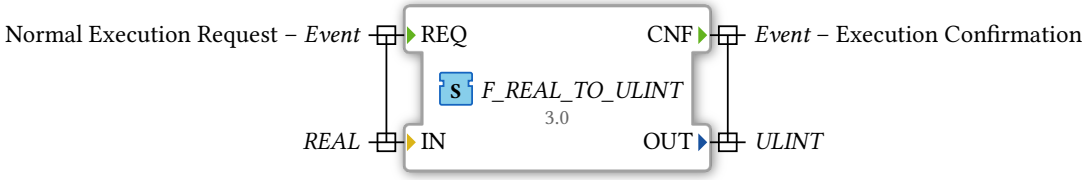
Application Scenarios

- Type conversion in control applications where floating-point values need to be converted to integers.
- Data preparation for systems that can only process unsigned integers.
- Interfaces between different system components with different data types.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks like `F_REAL_TO_INT` or `F_REAL_TO_UDINT`, this function block specializes in converting to unsigned 16-bit integers (UINT).
- Similar blocks might offer additional parameters such as rounding modes or range checks, which is not the case here.

Conclusion



The `F_REAL_TO_UINT` function block provides a simple and efficient way to convert floating-point numbers to unsigned integers. Its clear interface structure and direct functionality make it ideal for applications requiring fast and straightforward type conversion. However, when using it, care must be taken to ensure the valid range of values is observed to avoid unexpected behavior.

F_REAL_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_TO_ULINT` converts a `REAL` value (floating-point number) to a `ULINT` value (64-bit unsigned integer). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: Input for the `REAL` value to be converted.

Data Outputs

- **OUT**: Output for the converted `ULINT` value.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion as soon as the `REQ` event is triggered. The `REAL` value is converted at input `IN` to a `ULINT` value and output as `OUT`. The conversion is confirmed by the `CNF` event.

Technical Details

- The conversion is performed using the function `REAL_TO_ULINT`.
- This function block is part of the `iec61131::conversion` package.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Conversion State**: Performs the conversion and outputs the result.
3. **Acknowledgement State**: Sends the `CNF` event to confirm the conversion.

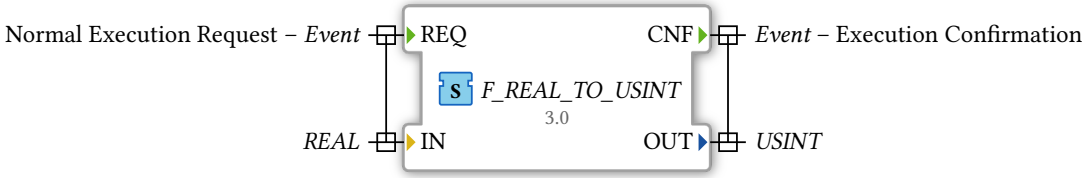
Application Scenarios

- Type conversion in control applications where floating-point numbers need to be converted to unsigned integers.
- Data processing in industrial automation systems.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_REAL_TO_INT` or `F_REAL_TO_LINT` perform conversions to other integer types. `F_REAL_TO_ULINT` is specific to 64-bit unsigned integers.

Conclusion



The `F_REAL_TO_ULINT` function block offers a simple and efficient way to convert `REAL` values into `ULINT` values. Its clear interface structure and simple functionality make it a valuable component in industrial automation.

F_REAL_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_REAL_TO_USINT` converts a REAL value (floating-point number) to a USINT value (unsigned 8-bit integer). This conversion is particularly useful when floating-point numbers need to be processed in a range that only accepts integer values.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. Triggered as soon as the converted value is available at data output `OUT`.

Data Inputs

- **IN**: REAL value to be converted to a USINT value.

Data Outputs

- **OUT**: The converted USINT value.

Adapters

This function block has no adapters.

Functionality

The function block performs a direct conversion of the REAL value at input `IN` to a USINT value. The conversion is performed by calling the internal function `REAL_TO_USINT`. Once the conversion is complete, the event `CNF` is triggered, and the converted value is available at output `OUT`.

Technical Features

- The conversion truncates the decimal portion (no rounding).
- The input value should be in the range of 0 to 255, as USINT can only represent values within this range. Values outside this range will result in undefined behavior or an overflow.

State Overview

1. **Idle**: Waits for the event `REQ`.
2. **Processing**: Performs the conversion.
3. **Completed**: Sends the event `CNF` and provides the converted value.

Application Scenarios

- Conversion of sensor values (e.g., temperature, pressure) into integer values for further processing.
- Preprocessing of data for systems that can only process integers.

⚖️ Comparison with Similar Function Blocks

- **F_REAL_TO_INT**: Converts REAL to INT (signed 16-bit integer count).
- **F_REAL_TO_UINT**: Converts REAL to UINT (unsigned 16-bit integer count).
- **F_REAL_TO_ULINT**: Converts REAL to ULINT (unsigned 64-bit integer count).

Conclusion

The function block `F_REAL_TO_USINT` is a simple and efficient tool for converting floating-point numbers to unsigned 8-bit integers. It is particularly suitable for applications where memory or processing resources are limited.

SINT

F_SINT_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_AS_STRING` converts a `SINT` value (8-bit integer) into a `STRING` (string). This block is particularly useful when numeric values are needed as text for display or further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The `SINT` value to be converted (8-bit integer).

Data Outputs

- **OUT**: The converted `STRING` value.

Adapters

No adapters are available.

Functionality

The function block performs the conversion as soon as the `REQ` event occurs. The `SINT` value at the input `IN` is converted to `STRING` and output at `OUT`. The conversion is performed using the function `SINT_AS_STRING`. After the conversion is complete, the `CNF` event is triggered.

Technical Features

- The conversion is performed directly without additional parameters.
- The function block is simple and efficient, as it only performs a basic data type conversion.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Conversion**: Performs the conversion and outputs the result.
3. **Confirmation**: Triggers the `CNF` event and returns to the idle state.

Application Scenarios

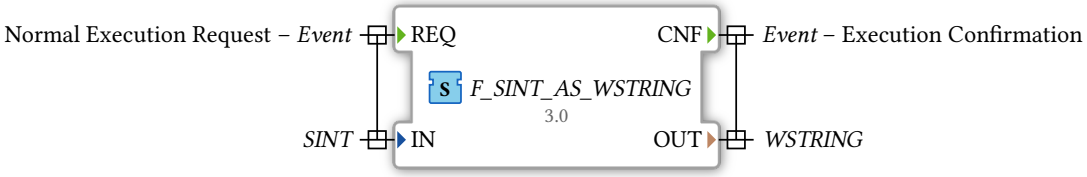
- Displaying numeric values in user interfaces.
- Logging numeric data as text.
- Preparing data for communication via text-based protocols.

⚖️ Comparison with similar building blocks

- **F_INT_AS_STRING**: Converts a `INT` value (16-bit) to a `STRING` value.
- **F_DINT_AS_STRING**: Converts a `DINT` value (32-bit) to a `STRING` value.
- **F_LINT_AS_STRING**: Converts a `LINT` value (64-bit) to a `STRING` value.

Compared to these building blocks, `F_SINT_AS_STRING` specializes in converting 8-bit integers.

Conclusion



The `F_SINT_AS_STRING` function block is a simple and efficient tool for converting `SINT` values to `STRING`s. Its clear interface and direct functionality make it ideal for applications where small integers need to be represented as text.

F_SINT_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_AS_WSTRING` is used to convert a SINT value (8-bit signed integer) into a WSTRING (wide string). This block is particularly useful when numeric values need to be converted into a text format suitable for display or further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs

- **IN**: The SINT value (8-bit signed integer) to be converted to a WSTRING.

Data Outputs

- **OUT**: The resulting WSTRING after the SINT value conversion.

Adapters

- No adapters are available.

Functionality

This function block performs the conversion of the SINT value (`IN`) to a WSTRING (`OUT`) as soon as the event `REQ` is triggered. The conversion is performed using the integrated function `SINT_AS_WSTRING`. After successful conversion, the event `CNF` is triggered.

Technical Features

- The function block has a simple structure and contains only one conversion algorithm.
- The conversion is performed directly without additional parameters or complex logic.

State Overview

1. **Idle State**: Waits for the `REQ` event.

2. **Conversion State**: Performs the conversion and outputs the result via `OUT`.
3. **Confirmation State**: Triggers the `CNF` event and returns to the idle state.

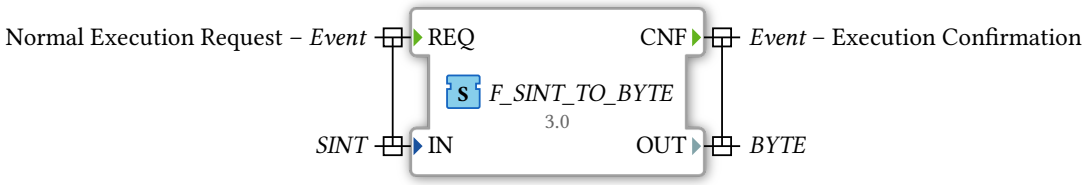
Application Scenarios

- Displaying numeric values in user interfaces.
- Logging numeric data in text format.
- Further processing of numeric values in text-based systems.

⚖️ Comparison with similar function blocks

- **F_INT_AS_WSTRING**: Converts an INT value (16-bit) to a WSTRING.
- **F_DINT_AS_WSTRING**: Converts a DINT value (32-bit) to a WSTRING.
- **F_LINT_AS_WSTRING**: Converts a LINT value (64-bit) to a WSTRING.

Conclusion



The `F_SINT_AS_WSTRING` function block offers a simple and efficient way to convert SINT values to WSTRINGs. Its clear interface and simple operation make it a useful component in various applications, especially where numeric values need to be represented or processed in text format.

F_SINT_TO_BYTE

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_SINT_TO_BYTE` converts a signed 8-bit integer value (SINT) to an unsigned 8-bit integer value (BYTE). This conversion is useful when exchanging data between systems that use different representations for 8-bit values.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs

- **IN** (SINT): The signed 8-bit integer value to be converted.

Data Outputs

- **OUT** (BYTE): The unsigned 8-bit integer value representing the result of the conversion.

Adapters

- No adapters are available.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The value at input `IN`, of type SINT, is converted to a BYTE value and output at `OUT`. The event `CNF` signals the successful completion of the conversion.

Technical Features

- The conversion is performed directly by the function `SINT_TO_BYTE`.
- The block is simple and deterministic, without internal states or complex logic.

State Overview

The function block has no internal states. The conversion occurs immediately after `REQ` is triggered, followed by the output of the result and confirmation by `CNF`.

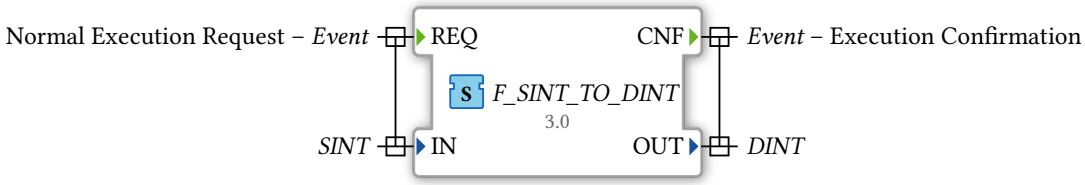
Application Scenarios

- Communication between systems that use signed and unsigned 8-bit values.
- Data processing in control systems where type conversion is required.
- Integration into larger function block networks that process different data types.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_SINT_TO_BYTE` specializes in converting SINT to BYTE and is therefore more efficient for this specific use case.
- Other blocks, such as `F_INT_TO_BYTE` or `F_DINT_TO_BYTE`, are designed for larger integer types.

Conclusion



The `F_SINT_TO_BYTE` function block is a simple yet effective tool for converting between signed and unsigned 8-bit integers. Its simplicity and determinism make it reliable for applications that require such type conversions.

F_SINT_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_DINT` converts a `SINT` value (8-bit signed count) to a `DINT` value (32-bit signed count). This block is particularly useful in scenarios where type conversion is required to prepare data for further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `SINT` to be converted.

Data Outputs

- **OUT**: The converted output value of type `DINT`.

Adapters

This function block has no adapters.

Operation

When the event input `REQ` is triggered, the value at the data input `IN` is read and converted to type `DINT`. The result is output at data output `OUT`, and the event `CNF` signals the successful completion of the conversion.

Technical Features

- The conversion is performed directly by assignment (`OUT := IN`), as `SINT` is automatically converted to `DINT`.

- The function block is simple and efficient because it does not perform any complex calculations.

State Overview

1. **Idle State**: Waits for the event `REQ`.
2. **Conversion State**: Upon receiving `REQ`, the conversion is performed, and `CNF` is triggered.

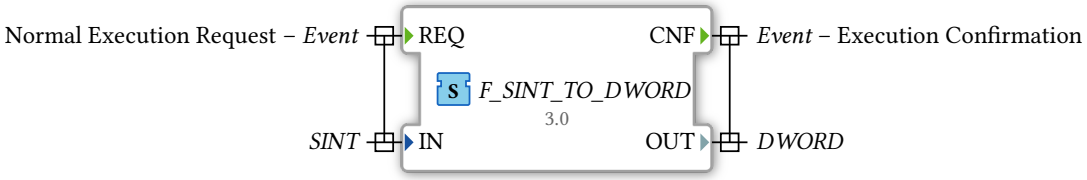
Application Scenarios

- Type conversion in control applications where `SINT` data needs to be converted to `DINT`.
- Preparing data for further processing steps that require `DINT`.

⚖ Comparison with Similar Function Blocks

- Similar function blocks such as `F_INT_TO_DINT` or `F_USINT_TO_UDINT` perform similar conversions, but with different output and input types, respectively.
- `F_SINT_TO_DINT` is specifically for converting `SINT` to `DINT`.

Conclusion



The `F_SINT_TO_DINT` function block is a simple and efficient building block for type conversion from `SINT` to `DINT`. Its clear interface structure and simple functionality make it a reliable component in control applications.

F_SINT_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_DWORD` converts a signed 8-bit integer value (SINT) to an unsigned 32-bit integer value (DWORD). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `SINT` to be converted.

Data Outputs

- **OUT**: The output value of type `DWORD`, containing the result of the conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The algorithm converts the `SINT` value at input `IN` into a `DWORD` value and stores the result at output `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Features

- The conversion is performed directly by the function `SINT_TO_DWORD(IN)`.

- The function block is implemented as a simple function block (SimpleFB), enabling fast and efficient execution.

State Overview

1. **Idle State**: Waiting for the `REQ` event.
2. **Conversion State**: Performs the conversion and sets the output `OUT`.
3. **Acknowledge State**: Triggers the `CNF` event and returns to the idle state.

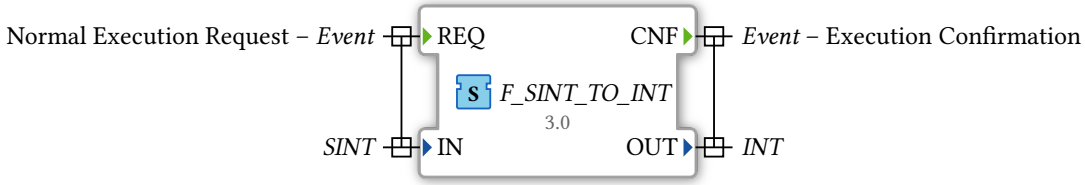
Application Scenarios

- Type conversion in control applications where `SINT` values need to be converted to `DWORD` values.
- Integration into larger control systems that process different data types.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_INT_TO_DINT` or `F_BYTE_TO_WORD` offer conversions between other data types, but not specifically between `SINT` and `DWORD`.
- Unlike generic conversion blocks, `F_SINT_TO_DWORD` is specialized and therefore more efficient for this specific use case.

Conclusion



The `F_SINT_TO_DWORD` function block is a specialized and efficient tool for converting `SINT` values to `DWORD` values. Its simple interface and direct operation make it ideal for applications that require fast and reliable type conversion.

F_SINT_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_INT` converts a `SINT` value (8-bit signed integer) to a `INT` value (16-bit signed integer count). This block is particularly useful in scenarios where type conversion between different integer formats is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (`SINT`): The input value to be converted.

Data Outputs

- **OUT** (`INT`): The converted output value.

Adapters

- No adapters are available.

Functionality

This function block directly assigns the `SINT` input value to the `INT` output. Since `SINT` is a smaller data type than `INT`, the conversion is performed without data loss.

The algorithm is defined as follows:

ALGORITHM REQ OUT := IN; END_ALGORITHM

Technical Features

- The conversion is lossless, as the value range of `SINT` (-128 to 127) fits completely within the value range of `INT` (-32768 to 32767).
- The function block is deterministic and has no internal states.

State Overview

The function block has no internal states. Execution occurs immediately upon receiving the `REQ` event.

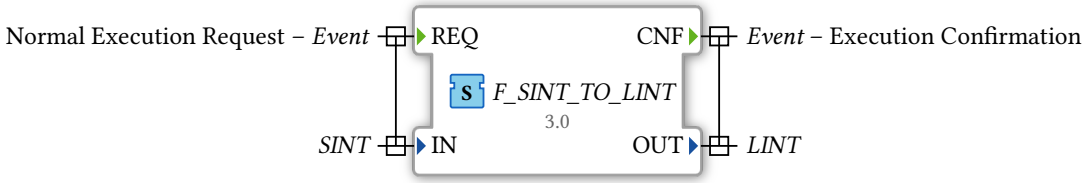
Application Scenarios

- Type conversion in control applications where various integer formats need to be processed.
- Integration into larger function block networks where uniform data type processing is required.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_INT_TO_SINT` perform the reverse conversion, but with potential data loss.
- Unlike generic conversion blocks, `F_SINT_TO_INT` is specialized and optimized for this specific conversion.

Conclusion



The `F_SINT_TO_INT` function block offers a simple and efficient way to convert `SINT` values to `INT` values. Its deterministic and lossless operation makes it a reliable component in control applications.

F_SINT_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_LINT` converts a `SINT` value (8-bit integer) to a `LINT` value (64-bit integer). This conversion is useful when processing data with different bit widths.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- `IN` (`SINT`): The 8-bit integer value to be converted.

Data Outputs

- `OUT` (`LINT`): The converted 64-bit integer value.

Adapters

No adapters are available.

Functionality

The function block performs a direct assignment of the input value `IN` to the output value `OUT`. Since `LINT` has a larger bit width than `SINT`, the conversion is lossless.

Technical Features

- The conversion is lossless because the `LINT` data type can represent all possible values of the `SINT` data type.
- The function block is deterministic and has no internal state.

State Overview

The function block has no internal state. Execution occurs immediately upon receiving the `REQ` event.

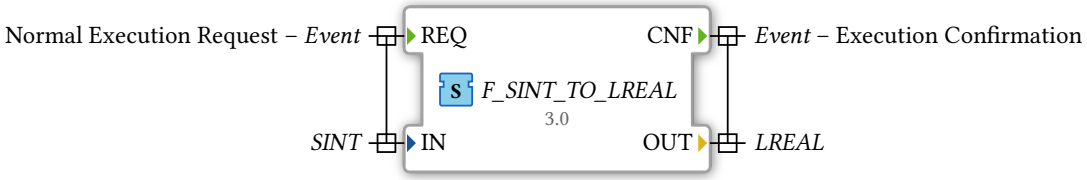
Application Scenarios

- Processing 8-bit sensor data in 64-bit systems
- Compatibility between systems with different bit widths
- Data conversion in automation systems

⚖️ Comparison with similar modules

- Compared to other conversion modules (e.g., `F_INT_TO_LINT`), this module specifically works with 8-bit input data.
- Similar to `F_BYTE_TO_LWORD`, but for signed integers.

Conclusion



The `F_SINT_TO_LINT` function module offers a simple and efficient way to convert 8-bit integers to 64-bit integers. Its simple structure and deterministic operation make it a reliable module in automation solutions.

F_SINT_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_LREAL` converts an integer value of type `SINT` (8-bit integer) to a floating-point value of type `LREAL` (64-bit floating-point). This block is particularly useful in applications where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: Input for the `SINT` value to be converted.

Data Outputs

- **OUT**: Output for the converted `LREAL` value.

Adapters

No adapters are available.

Functionality

The function block performs a direct type conversion. Upon the arrival of a `REQ` event, the value of `IN` is read, converted to the type `LREAL`, and output to `OUT`. Subsequently, the `CNF` event is triggered.

Technical Features

- The conversion is performed without any additional scaling or rounding.
- The function block is implemented simply and efficiently, as it requires only one assignment.

State Overview

The function block has no internal states. It reacts exclusively to the `REQ` event with an immediate conversion and output.

Application Scenarios

- Type conversion in control applications where `SINT` values need to be used in calculations with `LREAL` values.
- Data preparation for visualization or logging where higher accuracy is required.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_INT_TO_REAL` or `F_DINT_TO_LREAL` offer conversions between other data types, but not specifically from `SINT` to `LREAL`.
- This function block specializes in converting 8-bit integers to 64-bit floating-point numbers.

Conclusion

The `F_SINT_TO_LREAL` function block is a simple and efficient tool for type conversion in the 4diac IDE. Its clear interface and direct functionality make it a reliable component in control applications.

F_SINT_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_LWORD` converts a signed 8-bit integer value (`SINT`) to an unsigned 64-bit integer value (`LWORD`). This block is part of the `iec61131::conversion` package and is typically used in automation applications where data type conversions are required.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): Starts the execution of the function block. Linked to data input `IN`.

Event Outputs

- **CNF** (Execution Confirmation): Signals completion of the conversion. Linked to data output `OUT`.

Data Inputs

- **IN** (`SINT`): The signed 8-bit integer value to be converted.

Data Outputs

- **OUT** (`LWORD`): The resulting unsigned 64-bit integer value after conversion.

Adapters

This function block does not use adapters.

Adapters ## Functionality

This function block performs the conversion from `SINT` to `LWORD` as soon as the event `REQ` is triggered. The conversion is carried out using the integrated function `SINT_TO_LWORD`. After successful conversion, the event `CNF` is triggered, and the converted value is available at output `OUT`.

Technical Features

- The conversion is performed without additional parameters or configuration.
- The function block is deterministic and has no internal states.

State Overview

Since this is a simple function block, there are no state transitions or internal states. Execution occurs immediately upon receiving the `REQ` event.

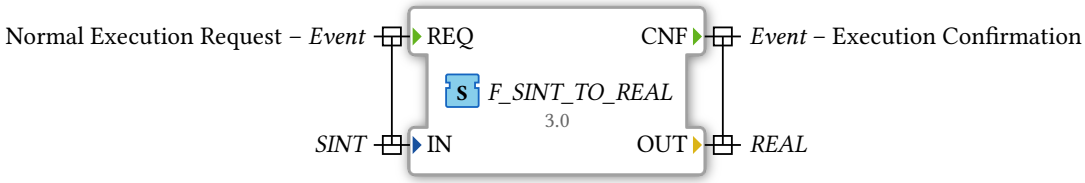
Application Scenarios

- Type conversion in control applications where different data types need to be processed.
- Integration into larger function block networks where data needs to be converted from a lower to a higher precision format.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_INT_TO_LWORD` or `F_DINT_TO_LWORD` perform conversions from other integer types to `LWORD`. `F_SINT_TO_LWORD` is specifically for converting 8-bit integers.
- Unlike generic conversion blocks, this function block offers a type-safe and optimized solution for this specific conversion.

Conclusion



The `F_SINT_TO_LWORD` function block offers an efficient and simple way to convert `SINT` values to `LWORD` values. Its deterministic operation and clear interfaces make it ideal for use in automation projects where such type conversions are regularly required.

F_SINT_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_REAL` converts a signed 8-bit integer value (`SINT`) into a floating-point value (`REAL`). This conversion is particularly useful in control applications where different data types need to be processed.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (`SINT`): The signed 8-bit integer value to be converted.

Data Outputs

- **OUT** (`REAL`): The resulting floating-point value after conversion.

Adapters

No adapters available.

Functionality

The function block performs a direct type conversion. When an event arrives at input `REQ`, the value of `IN` is converted to the data type `REAL` and output to `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

Technical Features

- **Simple Conversion**: The conversion occurs without additional calculations or scaling.
- **No Error Handling**: There is no special handling for overflow or underflow conditions.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

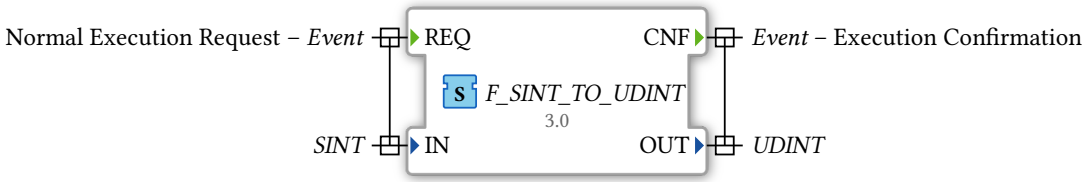
Application Scenarios

- **Measurement Processing**: Conversion of sensor data, which is available as `SINT`, to `REAL` for further calculations.
- **Control Algorithms**: Integration into control loops where floating-point values are required.

⚖️ Comparison with Similar Function Blocks

- **F_INT_TO_REAL**: Converts a 16-bit integer (`INT`) to `REAL`.
- **F_DINT_TO_REAL**: Converts a 32-bit integer (`DINT`) to `REAL`.
- **F_SINT_TO_REAL** is specific to 8-bit integers, providing a more compact solution for this data type.

Conclusion



The `F_SINT_TO_REAL` function block is a simple and efficient tool for converting 8-bit integer values to floating-point numbers. Its clear interface and direct functionality make it ideal for applications that require fast and straightforward type conversion.

F_SINT_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_UDINT` converts a signed 8-bit integer value (SINT) to an unsigned 32-bit integer value (UDINT). This conversion is particularly useful when exchanging data between systems that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `SINT` to be converted.

Data Outputs

- **OUT**: The output value of type `UDINT`, containing the result of the conversion.

Adapters

- No adapters are available.

Functionality

The function block performs the conversion by transforming the `SINT` value at input `IN` into a `UDINT` value and providing the result at output `OUT`. The conversion is triggered by an event at input `REQ` and confirmed by an event at output `CNF`.

Technical Details

- The conversion is performed using the function `SINT_TO_UDINT`.
- This function block is part of the package `iec61131::conversion`.

State Overview

1. **Idle State**: Waits for an event at input `REQ`.
2. **Active State**: Executes the conversion and signals its completion with an event at output `CNF`.

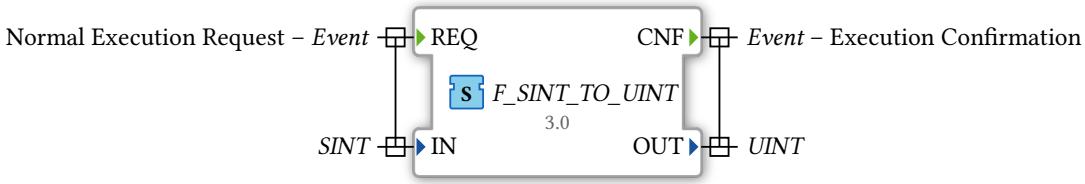
Application Scenarios

- Conversion of sensor values stored as `SINT` to a `UDINT` value for further processing.
- Data preparation for systems that expect unsigned integer values.

⚖️ Comparison with Similar Function Blocks

- **F_INT_TO_UDINT**: Converts a signed 16-bit integer (`INT`) to an unsigned 32-bit integer (`UDINT`).
- **F_DINT_TO_UDINT**: Converts a signed 32-bit integer (`DINT`) to an unsigned 32-bit integer (`UDINT`).

Conclusion



The function block `F_SINT_TO_UDINT` provides a simple and efficient way to convert `SINT` values to `UDINT` values. Its clear interface structure and simple operation make it ideal for applications requiring such conversion.

F_SINT_TO_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_UINT` converts a signed 8-bit integer value (`SINT`) into an unsigned 16-bit integer value (`UINT`). This conversion is particularly necessary when exchanging data between systems that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input expects a value of type `SINT` (signed 8-bit integer).

Data Outputs

- **OUT**: The output returns the converted value as `UINT` (unsigned 16-bit integer).

Adapters

- No adapters are present.

Operation

The function block performs the conversion as soon as the event `REQ` is received. The input value `IN`, of type `SINT`, is converted to a value of `UINT` and output `OUT`. Successful conversion is signaled by the event `CNF`.

Technical Features

- The conversion is performed using the function `SINT_TO_UINT`, which is implemented in the function block's algorithm.
- The function block is simple and requires no additional state management.

State Overview

Since this is a simple function block, there are no complex states. The block reacts directly to the `REQ` event by executing the conversion and outputting the result.

Application Scenarios

- Conversion of sensor values stored as `SINT` for systems that expect `UINT`.
- Data preparation for communication protocols that require unsigned values.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_SINT_TO_UINT` is specialized and optimized for converting `SINT` to `UINT`.
- Other blocks, such as `F_INT_TO_UINT` or `F_DINT_TO_UDINT`, offer similar functionality, but for different data types.

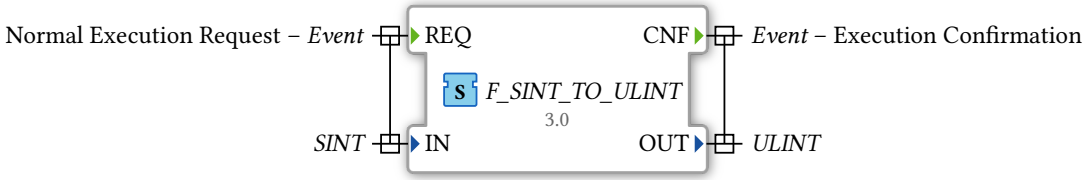
- Exercise_040_2
- Exercise_040_AX
- Exercise_041

Conclusion



The `F_SINT_TO_UINT` function block is an efficient tool for the specific conversion of signed to unsigned integer values. Its simplicity and direct operation make it a reliable solution in control and automation systems.

F_SINT_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_ULINT` converts a signed 8-bit integer value (`SINT`) to an unsigned 64-bit integer value (`ULINT`). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `SINT` to be converted.

Data Outputs

- **OUT**: The converted output value of type `ULINT`.

Adapters

No adapters are present.

Operation

The function block performs the conversion when the event `REQ` is received. The input value `IN`, of type `SINT`, is converted to a value of `ULINT` and output `OUT`. Successful conversion is indicated by the event `CNF`.

Technical Features

- The conversion is performed by the built-in function `SINT_TO_ULINT`.
- The function block is simple and deterministic, as it does not store any internal states.

State Overview

The function block has no internal state. The conversion occurs immediately upon receiving the `REQ` event.

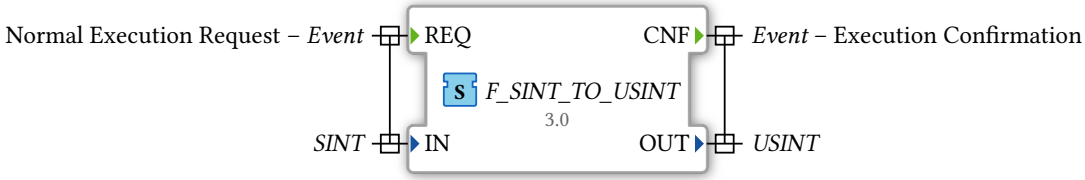
Application Scenarios

- Type conversion in control applications where `SINT` values need to be converted to larger unsigned integer types.
- Data processing in systems that work with different integer formats.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_INT_TO_ULINT` or `F_DINT_TO_ULINT` perform similar conversions, but with different input types.
- `F_SINT_TO_ULINT` is specifically optimized for converting `SINT` to `ULINT`.

Conclusion



The `F_SINT_TO_ULINT` function block provides a simple and efficient way to convert `SINT` values to `ULINT`. It is particularly useful in applications where safe and fast type conversion is required.

F_SINT_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_USINT` converts a signed 8-bit integer value (SINT) to an unsigned 8-bit integer value (USINT). This conversion is useful when exchanging data between systems that use different representations for numeric values.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN** (SINT): The signed 8-bit integer value to be converted.

Data Outputs

- **OUT** (USINT): The resulting unsigned 8-bit integer value after the conversion.

Adapters

This function block does not use any adapters.

Operation

When the event `REQ` is triggered, the algorithm that converts the value of `IN` from SINT to USINT is executed and outputs the result to `OUT`. The event `CNF` is then triggered to signal the successful completion of the conversion.

Technical Features

- The function block performs a direct type conversion, converting the signed value to an unsigned value.
- There is no additional logic for handling overflow conditions or invalid inputs.

State Overview

The function block has a simple state machine:

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion and triggers `CNF`.
3. No other states, as it is a simple, stateless block.

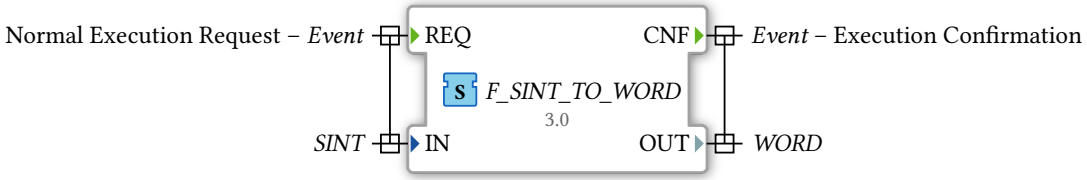
Application Scenarios

- Conversion of sensor values that are delivered as signed values but are to be processed as unsigned values.
- Data preparation for communication protocols that require unsigned values.

⚖️ Comparison with Similar Function Blocks

- **F_INT_TO_UINT**: Converts signed 16-bit integer values to unsigned 16-bit integer values.
- **F_DINT_TO_UDINT**: Converts signed 32-bit integer values to unsigned 32-bit integer values.
- **F_SINT_TO_USINT** is specific to 8-bit values and is therefore more efficient for this data size.

Conclusion



The `F_SINT_TO_USINT` function block is a simple yet effective tool for converting signed to unsigned 8-bit integer values. Its simplicity and efficiency make it ideal for applications where such conversions need to be performed regularly.

F_SINT_TO_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SINT_TO_WORD` converts a SINT value (8-bit signed integer count) to a WORD value (16-bit unsigned integer count). This block is particularly useful in scenarios where type conversion between different integer formats is required.

Interface Structure

Event Inputs

- `REQ` (Normal Execution Request): Starts the execution of the conversion. It is associated with the input value `IN`.

Event Outputs

- `CNF` (Execution Confirmation): Signals the completion of the conversion. Returns the converted value via `OUT`.

Data Inputs

- `IN` (SINT): The input value to be converted from SINT to WORD.

Data Outputs

- `OUT` (WORD): The converted WORD value.

Adapters

This function block does not use adapters.

Operation

When the `REQ` event is triggered, the algorithm that converts the `IN` value from SINT to WORD is executed. The result is output via `OUT`, and the `CNF` event signals successful conversion.

Technical Features

- The conversion is performed directly by the function `SINT_TO_WORD(IN)`.
- No additional error handling is required for overflow or underflow, as SINT (8-bit) is converted to WORD (16-bit), and therefore no values are lost.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering `REQ`.

Application Scenarios

- Type conversion in control applications where different integer formats need to be processed.
- Data preprocessing for communication protocols or sensor data.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_INT_TO_WORD` or `F_DINT_TO_WORD` offer conversions from other integer types to WORD.
- `F_SINT_TO_WORD` is specifically optimized for converting 8-bit signed integers to 16-bit unsigned integers.

Conclusion

The `F_SINT_TO_WORD` function block is a simple and efficient building block for type conversion from SINT to WORD. Its clear interface and direct functionality make it ideal for applications requiring fast and reliable conversion.

STRING

F_STRING_AS_BOOL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_BOOL` converts a `STRING` value to a `BOOL` value. This block is particularly useful when strings need to be converted into Boolean values, for example, when processing user input or interpreting text data.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This input triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. This output signals the successful completion of the conversion.

Data Inputs

- **IN** (`STRING`): The input string to be converted into a Boolean value.

Data Outputs

- **OUT** (`BOOL`): The resulting Boolean value after conversion.

Adapters

No adapters are present.

Functionality

The function block uses the function `STRING_AS_BOOL` to convert the input string `IN` into a Boolean value `OUT`. The conversion is triggered by the event `REQ`, and the event `CNF` is output upon completion of the operation.

Technical Features

- The conversion is performed according to the IEC 61131-3 specification for converting strings to Boolean values.
- The function block is part of the `iec61131::conversion` package.

State Overview

1. **Initialization**: The function block waits for the `REQ` event.
2. **Execution**: Upon receiving `REQ`, the string `IN` is converted to a Boolean value, and the result is output to `OUT`.
3. **Acknowledgement**: After successful conversion, the `CNF` event is output.

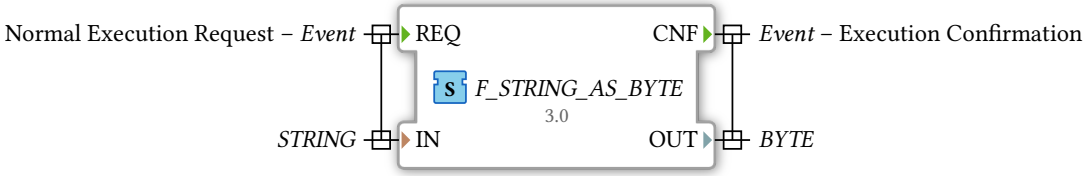
Application Scenarios

- Processing user input in string form (e.g., “true” or “false”).
- Interpreting text data from external sources (e.g., configuration files or network communication).
- Integration into systems that store or transmit Boolean values as strings.

⚖️ Comparison with Similar Function Blocks

- **F_STRING_TO_BOOL**: A similar function block that may offer additional options for string interpretation.
- **F_STRING_AS_***: Other conversion function blocks for various data types (e.g., `F_STRING_AS_INT`).

Conclusion



The `F_STRING_AS_BOOL` function block provides a simple and efficient way to convert string values to Boolean values. Its clear interface structure and reliability make it ideal for applications requiring such conversion.

F_STRING_AS_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_BYTE` converts a `STRING` value to a `BYTE` value. This functionality is particularly useful when strings need to be converted into their corresponding byte values, for example, for processing in protocols or when communicating with hardware.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This event input triggers the conversion. It is linked to the data input `IN`.

Event Outputs

- **CNF**: Execution confirmation. This event is triggered after successful conversion and is associated with the data output `OUT`.

Data Inputs

- **IN**: Input of type `STRING`, which is to be converted to a `BYTE` value.

Data Outputs

- **OUT**: Output of type `BYTE`, containing the result of the conversion.

Adapters

No adapters are present.

Functionality

The function block converts the `STRING` value `IN` to the `BYTE` value `OUT` as soon as the event `REQ` is received. The conversion is performed using the function `STRING_AS_BYTE`. After successful conversion, the event `CNF` is triggered.

Technical Features

- The function block is a simple function block (`SimpleFB`) and uses an ST algorithm for the conversion.
- The conversion occurs directly and without any additional delay.

State Overview

1. **Wait State**: The function block waits for the event `REQ`.
2. **Execution State**: Upon receiving `REQ`, the conversion is performed.
3. **Acknowledgement State**: After successful conversion, `CNF` is triggered, and the function block returns to the wait state.

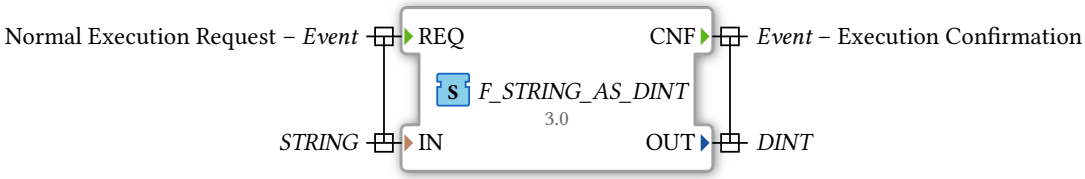
Application Scenarios

- Conversion of strings to byte values for communication with serial interfaces.
- Processing of ASCII characters in byte form for protocols or hardware controls.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks like `F_STRING_TO_INT` or `F_STRING_TO_REAL`, `F_STRING_AS_BYTE` is specifically designed to convert to a `BYTE` value.
- A similar block could be `F_CHAR_AS_BYTE`, which converts individual characters, while `F_STRING_AS_BYTE` works with strings.

Conclusion



The `F_STRING_AS_BYTE` function block offers a simple and efficient way to convert strings to byte values. Its clear interface structure and direct functionality make it ideal for applications requiring such conversion.

F_STRING_AS_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_DINT` converts a `STRING` value to a `DINT` value. This function is particularly useful when strings need to be converted into numeric values, for example, when processing user input or interpreting text data.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (`STRING`): The string value to be converted.

Data Outputs

- **OUT** (`DINT`): The result of the conversion as a 32-bit integer.

Adapters

No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The `STRING` value at input `IN` is converted into a `DINT` value and output at `OUT`. The conversion is performed using the function `STRING_AS_DINT`. Upon completion of the conversion, the event `CNF` is triggered.

Technical Details

- The conversion can fail if the value of `STRING` does not contain a valid numeric representation. In such cases, the output `OUT` may be undefined.
- The function block is part of the package `iec61131::conversion`.

State Overview

The function block has no internal state. The conversion occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Processing user input in the form of strings.
- Interpreting text data from files or network sources.
- Conversion of configurable parameters stored as strings.

⚖️ Comparison with similar function blocks

- Unlike `F_STRING_TO_*` function blocks, which perform explicit type conversions, `F_STRING_AS_DINT` directly interprets the `STRING` value as `DINT`.
- Similar function blocks like `F_STRING_TO_DINT` might offer additional formatting parameters, but they are not included in the standard library.

Conclusion

The `F_STRING_AS_DINT` function block provides a simple and efficient way to convert strings to 32-bit integers. Its use is particularly useful in scenarios where direct interpretation of the string as a numeric value is required.

F_STRING_AS_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_DWORD` converts a `STRING` value to a `DWORD` value. This functionality is particularly useful when strings need to be converted into numeric values, for example, for further processing in control algorithms.

Interface Structure

Event Inputs

- `REQ`: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- `IN` (`STRING`): The input value to be converted to a `DWORD` value.

Data Outputs

- `OUT` (`DWORD`): The result of the conversion.

Adapters

- No adapters available.

Functionality

The function block converts the input value `STRING`, `IN`, into a value `DWORD` as soon as the event `REQ` is triggered. The conversion is performed using the function `STRING_AS_DWORD`. After successful conversion, the event `CNF` is triggered, and the result value is available at the output `OUT`.

Technical Features

- The function block is a simple function block (`SimpleFB`) and performs the conversion in a single algorithm.
- The conversion is performed directly without additional state management.

State Overview

The function block has no internal states. Execution occurs immediately upon receiving the `REQ` event.

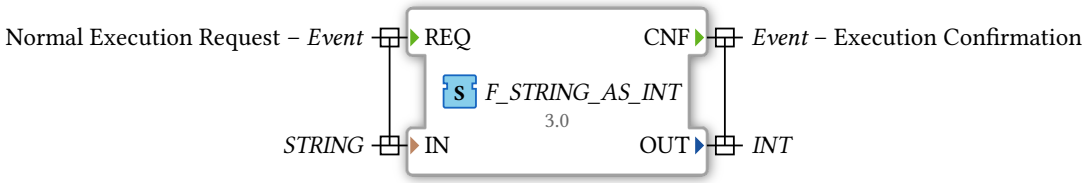
Application Scenarios

- Conversion of user input or communication data into numeric values.
- Use in control algorithms that require numeric values instead of strings.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion function blocks such as `F_STRING_TO_INT` or `F_STRING_TO_REAL`, this function block is specifically designed for conversion to the `DWORD` data type.
- Direct use of the `STRING_AS_DWORD` function enables efficient and specialized conversion.

Conclusion



The `F_STRING_AS_DWORD` function block offers a simple and efficient way to convert strings into `DWORD` values. Its clear interface structure and direct functionality make it ideal for applications requiring fast and reliable conversion.

F_STRING_AS_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_INT` converts a `STRING` value to a `INT` value. This functionality is particularly useful when strings representing numeric values need to be converted into integer values.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event input is triggered, the `STRING` value at the data input `IN` is converted to a `INT` value.

Event Outputs

- **CNF**: Signals successful completion of the conversion. This event, along with the converted `INT` value, is output at data output `OUT`.

Data Inputs

- **IN**: The `STRING` value to be converted to a `INT` value.

Data Outputs

- **OUT**: The converted `INT` value.

Adapters

No adapters are present.

Operation

The function block performs the conversion as soon as the REQ event is received. The built-in function STRING_AS_INT is used to convert the STRING value at input IN into a INT value. The result is output at OUT and confirmed by the CNF event.

Technical Features

- The conversion is performed directly without additional parameters.
- The function block is implemented simply and efficiently, without complex state logic.

State Overview

The function block has no internal states. The conversion occurs immediately upon receiving the REQ event.

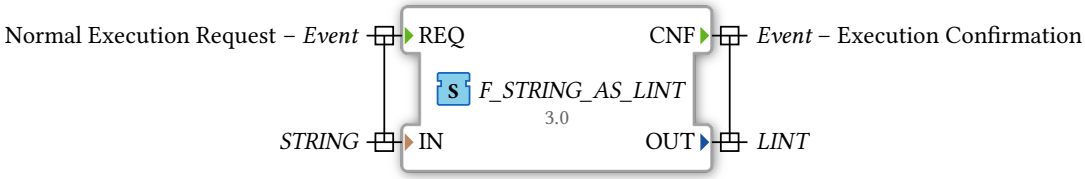
Application Scenarios

- Processing user input that is in string form but requires numeric values.
- Conversion of data from text files or communication protocols into numeric values.
- Integration into systems that use string-based data sources but require numerical processing.

⚖️ Comparison with similar building blocks

- Compared to generic conversion building blocks, F_STRING_AS_INT specializes in converting STRING to INT.
- Other building blocks might offer additional features such as error handling or support for various numeric formats, which is not the case here.

Conclusion



The F_STRING_AS_INT function block is a simple and effective tool for converting strings to integer values. Its strength lies in its simplicity and direct applicability, without added complexity. This building block is ideal for applications that require fast and straightforward conversion.

F_STRING_AS_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_STRING_AS_LINT converts a STRING value to a LINT value. This functionality is particularly useful when strings need to be converted into numeric values for use in further calculations or control logic.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the STRING value to a LINT value. This event input is linked to the data input IN.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output OUT.

Data Inputs

- **IN**: The input for the STRING value, which is to be converted to a LINT value.

Data Outputs

- **OUT**: The output for the converted LINT value.

Adapters

No adapters are available.

Functionality

The function block converts the `STRING` value to a `LINT` value as soon as the `REQ` event is triggered. The conversion is performed using the function `STRING_AS_LINT()`. After successful conversion, the `CNF` event is triggered, and the converted value is available at the `OUT` output.

Technical Features

- The function block is a simple function block (SimpleFB) and performs the conversion in a single algorithm.
- The conversion is performed directly without additional state management.

State Overview

Because it is a simple function block, there are no complex state transitions. The block performs the conversion on each `REQ` event and signals completion with the `CNF` event.

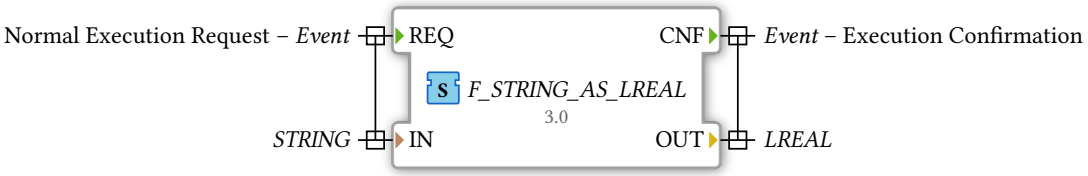
Application Scenarios

- Conversion of user input to numeric values.
- Processing of strings containing numeric data in control systems.
- Integration into larger control logics that require numeric calculations.

⚖️ Comparison with Similar Blocks

- **F_STRING_AS_INT**: Converts a `STRING` value to a `INT` value, but is limited to smaller numeric ranges.
- **F_STRING_AS_REAL**: Converts a `STRING` value to a `REAL` value; suitable for floating-point numbers.
- **F_LINT_AS_STRING**: Performs the reverse conversion, i.e., from `LINT` to `STRING`.

Conclusion



The function block `F_STRING_AS_LINT` offers a simple and efficient way to convert strings into large numeric values (`LINT`). Its direct functionality and clear interface structure make it ideal for use in control systems that require such conversion.

F_STRING_AS_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_LREAL` converts a STRING value to an LREAL value (64-bit floating-point number). This block is particularly useful when strings need to be converted into numeric values, for example, when processing user input or reading data from external sources.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- `IN` (STRING): The string value to be converted.

Data Outputs

- `OUT` (LREAL): The result of the conversion as a 64-bit floating-point number.

Adapters

This function block does not use any adapters.

Operation

When the `REQ` event is triggered, the value at the input `IN` is read as a string and converted into an LREAL value. The result is output as `OUT`, and the `CNF` event signals successful execution.

The conversion algorithm is implemented as ST code:
ALGORITHM REQ OUT := STRING_AS_LREAL(IN); END_ALGORITHM

Technical Features

- The conversion follows the standard rules for converting STRING to LREAL in IEC 61131-3.
- For invalid input values (e.g., non-numeric strings), the behavior may vary depending on the runtime environment.

State Overview

The function block has a simple state machine:

1. Waits for the `REQ` event
2. Performs the conversion
3. Sends the `CNF` event
4. Returns to wait state

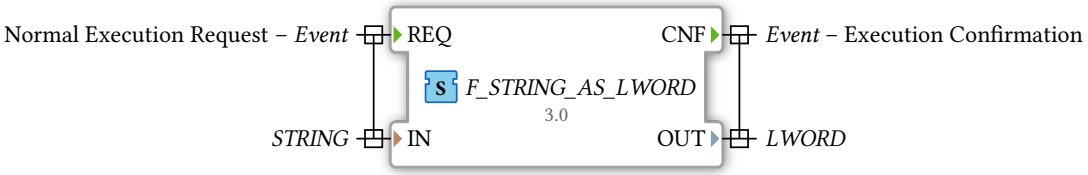
Application Scenarios

- Processing user input in numeric controllers
- Converting text data from files or network sources
- Interfaces to systems that transmit numeric data as strings

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, this function block specializes in STRING-to-LREAL conversion.
- Other similar blocks might offer additional parameters for number formatting.

Conclusion



The `F_STRING_AS_LREAL` function block offers a simple and efficient way to convert strings to 64-bit floating-point numbers. Its clear interface and simple functionality make it particularly suitable for standard conversion tasks in automation projects.

F_STRING_AS_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_LWORD` converts a `STRING` value to a `LWORD` value. It is part of the `iec61131::conversion` package and enables easy conversion between these two data types.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (`STRING`): The input string to be converted to a `LWORD` value.

Data Outputs

- **OUT** (`LWORD`): The converted `LWORD` value.

Adapters

No adapters are present.

Functionality

The function block performs the conversion when the `REQ` event is received. The input string `IN` is converted into a value `LWORD` using the function `STRING_AS_LWORD` and output as `OUT`. After the conversion is complete, the event `CNF` is triggered.

Technical Features

- The conversion is performed directly without additional parameters.
- The block is implemented as a simple function block (`SimpleFB`) containing only one algorithm.

State Overview

The function block has no internal state. The conversion is re-executed with each `REQ` event.

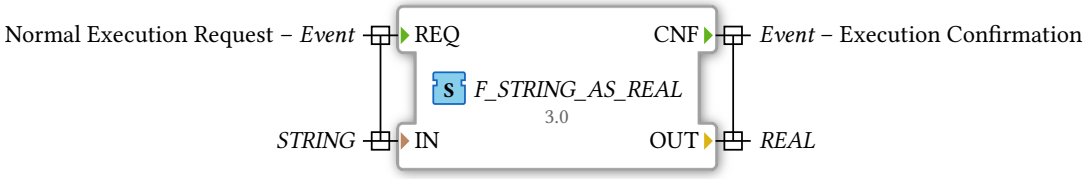
Application Scenarios

- Conversion of string data into `LWORD` values for further processing in control systems.
- Integration into systems that require `LWORD` values but receive string input.

⚖️ Comparison with Similar Building Blocks

- Compared to other conversion building blocks, `F_STRING_AS_LWORD` specializes in converting `STRING` to `LWORD`.
- Other building blocks, such as `F_STRING_TO_*`, may offer similar functionality for other data types.

Conclusion



The `F_STRING_AS_LWORD` function block provides a simple and efficient way to convert string data into `LWORD` values. It is particularly useful in scenarios where such conversions are needed regularly.

F_STRING_AS_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_REAL` converts a `STRING` value to a `REAL` value. It is particularly useful when data from a string needs to be converted into a numerical representation, for example, when processing user input or interpreting text files.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event is triggered, the algorithm for converting the `STRING` value to a `REAL` value is executed.

Event Outputs

- **CNF**: Signals successful completion of the conversion. This event is output along with the converted `REAL` value.

Data Inputs

- **IN** (`STRING`): The input value to be converted to a `REAL` value.

Data Outputs

- **OUT** (`REAL`): The result of the conversion.

Adapters

This function block does not use adapters.

Functionality

When the `REQ` event is triggered, the function block converts the `STRING` value (`IN`) into a `REAL` value. The conversion is performed using the built-in function `STRING_AS_REAL`. After successful conversion, the `CNF` event is triggered, and the result is output via `OUT`.

Technical Features

- The conversion can fail if the input `STRING` is not a valid `REAL` number. In this case, a runtime error may occur.
- The function block is simple and does not include any additional error handling.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Completed**: Sends the `CNF` event with the result.

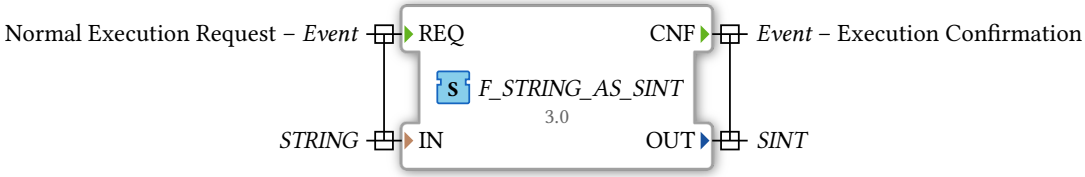
Application Scenarios

- Processing user input in string form.
- Interpreting data from text files or network communication.
- Converting configuration values stored as strings.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_STRING_AS_REAL` specializes in converting `STRING` to `REAL`.
- Other blocks might offer additional features such as error handling or formatting, but they are more complex.

Conclusion



The `F_STRING_AS_REAL` function block is a simple and efficient tool for converting strings to floating-point numbers. Its strength lies in its simplicity and direct applicability, although it lacks integrated error handling. For robust applications, additional security measures should be implemented.

F_STRING_AS_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_SINT` converts a `STRING` value into a `SINT` value (8-bit signed integer). This block is particularly useful when strings need to be converted into numeric values, for example, when processing user input or interpreting text data.

Interface Structure

Event Inputs

- `REQ`: Triggers the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- `IN` (`STRING`): The string to be converted into a `SINT` number.

Data Outputs

- `OUT` (`SINT`): The result of the conversion as an 8-bit signed integer.

Adapters

This function block does not use any adapters.

Functionality

When the `REQ` event is triggered, the function `STRING_AS_SINT` is applied to the value of the `IN` input. The result is stored in the `OUT` output, and the `CNF` event signals the successful completion of the operation.

Technical Features

- The conversion is performed according to the IEC 61131-3 specification for converting strings to numeric values.
- The function block is part of the `iec61131::conversion` package.

State Overview

1. **Idle**: Waiting for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Completed**: Signals completion with `CNF` and returns to the idle state.

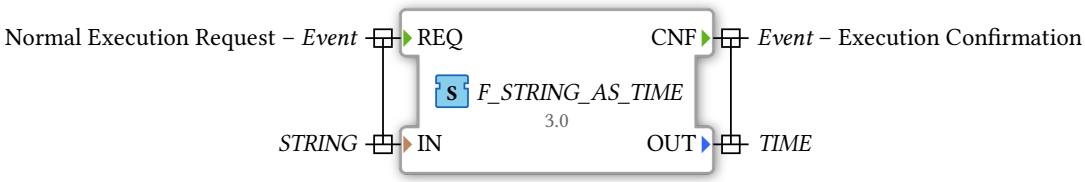
Application Scenarios

- Interpreting user input into numerical control commands.
- Processing text data from external sources (e.g., files or network communication).
- Converting configuration values into control parameters.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_STRING_AS_SINT` specializes in conversion to 8-bit integers.
- Similar blocks like `F_STRING_AS_INT` or `F_STRING_AS_DINT` offer conversions to larger integer types.

Conclusion



F_STRING_AS_SINT` is an efficient and specialized function block for converting strings to 8-bit integers. Its simple interface and clear functionality make it ideal for control applications that work with text-based input.

F_STRING_AS_TIME

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_STRING_AS_TIME` converts a time value in STRING format to TIME format. This is particularly useful when time values are in text format and need to be converted into a machine-readable format for further processing.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion of the time value. When this event input is triggered, the function block begins converting the string passed to `IN`.

Event Outputs

- `CNF`: Signals the successful completion of the conversion. This event, along with the converted time value, is output at data output `OUT`.

Data Inputs

- `IN` (STRING): The input for the time value in STRING format, which is to be converted to TIME format.

Data Outputs

- `OUT` (TIME): The output at which the converted time value is displayed in TIME format.

Adapters

No adapters are available.

Functionality

The function block uses the built-in function `STRING_AS_TIME` to convert the string received via input `IN` into a TIME value. The conversion is triggered by the event `REQ` and confirmed by the event `CNF` upon successful conversion.

Technical Features

- The conversion is performed directly without intermediate steps.
- The function block is part of the package `iec61131::conversion`.

State Overview

1. **Idle**: The function block waits for the event `REQ`.
2. **Processing**: Upon receiving `REQ`, the conversion is performed.
3. **Completion**: After successful conversion, the event `CNF` is triggered, and the state changes back to Idle.

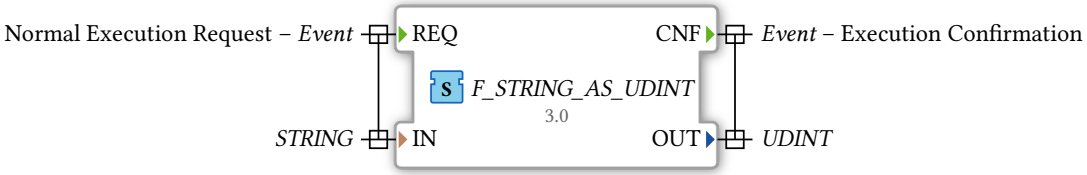
Application Scenarios

- Processing of time values that are available as text in user input or external data sources.
- Integration into systems that require time values in TIME format for control or regulation tasks.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks, `F_STRING_AS_TIME` specializes in converting time values and therefore offers a direct and efficient solution for this specific use case.

Conclusion



The `F_STRING_AS_TIME` function block is an efficient tool for converting time values in STRING format to TIME format. Its simple and direct operation makes it ideal for applications that require fast and reliable conversion.

F_STRING_AS_UDINT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_STRING_AS_UDINT` converts a `STRING` value to a `UDINT` value (unsigned double integer). It is part of the `iec61131::conversion` package and enables the easy conversion of strings to numeric values.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input expects a `STRING` value, which is to be converted to a `UDINT` value.

Data Outputs

- **OUT**: The output provides the converted `UDINT` value.

Adapters

The function block does not use any adapters.

Functionality

The function block performs the conversion using the built-in function `STRING_AS_UDINT`. When the event `REQ` is triggered, the `STRING` value at input `IN` is converted to a `UDINT` value and output `OUT`. The event `CNF` is then triggered to signal the successful completion of the conversion.

Technical Features

- The conversion is performed directly without additional parameters.
- The function block is optimized for simple conversions and does not support complex formatting or error handling.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Conversion**: Performs the conversion and outputs the result.
3. **Acknowledgement**: Triggers the event `CNF` and returns to the idle state.

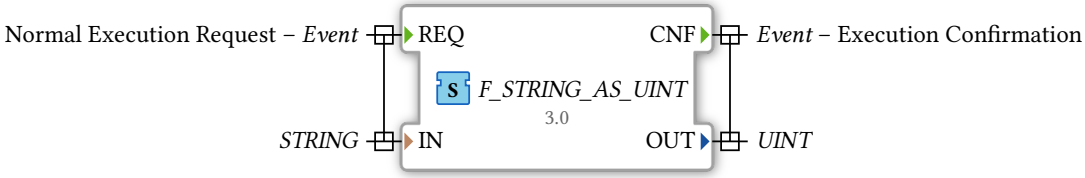
Application Scenarios

- Conversion of user input or communication data into numeric values.
- Integration into systems that require numeric processing but receive strings as input.

⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion function blocks, `F_STRING_AS_UDINT` offers a specialized and efficient solution for converting `STRING` to `UDINT`.
- Other function blocks might offer additional features such as error handling or formatting, but are more complex to use.

Conclusion



The `F_STRING_AS_UDINT` function block is a simple and efficient solution for converting strings to numeric values. It is particularly suitable for applications where a fast and direct conversion is required.

F_STRING_AS_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_STRING_AS_UINT converts a STRING value to a UINT value (unsigned integer). This function is particularly useful when numeric values are stored as strings and are needed in numerical form for further calculations or control tasks.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the STRING value to UINT. The input is linked to data input IN.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to data output OUT.

Data Inputs

- **IN** (STRING): The input for the string value to be converted.

Data Outputs

- **OUT** (UINT): The output for the converted numeric value.

Adapters

No adapters are available.

Functionality

When the event REQ is triggered, the algorithm is executed, which converts the STRING value from IN into a UINT value using the function STRING_AS_UINT. The result is output to OUT, and the event CNF signals the successful completion of the conversion.

Technical Features

- The function block has a simple structure and contains only one algorithm for the conversion.
- The conversion is performed directly without additional parameters or complex state logic.

State Overview

The function block has no internal states. Execution occurs immediately upon the triggering of REQ.

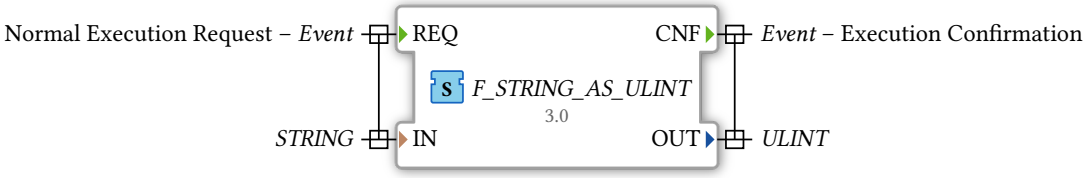
Application Scenarios

- Processing user input in string form.
- Converting data from text files or communication protocols for further numerical processing.
- Integration into control systems that require numerical values from string sources.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, F_STRING_AS_UINT specializes in converting STRING to UINT, thus providing a simple and direct solution for this specific use case.
- Other blocks might support additional features such as error handling or different numeric formats, which is not the case here.

Conclusion



The F_STRING_AS_UINT function block is an efficient and straightforward solution for converting strings to unsigned integer values. Its simplicity makes it particularly suitable for applications where a fast and direct conversion is required.

F_STRING_AS_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_ULINT` converts a `STRING` value to a `ULINT` value (unsigned 64-bit integer). This block is particularly useful when strings need to be converted to numeric values, for example, when processing user input or parsing data from external sources.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `STRING`, containing the string to be converted.

Data Outputs

- **OUT**: The output of type `ULINT`, containing the result of the conversion.

Adapters

No adapters are present.

Operation

The function block performs the conversion as soon as the event `REQ` is triggered. The built-in function `STRING_AS_ULINT` is used to convert the input `STRING` into a value `IN`. The result is output at `OUT`, and the event `CNF` signals the successful completion of the operation.

Technical Features

- The function block is part of the package `iec61131::conversion`.
- The conversion is performed directly without any additional parameters or settings.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

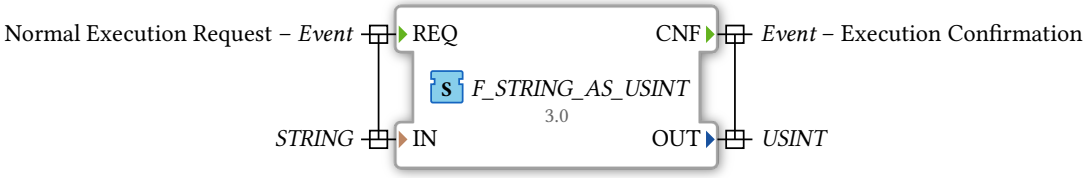
Application Scenarios

- **Data Processing**: Converting strings to numeric values for calculations or storage.
- **User Input**: Processing input that is in string form but should be interpreted as numbers.
- **Logging**: Converting logical or textual data to numeric formats for further analysis.

⚖️ Comparison with Similar Building Blocks

- **F_STRING_AS_INT**: Converts a `STRING` to a `INT` (signed 32-bit integer). In contrast, `F_STRING_AS_ULINT` works with a larger range of values and without a sign.
- **F_STRING_AS_LINT**: Similar, but for `LINT` (signed 64-bit integer). `F_STRING_AS_ULINT` is optimized for unsigned values.

Conclusion



The function block `F_STRING_AS_ULINT` provides a simple and efficient way to convert strings to unsigned 64-bit integer values. Its clear interface and direct functionality make it ideal for applications requiring fast and reliable conversion.

F_STRING_AS_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_USINT` converts a `STRING` value to a `USINT` value (Unsigned Short Integer). This block is part of the `iec61131::conversion` package and enables the easy conversion of strings to numeric values.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: This input expects a `STRING` value, which is to be converted to a `USINT` value.

Data Outputs

- **OUT**: Outputs the converted `USINT` value.

Adapters

This function block does not have any adapters.

Functionality

When the `REQ` event is triggered, the algorithm is executed, converting the `STRING` value at the `IN` input into a `USINT` value. The result is output at `OUT`, and the `CNF` event signals the completion of the conversion.

Technical Features

- The block uses the `STRING_AS_USINT` function for the conversion.
- The conversion occurs synchronously with the triggering of the `REQ` event.

State Overview

The function block has no internal states. The conversion occurs immediately after the `REQ` event is triggered.

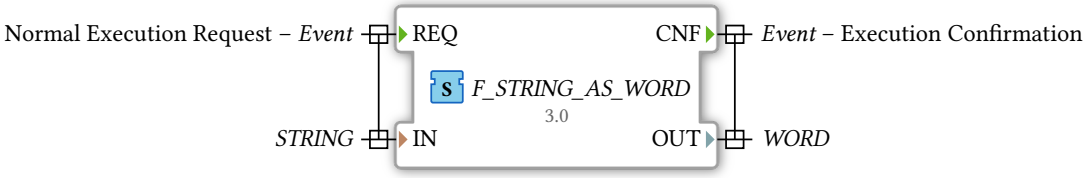
Application Scenarios

- Conversion of user input or communication data into numeric values.
- Use in control logic where strings need to be converted into numeric values.

⚖️ Comparison with Similar Blocks

- Compared to other conversion blocks such as `F_STRING_AS_INT` or `F_STRING_AS_UINT`, this block is specifically optimized for conversion to `USINT` values.

Conclusion



The `F_STRING_AS_USINT` function block provides a simple and efficient way to convert `STRING` values to `USINT` values. It is particularly useful in applications where strings need to be converted into numeric values.

F_STRING_AS_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_STRING_AS_WORD` is used to convert a `STRING` value to a `WORD` value. This functionality is particularly useful in scenarios where strings need to be converted into numeric values for use in further calculations or control logic.

Interface Structure

Event Inputs

- **REQ**: Normal execution request input. Used to start the conversion. Connected to the data input `IN`.

Event Outputs

- **CNF**: Execution Confirmation. Triggered after successful conversion. Associated with the data output `OUT`.

Data Inputs

- **IN**: Input of type `STRING`. Contains the string value to be converted.

Data Outputs

- **OUT**: Output of type `WORD`. Contains the result of the input string conversion.

Adapters

No adapters available.

Functionality

The function block performs the conversion when the event `REQ` is received. The input string `IN` is converted into a `WORD` value using the function `STRING_AS_WORD`, and the result is output to `OUT`. The confirmation event `CNF` is then triggered.

Technical Features

- The function block has a simple structure and contains only one conversion algorithm.
- The conversion is performed directly without additional state management.

State Overview

The function block has no internal states. Execution occurs immediately upon receiving the `REQ` event.

Application Scenarios

- Conversion of user input or communication data into numerical values.
- Use in control logic that requires numerical processing.
- Integration into larger automation systems that process string and word data.

⚖️ Comparison with similar function blocks

- Compared to other conversion function blocks such as `F_STRING_TO_INT` or `F_STRING_TO_REAL`, this function block specifically converts to the `WORD` data type.
- Simpler and more direct than function blocks with additional features such as error handling or formatting.

Conclusion

The `F_STRING_AS_WORD` function block offers a simple and efficient way to convert strings to `WORD` values. Its clear interface and direct functionality make it ideal for use in various automation and control scenarios.

F_STRING_TO_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_STRING_TO_WSTRING converts a STRING data type to a WSTRING data type. This is particularly useful in environments where conversion between narrow (8-bit) and wide (16-bit) strings is required, for example, when internationalizing applications or communicating with systems that use different character encodings.

Interface Structure

Event Inputs

- **REQ**: Initiates the conversion. When this event is triggered, the input value IN is read and processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event is output along with the converted output value OUT.

Data Inputs

- **IN** (STRING): The input string to be converted to WSTRING.

Data Outputs

- **OUT** (WSTRING): The resulting wide string after the conversion.

Adapters

This function block does not use any adapters.

Operation

The function block performs the conversion as soon as the REQ event arrives. The value STRING from IN is converted to WSTRING using the function STRING_TO_WSTRING, and the result is output to OUT. Simultaneously, the CNF event is triggered to signal the successful completion of the operation.

Technical Features

- The conversion is performed without additional parameters or configuration.
- The block is implemented as a simple function block (SimpleFB), which guarantees efficient execution.

State Overview

The function block has no internal states. The conversion is performed anew with each REQ event.

Application Scenarios

- **Internationalization**: Conversion of local strings to Unicode-enabled WSTRING values.
- **System Communication**: Exchange of data between systems using different character sets.
- **Data Processing**: Processing of text data in different encodings.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, F_STRING_TO_WSTRING specializes in converting between STRING and WSTRING.
- Other blocks, such as F_WSTRING_TO_STRING, offer the reverse functionality.

Conclusion

The F_STRING_TO_WSTRING function block is a simple and efficient tool for converting strings between different encodings. Its clear interface and direct functionality make it particularly suitable for applications that require fast and reliable conversion.

STRING Conversions

TIME

F_TIME_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_AS_STRING` is used to convert a `TIME` value into a `STRING` value. It is particularly useful when time values are needed for display or logging in textual form.

Interface Structure

Event Inputs

- **REQ**: Triggers the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the successful execution of the function block. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (`TIME`): The time value to be converted to a string.

Data Outputs

- **OUT** (`STRING`): The resulting string representing the converted time value.

Adapters

No adapters are defined for this function block.

Functionality

The function block performs the conversion as soon as the event `REQ` is received. The input value `TIME` is converted to a value `STRING` and output `OUT`. The conversion is performed using the function `TIME_AS_STRING`. After the conversion is complete, the event `CNF` is triggered.

Technical Features

- This function block is a simple function block (SimpleFB) and does not perform any complex state transitions.
- The conversion is performed directly without additional parameters.

State Overview

Since this is a simple function block, there are no state transitions. This block performs the conversion on every `REQ` event and signals completion with `CNF`.

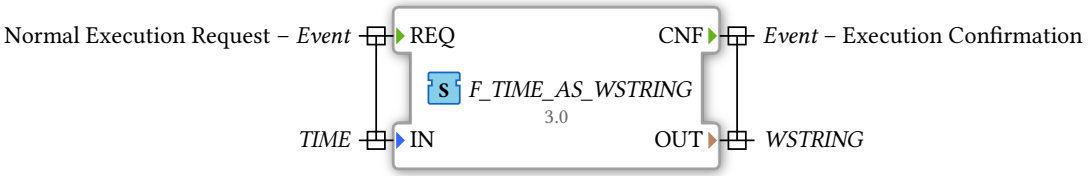
Application Scenarios

- Displaying timestamps in user interfaces.
- Logging timestamps in textual log files.
- Integration into systems that process timestamps as strings.

⚖️ Comparison with Similar Blocks

- Compared to other conversion blocks like `F_INT_AS_STRING` or `F_REAL_AS_STRING`, this block is specifically optimized for converting `TIME` values.
- Similar functionality could also be achieved with a custom algorithm, but this block offers a standardized and reusable solution.

Conclusion



The `F_TIME_AS_STRING` function block offers a simple and efficient way to convert time values into strings. Its clear interface and direct functionality make it a useful building block for various applications where time values are required in textual form.

F_TIME_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_AS_WSTRING` converts a TIME value to a WSTRING value. This is particularly useful when time values are needed for display or logging in a human-readable format.

Interface Structure

Event Inputs

- **REQ**: Normal execution call. When this input is triggered, the function block performs the conversion.

Event Outputs

- **CNF**: Confirmation of execution. Triggered after successful conversion.

Data Inputs

- **IN**: Input for the TIME value to be converted.

Data Outputs

- **OUT**: Output for the converted WSTRING value.

Adapters

This function block has no adapters.

Functionality

The function block converts the incoming TIME value (`IN`) into a WSTRING value (`OUT`) as soon as the event `REQ` is triggered. The conversion is performed using the function `TIME_AS_WSTRING`. After successful conversion, the event `CNF` is triggered.

Technical Features

- The function block has a simple structure and contains only one algorithm for the conversion.
- The conversion is performed directly and without additional parameters.

State Overview

The function block has no complex states. It responds to the `REQ` event by executing the algorithm and confirms the execution with the `CNF` event.

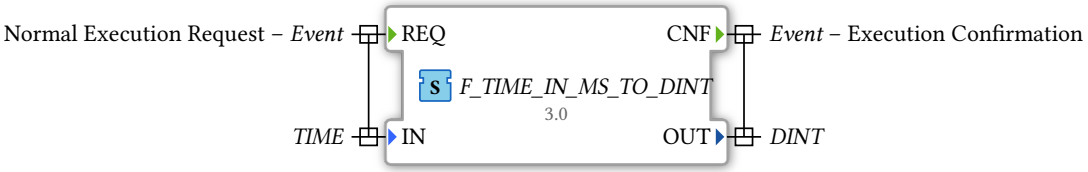
Application Scenarios

- Displaying time values in user interfaces.
- Logging timestamps in a readable format.
- Integration into systems that require time values as strings.

⚖️ Comparison with Similar Blocks

- Compared to other conversion blocks, `F_TIME_AS_WSTRING` specializes in converting TIME to WSTRING.
- Other blocks might offer additional formatting options, but this block is simple and efficient.

Conclusion



The `F_TIME_AS_WSTRING` function block is a simple and effective tool for converting TIME values to WSTRING. It is particularly suitable for applications where time values need to be displayed or processed in a readable form.

F_TIME_IN_MS_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_MS_TO_DINT` converts a TIME value in milliseconds to a DINT value. This is particularly useful when time values need to be converted into numerical values for use in calculations or for control purposes.

Interface Structure

Event Inputs

- **REQ**: Normal execution request event. Used to start the conversion. Linked to the data input `IN`.

Event Outputs

- **CNF**: Execution confirmation event. Signals the completion of the conversion. Linked to data output `OUT`.

Data Inputs

- **IN** (TIME): The input value in milliseconds to be converted.

Data Outputs

- **OUT** (DINT): The converted numeric value.

Adapters

No adapters are available.

Functionality

The function block performs the conversion by transforming the TIME value in milliseconds into a DINT value. The conversion occurs when the event `REQ` is triggered. After the conversion is complete, the event `CNF` is triggered, and the converted value is available at output `OUT`.

Technical Features

- The function block uses a simple algorithm for the direct conversion of TIME to DINT.
- The conversion is deterministic and occurs without delay.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Conversion State**: Performs the conversion and triggers the `CNF` event.

Application Scenarios

- Conversion of time values for use in numerical calculations.
- Integration into control systems that require numerical time values.
- Use in logging and monitoring systems that store timestamps in numerical form.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

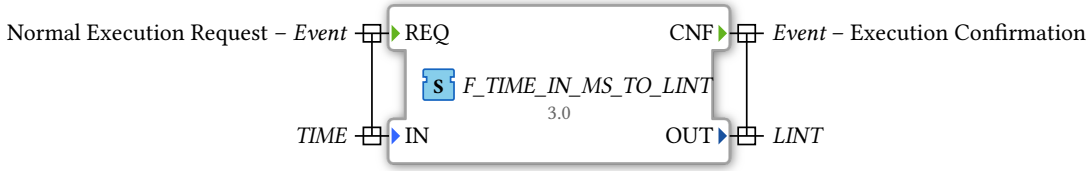
Use the block **`F_MULTIME`** (from the `arithmetic` category) for this purpose:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- **F_TIME_TO_UDINT**: Converts TIME to UDINT, while `F_TIME_IN_MS_TO_DINT` converts to DINT.
- **F_TIME_IN_US_TO_DINT**: Converts TIME in microseconds to DINT, while this function block uses milliseconds.

Conclusion



The function block `F_TIME_IN_MS_TO_DINT` is a simple and efficient tool for converting time values in milliseconds to numeric DINT values. It is particularly suitable for applications requiring fast and deterministic conversion.

F_TIME_IN_MS_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_MS_TO_LINT` converts a time value (`TIME`) in milliseconds into a 64-bit integer value (`LINT`). This functionality is particularly useful when time values are needed in numerical form for calculations or comparisons.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the time value. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: This input expects a time value (`TIME`) to be converted into milliseconds.

Data Outputs

- **OUT**: Outputs the converted time value as a 64-bit integer (`LINT`).

Adapters

This function block does not have any adapters.

Functionality

When the event input `REQ` is triggered, the algorithm is executed, which converts the time value `IN` into milliseconds and outputs the result as `LINT` via the output `OUT`. The event `CNF` signals the successful completion of the conversion.

Technical Features

- The function block uses the function `TIME_IN_MS_TO_LINT` to convert the time value.
- The conversion is performed with high accuracy because the `LINT` data type is 64 bits wide.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Time measurements where the results need to be processed further in numerical form.
- Control applications that require precise time intervals in milliseconds.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is sought to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion function block does not usually exist, as this is elegantly solved using multiplication.

Use the function block **`F_MULTIME`** (from the `arithmetic` category) for this:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Compared to other conversion function blocks that may only convert to smaller integer types, this function block offers higher accuracy by using the `LINT` data type.
- Similar function blocks might convert time to other units (e.g., seconds or microseconds), while this function block is specifically designed for milliseconds.

Conclusion

The `F_TIME_IN_MS_TO_LINT` function block is an efficient tool for the precise conversion of time values in milliseconds to a 64-bit integer value. Its simple and direct operation makes it particularly suitable for applications that require accurate time measurements and calculations.

F_TIME_IN_MS_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_MS_TO_LREAL` is used to convert a TIME value in milliseconds to an LREAL value. This is particularly useful when time values are needed for further calculations or analyses with higher precision.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. Triggered after successful conversion.

Data Inputs

- **IN**: Input variable of type `TIME`. The time value to be converted in milliseconds.

Data Outputs

- **OUT**: Output variable of type `LREAL`. The converted value is a floating-point number.

Adapters

- No adapters are available.

Functionality

The function block performs the conversion by transforming the incoming TIME value in milliseconds into an LREAL value. The conversion is performed using the algorithm `REQ`, which uses the function `TIME_IN_MS_TO_LREAL`.

Technical Features

- The function block has a simple structure and contains only one algorithm for the conversion.
- The conversion is performed directly and without any additional delay.

State Overview

The function block has no internal state. The conversion is re-executed with each `REQ` event.

Application Scenarios

- Conversion of time values for precise calculations.
- Integration into control systems that require floating-point values for time measurements.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

Use the block **`F_MULTIME`** (from the category `arithmetic`) for this purpose:

- Multiply your numeric value by the desired time base.

- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Compared to other conversion function blocks, this one is specifically designed for converting TIME to LREAL and therefore offers a simple and direct solution for this use case.

Conclusion

The `F_TIME_IN_MS_TO_LREAL` function block is a simple and efficient tool for converting time values in milliseconds to floating-point numbers. Its clear interface and direct functionality make it a reliable component in control systems.

F_TIME_IN_MS_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_MS_TO_UDINT` converts a `TIME` value in milliseconds to a `UDINT` value. This is particularly useful when time values are to be used in numerical calculations or for control purposes.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. Triggered after successful conversion.

Data Inputs

- **IN**: Input of type `TIME`. The time value in milliseconds to be converted.

Data Outputs

- **OUT**: Output of type `UDINT`. The converted numeric value.

Adapters

No adapters are available.

Functionality

The function block performs the conversion by transforming the `TIME` value in milliseconds into a `UDINT` value. The conversion occurs synchronously with the triggering of the `REQ` event. After the conversion is complete, the `CNF` event is triggered.

Technical Features

- The function block is simple and has no internal states.
- The conversion is immediate and instantaneous.

State Overview

Since it is a simple function block, there are no state transitions or complex state logic.

Application Scenarios

- Conversion of time values for numerical calculations.
- Integration into control logic that requires numerical time values.

Reverse Conversion (Numeric to TIME)

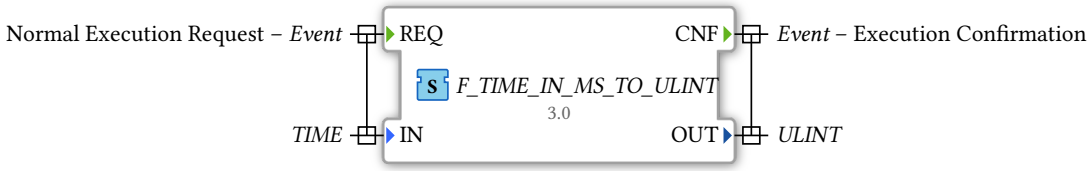
Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block does not usually exist, as this is elegantly solved using multiplication.

Use the function block **`F_MULTIME`** (from the category `arithmetic`):

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Compared to other conversion function blocks, this one is specifically designed for converting `TIME` to `UDINT`.
- Other function blocks might offer additional features such as scaling or filtering, which is not the case here.



Conclusion

The `F_TIME_IN_MS_TO_UDINT` function block is a simple and efficient tool for converting time values in milliseconds into numerical values. It is particularly suitable for applications where a fast and direct conversion is required.

F_TIME_IN_MS_TO_ULINT

• – ◦ • – ◦ • – ◦ •

The function block `F_TIME_IN_MS_TO_ULINT` converts a time value in milliseconds (`TIME`) into an unsigned 64-bit integer value (`ULINT`). This block is particularly useful when time values are needed in numerical form for further calculations or comparisons.

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.
- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.
- **IN**: This input expects a time value of type `TIME`, specified in milliseconds.
- **OUT**: Returns the converted value as an unsigned 64-bit integer (`ULINT`).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block has no adapters.

The function block performs the conversion by transforming the `TIME` value in milliseconds into a `ULINT` value. The conversion occurs synchronously when the `REQ` event occurs. After the conversion is complete, the `CNF` event is triggered, and the converted value is available at output `OUT`.

- The function block uses the `TIME_IN_MS_TO_ULINT` function for the conversion.
- The implementation is in Structured Text (ST).
- The function block is part of the `iec61131::conversion` package.

The function block has no internal states. The conversion occurs immediately upon the occurrence of the `REQ` event.

- Conversion of time values for mathematical operations.
- Integration into systems that store or process timestamps as numeric values.

Conclusion

F_TIME_IN_NS_TO_DINT

• – ◦ • – ◦ • – ◦ •

The function block `F_TIME_IN_NS_TO_DINT` converts a TIME value in nanoseconds to a DINT value. This conversion is useful when time values are needed in numerical calculations or for further processing.

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.
- **CNF**: Signals the successful completion of the conversion. This output is linked to the data output `OUT`.
- **IN** (TIME): The input for the time value in nanoseconds to be converted.
- **OUT** (DINT): The output for the converted numeric value.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters are included.

Functionality

Upon receiving an incoming `REQ` event, the function block converts the TIME value `IN` to a DINT value `OUT`. The conversion is performed using the function `TIME_IN_NS_TO_DINT`. After successful conversion, the `CNF` event is triggered.

- The function block has a simple structure and contains only one algorithm for the conversion.

1. **Waiting for REQ**: The function block waits for an incoming `REQ` event.
2. **Conversion**: Upon `REQ`, the TIME value `IN` is converted to DINT.
3. **Output**: After successful conversion, the `CNF` event is triggered.

- Conversion of time values for numerical calculations.
- Integration into control systems where time values are required as numerical values.

Application Scenarios

State Overview

Technical Features

Reverse Conversion (Numeric to TIME)

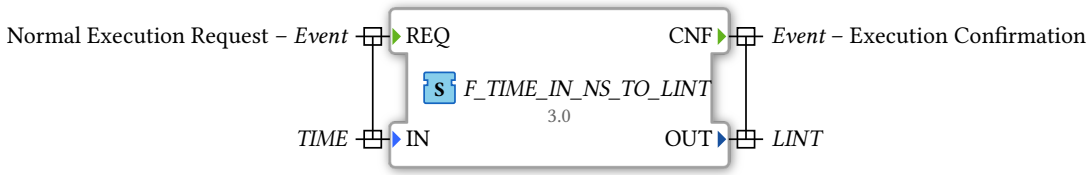
The function block `F_TIME_IN_NS_TO_DINT` provides a simple and efficient way to convert time values in nanoseconds into numerical DINT values. It is particularly useful in applications where time values need to be integrated into calculations or control logic.

⚖️ Vergleich mit ähnlichen Bausteinen



Conclusion

F_TIME_IN_NS_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_NS_TO_LINT` converts a time value in nanoseconds (`TIME`) into a 64-bit integer value (`LINT`). This conversion is useful when time values are needed in numerical form for calculations or comparisons.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: This input expects a time value of type `TIME`, specified in nanoseconds.

Data Outputs

- **OUT**: This output returns the converted value as a 64-bit integer (`LINT`).

Adapters

- No adapters are present.

Operation

This function block performs the conversion when the event `REQ` is triggered. The algorithm converts the time value `IN` in nanoseconds to a value `LINT` and stores the result in `OUT`. The event `CNF` is then triggered to signal the completion of the operation.

Technical Details

- The function block is implemented as a *SimpleFB*, meaning it has no internal state and is re-executed with each call to `REQ`.
- The conversion is performed directly by the function `TIME_IN_NS_TO_LINT`, which converts the value `TIME` to a value `LINT`.

State Overview

Since this is a simple function block, there are no state transitions or state machines.

Application Scenarios

- Time measurement and processing in control systems where numerical operations on time values are required.
- Integration into systems that need to store or transmit timestamps in a numerical format.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

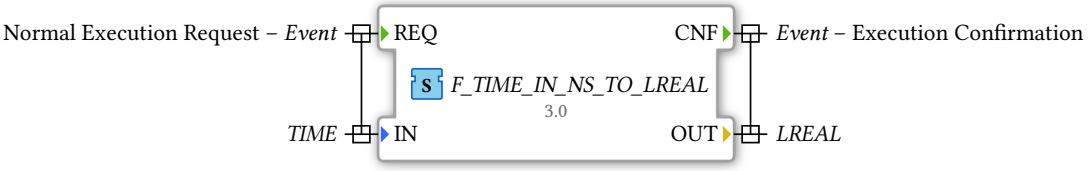
Use the function block **`F_MULTIME`** (from the category `arithmetic`):

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Unlike generic conversion blocks, this function block specializes in converting `TIME` to `LINT`.
- Other blocks might offer additional features such as scaling or formatting, which is not the case here.

Conclusion



The `F_TIME_IN_NS_TO_LINT` function block provides a simple and efficient way to convert time values in nanoseconds to 64-bit integers. It is particularly useful in applications that require precise time measurements and calculations.

F_TIME_IN_NS_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_NS_TO_LREAL` is used to convert a time value in nanoseconds (`TIME`) into a floating-point value (`LREAL`). This conversion is particularly useful in control applications where time values need to be used in mathematical calculations.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input expects a time value in nanoseconds (`TIME`).

Data Outputs

- **OUT**: Returns the converted floating-point value (`LREAL`).

Adapters

- No adapters are available.

Functionality

This function block converts the nanosecond time value `IN` (`TIME`) into a floating-point value (`LREAL`). The conversion occurs every time the event `REQ` is triggered. After successful conversion, the event `CNF` is triggered, and the result value is available at output `OUT`.

Technical Features

- The function block is implemented as a simple FB (`SimpleFB`).
- The conversion is performed using the built-in function `TIME_IN_NS_TO_LREAL`.

State Overview

The function block has no internal states. Execution occurs immediately upon the occurrence of the `REQ` event.

Application Scenarios

- Time measurements in control systems that require further processing in mathematical expressions.
- Integration into control loops where time values are required as floating-point numbers.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

Use the block **`F_MULTIME`** (from the `arithmetic` category) for this purpose:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with Similar Building Blocks

- Unlike generic conversion blocks, `F_TIME_IN_NS_TO_LREAL` is specifically optimized for converting time values in nanoseconds to floating-point numbers.
- Other blocks, such as `F_TIME_TO_LREAL`, might offer similar functionality, but without explicitly specifying the nanosecond unit.

Conclusion

The `F_TIME_IN_NS_TO_LREAL` function block provides an efficient and specialized solution for converting time values to floating-point numbers. Its ease of use and direct integration make it ideal for applications requiring precise time processing.

F_TIME_IN_NS_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_NS_TO_UDINT` converts a time value in nanoseconds (`TIME`) into an unsigned 32-bit integer value (`UDINT`). This conversion is particularly useful when time values are needed in a numeric format for further calculations or control purposes.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event input is triggered, the function block performs the conversion of the time value present at `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event is triggered as soon as the converted value is output to `OUT`.

Data Inputs

- **IN** (`TIME`): The input for the time value in nanoseconds to be converted.

Data Outputs

- **OUT** (`UDINT`): The output to which the converted unsigned 32-bit integer value is output.

Adapters

This function block does not use any adapters.

Functionality

The function block performs the conversion by converting the nanosecond time value (`TIME`) received at `IN` into an unsigned 32-bit integer value (`UDINT`) using the function `TIME_IN_NS_TO_UDINT`. The conversion occurs synchronously with the triggering of the `REQ` event. After successful conversion, the `CNF` event is triggered, and the converted value is output to `OUT`.

Technical Features

- The conversion is instantaneous and without delay.
- The function block is suitable for use in real-time applications.
- No additional parameters or configurations are required.

State Overview

1. **Idle State**: The function block waits for the `REQ` event.
2. **Conversion State**: When `REQ` is triggered, the time value is converted.
3. **Acknowledgement State**: After successful conversion, `CNF` is triggered, and the function block returns to the idle state.

Application Scenarios

- Conversion of timestamps for use in numerical calculations.
- Integration into control logic that needs to process time values in a numerical format.
- Use in diagnostic systems to display durations in a readable format.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

Use the block **`F_MULTIME`** (from the category `arithmetic`) for this purpose:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with Similar Blocks

- Unlike generic conversion blocks, this function block is specifically optimized for converting time values to nanoseconds.
- Similar blocks might offer additional parameters or configuration options, but this function block is designed for simplicity and efficiency.

Conclusion

The `F_TIME_IN_NS_TO_UDINT` function block provides a simple and efficient way to convert nanosecond time values to unsigned 32-bit integer values. Its clear interface and direct operation make it ideal for applications requiring fast and reliable conversion.

F_TIME_IN_NS_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_NS_TO_ULINT` converts a `TIME` value in nanoseconds to a `ULINT` value. This conversion is particularly useful when time values are needed in numerical calculations or for further processing steps.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input expects a `TIME` value in nanoseconds, which is to be converted.

Data Outputs

- **OUT**: Outputs the converted `ULINT` value.

Adapters

No adapters are available.

Functionality

The function block converts the nanosecond value `TIME` (`IN`) to a nanosecond value `ULINT` (`OUT`) as soon as the event `REQ` is triggered. The conversion is performed using the function `TIME_IN_NS_TO_ULINT`. After the conversion is complete, the event `CNF` is triggered.

Technical Features

- The function block has a simple structure and contains only one algorithm for the conversion.
- The conversion is direct and without any additional delay.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Conversion of time values for use in numerical calculations.
- Integration into control systems where time values need to be further processed as numerical values.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is sought to convert a numerical value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block does not usually exist, as this is elegantly solved using multiplication.

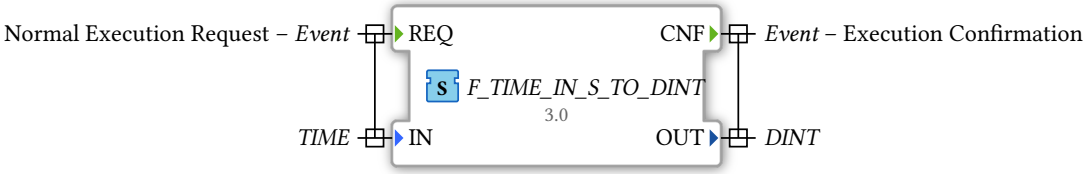
Use the function block **`F_MULTIME`** (from the category `arithmetic`) for this:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Compared to other conversion function blocks, this one is specifically designed to convert `TIME` to `ULINT`.
- Similar function blocks might use different data types or units, but this one is optimized for nanoseconds.

Conclusion



The `F_TIME_IN_NS_TO_ULINT` function block offers a simple and efficient way to convert time values in nanoseconds into `ULINT` values. Its clear interface and direct functionality make it a useful component in automation technology.

F_TIME_IN_S_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_S_TO_DINT` converts a time value in seconds (`TIME`) into a signed integer value (`DINT`). This conversion is useful when time values need to be used in numerical calculations or for control purposes.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input expects a time value of type `TIME` in seconds.

Data Outputs

- **OUT**: The output returns the converted value as a signed integer (`DINT`).

Adapters

No adapters are used.

Functionality

The function block performs the conversion when the event `REQ` is triggered. The algorithm converts the time value `IN` in seconds to a `DINT` value and stores the result in `OUT`. After the conversion is complete, the event `CNF` is triggered.

Technical Features

- The function block uses the function `TIME_IN_S_TO_DINT` for the conversion.
- The block is simple and efficient because it is directly based on the ST algorithm.

State Overview

The function block has no internal states. The conversion occurs immediately after `REQ` is triggered.

Application Scenarios

- Conversion of time values for numerical calculations.
- Integration into control logic that requires numerical time values.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

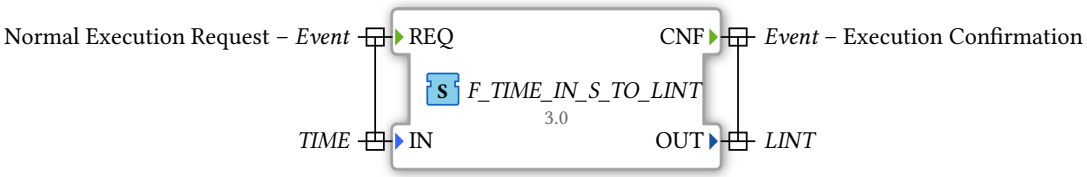
Use the block **`F_MULTIME`** (from the `arithmetic` category) for this purpose:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with Similar Building Blocks

- Compared to other conversion blocks, this one is specifically designed to convert `TIME` to `DINT`.
- Simpler and more direct than general conversion blocks, which may require additional parameters.

Conclusion



The `F_TIME_IN_S_TO_DINT` function block offers an efficient and simple solution for converting time values in seconds to signed integers. Its clear interface and direct functionality make it ideal for control applications.

F_TIME_IN_S_TO_LINT

• – ○ • – ○ • – ○ •

Introduction

The function block `F_TIME_IN_S_TO_LINT` converts a time value in seconds (`TIME`) into a 64-bit integer value (`LINT`). This conversion is particularly useful when time values are needed in numerical form for calculations or comparisons.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the time value. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input for the time value in seconds (`TIME`) to be converted.

Data Outputs

- **OUT**: The output for the converted 64-bit integer value (`LINT`).

Adapters

No adapters are present.

Functionality

The function block performs the conversion by transforming the time value in seconds (`TIME`) into a 64-bit integer value (`LINT`). The conversion occurs when the `REQ` event is triggered, and the result is output via the `OUT` data output, followed by a `CNF` event.

Technical Features

- The function block uses the standard `61499-1`.
- The conversion is performed using the function `TIME_IN_S_TO_LINT`, which is implemented in the function block's algorithm.
- The function block is part of the `iec61131::conversion` package.

State Overview

The function block does not have complex states. It reacts to the `REQ` event, performs the conversion, and signals completion with the `CNF` event.

Application Scenarios

- Conversion of time values for numerical calculations.
- Integration into control systems that require time values in a numerical format.
- Use in systems that require high precision in time measurement.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block is not usually available, as this is elegantly solved using multiplication.

Use the function block **`F_MULTIME`** (from the category `arithmetic`) for this:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Compared to other conversion function blocks that may support different data types, this function block is specifically designed for converting `TIME` to `LINT`.

Other function blocks might offer conversion to other integer types (e.g., `INT` or `DINT`), but this block offers higher precision by using `LINT`.

Conclusion

The `F_TIME_IN_S_TO_LINT` function block is an efficient tool for converting time values in seconds to 64-bit integers. Its simple and straightforward operation makes it a reliable component in control systems that require precise time measurements and calculations.

F_TIME_IN_S_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_S_TO_LREAL` converts a time value in seconds (`TIME`) into a floating-point value (`LREAL`). This conversion is useful when time values are needed in mathematical calculations or for further processing steps.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input expects a time value of type `TIME` in seconds, which is to be converted.

Data Outputs

- **OUT**: Outputs the converted value as a floating-point number (`LREAL`).

Adapters

- No adapters are available.

Functionality

The function block performs the conversion from `TIME` to `LREAL` as soon as the event `REQ` is triggered. The conversion is performed using the function `TIME_IN_S_TO_LREAL`, which converts the time value in seconds into a corresponding floating-point value. Upon completion of the conversion, the event `CNF` is triggered.

Technical Features

- The function block is a simple algorithm (`SimpleFB`) and does not perform any complex state transitions.
- The conversion is instantaneous and without any additional delay.

State Overview

Since it is a simple function block, there are no state transitions. The conversion occurs immediately upon triggering `REQ`.

Application Scenarios

- Conversion of time values for mathematical operations.
- Integration into control logic where time values are required as floating-point numbers.
- Use in control engineering or data processing where precise time measurements are necessary.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

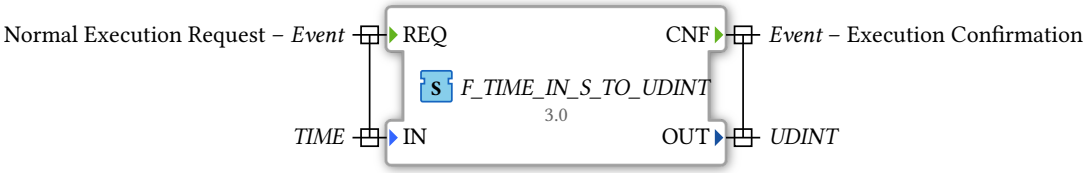
Use the block **`F_MULTIME`** (from the `arithmetic` category) for this purpose:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with Similar Function Blocks

- Unlike other conversion blocks that may require additional parameters or states, `F_TIME_IN_S_TO_LREAL` is designed for a specific and direct conversion.
- Similar function blocks could be, for example, `TIME_TO_STRING` or `TIME_TO_INT`, which, however, provide different output types.

Conclusion



The `F_TIME_IN_S_TO_LREAL` function block offers an efficient and direct way to convert time values in seconds to floating-point numbers. Its simple structure and fast execution make it ideal for applications that require precise and straightforward conversion.

F_TIME_IN_S_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_S_TO_UDINT` converts a TIME value in seconds to a UDINT value. This conversion is useful when time values are needed in numerical operations or for further processing steps.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. Triggered after successful conversion.

Data Inputs

- **IN**: TIME value in seconds to be converted.

Data Outputs

- **OUT**: Converted UDINT value.

Adapters

No adapters available.

Functionality

This function block converts the incoming TIME value (IN) in seconds into a UDINT value (OUT). The conversion is performed by calling the function `TIME_IN_S_TO_UDINT(IN)` in the algorithm. When the REQ event is triggered, the conversion is carried out and the CNF event is triggered.

Technical Features

- The function block is simple and efficient because it directly uses the built-in function `TIME_IN_S_TO_UDINT`.

- No additional states or complex logic are required.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the REQ event.

Application Scenarios

- Conversion of time values for numerical calculations.
- Integration into control systems where time values are required as numeric values.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

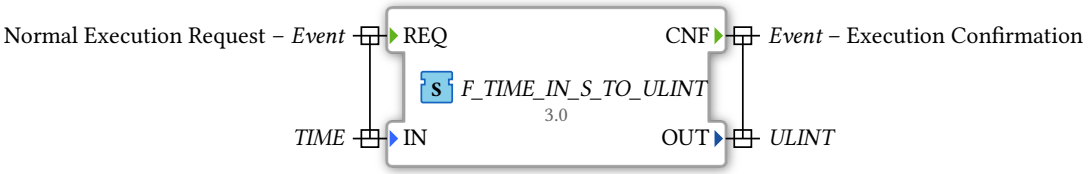
Use the function block **`F_MULTIME`** (from the category `arithmetic`) for this purpose:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Compared to other conversion function blocks, this one is specifically optimized for converting TIME to UDINT.
- Other function blocks might offer additional features such as scaling or limit checking, which is not the case here.

Conclusion



The `F_TIME_IN_S_TO_UDINT` function block is a simple and efficient function block for converting TIME values to UDINT. It is ideally suited for applications where time values are required in numerical form.

F_TIME_IN_S_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_S_TO_ULINT` converts a TIME value in seconds to a ULINT value. This is particularly useful when time values need to be converted into numerical formats for use in calculations or further processing.

Interface Structure

Event Inputs

- **REQ**: Normal execution request event. This event triggers the conversion and is linked to the data input `IN`.

Event Outputs

- **CNF**: Confirmation event after successful execution. This event is output along with the data output `OUT`.

Data Inputs

- **IN**: Input of type `TIME` containing the time value to be converted in seconds.

Data Outputs

- **OUT**: Output of type `ULINT` containing the converted numeric value.

Adapters

No adapters are present.

Functionality

The function block performs the conversion by transforming the TIME value (in seconds) into a ULINT value. The conversion occurs when the `REQ` event is triggered, and the result is output via the `OUT` output, accompanied by the `CNF` event.

Technical Features

- The function block uses the standard algorithm `TIME_IN_S_TO_ULINT` for the conversion.
- The function block is part of the `iec61131::conversion` package.

State Overview

The function block has no internal states. Execution occurs immediately upon the occurrence of the `REQ` event.

Application Scenarios

- Conversion of time values for use in numerical calculations.
- Integration into control systems that need to process time values in numerical form.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

Use the block **`F_MULTIME`** (from the category `arithmetic`) for this purpose:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with Similar Function Blocks

- Unlike generic conversion blocks, this function block specializes in converting TIME to ULINT.
- Other blocks might offer different output types or additional functionality, such as conversion to other numeric formats.

Conclusion

The `F_TIME_IN_S_TO_ULINT` function block provides a simple and efficient way to convert time values to ULINT numeric values. Its clear interface and straightforward functionality make it ideal for applications that require such conversions.

F_TIME_IN_US_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_US_TO_DINT` converts a TIME value in microseconds (µs) to a DINT value. This conversion is particularly useful when time values are to be used in numerical calculations or for control purposes.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. Upon this event, the input value `IN` is processed, and the result is output at `OUT`.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. This event, along with the converted value, is output at `OUT`.

Data Inputs

- **IN**: The input value of type `TIME`, specified in microseconds, to be converted to a DINT value.

Data Outputs

- **OUT**: The converted value of type `DINT`, representing the result of converting the TIME value to microseconds.

Adapters

This function block does not use any adapters.

Operation

The function block performs the conversion by transforming the TIME value in microseconds into a DINT value. The conversion occurs synchronously with the arrival of the `REQ` event. The result is immediately output at `OUT` and confirmed by the `CNF` event.

Technical Features

- The conversion is performed directly and without delay.
- The function block is suitable for use in real-time applications.
- No additional parameters or configurations are required.

State Overview

1. **Idle State**: The function block waits for the `REQ` event.
2. **Active State**: Upon receipt of `REQ`, the conversion is performed and the result is output.
3. **Confirmation State**: The `CNF` event is triggered to signal successful conversion.

Application Scenarios

- Conversion of time values for use in numerical calculations.
- Integration into control algorithms that require time values in a different format.
- Use in systems that process timestamps or durations in microseconds.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is sought to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block does not usually exist, as this is elegantly solved using multiplication.

For this purpose, use the block **`F_MULTIME`** (from the category `arithmetic`):

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Compared to generic conversion function blocks, this function block specializes in converting TIME to DINT.
- Other function blocks might offer additional features such as scaling or filtering, which is not the case here.

Conclusion

The `F_TIME_IN_US_TO_DINT` function block is a simple and efficient tool for converting time values in microseconds to a DINT value. Its simple interface and direct functionality make it ideal for applications that require fast and reliable conversion.

F_TIME_IN_US_TO_LINT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_TIME_IN_US_TO_LINT` converts a TIME value in microseconds (µs) into a LINT value (64-bit integer). This conversion is useful when time values are needed in numerical calculations or for further processing.

Interface Structure

Event Inputs

- `REQ` (Normal Execution Request): Starts the execution of the function block. Linked to input `IN`.

Event Outputs

- `CNF` (Execution Confirmation): Signals the completion of the conversion. Linked to output `OUT`.

Data Inputs

- `IN` (TIME): The input value in microseconds (µs) to be converted into a LINT value.

Data Outputs

- `OUT` (LINT): The converted 64-bit integer value.

Adapters

This function block does not use adapters.

Functionality

The function block performs the conversion by transforming the TIME input value (`IN`) in microseconds into a LINT value (`OUT`). The conversion occurs when the `REQ` event is triggered and is confirmed by the `CNF` event.

Technical Features

- The algorithm uses the function `TIME_IN_US_TO_LINT` to perform the conversion.
- The function block is suitable for use in real-time applications.

State Overview

The function block has a simple state machine:

1. **Idle State**: Waits for the `REQ` event.
2. **Execution State**: Performs the conversion and triggers the `CNF` event.

Application Scenarios

- Time measurement and processing in control systems.
- Integration of time values into numerical calculations.
- Logging and analysis of time durations.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block does not usually exist, as this is elegantly solved using multiplication.

Use the function block **`F_MULTIME`** (from the category `arithmetic`) for this:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Compared to other conversion function blocks, this one is specifically optimized for converting TIME to LINT.
- Similar function blocks might use different data types or units, e.g., milliseconds instead of microseconds.

Conclusion

The `F_TIME_IN_US_TO_LINT` function block provides an efficient and reliable way to convert time values in microseconds to 64-bit integers. Its simple interface and clear functionality make it ideal for a wide range of applications in automation technology.

F_TIME_IN_US_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_US_TO_LREAL` converts a time value in microseconds (`TIME`) into a double-precision floating-point number (`LREAL`). This conversion is particularly useful in control applications where time values are needed for further calculations.

Interface Structure

Event Inputs

- **REQ**: Trigger for the conversion. Upon this event, the input value `IN` is processed, and the result is output to `OUT`.

Event Outputs

- **CNF**: Confirms successful completion of the conversion. This event is output along with the converted value `OUT`.

Data Inputs

- **IN** (`TIME`): The input value in microseconds to be converted to a `LREAL` value.

Data Outputs

- **OUT** (`LREAL`): The converted value as a double-precision floating-point number.

Adapters

This function block does not use adapters.

Functionality

The function block performs the conversion by transforming the `TIME` input value `IN` into a `LREAL` value using the function `TIME_IN_US_TO_LREAL`. The result is passed to the output `OUT` and confirmed by the event `CNF`.

Technical Features

- The conversion is performed directly and without any additional delay.
- The function block is optimized for real-time applications and supports precise time measurements.

State Overview

The function block has no internal states. The conversion is performed every time the `REQ` event occurs.

Application Scenarios

- Conversion of time durations for mathematical calculations.

- Integration into control systems that require floating-point values for control algorithms.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

Use the function block **`F_MULTIME`** (from the category `arithmetic`) for this purpose:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ **Comparison with Similar Blocks**

- Unlike generic conversion blocks, this function block specializes in converting `TIME` to `LREAL` and therefore offers optimized performance.
- Other blocks might have additional parameters or states, which is not the case here.

Conclusion

The `F_TIME_IN_US_TO_LREAL` function block is an efficient tool for the precise conversion of time values to floating-point numbers. Its simple and direct operation makes it ideal for applications that require fast and accurate conversions.

F_TIME_IN_US_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_US_TO_UDINT` converts a TIME value in microseconds (µs) into a UDINT value. This conversion is particularly useful in applications where time values need to be processed further in numerical form.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `TIME`, containing the time value to be converted in microseconds.

Data Outputs

- **OUT**: The output of type `UDINT`, containing the result of the conversion.

Adapters

No adapters are present.

Functionality

This function block converts the TIME value (in µs) passed to `IN` into a UDINT value. The conversion is performed by calling the function `TIME_IN_US_TO_UDINT(IN)`. After successful conversion, the result is output to `OUT`, and the event `CNF` is triggered.

Technical Features

- The function block has a simple structure and contains only one algorithm (`REQ`) that performs the conversion.
- There is no state machine or complex logic, as the block is solely responsible for the conversion.

State Overview

Because it is a simple function block, there are no state transitions or state machines. The block performs the conversion on each `REQ` event and signals completion with `CNF`.

Application Scenarios

- Time measurement and processing in control systems.
- Conversion of time values for storage or transmission in numerical form.
- Integration into systems that need to process time values in µs as UDINT.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block doesn't usually exist, as this is elegantly solved using multiplication.

Use the block **`F_MULTIME`** (from the `arithmetic` category) for this purpose:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with Similar Blocks

- Compared to other conversion blocks, `F_TIME_IN_US_TO_UDINT` specializes in converting TIME to UDINT.
- Similar blocks might support other time formats or other target data types, e.g., TIME to REAL or TIME to STRING.

Conclusion

The `F_TIME_IN_US_TO_UDINT` function block offers a simple and efficient way to convert microsecond time values to UDINT values. Its streamlined design makes it particularly suitable for applications where performance and simplicity are paramount.

F_TIME_IN_US_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_TIME_IN_US_TO_ULINT` converts a time value in microseconds (`TIME`) into an unsigned 64-bit integer value (`ULINT`). This is particularly useful when time values need to be converted for numerical calculations or further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: This input expects a time value of type `TIME` (in microseconds) to be converted.

Data Outputs

- **OUT**: Returns the converted value as an unsigned 64-bit integer (`ULINT`).

Adapters

- No adapters are available.

Functionality

The function block uses the algorithm `REQ` to convert the incoming `TIME` value into a `ULINT` value in microseconds. The conversion is performed by the function `TIME_IN_US_TO_ULINT(IN)`. Once the conversion is complete, the event `CNF` is triggered to signal successful completion.

Technical Features

- The function block has a simple structure and contains only one algorithm.
- The conversion is direct and requires no additional parameters or state management.

State Overview

Because it is a simple function block, there are no complex state transitions. The block responds to the `REQ` event, performs the conversion, and signals completion with `CNF`.

Application Scenarios

- Time measurement and processing in control systems.
- Conversion of time values for use in calculations or logging systems.
- Integration into larger control algorithms that require numeric time values.

Reverse Conversion (Numeric to TIME)

Often, a function like `DINT_TO_TIME` is needed to convert a numeric value (e.g., 500) back into a time value (e.g., 500 ms). Such an explicit conversion block is not usually available, as this is elegantly solved using multiplication.

Use the function block **`F_MULTIME`** (from the category `arithmetic`) for this:

- Multiply your numeric value by the desired time base.
- **Example:** `500 * T#1ms = T#500ms`
- This allows for flexible scaling (e.g., * T#1s for seconds, * T#100ms for tenths of a second).

⚖️ Comparison with similar function blocks

- Compared to generic conversion blocks, `F_TIME_IN_US_TO_ULINT` specializes in converting `TIME` to `ULINT`.
- Other blocks might offer additional features such as scaling or filtering, which is not the case here.

Conclusion

The function block `F_TIME_IN_US_TO_ULINT` is a simple yet effective tool for converting microsecond time values into numerical values. Its simplicity and direct operation make it a reliable component in control applications that require precise time processing.

UDINT

F_UDINT_AS_STRING

• – ◦ • – ◦ • – ◦ •

The function block F_UDINT_AS_STRING converts an unsigned 32-bit integer value (UDINT) into a string (STRING). This block is particularly useful when numeric values need to be converted into a readable text format for display or logging.

- **REQ**: Starts the conversion. This input is linked to the data input IN.
- **CNF**: Signals the completion of the conversion. The output is linked to the data output OUT.
- **IN**: The unsigned 32-bit integer value (UDINT) to be converted to a string.
- **OUT**: The resulting string (STRING) after conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- No adapters are available.

When the event REQ is triggered, the algorithm is executed, converting the value of the input IN into a string and outputting the result to OUT. The event CNF is then triggered to signal the successful completion of the operation.

- The function block uses the function UDINT_AS_STRING for conversion.
- The implementation is in Structured Text (ST).

1. **Initialization**: The function block is ready and waiting for the REQ event.
2. **Conversion**: Upon receiving REQ, the value of IN is converted and output to OUT.
3. **Acknowledgement**: The CNF event is triggered to signal the completion of the conversion.

- Displaying numerical values in user interfaces.
- Logging measured values to text files or databases.
- Preparing data for communication via text protocols (e.g., HTTP, MQTT).
- Compared to generic conversion modules, F_UDINT_AS_STRING offers a specialized solution for converting UDINT to STRING.
- Other modules might support additional parameters such as formatting or length limits, which is not the case here.

The F_UDINT_AS_STRING function block is a simple and efficient module for converting unsigned 32-bit integers to strings. Its clear interface and simple functionality make it ideal for basic conversion tasks in automation projects.

Functionality

Technical Features

Application Scenarios

⚖️ Vergleich mit ähnlichen Bausteinen

Conclusion

F_UDINT_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UDINT_AS_WSTRING` converts an unsigned 32-bit integer value (`UDINT`) into a Unicode string (`WSTRING`). This functionality is particularly useful when numeric values are needed as text for display or further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The unsigned 32-bit integer value (`UDINT`) to be converted to a Unicode string.

Data Outputs

- **OUT**: The resulting Unicode string (`WSTRING`) after conversion.

Adapters

No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The algorithm converts the value of `IN` into a `WSTRING` representation and stores the result in `OUT`. The event `CNF` is then triggered to signal the completion of the operation.

Technical Features

- The conversion is performed directly without additional parameters.
- The function block is optimized for use in IEC 61131-compliant environments.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Completed**: Signals completion with `CNF` and returns to the idle state.

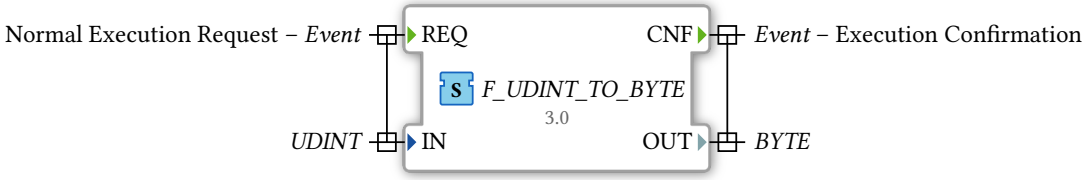
Application Scenarios

- Displaying numeric values in user interfaces.

- Logging numeric data to text files.
- Preparing data for communication via text-based protocols.

⚖️ Comparison with Similar Function Blocks

- Compared to `F_DINT_AS_WSTRING`, this function block processes unsigned values.
- Similar to `F_UDINT_AS_STRING`, but with Unicode support.



Conclusion

The `F_UDINT_AS_WSTRING` function block provides a simple and efficient way to convert unsigned 32-bit integer values to Unicode strings. Its clear interface and straightforward functionality make it a valuable tool in many automation applications.

F_UDINT_TO_BYTE

• – ◦ • – ◦ • – ◦ •

The function block `F_UDINT_TO_BYTE` converts a 32-bit unsigned integer (UDINT) value to an 8-bit unsigned integer (BYTE) value. This conversion is useful when data needs to be exchanged between systems with different word lengths or when memory space needs to be optimized.

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.
- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.
- **IN**: The 32-bit unsigned integer value (UDINT) to be converted.
- **OUT**: The resulting 8-bit unsigned integer value (BYTE) after the conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters are present.

Functionality

The function block performs the conversion when the event `REQ` is received. The value at input `IN`, of type UDINT, is converted to a BYTE value and output at `OUT`. The event `CNF` signals the successful completion of the conversion.

- The conversion is performed by the function `UDINT_TO_BYTE`, which maps the UDINT value to a BYTE value. Data loss can occur if the original value is outside the representable range of a BYTE (0 to 255).
- The function block is implemented as a simple function block (SimpleFB) and uses an ST algorithm for the conversion.

1. **Idle State**: The function block waits for the event `REQ`.
2. **Conversion State**: Upon receiving `REQ`, the conversion is performed, and `CNF` is triggered.

- **Data Reduction**: When only the lower 8 bits of a 32-bit value are relevant.
- **Interface Adaptation**: For communication with systems that can only process BYTE data.
- **Memory Optimization**: In environments with limited memory.
- **F_DINT_TO_BYTE**: Converts a 32-bit signed integer (DINT) to a BYTE value.

- **F_INT_TO_BYTE**: Converts a 16-bit signed integer (INT) to a BYTE value.
- **F_UDINT_TO_WORD**: Converts a 32-bit unsigned integer (UDINT) to a 16-bit unsigned integer (WORD).

The function block `F_UDINT_TO_BYTE` provides a simple and efficient way to convert 32-bit unsigned integer values to 8-bit unsigned integer values. It is particularly useful in scenarios where memory or communication bandwidth needs to be optimized. However, be aware of the potential data loss with values outside the byte range.

Technical Features

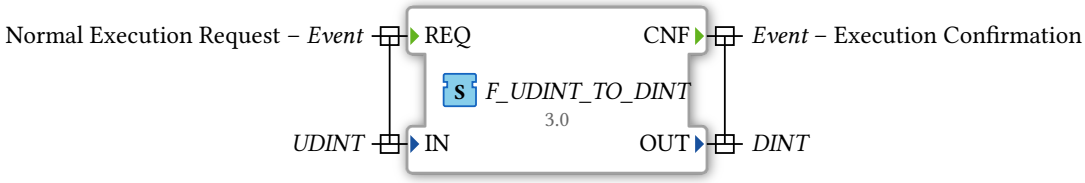
⚖️ Vergleich mit ähnlichen Bausteinen



Conclusion

F_UDINT_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UDINT_TO_DINT` converts an unsigned 32-bit integer value (UDINT) to a signed 32-bit integer value (DINT). This conversion is useful in scenarios where data is exchanged between systems that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (UDINT): The unsigned 32-bit integer value to be converted.

Data Outputs

- **OUT** (DINT): The resulting signed 32-bit integer value after conversion.

Adapters

No adapters are present.

Functionality

The function block performs the conversion by transforming the value of input `IN` from type `UDINT` to type `DINT`. The conversion occurs synchronously when the event `REQ` is triggered. After the conversion is complete, the event `CNF` is triggered, and the converted value is available at output `OUT`.

Technical Features

- The conversion is performed directly without additional processing.
- The function block is suitable for use in real-time systems.
- The implementation is in Structured Text (ST).

State Overview

1. **Idle State**: Waits for the event `REQ`.
2. **Conversion State**: Performs the conversion when `REQ` is triggered.
3. **Acknowledgement State**: Triggers `CNF` as soon as the conversion is complete.

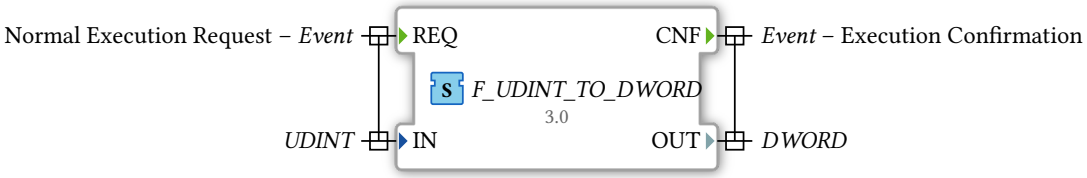
Application Scenarios

- Data conversion in control systems.
- Interfaces between systems that use different data types.
- Real-time data processing requiring type conversions.

⚖️ Comparison with similar function blocks

- Compared to generic conversion function blocks, `F_UDINT_TO_DINT` specializes in converting between `UDINT` and `DINT`.
- Other function blocks might offer additional features such as range checks or error handling, which is not the case here.

Conclusion



The function block `F_UDINT_TO_DINT` is a simple and efficient function block for converting between unsigned and signed 32-bit integers. It is particularly useful in scenarios where fast and direct type conversion is required.

F_UDINT_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UDINT_TO_DWORD` converts a `UDINT` value (32-bit unsigned integer) into a `DWORD` value (32-bit data word). This conversion is particularly useful in scenarios where numeric values need to be further processed or transmitted as bit patterns.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (`UDINT`): The 32-bit unsigned integer value to be converted.

Data Outputs

- **OUT** (`DWORD`): The result of the conversion as a 32-bit data word.

Adapters

No adapters available.

Functionality

When the `REQ` event is triggered, the input value `IN` of type `UDINT` is converted to a `DWORD` value and output `OUT`. The `CNF` event signals the successful completion of the conversion.

The underlying algorithm is implemented in Structured Text (ST):

ALGORITHM REQ OUT := UDINT_TO_DWORD(IN); END_ALGORITHM

Technical Features

- The conversion is performed directly through type conversion, without changing the bit representation.
- The function block is deterministic and has no internal states.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Conversion of numeric values for bitwise processing.
- Compatibility with systems that expect `DWORD` data.
- Data preparation for communication protocols or hardware registers.

⚖️ Comparison with Similar Function Blocks

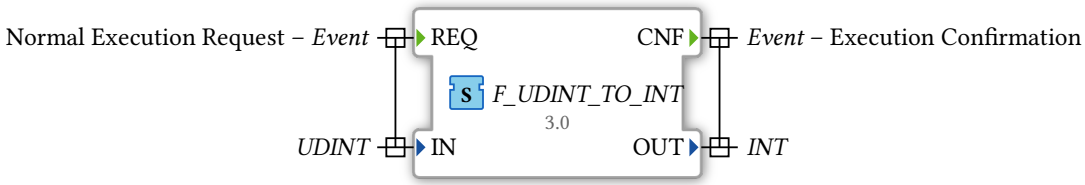
- Unlike arithmetic function blocks, `F_UDINT_TO_DWORD` does not change the value, but only the data type.

Similar conversion blocks exist for other data types (e.g., `INT_TO_DINT`), but with different source and target types.

🛠️ Related Exercises

- Exercise_034b
- Exercise_152
- Exercise_153

Conclusion



F_UDINT_TO_DWORD` is a simple yet essential function block for type conversions in IEC 61499-based control systems. Its deterministic operation and clear interface make it a reliable tool for data transformations.

F_UDINT_TO_INT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_UDINT_TO_INT` converts a `UDINT` value (32-bit unsigned integer) to a `INT` value (16-bit signed integer). This conversion is useful when data needs to be exchanged between systems or components that use different data types.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. Triggered after successful conversion.

Data Inputs

- **IN** (`UDINT`): The input value to be converted.

Data Outputs

- **OUT** (`INT`): The converted output value.

Adapters

- No adapters available.

Functionality

This function block performs the conversion from `UDINT` to `INT` when the `REQ` event is received. The algorithm uses the built-in function `UDINT_TO_INT` to perform the conversion. After successful conversion, the `CNF` event is triggered, and the converted value is available at the `OUT` output.

Technical Features

- Data loss can occur if the `UDINT` value is outside the representable range of `INT` (i.e., greater than 32767 or less than −32768).
- The function block is simple and has no internal states or complex logic.

State Overview

The function block has no internal state. It responds exclusively to the `REQ` event and performs the conversion immediately.

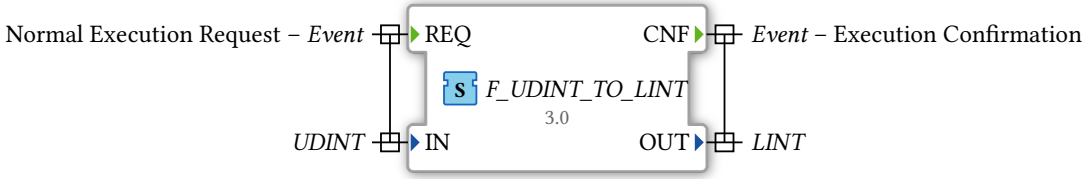
Application Scenarios

- Data conversion in control systems where different data types are used.
- Integration of components that expect or deliver different data types.
- Logging or displaying data originally stored as `UDINT` but intended to be displayed as `INT`.

⚖️ Comparison with similar building blocks

- **F_DINT_TO_INT**: Converts `DINT` (32-bit signed) to `INT`.
- **F_UDINT_TO_DINT: `Konvertiert UDINTzuDINT(32-Bit vorzeichenbehaftet), ohne Datenverlust, da der Wertebereich vonDINT` is larger.
- **F_INT_TO_UDINT**: Performs the reverse conversion (`INT` to `UDINT`).

Conclusion



The `F_UDINT_TO_INT` function block is a simple and efficient tool for converting `UDINT` to `INT` values. It is particularly useful in scenarios where such a type conversion is required; however, potential data loss with large values should be considered.

F_UDINT_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UDINT_TO_LINT` converts a 32-bit unsigned integer value (UDINT) to a 64-bit signed integer value (LINT). This block is part of the `iec61131::conversion` package and enables simple and efficient type conversion between these two data types.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (UDINT): The 32-bit unsigned integer value to be converted.

Data Outputs

- **OUT** (LINT): The resulting 64-bit signed integer value after the conversion.

Adapters

This function block does not use adapters.

Operation

When the event input `REQ` is triggered, the value of the data input `IN` (UDINT) is copied to the data output `OUT` (LINT). The conversion is performed directly because LINT covers a larger range of values than UDINT and can therefore represent all possible UDINT values without data loss. After the conversion is complete, the event `CNF` is triggered.

Technical Features

- **Algorithm**: The function block uses a simple ST algorithm that directly assigns the input value to the output value.
- **Data Loss**: Since LINT has a larger range of values than UDINT, there is no data loss during this conversion.
- **Performance**: The conversion is very efficient and takes place in constant time.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

Application Scenarios

- **Type Conversion**: In scenarios where an unsigned 32-bit value needs to be converted to a signed 64-bit value, e.g., when processing sensor data or in mathematical calculations.
- **Data Compatibility**: When integrating systems that use different integer types.

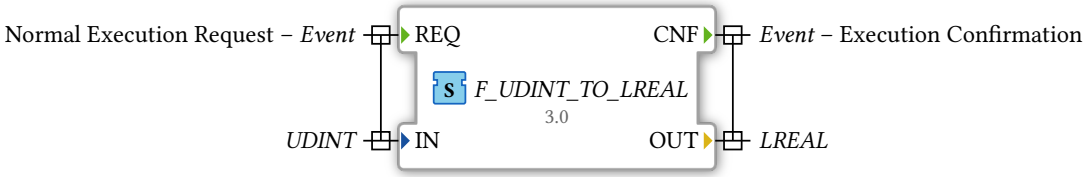
⚖️ Comparison with Similar Components

- **F_UDINT_TO_DINT**: Converts UDINT to DINT (32-bit signed), but can cause overflow because DINT has a smaller range of values.
- **F_UDINT_TO_ULINT**: Converts UDINT to ULINT (64-bit unsigned), but retains the unsigned nature.

🛠️ Related Exercises

- Exercise_072c

Conclusion



The `F_UDINT_TO_LINT` function block provides a simple and efficient way to convert unsigned 32-bit integer values to signed 64-bit integer values. Its direct and lossless conversion makes it ideal for applications that require an extended range of values.

F_UDINT_TO_LREAL

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_UDINT_TO_LREAL` converts a 32-bit unsigned integer value (UDINT) into a 64-bit floating-point value (LREAL). This block is particularly useful in applications where numerical values of varying precision need to be processed.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is processed.

Event Outputs
- **CNF**: Signals the completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs
- **IN** (UDINT): The unsigned 32-bit integer value to be converted.

Data Outputs
- **OUT** (LREAL): The resulting 64-bit floating-point value after conversion.

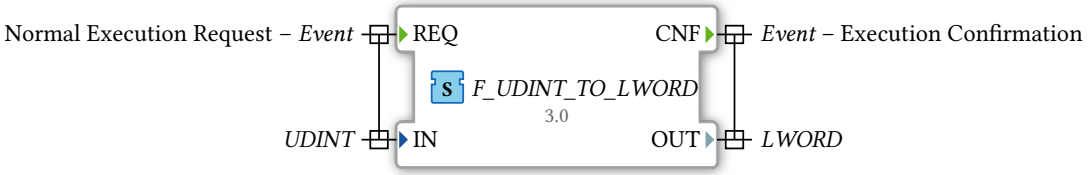
Adapters
This function block does not use any adapters.

Operation
When event input `REQ` is triggered, the value at input `IN` (of type UDINT) is read and converted to an LREAL value. The result is output at `OUT`, and event `CNF` signals successful conversion.

Technical Features
- The algorithm is implemented directly in ST (Structured Text) and performs a simple type conversion.
- No additional error handling or limit checks are required, as UDINT values can be directly converted to LREAL.

State Overview
1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Converts `IN` to `OUT`.
3. **Completed**: Sends `CNF` and returns to the idle state.

Application Scenarios
- Data processing in control systems where different numeric formats need to be processed.
- Integration into larger systems that require both integer and floating-point operations.



⚖️ Comparison with Similar Function Blocks
- Compared to generic conversion blocks, `F_UDINT_TO_LREAL` specializes in converting UDINT to LREAL and is therefore more efficient in this specific application.
- Other blocks might offer additional functionalities such as range checks or scaling, which are not necessary here.

Conclusion
The `F_UDINT_TO_LREAL` function block is a simple yet effective block for the specific conversion of unsigned 32-bit integers to 64-bit floating-point numbers. Its simplicity and direct implementation make it a reliable choice for such applications.

F_UDINT_TO_LWORD

• − ◦ • − ◦ • − ◦ •

Introduction
The function block `F_UDINT_TO_LWORD` converts a 32-bit unsigned integer value (UDINT) to a 64-bit unsigned integer value (LWORD). This block is particularly useful in scenarios where an extension of the data bit width is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input for the UDINT value to be converted.

Data Outputs

- **OUT**: The output for the converted LWORD value.

Adapters

No adapters are present.

Functionality

The function block performs the UDINT to LWORD conversion by expanding the incoming 32-bit value to a 64-bit value. The conversion occurs each time the `REQ` event occurs and is confirmed by the `CNF` event.

Technical Features

- The function block uses the built-in function `UDINT_TO_LWORD` for the conversion.
- This is a simple function block without a state machine or complex logic.

State Overview

Because it is a simple function block, there are no state transitions or internal states.

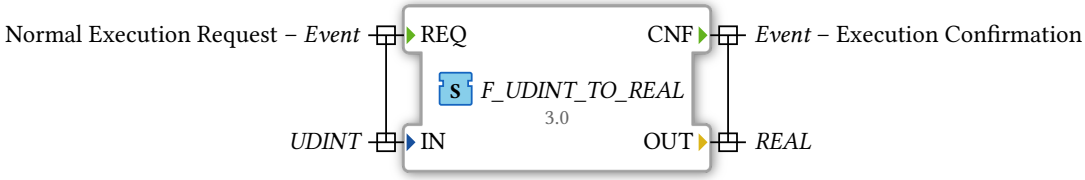
Application Scenarios

- Extending data widths in control systems.
- Compatibility with systems that use different bit widths.
- Data processing in industrial automation solutions.

⚖️ Comparison with Similar Blocks

Compared to other conversion blocks such as `F_DINT_TO_LWORD` or `F_UINT_TO_LWORD`, this one is specifically optimized for converting UDINT to LWORD. It offers a direct and efficient solution for this specific conversion.

Conclusion



The `F_UDINT_TO_LWORD` function block is a simple and efficient building block for converting 32-bit unsigned integer values to 64-bit unsigned integer values. Its clear interface structure and simple functionality make it a reliable component in industrial automation solutions.

F_UDINT_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UDINT_TO_REAL` converts an unsigned 32-bit integer value (`UDINT`) into a 32-bit floating-point value (`REAL`). This block is particularly useful in scenarios where numeric values of different data types need to be processed.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at the data output `OUT`.

Data Inputs

- **IN**: Expects an input value of type `UDINT` (unsigned 32-bit integer).

Data Outputs

- **OUT**: Outputs the converted value as `REAL` (32-bit floating-point number).

Adapters

- No adapters available.

Functionality

When the event input `REQ` is triggered, the algorithm is started. This algorithm converts the `UDINT` value at input `IN` into a `REAL` value and provides the result at output `OUT`. The event `CNF` is then triggered to signal the successful completion of the conversion.

Technical Features

- The conversion is performed directly using the built-in function `UDINT_TO_REAL`.
- The function block is simple and efficient because it does not require complex state machines or additional processing steps.

State Overview

The function block has no internal states. Processing occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Conversion of raw data (e.g., from sensors or communication protocols) into floating-point values for further calculations.
- Integration into control systems where different data types need to be processed.

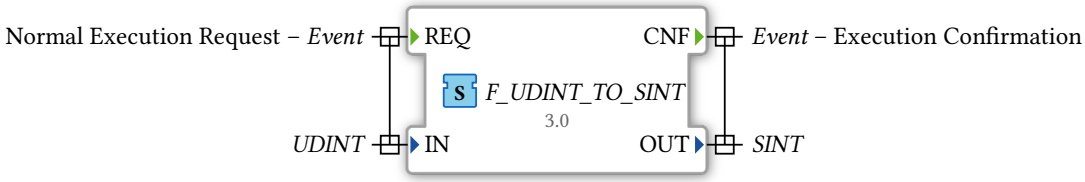
⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion function blocks, `F_UDINT_TO_REAL` is specialized and optimized for the specific conversion of `UDINT` to `REAL`.
- Similar function blocks might offer additional features such as range checks or scaling, which is not the case here.

🛠️ Related Exercises

- Exercise_151
- Exercise_151_AX
- Exercise_152
- Exercise_153

Conclusion



The `F_UDINT_TO_REAL` function block is a simple and efficient building block for converting unsigned 32-bit integers to floating-point numbers. Its simplicity makes it particularly suitable for applications where fast and direct conversion is required.

F_UDINT_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UDINT_TO_SINT` converts a 32-bit unsigned integer value (UDINT) to an 8-bit signed integer value (SINT). This conversion is useful when data needs to be exchanged between systems or components that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs

- **IN** (UDINT): The unsigned 32-bit integer value to be converted.

Data Outputs

- **OUT** (SINT): The resulting signed 8-bit integer value after conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion when the event `REQ` is triggered. The algorithm converts the value of `IN` (UDINT) to a SINT value and stores the result in `OUT`. The event `CNF` is then triggered to signal the completion of the operation.

Technical Features

- The function block is simple and deterministic, as it only performs a direct type conversion.
- There is no additional logic or error handling for values that are outside the representable range of SINT.

State Overview

The function block has no internal state. The conversion occurs immediately upon triggering `REQ`.

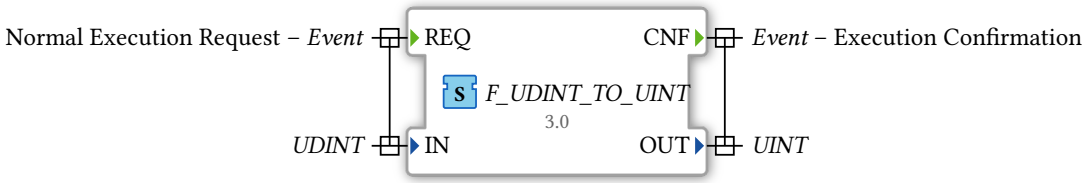
Application Scenarios

- Data conversion in control systems where different data types are used.
- Interfaces between systems that require different integer formats.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_DINT_TO_SINT` or `F_INT_TO_SINT` perform similar conversions, but with different output or input data types.
- `F_UDINT_TO_SINT` is specifically for converting UDINT to SINT.

Conclusion



The `F_UDINT_TO_SINT` function block is a simple and efficient tool for converting unsigned 32-bit integers to signed 8-bit integers. It is particularly useful in scenarios where such type conversions are needed regularly.

F_UDINT_TO_UINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UDINT_TO_UINT` converts a 32-bit unsigned integer value (UDINT) to a 16-bit unsigned integer value (UINT). This block is part of the `iec61131::conversion` package.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion of the input value. The input value `IN` is passed with this event.

Event Outputs

- **CNF**: Signals successful conversion and outputs the converted value `OUT`.

Data Inputs

- **IN** (UDINT): The 32-bit unsigned integer value to be converted.

Data Outputs

- **OUT** (UINT): The converted 16-bit unsigned integer value.

Adapters

This function block does not have any adapters.

Operation

Upon receiving the event `REQ`, the input value `IN` of type UDINT is converted to type UINT and output via `OUT`. Simultaneously, the event `CNF` is triggered to signal the successful completion of the conversion.

Technical Features

- The conversion is performed by direct type conversion, whereby the higher-order bits of the UDINT value are truncated if the value is outside the representable range of UINT.
- The block is suitable for use in real-time systems.

State Overview

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

Application Scenarios

- Conversion of 32-bit values to 16-bit values in control applications.
- Use in systems that need to work with different integer sizes.

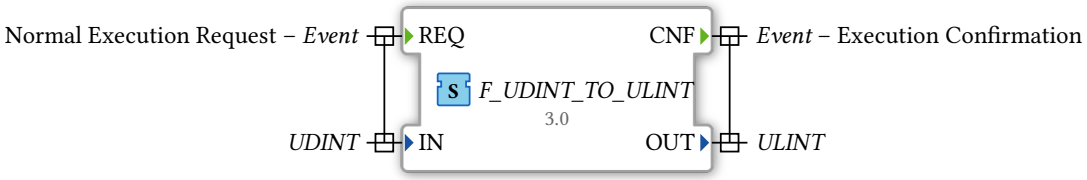
⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_UDINT_TO_UINT` is specialized for converting UDINT to UINT and is therefore more efficient in execution.
- Similar blocks like `F_DINT_TO_INT` convert between other integer types.

🛠️ Related Exercises

- Exercise_103

Conclusion



The F_UDINT_TO_UINT function block is a specialized and efficient building block for converting 32-bit to 16-bit unsigned integer values. It is particularly suitable for applications where fast and direct type conversion is required.

F_UDINT_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_UDINT_TO_ULINT converts a 32-bit unsigned integer (UDINT) value to a 64-bit unsigned integer (ULINT). This block is particularly useful when exchanging data between systems or components that use different integer sizes.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the function block reads the value at the data input IN and performs the conversion.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is activated along with the converted value at data output OUT.

Data Inputs

- **IN**: The input for the 32-bit unsigned integer (UDINT) value to be converted.

Data Outputs

- **OUT**: The output for the converted 64-bit unsigned integer (ULINT) value.

Adapters

This function block does not use adapters.

Operation

The function block performs a direct type conversion. When the REQ event is triggered, the value of IN is read and assigned to OUT without further processing. Since ULINT covers a larger range of values than UDINT, this conversion is always safe and lossless.

The algorithm is implemented as follows:
ALGORITHM REQ OUT := IN; END_ALGORITHM

Technical Features

- **Lossless Conversion**: Since ULINT can represent all values of UDINT, there is no data loss.
- **Simple Implementation**: The function block requires no additional logic or error handling.

State Overview

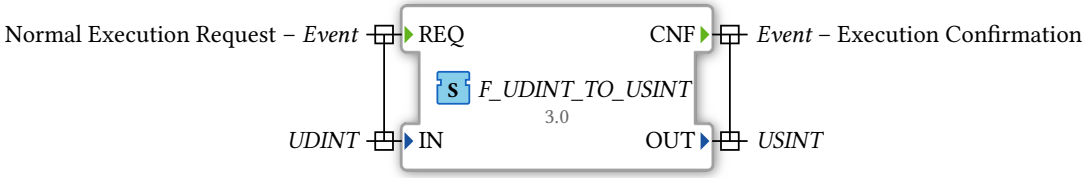
The function block has no internal states. The conversion occurs immediately upon triggering the REQ event.

Application Scenarios

- **Data Compatibility**: Used when systems need to communicate with different integer sizes.
- **Extended Value Range**: Enables the use of UDINT values in contexts that require ULINT.

⚖️ Comparison with Similar Function Blocks

- **F_UDINT_TO_LINT**: Converts UDINT to a 64-bit signed integer (LINT). In contrast, `F_UDINT_TO_ULINT` retains the unsigned character.
- **F_DINT_TO_ULINT**: Converts a 32-bit signed integer (DINT) to ULINT. `F_UDINT_TO_ULINT` is specific for unsigned values.



Conclusion

The `F_UDINT_TO_ULINT` function block is a simple and efficient tool for safely converting 32-bit unsigned integers to 64-bit unsigned integers. Its lossless operation and ease of use make it ideal for applications requiring an extended range of values.

F_UDINT_TO_USINT

• – ◦ • – ◦ • – ◦ •

The function block `F_UDINT_TO_USINT` converts a 32-bit unsigned integer value (UDINT) to an 8-bit unsigned integer value (USINT). This block is particularly useful in scenarios where type conversion between numerical values of different sizes is required.

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.
- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.
- **IN**: The input expects a 32-bit unsigned integer value (UDINT) to be converted.
- **OUT**: The output provides the converted 8-bit unsigned integer value (USINT).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is received. The algorithm converts the value of `IN` (UDINT) to the corresponding `OUT` (USINT) value. After successful conversion, the event `CNF` is triggered.

- The conversion is performed by the built-in function `UDINT_TO_USINT`.
- No range check is performed. Values outside the USINT range (0 to 255) may produce unexpected results.

The function block has no internal states. The conversion is performed anew with each `REQ` event.

- Type conversion in control applications where memory optimization is crucial.
- Communication between systems using different data types.
- Compared to generic conversion blocks, `F_UDINT_TO_USINT` is specialized and therefore more efficient in execution.
- Other blocks might offer additional functionalities such as range checks, which is not the case here.

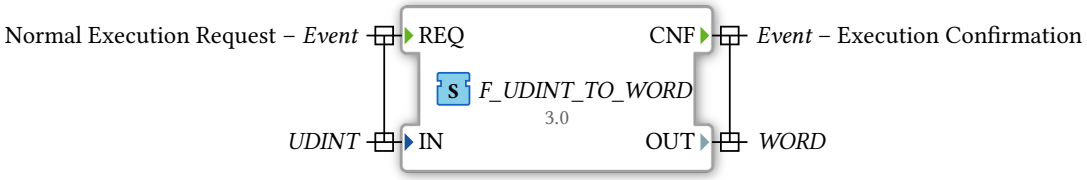
The `F_UDINT_TO_USINT` function block is a simple and efficient building block for the specific conversion of UDINT to USINT values. It is particularly suitable for applications where fast and direct type conversion is required.

Technical Features

State Overview

Application Scenarios

⚖️ Vergleich mit ähnlichen Bausteinen



Conclusion

F_UDINT_TO_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UDINT_TO_WORD` converts a 32-bit unsigned integer value (UDINT) to a 16-bit unsigned integer value (WORD). This conversion is particularly necessary in scenarios where data needs to be exchanged between systems with different word lengths.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (UDINT): The 32-bit unsigned integer value to be converted.

Data Outputs

- **OUT** (WORD): The resulting 16-bit unsigned integer value after conversion.

Adapters

No adapters are available.

Functionality

This function block performs the conversion from UDINT to WORD by executing the algorithm `REQ`. The input value `IN`, of type UDINT, is converted into a WORD value and output at `OUT`. The conversion occurs synchronously with the event `REQ`, and the result is confirmed with the event `CNF`.

Technical Details

- The conversion truncates the 16 most significant bits of the UDINT value, since a WORD only contains 16 bits.
- The function block is part of the package `iec61131::conversion`.

State Overview

The function block has no internal state. The conversion is re-executed with each event `REQ`.

Application Scenarios

- Data reduction from 32-bit to 16-bit in embedded systems.
- Compatibility with legacy systems that can only process 16-bit data.
- Memory optimization in resource-constrained environments.

⚖️ Comparison with Similar Function Blocks

- Compared to `F_DINT_TO_WORD` or `F_INT_TO_WORD`, this function block processes unsigned values.
- Similar function blocks like `F_UDINT_TO_DWORD` do not perform bit width reduction.

Conclusion

The `F_UDINT_TO_WORD` function block provides a simple and efficient way to convert 32-bit unsigned integer values to 16-bit unsigned integer values. It is particularly useful in scenarios where a reduction in data width is required without altering the fundamental semantics of the data.

UINT

F_UINT_AS_STRING

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_UINT_AS_STRING` converts an unsigned integer value (`UINT`) into a string (`STRING`). This functionality is particularly useful when numeric values are needed as text for output, logging, or further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is activated along with the converted value at data output `OUT`.

Data Inputs

- **IN** (`UINT`): The unsigned integer value to be converted to a string.

Data Outputs

- **OUT** (`STRING`): The string generated from the input value `IN`.

Adapters

This function block has no adapters.

Functionality

When the event input `REQ` is triggered, the algorithm is started, which converts the value of `IN` to `STRING` using the function `UINT_AS_STRING`. The result is output to `OUT`, and the event `CNF` signals successful conversion.

Technical Features

- The conversion is performed directly and without delay.
- The function block is implemented simply and efficiently, without additional states or complex logic.

State Overview

The function block has no internal state. Each execution is independent of previous calls.

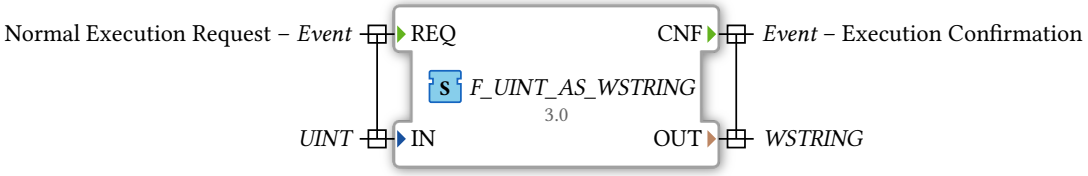
Application Scenarios

- Displaying numerical values in user interfaces.
- Logging measured values to text files.
- Preparing data for communication via text-based protocols.

⚖️ Comparison with similar building blocks

- Unlike generic conversion blocks, `F_UINT_AS_STRING` specializes in converting `UINT` to `STRING`.
- Other blocks might support additional parameters such as formatting or base (decimal, hexadecimal), which is not the case here.

Conclusion



The `F_UINT_AS_STRING` function block is a simple and effective tool for converting unsigned integer values to strings. Its strength lies in its simplicity and direct applicability in scenarios where a fast and straightforward conversion is required.

F_UINT_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_AS_WSTRING` converts an unsigned integer value (`UINT`) into a wide-string representation (`WSTRING`). This block is particularly useful in scenarios where numeric values need to be converted into human-readable text.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event is triggered, the value at data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event, along with the converted value, is output at data output `OUT`.

Data Inputs

- **IN**: The input for the `UINT` value to be converted.

Data Outputs

- **OUT**: The output for the converted `WSTRING` value.

Adapters

This function block does not use adapters.

Functionality

When the `REQ` event is triggered, the algorithm is executed, converting the `UINT` value at input `IN` into a `WSTRING` value. The result is provided at output `OUT`, and the `CNF` event signals successful conversion.

Technical Features

- The function block is implemented simply and efficiently, without additional states or complex logic.
- The conversion is performed directly via the built-in function `UINT_AS_WSTRING`.

State Overview

The function block has no internal states. Processing occurs immediately upon triggering the `REQ` event.

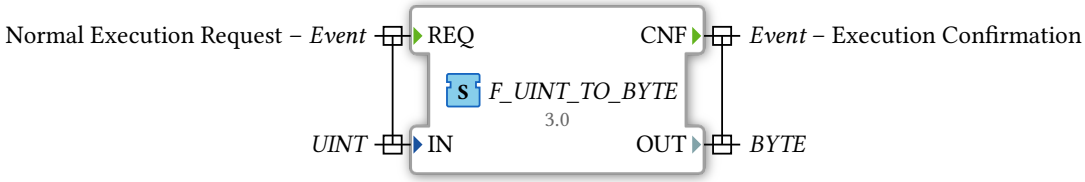
Application Scenarios

- Displaying numeric values in user interfaces.
- Logging and debugging, where numeric values need to be output as text.
- Communication with systems that expect string data.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_UINT_AS_WSTRING` specializes in converting `UINT` to `WSTRING` and is therefore more efficient for this specific use case.
- Other blocks might offer additional features such as formatting or locale adjustment, which is not the case here.

Conclusion



The `F_UINT_AS_WSTRING` function block is a simple and effective block for converting unsigned integer values to wide strings. Its simplicity and direct functionality make it ideal for applications that require quick and straightforward conversion.

F_UINT_TO_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_BYTE` converts an unsigned 16-bit integer value (UINT) to an 8-bit byte value (BYTE). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input for the UINT value to be converted.

Data Outputs

- **OUT**: The output for the converted BYTE value.

Adapters

No adapters are present.

Functionality

The function block performs the conversion as soon as an event arrives at input `REQ`. The value at input `IN`, of type UINT, is converted into a BYTE value and output at output `OUT`. The conversion is performed using the function `UINT_TO_BYTE`. After the conversion is complete, event `CNF` is triggered.

Technical Features

- The conversion is performed without additional parameters or configuration.
- The function block is deterministic and has no internal states.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

Application Scenarios

- Type conversion in communication protocols where BYTE data is expected.
- Data reduction when only the lower 8 bits of a UINT value are relevant.

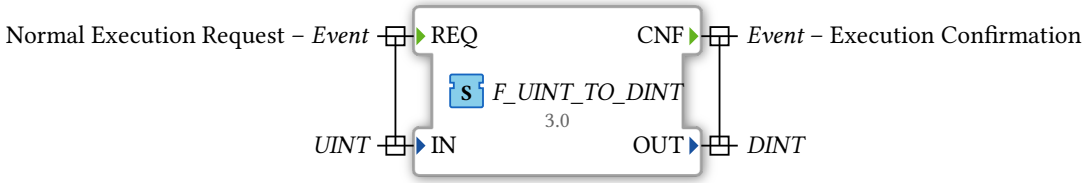
⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_UINT_TO_BYTE` is specialized in converting UINT to BYTE.
- Other blocks might offer additional features such as range checks or scaling, which is not the case here.

🛠️ Related Exercises

- Exercise_12x_sub

Conclusion



The `F_UINT_TO_BYTE` function block is a simple and efficient building block for the specific conversion of UINT to BYTE. It is particularly suitable for applications where fast and direct type conversion is required.

F_UINT_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_DINT` converts an unsigned 16-bit integer value (UINT) to a signed 32-bit integer value (DINT). This conversion is useful when exchanging data between systems that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `UINT` to be converted.

Data Outputs

- **OUT**: The output value of type `DINT`, containing the result of the conversion.

Adapters

This function block does not use any adapters.

Operation

When an event is received at input `REQ`, the value of `IN` is read and directly converted to the data type `DINT`. The result is output to `OUT`, and the event `CNF` is triggered to signal the completion of the conversion.

Technical Features

- The function block performs a direct type conversion without additional calculations or scaling.
- The conversion is lossless because the `DINT` type covers a larger range of values than `UINT`.

State Overview

1. **Idle**: Waits for an event at input `REQ`.
2. **Converting**: Performs the conversion and outputs the result.
3. **Completed**: Signals the completion of the conversion with the event `CNF`.

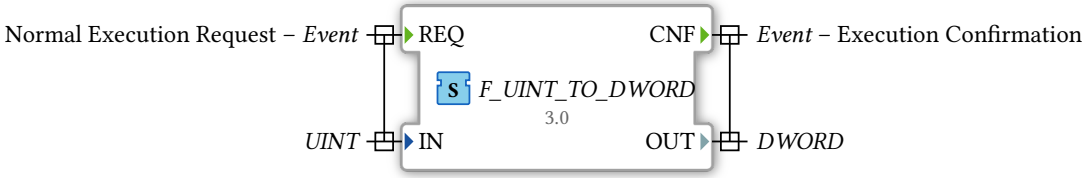
Application Scenarios

- Data conversion in control systems that use different data types.
- Integration of sensor data in the format `UINT` into systems that expect `DINT`.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_UINT_TO_DINT` is specialized and efficient for converting `UINT` to `DINT`.
- Other blocks might offer additional features such as scaling or range checking, which are not required here.

Conclusion



The `F_UINT_TO_DINT` function block is a simple and efficient building block for the direct conversion of `UINT` to `DINT`. It is particularly useful in scenarios where lossless type conversion is required.

F_UINT_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_DWORD` converts a UINT value (16-bit unsigned integer) to a DWORD value (32-bit unsigned integer). This conversion is particularly necessary in scenarios where data with different bit widths needs to be processed or transmitted.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: UINT value (16-bit) to be converted to a DWORD value.

Data Outputs

- **OUT**: DWORD value (32-bit) containing the result of the conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion as soon as an event arrives at input `REQ`. The algorithm `REQ` converts the UINT value at input `IN` to a DWORD value and stores the result in `OUT`. The event `CNF` is then triggered to signal the completion of the conversion.

Technical Features

- The conversion is performed without data loss, as the value range of UINT (0 to 65535) can be fully mapped to DWORD (0 to 4294967295).
- The function block is part of the `iec61131::conversion` package.

State Overview

The function block has no internal state. The conversion is re-executed with each `REQ` event.

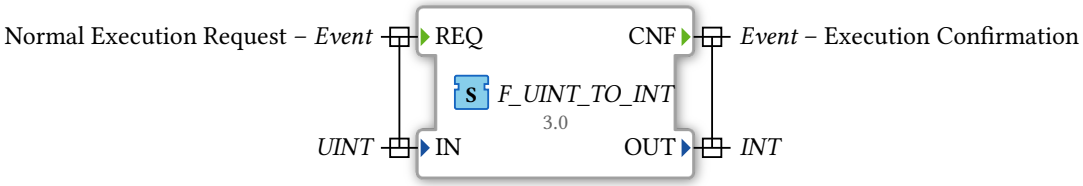
Application Scenarios

- Data conversion in control systems when different bit widths need to be harmonized.
- Integration into larger function block networks that process both UINT and DWORD data.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks (e.g., `F_INT_TO_DINT`), `F_UINT_TO_DWORD` specializes in converting 16-bit to 32-bit unsigned integers.
- Similar blocks might offer additional features such as scaling or limit checks, which is not the case here.

Conclusion



The `F_UINT_TO_DWORD` function block provides a simple and efficient way to convert UINT values to DWORD values. Its clear interface and deterministic operation make it ideal for use in control and automation solutions.

F_UINT_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_INT` converts an unsigned integer value (UINT) to a signed integer value (INT). This functionality is particularly useful when exchanging data between systems that use different integer formats.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the function block reads the value at the data input `IN` and performs the conversion.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. Simultaneously, the converted value is output at data output `OUT`.

Data Inputs

- **IN**: The unsigned integer value (UINT) to be converted is entered here.

Data Outputs

- **OUT**: Outputs the converted signed integer value (INT).

Adapters

This function block does not have any adapter interfaces.

Functionality

When the event input `REQ` is triggered, the function block's algorithm is activated. It reads the value at input `IN`, converts it from UINT to INT, and outputs the result at output `OUT`. The event `CNF` is then triggered to signal the successful completion of the conversion.

The conversion is performed using the built-in function `UINT_TO_INT()`.

Technical Features

- The function block has a simple structure and contains only one algorithm.
- No additional libraries or adapters are required.
- The conversion is performed directly and without delay.

State Overview

The function block has no internal states. The conversion is performed anew each time `REQ` is triggered.

Application Scenarios

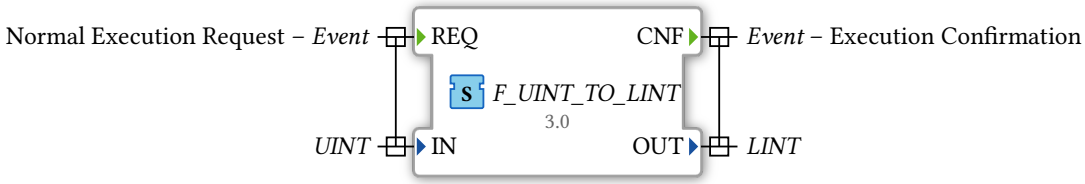
- Data conversion between systems that use different integer formats.
- Preprocessing of sensor data that is delivered as UINT but is to be further processed as INT.
- Establishing compatibility between different protocols or interfaces.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_UINT_TO_INT` is specialized and therefore more efficient.
- Similar blocks like `F_INT_TO_UINT` perform the reverse conversion.
- General-purpose blocks like `F_ANY_TO_ANY` offer more flexibility but may be less performant.

Conclusion

The `F_UINT_TO_INT` function block is a simple yet effective tool for converting between unsigned and signed integer values. Its simplicity and straightforward functionality make it a reliable solution for relevant use cases.



F_UINT_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_LINT` converts an unsigned 16-bit integer value (UINT) to a signed 64-bit integer value (LINT). This conversion is particularly useful when data needs to be exchanged or processed between systems with different word lengths.

• – ◦ • – ◦ • – ◦ •

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `UINT`, which is to be converted to a value of `LINT`.

Data Outputs

- **OUT**: The converted output value of type `LINT`.

Adapters

- No adapters are available.

• – ◦ • – ◦ • – ◦ •

Functionality

The function block performs a direct assignment of the input value `IN` to the output `OUT`. Since `LINT` has a larger value range than `UINT`, the conversion is lossless. The block is activated by the event `REQ` and signals the completion of the operation with the event `CNF`.

• – ◦ • – ◦ • – ◦ •

Technical Features

- **Lossless Conversion**: Since `LINT` (64 bits) covers a larger value range than `UINT` (16 bits), no information is lost during the conversion.
- **Simple Implementation**: The block uses a simple algorithm for direct value assignment.

• – ◦ • – ◦ • – ◦ • –

State Overview

1. **Idle State**: The block is waiting for the event `REQ`.
2. **Activation State**: Upon receiving `REQ`, the input value `IN` is read and converted.
3. **Acknowledgement State**: After successful conversion, the event `CNF` is triggered, and the block returns to the idle state.

• – ◦ • – ◦ • – ◦ •

Application Scenarios

- **Data Conversion**: In systems that need to process both 16-bit and 64-bit data.

- **Interface Adaptation**: For communication between devices with different word widths.
- **Data Processing**: In algorithms that require higher precision for calculations.

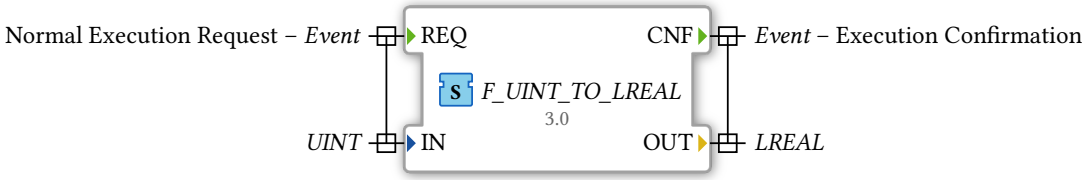
• – ◦ • – ◦ • – ◦ •

⚖️ Comparison with similar function blocks

- **F_UINT_TO_INT**: Converts `UINT` to `INT` (16 bits), but with a signed value.
- **F_UINT_TO_DINT**: Converts `UINT` to `DINT` (32 bits), offering a wider range of values than `INT`, but less than `LINT`.
- **F_UINT_TO_ULINT**: Converts `UINT` to `ULINT` (64 bits), remaining unsigned.

• – ◦ • – ◦ • – ◦ •

Conclusion



The `F_UINT_TO_LINT` function block is a simple and efficient tool for converting 16-bit unsigned integer values to 64-bit signed integer values. Its lossless conversion and ease of use make it ideal for applications requiring higher precision or compatibility with 64-bit systems.

F_UINT_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_LREAL` converts an unsigned 16-bit integer value (UINT) to a 64-bit floating-point value (LREAL). This conversion is particularly useful in control applications where different data types need to be processed.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. Upon this event, the value at input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at output `OUT`.

Data Inputs

- **IN** (UINT): The unsigned 16-bit integer value to be converted to an LREAL value.

Data Outputs

- **OUT** (LREAL): The resulting 64-bit floating-point value after conversion.

Adapters

No adapters are available.

Functionality

The function block performs the conversion by directly converting the UINT value from `IN` to an LREAL value and outputting it to `OUT`. The conversion occurs when the event `REQ` is triggered, and the event `CNF` signals completion.

Technical Features

- **Algorithm**: The algorithm is implemented in Structured Text (ST) and consists of a simple assignment (`OUT := IN`).
- **Data Types**: Supports conversion from UINT (0 to 65535) to LREAL (64-bit floating point).

State Overview

1. **Idle**: Waits for the event `REQ`.
2. **Conversion**: Upon `REQ`, the value from `IN` is read and converted.
3. **Completion**: The event `CNF` is triggered, and the converted value is available at `OUT`.

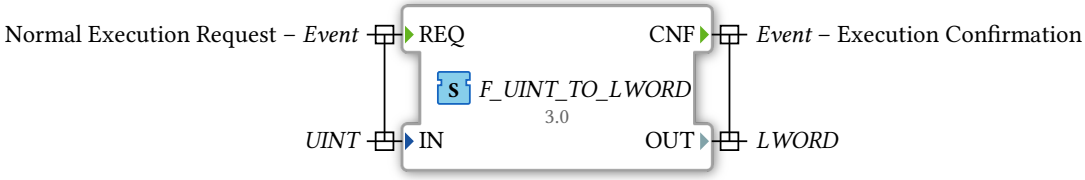
Application Scenarios

- **Measurement Processing**: Conversion of discrete sensor values (e.g., raw ADC data) into floating-point values for further calculations.
- **Data Communication**: Conversion of integer values for use in floating-point operations.

⚖️ Comparison with Similar Function Blocks

- **F_INT_TO_LREAL**: Converts a signed integer (INT) to LREAL.
- **F_DINT_TO_LREAL**: Converts a 32-bit integer (DINT) to LREAL.
- **F_ULINT_TO_LREAL**: Converts a 64-bit unsigned integer (ULINT) to LREAL.

Conclusion



The `F_UINT_TO_LREAL` function block provides a simple and efficient way to convert unsigned 16-bit integer values to 64-bit floating-point values. Its clear interface and direct operation make it ideal for applications requiring fast and reliable type conversion.

F_UINT_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_LWORD` converts a `UINT` value (16-bit unsigned integer) to a `LWORD` value (64-bit unsigned integer). This conversion is particularly necessary in scenarios where data with different bit widths needs to be processed or transmitted.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `UINT`, which is to be converted to a `LWORD` value.

Data Outputs

- **OUT**: The converted output value of type `LWORD`.

Adapters

This function block has no adapters.

Operation

The function block performs the conversion using the algorithm `REQ`, which is activated when the event `REQ` is triggered. The algorithm converts the `UINT` input value `IN` into a `LWORD` value and assigns it to the output `OUT`. After the conversion is complete, the event `CNF` is triggered.

Technical Features

- The conversion is performed without data loss because the `LWORD` type covers a larger range of values than `UINT`.
- The function block is deterministic and has no internal states.

State Overview

Since this is a simple function block, there are no state transitions or internal states. The conversion occurs immediately upon triggering the `REQ` event.

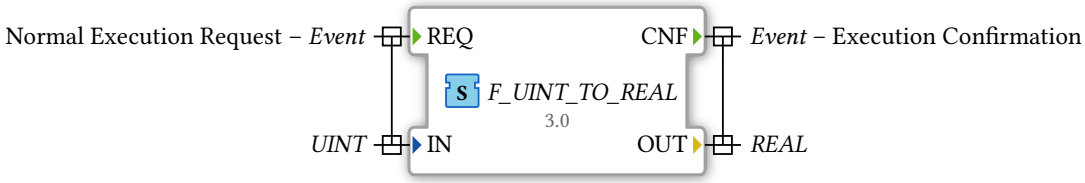
Application Scenarios

- Data conversion in control systems where different data types need to be processed.
- Integration into larger function block networks that process data with varying bit widths.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_UINT_TO_LWORD` specializes in converting `UINT` to `LWORD`, thus offering an optimized and type-safe solution.
- Other conversion blocks might offer additional features such as error handling or overflow checking, which is not the case here.

Conclusion



The `F_UINT_TO_LWORD` function block offers a simple and efficient way to convert `UINT` values to `LWORD` values. Its simplicity and determinism make it a reliable component in control applications. However, for more complex requirements, such as error handling, more advanced function blocks should be considered.

F_UINT_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_REAL` converts an unsigned integer value (`UINT`) into a floating-point number (`REAL`). This functionality is particularly useful when exchanging data between systems that use different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `UINT`, which is to be converted to a `REAL` value.

Data Outputs

- **OUT**: The output value of type `REAL`, which represents the result of the conversion.

Adapters

This function block has no adapters.

Operation

The function block performs the conversion as soon as the event `REQ` is triggered. The algorithm within the block directly assigns the value of `IN` to `OUT`, performing an implicit type conversion from `UINT` to `REAL`. Upon completion of the conversion, the event `CNF` is triggered.

Technical Features

- The conversion is performed without any additional parameters or settings.
- The block is part of the package `iec61131::conversion`.

State Overview

The function block has no internal state. The conversion occurs immediately upon the triggering of `REQ`.

Application Scenarios

- Conversion of sensor values stored as `UINT` to `REAL` for further calculations.
- Compatibility between systems using different data types.

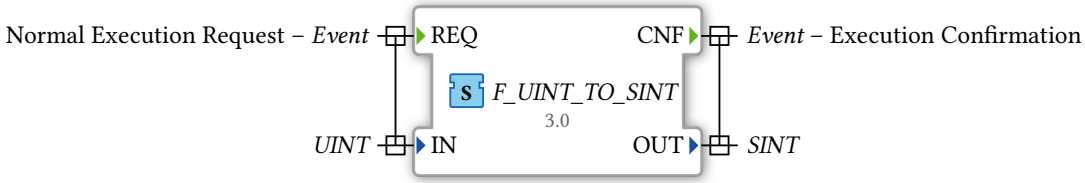
⚖️ Comparison with Similar Blocks

- Unlike more complex conversion blocks, `F_UINT_TO_REAL` offers a simple, direct conversion without additional functionality.
- Similar blocks might offer additional features such as scaling or range checks, which is not the case here.

🛠️ Related Exercises

- Exercise_072c

Conclusion



The `F_UINT_TO_REAL` function block is a simple and efficient tool for converting the type from `UINT` to `REAL`. Its strength lies in its simplicity and direct applicability, without the overhead of additional functions.

F_UINT_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_SINT` converts an unsigned 16-bit integer value (UINT) to a signed 8-bit integer value (SINT). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When activated, the input value `IN` is read and processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output value `OUT` is then available.

Data Inputs

- **IN** (UINT): The unsigned 16-bit integer value to be converted.

Data Outputs

- **OUT** (SINT): The resulting signed 8-bit integer value after the conversion.

Adapters

- No adapters are available.

Functionality

The function block performs the conversion by converting the `UINT` value at input `IN` to a `SINT` value and outputting it at output `OUT`. The conversion occurs when the `REQ` event is triggered, and the `CNF` event signals completion.

Technical Features

- Data loss can occur during the conversion if the `UINT` value is outside the representable range of `SINT` (0 to 127).
- The function block is implemented as a simple function block (SimpleFB) and uses an ST algorithm for the conversion.

State Overview

The function block has no internal states. The conversion occurs immediately upon the triggering of the `REQ` event.

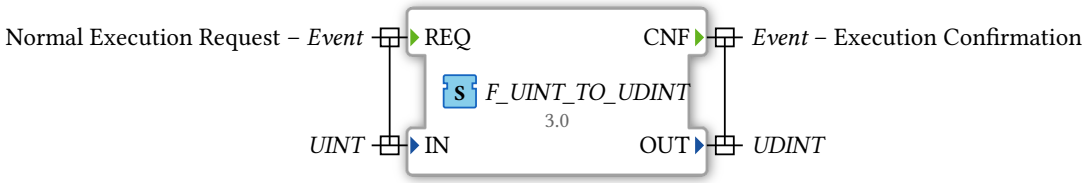
Application Scenarios

- Type conversion in control applications, where `UINT` values need to be converted to `SINT` values.
- Data processing in industrial automation systems, where different data types are processed.

⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion function blocks, `F_UINT_TO_SINT` specializes in converting `UINT` to `SINT`.
- Other conversion function blocks might offer additional features such as range checks or error handling.

Conclusion



The `F_UINT_TO_SINT` function block is an efficient tool for the specific conversion of `UINT` to `SINT`. Its simplicity and direct functionality make it ideal for applications requiring fast and straightforward type conversion.

F_UINT_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_UDINT` converts a 16-bit unsigned integer value (`UINT`) to a 32-bit unsigned integer value (`UDINT`). This block is part of the `iec61131::conversion` package and is suitable for applications requiring an extension of the bit width of numeric values.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The 16-bit unsigned integer value to be converted (`UINT`).

Data Outputs

- **OUT**: The converted 32-bit unsigned integer value (`UDINT`).

Adapters

This function block does not use any adapters.

Functionality

When the event input `REQ` is triggered, the value of the data input `IN` is read and directly assigned to the data output `OUT`. Since `UDINT` has a larger bit width than `UINT`, the conversion occurs without data loss. The event `CNF` is then triggered to signal the completion of the operation.

Technical Features

- The conversion is lossless because `UDINT` completely covers the value range of `UINT`.
- The block is deterministic and has no internal states.

State Overview

The function block has no internal states. The operation is re-executed with each `REQ` event.

Application Scenarios

- Extending the bit width of sensor data for further processing.
- Ensuring compatibility between systems that use different integer formats.
- Preprocessing data for algorithms that require `UDINT`.

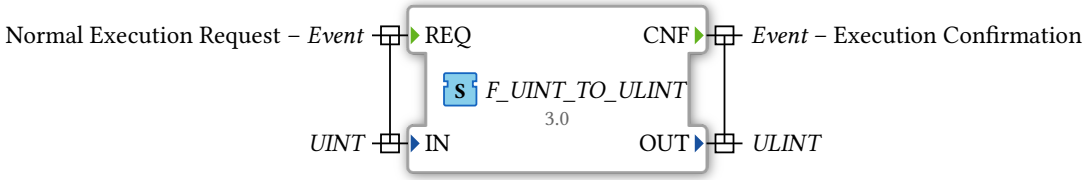
⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_UINT_TO_UDINT` is specialized and optimized for the specific conversion of `UINT` to `UDINT`.
- Other blocks, such as `F_INT_TO_DINT`, handle signed integers, while this block processes unsigned values.

🛠️ Related Exercises

- Exercise_015
- Exercise_015a

Conclusion



The `F_UINT_TO_UDINT` function block is an efficient and reliable tool for converting 16-bit to 32-bit unsigned integer values. Its simplicity and determinism make it ideal for real-time applications where performance and precision are critical.

F_UINT_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_ULINT` converts an unsigned 16-bit integer value (`UINT`) into an unsigned 64-bit integer value (`ULINT`). This conversion is particularly necessary when exchanging values between systems with different word widths.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `UINT` to be converted.

Data Outputs

- **OUT**: The converted output value of type `ULINT`.

Adapters

No adapters are available.

Functionality

This function block performs a direct conversion of the input value `IN` of type `UINT` to the output value `OUT` of type `ULINT`. The conversion occurs without changing the numerical value; only the data type is extended.

Technical Features

- The conversion is lossless because the `ULINT` type covers a larger range of values than `UINT`.
- The function block is deterministic and has no internal states.

State Overview

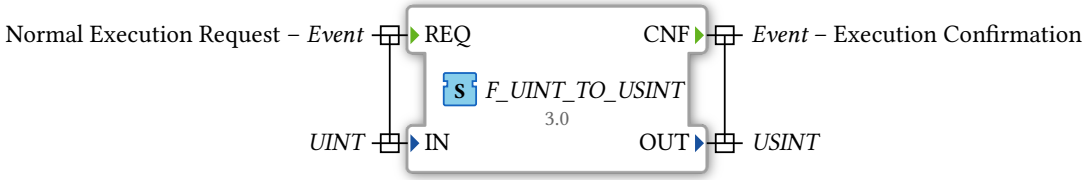
The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

Application Scenarios

- Integration of systems with different word widths
- Data processing in controllers that need to handle both 16-bit and 64-bit data
- Data extension for subsequent calculations requiring higher precision

⚖️ Comparison with similar function blocks

- Unlike `F_INT_TO_LINT`, this function block processes unsigned data types
- Similar conversion function blocks exist for other data type combinations (e.g., `F_BYTE_TO_WORD`)



Conclusion

The `F_UINT_TO_ULINT` function block offers a simple and efficient way to convert 16-bit unsigned integers to 64-bit unsigned integers. Its simple structure and deterministic operation make it a reliable function block for systems with mixed word widths.

F_UINT_TO_USINT

• – ◦ • – ◦ • – ◦ •

The function block `F_UINT_TO_USINT` converts an unsigned 16-bit integer value (UINT) to an unsigned 8-bit integer value (USINT). This block is part of the `iec61131::conversion` library and implements a simple type conversion.

- **REQ**: Starts the conversion process. This input is linked to the data input `IN`.
- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.
- **IN** (UINT): The unsigned 16-bit integer value to be converted.
- **OUT** (USINT): The resulting unsigned 8-bit integer value after conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapters.

When the `REQ` event is triggered, the algorithm that converts the `IN` value from UINT to USINT is executed and outputs the result to `OUT`. The `CNF` event is then triggered to signal the successful completion of the operation. The conversion is performed by truncating the higher-order bits if the input value exceeds the USINT range.

- **Value Range Handling**: Since USINT can only represent values from 0 to 255, higher-order bits are discarded for input values outside this range. This can lead to data loss.
- **Deterministic Behavior**: The conversion is performed in a single execution step without state management.

The function block is stateless and re-executes the conversion with each `REQ` event.

- **Data Reduction**: Use in systems where storage space is limited and data size reduction is required.
- **F_UINT_TO_SINT**: Converts UINT to a signed 8-bit integer (SINT), handling the value range differently.
- **F_UINT_TO_INT**: Retains the 16-bit size but converts to a signed type.

F_UINT_TO_USINT` is a simple and efficient function block for converting 16-bit to unsigned 8-bit data. Its use is ideal in scenarios where a space-saving representation is required; however, the possibility of data loss with large input values should be considered.

Conclusion

F_UINT_TO_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_UINT_TO_WORD` converts an unsigned 16-bit integer value (UINT) into a 16-bit word (WORD). This conversion is particularly necessary in scenarios where data needs to be exchanged between different representation formats or systems.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs
- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs
- **IN**: The UINT value to be converted.

Data Outputs
- **OUT**: The converted WORD value.

Adapters
- No adapters available.

Functionality
The function block performs the conversion by converting the UINT value of `IN` into a WORD using the function `UINT_TO_WORD` and outputting the result to `OUT`. The conversion is triggered by the event `REQ` and confirmed by `CNF`.

Technical Features
- The conversion is performed directly without any additional processing.
- The function block is deterministic and has no internal states.

State Overview
The function block has no internal states. Execution occurs immediately upon receiving the `REQ` event.

Application Scenarios
- Data conversion in control systems.
- Communication between systems that use different data types.
- Integration of legacy systems that require WORD data types.

⚖️ Comparison with Similar Function Blocks
- Compared to other conversion blocks such as `F_INT_TO_WORD` or `F_BYTE_TO_WORD`, `F_UINT_TO_WORD` is specifically designed for converting unsigned 16-bit integers.
- The function block has a simpler structure than generic conversion blocks that support multiple data types.

Conclusion
The `F_UINT_TO_WORD` function block offers an efficient and direct solution for converting UINT to WORD values. Its simplicity and determinism make it a reliable choice for control and communication applications.

ULINT

F_ULINT_AS_STRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_AS_STRING` converts a `ULINT` value (64-bit unsigned integer) into a `STRING` value. This functionality is particularly useful when numeric values are needed as strings for output, logging, or further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (`ULINT`): The 64-bit unsigned integer value to be converted.

Data Outputs

- **OUT** (`STRING`): The result string after the conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion when the event `REQ` is received. The `ULINT` value at input `IN` is converted to `STRING` and output at `OUT`. Successful conversion is signaled by the event `CNF`.

Technical Features

- The function block has a simple structure and contains only one algorithm that performs the conversion.
- The conversion is performed directly without additional parameters or complex logic.

State Overview

The function block has no internal states. The conversion is performed anew with each `REQ` event.

Application Scenarios

- **Logging**: Conversion of numeric values for output to log files.
- **User Interfaces**: Display of numeric values as text in user interfaces.
- **Data Communication**: Preparation of numeric values for transmission as strings.

⚖️ Comparison with similar building blocks

- **F_INT_AS_STRING**: Converts a `INT` value to a `STRING` value. In contrast, `F_ULINT_AS_STRING` supports the larger `ULINT` data type.
- **F_DINT_AS_STRING**: Converts a `DINT` value to a `STRING` value. Similar, but for 32-bit signed integers.

Conclusion

The function block `F_ULINT_AS_STRING` offers a simple and efficient way to convert `ULINT` values to `STRING` values. Its clear interface and direct functionality make it ideal for applications requiring such a conversion.

F_ULINT_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_AS_WSTRING` converts an unsigned 64-bit integer value (`ULINT`) into a Unicode string (`WSTRING`). This functionality is particularly useful in scenarios where numeric values are needed for display or further processing as text.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN**: The unsigned 64-bit integer value (`ULINT`) to be converted to a Unicode string.

Data Outputs

- **OUT**: The resulting Unicode string (`WSTRING`) after the conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion when the event `REQ` is triggered. The value at input `IN` is converted into a Unicode string using the function `ULINT_AS_WSTRING` and output at `OUT`. The event `CNF` signals the successful completion of the conversion.

Technical Features

- Uses the function `ULINT_AS_WSTRING` for the conversion.
- Supports the full value range of `ULINT` (0 to 18,446,744,073,709,551,615).

State Overview

- **Idle**: Waits for the `REQ` event.
- **Converting**: Performs the conversion and outputs the result via `CNF`.

Application Scenarios

- Displaying large numeric values in user interfaces.
- Logging numeric data in text format.
- Preparing data for communication with systems that expect string data.

⚖️ Comparison with Similar Function Blocks

- Compared to `F_INT_AS_WSTRING` or `F_DINT_AS_WSTRING`, this function block supports the larger value range of `ULINT`.
- Similar to `F_ULINT_TO_WSTRING`, but with direct conversion without additional formatting options.

Conclusion

The `F_ULINT_AS_WSTRING` function block offers a simple and efficient way to convert large unsigned integer values into Unicode strings. Its clear interface and reliable functionality make it a valuable component in the 4diac IDE.

F_ULINT_TO_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_TO_BYTE` converts a 64-bit unsigned integer value (ULINT) to an 8-bit unsigned integer value (BYTE). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. It is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. Linked to the data output `OUT`.

Data Inputs

- **IN** (ULINT): The 64-bit unsigned integer value to be converted.

Data Outputs

- **OUT** (BYTE): The resulting 8-bit unsigned integer value after conversion.

Adapters

No adapters available.

Functionality

This function block performs the ULINT to BYTE conversion when the `REQ` event is triggered. The conversion is performed using the function `ULINT_TO_BYTE(IN)`. After successful conversion, the `CNF` event is triggered, and the converted value is available at output `OUT`.

Technical Features

- The function block is a simple algorithm without state management.
- Data loss can occur during conversion if the ULINT value is outside the representable range of a BYTE (0 to 255).

State Overview

Because it is a simple function block, there are no state transitions or complex state logic.

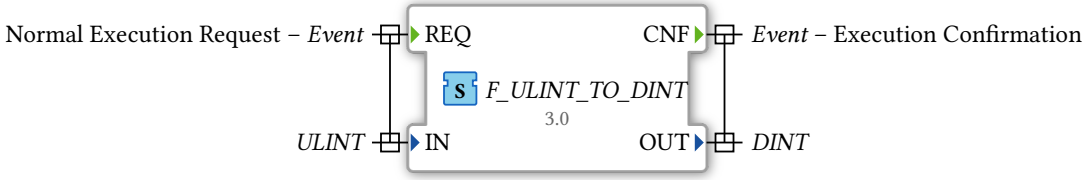
Application Scenarios

- Type conversion in control applications where ULINT values need to be reduced to BYTEs.
- Data processing in embedded systems with limited memory capacity.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_DINT_TO_BYTE` or `F_UINT_TO_BYTE` perform similar conversions, but with different output data types.
- `F_ULINT_TO_BYTE` is specifically for converting 64-bit unsigned integers to 8-bit unsigned integers.

Conclusion



The `F_ULINT_TO_BYTE` function block provides a simple and efficient way to convert ULINT values to BYTE values. It is particularly useful in applications where data width reduction is required; however, potential data loss should be considered.

F_ULINT_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_TO_DINT` converts a `ULINT` value (64-bit unsigned integer) to a `DINT` value (32-bit signed integer). This conversion is particularly relevant in scenarios where data needs to be exchanged between systems with different data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN** (`ULINT`): The unsigned 64-bit value to be converted.

Data Outputs

- **OUT** (`DINT`): The result of the conversion as a signed 32-bit value.

Adapters

No adapters are present.

Functionality

When the `REQ` event is triggered, the algorithm is executed, converting the `ULINT` value at input `IN` to a `DINT` value and outputting the result at output `OUT`. Subsequently, the `CNF` event is triggered to signal the completion of the conversion.

Technical Details

- Data loss can occur if the original `ULINT` value is outside the representable range of `DINT` (i.e., greater than 2^{31}-1).
- The function block is part of the `iec61131::conversion` package.

State Overview

The function block has no internal states. The conversion occurs immediately upon receipt of the `REQ` event.

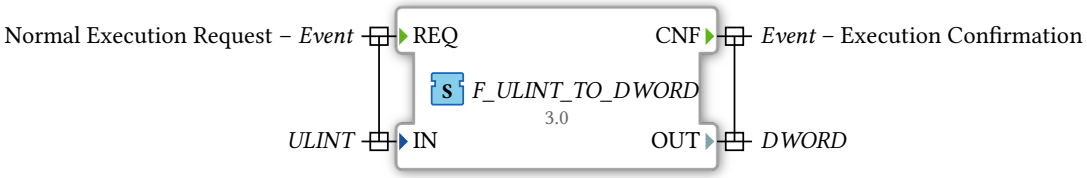
Application Scenarios

- Data conversion in control systems that use different data types.
- Integration of systems that use different bit widths for integers.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_ULINT_TO_DINT` specializes in converting `ULINT` to `DINT`.
- Other conversion blocks may support different data types or conversion directions.

Conclusion



The `F_ULINT_TO_DINT` function block offers a simple and efficient way to convert unsigned 64-bit values to signed 32-bit values. Its use is beneficial in scenarios with varying data type requirements; however, potential data loss during the conversion should be considered.

F_ULINT_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_TO_DWORD` converts a `ULINT` value (64-bit unsigned integer) to a `DWORD` value (32-bit unsigned integer). This block is part of the `iec61131::conversion` package and enables simple and efficient type conversion.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- **IN** (`ULINT`): The 64-bit unsigned integer value to be converted to `DWORD`.

Data Outputs

- **OUT** (`DWORD`): The resulting 32-bit unsigned integer value after the conversion.

Adapters

This function block does not use any adapters.

Operation

The function block performs the conversion as soon as the `REQ` event is received. The `ULINT` value at input `IN` is converted to a `DWORD` value and output `OUT`. The conversion is confirmed by the `CNF` event.

Technical Features

- Data loss can occur if the `ULINT` value is greater than the maximum representable value of a `DWORD` (2^{32} - 1).
- The function block is implemented as a simple FB (`SimpleFB`) and uses an ST algorithm for the conversion.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Conversion**: Performs the conversion and outputs the result via `OUT`.
3. **Acknowledgement**: Sends the `CNF` event and returns to the idle state.

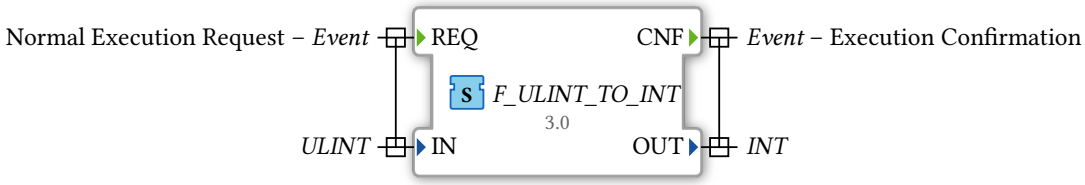
Application Scenarios

- Type conversion in control applications where 64-bit values need to be converted to 32-bit values.
- Data processing in systems with different word lengths.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_DINT_TO_DWORD` or `F_LINT_TO_DWORD` offer conversions between other data types, but not specifically from `ULINT` to `DWORD`.
- Unlike generic conversion blocks, this one is specialized and optimized for the `ULINT` to `DWORD` conversion.

Conclusion



The `F_ULINT_TO_DWORD` function block provides a simple and efficient solution for converting 64-bit unsigned integers to 32-bit unsigned integers. Its clear interface structure and simple functionality make it ideal for applications that require such type conversions. However, be aware of the potential for data loss with large input values.

F_ULINT_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_TO_INT` converts a 64-bit unsigned integer value (ULINT) into a 16-bit signed integer value (INT). This conversion is particularly necessary when data needs to be exchanged between systems with different data types.

Interface Structure

Event Inputs

- **REQ**: This input triggers the conversion. Upon arrival of this event, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: This event signals the completion of the conversion. It is output along with the converted value at data output `OUT`.

Data Inputs

- **IN** (ULINT): This input provides the 64-bit unsigned integer value to be converted.

Data Outputs

- **OUT** (INT): This output provides the converted 16-bit signed integer value.

Adapters

This function block does not have any adapters.

Functionality

The function block performs the conversion from ULINT to INT as soon as the event `REQ` occurs. The conversion is performed using the function `ULINT_TO_INT(IN)`, which converts the value of `IN` to the target type `INT`. After successful conversion, the event `CNF` is triggered, and the converted value is output to `OUT`.

Technical Features

- **Data Type Conversion**: Converting ULINT (64-bit) to INT (16-bit) can result in data loss if the original value is outside the representable range of INT (i.e., greater than 32767 or less than −32768).
- **Simple Implementation**: The function block is implemented as a SimpleFB and uses a simple ST algorithm for the conversion.

State Overview

1. **Idle State**: The function block waits for the event `REQ`.
2. **Conversion State**: The conversion is performed upon receipt of `REQ`.
3. **Acknowledge State**: After the conversion, `CNF` is triggered, and the function block returns to the idle state.

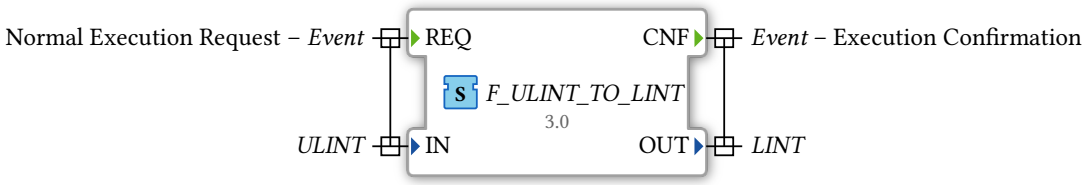
Application Scenarios

- **Data Compatibility**: Used when systems need to communicate with different data types.
- **Data Reduction**: Can be used to save memory when the higher precision of ULINT is not required.

⚖️ Comparison with Similar Blocks

- **F_ULINT_TO_DINT**: Converts ULINT to DINT (32-bit), offering a larger value range than INT.
- **F_ULINT_TO_LINT**: Converts ULINT to LINT (64-bit), maintaining full precision.

Conclusion



The function block `F_ULINT_TO_INT` is a simple yet effective tool for converting 64-bit unsigned integer values to 16-bit signed integer values. It is particularly useful in scenarios where memory efficiency or compatibility with older systems is required. However, be aware of potential data loss when converting large values.

F_ULINT_TO_LINT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_ULINT_TO_LINT` converts an unsigned 64-bit integer value (ULINT) to a signed 64-bit integer value (LINT). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (ULINT): The unsigned 64-bit integer value to be converted.

Data Outputs

- **OUT** (LINT): The resulting signed 64-bit integer value after conversion.

Adapters

- No adapters are available.

Functionality

The function block performs the conversion by transforming the value of input `IN` from type `ULINT` to type `LINT`. The conversion is performed directly and without further processing. The result is output at `OUT` as soon as the event `CNF` is triggered.

Technical Features

- The conversion is performed using the function `ULINT_TO_LINT`, which is implemented in the function block's algorithm.
- The block is suitable for use in real-time systems because it does not involve any delays or complex calculations.

State Overview

The function block has no internal states. The conversion is performed and immediately acknowledged each time the `REQ` event occurs.

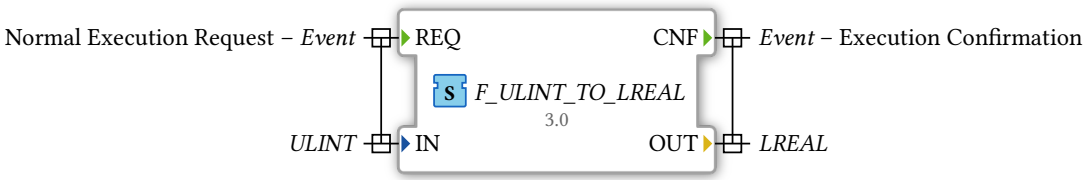
Application Scenarios

- Type conversion in control and automation systems.
- Data processing in industrial applications where unsigned and signed values need to be processed.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks, such as `F_DINT_TO_INT`, this one is specifically designed for 64-bit data types.
- Similar blocks might include additional features like range checks or error handling, which is not the case here.

Conclusion



The `F_ULINT_TO_LINT` function block is a simple and efficient tool for converting between the data types `ULINT` and `LINT`. Its simplicity makes it reliable and easy to integrate into existing systems.

F_ULINT_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_TO_LREAL` converts a `ULINT` value (64-bit unsigned integer) to a `LREAL` value (64-bit floating point). This conversion is particularly necessary in scenarios where integer values need to be converted to floating-point numbers for further calculations.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- `IN` (`ULINT`): The input value to be converted.

Data Outputs

- `OUT` (`LREAL`): The converted output value.

Adapters

No adapters available.

Functionality

The function block performs the conversion from `ULINT` to `LREAL` when the `REQ` event is triggered. The conversion is carried out using the built-in function `ULINT_TO_LREAL`. After the conversion is complete, the `CNF` event is triggered, and the converted value is made available at output `OUT`.

Technical Features

- The function block has a simple structure and contains only one algorithm (`REQ`) that performs the conversion.
- The conversion is lossless because `LREAL` covers a larger range of values than `ULINT`.

State Overview

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

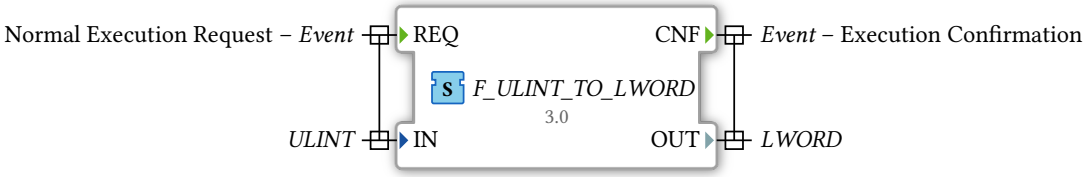
Application Scenarios

- Conversion of integer values to floating-point numbers for further calculations.
- Use in control systems where floating-point operations are required.

⚖️ Comparison with Similar Blocks

- Compared to other conversion blocks (e.g., `F_INT_TO_REAL`), this one is specifically optimized for converting 64-bit unsigned integers to 64-bit floating points.
- Similar blocks may have lower precision or a smaller range of values.

Conclusion



The `F_ULINT_TO_LREAL` function block offers a simple and efficient way to convert `ULINT` values to `LREAL` values. Its clear interface and lossless conversion make it a useful component in various applications.

F_ULINT_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_TO_LWORD` converts a ULINT data type (64-bit unsigned integer) to an LWORD data type (64-bit bit string). This block is particularly useful in applications where direct type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. When activated, the input value `IN` is read and processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output value `OUT` is available at this time.

Data Inputs

- **IN**: ULINT (64-bit unsigned integer) - The input value to be converted to an LWORD.

Data Outputs

- **OUT**: LWORD (64-bit bit string) - The result of the conversion.

Adapters

This function block does not use any adapters.

Functionality

The function block performs the conversion by transforming the ULINT input value `IN` into an LWORD output value `OUT`. The conversion is performed directly without any further processing. When the event input `REQ` is activated, the algorithm is executed and the result is signaled via the event output `CNF`.

Technical Features

- The conversion is direct and without data loss, as both data types are 64 bits wide.
- The function block is deterministic and has no internal states.

State Overview

The function block has no internal states. Execution occurs immediately upon activation of the `REQ` event.

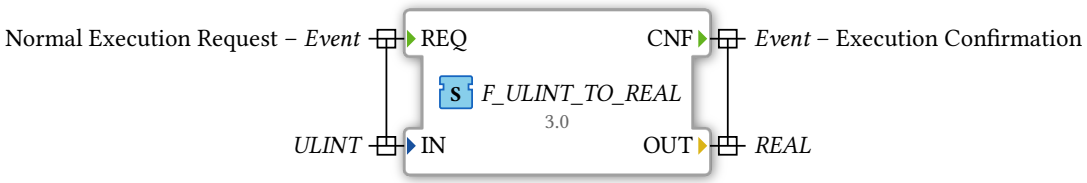
Application Scenarios

- Type conversion in control applications where ULINT values must be processed as bit strings.
- Communication between systems that use different data types.
- Debugging and logging where bit representations of numeric values are required.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks like `F_DINT_TO_LWORD` or `F_UDINT_TO_LWORD`, this block works with the larger ULINT data type.
- Similar blocks might offer additional features like scaling or formatting, but this block specializes in pure type conversion.

Conclusion



The `F_ULINT_TO_LWORD` function block is a simple and efficient block for directly converting ULINT to LWORD. Its deterministic and stateless nature makes it reliable and easy to integrate into existing applications.

F_ULINT_TO_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_TO_REAL` converts a `ULINT` value (64-bit unsigned integer) to a `REAL` value (32-bit floating-point number). This block is particularly useful in scenarios where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `ULINT`, which is to be converted to a `REAL` value.

Data Outputs

- **OUT**: The output value of type `REAL`, representing the result of the conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is triggered. The algorithm within the function block uses the function `ULINT_TO_REAL` to convert the value `ULINT` into a value `REAL`. The result is output via the data output `OUT`, and the event `CNF` signals successful execution.

Technical Features

- The function block is part of the package `iec61131::conversion`.
- Supports the conversion of 64-bit unsigned integers to 32-bit floating-point numbers.
- Simple and direct implementation without additional parameters or complex logic.

State Overview

The function block has a simple state machine:

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Complete**: Sends the `CNF` event and outputs the result.

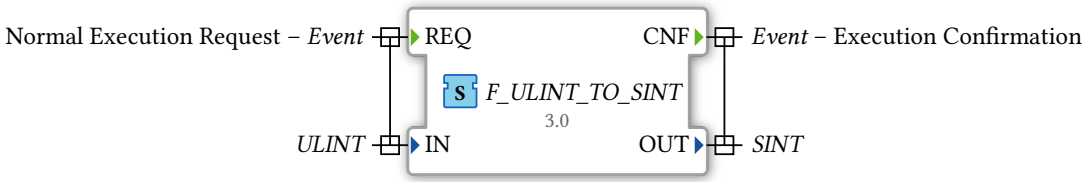
Application Scenarios

- Data processing in control systems where type conversion is required.
- Integration into larger control algorithms that perform floating-point calculations with values originally stored as integers.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_DINT_TO_REAL` or `F_LINT_TO_REAL` offer conversions from other integer types to `REAL`, but with different input sizes and precisions.
- `F_ULINT_TO_REAL` is specifically optimized for 64-bit unsigned integers.

Conclusion



The `F_ULINT_TO_REAL` function block is a simple yet essential building block for type conversion in IEC 61499-based control systems. Its clear interface and efficient operation make it a reliable solution for conversion tasks.

F_ULINT_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_ULINT_TO_SINT` converts a `ULINT` value (64-bit unsigned integer) to a `SINT` value (8-bit signed integer). This block is particularly useful in applications where type conversion between these two data types is required.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs
- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.

Data Inputs
- **IN**: The input expects a `ULINT` value to be converted.

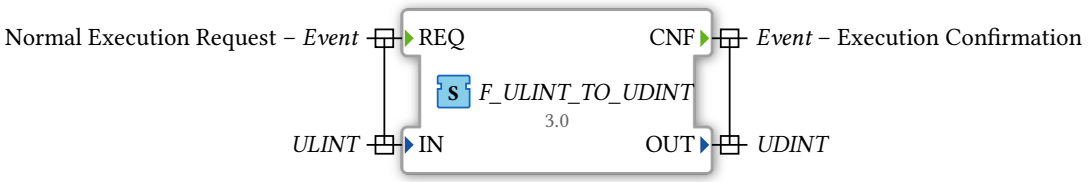
Data Outputs
- **OUT**: The output provides the converted `SINT` value.

Adapters
No adapters are present.

Functionality
The function block performs the conversion as soon as the `REQ` event is triggered. The algorithm converts the `ULINT` value to `IN` and stores the result in `OUT`. The event `CNF` is then triggered to signal the completion of the operation.

Technical Details
- The conversion is performed directly by the function `ULINT_TO_SINT`.
- Note that data loss can occur when converting from a larger to a smaller data type if the `ULINT` value is outside the representable range of `SINT`.

State Overview
The function block has no internal state. The conversion is performed on every `REQ` event.



Application Scenarios
- Type conversion in control applications
- Data processing where different data types need to be handled
- Communication between systems with different data types

⚖️ Comparison with Similar Function Blocks
- Similar function blocks like `F_DINT_TO_SINT` or `F_LINT_TO_SINT` perform similar conversions, but with different output data types.
- `F_ULINT_TO_SINT` is specifically for converting `ULINT` to `SINT`.

Conclusion
The `F_ULINT_TO_SINT` function block provides a simple and efficient way to convert `ULINT` values to `SINT` values. It is particularly useful in applications where type conversion is required; however, potential data loss during the conversion should be considered.

F_ULINT_TO_UDINT
• – ◦ • – ◦ • – ◦ •

Introduction
The function block `F_ULINT_TO_UDINT` converts a 64-bit unsigned integer value (ULINT) to a 32-bit unsigned integer value (UDINT). This conversion is useful when exchanging data between systems or components that use different data types.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. It is linked to the data input `IN`.

Event Outputs
- **CNF**: Signals the completion of the conversion. Linked to the data output `OUT`.

Data Inputs
- **IN**: ULINT (64-bit unsigned integer) - The input value to be converted.

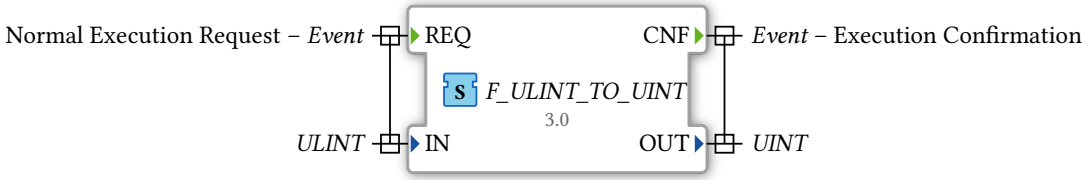
Data Outputs
- **OUT**: UDINT (32-bit unsigned integer) - The converted output value.

Adapters
No adapters are available.

Functionality
This function block performs a direct conversion of a ULINT value to a UDINT value. The conversion is carried out by calling the function `ULINT_TO_UDINT` within the algorithm `REQ`. During the conversion, the 64-bit value is truncated to 32 bits. Note that data loss can occur if the original value is greater than the maximum value of a UDINT.

Technical Features
- The function block is simple and has no internal states.
- The conversion is performed by a single algorithm (`REQ`) that is executed with each call to the `REQ` event.
- There is no overflow error handling. The user must ensure that the input value is within the valid range for UDINT.

State Overview
Since the function block is stateless, there are no state transitions or internal states.



Application Scenarios
- Data conversion in control systems where different data types are used.
- Reduced memory requirements when 64-bit values are not needed.
- Compatibility with older systems that only support 32-bit values.

⚖️ Comparison with Similar Function Blocks
- **F_ULINT_TO_INT**: Converts ULINT to INT (signed integer), taking the sign into account.
- **F_ULINT_TO_LINT**: Converts ULINT to LINT (64-bit signed integer), which does not reduce the data size but does change the sign.
- **F_UDINT_TO_ULINT**: Reverse conversion from UDINT to ULINT, which does not result in any data loss.

Conclusion
The `F_ULINT_TO_UDINT` function block is a simple and efficient tool for converting 64-bit unsigned integer values to 32-bit unsigned integer values. It is particularly useful in scenarios where memory efficiency or compatibility with older systems is required. However, users should be careful to avoid overflows, as the function block does not offer automatic error handling.

F_ULINT_TO_UINT
• − ◦ • − ◦ • − ◦ •

The function block `F_ULINT_TO_UINT` converts a 64-bit unsigned integer value (ULINT) to a 16-bit unsigned integer value (UINT). This block is part of the `iec61131::conversion` package and implements a simple type conversion.

- **REQ**: Starts the conversion process. This input is connected to the data input `IN`.
- **CNF**: Signals the completion of the conversion. The output is connected to the data output `OUT`.
- **IN**: ULINT (64-bit unsigned integer) - The input value to be converted.
- **OUT**: UINT (16-bit unsigned integer) - The result of the conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters are present.

Functionality

The function block performs the conversion from ULINT to UINT when the `REQ` event occurs. The conversion is carried out using the function `ULINT_TO_UINT`. After the conversion is complete, the `CNF` event is triggered.

- The function block performs a direct type conversion, truncating the higher-order bits of the ULINT value if the value is outside the UINT range.
- The function block is deterministic and has no internal states.

The function block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

- Type conversion in control applications where ULINT values need to be reduced to UINT.
- Data processing in embedded systems with limited memory capacity.
- Compared to generic conversion function blocks, `F_ULINT_TO_UINT` is specialized and optimized for the specific conversion of ULINT to UINT.

Other function blocks might offer additional functionalities such as range checks or scaling, which is not the case here.

The `F_ULINT_TO_UINT` function block is a simple and efficient building block for converting 64-bit unsigned integer values to 16-bit unsigned integer values. It is particularly useful in applications where direct and fast type conversion is required.

Technical Features

Conclusion

F_ULINT_TO_USINT

• – ◦ • – ◦ • – ◦ •

The function block F_ULINT_TO_USINT converts a 64-bit unsigned integer value (ULINT) to an 8-bit unsigned integer value (USINT). This block is particularly useful in scenarios where type conversion between these two data types is required.

- **REQ**: Starts the execution of the function block. Connected to the data input IN.
- **CNF**: Signals successful completion of the conversion. Connected to the data output OUT.
- **IN**: The input value of type ULINT (64-bit unsigned integer) to be converted.
- **OUT**: The output value of type USINT (8-bit unsigned integer) containing the result of the conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapters.

When the event REQ is triggered, the algorithm is executed, converting the value of IN of type ULINT to type USINT and outputting the result to OUT. The event CNF is then triggered to signal the successful completion of the operation.

- The conversion truncates the value of ULINT to the size of USINT. It is important to ensure that the input value is within the range of USINT (0 to 255) to avoid unexpected results.

The function block has a simple state machine:

1. **Idle**: Waits for the REQ event.
2. **Processing**: Performs the conversion and triggers CNF.

- Type conversion in control systems where data is in different formats.
- Reducing data storage size when only small value ranges are needed.
- Similar function blocks such as F_DINT_TO_INT or F_LREAL_TO_REAL perform similar type conversions, but for different data types.

Unlike generic conversion blocks, F_ULINT_TO_USINT is specialized and optimized for converting between ULINT and USINT.

The F_ULINT_TO_USINT function block provides an efficient and simple way to convert values from ULINT to USINT. Its clear interface and simple operation make it a useful building block in IEC 61131 programming.

Conclusion

F_ULINT_TO_WORD

• – ◦ • – ◦ • – ◦ •

The function block `F_ULINT_TO_WORD` converts a 64-bit unsigned integer value (ULINT) to a 16-bit unsigned integer value (WORD). This block is part of the `iec61131::conversion` package and implements a simple type conversion.

- **REQ**: Starts the conversion process. This input is connected to the data input `IN`.
- **CNF**: Signals successful completion of the conversion. The output is connected to the data output `OUT`.
- **IN**: ULINT (64-bit unsigned integer) - The input value to be converted.
- **OUT**: WORD (16-bit unsigned integer) - The result of the conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters are available.

Functionality

This function block performs the conversion from ULINT to WORD when the `REQ` event occurs. The conversion is carried out using the built-in function `ULINT_TO_WORD`. After successful conversion, the `CNF` event is triggered.

- The block does not support overflow error handling (since ULINT has a larger value range than WORD).
- The conversion is instantaneous and without any additional delay.

The block has no internal states. The conversion occurs immediately upon receiving the `REQ` event.

- Type conversion in control applications where ULINT values need to be converted to WORD values.
- Data reduction when only the lower 16 bits of a ULINT value are relevant.
- Similar blocks such as `F_DINT_TO_WORD` or `F_LINT_TO_WORD` offer conversions from other integer types to WORD, but with different value ranges and precision.

The `F_ULINT_TO_WORD` function block is a simple and efficient tool for converting ULINT to WORD values. It is particularly useful in scenarios where data width reduction is required. However, be aware of the potential data loss when converting from larger to smaller data types.

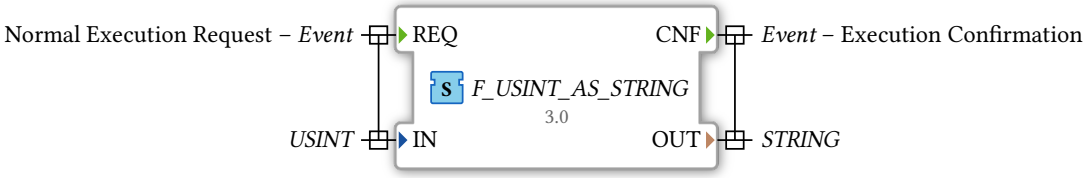
Conclusion

ULINT Conversions



Here you will find functions for converting the ULINT data type.

USINT

F_USINT_AS_STRING

• – ◦ • – ◦ • – ◦ •

The function block `F_USINT_AS_STRING` converts an unsigned 8-bit integer value (USINT) into a string (STRING). This functionality is particularly useful when numeric values need to be converted into a readable text format for display or logging.

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.
- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.
- **IN**: An unsigned 8-bit integer value (USINT) to be converted to a string.
- **OUT**: The resulting string (STRING) containing the converted value.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- No adapters are present.

Functionality

When the event input `REQ` is triggered, the algorithm is executed, converting the USINT value `IN` to a string and outputting the result to `OUT`. The event `CNF` is then triggered to signal the successful completion of the operation.

- The function block uses the function `USINT_AS_STRING` for conversion.
- It is a simple function block without a state machine or complex logic.

Since it is a simple function block, there are no state transitions or management. The operation is executed on each `REQ` event and acknowledged with `CNF`.

- Displaying numerical values on a control panel.
- Logging measured values to a text file or database.
- Preparing data for communication via text protocols (e.g., HTTP, MQTT).

- Compared to generic conversion blocks, `F_USINT_AS_STRING` specializes in converting USINT to STRING and is therefore more efficient in this specific application.
- Other blocks might offer additional options such as formatting or locale settings, which is not the case here.

The `F_USINT_AS_STRING` function block is a simple and efficient tool for converting unsigned 8-bit integers to strings. Its simplicity makes it particularly suitable for applications where performance and reliability are paramount.

Conclusion

F_USINT_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_AS_WSTRING` converts an unsigned 8-bit integer value (`USINT`) into a Unicode string (`WSTRING`). This functionality is particularly useful in scenarios where numeric values need to be output or processed as text.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at data output `OUT`.

Data Inputs

- **IN**: An unsigned 8-bit integer value (`USINT`) to be converted to a Unicode string.

Data Outputs

- **OUT**: The resulting Unicode string (`WSTRING`) after the conversion.

Adapters

- No adapters are available.

Operation

The function block performs the conversion as soon as the event `REQ` is triggered. The input value `IN` is taken and converted into a Unicode string using the function `USINT_AS_WSTRING`. The result is output `OUT`, and the event `CNF` signals successful execution.

Technical Features

- Uses the built-in function `USINT_AS_WSTRING` for conversion.
- Supports the full value range of `USINT` (0 to 255).

State Overview

1. **Idle**: Waits for the event `REQ`.
2. **Conversion**: Processes the input value and generates the output.
3. **Acknowledgement**: Sends the event `CNF` and returns to the idle state.

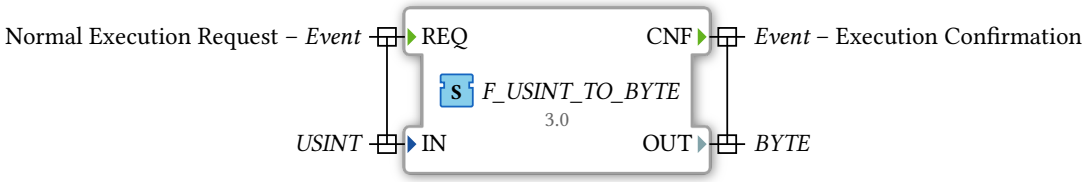
Application Scenarios

- Displaying numeric values in user interfaces.
- Logging numeric data to text files.
- Communicating with systems that expect text data.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_USINT_AS_WSTRING` specializes in converting `USINT` to `WSTRING`.
- Other blocks might support different data types or additional formatting options.

Conclusion



The `F_USINT_AS_WSTRING` function block provides a simple and efficient way to convert unsigned 8-bit integer values to Unicode strings. Its clear interface and direct functionality make it ideal for projects that require such conversions.

F_USINT_TO_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_TO_BYTE` converts an unsigned 8-bit integer value (USINT) into a byte value (BYTE). This conversion is particularly necessary in scenarios where data needs to be exchanged between different formats or systems.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `USINT` (unsigned 8-bit integer) to be converted to a `BYTE` value.

Data Outputs

- **OUT**: The output value of type `BYTE`, representing the result of the conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion as soon as the event `REQ` is received. The input value `IN`, of type `USINT`, is converted to a value of `BYTE` and output `OUT`. The event `CNF` signals the successful completion of the conversion.

Technical Features

- The conversion is performed directly without any additional processing steps.

- The block is suitable for use in real-time systems because it does not perform any time-critical operations.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Conversion**: Performs the conversion and outputs the result via `OUT`.
3. **Confirmation**: Sends the `CNF` event to confirm successful conversion.

Application Scenarios

- Data conversion in control systems.
- Communication between systems with different data types.
- Preprocessing of sensor data.

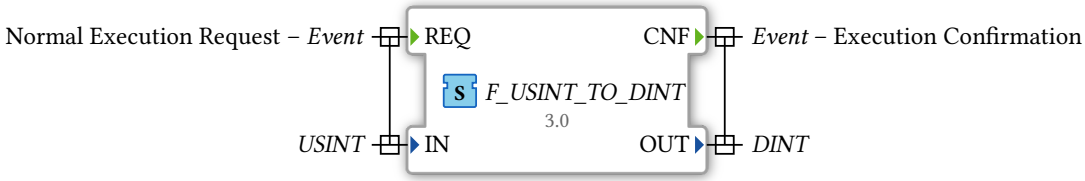
⚖️ Comparison with similar function blocks

- **F_BYTE_TO_USINT**: Performs the reverse conversion (BYTE to USINT).
- **F_INT_TO_STRING**: Converts an integer value to a string, but is more complex to handle.

🛠️ Related Exercises

- Exercise_126b_sub

Conclusion



The `F_USINT_TO_BYTE` function block is a simple and efficient tool for converting `USINT` values to `BYTE` values. Its clear interface structure and direct functionality make it ideal for use in various industrial applications.

F_USINT_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_TO_DINT` converts a `USINT` value (8-bit unsigned integer) to a `DINT` value (32-bit signed integer). This conversion is useful when values need to be converted between different data types, especially when an extension of the bit width is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event is triggered, the value of `IN` is converted to `OUT`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event is output along with the updated value of `OUT`.

Data Inputs

- **IN** (`USINT`): The input value to be converted.

Data Outputs

- **OUT** (`DINT`): The converted output value.

Adapters

No adapters available.

Functionality

The function block directly assigns the input value `IN` (of type `USINT`) to the output `OUT` (of type `DINT`). Since `DINT` has a larger bit width than `USINT`, the value is extended without data loss.

The algorithm is triggered by the `REQ` event and outputs the `CNF` event after the conversion.

Technical Features

- The function block is deterministic and has no internal state.
- The conversion is lossless, as `DINT` can represent all values of `USINT`.

State Overview

The function block has no internal states. Execution occurs immediately after the `REQ` event is triggered.

Application Scenarios

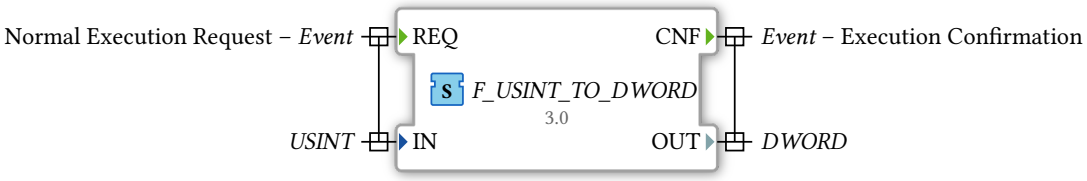
- Extension of 8-bit unsigned values to 32-bit signed values in control applications.
- Compatibility between different parts of a control system that use different data types.

⚖️ Comparison with Similar Function Blocks

- Compared to `F_SINT_TO_DINT` or `F_INT_TO_DINT`, this function block handles only unsigned 8-bit values.

Similar conversion blocks exist for other data types, such as `F_BOOL_TO_INT` or `F_REAL_TO_LREAL`.

Conclusion



The `F_USINT_TO_DINT` function block is a simple and efficient building block for converting 8-bit unsigned integer values to 32-bit signed integer values. It is particularly useful in scenarios where type extension without data loss is required.

F_USINT_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_TO_DWORD` converts a `USINT` value (8-bit unsigned integer) to a `DWORD` value (32-bit unsigned integer). This conversion is particularly useful when data needs to be exchanged or processed between systems with different word lengths.

Interface Structure

Event Inputs

- `REQ` (Normal Execution Request): Starts the conversion. This input is connected to the data input `IN`.

Event Outputs

- `CNF` (Execution Confirmation): Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs

- `IN` (USINT): The input value to be converted. The data type is `USINT` (8-bit unsigned integer).

Data Outputs

- `OUT` (DWORD): The converted output value. The data type is `DWORD` (32-bit unsigned integer).

Adapters

No adapters available.

Functionality

The function block performs the conversion from `USINT` to `DWORD` as soon as the event `REQ` is triggered. The algorithm `REQ` uses the function `USINT_TO_DWORD` to convert the input value `IN` to the output value `OUT`. After successful conversion, the event `CNF` is triggered.

Technical Features

- The function block has a simple structure and contains only one algorithm.
- The conversion is performed without data loss because the `DWORD` data type covers a larger value range than `USINT`.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Conversion State**: Performs the conversion.
3. **Acknowledgement State**: Triggers the `CNF` event and returns to the idle state.

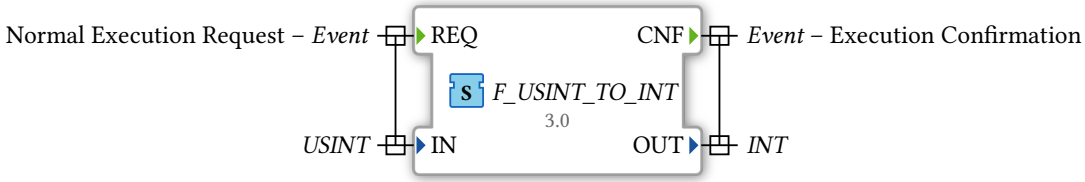
Application Scenarios

- Data conversion in control systems that use different word lengths.
- Integration of peripheral devices that deliver data in different formats.
- Data processing in industrial automation solutions.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_BYTE_TO_DWORD` or `F_WORD_TO_DWORD` offer conversions between other data types.
- `F_USINT_TO_DWORD` specializes in converting 8-bit unsigned integers to 32-bit unsigned integers.

Conclusion



The `F_USINT_TO_DWORD` function block is a simple and efficient tool for converting `USINT` values to `DWORD` values. Its clear interface structure and simple functionality make it a reliable solution for data conversion tasks in industrial automation systems.

F_USINT_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_TO_INT` converts an unsigned 8-bit integer value (USINT) to a signed 16-bit integer value (INT). This block is part of the `iec61131::conversion` package and enables simple type conversion between these two data types.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN** (USINT): The unsigned 8-bit integer value to be converted.

Data Outputs

- **OUT** (INT): The resulting signed 16-bit integer value after the conversion.

Adapters

This function block does not use any adapters.

Operation

The function block performs the conversion by directly assigning the value of input `IN` to output `OUT`. The conversion occurs when event `REQ` is triggered and is confirmed by event `CNF`.

Technical Features

- **Simple Type Conversion**: The function block performs no additional processing or validation of the data.
- **Efficient Implementation**: The conversion is performed directly in an ST algorithm without additional logic.

State Overview

The function block has no internal states. The conversion occurs immediately upon the occurrence of the `REQ` event.

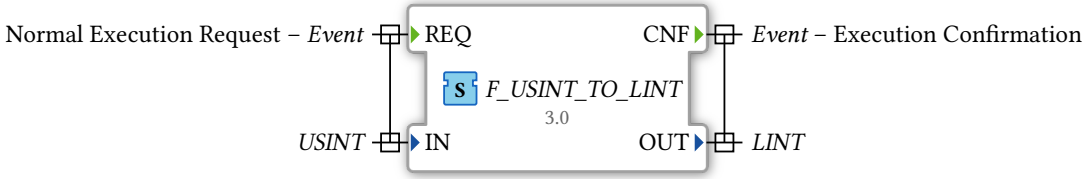
Application Scenarios

- **Type Conversion in Control Applications**: When an unsigned 8-bit value needs to be converted to a signed 16-bit value.
- **Data Compatibility**: In scenarios where different components expect different data types.

⚖️ Comparison with Similar Function Blocks

- **F_USINT_TO_UINT**: Converts USINT to UINT (unsigned 16-bit integer).
- **F_USINT_TO_DINT**: Converts USINT to DINT (signed 32-bit integer).
- **F_USINT_TO_UDINT**: Converts USINT to UDINT (unsigned 32-bit integer).

Conclusion



The `F_USINT_TO_INT` function block provides a simple and efficient way to convert unsigned 8-bit integer values to signed 16-bit integer values. It is particularly useful in applications where type conversion without additional processing is required.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_TO_LINT` converts a `USINT` value (8-bit unsigned integer) to a `LINT` value (64-bit signed integer). This conversion is particularly useful when values from smaller data types need to be converted to larger ones without losing the original information.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `USINT` to be converted.

Data Outputs

- **OUT**: The converted output value of type `LINT`.

Adapters

No adapters are available.

Functionality

This function block directly assigns the input value `IN` to the output value `OUT`. Since `USINT` is an 8-bit unsigned integer and `LINT` is a 64-bit signed integer, the value is converted to the larger data type without any change to the numeric value.

Technical Features

- **Algorithm**: The algorithm consists of a simple assignment (`OUT := IN;`).
- **Data Type Compatibility**: Since `USINT` is an unsigned data type and `LINT` is a signed data type, the value is implicitly extended without any data loss.

State Overview

The function block has no internal state. The conversion occurs immediately upon receiving the `REQ` event.

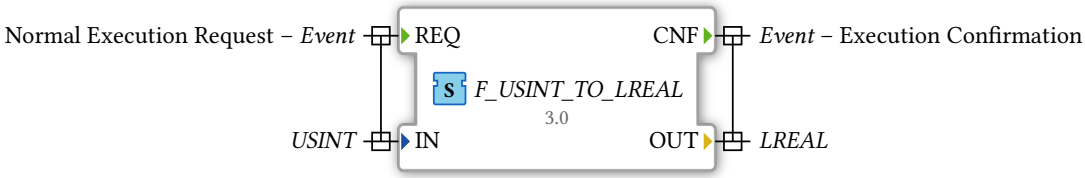
Application Scenarios

- **Data Processing**: When values need to be converted from smaller to larger data types.
- **Communication**: When transferring data between systems with different data type requirements.

⚖️ Comparison with Similar Function Blocks

- **F_USINT_TO_INT**: Converts `USINT` to `INT` (16-bit signed integer). In contrast, `F_USINT_TO_LINT` offers greater range due to its 64-bit output.
- **F_USINT_TO_ULINT**: Converts `USINT` to `ULINT` (64-bit unsigned integer). Here, the output is also treated as unsigned.

Conclusion



The `F_USINT_TO_LINT` function block is a simple yet effective building block for converting 8-bit unsigned integer values to 64-bit signed integer values. Its direct and lossless conversion makes it ideal for applications where preserving the numeric value in a larger data type is required.

F_USINT_TO_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_TO_LREAL` converts an unsigned 8-bit integer value (USINT) to a 64-bit floating-point value (LREAL). This conversion is particularly useful when data needs to be exchanged or processed between systems with different data types.

Interface Structure

Event Inputs

- `REQ`: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- `IN` (USINT): The input value to be converted.

Data Outputs

- `OUT` (LREAL): The converted output value.

Adapters

- No adapters are available.

Functionality

The function block performs a direct type conversion. Upon the arrival of a `REQ` event, the value of `IN` is converted to the LREAL data type and output to `OUT`. The `CNF` event is then triggered to signal the completion of the conversion.

Technical Features

- The conversion is performed without any additional scaling or adaptation.
- The block is optimized for simple type conversions and has no complex logic or state management.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

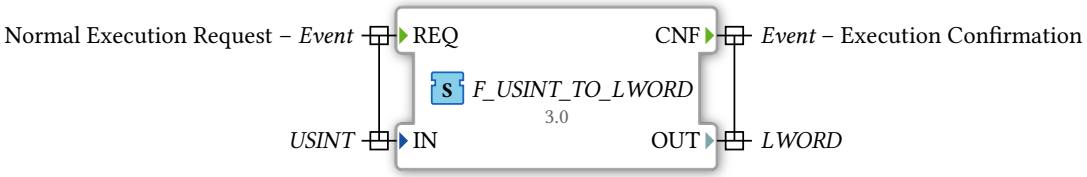
Application Scenarios

- Conversion of sensor data in USINT format for calculations requiring LREAL.
- Interfaces between systems with different data type requirements.
- Simple type conversions in automation applications.

⚖️ Comparison with similar blocks

- Compared to generic conversion blocks, `F_USINT_TO_LREAL` is specialized and therefore more efficient for this specific conversion.
- Other blocks might offer additional features such as scaling or range checks, which are not required here.

Conclusion



The `F_USINT_TO_LREAL` function block is a simple and efficient building block for the direct conversion of USINT to LREAL. Its strength lies in its simplicity and specialization, making it ideal for specific use cases where no additional logic is needed.

F_USINT_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_TO_LWORD` converts a `USINT` value (8-bit unsigned integer) to a `LWORD` value (64-bit unsigned integer). This conversion is useful when processing data with different bit lengths, especially in systems that require a uniform data width.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input `IN` is read and converted.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at the data output `OUT`.

Data Inputs

- **IN**: Expects a `USINT` value (8-bit unsigned integer) to be converted.

Data Outputs

- **OUT**: Returns the converted `LWORD` value (64-bit unsigned integer).

Adapters

This function block has no adapter interfaces.

Operation

The function block performs the conversion as soon as the `REQ` event is triggered. The algorithm reads the value of `IN`, converts it from `USINT` to `LWORD`, and provides the result to `OUT`. The `CNF` event is then triggered to signal the successful completion of the operation.

Technical Features

- The conversion is lossless because the `USINT` value is converted to the larger `LWORD` type.
- The function block is deterministic and has no internal state.

State Overview

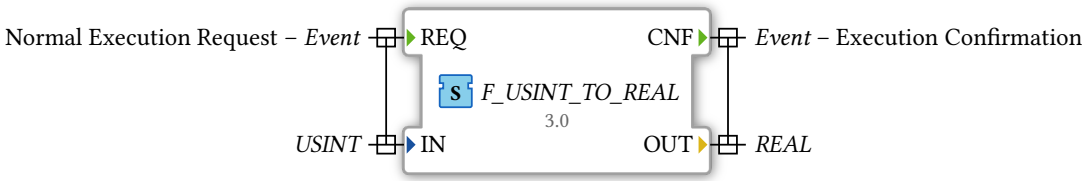
The function block has no internal state. Execution is purely event-driven, triggered by the `REQ` event.

Application Scenarios

- Data conversion in control systems where different data widths need to be processed.
- Integration into larger function block networks that require a uniform data width.

⚖️ Comparison with Similar Blocks

- Compared to other conversion blocks (e.g., `F_INT_TO_LWORD`), this one is specifically optimized for converting 8-bit unsigned integers.
- Similar blocks might offer additional features such as scaling or error handling, but this block is limited to pure conversion.



Conclusion

The `F_USINT_TO_LWORD` function block is a simple and efficient block for converting 8-bit unsigned integers to 64-bit unsigned integers. Its simplicity and determinism make it a reliable component in control systems.

F_USINT_TO_REAL

• – ◦ • – ◦ • – ◦ •

The function block `F_USINT_TO_REAL` converts an unsigned 8-bit integer value (USINT) into a 32-bit floating-point value (REAL). This conversion is particularly necessary in scenarios where numeric values of different data types need to be processed or used further.

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.
- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.
- **IN**: An unsigned 8-bit integer value (USINT) to be converted to a REAL value.
- **OUT**: The resulting 32-bit floating-point value (REAL) after the conversion.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapters.

The function block performs the conversion by directly converting the USINT value from `IN` to the REAL data type and outputting it to `OUT`. The conversion occurs synchronously upon receiving the `REQ` event and is confirmed by the `CNF` event.

- The conversion is performed without additional scaling or rounding.
- The block is optimized for simple conversions and does not provide error handling for invalid values.

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Completed**: Sends the `CNF` event and outputs the converted value.

- Conversion of sensor values (e.g., raw ADC data) into floating-point values for further calculations.
- Compared to generic conversion blocks, `F_USINT_TO_REAL` is specialized and therefore more efficient for this specific conversion.
- Other blocks, such as `F_INT_TO_REAL` or `F_DINT_TO_REAL`, are designed for other integer data types.

The `F_USINT_TO_REAL` function block is a simple and efficient function block for converting unsigned 8-bit integers to floating-point values. Its simplicity and direct operation make it ideal for applications requiring fast and reliable type conversion.

F_USINT_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_USINT_TO_SINT` converts an unsigned 8-bit integer value (USINT) to a signed 8-bit integer value (SINT). This block is particularly useful when exchanging data between systems that use different data types.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. When activated, the input value `IN` is processed.

Event Outputs
- **CNF**: Signals the completion of the conversion. The output value `OUT` is then available.

Data Inputs
- **IN** (USINT): The unsigned 8-bit integer value to be converted.

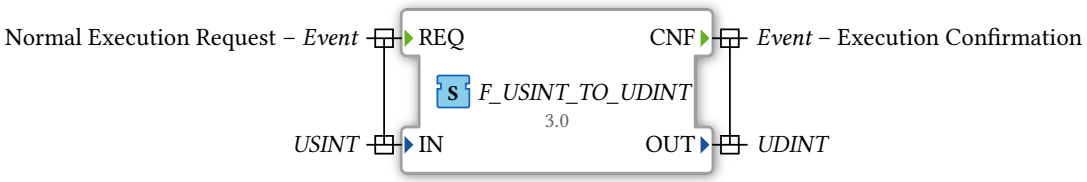
Data Outputs
- **OUT** (SINT): The resulting signed 8-bit integer value after the conversion.

Adapters
No adapters are available.

Functionality
The function block performs the conversion by converting the USINT value `IN` to a SINT value `OUT`. The conversion occurs directly upon activation of the `REQ` event, and the result is output via the `CNF` event.

Technical Features
- The conversion is performed without additional parameters or configuration.
- The algorithm is implemented in Structured Text (ST) and uses the function `USINT_TO_SINT`.

State Overview
1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Completed**: Sends the `CNF` event with the result.



Application Scenarios
- Data conversion in control systems.
- Communication between devices with different data types.
- Preprocessing of sensor data.

⚖️ Comparison with Similar Function Blocks
- Similar function blocks such as `F_INT_TO_REAL` or `F_BOOL_TO_INT` offer conversions between other data types.
- `F_USINT_TO_SINT` specializes in conversion between 8-bit integer types.

Conclusion
The `F_USINT_TO_SINT` function block is a simple and efficient building block for converting between unsigned and signed 8-bit integer values. Its clear interface and direct functionality make it ideal for use in various control and communication applications.

F_USINT_TO_UDINT
• – ◦ • – ◦ • – ◦ •

Introduction
The function block `F_USINT_TO_UDINT` converts a `USINT` value (8-bit unsigned integer) to a `UDINT` value (32-bit unsigned integer). This block is particularly useful in scenarios where type conversion without data loss is required.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. This input is connected to the data input `IN`.

Event Outputs
- **CNF**: Signals the completion of the conversion. This output is connected to the data output `OUT`.

Data Inputs
- **IN** (`USINT`): The input value to be converted.

Data Outputs
- **OUT** (`UDINT`): The converted output value.

Adapters
No adapters are available.

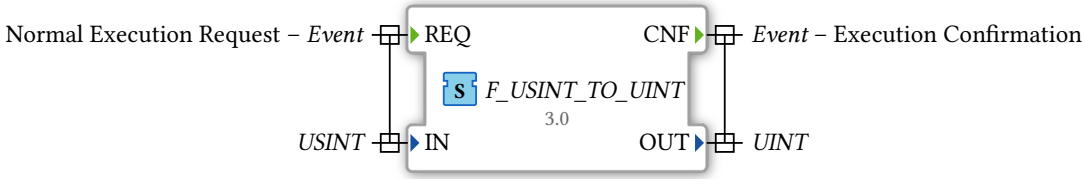
Functionality
This function block directly assigns the input value `IN` of type `USINT` to the output value `OUT` of type `UDINT`. Since `UDINT` covers a larger range of values than `USINT`, the conversion occurs without data loss.

Technical Features
- **Algorithm**: The algorithm `REQ` performs the assignment `OUT := IN`.
- **Data Integrity**: The original value is preserved during conversion to a larger data type.

State Overview
The function block has no internal states. The conversion occurs immediately upon the occurrence of the `REQ` event.

Application Scenarios
- **Type Conversion**: In control systems where different data types need to be processed.
- **Data Processing**: In communication between components that use different data types.

⚖️ Comparison with similar function blocks
- **F_USINT_TO_INT**: Converts `USINT` to `INT`, but with a potential sign change.
- **F_USINT_TO_UINT**: Converts `USINT` to `UINT` (16-bit), which offers a smaller value range than `UDINT`.



🛠️ Related Exercises
- Exercise_111

Conclusion
The `F_USINT_TO_UDINT` function block is a simple and efficient building block for the safe conversion of `USINT` to `UDINT`. Its direct assignment and the wider range of values for the output type make it ideal for applications where data integrity must be guaranteed.

F_USINT_TO_UINT

• – ◦ • – ◦ • – ◦ •

Introduction
The function block `F_USINT_TO_UINT` converts a `USINT` value (Unsigned Short Integer) to a `UINT` value (Unsigned Integer). This block is particularly useful in scenarios where a type conversion without data loss is required.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input value of type `USINT` to be converted.

Data Outputs

- **OUT**: The output value of type `UINT`, containing the result of the conversion.

Adapters

No adapters available.

Functionality

This function block directly assigns the input value `IN` of type `USINT` to the output value `OUT` of type `UINT`. Since `USINT` has a smaller value range than `UINT`, the conversion occurs without data loss.

The algorithm is triggered by the event `REQ` and outputs the result via the event `CNF`.

Technical Features

- The function block is implemented in the ST (Structured Text) programming language.
- The conversion occurs without additional calculations or checks, as `USINT` can be automatically converted to `UINT`.

State Overview

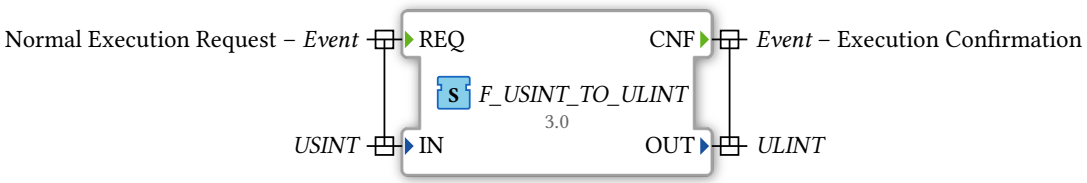
The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Type conversion in control applications, where `USINT` values need to be converted to `UINT`.
- Use in data processing chains where different data types need to be made compatible.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion function blocks such as `F_INT_TO_REAL` or `F_BOOL_TO_STRING`, this function block is specifically for conversion between two unsigned integer types.
- Similar function blocks might perform additional checks or scaling, which is not necessary here.



Conclusion

The `F_USINT_TO_UINT` function block is a simple and efficient building block for converting `USINT` to `UINT`. It is ideally suited for applications where fast and lossless type conversion is required.

F_USINT_TO_ULINT

• – ◦ • – ◦ • – ◦ •

The function block `F_USINT_TO_ULINT` converts a `USINT` value (8-bit unsigned integer) to a `ULINT` value (64-bit unsigned integer). This conversion is useful when data needs to be exchanged or processed between systems with different word lengths.

- `REQ`: Starts the execution of the conversion. This input is linked to the data input `IN`.
- `CNF`: Signals the completion of the conversion. This output is linked to the data output `OUT`.

- `IN` (USINT): The input value to be converted.
- `OUT` (ULINT): The converted output value.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters available.

The function block performs a direct conversion of the input value `IN` of type `USINT` to the output value `OUT` of type `ULINT`. The conversion is lossless because the value range of `USINT` (0 to 255) can be fully mapped to `ULINT` (0 to 2^64-1).

- The conversion is performed using a single algorithm (`REQ`), which is executed when the `REQ` event is triggered.
- The algorithm is implemented in ST (Structured Text) and consists of a simple assignment: `OUT := IN;`.

The function block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

- Data conversion in control systems that use different word widths.
- Integration of peripheral devices that provide data in different formats.
- General type conversion in IEC 61131-3-based programs.
- Similar function blocks such as `F_SINT_TO_LINT` or `F_UINT_TO_UDINT` perform similar conversions, but between different data types.
- `F_USINT_TO_ULINT` is specifically optimized for converting 8-bit to 64-bit unsigned integers.

The function block `F_USINT_TO_ULINT` provides a simple and efficient way to convert values of type `USINT` to `ULINT`. Its clear interface and direct functionality make it ideal for applications requiring type conversion without additional logic.

Conclusion

F_USINT_TO_WORD

• – ○ • – ○ • – ○ •

Introduction

The function block `F_USINT_TO_WORD` converts an unsigned 8-bit integer value (USINT) into a 16-bit word value (WORD). This conversion is particularly necessary in scenarios where data with different bit widths needs to be processed or transmitted.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (USINT): The unsigned 8-bit integer value to be converted.

Data Outputs

- **OUT** (WORD): The resulting 16-bit word value after conversion.

Adapters

- No adapters are present.

Functionality

The function block performs the conversion by taking the USINT value from `IN` and converting it to a WORD value. This is done by direct assignment using the function `USINT_TO_WORD(IN)`. The conversion is triggered by the event `REQ` and acknowledged by `CNF`.

Technical Features

- The conversion is lossless, as a USINT (0-255) can be easily converted into a WORD (0-65535).
- The function block is deterministic and has no internal states.

State Overview

The function block has no internal states. Execution is purely event-driven:

1. The conversion is performed upon receipt of `REQ`.
2. Upon completion, `CNF` is triggered.

Application Scenarios

- Data preparation for communication protocols that expect WORD data.
- Integration of sensor data in USINT format into systems that process WORD.
- General type conversion in automation applications.

⚖️ Comparison with Similar Building Blocks

- Compared to generic conversion blocks, `F_USINT_TO_WORD` is specialized and optimized for the specific conversion of USINT to WORD.
- Other blocks might offer additional features such as scaling or error handling, but they are more complex.

Conclusion

The `F_USINT_TO_WORD` function block is a simple and efficient building block for the specific conversion of USINT to WORD. Its simplicity and determinism make it a reliable choice in scenarios that require this conversion.

WORD

F_WORD_AS_STRING

• – ◦ • – ◦ • – ◦ •

The function block `F_WORD_AS_STRING` converts a `WORD` data type to a `STRING`. This is particularly useful when numeric values need to be output or further processed in a human-readable format.

- **REQ**: Starts the conversion. When this event is triggered, the value of the data input `IN` is processed.
- **CNF**: Signals the completion of the conversion. This event, along with the converted value, is output at data output `OUT`.
- **IN**: Expects an input value of type `WORD`, which is to be converted to `STRING`.
- **OUT**: Outputs the converted value as `STRING`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- No adapters are available.

Functionality

The function block uses the algorithm `REQ` to convert the `WORD` value at input `IN` to `STRING`. The conversion is performed by the function `WORD_AS_STRING(IN)`. After successful conversion, the event `CNF` is triggered, and the converted value is provided at output `OUT`.

- The function block has a simple structure and requires no additional parameters or complex logic.
- The conversion is performed directly without intermediate steps.

1. **Initialization**: The function block waits for the event `REQ`.
2. **Processing**: Upon receiving `REQ`, the value of `IN` is converted.
3. **Completion**: After the conversion, `CNF` is triggered and the value is output to `OUT`.

- Displaying numeric values in user interfaces.
- Logging `WORD` values in a readable format.
- Further processing of numeric values in systems that expect `STRING` data.
- Compared to generic conversion blocks, `F_WORD_AS_STRING` specializes in converting `WORD` to `STRING` and is therefore more efficient for this specific use case.

The F_WORD_AS_STRING function block is a simple and efficient tool for converting WORD values to STRING. Its clear interface and direct functionality make it ideal for applications requiring fast and straightforward conversion.

F_WORD_AS_WSTRING

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_WORD_AS_WSTRING converts a WORD data type to a WSTRING data type. This function block is particularly useful in scenarios where numeric values need to be converted into a string, for example, for display or logging.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the value at the data input IN is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion. The converted value is available at data output OUT.

Data Inputs

- **IN** (WORD): The input value to be converted to WSTRING.

Data Outputs

- **OUT** (WSTRING): The output value after conversion.

Adapters

This function block has no adapters.

Functionality

When the event input REQ is triggered, the algorithm is executed that converts the value at input IN of type WORD to WSTRING. The result is provided at output OUT, and the event CNF signals successful execution.

Technical Features

- The conversion is performed directly without intermediate steps.
- The function block is optimized for simple conversions and requires no additional configuration.

State Overview

1. **Idle**: Waits for the REQ event.
2. **Processing**: Performs the conversion.
3. **Completed**: Signals completion with CNF.

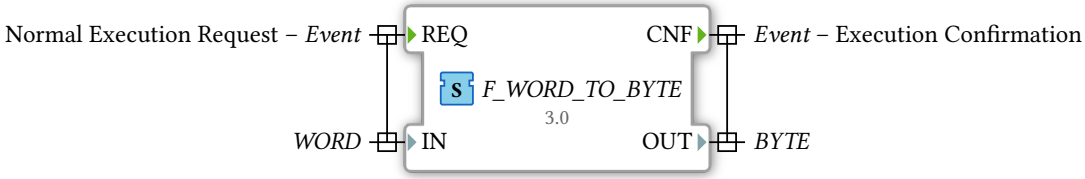
Application Scenarios

- Displaying numeric values in a user interface.
- Logging `WORD` values as readable strings.
- Data conversion for communication with systems that expect `WSTRING`.

⚖️ Comparison with similar function blocks

- Compared to generic conversion function blocks, `F_WORD_AS_WSTRING` is specialized and therefore more efficient for this specific task.
- Other function blocks might support additional parameters or more complex conversions, which is not necessary here.

Conclusion



The `F_WORD_AS_WSTRING` function block is a simple and efficient function block for converting `WORD` to `WSTRING`. Its strength lies in its simplicity and direct applicability for specific conversion tasks.

F_WORD_TO_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_BYTE` is used to convert a `WORD` data type to a `BYTE` data type. It is part of the `iec61131::conversion` package and is suitable for applications where type conversion between these two data types is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN** (`WORD`): The input value to be converted from `WORD` to `BYTE`.

Data Outputs

- **OUT** (`BYTE`): The converted output value of type `BYTE`.

Adapters

No adapters are defined for this function block.

Operation

The function block performs the conversion when the event `REQ` is received. The input value `IN`, of type `WORD`, is converted to a `BYTE` value using the function `WORD_TO_BYTE` and output `OUT`. After the conversion is complete, the event `CNF` is triggered.

Technical Features

- The function block is a simple function block (`SimpleFB`) and uses an ST algorithm for the conversion.
- The conversion is performed directly and without any additional delay.

State Overview

1. **Idle State**: The function block waits for the event `REQ`.
2. **Conversion State**: Upon receiving `REQ`, the conversion is performed and `CNF` is triggered.

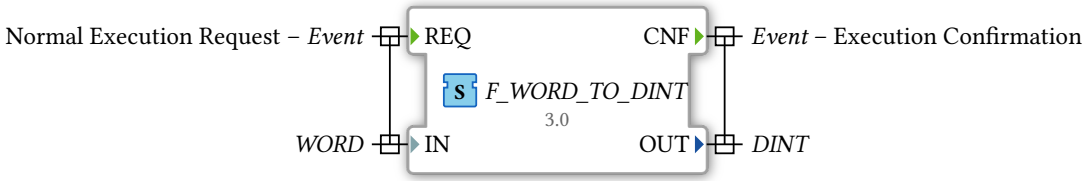
Application Scenarios

- Type conversion in control applications where `WORD` data needs to be converted to `BYTE` data.
- Integration into larger control systems that require compatible data type conversion.

⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion functions, this function block offers a specialized and optimized solution for converting `WORD` to `BYTE`.
- Other similar blocks might offer additional features such as error handling or optional parameters, which is not the case here.

Conclusion



The `F_WORD_TO_BYTE` function block is an efficient and simple solution for converting `WORD` to `BYTE` data. It is particularly suitable for applications where fast and direct type conversion is required.

F_WORD_TO_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_DINT` converts a `WORD` data type to a `DINT` data type. This function block is particularly useful in scenarios where type conversion between these two data types is required, for example, when processing data from different sources or adapting data for different system components.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This input triggers the conversion. It is linked to the data input `IN`.

Event Outputs

- **CNF**: Execution Confirmation. This output signals the completion of the conversion. It is linked to the data output `OUT`.

Data Inputs

- **IN**: Input variable of type `WORD` containing the value to be converted.

Data Outputs

- **OUT**: Output variable of type `DINT` containing the result of the conversion.

Adapters

This function block has no adapters.

Functionality

The function block `F_WORD_TO_DINT` performs the conversion from a `WORD` to a `DINT` data type. When the `REQ` event is triggered, the value at input `IN` is read and converted using the function `WORD_TO_DINT`. The result is output to `OUT`, and the `CNF` event signals the completion of the operation.

Technical Features

- The function block has a simple structure and contains only one algorithm for the conversion.
- The conversion occurs directly and without any additional delay as soon as the `REQ` event arrives.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

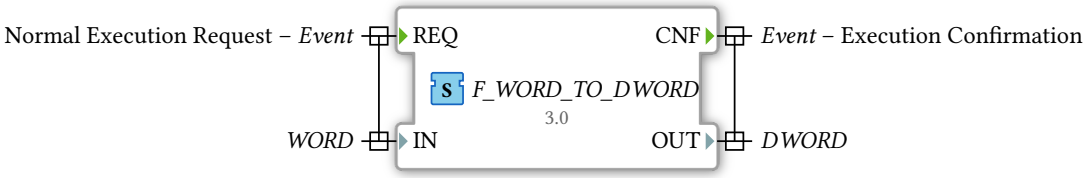
Application Scenarios

- Type conversion in control systems where data of different types needs to be processed.
- Integration of components that use different data types.
- Data preparation for further processing steps.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion function blocks such as `F_INT_TO_REAL` or `F_BOOL_TO_BYTE`, `F_WORD_TO_DINT` is specifically designed for converting `WORD` to `DINT`.
- Similar function blocks might offer additional features such as range checks or scaling, which is not the case here.

Conclusion



The function block `F_WORD_TO_DINT` is a simple and efficient tool for converting `WORD` values to `DINT` values. Its clear interface structure and direct functionality make it a reliable component in control applications where such type conversions are required.

F_WORD_TO_DWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_DWORD` converts a `WORD` value to a `DWORD` value. It is part of the `iec61131::conversion` package and enables simple and efficient type conversion.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `WORD` to be converted.

Data Outputs

- **OUT**: The output of type `DWORD`, containing the result of the conversion.

Adapters

No adapters are present.

Functionality

The function block performs the conversion from `WORD` to `DWORD` as soon as the event `REQ` is received. The conversion is performed using the function `WORD_TO_DWORD(IN)`. After successful conversion, the event `CNF` is triggered.

Technical Features

- The function block is a simple function block (`SimpleFB`) and uses an ST algorithm for the conversion.
- The conversion is performed directly without any additional processing steps.

State Overview

1. **Idle**: Waits for the event `REQ`.
2. **Processing**: Performs the conversion.

3. **Completed**: Sends the event `CNF` and returns to the idle state.

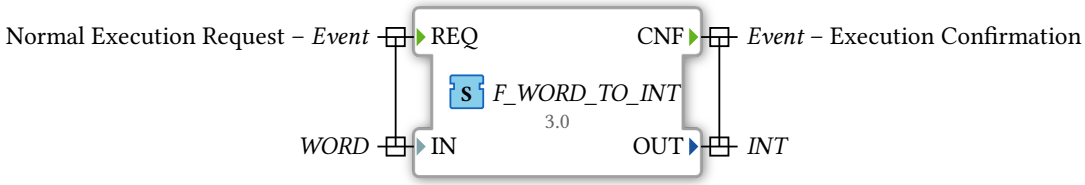
Application Scenarios

- Type conversion in control applications where `WORD` values need to be converted to `DWORD` values.
- Integration into larger control systems that require type compatibility.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks, `F_WORD_TO_DWORD` offers specialized functionality for converting `WORD` to `DWORD` without additional features or complexity.

Conclusion



The `F_WORD_TO_DWORD` function block is a simple and efficient tool for type conversion in IEC 61131-3-based control systems. Its clear interface structure and direct functionality make it a reliable solution for conversion tasks.

F_WORD_TO_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_INT` converts a `WORD` data type to a `INT` data type. It is part of the `iec61131::conversion` package and enables simple and efficient type conversion within IEC 61131-3-based control systems.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `WORD`, which is to be converted to a `INT` value.

Data Outputs

- **OUT**: The output of type `INT`, which contains the result of the conversion.

Adapters

- No adapters are present.

Operation

The function block performs the conversion as soon as the event `REQ` is triggered. The conversion is performed using the function `WORD_TO_INT`, which converts the value of input `IN` to a value of `INT` and passes the result to output `OUT`. Upon completion of the conversion, the event `CNF` is triggered.

Technical Features

- The function block is a simple function block (`SimpleFB`) and uses an ST algorithm for the conversion.
- The conversion is performed directly and without any additional delay.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

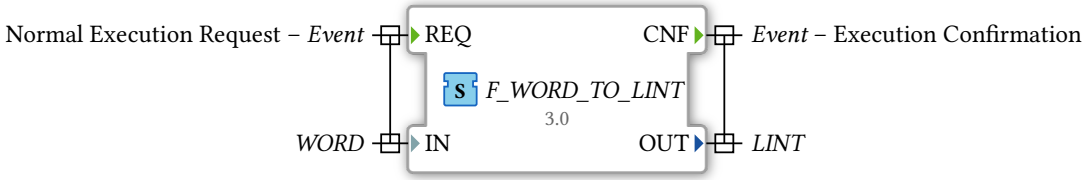
Application Scenarios

- Type conversion in control applications where `WORD` data needs to be converted to `INT` data.
- Integration into larger control systems that require type compatibility.

⚖️ Comparison with Similar Blocks

- Similar function blocks could be `F_BYTE_TO_INT` or `F_DWORD_TO_INT`, but these convert different data types.
- Unlike more complex conversion blocks, `F_WORD_TO_INT` offers a simple and direct solution for the specific conversion of `WORD` to `INT`.

Conclusion



The `F_WORD_TO_INT` function block is an efficient and easy-to-use tool for type conversion in IEC 61131-3-based systems. Its clear interface and direct operation make it ideal for applications requiring fast and reliable conversion.

F_WORD_TO_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_LINT` converts a `WORD` data type to a `LINT` data type. It is part of the `iec61131::conversion` package and enables simple and efficient type conversion within IEC 61499-based control systems.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals successful completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `WORD` to be converted.

Data Outputs

- **OUT**: The output of type `LINT`, containing the result of the conversion.

Adapters

- No adapters are present.

Functionality

This function block performs the conversion from `WORD` to `LINT` as soon as the event `REQ` is triggered. The conversion is performed using the function `WORD_TO_LINT`, which converts the input value `IN` and outputs the result to `OUT`. Upon successful conversion, the event `CNF` is triggered.

Technical Features

- The function block is a simple algorithm without a state machine.
- The conversion occurs directly and without any additional delay.
- The block is optimized for use in real-time control systems.

State Overview

Since it is a simple function block, there are no state transitions or complex state logic. Execution occurs immediately upon receiving the `REQ` event.

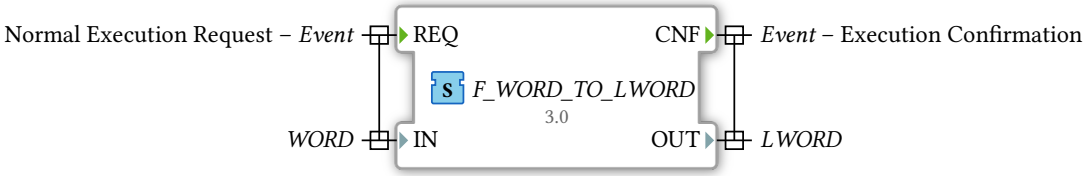
Application Scenarios

- Type conversion in control applications where `WORD` data needs to be converted to `LINT`.
- Integration into larger control systems that process different data types.
- Use in data processing chains where bit width extension is required.

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_WORD_TO_LINT` is specialized and therefore more efficient.
- Other blocks, such as `F_INT_TO_LINT` or `F_DWORD_TO_LINT`, offer similar functionality, but for different data types.

Conclusion



The `F_WORD_TO_LINT` function block is a simple and efficient building block for type conversion from `WORD` to `LINT`. It is ideally suited for applications requiring fast and direct conversion and can be easily integrated into existing control systems.

F_WORD_TO_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_LWORD` is used to convert a `WORD` data type to a `LWORD` data type. This function block is particularly useful in scenarios where an extension of the data width is required, for example, in communication between systems with different data word sizes.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN**: Expects an input of type `WORD`, which is to be converted to `LWORD`.

Data Outputs

- **OUT**: Outputs the converted result of type `LWORD`.

Adapters

This function block has no adapters.

Functionality

The function block performs the conversion as soon as the event `REQ` is received. The conversion is performed using the function `WORD_TO_LWORD`, which converts the input value `IN` of type `WORD` into the output value `OUT` of type `LWORD`. Upon successful conversion, the event `CNF` is triggered.

Technical Features

- The conversion is direct and requires no additional parameters or state management.

- The function block is suitable for use in real-time systems because it does not involve any delays or complex calculations.

State Overview

The function block has no internal states. The operation is stateless and is re-executed with each `REQ` event.

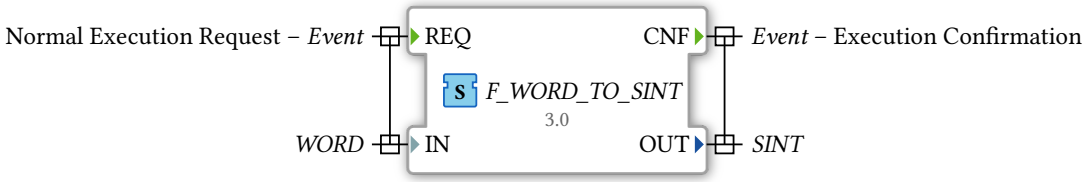
Application Scenarios

- Extending the data width for subsequent processing steps.
- Ensuring compatibility between systems with different word sizes.
- Simple data type conversion in control and automation systems.

⚖️ Comparison with Similar Function Blocks

Compared to generic conversion blocks, `F_WORD_TO_LWORD` offers a specialized and efficient solution for converting `WORD` to `LWORD`. Other blocks might be more general, but less optimized for this specific task.

Conclusion



The `F_WORD_TO_LWORD` function block is a simple yet effective block for the specific conversion of `WORD` to `LWORD`. Its simplicity and direct functionality make it a reliable choice in many automation and control scenarios.

F_WORD_TO_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_SINT` converts a `WORD` data type to a `SINT` data type. It is part of the `iec61131::conversion` package and enables simple and efficient type conversion within 4diac IDE applications.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN** (`WORD`): The input value to be converted from `WORD` to `SINT`.

Data Outputs

- **OUT** (`SINT`): The converted output value of type `SINT`.

Adapters

This function block has no adapters.

Functionality

When the `REQ` event is triggered, the algorithm is executed. This algorithm converts the `WORD` value at input `IN` into a `SINT` value and outputs the result at output `OUT`. Subsequently, the `CNF` event is triggered to signal the successful completion of the conversion.

Technical Features

- The function block is a simple function block (`SimpleFB`) and performs the conversion in a single algorithm step.
- The conversion is performed using the built-in function `WORD_TO_SINT`.

State Overview

The function block has no internal states. Execution occurs directly upon triggering the `REQ` event.

Application Scenarios

- Type conversion in control applications where `WORD` data needs to be converted to `SINT` data.
- Integration into larger control systems that process different data types.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_INT_TO_SINT` or `F_DWORD_TO_SINT` offer conversions between other data types but are comparable in their functionality.

Conclusion

The `F_WORD_TO_SINT` function block offers a simple and efficient way to convert `WORD` data to `SINT` data. Its clear interface structure and direct functionality make it ideal for applications requiring fast and reliable type conversion.

F_WORD_TO_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_UDINT` converts a `WORD` data type to a `UDINT` data type. This function block is particularly useful in scenarios where type conversion is required to prepare data for further processing.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event is triggered, the input value `IN` is processed.

Event Outputs

- **CNF**: Signals the completion of the conversion and outputs the result via output `OUT`.

Data Inputs

- **IN**: The input value of type `WORD`, which is to be converted to `UDINT`.

Data Outputs

- **OUT**: The result of the conversion as `UDINT`.

Adapters

This function block has no adapters.

Functionality

When the `REQ` event is triggered, the algorithm is started, which converts the `WORD` value at the `IN` input into a `UDINT` value. The result is provided at the `OUT` output, and the `CNF` event signals successful execution.

Technical Features

- The function block uses the built-in function `WORD_TO_UDINT` for the conversion.
- The conversion is performed without additional parameters or complex logic, enabling fast and efficient processing.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Processing State**: Performs the conversion.
3. **Completion State**: Sends the `CNF` event and outputs the result.

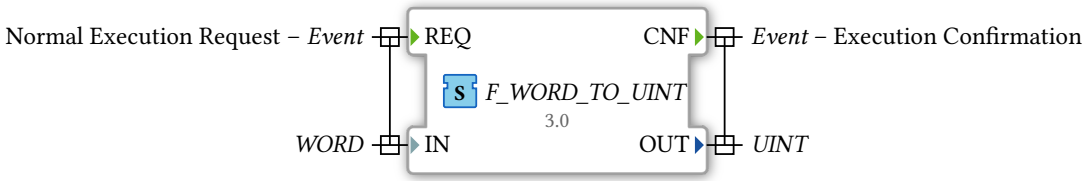
Application Scenarios

- Type conversion in control applications.
- Preparing data for further calculations or storage.
- Integration into larger automation solutions where different data types need to be processed.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks such as `F_INT_TO_REAL` or `F_BOOL_TO_BYTE` offer similar functionality for other data types.
- `F_WORD_TO_UDINT` specializes in converting `WORD` to `UDINT` and therefore offers an optimized solution for this specific use case.

Conclusion



The `F_WORD_TO_UDINT` function block is a simple and efficient building block for converting `WORD` values to `UDINT` values. Its clear interface and simple functionality make it a reliable component in automation projects.

F_WORD_TO_UINT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_WORD_TO_UINT` converts a `WORD` data type to a `UINT` data type. This conversion is particularly useful in scenarios where type conversion between these two data types is required, for example, in communication between different systems or when processing data from different sources.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: The input of type `WORD` to be converted.

Data Outputs

- **OUT**: The output of type `UINT`, containing the result of the conversion.

Adapters

This function block has no adapters.

Operation

The function block performs the conversion from `WORD` to `UINT` as soon as the event `REQ` is received. The conversion is performed using the function `WORD_TO_UINT(IN)`. After successful conversion, the result is output via output `OUT`, and the event `CNF` is triggered.

Technical Features

- The function block has a simple structure and contains only one algorithm for the conversion.
- The conversion is performed directly without any additional processing steps.

State Overview

The function block has no internal states. The conversion is re-executed with each `REQ` event.

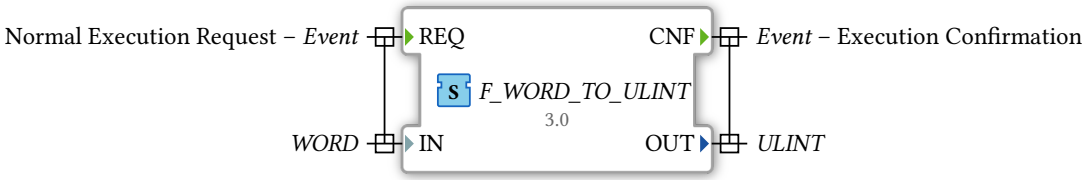
Application Scenarios

- Type conversion in control systems.
- Data processing in industrial automation solutions.
- Communication between systems with different data types.

⚖️ Comparison with Similar Building Blocks

Compared to other conversion building blocks, `F_WORD_TO_UINT` is specifically designed to convert `WORD` to `UINT`. Other building blocks might offer additional functions or a wider range of conversions, but they may be more complex in their structure.

Conclusion



The `F_WORD_TO_UINT` function block is a simple and efficient tool for the specific conversion of `WORD` to `UINT`. Its simplicity makes it particularly suitable for applications where fast and direct type conversion is required.

F_WORD_TO_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_ULINT` is used to convert a `WORD` data type to a `ULINT` data type. This function block is particularly useful in scenarios where data formats need to be extended or converted.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- **IN**: Expects a `WORD` value to be converted.

Data Outputs

- **OUT**: Outputs the converted `ULINT` value.

Adapters

No adapters are available.

Functionality

This function block performs the conversion from `WORD` to `ULINT` as soon as the `REQ` event occurs. The conversion is performed using the built-in function `WORD_TO_ULINT`. After successful conversion, the `CNF` event is triggered.

Technical Features

- This function block is part of the `iec61131::conversion` package.
- The conversion is performed without additional parameters or settings.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Done**: Sends the `CNF` event and outputs the result.

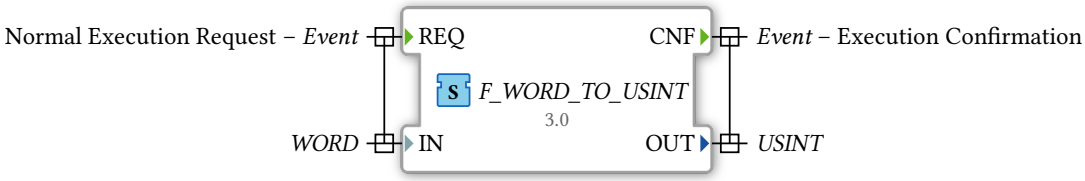
Application Scenarios

- Data processing in control systems where different data types need to be made compatible.
- Data extension for further calculations or storage.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks might offer direct conversions between other data types, e.g., `F_WORD_TO_INT`.
- This function block specializes in converting to `ULINT`, which is particularly relevant for large, unsigned numbers.

Conclusion



The `F_WORD_TO_ULINT` function block is a simple yet effective function block for converting `WORD` to `ULINT`. Its clear interface and simple functionality make it a reliable solution in many automation scenarios.

F_WORD_TO_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WORD_TO_USINT` converts a `WORD` data type to a `USINT` data type. It is part of the `iec61131::conversion` package and is suitable for applications where type conversion between these two data types is required.

Interface Structure

Event Inputs

- `REQ` (Event): Starts the execution of the function block. This input is linked to the data input `IN`.

Event Outputs

- `CNF` (Event): Signals the completion of the conversion. This output is linked to the data output `OUT`.

Data Inputs

- `IN` (WORD): The input value to be converted.

Data Outputs

- `OUT` (USINT): The converted output value.

Adapters

No adapters are present.

Functionality

The function block performs the conversion from `WORD` to `USINT` as soon as the event `REQ` is received. The conversion is performed using the function `WORD_TO_USINT`, which converts the input value `IN` into the output value `OUT`. Upon completion of the conversion, the event `CNF` is triggered.

Technical Features

- The function block is a simple function block (SimpleFB) and uses an ST algorithm for the conversion.
- The conversion occurs directly and without any additional delay.

State Overview

1. **Idle State**: The function block waits for the event `REQ`.
2. **Execution State**: Upon receiving `REQ`, the conversion is performed.
3. **Confirmation State**: After successful conversion, `CNF` is triggered, and the function block returns to its idle state.

Application Scenarios

- Type conversion in control applications where a `WORD` value needs to be converted to a `USINT` value.
- Integration into larger control systems that need to process different data types.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion function blocks such as `F_INT_TO_REAL` or `F_BOOL_TO_STRING`, `F_WORD_TO_USINT` specializes in converting `WORD` to `USINT`.
- Similar building blocks could be `F_USINT_TO_WORD`, which performs the reverse conversion.

Conclusion

The function block `F_WORD_TO_USINT` offers a simple and efficient way to convert `WORD` values to `USINT` values. Its clear interface structure and simple functionality make it ideal for applications requiring such type conversion.

Word Conversions

WSTRING

F_WSTRING_AS_BOOL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_BOOL` is used to convert a WSTRING value to a BOOL value. This is particularly useful in scenarios where strings need to be converted to Boolean values, for example, when processing user input or interpreting configuration data.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. Triggered after successful conversion.

Data Inputs

- **IN**: WSTRING. The input value to be converted to a BOOL value.

Data Outputs

- **OUT**: BOOL. The result of the conversion.

Adapters

No adapters available.

Functionality

The function block performs the conversion when the event `REQ` is received. The conversion is carried out using the function `WSTRING_AS_BOOL`, which converts the WSTRING input value `IN` into a BOOL value `OUT`. After successful conversion, the event `CNF` is triggered.

Technical Features

- The conversion is performed directly and without any additional delay.
- The function block is implemented as a simple function block (SimpleFB) and uses an ST algorithm for the conversion.

State Overview

1. **Idle**: Waits for the event `REQ`.
2. **Processing**: Performs the conversion.
3. **Complete**: Triggers the event `CNF` and returns to the idle state.

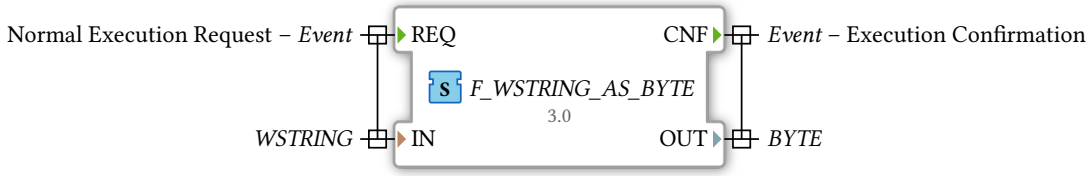
Application Scenarios

- Processing user input in string form.
- Interpreting configuration files that store Boolean values as strings.
- Interfaces between systems that use different data types.

⚖️ Comparison with Similar Function Blocks

- **F_STRING_AS_BOOL**: Converts STRING to BOOL instead of WSTRING.
- **F_BOOL_AS_WSTRING**: Performs the reverse conversion (BOOL to WSTRING).

Conclusion



The `F_WSTRING_AS_BOOL` function block offers a simple and efficient way to convert WSTRING values to BOOL values. Its clear interface structure and direct functionality make it a useful tool in various application scenarios.

F_WSTRING_AS_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_BYTE` is used to convert a WSTRING data type to a BYTE data type. This block is particularly useful in scenarios where converting wide strings into individual bytes is required.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. The input value `IN` is processed upon this event.

Event Outputs

- **CNF**: Signals the completion of processing and outputs the result via the output `OUT`.

Data Inputs

- **IN** (WSTRING): The input value to be converted into a BYTE value.

Data Outputs

- **OUT** (BYTE): The result of the conversion.

Adapters

- No adapters available.

Functionality

When the `REQ` event occurs, the function block converts the WSTRING input `IN` into a BYTE value. The result is output via `OUT`, and the `CNF` event signals the successful completion of the operation.

Technical Features

- The function block uses the `WSTRING_AS_BYTE` function for the conversion.
- This is a simple function block without internal state management.

State Overview

The function block has no internal states. Processing occurs directly upon the occurrence of the `REQ` event.

Application Scenarios

- Conversion of WSTRING data to BYTE values for further processing in systems that only support BYTE data.
- Use in communication protocols where strings need to be converted to bytes.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks such as `F_STRING_AS_BYTE`, this one is specifically designed for WSTRING data types.
- Similar blocks might have additional parameters or states, but this function block is limited to simple conversion.

Conclusion

The `F_WSTRING_AS_BYTE` function block offers a simple and efficient way to convert WSTRING data into BYTE values. Its clear interface structure and direct functionality make it a reliable solution for corresponding use cases.

F_WSTRING_AS_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_DINT` converts a WSTRING value to a DINT value. It is part of the package `iec61131::conversion` and enables the easy conversion of wide strings to integer values.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. Triggered after successful conversion.

Data Inputs

- **IN**: Input variable of type `WSTRING`. Contains the string to be converted.

Data Outputs

- **OUT**: Output variable of type `DINT`. Contains the result of the conversion.

Adapters

This function block does not use any adapters.

Functionality

The function block converts the value of the input variable `IN` of type `WSTRING` to a value of type `DINT` and stores the result in the output variable `OUT`. The conversion is performed by calling the function `WSTRING_AS_DINT` within the algorithm `REQ`.

Technical Features

- The conversion is performed directly via the built-in function `WSTRING_AS_DINT`.
- The function block is simple and has no additional states or complex logic.

State Overview

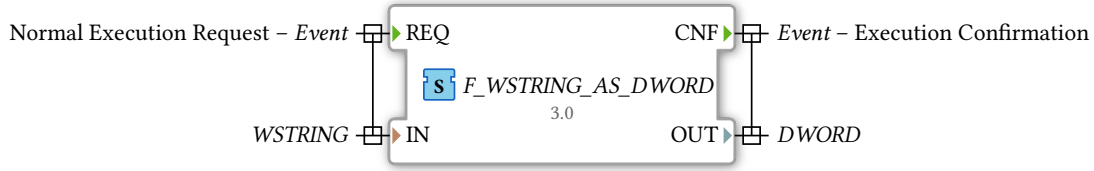
The function block has no internal states. Execution occurs directly upon receiving the `REQ` event.

Application Scenarios

- Conversion of user input into numeric values.
- Processing of strings containing numeric data in control systems.

⚖️ Comparison with Similar Function Blocks

- Similar function blocks like `F_STRING_AS_DINT` convert simple strings (`STRING`) to `DINT`, while this block processes wide strings (`WSTRING`).
- Compared to generic conversion blocks, this one is specifically designed to convert `WSTRING` to `DINT`.



Conclusion

The `F_WSTRING_AS_DINT` function block provides a simple and efficient way to convert wide strings to integer values. It is particularly useful in scenarios where wide strings need to be processed.

F_WSTRING_AS_DWORD

• – ◦ • – ◦ • – ◦ •

The function block `F_WSTRING_AS_DWORD` is used to convert a WSTRING value to a DWORD value. This functionality is particularly useful when strings need to be converted into numeric values, for example, for further processing in control algorithms.

- **REQ**: Normal execution request. Triggers the conversion.
- **CNF**: Execution confirmation. Triggered after successful conversion.
- **IN**: Input of type WSTRING. The string to be converted to a DWORD value.
- **OUT**: Output of type DWORD. The converted numeric value.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters available.

Functionality

The function block performs the conversion as soon as the event `REQ` is received. The conversion is carried out using the function `WSTRING_AS_DWORD`, which converts the WSTRING input value into a DWORD value. After successful conversion, the event `CNF` is triggered, and the converted value is available at output `OUT`.

- The function block is a simple function block (SimpleFB) and has a single algorithm that is executed when `REQ` is triggered.

The function block has no internal state. The conversion is performed anew with each `REQ` event.

- Conversion of user input (e.g., via HMI) into numeric values for control.
- Processing of strings containing numeric information in control algorithms.
- Compared to other conversion blocks such as `F_STRING_AS_DWORD`, this one is specifically designed for WSTRING input.
- Similar function blocks might offer additional parameters or error handling, but this function block is limited to basic conversion.

The `F_WSTRING_AS_DWORD` function block offers a simple and efficient way to convert WSTRING values to DWORD values. Its simplicity makes it particularly suitable for applications where direct conversion without additional complexity is required.

F_WSTRING_AS_INT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_INT` is used to convert a WSTRING value to an INT value. This block is particularly useful when strings need to be converted into numeric values, for example, when processing user input or interpreting text data.

Interface Structure

Event Inputs
- **REQ**: This event input triggers the execution of the function block. It is linked to the data input `IN`.

Event Outputs
- **CNF**: This event output signals the successful execution of the function block. It is linked to the data output `OUT`.

Data Inputs
- **IN**: This input expects a WSTRING value, which is to be converted to an INT value.

Data Outputs
- **OUT**: This output provides the converted INT value.

Adapters
This function block has no adapters.

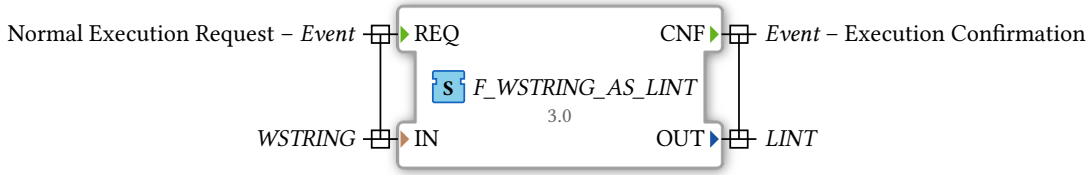
Functionality
The function block performs the conversion as soon as the event `REQ` is received. The conversion is carried out using the function `WSTRING_AS_INT`, which converts the WSTRING value from `IN` into an INT value and outputs the result to `OUT`. The event `CNF` is then triggered to signal successful execution.

Technical Features
- The function block is a simple block without internal states or complex logic.
- The conversion is performed directly and without delay.

State Overview
Because it is a simple function block, there are no state transitions or internal states.

Application Scenarios
- Processing user input that is in string form but must be interpreted as numeric values.
- Interpreting text data from external sources that needs to be converted into numeric values.
- Integration into systems that need to process strings and numeric values.

⚖️ Comparison with Similar Blocks
- Compared to other conversion blocks such as `F_STRING_AS_INT` or `F_WSTRING_AS_REAL`, this block is specifically designed for converting WSTRING to INT.



Other blocks might offer additional features like error handling or formatting, but this block is limited to basic conversion.

Conclusion
The `F_WSTRING_AS_INT` function block is a simple and efficient tool for converting WSTRING values to INT values. Its clear interface and straightforward functionality make it ideal for applications requiring fast and uncomplicated conversion.

F_WSTRING_AS_LINT

• − ◦ • − ◦ • − ◦ •

Introduction
The function block `F_WSTRING_AS_LINT` is used to convert a WSTRING value to a LINT value. This block is particularly useful in scenarios where strings need to be converted into numeric values, for example, when processing user input or interpreting text data.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This event input triggers the conversion. It is linked to the data input `IN`.

Event Outputs

- **CNF**: Execution confirmation. This event is output after successful conversion and is linked to the data output `OUT`.

Data Inputs

- **IN** (WSTRING): The input for the string to be converted to a LINT value.

Data Outputs

- **OUT** (LINT): The output for the converted LINT value.

Adapters

This function block does not use any adapters.

Functionality

The function block converts the WSTRING value at input `IN` to a LINT value at output `OUT` as soon as the event `REQ` is received. The conversion is performed using the function `WSTRING_AS_LINT`. After successful conversion, the event `CNF` is output.

Technical Features

- The function block has a simple structure and contains only one conversion algorithm.
- The conversion can fail if the string does not contain a valid numeric representation. In this case, the event `CNF` is not output.

State Overview

1. **Idle**: The function block waits for the event `REQ`.
2. **Processing**: Upon receiving `REQ`, the conversion is performed.
3. **Confirmation**: After successful conversion, `CNF` is output, and the function block returns to the idle state.

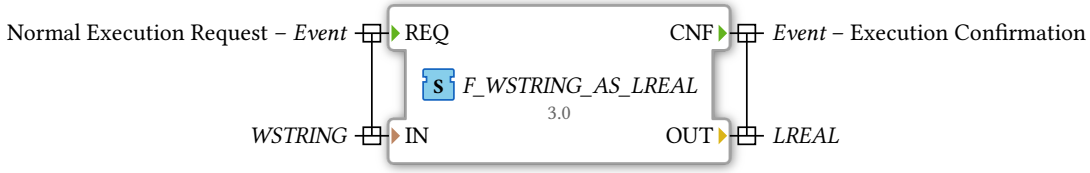
Application Scenarios

- Processing user input that is in string form but should be interpreted as numeric values.
- Interpreting text data from external sources that contains numeric information.

⚖️ Comparison with Similar Function Blocks

- **F_STRING_AS_LINT**: Similar function block, but for the STRING data type instead of WSTRING.
- **F_WSTRING_AS_INT**: Converts WSTRING to INT, but offers a smaller value range than LINT.

Conclusion



The `F_WSTRING_AS_LINT` function block is a simple and effective tool for converting strings to large numeric values. Its clear interface and simple functionality make it a reliable solution for corresponding use cases.

F_WSTRING_AS_LREAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_LREAL` is used to convert a WSTRING value into an LREAL value. This block is particularly useful when strings need to be converted into numerical values, for example, for mathematical calculations or data processing.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. When this input is activated, the conversion of the WSTRING value at input `IN` into an LREAL value begins.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. The converted LREAL value is available at output `OUT`.

Data Inputs

- **IN** (WSTRING): The input for the string to be converted to an LREAL value.

Data Outputs

- **OUT** (LREAL): The output for the converted LREAL value.

Adapters

This function block has no adapters.

Functionality

When the `REQ` event is triggered, the function block converts the WSTRING value at input `IN` into an LREAL value. The conversion is performed using the function `WSTRING_AS_LREAL`. After successful conversion, the `CNF` event is triggered, and the converted value is provided at output `OUT`.

Technical Features

- The conversion is performed directly without additional parameters.
- The function block is optimized for use in real-time systems.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Complete**: Signals completion with the `CNF` event.

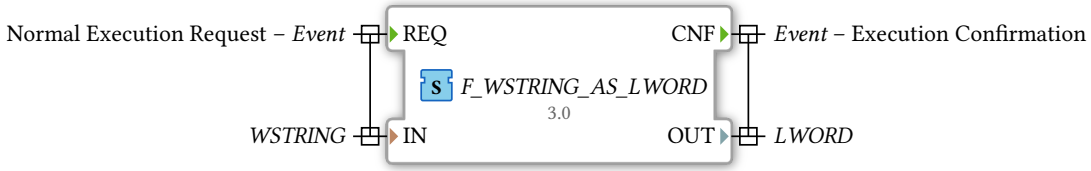
Application Scenarios

- Conversion of user input into numeric values.
- Processing of text data from external sources for calculations.
- Integration into systems that need to process both strings and numeric values.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion blocks, `F_WSTRING_AS_LREAL` is specifically designed for converting WSTRING to LREAL.
- Other blocks might offer additional parameters or error handling, but this block is optimized for simplicity and efficiency.

Conclusion



The F_WSTRING_AS_LREAL function block provides a simple and efficient way to convert WSTRING values to LREAL values. Its clear interface structure and direct functionality make it a valuable component in many applications.

F_WSTRING_AS_LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_WSTRING_AS_LWORD is used to convert a WSTRING data type to an LWORD data type. This functionality is particularly useful in scenarios where strings need to be converted into a binary form suitable for further processing.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This event input triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. This event is output after successful conversion.

Data Inputs

- **IN**: Input of type WSTRING. This is the string to be converted.

Data Outputs

- **OUT**: Output of type LWORD. This is the result of the conversion.

Adapters

No adapters available.

Functionality

The function block performs the conversion from WSTRING to LWORD as soon as the event REQ is received. The conversion is carried out using the integrated function WSTRING_AS_LWORD. After successful conversion, the event CNF is output, along with the converted value.

Technical Features

- The function block is a simple FB (SimpleFB) and uses an ST algorithm for the conversion.
- The conversion is performed directly and without any further delay.

State Overview

1. **Idle**: Waits for the event REQ.
2. **Processing**: Performs the conversion.
3. **Completed**: Outputs the event CNF and returns to the idle state.

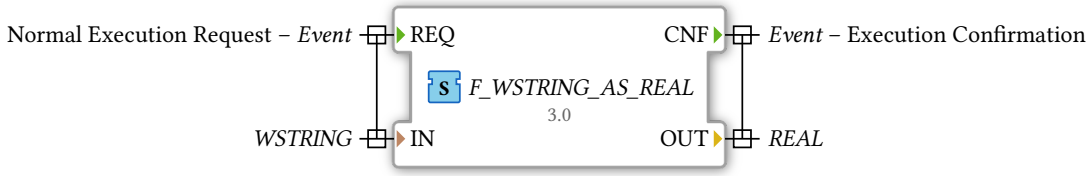
Application Scenarios

- Conversion of strings to binary data for further processing in control systems.
- Use in protocol conversions where strings need to be converted to binary form.

⚖️ Comparison with Similar Function Blocks

- Compared to other conversion function blocks such as F_STRING_AS_LWORD, this function block specifically works with the WSTRING data type, which supports Unicode characters.

Conclusion



The F_WSTRING_AS_LWORD function block provides a simple and efficient way to convert WSTRING data to LWORD data. Its clear interface structure and direct functionality make it a useful tool in various applications.

F_WSTRING_AS_REAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_WSTRING_AS_REAL is used to convert a WSTRING value into a REAL value. This block is particularly useful when strings representing numeric values need to be converted into numeric data types for further calculations or control logic.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this input is triggered, the WSTRING value contained in the data input IN is converted into a REAL value.

Event Outputs

- **CNF**: Signals the completion of the conversion. This output is activated as soon as the conversion is complete and the result value is available in the data output OUT.

Data Inputs

- **IN**: Enter the WSTRING value to be converted into a REAL value here.

Data Outputs

- **OUT**: Contains the converted REAL value after successful execution of the function block.

Adapters

This function block does not use any adapters.

Functionality

The function block performs the conversion as soon as the event REQ is triggered. The conversion is carried out using the internal function WSTRING_AS_REAL, which converts the WSTRING input IN into a REAL value and stores the result in the output OUT. The event CNF is then triggered to signal the successful completion of the operation.

Technical Features

- The function block supports WSTRING to REAL conversion, which is particularly useful in international applications because WSTRING supports Unicode characters.
- The conversion is performed in a single algorithm step, ensuring efficient execution.

State Overview

1. **Idle State**: The function block waits for the REQ event to be triggered.
2. **Conversion State**: The conversion is performed when REQ is triggered.
3. **Confirmation State**: After successful conversion, CNF is triggered, and the function block returns to the idle state.

Application Scenarios

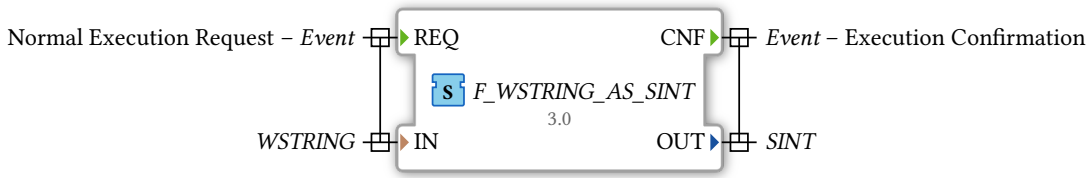
- **Data Processing**: Conversion of user input or read strings into numeric values for calculations.

- **Interface Communication**: Conversion of strings received via networks or interfaces into numeric values for control logic.
- **International Applications**: Processing of Unicode-encoded strings containing numeric data.

⚖️ Comparison with Similar Function Blocks

- **F_STRING_AS_REAL**: Similar function block, but for the STRING data type instead of WSTRING. `F_WSTRING_AS_REAL` is preferable when Unicode support is required.
- **F_WSTRING_TO_***: Other conversion blocks for WSTRING, but they convert to other data types such as INT or BOOL.

Conclusion



The `F_WSTRING_AS_REAL` function block is an efficient tool for converting Unicode strings into numeric REAL values. Its simple interface and reliable operation make it ideal for applications requiring international character sets or complex data processing.

F_WSTRING_AS_SINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_SINT` converts a WSTRING value to a SINT value (8-bit integer). This block is particularly useful in scenarios where strings need to be converted to numeric values.

Interface Structure

Event Inputs

- **REQ**: Triggering event for the conversion. Linked to the data input `IN`.

Event Outputs

- **CNF**: Confirms successful completion of the conversion. Linked to the data output `OUT`.

Data Inputs

- **IN** (WSTRING): The input string to be converted to a SINT value.

Data Outputs

- **OUT** (SINT): The resulting 8-bit integer value after conversion.

Adapters

No adapters available.

Functionality

The function block performs the conversion as soon as the `REQ` event occurs. The function `WSTRING_AS_SINT` is applied to the input value `IN`, and the result is output to `OUT`. Successful execution is indicated by the `CNF` event.

Technical Features

- The conversion is performed using the built-in function `WSTRING_AS_SINT`.
- The block is optimized for use in IEC 61131-3 compliant environments.

State Overview

The block has no internal states. The conversion occurs immediately upon triggering the `REQ` event.

Application Scenarios

- Conversion of user input to numeric values.
- Processing of strings from external sources (e.g., sensors or network communication).

⚖️ Comparison with Similar Blocks

- Compared to generic conversion blocks, `F_WSTRING_AS_SINT` specializes in converting WSTRING to SINT.
- Other blocks might offer additional features such as error handling or type checking.

Conclusion

The `F_WSTRING_AS_SINT` block offers an efficient and direct method for converting WSTRING values to SINT values. Its simplicity and specialization make it ideal for specific use cases.

F_WSTRING_AS_TIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_TIME` is used to convert a string in WSTRING format into a TIME value. This block is particularly useful when time values are in string format and need to be converted to TIME format for use in further calculations or control logic.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. When this event input is triggered, the WSTRING value contained in the data input `IN` is converted into a TIME value.

Event Outputs

- **CNF**: Signals the successful completion of the conversion. This event, along with the converted TIME value, is output at data output `OUT`.

Data Inputs

- **IN** (WSTRING): The string to be converted into a TIME value.

Data Outputs

- **OUT** (TIME): The converted TIME value.

Adapters

This function block has no adapters.

Functionality

When event input `REQ` is triggered, the WSTRING value contained in data input `IN` is converted into a TIME value using the function `WSTRING_AS_TIME`. The result is output at the data output `OUT`, and the event `CNF` signals the successful completion of the conversion.

Technical Features

- The function block has a simple structure and contains only one algorithm that performs the conversion.
- There are no additional states or complex logic, as the conversion is performed directly without intermediate steps.

State Overview

Since it is a simple function block, there are no explicit states. The conversion occurs immediately upon triggering the `REQ` event.

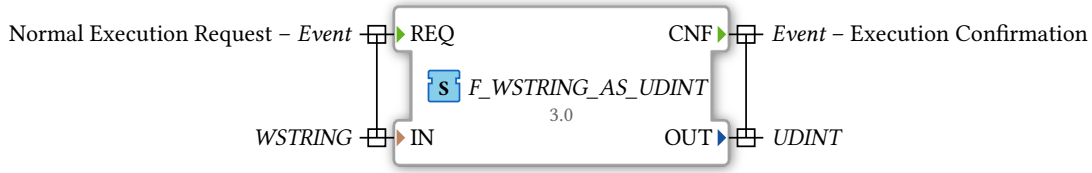
Application Scenarios

- **Data Conversion**: When time values are available as strings (e.g., from user input or an external data source) and need to be converted into the TIME format.
- **Interface Communication**: When communicating with systems that transmit time values as strings.

⚖️ Comparison with Similar Function Blocks

- **F_STRING_AS_TIME**: Similar function block, but it uses STRING instead of WSTRING. `F_WSTRING_AS_TIME` is suitable for Unicode strings.
- **F_TIME_AS_WSTRING**: Performs the reverse conversion (TIME to WSTRING).

Conclusion



The function block `F_WSTRING_AS_TIME` is a simple and effective tool for converting WSTRING strings to TIME values. Its clear interface and direct functionality make it a reliable solution for relevant use cases.

F_WSTRING_AS_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_UDINT` is used to convert a WSTRING value to a UDINT value. This block is particularly useful in scenarios where strings need to be converted into numeric values, for example, when processing user input or interpreting data from external sources.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This input triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. This output signals the completion of the conversion.

Data Inputs

- **IN**: WSTRING. The input string to be converted to a UDINT value.

Data Outputs

- **OUT**: UDINT. The converted numeric value.

Adapters

This function block does not use any adapters.

Operation

The function block performs the conversion when the event `REQ` is received. The conversion is carried out using the function `WSTRING_AS_UDINT`, which converts the WSTRING input `IN` into a UDINT value and outputs the result to `OUT`. Upon completion of the conversion, the event `CNF` is triggered.

Technical Features

- The function block is simple and efficient because it directly utilizes the built-in conversion function.
- There is no additional error handling for invalid input; the conversion is performed according to the rules of IEC 61131-3.

State Overview

The function block has a simple state machine:

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Complete**: Sends the `CNF` event and returns to the idle state.

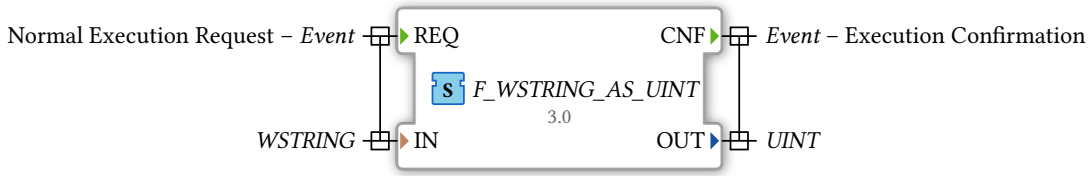
Application Scenarios

- **Data Processing**: Converts user input or external data into numeric values.
- **Logging**: Converts strings into numeric IDs for storage or further processing.
- **Interface Communication**: Prepares data for transmission via protocols that require numeric values.

⚖️ Comparison with Similar Function Blocks

- **F_STRING_AS_UDINT**: Similar function block, but for STRING instead of WSTRING.
- **F_UDINT_AS_WSTRING**: Performs the reverse conversion (UDINT to WSTRING).

Conclusion



The `F_WSTRING_AS_UDINT` function block is a simple and effective tool for converting WSTRING values to UDINT. Its clear interface and direct functionality make it ideal for applications that require such conversions.

F_WSTRING_AS_UINT

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `F_WSTRING_AS_UINT` is used to convert a WSTRING value to a UINT value. This function is particularly useful when strings need to be converted into numeric values, for example, for further calculations or control tasks.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. This input triggers the conversion.

Event Outputs

- **CNF**: Execution confirmation. This output signals the completion of the conversion.

Data Inputs

- **IN**: WSTRING value to be converted to a UINT value.

Data Outputs

- **OUT**: UINT value resulting from the conversion of the WSTRING input.

Adapters

- No adapters available.

Functionality

The function block converts the WSTRING input `IN` to a UINT value `OUT` as soon as the event `REQ` is triggered. The conversion is performed using the built-in function `WSTRING_AS_UINT`. After successful conversion, the event `CNF` is triggered to signal the completion of the operation.

Technical Features

- The function block is a simple function block (SimpleFB) and performs the conversion in a single algorithm.
- The conversion is direct and occurs without additional state management.

State Overview

Since this is a simple function block, there are no complex state transitions. The block responds to the `REQ` event, performs the conversion, and signals completion with `CNF`.

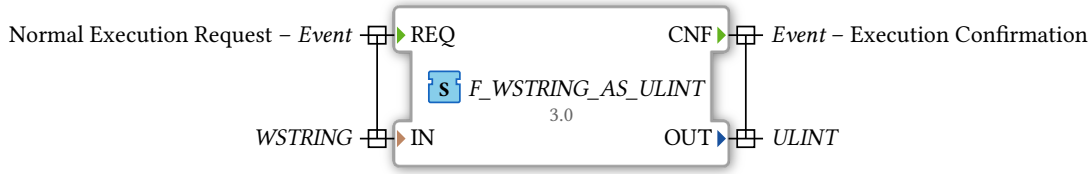
Application Scenarios

- Converting user input to numeric values.
- Processing strings containing numeric data for control purposes.
- Integration into larger control systems that need to process both strings and numeric values.

⚖️ Comparison with Similar Blocks

- Compared to other conversion blocks such as `F_STRING_AS_INT` or `F_WSTRING_AS_INT`, this block specifically converts to a UINT value, which is suitable for non-negative numbers.
- Using WSTRING allows for the processing of Unicode strings, which is more flexible compared to simple STRING conversions.

Conclusion



The `F_WSTRING_AS_UINT` function block provides a simple and efficient way to convert WSTRING values to UINT values. Its straightforward operation and clear interface make it a useful component in control applications that work with strings and numeric values.

F_WSTRING_AS_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_ULINT` is used to convert a WSTRING data type to a ULINT data type. This function block is particularly useful in scenarios where strings need to be converted into numeric values, for example, when processing user input or parsing data from external sources.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. This event input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. This event output is linked to the data output `OUT`.

Data Inputs

- **IN** (WSTRING): The input string to be converted to a ULINT value.

Data Outputs

- **OUT** (ULINT): The converted numeric value.

Adapters

No adapters are defined for this function block.

Functionality

The function block performs the conversion when the `REQ` event is received. The conversion is performed using the function `WSTRING_AS_ULINT`, which converts the string `IN` to an unsigned 64-bit integer (`ULINT`). After successful conversion, the `CNF` event is triggered, and the converted value is available at output `OUT`.

Technical Features

- The conversion is strictly typed, meaning the input must contain a valid numeric representation in the string to produce correct results.
- The function block does not support error handling for invalid input. It is the user's responsibility to ensure that the input is correctly formatted.

State Overview

1. **Idle**: The function block waits for the `REQ` event.
2. **Processing**: The conversion is performed upon receipt of `REQ`.
3. **Completed**: After the conversion, the `CNF` event is triggered, and the function block returns to its idle state.

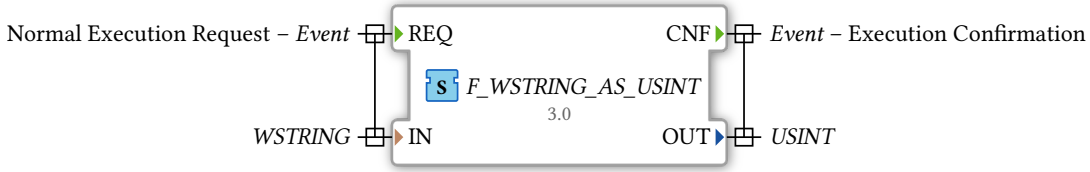
Application Scenarios

- Converting user input to numeric values.
- Parsing data from external sources (e.g., files, network) into numeric formats.
- Use in control applications where strings need to be converted to control values.

⚖️ Comparison with Similar Function Blocks

- Compared to generic conversion function blocks, `F_WSTRING_AS_ULINT` specializes in converting WSTRING to ULINT and therefore offers an optimized and type-safe solution for this specific use case.
- Other function blocks, such as `F_STRING_AS_INT` or `F_WSTRING_AS_LINT`, offer similar functionality, but for different data types.

Conclusion



The `F_WSTRING_AS_ULINT` function block is an efficient tool for converting strings to unsigned 64-bit integer values. Its simplicity and specialization make it ideal for applications requiring fast and type-safe conversion. However, note that it lacks built-in error handling for invalid input.

F_WSTRING_AS_USINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_WSTRING_AS_USINT` converts a WSTRING value to a USINT value. It is part of the package `iec61131::conversion` and enables the easy conversion of wide strings to unsigned 8-bit integers.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the conversion. This input is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the completion of the conversion. The output is linked to the data output `OUT`.

Data Inputs

- **IN** (WSTRING): The input string to be converted to a USINT value.

Data Outputs

- **OUT** (USINT): The result of the conversion as an unsigned 8-bit integer.

Adapters

This function block does not use any adapters.

Functionality

The function block performs the conversion when the event `REQ` is triggered. The conversion is carried out using the function `WSTRING_AS_USINT`, which converts the WSTRING input value to a USINT value. After the conversion is complete, the event `CNF` is triggered, and the result value is available at output `OUT`.

Technical Features

- The conversion is performed directly without additional parameters.
- The function block is optimized for use in IEC 61499-compliant environments.

State Overview

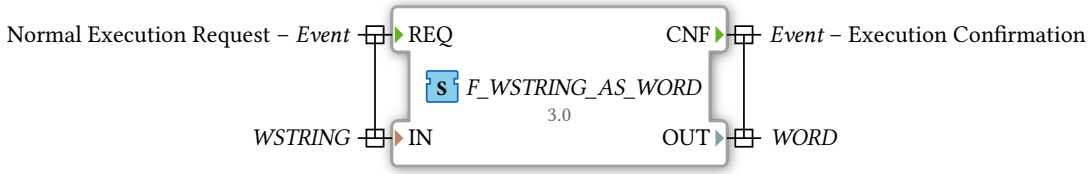
1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Done**: Sends the `CNF` event and provides the result.

Application Scenarios

- Conversion of character strings to numeric values for control applications.
- Use in systems that use character strings as input but require numeric processing.

⚖️ Comparison with Similar Function Blocks

- Unlike generic conversion blocks, `F_WSTRING_AS_USINT` specializes in converting WSTRING to USINT.
- Other blocks might offer additional parameters or error handling, but this block is designed for simplicity and efficiency.



Conclusion

The `F_WSTRING_AS_USINT` function block provides a simple and efficient way to convert WSTRING values to USINT values. Its clear interface and direct functionality make it ideal for applications that require fast and straightforward conversions.

F_WSTRING_AS_WORD

• – ◦ • – ◦ • – ◦ •

The function block `F_WSTRING_AS_WORD` converts a WSTRING data type to a WORD data type. This functionality is particularly useful when strings need to be converted into numeric values, for example, for further processing in control algorithms.

- **REQ**: Starts the execution of the function block. This event input is linked to the data input `IN`.
- **CNF**: Signals the successful completion of the conversion. This event output is linked to the data output `OUT`.
- **IN**: Expects an input of type `WSTRING`, which is to be converted into a `WORD` value.
- **OUT**: Returns the result of the conversion as `WORD`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters
This function block has no adapters.

Functionality
The function block performs the conversion as soon as the event `REQ` is received. The conversion is performed using the function `WSTRING_AS_WORD`, which converts the input `WSTRING` into a value `IN` and outputs the result via the output `OUT`. Successful execution is signaled by the event `CNF`.

- The conversion is performed directly without additional parameters.
- The function block is optimized for use in IEC 61131-compliant environments.

The function block has no internal states. Execution occurs immediately upon receiving the event `REQ`.

- Conversion of strings to numeric values for control commands.
- Integration into systems that require conversion between different data types.
- Compared to generic conversion function blocks, `F_WSTRING_AS_WORD` specializes in converting `WSTRING` to `WORD`.
- Other function blocks might offer additional parameters or error handling, but this function block is designed for simplicity and efficiency.

The `F_WSTRING_AS_WORD` function block provides a simple and efficient way to convert `WSTRING` data to `WORD` values. Its clear interface and direct operation make it ideal for applications that require fast and reliable conversions.

F_WSTRING_TO_STRING
• – ◦ • – ◦ • – ◦ •

Introduction
The function block `F_WSTRING_TO_STRING` is used to convert a WSTRING data type to a STRING data type. This function block is particularly useful in scenarios where converting wide strings (Unicode) to simple strings (ASCII or similar) is required.

Interface Structure

Event Inputs
- **REQ**: Starts the conversion. When this event is triggered, the WSTRING input `IN` is processed.

Event Outputs
- **CNF**: Signals the completion of the conversion and outputs the result via the STRING output `OUT`.

Data Inputs
- **IN** (WSTRING): The input string in WSTRING format to be converted.

Data Outputs
- **OUT** (STRING): The converted string in STRING format.

Adapters
- No adapters are available.

Functionality
The function block performs the conversion as soon as the event `REQ` is triggered. The conversion is performed using the integrated function `WSTRING_TO_STRING`, which converts the WSTRING input `IN` into a STRING output `OUT`. After successful conversion, the event `CNF` is triggered.

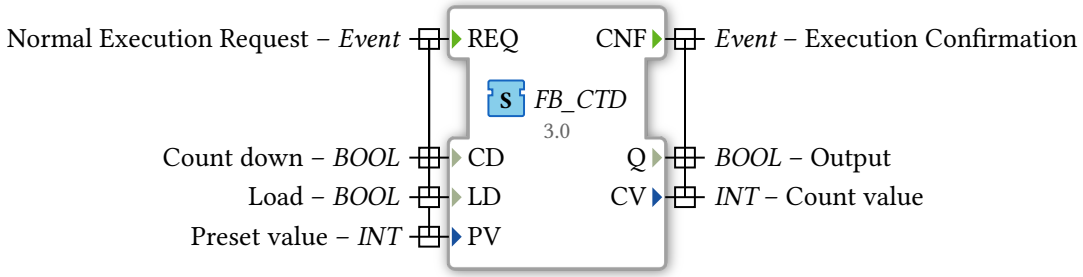
Technical Features
- The function block does not support any additional parameters or configurations for the conversion.
- The conversion is performed directly without intermediate storage.

State Overview
1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Performs the conversion.
3. **Complete**: Triggers `CNF` and outputs the result.

Application Scenarios
- Conversion of Unicode text to ASCII text.
- Use in systems that do not support wide strings.
- Integration into existing systems that only work with STRING data types.

⚖️ Comparison with Similar Function Blocks
- Unlike generic conversion blocks, `F_WSTRING_TO_STRING` specializes in converting WSTRING to STRING.
- Similar function blocks might offer additional options such as character set conversion, but this block is limited to basic functionality.

Conclusion
The `F_WSTRING_TO_STRING` function block provides a simple and efficient way to convert WSTRING data to STRING data. Its clear interface and direct functionality make it ideal for projects that require fast and straightforward conversion.



WSTRING Conversions

…

2.11.4.8 Counters
Here you will find function blocks for various counter types (forward, reverse, etc.).

FB_CTD
• – ◦ • – ◦ • – ◦ •

The FB_CTD (Down Counter) is a function block that acts as a down counter. It counts down the internal counter value on each trigger event and outputs a signal when the counter reaches or falls below a specific value.

- **REQ**: Normal execution request that starts the counting process.
- **CNF**: Acknowledgement of execution, triggered after the counting process.
- **CD (BOOL)**: Count Down - Signal to count down the counter.
- **LD (BOOL)**: Load - Signal to load the preset value into the counter.
- **PV (INT)**: Preset Value - Preset value loaded into the counter.
- **Q (BOOL)**: Output - Signal activated when the counter value is ≤ 0.
- **CV (INT)**: Count Value - Current counter value.

Adapters

No adapters available.

Adapter

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

The FB_CTD performs the following operations:

1. When the **LD** signal is active, the **PV** value is loaded into the counter (**CV**).
2. When the **CD** signal is active and the counter value (**CV**) is greater than −32768, the counter is decremented by 1.
3. The output signal **Q** is set to `TRUE` when the counter value (**CV**) is ≤ 0.

- The counter value (**CV**) is a 16-bit integer with a range of −32768 to 32767.
- The FB_CTD is a simple function block without an internal state machine.

The FB_CTD has no explicit states but reacts directly to the input signals.

- Controlling processes that require a specific number of steps.
- Monitoring time intervals or event counts.
- Use in automation systems where a counting counter is needed.
- **FB_CTU (Up Counter)**: Counts upwards instead of downwards.
- **FB_CTUD (Up-Down Counter)**: Combines up and down counting in one function block.

The FB_CTD is a simple and efficient function block for downcounting operations in automation applications. Its clear interface and simple functionality make it ideal for basic counting tasks.

Conclusion

FB_CTD_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_CTD_DINT` is a down counter for 32-bit integers (DINT). It is used to decrease a value incrementally and output a signal when a specific threshold is reached.

Interface Structure

Event Inputs

- `REQ`: Normal execution request (trigger for the counting process)

Event Outputs

- `CNF`: Execution confirmation (triggered after completion of the counting process)

Data Inputs

- `CD` (BOOL): Count Down command
- `LD` (BOOL): Load command
- `PV` (DINT): Preset Value

Data Outputs

- `Q` (BOOL): Output signal (is TRUE if CV ≤ 0)
- `CV` (DINT): Current Count Value

Functionality

1. When the `REQ` event is triggered, the following algorithm is executed:

- If `LD` is TRUE, the counter is set to the value of `PV`
- If `CD` is TRUE and the current value (`CV`) is greater than −2147483648, `CV` is decremented by 1

1. The output signal `Q` is set to TRUE if `CV` is less than or equal to 0 is
2. Upon completion, the `CNF` event is triggered

Technical Features

- Uses 32-bit integers (DINT) with a value range of −2147483648 to 2147483647
- The counter stops when the minimum DINT value (-2147483648) is reached
- The block is included in the IEC 61131-3 standard library under `iec61131::counters`

State Overview

The function block has no explicit states but operates event-driven:

1. Waits for the `REQ` event

2. Performs the counting operation
3. Sends the `CNF` event

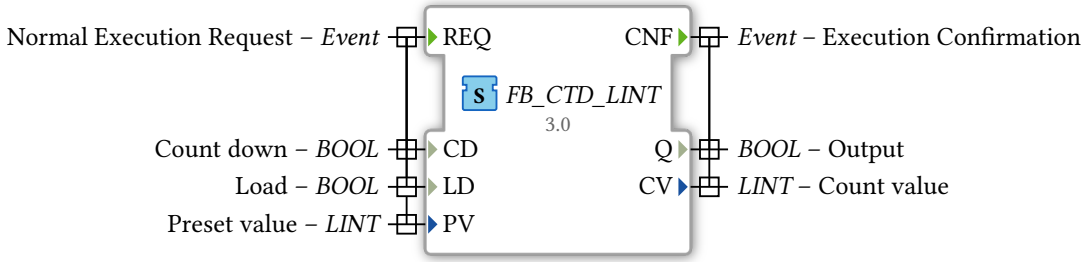
Application Scenarios

- Down counting in production processes
- Time controls with countdown function
- Monitoring of remaining quantities or steps

⚖️ Comparison with similar blocks

- Unlike up counters (CTU), this block decrements the counter value
- Compared to 16-bit counters (INT), this block offers a larger value range
- Similar to timers, but for general counting purposes without a time reference

Conclusion



The `FB_CTD_DINT` is a robust and easy-to-use down counter for 32-bit values. Its clear interface and deterministic operation make it ideal for control tasks where reliable down counting is required.

FB_CTD_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_CTD_LINT` is a countdown counter for 64-bit integers (LINT). It allows counting down an internal counter value and provides functions for loading a predefined value. The block is particularly suitable for applications that need to work with large ranges of numbers.

Interface Structure

Event Inputs

- `REQ`: Starts the normal execution of the counting process. Linked to the data `CD`, `PV`, and `LD`.

Event Outputs

- `CNF`: Confirms execution and returns the current values of `Q` and `CV`.

Data Inputs

- `CD` (BOOL): Signals whether the counter should be decremented.
- `LD` (BOOL): Loads the predefined value (`PV`) into the counter.
- `PV` (LINT): The predefined value that is loaded when `LD` is active.

Data Outputs

- `Q` (BOOL): Signals whether the counter value (`CV`) is less than or equal to zero.
- `CV` (LINT): The current counter value.

Adapters

No adapters available.

Functionality

The function block operates according to the following logic:

1. When `LD` is active, the predefined value (`PV`) is loaded into the counter (`CV`).

2. If `CD` is active and the counter value (`CV`) has not reached the minimum 64-bit value, `CV` is decremented by 1.
3. The output `Q` is set to `TRUE` if `CV` is less than or equal to zero.

Technical Features

- Uses the data type `LINT` (64-bit integer), which allows for a very large number range.
- The minimum value for `LINT` is taken into account to prevent overflows.

Status Overview

- **Initialization**: No specific initialization; `CV` starts with an undefined value.
- **Loading**: When `LD` is active, `CV` is overwritten with `PV`.
- **Counting**: When `CD` is active, `CV` is decremented unless the minimum value has been reached.
- **Output**: `Q` is set based on the current value of `CV`.

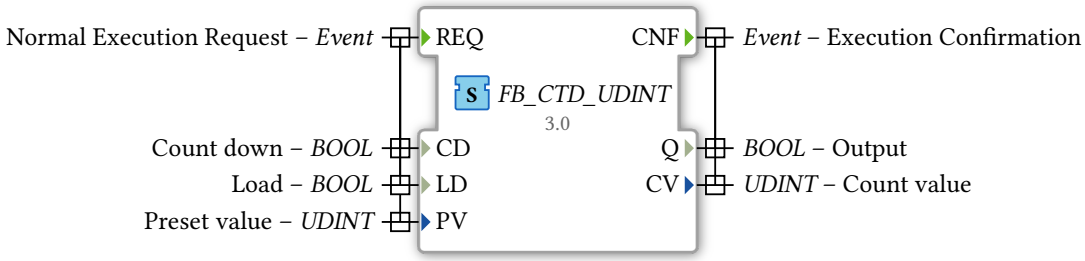
Application Scenarios

- Controlling processes with large counting ranges, e.g., in production automation.
- Monitoring of time intervals or event counts in industrial control systems.

⚖️ Comparison with similar components

- Similar to `FB_CTD_INT`, but with an extended number range (`LINT` instead of `INT`).
- Offers greater flexibility compared to simpler counters due to its large value range and loading function.

Conclusion



The `FB_CTD_LINT` is a powerful down counter for applications requiring large number ranges. Its ease of use and robust implementation make it a reliable choice for complex control tasks.

FB_CTD_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_CTD_UDINT` is a down counter for unsigned 32-bit integers (UDINT). It is used to decrement a counter value on each event until it reaches zero.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Used to trigger the counting process or the loading of a new value.

Event Outputs

- **CNF**: Execution confirmation. Triggered after the request has been processed and returns the current counter value and the output state.

Data Inputs

- **CD** (BOOL): Counts down when `TRUE` is active and the counter value is greater than zero.
- **LD** (BOOL): Loads the specified value (`PV`) into the counter when `TRUE` is active.
- **PV** (UDINT): Specified value loaded into the counter when `LD` is active.

Data Outputs

- **Q** (BOOL): Outputs `TRUE` when the counter value is less than or equal to zero.

- **CV** (UDINT): Current counter value.

Adapters

No adapters available.

Functionality

The function block processes the input events and data as follows:

1. If `LD` is enabled (`TRUE`), the specified value (`PV`) is loaded into the counter (`CV`).
2. If `CD` is enabled (`TRUE`) and the counter value (`CV`) is greater than zero, the counter value is decremented by one.
3. The output `Q` is set to `TRUE` if the counter value (`CV`) is less than or equal to zero.
4. After processing, the output event `CNF` is triggered to confirm the new state.

Technical Features

- The counter uses unsigned 32-bit integers (UDINT).
- The counter value is only decremented if `CD` is enabled and the current value is greater than zero.
- The output `Q` signals when the counter value reaches zero or below.

State Overview

- **Initialization**: The counter value (`CV`) is undefined until a `LD` signal is received.
- **Loading**: When `LD` is enabled, `PV` is loaded into `CV`.
- **Countdown**: When `CD` and `CV > 0` are enabled, `CV` is decremented by one.
- **Initial State**: `Q` becomes `TRUE` when `CV <= 0` is enabled.

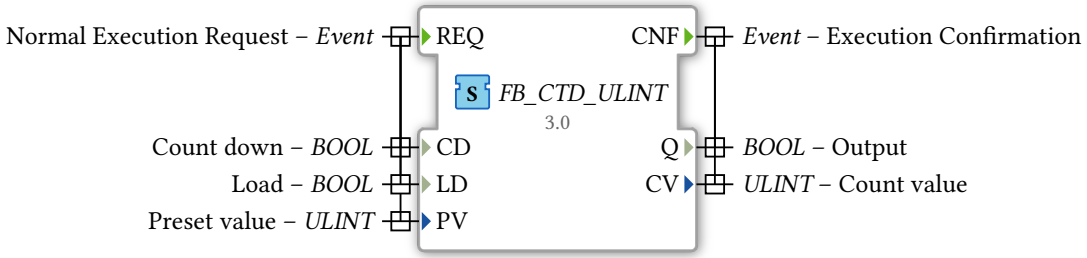
Application Scenarios

- Controlling processes that require a specific number of steps or events.
- Time-controlled processes that require a countdown.
- Monitoring cycles or repetitions in automated systems.

⚖️ Comparison with Similar Components

- Unlike an up counter (CTU), this component decrements the counter value.
- Similar to other counter components, but specialized for unsigned 32-bit integers.

Conclusion



The `FB_CTD_UDINT` is an efficient and simple down counter for applications requiring a counting function with unsigned 32-bit integers. Its clear interface and simple operation make it a useful component in automation technology.

FB_CTD_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The FB_CTD_ULINT is a down counter for the ULINT (Unsigned Long Integer) data type. It is used to count down from a predefined starting value and signals when the counter reaches or falls below 0.

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request. Used to update the counter. Linked to the data inputs CD, PV, and LD.

Event Outputs

- **CNF**: Execution Confirmation. Triggered after the counter has been updated. Linked to the data outputs Q and CV.

Data Inputs

- **CD (BOOL)**: Signals that the counter should be decremented by 1 (Count Down).
- **LD (BOOL)**: Signals that the counter should be loaded with the value of PV (Load).
- **PV (ULINT)**: The preset value with which the counter is loaded when LD is enabled.

Data Outputs

- **Q (BOOL)**: Signals whether the counter reading is less than or equal to 0.
- **CV (ULINT)**: The current counter reading (Count Value).

Adapters

No adapters are defined for this function block.

Functionality

The function block operates according to the following rules:

1. When LD (Load) is enabled, the counter reading (CV) is set to the preset value (PV).
2. If CD (Count Down) is enabled and the counter value (CV) is greater than 0, the counter value is decremented by 1.
3. Output Q is set to TRUE if the counter value (CV) is less than or equal to 0.

Technical Features

- The counter uses the ULINT data type, which allows for very large positive numbers (0 to 18,446,744,073,709,551,615).
- The counter is only updated when the REQ event is triggered.

State Overview

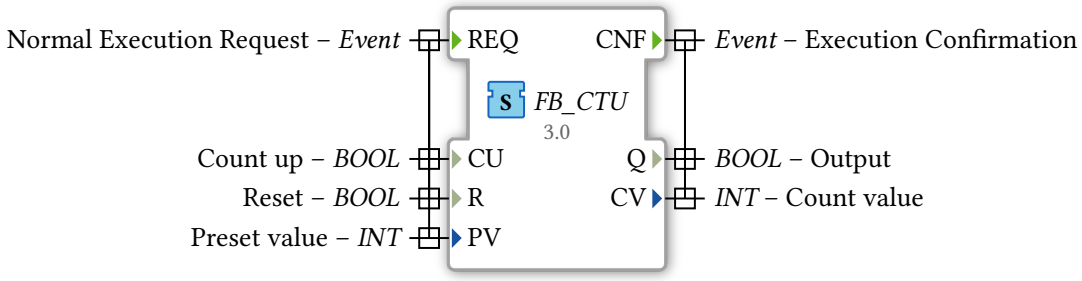
- **Initialization**: The counter value (CV) is undefined until the first REQ event.
- **Loading (LD)**: CV is set to PV.
- **Count (CD)**: CV is decremented by 1 as long as CV > 0.
- **Output Q**: TRUE if CV ≤ 0.

Application Scenarios

- Controlling production processes with downward counting (e.g., remaining parts in a warehouse).
- Time control with large time intervals.
- Monitoring of events with a limited number of occurrences.

⚖️ Comparison with Similar Function Blocks

- Compared to other counters (e.g., FB_CTD_INT), this function block offers a larger number range through ULINT.
- Similar to FB_CTD, but specifically optimized for ULINT values.



Conclusion

The FB_CTD_ULINT is a powerful downward counter for applications requiring very large counting ranges. Its simple and clear interface makes it easy to integrate into various control systems.

FB_CTU

• − ◦ • − ◦ • − ◦ •

The FB_CTU (Up Counter) is a function block that acts as an up counter. It increments the number of events and can be reset. The counter value is compared to a predefined value (PV), and an output signal (Q) is triggered as soon as the counter value reaches or exceeds the predefined value.

- **REQ**: Normal Execution Request. Used to trigger the counting process. Linked to the data inputs `CU` and `R`.
- **CNF**: Execution Acknowledgement. Triggered after the counting process is complete. Linked to the data outputs `Q` and `CV`.
- **CU** (BOOL): Increments when `TRUE` is reached. Only evaluated when `R` is reached or `FALSE` is reached.
- **R** (BOOL): Resets the counter value (`CV`) to `0` when `TRUE` is reached.
- **PV** (INT): Predefined value against which the counter value (`CV`) is compared.
- **Q** (BOOL): Outputs `TRUE` when the counter value (`CV`) reaches or exceeds the predefined value (`PV`).
- **CV** (INT): Current counter value.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters available.

Functionality

The FB_CTU performs the following steps when the event `REQ` occurs:

1. If `R` is `TRUE`, the counter value (`CV`) is reset to `0`. ...
2. The output `Q` is set to `TRUE` if `CV` is greater than or equal to `PV`.

- The counter value (`CV`) is limited to a maximum value of 32767.
- The FB_CTU is a simple function block without internal state management between calls.

The FB_CTU has no internal states. The logic is re-executed with each `REQ` event.

- Counting events, e.g., production steps in a manufacturing line.
- Monitoring processes where a specific number of steps must be completed.
- Controlling sequences that should trigger an action after a certain number of repetitions.
- **FB_CTD**: A down counter that, unlike FB_CTU, counts down.
- **FB_CTUD**: A combined up and down counter that can count both up and down.

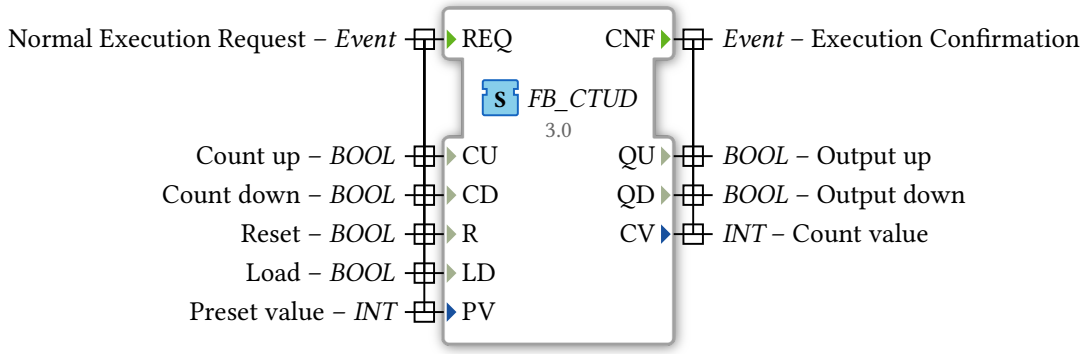
The FB_CTU is a simple and effective function block for up counting operations. It is particularly suitable for applications where events need to be counted and an action triggered when a specific value is reached. Its clear interface structure and simple functionality make it a useful component in control engineering.

Technical Features

State Overview

Application Scenarios

⚖️ Vergleich mit ähnlichen Bausteinen



Conclusion

FB_CTUD

• – ◦ • – ◦ • – ◦ •

Introduction

The FB_CTUD (Up Down Counter) is a function block that acts as a counter with up and down counting capabilities. It allows events to be counted in both directions and offers additional functions such as reset and loading a predefined value.

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request. This event input triggers the execution of the counting process and is linked to the data inputs CU, CD, R, LD, and PV.

Event Outputs

- **CNF**: Execution Confirmation. This event is output after the counting process is complete and is linked to the data outputs QU, QD, and CV.

Data Inputs

- **CU** (BOOL): Counts up.
- **CD** (BOOL): Counts down.
- **R** (BOOL): Resets the counter value to 0.
- **LD** (BOOL): Loads the predefined value PV into the counter.
- **PV** (INT): Predefined value that is loaded into the counter when LD is enabled.

Data Outputs

- **QU** (BOOL): Signals whether the counter value is greater than or equal to the predefined value PV.
- **QD** (BOOL): Signals whether the counter value is less than or equal to 0.
- **CV** (INT): Current counter value.

Adapters

The FB_CTUD does not have any adapters.

Functionality

The function block FB_CTUD performs the following operations:

1. **Reset (R)**: When R is enabled, the counter value (CV) is set to 0.
2. **Load (LD)**: When LD is enabled, the predefined value (PV) is loaded into the counter (CV).

3. **Count (CU/CD)**:

- When CU is enabled and the counter value (CV) is less than 32767, CV is incremented by 1.
- When CD is enabled and the counter value (CV) is greater than −32768, CV is decremented by 1.
- CU and CD cannot be enabled simultaneously.

1. **Outputs (QU/QD)**:

- QU is enabled when CV is greater than or equal to PV.
- QD is enabled when CV is less than or equal to 0.

Technical Features

- The counter value (CV) is of type INT and has a range of −32768 to 32767.
- The FB_CTUD is a simple function block (SimpleFB) and uses a Structured Text (ST) algorithm to implement its logic.

State Overview

The FB_CTUD has no explicit states, but the counter value (CV) can be considered a state, which is changed by the inputs CU, CD, R, and LD.

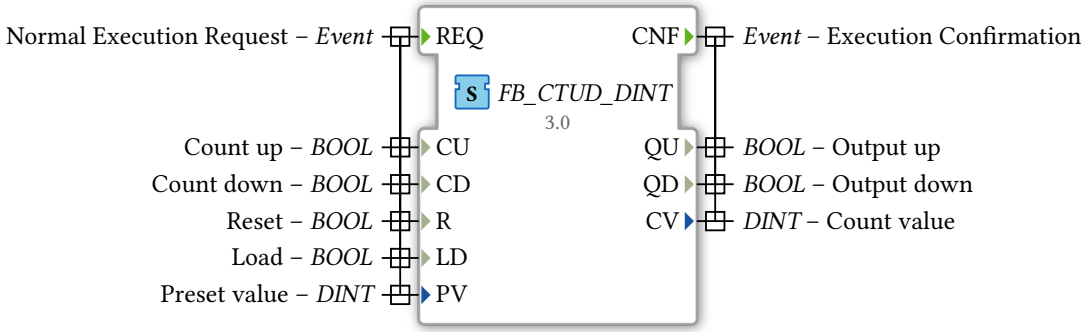
Application Scenarios

- **Production Lines**: Counting units produced (count up) or remaining units (count down).
- **Warehouse Management**: Monitoring inventory levels.
- **Control Engineering**: Time-controlled processes or event counting.

⚖️ Comparison with Similar Function Blocks

- **FB_CTU**: Simple up counter without a down counter function.
- **FB_CTD**: Simple down counter without up counting functionality.
- **FB_CTUD**: Combines both functions in one block and also offers reset and load functions.

Conclusion



The FB_CTUD is a versatile function block that combines both up and down counting functions in a single block. With its additional functions, such as reset and loading a predefined value, it is suitable for a wide range of control engineering applications. Its ease of use and clear interface structure make it a practical solution for counting tasks.

FB_CTUD_DINT

• − ◦ • − ◦ • − ◦ •

Introduction

The FB_CTUD_DINT is a function block that acts as an up/down counter with a DINT counter value. It allows counting in both directions as well as resetting and loading a predefined value. The counter is particularly suitable for control applications where a flexible counting function is required.

Interface Structure

Event Inputs

- **REQ**: Normal execution request (triggers the counting operation)

Event Outputs

- **CNF**: Execution confirmation (triggered after completion of the counting operation)

Data Inputs

- **CU** (BOOL): Counts up
- **CD** (BOOL): Counts down
- **R** (BOOL): Resets the counter
- **LD** (BOOL): Loads the preset value
- **PV** (DINT): Preset value

Data Outputs

- **QU** (BOOL): Signals whether the count has reached or exceeded the preset value
- **QD** (BOOL): Signals whether the Output down (CV)
- **CV** (DINT): Current count value

Adapter

No adapters available.

Functionality

The function block performs the following operations when the REQ event occurs:

1. **Reset (R)**: Sets the count value (CV) to 0 if R is active.
2. **Load (LD)**: Loads the preset value (PV) into the count value (CV) if LD is active.
3. **Count (CU/CD)**:

- If CU is active and the count value has not reached the maximum value (2147483647), the count value is incremented by 1.
- If CD is active and the count value has not reached the minimum value (-2147483648), the count value is decremented by 1.

1. **Setting Outputs**:

- QU is set to TRUE when the counter value reaches or exceeds the preset value.
- QD is set to TRUE when the counter value reaches or falls below 0.

Technical Features

- The counter value (CV) is of type DINT (32-bit signed integer), which allows for a large counting range.
- The function block prevents the counter value from overflowing by checking the limit values.
- Simultaneously activating CU and CD does not change the counter value.

State Overview

The function block does not have an internal state in the sense of a state machine. The logic is re-executed with each REQ event.

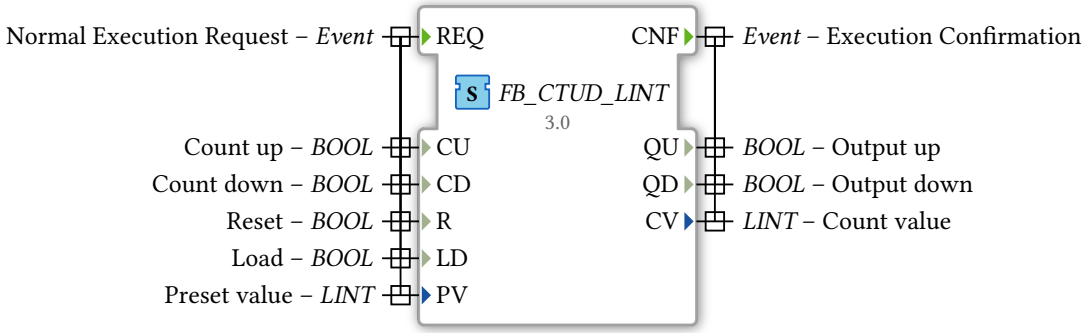
Application Scenarios

- Production counting (e.g., piece counting on a conveyor belt)
- Position detection (e.g., in linear axes)
- Event counting with the option to reverse direction

⚖️ Comparison with similar function blocks

- Compared to simple counters (e.g., CTU or CTD), this function block offers both counting directions in a single block.
- Compared to counters with a smaller data type (e.g., INT), the DINT type offers a larger counting range.

Conclusion



The FB_CTUD_DINT is a versatile counter function block for applications requiring bidirectional counting functions with a large counting range. Its integrated reset and load functions, as well as the status outputs QU and QD, make it particularly suitable for complex control tasks.

FB_CTUD_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The FB_CTUD_LINT is a function block for an incrementing and decrementing counter with 64-bit integer values (LINT). It provides functions for counting up and down, resetting the counter, and loading a predefined value. The counter is particularly suitable for applications requiring large number ranges.

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request. Used to start the counting process. Linked to the data inputs CU, CD, R, LD, and PV.

Event Outputs

- **CNF**: Execution Confirmation. Outputted after completion of the counting operation. Linked to the data outputs QU, QD, and CV.

Data Inputs

- **CU (BOOL)**: Count Up signal.
- **CD (BOOL)**: Count Down signal.
- **R (BOOL)**: Reset counter signal.
- **LD (BOOL)**: Load predefined value signal.
- **PV (LINT)**: Predefined value loaded when LD is active.

Data Outputs

- **QU (BOOL)**: Signal indicating whether the counter value is greater than or equal to the predefined value.
- **QD (BOOL)**: Signal indicating whether the counter value is less than or equal to 0.
- **CV (LINT)**: Current counter value.

Adapter

No adapters available.

Functionality

The function block performs the following operations when the REQ event occurs:

1. **Reset (R)**: Resets the counter value (CV) to 0.
2. **Load (LD)**: Loads the predefined value (PV) into the counter value (CV).
3. **Count Up (CU)**: Increments the counter value by 1, provided the maximum value (9223372036854775807) is not exceeded.
4. **Count Down (CD)**: Decrements the counter value by 1, provided the minimum value (-9223372036854775808) is not undercut.
5. **Outputs QU and QD**: Updated based on the current counter value.

Technical Features

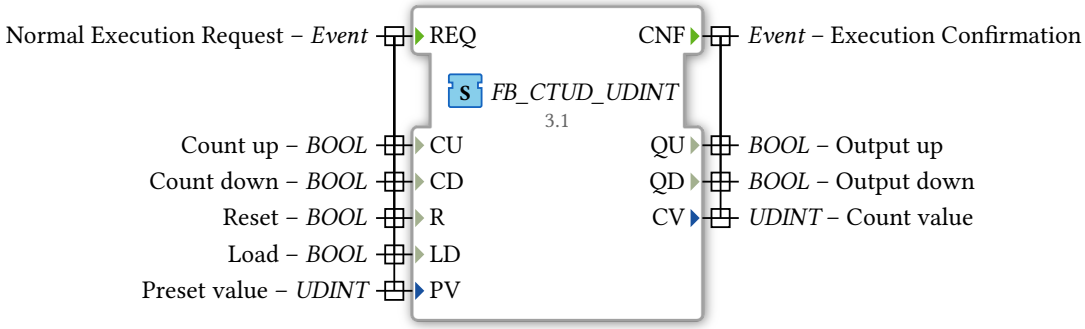
- Uses 64-bit integers (LINT) for the counter value and the predefined value.
- Supports both counting up and down with overflow and underflow protection.
- Simultaneous activation of CU and CD is not possible (prevents conflicts).

State Overview

The function block has no internal state other than the current counter value (CV). The logic is re-executed with each REQ event.

Application Scenarios

- Industrial controllers with large counting ranges.
- Monitoring of production processes.
- Time measurement or event counting over long periods.



⚖️ Comparison with Similar Function Blocks

- Compared to simple counters, FB_CTUD_LINT offers a larger number range (64-bit).
- Similar to FB_CTUD, but with a LINT data type for more advanced applications.

Conclusion

The FB_CTUD_LINT is a high-performance counter for applications requiring large number ranges. Its flexibility and robustness make it ideal for industrial controls and complex counting tasks.

FB_CTUD_UDINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_CTUD_UDINT` is a combined up/down counter for data type `UDINT` (32-bit unsigned integer). It counts up on `CU` and down on `CD`, can be loaded with a preset value `PV` via `LD`, and reset to `0` via `R`.

Interface Structure

Event Inputs

- **REQ**: Triggers execution, linked with `CU`, `CD`, `R`, `LD`, `PV`.

Event Outputs

- **CNF**: Confirms execution, linked with `QU`, `QD`, `CV`.

Data Inputs

- **CU** (BOOL): Count up when `TRUE`.
- **CD** (BOOL): Count down when `TRUE`.
- **R** (BOOL): Reset — sets `CV` to `0`, takes priority over `LD`/`CU`/`CD`.
- **LD** (BOOL): Load — loads `PV` into `CV`, provided `R` is not active.
- **PV** (UDINT): Preset value compared against `CV`.

Data Outputs

- **QU** (BOOL): `TRUE` when `CV >= PV`.
- **QD** (BOOL): `TRUE` when `CV <= 0`.
- **CV** (UDINT): Current count value.

Functionality

On every `REQ` event, the block evaluates the inputs in the following priority: if `R` is active, `CV := 0`. Otherwise, if `LD` is active, `CV := PV`. If neither `R` nor `LD` is active and `CU`/`CD` are not active at the same time, `CV` is incremented by 1 on `CU` (provided `CV < 4294967295`) or decremented by 1 on `CD` (provided `CV > 0`). Finally, `QU := CV >= PV` and `QD := CV <= 0` are computed.

Technical Features

- **Prioritization**: `R` (reset) takes priority over `LD` (load), which in turn takes priority over the actual counting operation.
- **Simultaneous `CU+CD`**: If both are `TRUE` at the same time, no count change occurs (`NOT(CU AND CD)` condition in the algorithm's ST).
- **Range limiting**: The count value is clamped at `4294967295` (the maximum value of `UDINT`) on the upper end and at `0` on the lower end.

State Overview

1. **Reset**: `R = TRUE` ⟶ `CV := 0`.
2. **Load**: `R = FALSE`, `LD = TRUE` ⟶ `CV := PV`.
3. **Counting**: `R = FALSE`, `LD = FALSE` ⟶ `CV` is adjusted based on `CU`/`CD`.
4. **Output**: `QU`/`QD` are recomputed from the current `CV`, `CNF` is triggered.

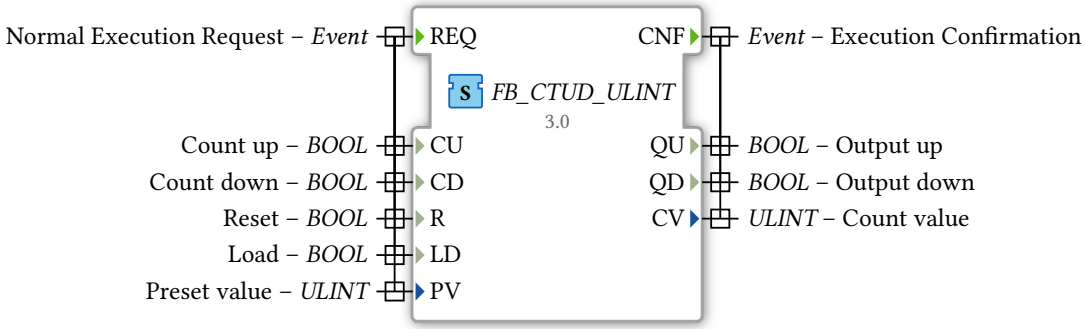
Application Scenarios

- **Bidirectional counting tasks with a large value range**, e.g. piece counts or position values that need both incrementing and decrementing and can exceed the range of `UINT`/`DINT`.
- **Fill-level or buffer counting**, where `QU`/`QD` act as upper/lower-bound signals for downstream logic.

Comparison with similar function blocks

- **`FB_CTUD`**: the same functionality for data type `INT`.
- **`FB_CTUD_DINT`/`FB_CTUD_LINT`/`FB_CTUD_ULINT`**: the same functionality for other integer types.
- **`FB_CTU_UDINT`/`FB_CTD_UDINT`**: the pure up- or down-counter variants for `UDINT`, without the combined `LD` function.

Conclusion



`FB_CTUD_UDINT` provides a complete up/down counter with load and reset functionality for the `UDINT` value range, closing the gap between the already available `FB_CTUD_*` variants for other data types.

FB_CTUD_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_CTUD_ULINT` is a counter with up and down counting functionality for the data type `ULINT` (unsigned 64-bit integer). It offers additional functions such as reset, loading a default value, and status outputs for the counting direction.

Interface Structure

Event Inputs

- `REQ`: Starts the normal execution of the counting process. Linked to the data inputs `CU`, `CD`, `R`, `LD`, and `PV`.

Event Outputs

- `CNF`: Confirms execution and provides the current counter values via the data outputs `QU`, `QD`, and `CV`.

Data Inputs

- `CU` (BOOL): Count Up Signal
- `CD` (BOOL): Count Down Signal
- `R` (BOOL): Reset Signal (sets the counter to 0)
- `LD` (BOOL): Load Signal (loads the preset value `PV` into the counter)
- `PV` (ULINT): Preset Value (default value for the counter)

Data Outputs

- `QU` (BOOL): Signals whether the counter value is greater than or equal to the preset value
- `QD` (BOOL): Signals whether the counter value is less than or equal to 0
- `CV` (ULINT): Current counter value

Functionality

The counter performs the following operations on the `REQ` event:

1. When `R` (Reset) is active, the counter is reset to 0.
2. When `LD` (Load) is active, the default value `PV` is loaded into the counter.
3. If neither Reset nor Load is active:

- When `CU` is active (and not simultaneously `CD`), the counter is incremented (up to the maximum value). 18446744073709551615)
- When `CD` is active (and not simultaneously `CU`), the counter counts down (to the minimum value of 0).

1. The outputs `QU` and `QD` are updated according to the current counter value.

Technical Features

- Uses the 64-bit unsigned integer data type (ULINT)
- Maximum counter value: 18446744073709551615
- Special handling for the simultaneous activation of `CU` and `CD` (no counting operation)
- Status outputs for exceeding/falling below the limit

Application Scenarios

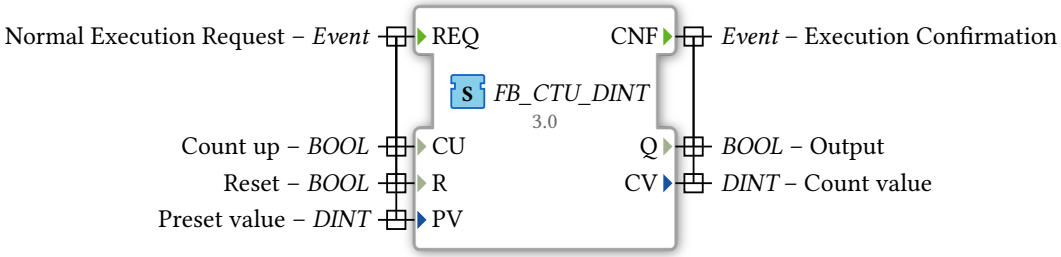
- Industrial counting tasks with large Number ranges
- Position detection in large systems
- Material flow monitoring with high production volumes
- General control tasks with up/down counting function

⚖️ Comparison with similar function blocks

- Compared to simple counters, this function block offers both counting directions
- Compared to smaller data types (e.g., INT), ULINT enables extremely large counting ranges
- Integrated status outputs (`QU`, `QD`) simplify monitoring

Conclusion

The `FB_CTUD_ULINT` is a powerful counter function block for applications requiring large number ranges and flexible counting functions. Its combined up/down counting function and additional control and status options make it suitable for complex counting tasks in industrial control systems.



FB_CTU_DINT

• – ◦ • – ◦ • – ◦ •

Introduction

The FB_CTU_DINT is an up counter for the DINT data type (32-bit count). It increments with each count pulse and can be reset to a predefined value. This function block is particularly suitable for applications requiring large count ranges.

•

Interface Structure

Event Inputs

- **REQ**: Normal execution request (triggers the counting process)

Event Outputs

- **CNF**: Execution confirmation (triggered after completion of the counting process)

Data Inputs

- **CU** (BOOL): Count input (increments the counter when TRUE)
- **R** (BOOL): Reset input (sets the counter value to 0 when TRUE)
- **PV** (DINT): Preset value (defines the comparison value for the Q output)

Data Outputs

- **Q** (BOOL): Status output (becomes TRUE if CV ≥ PV)
- **CV** (DINT): Current counter value (Count Value)

Adapters

No adapters available.

Functionality

The FB_CTU_DINT operates according to the following rules:

1. When reset is active (R=TRUE), the counter value (CV) is reset to 0.
2. When the counter input is active (CU=TRUE) and reset is inactive, the counter value is incremented by 1 (up to the maximum value of 2147483647).
3. The output Q is set to TRUE as soon as the counter value (CV) reaches or exceeds the preset value (PV).

Technical Features

- Uses 32-bit integers (DINT) for counter values
- Maximum counter value: 2147483647
- Implemented as a simple function block (SimpleFB)
- Supports the IEC 61131-3 standard

State Overview

The function block does not have an internal state machine. The logic is executed on each REQ event.

Application Scenarios

- Production counting in manufacturing plants
- Event counting in process control systems
- Cycle time monitoring
- General counting tasks in automation technology

⚖️ Comparison with similar function blocks

- Compared to FB_CTU_INT, FB_CTU_DINT offers a larger counting range (32-bit vs. 16-bit)
- Compared to FB_CTU_LINT, FB_CTU_DINT has a smaller value range but lower memory requirements
- Similar to IEC 61131-3 CTU function blocks, but implemented in the 4diac IDE

Conclusion

The FB_CTU_DINT is a robust and easy-to-use increment counter for applications with medium to large counting ranges. Its clear interface and simple functionality make it particularly suitable for standard counting tasks in automation technology.

FB_CTU_LINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_CTU_LINT` is a counter-up function for large integers. It increments with each incoming counting event and can be reset to a predefined value. The block uses the data type `LINT` (64-bit integer) for the counter value and the setpoint.

Interface Structure

Event Inputs

- **REQ**: Normal execution request, triggers the counting operation. It is associated with the data `CU` and `R`.

Event Outputs

- **CNF**: Execution confirmation, output after the counting operation. Linked to the data `Q` and `CV`.

Data Inputs

- **CU** (BOOL): Count Up command. If TRUE, the counter is incremented.
- **R** (BOOL): Reset. If TRUE, the counter is reset to 0.
- **PV** (LINT): Preset Value. The setpoint at which output `Q` is set to TRUE.

Data Outputs

- **Q** (BOOL): Output. Becomes TRUE when the counter value (`CV`) reaches or exceeds the setpoint value (`PV`).
- **CV** (LINT): Current Value. Current counter reading.

Adapters

This function block does not use adapters.

Functionality

The function block performs the following operations on each `REQ` event:

1. If `R` is TRUE, the counter (`CV`) is reset to 0.
2. If `CU` is TRUE and the counter has not yet reached its maximum value (9223372036854775807), the counter is incremented by 1.
3. The output `Q` is set to TRUE when the counter value (`CV`) reaches or exceeds the setpoint (`PV`).

Technical Features

- Uses 64-bit integers (`LINT`) for counter value and setpoint
- Maximum counter value: 9223372036854775807 (2^63-1)
- Implemented in Structured Text (ST)

State Overview

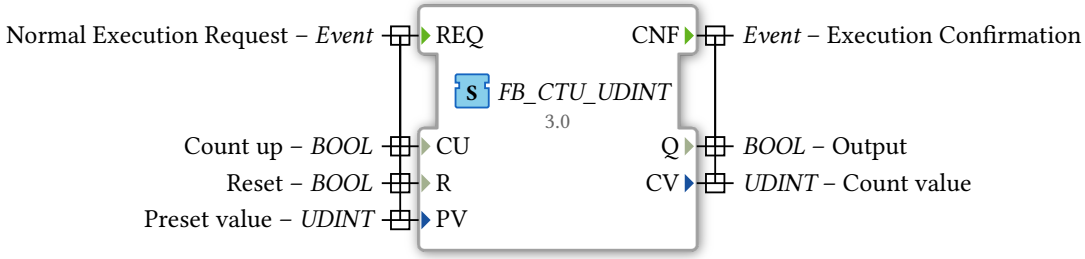
The function block does not have an internal state machine. The logic is re-executed with each `REQ` event.

Application Scenarios

- Counting events in large number ranges
- Monitoring production quantities
- Controlling processes with high count values

⚖️ Comparison with similar blocks

- Compared to `FB_CTU` (standard counter), this block supports larger number ranges (`LINT` instead of `INT`)
- Similar to `FB_CTUD`, but without a down counting function



Conclusion

The `FB_CTU_LINT` is a powerful up counting block for applications requiring large counting ranges. Its simple interface and robust implementation make it a useful building block for industrial control applications.

FB_CTU_UDINT

• – ◦ • – ◦ • – ◦ •

The function block `FB_CTU_UDINT` is an up counter for the data type `UDINT` (unsigned double integer). It increments with each event `REQ` as long as the input `CU` is active, and can be reset via the input `R`. The counter compares the current counter value with a predefined setpoint (`PV`) and outputs a signal via the output `Q` when this setpoint is reached or exceeded.

- **REQ**: Starts the execution of the function block. It is linked to the data inputs `CU` and `R`.
- **CNF**: Confirms the execution of the function block. It is linked to the data outputs `Q` and `CV`.
- **CU** (`BOOL`): Increment signal. The counter value is incremented on `TRUE`.
- **PV** (`UDINT`): Preset value against which the current counter reading is compared.
- **Q** (`BOOL`): Signal generated when the counter reading (`CV`) reaches or exceeds the preset value (`PV`).
- **CV** (`UDINT`): Current counter reading.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

The function block performs the following steps on each `REQ` event:

1. If `R` is active (`TRUE`), the counter value (`CV`) is reset to `0`.
2. If `CU` is active (`TRUE`) and the counter value (`CV`) is less than the maximum value (`4294967295`), the counter value is incremented by `1`.
3. The output `Q` is set to `TRUE` when the counter reading (`CV`) reaches or exceeds the target value (`PV`).

- The counter reading (`CV`) is of type `UDINT` and can take values between `0` and `4294967295`.

- The function block is deterministic and performs the counting operation on every `REQ` event.

The function block has no internal states other than the current counter reading (`CV`). The logic is re-evaluated with each `REQ` event.

- Counting events in control applications (e.g., production counters).
- Monitoring processes where a specific number of steps must be completed.
- As part of a larger control logic that reacts to counter readings.
- Compared to other counters (e.g., `FB_CTU_INT`), this function block uses the `UDINT` data type, which allows for a larger range of values.
- Similar function blocks might offer additional features such as counting down or combined counting up/down.

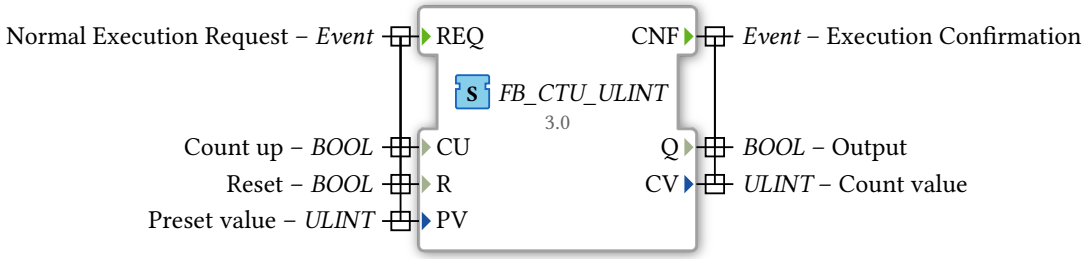
The `FB_CTU_UDINT` is a simple and efficient up counter for applications that require a large range of values. Its clear interface and deterministic functionality make it a reliable component in control applications.

Technical Features

State Overview

Application Scenarios

⚖️ Vergleich mit ähnlichen Bausteinen



Conclusion

FB_CTU_ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_CTU_ULINT` is an up counter for the data type `ULINT` (Unsigned Long Integer). It increments with each counting event and can be reset to a predefined value. This block is particularly suitable for applications requiring large counting ranges.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Used to trigger the counting process. Linked to the data `CU` and `R`.

Event Outputs

- **CNF**: Execution Confirmation. Triggered after processing the counting operation. Linked to the data `Q` and `CV`.

Data Inputs

- **CU** (BOOL): Count Request. Increments the counter when `TRUE` is active, unless `R` is active.
- **R** (BOOL): Reset. Resets the counter value (`CV`) to `0` when `TRUE` is active.
- **PV** (ULINT): Preset Value. Defines the threshold at which the output `Q` is activated.

Data Outputs

- **Q** (BOOL): Output. Outputs `TRUE` when the counter value (`CV`) reaches or exceeds the preset value (`PV`).
- **CV** (ULINT): Current Counter Value. Returns the current counter value.

Functionality

This function block increments the counter value (`CV`) by 1 when the input `CU` is activated (`TRUE`) and the counter value has not reached the maximum value (`18446744073709551615`). When the input `R` is enabled (`TRUE`), the counter value is reset to `0`. The output `Q` is set to `TRUE` as soon as the counter value (`CV`) reaches or exceeds the preset value (`PV`).

Technical Features

- The counter value (`CV`) is of type `ULINT`, which allows for a very large counting range (0 to 18446744073709551615).
- The block is deterministic and suitable for real-time applications.

Status Overview

- **Reset State**: `CV = 0` (if `R = TRUE`).
- **Count State**: `CV` is incremented by 1 (if `CU = TRUE` and `R = FALSE`).
- **Threshold Reached**: `Q = TRUE` (if `CV >= PV`).

Application Scenarios

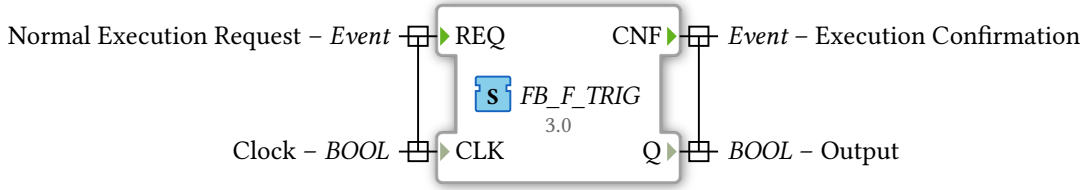
- Counting production units in high-speed systems.
- Monitoring events in long-running systems.
- Controlling processes with large counting ranges.

⚖️ Comparison with Similar Function Blocks

- Compared to `FB_CTU_INT` or `FB_CTU_DINT`, `FB_CTU_ULINT` offers a significantly larger counting range.
- Similar to `FB_CTU`, but specialized for the `ULINT` data type.

Conclusion

The `FB_CTU_ULINT` is a powerful increment counter for applications requiring large counting ranges. Its ease of use and deterministic operation make it a reliable choice for industrial control applications.



2.11.4.9 Edge Detection

Here you will find function blocks for detecting signal edges (rising, falling).

FB_F_TRIG

• – ◦ • – ◦ • – ◦ •

The function block `FB_F_TRIG` is used to detect the falling edge of a Boolean signal. It is frequently used in control applications to detect state changes from `TRUE` to `FALSE` and trigger corresponding actions.

- `REQ` (Normal Execution Request): Starts the execution of the function block. It is linked to the data input `CLK`.
- `CNF` (Execution Confirmation): Confirms the execution of the function block. Linked to the data output `Q`.
- `CLK` (BOOL): The signal to be monitored, whose falling edge is to be detected.
- `Q` (BOOL): Outputs `TRUE` if a falling edge is detected, otherwise `FALSE`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- No adapters available.

The function block stores the previous state of the `CLK` signal in an internal variable `MEM`. On each call via the `REQ` event, it checks whether the current `CLK` signal is `FALSE` and whether the previous state (`MEM`) was `TRUE`. If so, `Q` is set to `TRUE`; otherwise, it is set to `FALSE`. The current state of `CLK` is then stored in `MEM`.

- The function block uses an internal memory variable (`MEM`) to store the previous state of the `CLK` signal.
- The logic for detecting the falling edge is implemented in an ST algorithm.

1. **Initialization**: `MEM` is initialized with `TRUE`.
2. **Falling Edge Detection**:

- When `CLK` transitions from `TRUE` to `FALSE`, `Q` is set to `TRUE`.
- In all other cases, `Q` is set to `FALSE`.

1. **Saving the Current State**: The current state of `CLK` is saved to `MEM`.

- Detection of button or switch actuations in control systems.
- Synchronization of processes upon signal changes.
- Triggering of actions on falling edges in time-critical applications.
- **FB_R_TRIG**: Detection of a rising edge (from `FALSE` to `TRUE`).
- **FB_R_F_TRIG**: Combined detection of rising and falling edges. - **FB_F_TRIG** is specialized for detecting falling edges and is therefore more efficient in this specific application.
- Exercise_178
- Exercise_178_AX

The `FB_F_TRIG` function block is a simple and efficient function block for detecting falling edges in Boolean signals. Its clear interface and simple operation make it ideal for control applications where state changes need to be detected.

Conclusion

FB_R_TRIG

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_R_TRIG` is used to detect the rising edge of a Boolean signal. It is typically used to detect and react to state changes from `FALSE` to `TRUE`.

Interface Structure

Event Inputs

- **REQ**: Normal Execution Request. Used to trigger edge detection. Linked to the data input `CLK`.

Event Outputs

- **CNF**: Execution Acknowledgement. Triggered after edge detection is complete. Linked to the data output `Q`.

Data Inputs

- **CLK** (BOOL): The input signal whose rising edge is to be detected.

Data Outputs

- **Q** (BOOL): The output signal `TRUE` is generated when a rising edge is detected at the input `CLK`.

Adapters

This function block does not use any adapters.

Functionality

`FB_R_TRIGstores the previous state of the input signalCLKin an internal variableMEM. Each time the algorithm is called via the event REQ, it checks whether the current state was CLKorTRUEand the previous state wasFALSE. If so, the output Qis set toTRUE; otherwise, it is set to FALSE. The current state of CLKis then stored inMEM` for the next iteration.

Technical Features

- The function block is implemented according to the IEC 61499-1 standard.
- It uses a simple edge detection algorithm that can be executed efficiently and quickly.

State Overview

This function block does not have a complex state machine. The state is represented solely by the value of the internal variable `MEM`, which stores the previous state of `CLK`.

Application Scenarios

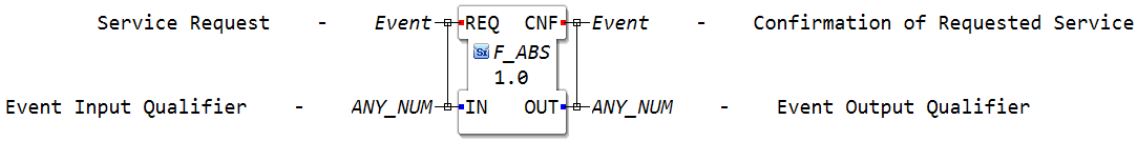
- Detection of key presses or switch activations.
- Synchronization of processes to rising edges of control signals.
- Triggering of actions upon specific events.

⚖️ Comparison with Similar Function Blocks

- **FB_F_TRIG**: Detection of a falling edge (from `TRUE` to `FALSE`).
- **FB_R_TRIG** is specific for rising edges and therefore complementary to `FB_F_TRIG`.

🛠️ Related Exercises

- Exercise_177
- Exercise_177_AX

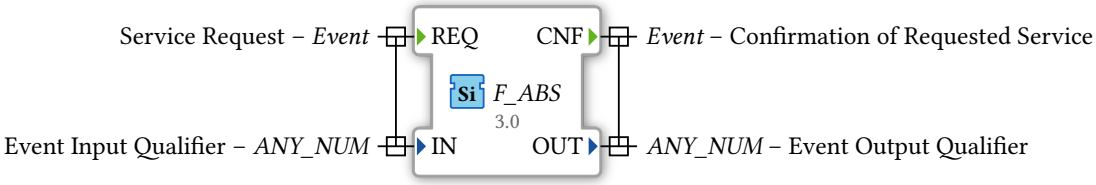


Conclusion

The `FB_R_TRIG` function block is a simple and effective function block for detecting rising edges. Its clear interface structure and simple functionality make it a useful component in many control applications.

2.11.4.10 Numerical Functions

Here you will find mathematical functions such as trigonometric functions, logarithms, roots, etc. ...



F_ABS

• – ◦ • – ◦ • – ◦ •

Introduction

The F_ABS function block calculates the absolute value of a numeric input. It belongs to the category of standard functions for numeric variables according to IEC 61131-3 and is part of the iec61131::numerical package.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the calculation of the absolute value

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs

- **IN**: Numeric Input (ANY_NUM) - the value whose absolute value is to be calculated

Data Outputs

- **OUT**: Numeric Output (ANY_NUM) - the calculated absolute value of the input

Adapters

No adapter interfaces are available.

Functionality

Upon receiving a REQ event, the F_ABS block calculates the absolute value of the numeric value passed to IN. The result is output to OUT and confirmed by a CNF event. The block supports all numeric data types (ANY_NUM).

Technical Features

- Supports all numeric data types according to IEC 61131-3
- Simple, deterministic operation without internal states
- Immediate calculation upon REQ event

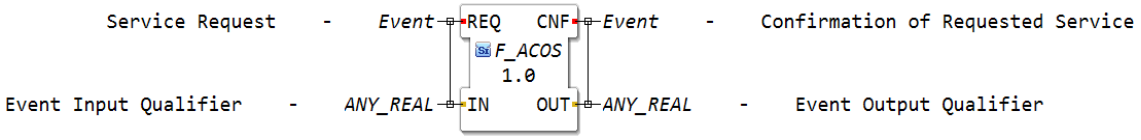
State Overview

The F_ABS block has no internal states. It behaves purely functionally and reacts immediately to incoming REQ events.

Application Scenarios

- Signal processing for sign removal
- Magnitude calculations in mathematical operations
- Use in control engineering for distance calculations

- Preprocessing of measured values



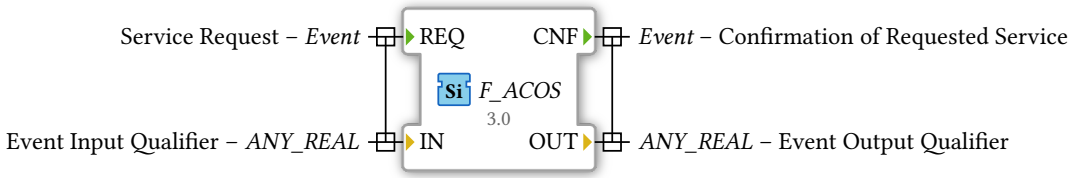
⚖️ Comparison with Similar Function Blocks

Compared to other mathematical function blocks, F_ABS stands out due to its simplicity and specific functionality. While blocks like F_ADD or F_MUL perform more complex operations, F_ABS focuses exclusively on magnitude calculation.

Conclusion

The F_ABS function block offers a reliable and standards-compliant solution for calculating absolute values in IEC 61131-3-based control systems. Its simple interface and deterministic functionality make it a robust building block for numerical operations.

F_ACOS



• – ◦ • – ◦ • – ◦ •

Introduction

The F_ACOS function block calculates the principal value of the arccosine of a numerical input. It implements the mathematical function for determining the angle whose cosine corresponds to the input value. The block belongs to the category of standard functions for numeric variables according to IEC 61131-3.

•

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the calculation of the arccosine

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs

- **IN**: Input value of type ANY_REAL - the value for which the arccosine is to be calculated

Data Outputs

- **OUT**: Output value of type ANY_REAL - the result of the arccosine calculation

Adapters

No adapter interfaces are available.

Functionality

Upon receipt of a REQ event, the F_ACOS block calculates the arccosine of the current IN value. The result is output to the OUT port, and a CNF event is simultaneously generated to signal the successful completion of the operation.

The function calculates the prime value of the arccosine, which lies in the range from 0 to π (0° to 180°).

Technical Features

- Supports the ANY_REAL data type for maximum flexibility with numeric inputs
- Compliant with the IEC 61131-3 standard for programmable logic controllers (PLCs)

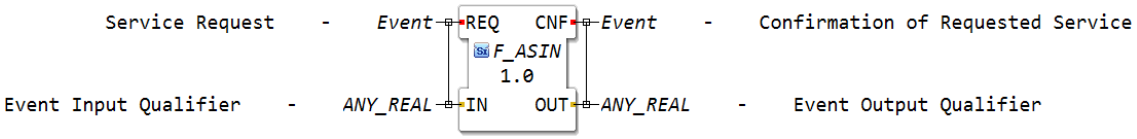
- Returns the mathematically correct principal value of the arccosine
- Guarantees defined behavior for valid input values in the range [−1, 1]

State Transitions

1. **Idle State**: Waits for a REQ event
2. **Calculating State**: Processes the arccosine function upon REQ input
3. **Output State**: Sends a CNF event with the calculated OUT value

Application Scenarios

- Angle measurement and calculation in technical systems
- Robotics and motion control
- Signal processing and control engineering
- Scientific calculations and simulations
- Geometric transformations in CAD/CAM systems

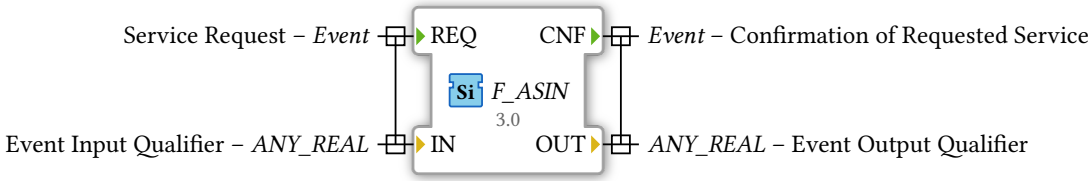


⚖️ Comparison with Similar Function Blocks

Compared to other trigonometric functions such as F_SIN F_ACOS (sine) or F_COS (cosine) provides the inverse operation. While F_COS maps an angle to a value between −1 and 1, F_ACOS maps a value between −1 and 1 to an angle between 0 and π.

Conclusion

The F_ACOS function block provides a reliable and standards-compliant implementation of the arccosine function for industrial control systems. Its simple interface and deterministic operation make it ideal for real-time applications in automation solutions.



F_ASIN

• – ◦ • – ◦ • – ◦ •

Introduction

The F_ASIN function block is a standard function block according to IEC 61131-3 that calculates the arcsine of a numeric input. It belongs to the category of standard mathematical functions for a numeric variable and returns the principal value of the arcsine function.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the arcsine calculation

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs

- **IN**: Input value of type ANY_REAL - the value for which the arcsine is to be calculated

Data Outputs

- **OUT**: Output value of type ANY_REAL - the result of the arcsine calculation

Adapters

No adapter interfaces are available.

Functionality

The F_ASIN function block calculates the arcsine (inverse sine function) of the input value IN. The calculation is performed when the REQ event is triggered. After the calculation is complete, the CNF event is output along with the result value OUT.

The function operates according to the mathematical definition: OUT = arcsin(IN), where the result lies in the range [-π/2, π/2] radians.

Technical Features

- Supports the ANY_REAL data type for maximum flexibility with various real number types
- Compliant with the IEC 61131-3 standard for numeric functions
- Simple event-driven processing
- Returns the principal value of the arcsine function

State Overview

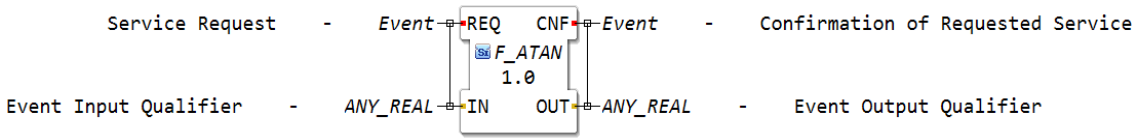
The function block has a simple state machine:

1. **Wait State**: Waits for a REQ event
2. **Calculate State**: Performs an arcsine calculation
3. **Output State**: Sends a CNF event with the result

Application Scenarios

- Calculating angles from sine values in trigonometric applications
- Signal processing in control engineering and automation
- Geometric calculations in technical systems
- Scientific and engineering calculations

⚖️ Comparison with Similar Function Blocks

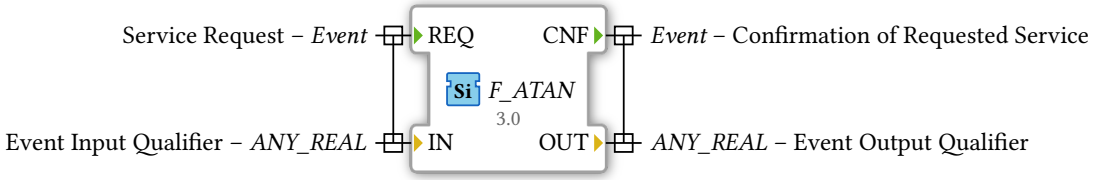


Compared to other trigonometric functions:

- F_ASIN is the inverse function of F_SIN
- Similar to F_ACOS (Arc cosine) and F_ATAN (Arc tangent)
- Returns results within the specific range of values for the arcsine function

Conclusion

The F_ASIN function block provides a standards-compliant, reliable implementation of the arcsine function for automation applications. Its simple interface and event-driven processing make it ideal for use in more complex control algorithms that require trigonometric calculations.



F_ATAN

• — ○ • — ○ • — ○ •

Introduction

The F_ATAN function block calculates the arctangent of a real number. It is a standard function for a numeric variable according to IEC 61131-3. The function block converts a tangent value into the corresponding angle in radians.

Interface Structure

Event Inputs
- **REQ**: Service Request - triggers the calculation of the arctangent

Event Outputs
- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs
- **IN**: Input value of type ANY_REAL - the tangent value for which the arctangent is to be calculated

Data Outputs
- **OUT**: Output value of type ANY_REAL - the calculated arctangent value in radians

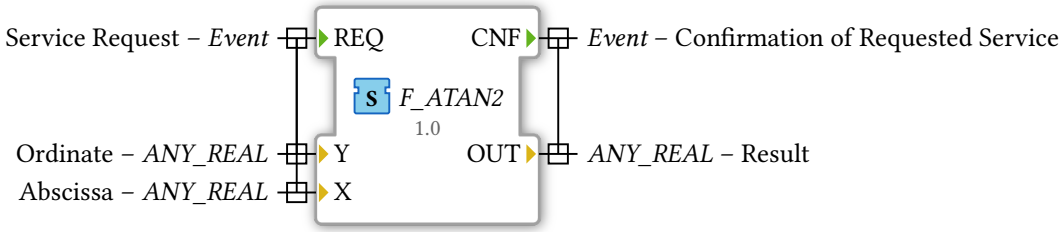
Adapters
No adapter interfaces are available.

Functionality
Upon receiving a REQ event, the F_ATAN function block calculates the arctangent of the value passed to IN. The result is output to OUT, and a CNF event is simultaneously generated to signal the completion of the calculation.

The function calculates the principal value of the arctangent, which lies in the range of $-\pi/2$ to $\pi/2$.

Technical Features
- Supports the ANY_REAL data type, enabling various real data types (REAL, LREAL)
- Compliant with the IEC 61131-3 standard
- Deterministic computational behavior
- Suitable for real-time applications

State Transitions
1. **Initial State**: Waits for a REQ event
2. **Computation State**: ATAN(IN) is calculated upon a REQ event
3. **Output State**: The result is sent to OUT and a CNF event is triggered
4. Returns to the initial state



Application Scenarios
- Angle measurement and calculation in control systems
- Coordinate transformations in robotics applications
- Control engineering for position controllers
- Signal processing in mathematical calculations
- Navigation and orientation systems

⚖️ Comparison with Similar Function Blocks
- **F_ATAN2**: Calculates the arctangent of two coordinates (x,y) and returns an angle in the range from $-\pi$ to π
- **F_SIN/F_COS**: Basic trigonometric functions for sine and cosine
- **F_TAN**: Calculates the tangent of an angle (inverse function of F_ATAN)

Conclusion

The F_ATAN function block offers a reliable and standards-compliant implementation of the arctangent function for automation applications. Its simple interface and deterministic operation make it ideal for real-time applications in industrial automation where trigonometric calculations are required.

F_ATAN2

• – ◦ • – ◦ • – ◦ •

Introduction

`F_ATAN2` computes the principal value of the arc tangent of `Y/X`, taking into account the signs of both arguments (two-parameter arc tangent). Unlike the plain `ATAN` function (which takes only one argument), `F_ATAN2` returns the angle in the correct quadrant across the full angular range from `-π` to `+π`.

Interface Structure

Event Inputs

- **REQ**: Triggers the calculation, carries `Y` and `X`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **Y** (ANY_REAL): Ordinate (Y coordinate).
- **X** (ANY_REAL): Abscissa (X coordinate).

Data Outputs

- **OUT** (ANY_REAL): The computed angle in radians, in the range `(-π, π]`.

Functionality

On `REQ`, the block computes the angle between the positive X axis and the point `(X, Y)` — equivalent to `ATAN(Y/X)`, but evaluating the signs of `X` and `Y` individually to determine the correct quadrant (including the special case `X = 0`). The result is output via `OUT`, then `CNF` is triggered.

Technical Features

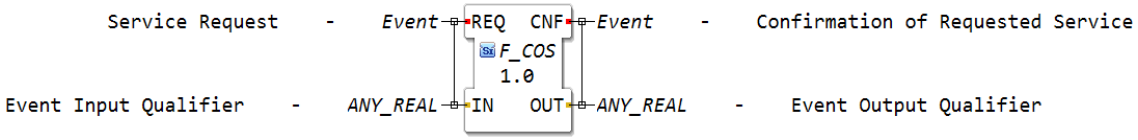
- **Quadrant correctness**: Unlike `ATAN(Y/X)`, `F_ATAN2` returns the correct angle even for negative `X` (2nd and 3rd quadrant), without the caller having to manually correct for the quadrant.
- **`ANY_REAL` typing**: Accepts both `REAL` and `LREAL` for `Y`, `X`, and `OUT`.
- **Special case `X = 0`**: Returns `+π/2` or `-π/2` depending on the sign of `Y`, instead of a division by zero as with directly using `ATAN(Y/X)`.

State Overview

Stateless: every `REQ` immediately results in the calculation and `CNF`.

Application Scenarios

- **Angle calculation from Cartesian coordinates**: e.g. determining the heading or orientation of an object from its X/Y position relative to a reference point.
- **Control engineering**: Computing phase angles or steering angles from two component signals.
- **Navigation**: Course calculation from velocity components.

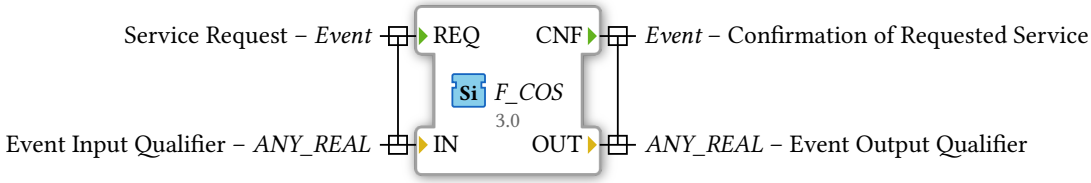


Comparison with similar function blocks

- **F_ATAN**: computes the arc tangent of a single value, only returns angles in the range (-π/2, π/2), and requires manual quadrant correction.

Conclusion

F_ATAN2 provides quadrant-correct angle calculation from two Cartesian components and is the standard block for angle/direction calculations where ATAN alone is insufficient.



F_COS

• — ◦ • — ◦ • — ◦ •

Introduction

The F_COS function block calculates the cosine of an input value in radians. It is a standard function for numerical calculations according to IEC 61131-3.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the cosine calculation

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs

- **IN**: Input value in radians (ANY_REAL data type)

Data Outputs

- **OUT**: Calculated cosine value of the input value (ANY_REAL data type)

Adapters

No adapters available.

Functionality

Upon receiving a REQ event, the F_COS block calculates the cosine of the value passed to IN. The input value is interpreted as an angle in radians. After the calculation is complete, the CNF event is output to OUT along with the result.

Technical Features

- Supports the ANY_REAL data type for maximum flexibility
- Calculations are performed in radians
- Compliant with the IEC 61131-3 standard
- Part of the iec61131::numerical package

State Transitions

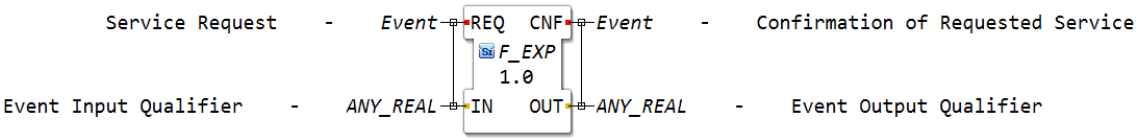
1. **Wait State**: Block waits for a REQ event
2. **Calculate State**: Cosine is calculated upon a REQ event
3. **Output State**: CNF event with result is output

4. **Return**: Returns to the wait state

Application Scenarios

- Signal processing in control engineering
- Mathematical calculations in control systems
- Trigonometric functions in technical applications
- Calculations in robotics and motion control

⚖️ Comparison with Similar Function Blocks

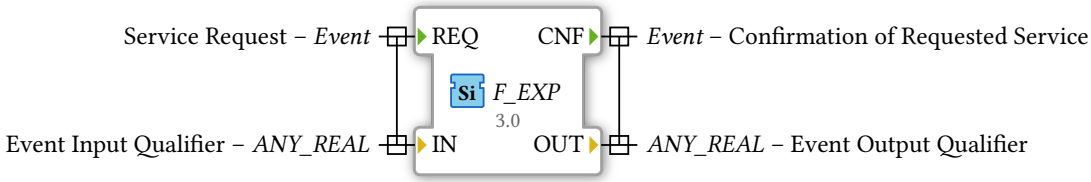


Compared to other trigonometric functions:

- F_SIN: Calculates sine instead of cosine
- F_TAN: Calculates tangent
- F_ACOS: Calculates Arccosine (Inverse Function)

Conclusion

The F_COS function block offers a reliable and standards-compliant implementation of the cosine function for industrial control systems. Its simple interface and flexible data type support make it ideal for various automation applications.



F_EXP

• – ◦ • – ◦ • – ◦ •

Introduction

The F_EXP function block calculates the natural exponential function (e^x) for numerical input values. It is one of the standard functions for numerical variables according to IEC 61131-3 and is used for mathematical calculations in control applications.

Interface Structure

Event Inputs

- **REQ**: Service Request - Triggers the calculation of the exponential function

Event Outputs

- **CNF**: Confirmation of Requested Service - Confirms successful calculation

Data Inputs

- **IN**: ANY_REAL - Numeric input value for which the exponential function is to be calculated

Data Outputs

- **OUT**: ANY_REAL - Result of the exponential function (e^IN)

Adapters

No adapter interfaces are available.

Functionality

Upon receipt of a REQ event, the F_EXP block calculates the natural exponential function of the value passed to IN. The result is output to OUT and confirmed by a CNF event. The function is mathematically equivalent to calculating e^x, where x is the input value.

Technical Features

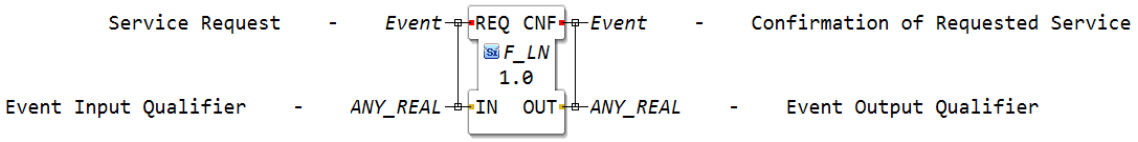
- Supports the ANY_REAL data type for maximum flexibility with numerical inputs
- Real-time calculation of the exponential function
- Simple and direct interface without additional parameters
- Implemented in accordance with the IEC 61131-3 standard

State Transitions

1. **Wait State**: Block waits for REQ event
2. **Calculate State**: Upon REQ event, e^IN is calculated
3. **Output State**: Result is set to OUT and a CNF event is triggered
4. Return to Wait State

Application Scenarios

- Mathematical modeling and simulation
- Gain calculations in control engineering
- Growth processes and exponential developments
- Signal processing and filtering
- Scientific calculations in industrial control systems

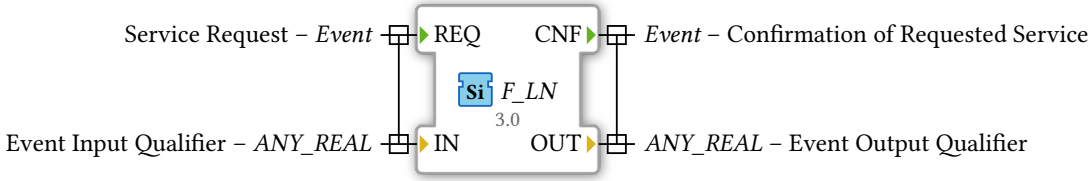


⚖️ Comparison with similar function blocks

Compared to other mathematical function blocks such as F_LN (natural logarithm) or F_POWER (power function), F_EXP offers a A specialized implementation for the exponential function with optimized performance. The use of ANY_REAL enables broader compatibility than type-specific implementations.

Conclusion

The F_EXP function block provides a reliable and standards-compliant implementation of the natural exponential function for industrial control systems. Its simple interface and flexible data type support make it ideal for various mathematical applications in automation projects.



F_LN

• — ○ • — ○ • — ○ •

Introduction

The F_LN function block calculates the natural logarithm (logarithm to base e) of a numeric input value. It belongs to the category of standard functions for a numeric variable according to the IEC 61131-3 standard.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the calculation of the natural logarithm

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs

- **IN**: Numeric input value of type ANY_REAL for which the natural logarithm is to be calculated

Data Outputs

- **OUT**: Calculated natural logarithm of the input value of type ANY_REAL

Adapters

No adapter interfaces are available.

Functionality

Upon receiving a REQ event, the F_LN block calculates the natural logarithm (ln) of the value passed to IN. The result is output to OUT, and simultaneously, a CNF event is generated to signal the successful completion of the operation.

Technical Features

- Supports the ANY_REAL data type, which includes various numeric data types such as REAL, LREAL, etc.
- Implemented according to the IEC 61131-3 standard for numeric functions
- Real-time execution with event-driven control

State Overview

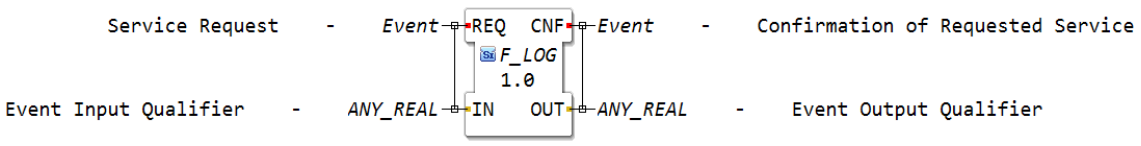
The function block features a simple state machine:

1. **Wait State**: Block waits for a REQ event
2. **Calculate State**: Processes the logarithm calculation
3. **Output State**: Sends a CNF event with the calculated result

Application Scenarios

- Scientific calculations and mathematical modeling
- Signal processing and data analysis
- Control engineering for exponential processes
- Scaling of measured values in logarithmic representations

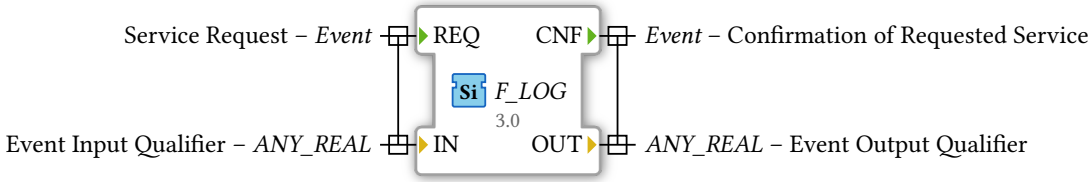
⚖️ Comparison with Similar Blocks



Compared to other mathematical function blocks:

- F_LN specializes in natural logarithms (base e)
- F_LOG calculates logarithms to any value Basis
- F_EXP calculates the exponential function (inverse function of LN)
- Simpler structure than general logarithm functions

Conclusion



The F_LN function block offers an efficient and standards-compliant implementation for calculating the natural logarithm. Its event-driven architecture makes it particularly suitable for real-time applications where mathematical operations must be performed precisely and reliably.

F_LOG

Introduction

The F_LOG function block calculates the base-10 logarithm (decimal logarithm) of a numeric input value. It belongs to the category of standard functions for a numeric variable according to IEC 61131-3 and is part of the package `iec61131::numerical`.

Interface Structure

Event Inputs

- **REQ**: Service request - triggers the calculation of the logarithm

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs

- **IN**: Numeric input value of type ANY_REAL for which the logarithm is to be calculated

Data Outputs

- **OUT**: Calculated logarithm value of type ANY_REAL

Adapters

No adapter interfaces are available.

Functionality

Upon arrival of a REQ event, the F_LOG block calculates the base-10 logarithm ($\log_{10}$) of the current IN value. The result is output at the OUT output, and simultaneously a CNF event is generated to signal successful computation.

Technical Features

- Supports the ANY_REAL data type, enabling various numeric data types such as REAL, LREAL, etc.
- Complies with the IEC 61131-3 standard specification
- Simple and deterministic operation without internal states

State Overview

The function block has no complex internal states. It behaves purely functionally: REQ event ⟶ computation ⟶ CNF event.

Application Scenarios

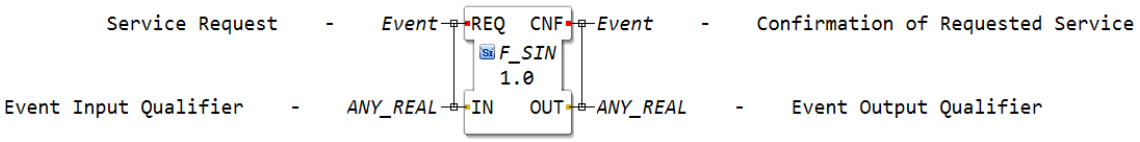
- Scientific calculations and measurement data processing
- Signal processing in automation technology
- Scaling of measured values in logarithmic representations
- Audio and acoustics applications (e.g., dB calculations)

⚖️ Comparison with similar blocks

Compared to other logarithmic functions:

- F_LN: Calculates the natural logarithm (base e)
- F_LOG: Specifically calculates the base-10 logarithm
- Both blocks follow the same event/data flow paradigm

Conclusion



The F_LOG function block offers a standardized, reliable implementation for calculating the base-10 logarithm in 4diac control systems. Its simple interface and deterministic operation make it ideal for use in real-time automation applications.

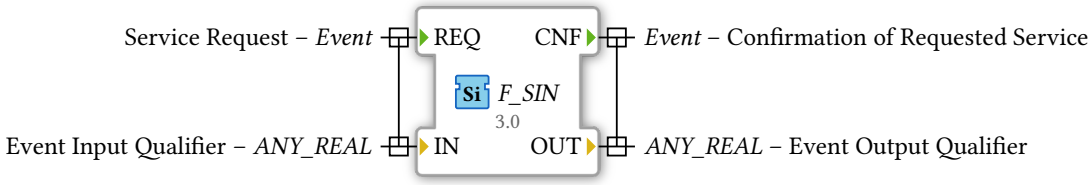
]



F_SIN

• – ◦ • – ◦ • – ◦ •

Introduction

The F_SIN function block calculates the sine of an input value in radians. It is a standard function for numerical calculations according to IEC 61131-3, enabling mathematical sine operations in control applications.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the sine calculation

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs

- **IN**: Input value in radians (Type: ANY_REAL) - the angle whose sine is to be calculated

Data Outputs

- **OUT**: Output value (Type: ANY_REAL) - the result of the sine calculation

Adapters

No adapter interfaces are available.

Functionality

Upon receiving a REQ event, the function block calculates the sine of the value passed to IN. The result is output to OUT, and simultaneously a CNF event is generated to signal successful calculation. The calculation is performed according to the standard mathematical definition of the sine function.

Technical Features

- Supports the ANY_REAL data type for maximum flexibility with numerical inputs
- Compliant with the IEC 61131-3 standard for programmable logic controllers (PLCs)
- Simple event-driven processing
- Direct mapping of the mathematical sine function

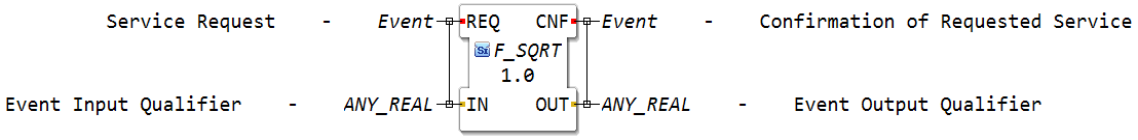
State Transitions

The function block has two main states:

1. **Wait State**: Waits for a REQ event
2. **Calculate State**: Processes the sine calculation and generates a CNF event

Application Scenarios

- Signal processing in control engineering
- Calculation of oscillations and periodic processes
- Mathematical transformations in technical applications
- Position calculations in robotics and motion control

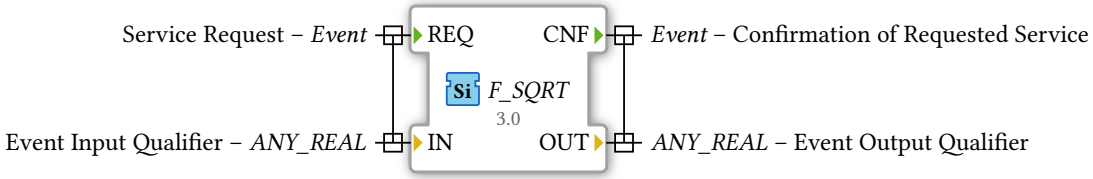


⚖️ Comparison with Similar Function Blocks

Compared to other trigonometric functions such as F_COS (cosine) or F_TAN (tangent), F_SIN offers a specific sine calculation. Compared to general-purpose mathematical blocks, F_SIN stands out due to its specialized and optimized implementation.

Conclusion

The F_SIN function block provides a reliable and standards-compliant solution for sine calculations in IEC 61131-3-based control systems. Its simple interface and direct functionality make it ideal for numerous technical applications requiring trigonometric calculations.



F_SQRT

• — ◦ • — ◦ • — ◦ •

Introduction

The F_SQRT function block is a standard function block according to IEC 61131-3 that calculates the square root of a numeric input. It belongs to the category of numeric functions and is used for the mathematical calculation of the square root of any real input value.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the square root calculation

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs

- **IN** (ANY_REAL): Input value from which the square root is to be calculated

Data Outputs

- **OUT** (ANY_REAL): Result of the square root calculation

Adapters

No adapter interfaces are available.

Functionality

The F_SQRT function block calculates the square root of the input value IN. The calculation is performed when activated by the REQ event. After the calculation is complete, the CNF event is triggered, and the result is output via the OUT variable.

Technical Features

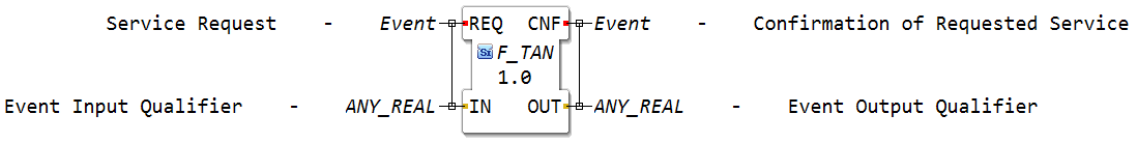
- Uses the ANY_REAL data type for maximum flexibility with various real number types
- Complies with the IEC 61131-3 standard specification
- Simple and direct functionality without additional parameters

State Transitions

1. **Wait State**: Block waits for a REQ event
2. **Calculate State**: Upon a REQ event, the square root is calculated
3. **Output State**: After calculation, a CNF event is triggered and the result is output

Application Scenarios

- Mathematical calculations in control systems
- Signal processing and filtering
- Scientific and technical applications
- Control engineering and process control

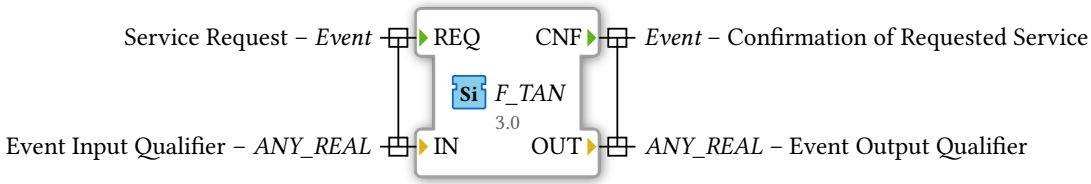


⚖️ Comparison with Similar Blocks

Compared to other mathematical function blocks, F_SQRT offers a specialized function for calculating square roots. Other blocks such as F_ADD or F_MUL offer basic arithmetic operations, while F_SQRT provides a specific mathematical function.

Conclusion

The F_SQRT function block is an essential tool for numerical calculations in IEC 61131-3 based control systems. Its simple interface and reliable functionality make it a valuable component for mathematical operations in industrial automation solutions.



F_TAN

• – ◦ • – ◦ • – ◦ •

Introduction

The F_TAN function block calculates the tangent of an input value in radians. It is a standard function for numerical calculations according to IEC 61131-3.

Interface Structure

Event Inputs

- **REQ**: Service request - triggers the tangent calculation

Event Outputs

- **CNF**: Confirmation of requested service - signals the completion of the calculation

Data Inputs

- **IN**: Input value in radians (ANY_REAL data type)

Data Outputs

- **OUT**: Calculated tangent value (ANY_REAL data type)

Adapters

No adapter interfaces are available.

Functionality

Upon receiving a REQ event, the F_TAN block calculates the tangent of the angle passed to IN in radians. The result is output to OUT, and simultaneously, a CNF event is generated to signal the completion of the calculation.

Technical Features

- Supports the ANY_REAL data type for maximum flexibility with numeric inputs
- Calculations are performed in radians (not degrees)
- Implemented according to the IEC 61131-3 standard for numeric functions
- Mathematical peculiarity: Very large values or overflows can occur for angles close to $\pi/2 + k\pi$ ($k \in \mathbb{Z}$)

State Transitions

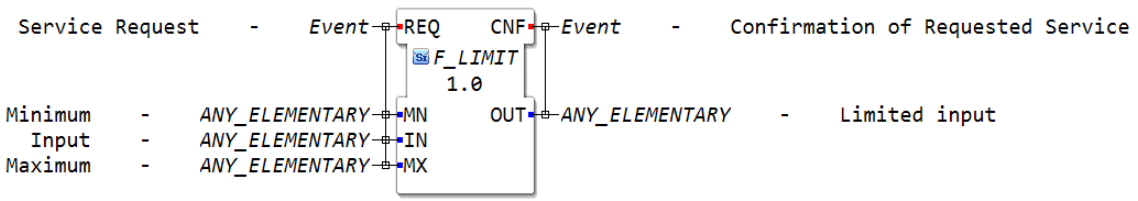
1. **Wait State**: Block waits for a REQ event
2. **Calculate State**: Upon a REQ event, the tangent is calculated
3. **Output State**: Result is sent to OUT and a CNF event is generated
4. Return to Wait State

Application Scenarios

- Trigonometric calculations in control systems
- Signal processing and filtering
- Robotics and motion control
- Mathematical modeling and simulation
- Control engineering and position determination

⚖️ Comparison with similar function blocks

- **F_SIN**: Calculates sine instead of tangent
- **F_COS**: Calculates cosine instead of tangent
- **F_ATAN**: Inverse function (arcutangent)
- **F_TAN** specifically provides the tangent function for trigonometric applications

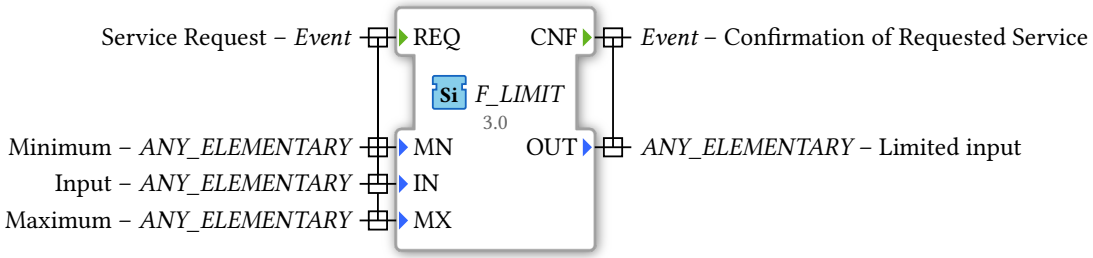


Conclusion

The F_TAN function block is an essential element for trigonometric calculations in IEC 61131-3 based control systems. Its simple and standards-compliant interface enables reliable integration into more complex control algorithms, especially in applications requiring trigonometric functions.

2.11.4.11 Selection Functions

Here you will find functions for selecting values (Max, Min, Limit, Mux, etc.).



F_LIMIT

• – ◦ • – ◦ • – ◦ •

Introduction

The F_LIMIT function block is a standard selection function block according to IEC 61131-3 that acts as a limiter. It limits an input value to a defined range between a lower and upper limit.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the limiting operation

Event Outputs

- **CNF**: Acknowledgement of the requested service operation

Data Inputs

- **MN**: Minimum - lower limit for the limit
- **IN**: Input - input value to be limited
- **MX**: Maximum - upper limit for the limit

Data Outputs

- **OUT**: Limited Input - the limited output value

Adapters

No adapter interfaces are available.

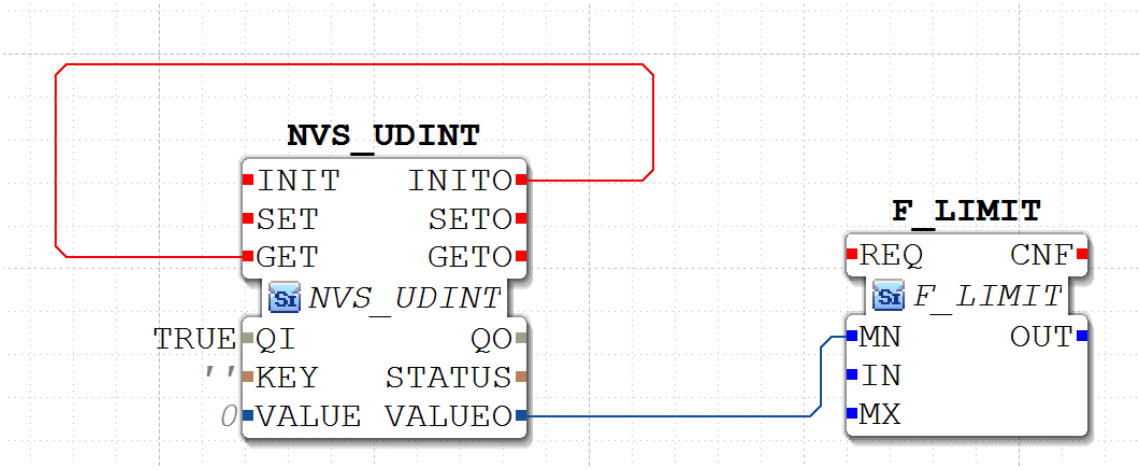
Functionality

The F_LIMIT function block takes an input value (IN) and limits it to the range between the minimum (MN) and maximum (MX). When activated by the REQ event, the following operation is performed:

- If IN < MN, dann OUT = MN
- Wenn IN > MX, then OUT = MX
- If MN ≤ IN ≤ MX, then OUT = IN

After the operation is complete, the CNF event is output with the calculated OUT value.

Technical Features



- Uses the generic data type ANY_ELEMENTARY, meaning the block can be used with various elementary data types (INT, REAL, etc.)
- All data inputs and the data output use the same data type for consistent operation
- EPL-2.0 License (Eclipse Public License)

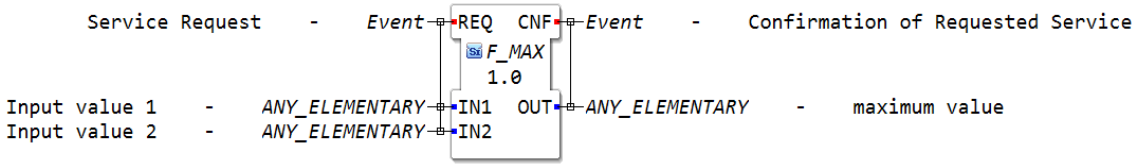
State Transitions

1. **Wait State**: Block waits for a REQ event
2. **Active**: The limiting operation is performed upon a REQ event
3. **Output**: After calculation, a CNF event with an OUT value is output
4. **Return**: Returns to the wait state

Application Scenarios

- Signal limiting in control engineering
- Protection against exceeding and falling below limit values
- Normalization of measured values to a permissible range
- Safety limiting in process control

⚖️ Comparison with similar blocks

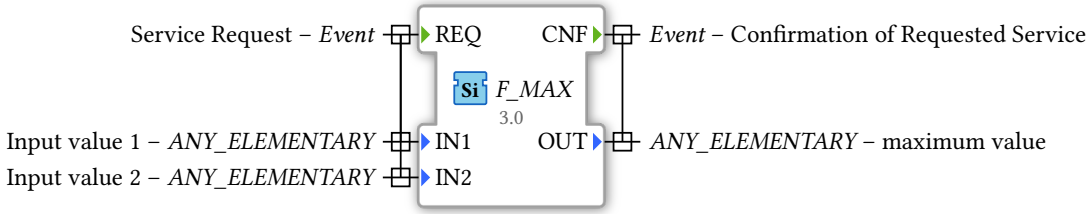


Compared to Other selection function blocks:

- F_LIMIT specifically optimized for value limiting
- Simpler than complex comparison blocks with multiple outputs
- More universally applicable due to the ANY_ELEMENTARY data type

Conclusion

The F_LIMIT function block offers a simple and efficient solution for value limiting in IEC 61131-3 based control systems. Its generic type support makes it flexible for various applications where input values need to be restricted to a defined range.



F_MAX

• – ○ • – ○ • – ○ •

Introduction

The F_MAX function block is a standard selection function block according to IEC 61131-3 that determines the maximum value from two input values. The block compares any two elementary data types and returns the larger of the two values as the result.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the calculation of the maximum

Event Outputs

- **CNF**: Confirmation of the requested service - signals completion of the calculation

Data Inputs

- **IN1**: Input value 1 (any elementary data type)
- **IN2**: Input value 2 (any elementary data type)

Data Outputs

- **OUT**: Maximum value (same data type as the inputs)

Adapters

No adapter interfaces are available.

Functionality

When a REQ event arrives, the F_MAX block compares the two input values IN1 and IN2. The larger of the two values is output at OUT. Simultaneously, a CNF event is generated to signal the completion of the operation. The block supports all elementary data types (ANY_ELEMENTARY), making it universally applicable for various numeric and non-numeric comparisons.

Technical Features

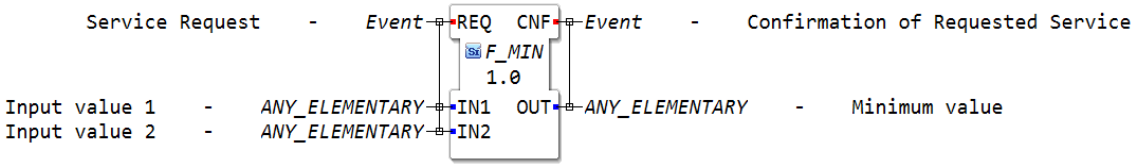
- Use of the generic data type ANY_ELEMENTARY for maximum flexibility
- Automatic type matching between inputs and output
- Real-time capable execution
- Standard-compliant implementation according to IEC 61131-3

State Transitions

1. **Wait State**: Block waits for REQ event
2. **Calculation State**: Upon REQ event, IN1 and IN2 are compared
3. **Output State**: Maximum is output to OUT and a CNF event is generated
4. Return to Wait State

Application Scenarios

- Determining the maximum in control algorithms
- Limit monitoring in process control systems
- Signal processing and filtering
- Quality assurance of measured values
- Prioritization logic in controllers

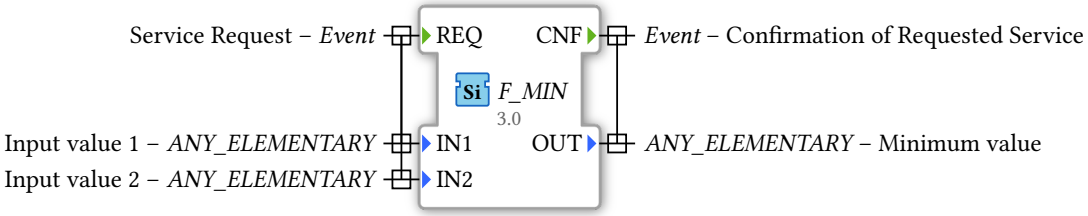


⚖️ Comparison with similar blocks

Compared to specific maximum blocks (such as MAX_INT, MAX_REAL, etc.), F_MAX offers the advantage of type independence. While specific blocks can only process one data type, F_MAX is universally applicable to all elementary data types.

Conclusion

The F_MAX function block represents a flexible and standards-compliant solution for determining maximum values in automation systems. Its type independence makes it particularly versatile, while its simple interface structure enables intuitive integration into various applications.



F_MIN

• — ○ • — ○ • — ○ •

Introduction

The F_MIN function block is a standard selection function block according to IEC 61131-3 that determines the minimum of two input values. The block compares any two elementary data types and returns the smaller of the two values as the result.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the calculation of the minimum

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the calculation

Data Inputs

- **IN1**: Input value 1 (any elementary data type)
- **IN2**: Input value 2 (any elementary data type)

Data Outputs

- **OUT**: Minimum value (same data type as the inputs)

Adapters

No adapter interfaces are available.

Functionality

When the REQ event is activated, the F_MIN block compares the two input values IN1 and IN2. The smaller of the two values is output at OUT. Simultaneously, the CNF event is generated to signal the completion of the operation.

Technical Features

- Supports any elementary data type (ANY_ELEMENTARY)
- Type safety: Output has the same data type as the inputs
- Real-time capable execution
- Simple and deterministic operation

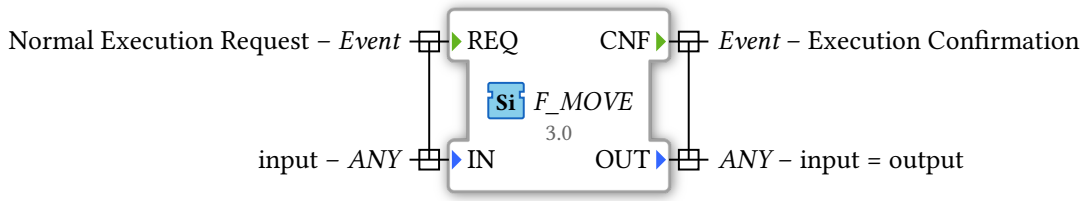
State Transitions

1. **Wait State**: Block waits for REQ event
2. **Compute State**: Upon REQ event, IN1 and IN2 are compared
3. **Output State**: Minimum value is output to OUT and a CNF event is generated
4. Return to Wait State

Application Scenarios

- Limit monitoring in control engineering
- Minimum selection in data processing chains
- Safety-relevant limits
- Signal processing with dynamic input values

⚖️ Comparison with similar function blocks



Compared to F_MAX (maximum function), F_MIN determines the smaller value instead of the larger one. Both blocks share the same interface structure and work with any elementary data type.

Conclusion

The F_MIN block represents a simple, reliable, and standards-compliant solution for minimum determination in IEC 61131-3-based control systems. Its flexibility regarding supported data types makes it a universally applicable building block in various automation applications.

F_MOVE

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_MOVE** is a universal function block for type-safe data transfer, developed under the EPL-2.0 license. Version 1.0 enables the transfer of any data type (ANY) between variables in control applications.

Interface Structure

Event Inputs

- `REQ`: Transfer request (with input value)

Event Outputs

- `CNF`: Transfer acknowledgment (with output value)

Data Inputs

- `IN` (ANY): Source data (any type)

Data Outputs

- `OUT` (ANY): Destination data (identical type to input)

Functionality

1. **Activation**:

- Triggered by the `REQ` event
- Processes any data type (ANY)

1. **Data Transfer**:

- 1:1 copy of the input value
- Type-preserving transfer
- Supports all IEC 61131-3 Data Types

1. **Confirmation**:

- `CNF` event after successful transfer
- OUT receives an exact copy of IN

Technical Specifications

✓ Generic Type Support (ANY) **✓ Bit-perfect data copy ✓ One-cycle latency ✓ IEC 61131-3 compliant**

Application Examples

- **Data Conversion**: Type conversions
- **Signal Forwarding**: Process data distribution
- **Buffer Operations**: Intermediate storage
- **Interfaces**: Data encapsulation

Special Notes

- **Type Compatibility**:
- Input and output types must be identical
- No automatic type conversion
- **Performance**:
- Consistently fast execution

- Independent of data type

⚖️ Comparison with similar function blocks

Feature	F_MOVE	F_BLOCK_MOVE	F_CAST
Functionality	Single Value	Memory Block	Type Conversion

Conclusion

The F_MOVE block offers essential data transfer functions:

- Universal type support
- Reliable 1:1 data copying
- Minimal resource consumption

Indispensable for control applications with complex data structures or type-sensitive operations. The generic implementation as GEN_FORTE_F_MOVE enables maximum flexibility in heterogeneous automation environments.

F_MUX_16

• — ○ • — ○ • — ○ •

Introduction

The `F_MUX_16` is a multiplexer according to IEC 61131-3 (standard selection function, generic block) that, based on the selector `K`, switches one of **16 inputs** to the output `OUT`. It is the 16-channel variant of `F_MUX_8` and `F_MUX_4`.

Interface Structure

Event Inputs

- **REQ**: Service request. Associated data: `IN1` to `IN16`, `K`

Event Outputs

- **CNF**: Confirmation of the requested service. Associated data: `OUT`

Data Inputs

- **K** (`ANY_INT`): Selects one of the inputs
- **IN1** to **IN16** (`ANY`): Input values 1 to 16

Data Outputs

- **OUT** (ANY): Selected input value (see table)

Adapters

This function block uses no adapters.

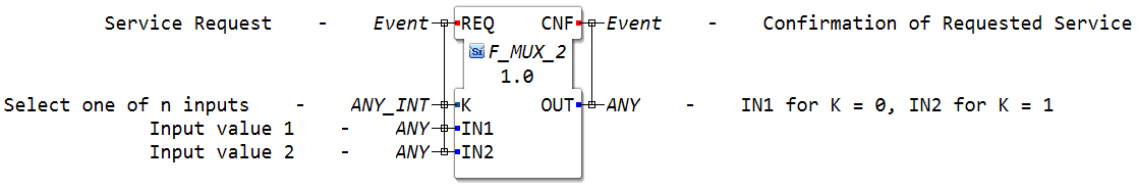
How it works

On REQ, the input selected by K is output at OUT, then CNF is fired. K counts from 0:

K	OUT	K	OUT
0	IN1	8	IN9
1	IN2	9	IN10
2	IN3	10	IN11
3	IN4	11	IN12
4	IN5	12	IN13
5	IN6	13	IN14
6	IN7	14	IN15
7	IN8	15	IN16

Technical Details

- Generic block (GEN_F_MUX, FORTE); the input data types are ANY and must match OUT.
- Belongs to the package iec61131::selection.

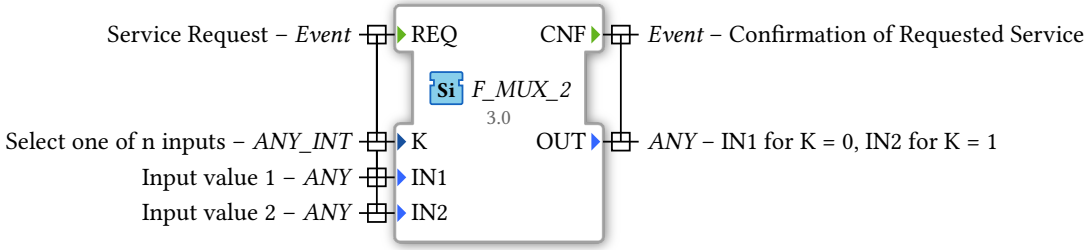


Application Scenarios

- Selecting one of up to 16 values, e.g. constants, setpoints or object IDs, via an index

Summary

F_MUX_16 switches one of 16 input values to the output based on the index K (0 to 15).



F_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

The F_MUX_2 is a multiplexer function block according to IEC 61131-3, classified as a standard selection function. This block allows selection between two input signals based on a control signal.

Interface Structure

Event Inputs
- **REQ**: Service Request - triggers multiplexer processing

Event Outputs
- **CNF**: Confirmation of requested service - signals completion of processing

Data Inputs
- **K**: Control input for selecting one of n inputs (ANY_INT type)
- **IN1**: Input value 1 (ANY type)
- **IN2**: Input value 2 (ANY type)

Data Outputs
- **OUT**: Output value - returns IN1 for K = 0, IN2 for K = 1 (ANY type)

Adapters
No adapter interfaces are available.

Functionality
The F_MUX_2 operates as a 2:1 multiplexer. Upon receiving a REQ event, the function block evaluates the control input K:

- If K = 0, the value of IN1 is passed to OUT.
- If K = 1, the value of IN2 is passed to OUT.

After successful processing, the CNF event is triggered to signal the completion of the operation. ...

Technical Features
- Use of generic data types (ANY and ANY_INT) for maximum flexibility
- Support for various data types for input values
- Simple and deterministic processing
- EPL 2.0 license

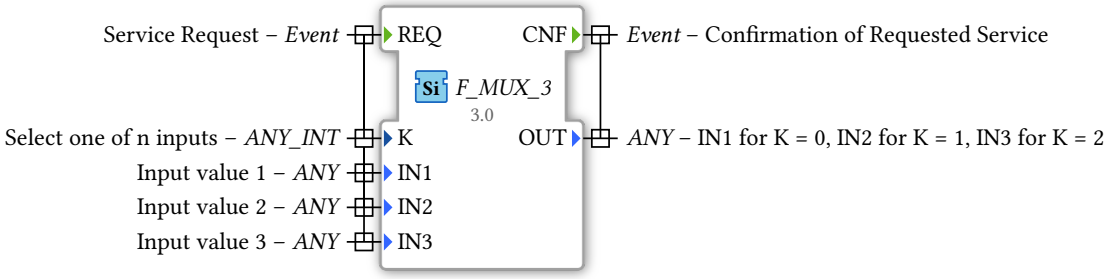
State Transitions
1. **Wait Time**: No active processing
2. **Processing**: Upon REQ event - evaluation of K and selection of the corresponding input
3. **Completion**: Triggering of CNF after successful data transmission

Application Scenarios
- Signal diverter in control applications
- Selection between different operating modes
- Switching between redundant signal sources
- Processing path selection in complex control systems

⚖️ Comparison with Similar Components
Compared to other multiplexers, F_MUX_2 offers:

- Specifically optimized for 2 inputs
- Simpler design than multiplexers with more inputs
- Direct and clear control logic
- Lower resource consumption with 2-way selection

🛠️ Related Exercises
- Exercise_090a1



Conclusion
The F_MUX_2 is an efficient and reliable multiplexer for applications requiring selection between two input signals. Its simple structure and use of generic data types make it a versatile solution for various control tasks.

F_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_MUX_3` is a multiplexer that selects three input signals based on a control signal and forwards them to the output. It is part of the IEC 61131-3 standard library and is used for signal selection in automation applications.

Interface Structure

Event Inputs

- **REQ**: Service Request – triggers the selection and forwarding of the corresponding input signal. Linked to the data inputs `IN1`, `IN2`, `IN3`, and `K`.

Event Outputs

- **CNF**: Confirmation of Requested Service – confirms the successful selection and forwarding of the signal. Linked to the data output `OUT`.

Data Inputs

- **K** (ANY_INT): Control signal indicating which input is selected (0 for `IN1`, 1 for `IN2`, 2 for `IN3`).
- **IN1** (ANY): Input value 1.
- **IN2** (ANY): Input value 2.
- **IN3** (ANY): Input value 3.

Data Outputs

- **OUT** (ANY): Output value corresponding to the selected input (`IN1` for `K = 0`, `IN2` for `K = 1`, `IN3` for `K = 2`).

Adapters

No adapters included.

Functionality

Upon a `REQ` event, the function block evaluates the value of `K` and forwards the corresponding input (`IN1`, `IN2`, or `IN3`) to the output `OUT`. The `CNF` event is then triggered to confirm the successful operation.

Technical Specifications

- Supports any data type (`ANY`) for the inputs and output.
- The control input `K` must be an integer type (`ANY_INT`).
- Initial values for the inputs are not predefined.

State Overview

The function block has no internal states. Selection and routing occur immediately upon a `REQ` event.

Application Scenarios

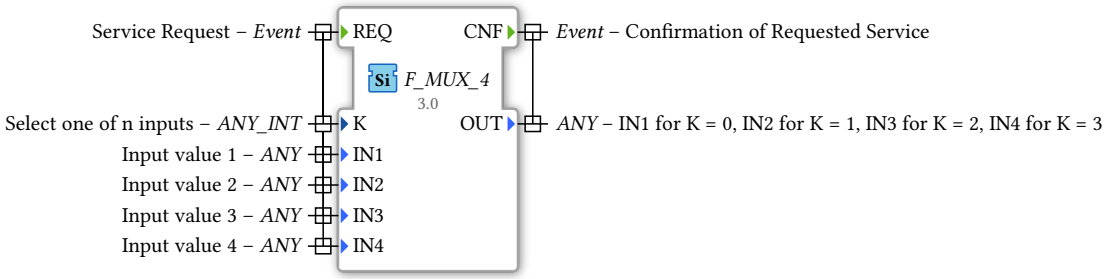
- Signal routing in control applications.
- Selection between different sensor data.
- Dynamic configuration of signal paths.

⚖️ Comparison with Similar Function Blocks

- `F_MUX_2`: A simpler multiplexer with only two inputs.
- `F_SEL`: A more general selector that may support more complex selection criteria.

🛠️ Related Exercises

- Exercise_090a2



Conclusion

The `F_MUX_3` is a simple and efficient multiplexer for applications where selection between three signals is required. Its flexibility regarding data types makes it versatile.

F_MUX_4

• – ◦ • – ◦ • – ◦ •

The function block `F_MUX_4` is a four-input multiplexer that selects one of four input values based on a control signal and outputs it. It is part of the IEC 61131-3 standard library and is used for selection operations in control applications.

- `REQ`: Service request. Triggers the selection and output of the corresponding input value. Linked to the data inputs `IN1`, `IN2`, `IN3`, `IN4`, and `K`.
- `CNF`: Confirmation of the requested service. Triggered after the output value is set. Linked to the data output `OUT`.
- `K` (`ANY_INT`): Control signal that determines the input to be selected.
- `CNF`: Confirmation of the requested service. Triggered after the output value is set.
- `K` (`ANY_INT`): Control signal that determines the input to be selected ...### **Event Outputs**
- `K = 1`: Selects `IN2`
- `K = 2`: Selects `IN3`
- `K = 3`: Selects `IN4`
- `IN1` (`ANY`): Input value 1
- `IN2` (`ANY`): Input value 2
- `IN3` (`ANY`): Input value 3.
- `IN4` (`ANY`): Input value 4.
- `OUT` (`ANY`): Output value corresponding to the input selected by `K`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters available.

Functionality

Upon receiving the event REQ, the function block evaluates the value of K and outputs the corresponding input value (IN1 to IN4) at output OUT. The event CNF is then triggered to confirm successful selection and output.

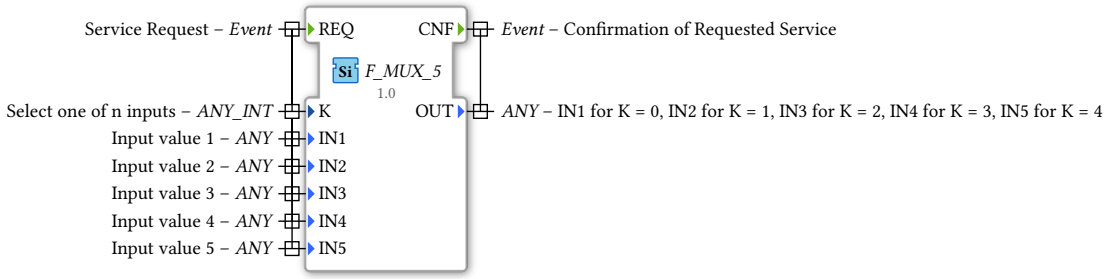
- Supports any data type (ANY) for the inputs and output.
- The control input K must be an integer value (ANY_INT).
- The initial values of the inputs are empty; no default values are provided.

1. **Idle State**: Waits for the event REQ.
2. **Selection State**: Evaluates K and selects the corresponding input.
3. **Output State**: Sets OUT to the selected value and triggers CNF.

- Selection between different sensor data based on control logic.
- Switching between different operating modes in a controller.
- Dynamic selection of data sources depending on external conditions.
- F_MUX_2: Simple multiplexer with only two inputs.
- F_MUX_3: Three-input multiplexer.
- F_MUX_4 offers an extension to four inputs, providing greater flexibility in selection.

The F_MUX_4 is a versatile and easy-to-use multiplexer, ideally suited for applications requiring selection between four different input values. Its support for arbitrary data types and clear event-driven control make it a valuable component in the IEC 61131-3 standard library.

Technical Features



State Overview

Conclusion

F_MUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

F_MUX_5 is the generic 5-input variant of the standard multiplexer block F_MUX (cf. F_MUX_2/F_MUX_3/F_MUX_4). Based on the selector K, it picks one of 5 input values (IN1, IN2, IN3, IN4, IN5) and outputs it via OUT.

Interface Structure

Event Inputs

- **REQ**: Triggers the selection, carries K and IN1, IN2, IN3, IN4, IN5.

Event Outputs

- **CNF**: Confirms completion, carries OUT.

Data Inputs

- **K** (ANY_INT): Selects one of the 5 inputs (0-based).

- IN1, IN2, IN3, IN4, IN5 (ANY): The 5 candidate input values.

Data Outputs

- **OUT** (ANY): The selected input value: IN1 when K = 0, IN2 when K = 1, IN3 when K = 2, IN4 when K = 3, IN5 when K = 4.

Functionality

On REQ, depending on the value of K, the corresponding input (IN1, IN2, IN3, IN4, IN5) is passed through to OUT: IN1 when K = 0, IN2 when K = 1, IN3 when K = 2, IN4 when K = 3, IN5 when K = 4. CNF is then triggered.

Technical Features

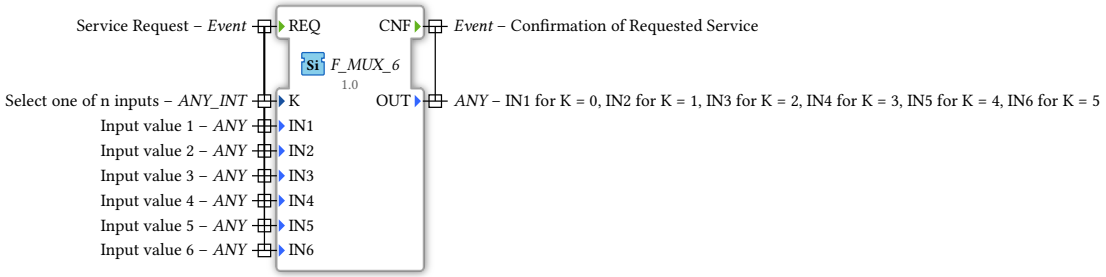
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_F_MUX', the same C++ base as F_MUX_2/F_MUX_3/F_MUX_4; only the number of inputs differs per instantiation.
- **ANY data type**: Both inputs IN1…IN5 and OUT are generically typed and adapt to the connected data type when wired.
- **0-based selector**: K = 0 selects IN1, K = 4 selects IN5.

State Overview

Stateless: every REQ immediately results in the selection and CNF.

Application Scenarios

- **Multi-way selection with more than 4 sources**: Wherever a selection is needed among more than the 4 inputs supported by F_MUX_4, without cascading multiple F_MUX blocks.
- **Signal switching**: Selecting one of several sensor or source signals based on a control value K.



Comparison with similar function blocks

- **F_MUX_4**: the same generic implementation with 4 instead of 5 inputs.
- **F_SEL**: binary selection between exactly two values based on a BOOL selector, functionally a special case of F_MUX_2.

Conclusion

F_MUX_5 extends the multiplexer principle of F_MUX_2/F_MUX_3/F_MUX_4 to 5 selectable inputs and is the generic, 5-input-instantiated variant of the same underlying implementation.

F_MUX_6

• – ○ • – ○ • – ○ •

Introduction

F_MUX_6 is the generic 6-input variant of the standard multiplexer block F_MUX (cf. F_MUX_2/F_MUX_3/F_MUX_4). Based on the selector K, it picks one of 6 input values (IN1, IN2, IN3, IN4, IN5, IN6) and outputs it via OUT.

Interface Structure

Event Inputs

- **REQ**: Triggers the selection, carries K and IN1, IN2, IN3, IN4, IN5, IN6.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **K** (ANY_INT): Selects one of the 6 inputs (`0`-based).
- `IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6` (ANY): The 6 candidate input values.

Data Outputs

- **OUT** (ANY): The selected input value: `IN1` when `K = 0`, `IN2` when `K = 1`, `IN3` when `K = 2`, `IN4` when `K = 3`, `IN5` when `K = 4`, `IN6` when `K = 5`.

Functionality

On `REQ`, depending on the value of `K`, the corresponding input (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`) is passed through to `OUT`: `IN1` when `K = 0`, `IN2` when `K = 1`, `IN3` when `K = 2`, `IN4` when `K = 3`, `IN5` when `K = 4`, `IN6` when `K = 5`. `CNF` is then triggered.

Technical Features

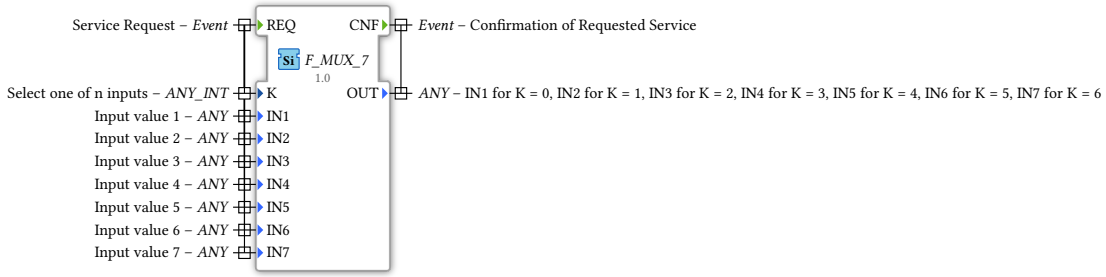
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_F_MUX'`, the same C++ base as `F_MUX_2`/`F_MUX_3`/`F_MUX_4`; only the number of inputs differs per instantiation.
- **`ANY` data type**: Both inputs `IN1`…`IN6` and `OUT` are generically typed and adapt to the connected data type when wired.
- **`0`-based selector**: `K = 0` selects `IN1`, `K = 5` selects `IN6`.

State Overview

Stateless: every `REQ` immediately results in the selection and `CNF`.

Application Scenarios

- **Multi-way selection with more than 4 sources**: Wherever a selection is needed among more than the 4 inputs supported by `F_MUX_4`, without cascading multiple `F_MUX` blocks.
- **Signal switching**: Selecting one of several sensor or source signals based on a control value `K`.



Comparison with similar function blocks

- **`F_MUX_5`**: the same generic implementation with 5 instead of 6 inputs.
- **`F_SEL`**: binary selection between exactly two values based on a `BOOL` selector, functionally a special case of `F_MUX_2`.

Conclusion

`F_MUX_6` extends the multiplexer principle of `F_MUX_2`/`F_MUX_3`/`F_MUX_4` to 6 selectable inputs and is the generic, 6-input-instantiated variant of the same underlying implementation.

F_MUX_7

• – ○ • – ○ • – ○ •

Introduction

`F_MUX_7` is the generic 7-input variant of the standard multiplexer block `F_MUX` (cf. `F_MUX_2`/`F_MUX_3`/`F_MUX_4`). Based on the selector `K`, it picks one of 7 input values (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7`) and outputs it via `OUT`.

Interface Structure

Event Inputs

- **REQ**: Triggers the selection, carries `K` and `IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **K** (ANY_INT): Selects one of the 7 inputs (`0`-based).
- `IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7` (ANY): The 7 candidate input values.

Data Outputs

- **OUT** (ANY): The selected input value: `IN1` when `K = 0`, `IN2` when `K = 1`, `IN3` when `K = 2`, `IN4` when `K = 3`, `IN5` when `K = 4`, `IN6` when `K = 5`, `IN7` when `K = 6`.

Functionality

On `REQ`, depending on the value of `K`, the corresponding input (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7`) is passed through to `OUT`: `IN1` when `K = 0`, `IN2` when `K = 1`, `IN3` when `K = 2`, `IN4` when `K = 3`, `IN5` when `K = 4`, `IN6` when `K = 5`, `IN7` when `K = 6`. `CNF` is then triggered.

Technical Features

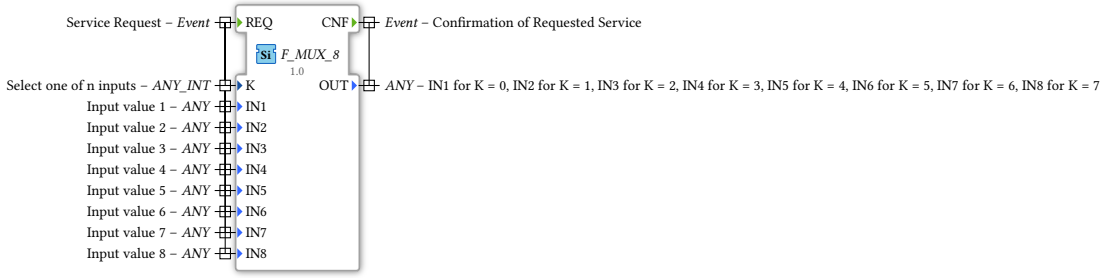
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_F_MUX'`, the same C++ base as `F_MUX_2`/`F_MUX_3`/`F_MUX_4`; only the number of inputs differs per instantiation.
- **`ANY` data type**: Both inputs `IN1`…`IN7` and `OUT` are generically typed and adapt to the connected data type when wired.
- **`0`-based selector**: `K = 0` selects `IN1`, `K = 6` selects `IN7`.

State Overview

Stateless: every `REQ` immediately results in the selection and `CNF`.

Application Scenarios

- **Multi-way selection with more than 4 sources**: Wherever a selection is needed among more than the 4 inputs supported by `F_MUX_4`, without cascading multiple `F_MUX` blocks.
- **Signal switching**: Selecting one of several sensor or source signals based on a control value `K`.



Comparison with similar function blocks

- **`F_MUX_6`**: the same generic implementation with 6 instead of 7 inputs.
- **`F_SEL`**: binary selection between exactly two values based on a `BOOL` selector, functionally a special case of `F_MUX_2`.

Conclusion

`F_MUX_7` extends the multiplexer principle of `F_MUX_2`/`F_MUX_3`/`F_MUX_4` to 7 selectable inputs and is the generic, 7-input-instantiated variant of the same underlying implementation.

F_MUX_8

• – ○ • – ○ • – ○ •

Introduction

F_MUX_8 is the generic 8-input variant of the standard multiplexer block F_MUX (cf. F_MUX_2/F_MUX_3/F_MUX_4). Based on the selector K, it picks one of 8 input values (IN1, IN2, IN3, IN4, IN5, IN6, IN7, IN8) and outputs it via OUT.

Interface Structure

Event Inputs

- **REQ**: Triggers the selection, carries K and IN1, IN2, IN3, IN4, IN5, IN6, IN7, IN8.

Event Outputs

- **CNF**: Confirms completion, carries OUT.

Data Inputs

- **K** (ANY_INT): Selects one of the 8 inputs (0-based).
- IN1, IN2, IN3, IN4, IN5, IN6, IN7, IN8 (ANY): The 8 candidate input values.

Data Outputs

- **OUT** (ANY): The selected input value: IN1 when K = 0, IN2 when K = 1, IN3 when K = 2, IN4 when K = 3, IN5 when K = 4, IN6 when K = 5, IN7 when K = 6, IN8 when K = 7.

Functionality

On REQ, depending on the value of K, the corresponding input (IN1, IN2, IN3, IN4, IN5, IN6, IN7, IN8) is passed through to OUT: IN1 when K = 0, IN2 when K = 1, IN3 when K = 2, IN4 when K = 3, IN5 when K = 4, IN6 when K = 5, IN7 when K = 6, IN8 when K = 7. CNF is then triggered.

Technical Features

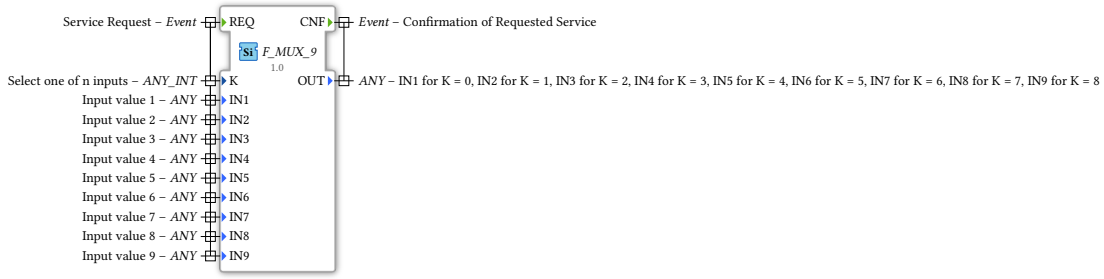
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_F_MUX', the same C++ base as F_MUX_2/F_MUX_3/F_MUX_4; only the number of inputs differs per instantiation.
- **ANY data type**: Both inputs IN1…IN8 and OUT are generically typed and adapt to the connected data type when wired.
- **0-based selector**: K = 0 selects IN1, K = 7 selects IN8.

State Overview

Stateless: every REQ immediately results in the selection and CNF.

Application Scenarios

- **Multi-way selection with more than 4 sources**: Wherever a selection is needed among more than the 4 inputs supported by F_MUX_4, without cascading multiple F_MUX blocks.
- **Signal switching**: Selecting one of several sensor or source signals based on a control value K.



Comparison with similar function blocks

- **F_MUX_7**: the same generic implementation with 7 instead of 8 inputs.
- **F_SEL**: binary selection between exactly two values based on a BOOL selector, functionally a special case of F_MUX_2.

Conclusion

F_MUX_8 extends the multiplexer principle of F_MUX_2/F_MUX_3/F_MUX_4 to 8 selectable inputs and is the generic, 8-input-instantiated variant of the same underlying implementation.

F_MUX_9

• – ○ • – ○ • – ○ •

Introduction

`F_MUX_9` is the generic 9-input variant of the standard multiplexer block `F_MUX` (cf. `F_MUX_2`/`F_MUX_3`/`F_MUX_4`). Based on the selector `K`, it picks one of 9 input values (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7`, `IN8`, `IN9`) and outputs it via `OUT`.

Interface Structure

Event Inputs

- **REQ**: Triggers the selection, carries `K` and `IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7`, `IN8`, `IN9`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **K** (ANY_INT): Selects one of the 9 inputs (`0`-based).
- `IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7`, `IN8`, `IN9` (ANY): The 9 candidate input values.

Data Outputs

- **OUT** (ANY): The selected input value: `IN1` when `K = 0`, `IN2` when `K = 1`, `IN3` when `K = 2`, `IN4` when `K = 3`, `IN5` when `K = 4`, `IN6` when `K = 5`, `IN7` when `K = 6`, `IN8` when `K = 7`, `IN9` when `K = 8`.

Functionality

On `REQ`, depending on the value of `K`, the corresponding input (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7`, `IN8`, `IN9`) is passed through to `OUT`: `IN1` when `K = 0`, `IN2` when `K = 1`, `IN3` when `K = 2`, `IN4` when `K = 3`, `IN5` when `K = 4`, `IN6` when `K = 5`, `IN7` when `K = 6`, `IN8` when `K = 7`, `IN9` when `K = 8`. `CNF` is then triggered.

Technical Features

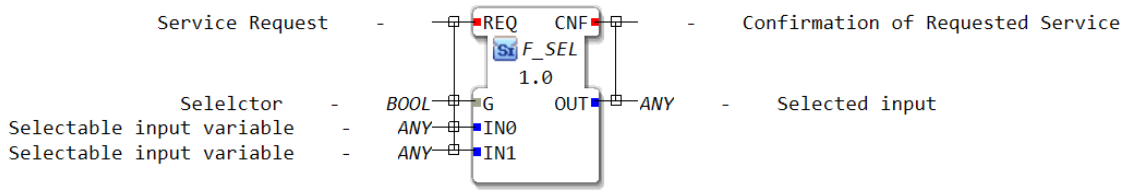
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_F_MUX'`, the same C++ base as `F_MUX_2`/`F_MUX_3`/`F_MUX_4`; only the number of inputs differs per instantiation.
- **`ANY` data type**: Both inputs `IN1`…`IN9` and `OUT` are generically typed and adapt to the connected data type when wired.
- **`0`-based selector**: `K = 0` selects `IN1`, `K = 8` selects `IN9`.

State Overview

Stateless: every `REQ` immediately results in the selection and `CNF`.

Application Scenarios

- **Multi-way selection with more than 4 sources**: Wherever a selection is needed among more than the 4 inputs supported by `F_MUX_4`, without cascading multiple `F_MUX` blocks.
- **Signal switching**: Selecting one of several sensor or source signals based on a control value `K`.



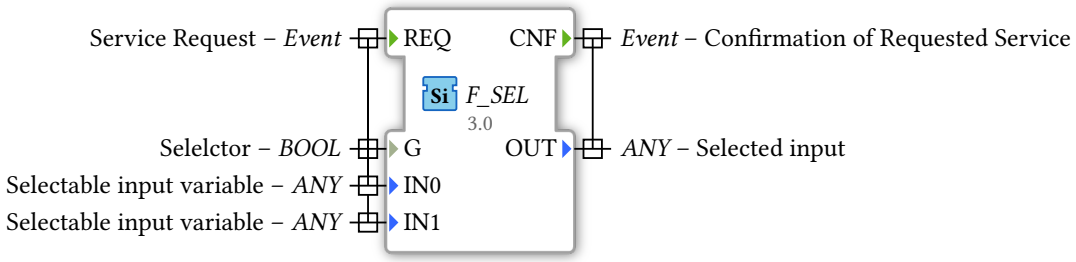
Comparison with similar function blocks

- **`F_MUX_8`**: the same generic implementation with 8 instead of 9 inputs.
- **`F_SEL`**: binary selection between exactly two values based on a `BOOL` selector, functionally a special case of `F_MUX_2`.

Conclusion

`F_MUX_9` extends the multiplexer principle of `F_MUX_2`/`F_MUX_3`/`F_MUX_4` to 9 selectable inputs and is the generic, 9-input-instantiated variant of the same underlying implementation.

F_SEL



https://content.helpme-codesys.com/en/CODESYS%20Development%20System/_cds_operator_sel.html

• – ◦ • – ◦ • – ◦ •

Introduction

The F_SEL function block is a binary selector according to the IEC 61131-3 standard. It enables selection between two input values based on a control signal. The block is used for conditional data selection in control applications.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the selection operation

Event Outputs

- **CNF**: Confirmation of the requested service operation

Data Inputs

- **G**: Selector (BOOL) - Control signal for selection
- **IN0**: Selectable Input Variable (ANY) - First Input
- **IN1**: Selectable Input Variable (ANY) - Second Input

Data Outputs

- **OUT**: Selected Input (ANY) - Result of the selection

Adapters

No adapter interfaces available.

Functionality

When a REQ event arrives, the F_SEL block evaluates the selector input G:

- If G = FALSE (0): OUT is set to the value of IN0
- If G = TRUE (1): OUT is set to the value of IN1

After the selection operation is complete, the CNF event is output with the calculated output value.

Technical Features

- Uses generic data types (ANY) for the inputs and outputs IN0, IN1, and OUT
- Enables the processing of various data types

- Real-time execution upon event triggering
- Simple and deterministic operation

State Transitions

1. **Wait State**: Block waits for REQ event
2. **Execute State**: Upon REQ event, G is evaluated and data is selected
3. **Output State**: CNF event with result is output, return to wait state

Application Scenarios

- Switching between two sensors or measured values
- Selection between different operating modes
- Conditional data forwarding in process chains
- Implementation of multiplexer functionality

⚖️ Comparison with Similar Function Blocks

Compared to other selection blocks, F_SEL offers:

- Simple binary selection (only two inputs)
- Flexible type support through ANY data type
- Standardized Event Control according to IEC 61131-3

🛠️ Related Exercises

- Exercise_015
- Exercise_016
- Exercise_060

Conclusion

The F_SEL block provides a fundamental and versatile selection function for control applications. Its simple structure and flexible type support make it a valuable component for various selection and switching tasks in industrial automation systems.

• – ◦ • – ◦ • – ◦ •

The following text was generated by https://chat.deepseek.com/ on February 5, 2025, and has not yet been proofread (HF)

Introduction

Important note: This function block only functions correctly if it is called cyclically.

The FB_TOF function block in IEC 61131-3: An Overview

Overview

IEC 61131-3 is an international standard that governs the programming of programmable logic controllers (PLCs). A central concept in this standard is the function block (FB), which serves as a reusable component for control logic. The **FB_TOF** (Off-Delay Timer) block is an example of such a function block used in IEC 61131-3 to model a delayed shutdown function. This paper describes the structure, behavior, and application of the FB_TOF block using the provided source code. An important aspect to emphasize is that this block only functions correctly if it is called **cyclically**.

Structure of the FB_TOF Block

The FB_TOF block is a standardized function block according to IEC 61131-3. It consists of an interface that defines input and output variables as well as events.

Interface

The interface of the FB_TOF block consists of:

- **Input Event**:
- **REQ (Request)**: This event triggers the execution of the block. It is linked to the input variables **IN** and **PT**.
- **Output Event**:
- **CNF (Confirmation)**: This event is triggered when the execution of the block is complete. It is linked to the output variables **Q** and **ET**.
- **Input Variables**:
- **IN (Input)**: This is a Boolean variable that controls the state of the timer. If **IN** is set to **TRUE**, the timer starts. If **IN** is set to **FALSE**, the delay time begins.
- **PT (Process Time)**: This is a time variable (TIME) that defines the delay time after which the output **Q** is set to **FALSE**.
- **Output Variables**:
- **Q (Output)**: This is a Boolean variable that indicates the timer's state. It remains **TRUE** until the delay time **PT** has elapsed.
- **ET (Elapsed Time)**: This is a time variable (TIME) that indicates the elapsed time since the delay started.

Behavior of the FB_TOF Block

The FB_TOF block behaves like an off-delay timer, implementing a delayed shutdown function. The block's behavior can be described as follows:

1. **Timer Start**: When the **REQ** event occurs and the input variable **IN** is set to **TRUE**, the timer starts. The output **Q** is set to **TRUE**, and the elapsed time **ET** begins to count.
2. **Delay Time**: When the input variable **IN** is set to **FALSE**, the delay time **PT** begins. The output **Q** remains **TRUE** until the delay time has elapsed.
3. **Delay Time Expiration**: Once the delay time **PT** has elapsed, the output **Q** is set to **FALSE**, and the **CNF** event is triggered to signal the end of the delay.

Cyclic Calling of the FB_TOF Block

A critical aspect of the FB_TOF block is that it must be called **cyclically** to function correctly. This means that the block must be executed in every cycle of the PLC program to update the timer correctly. If the function block is not called cyclically, the elapsed time **ET** cannot be calculated correctly, and the output **Q** might not be set to **FALSE** in time.

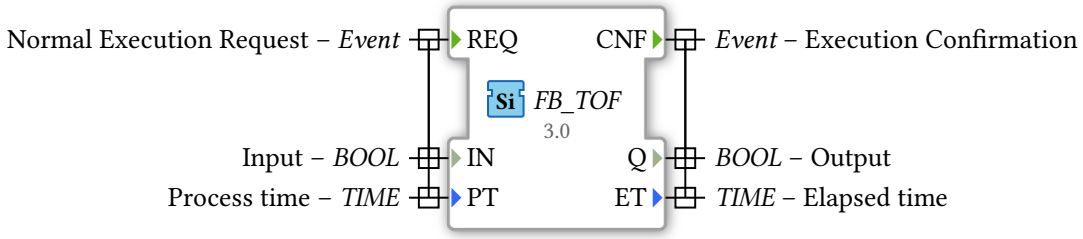
Cyclical calling is necessary because the function block must update the timer's state (i.e., the elapsed time **ET**) in each cycle. If the function block is not called regularly, the timer cannot function correctly, and the delay time **PT** might not be adhered to.

Application Examples

The FB_TOF function block can be used in various industrial control applications, especially in scenarios where a delayed shutdown function is required. Some examples are:

- **Machine Control**: The function block can be used to ensure that a machine continues to run for a specific period of time after being switched off, for example, to complete processes or to implement safety precautions.
- **Lighting Control**: This function block can be used in lighting systems to keep the light on for a specific period of time after the switch is turned off.
- **Valve Control**: This function block can be used to keep a valve open for a specific period of time after it has closed, for example, to release pressure.

🛠️ Related Exercises



- Exercise_020e2
- Exercise_020e2_AX

Conclusion

The FB_TOF function block is a simple yet powerful function block in IEC 61131-3 that implements a delayed shutdown function. Its clear structure and ease of use make it ideal for applications requiring

time-delayed control. An important aspect to consider is that the function block must be called **cyclically** to function correctly. Only through regular calls in each PLC cycle can the timer accurately calculate the elapsed time and maintain the delay time.

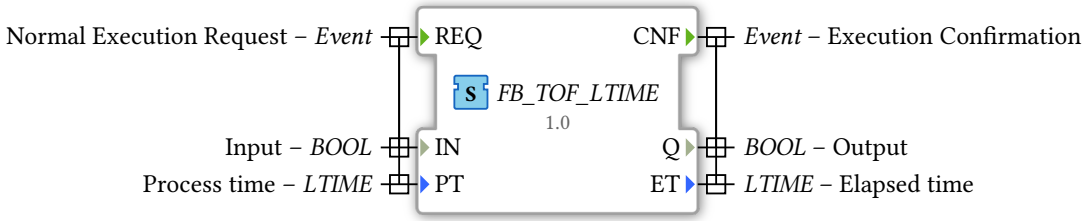
The provided source code demonstrates how the FB_TOF function block can be implemented in practice and offers a solid foundation for developing similar function blocks in industrial control systems. The cyclical calling is a crucial factor for the correct operation of the function block.

⚖️ Comparison of E_TOF and FB_TOF

Chapter 1: The FB_TOF Function Block

The **FB_TOF** (Off-Delay Timer) is a standardized function block according to IEC 61131-3 that implements a delayed shutdown function. A key feature of this function block is the **ET** (Elapsed Time) output, which displays the elapsed time since the delay started. This output is particularly useful for monitoring the delay time progress and for use in control logic.

``A critical aspect of the FB_TOF block, however, is that it **must be called cyclically** to function correctly. This means that the block must be executed in every cycle of the PLC program to correctly calculate the elapsed time **ET** and adhere to the delay time **PT**. If the block is not called regularly, the timer cannot operate correctly, and the delay time may not be adhered to. This dependency on cyclic calling makes the FB_TOF block ideal for traditional PLC systems that operate in fixed cycles.



Chapter 2: The E_TOF Block

The **E_TOF** (Event-driven Off-Delay Timer) is a function block according to IEC 61499 that also implements a delayed shutdown function. Unlike the FB_TOF, the E_TOF **does not have an output ET** that displays the elapsed time. Instead, the E_TOF function block is internally based on the **E_DELAY** block, which is specified in IEC 61499 and provides an event-driven delay function.

A key advantage of the E_TOF function block is that it **does not need to be called cyclically** to function correctly. Because the internal **E_DELAY** block operates independently of the cyclic call of the parent block, the E_TOF can also be used in systems that do not operate cyclically, such as event-driven or distributed control systems. This makes the E_TOF function block particularly flexible and suitable for modern, distributed control architectures where cyclic calls are not always guaranteed.

In summary, the FB_TOF function block enables detailed monitoring of elapsed time through its **ET** output, but requires a cyclic call. The E_TOF, on the other hand, does without the output **ET**, but offers the flexibility to work independently of cyclic calls, making it ideal for event-driven systems.

FB_TOF_LTIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_TOF_LTIME` is the `LTIME` variant (64-bit duration, nanosecond resolution) of the standard timer block `FB_TOF` (off-delay). It behaves functionally identically to `FB_TOF`, but uses data type `LTIME` instead of `TIME` for `PT/ET`.

Interface Structure

Event Inputs

- **REQ**: Triggers execution, linked with `IN` and `PT`.

Event Outputs

- **CNF**: Confirms execution, linked with `Q` and `ET`.

Data Inputs

- **IN** (BOOL): Input signal.
- **PT** (LTIME): Preset time.

Data Outputs

- **Q** (BOOL): Output signal, see Functionality.
- **ET** (LTIME): Elapsed time since the timing started.

Functionality

Q becomes TRUE immediately when IN switches to TRUE. When IN switches to FALSE, Q stays TRUE for the duration PT before falling back to FALSE. Internally, the block (analogous to `FB_TOF`) holds the internal helper variables `MEM` and `StartTime` to track edge transitions of `IN` and the start time of the measurement — at `LTIME` resolution instead of `TIME`.

Technical Features

- **`LTIME` instead of `TIME`**: Provides 64-bit nanosecond resolution instead of the 32-bit millisecond resolution of `TIME`, relevant for very long or very precise timing.
- **Functionally identical to `FB_TOF`**: Same timing behaviour, only the data type of `PT`/`ET` differs.

State Overview

See `FB_TOF` — identical state behaviour, just with `LTIME` values instead of `TIME`.

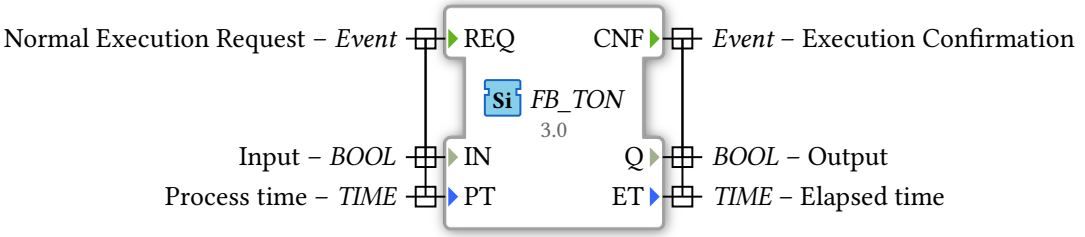
Application Scenarios

- **Timing with very high precision or very long duration**, where the millisecond resolution or value range of `TIME` is insufficient.
- **Consistent `LTIME` usage** in applications that work with `LTIME` throughout, to avoid data type conversions.

Comparison with similar function blocks

- **`FB_TOF`**: the same functionality with `TIME` instead of `LTIME`.

Conclusion



`FB_TOF_LTIME` provides the same off-delay functionality as `FB_TOF`, but with `LTIME` resolution, and is suitable for applications working with high-resolution time values throughout.

FB_TON

• – ◦ • – ◦ • – ◦ •

Introduction

Important note: This function block only functions correctly if it is called cyclically. The FB_TON is a standardized timer function block according to IEC 61131-3 that implements an on-delay. This function block is used to implement time-controlled delays in control programs.

Interface Structure

Event Inputs
- **REQ**: Normal Execution Request - Starts time monitoring when an IN signal is active

Event Outputs
- **CNF**: Execution Confirmation - Confirms completion of time monitoring

Data Inputs
- **IN**: Input - Boolean input that starts the timer (TRUE = timer is running)
- **PT**: Process Time - Time value that defines the delay duration

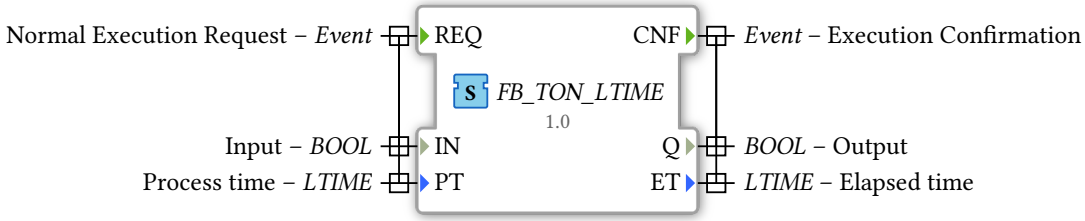
Data Outputs
- **Q**: Output - Boolean output that becomes TRUE after the delay time has elapsed
- **ET**: Elapsed Time - Displays the elapsed time

Adapters
No adapter interfaces are available.

Functionality
The FB_TON starts the time measurement when the IN input changes from FALSE to TRUE. Once the specified time PT has elapsed, output Q is set to TRUE. Output ET continuously displays the elapsed time. If IN is set to FALSE during the time measurement, the timer is reset and Q remains FALSE.

Technical Features
- Time values are processed in the TIME data type
- The timer is immediately reset when IN=FALSE
- ET always displays the current elapsed time, even if the timer is still running
- Implementation compliant with the IEC 61131-3 standard

State Transitions
1. **Inactive**: IN = FALSE, Q = FALSE, ET = 0
2. **Active (Timer running)**: IN = TRUE, Q = FALSE, ET counts up
3. **Time expired**: IN = TRUE, Q = TRUE, ET = PT



Application Scenarios
- Delayed switching operations in machine controls
- Safety time monitoring
- Process controls with defined waiting times
- Delayed alarm triggers

⚖️ Comparison with similar function blocks
- **FB_TOF**: Off-delay instead of on-delay
- **FB_TP**: Pulse timer with fixed pulse duration
- **FB_TON_EXT**: Extended timer variants with additional functions

🛠️ Related Exercises
- Exercise_020c3
- Exercise_020c3_AX

Conclusion
The FB_TON is a basic and robust timer module for standard turn-on delays in industrial control systems. Its simple and intuitive operation, as well as its compliance with the IEC 61131-3 standard, make it a reliable choice for time-controlled applications.

FB_TON_LTIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_TON_LTIME` is the `LTIME` variant (64-bit duration, nanosecond resolution) of the standard timer block `FB_TON` (on-delay). It behaves functionally identically to `FB_TON`, but uses data type `LTIME` instead of `TIME` for `PT`/`ET`.

Interface Structure

Event Inputs

- **REQ**: Triggers execution, linked with `IN` and `PT`.

Event Outputs

- **CNF**: Confirms execution, linked with `Q` and `ET`.

Data Inputs

- **IN** (BOOL): Input signal.
- **PT** (LTIME): Preset time.

Data Outputs

- **Q** (BOOL): Output signal, see Functionality.
- **ET** (LTIME): Elapsed time since the timing started.

Functionality

Q only becomes TRUE once IN has been continuously TRUE for PT. If IN falls back to FALSE before PT elapses, Q stays FALSE. Internally, the block (analogous to `FB_TON`) holds the internal helper variables `MEM` and `StartTime` to track edge transitions of `IN` and the start time of the measurement — at `LTIME` resolution instead of `TIME`.

Technical Features

- **`LTIME` instead of `TIME`**: Provides 64-bit nanosecond resolution instead of the 32-bit millisecond resolution of `TIME`, relevant for very long or very precise timing.
- **Functionally identical to `FB_TON`**: Same timing behaviour, only the data type of `PT`/`ET` differs.

State Overview

See `FB_TON` — identical state behaviour, just with `LTIME` values instead of `TIME`.

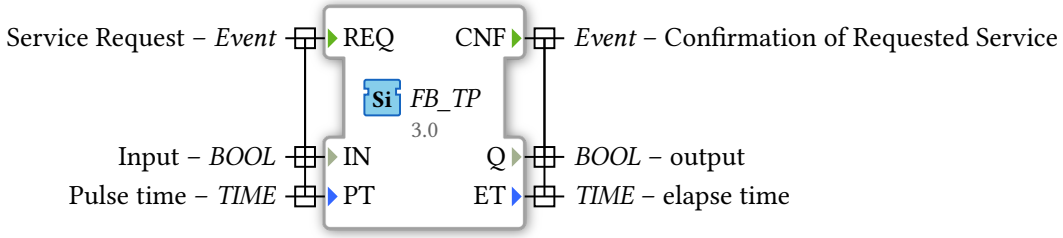
Application Scenarios

- **Timing with very high precision or very long duration**, where the millisecond resolution or value range of `TIME` is insufficient.
- **Consistent `LTIME` usage** in applications that work with `LTIME` throughout, to avoid data type conversions.

Comparison with similar function blocks

- **`FB_TON`**: the same functionality with `TIME` instead of `LTIME`.

Conclusion



`FB_TON_LTIME` provides the same on-delay functionality as `FB_TON`, but with `LTIME` resolution, and is suitable for applications working with high-resolution time values throughout.

FB_TP

• – ◦ • – ◦ • – ◦ •

Introduction

Important note: This function block only functions correctly if it is called cyclically. The FB_TP (Timer Pulse) is a standardized timer function block according to IEC 61131-3 that provides a pulsed output function. The function block generates a pulse with a defined duration, independent of the duration of the input signal.

Interface Structure

Event Inputs

- **REQ**: Service Request - Starts the timer

Event Outputs

- **CNF**: Confirmation of requested service - Signals the end of the time pulse

Data Inputs

- **IN**: Input signal (BOOL) - Controls the start of the timer
- **PT**: Pulse Time (TIME) - Defines the duration of the output pulse

Data Outputs

- **Q**: Output signal (BOOL) - Outputs the current state of the timer
- **ET**: Elapsed Time (TIME) - Displays the elapsed time of the current pulse

Adapters

No adapter interfaces are available.

Functionality

The FB_TP functions as a monostable multivibrator (one-shot). On a rising edge at the IN input, the timer starts and sets the Q output to TRUE for the duration defined in PT. The elapsed time is continuously output at the ET output. After the set time PT has expired, Q is automatically reset to FALSE, regardless of the state of the IN input.

When a rising edge is detected at the IN input, the timer starts and sets the Q output to TRUE for the duration defined in PT.

Technical Features

- Time measurement is independent of the input signal duration
- ET output displays the current pulse propagation time
- Immediate response to a rising edge at the IN input
- Automatic reset after time elapses

State Transitions

1. **Idle State**: IN = FALSE, Q = FALSE, ET = 0
2. **Start**: Rising edge at IN ⟶ Q = TRUE, ET counting begins
3. **Progression Time**: Q remains TRUE while ET < PT
4. **End**: When ET ≥ PT ⟶ Q = FALSE, ET counting stops

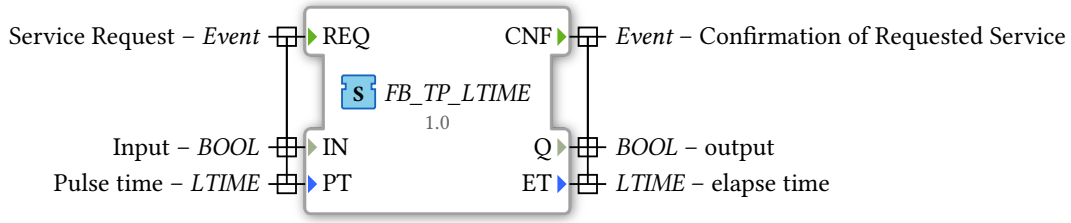
Application Scenarios

- Generation of precisely defined pulses

- Time-controlled sequences
- Delay circuits
- Clock generation for process control
- Safety time monitoring

⚖️ Comparison with similar function blocks

- **FB_TON**: Switch-on delay - Q only becomes active after PT has elapsed
- **FB_TOF**: Switch-off delay - Q remains active for PT after IN reset
- **FB_TP**: Pulse generator - Generates a fixed pulse independent of IN



🛠️ Related exercises

- Exercise_020f2
- Exercise_020f2_AX

Conclusion

The FB_TP is an essential component for time-controlled applications in automation technology. Its ease of use and reliable operation make it ideal for applications requiring precise time pulses. The clear separation of the start pulse and pulse duration enables flexible control concepts.

FB_TP_LTIME

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_TP_LTIME` is the `LTIME` variant (64-bit duration, nanosecond resolution) of the standard timer block `FB_TP` (pulse). It behaves functionally identically to `FB_TP`, but uses data type `LTIME` instead of `TIME` for `PT`/`ET`.

Interface Structure

Event Inputs

- **REQ**: Triggers execution, linked with `IN` and `PT`.

Event Outputs

- **CNF**: Confirms execution, linked with `Q` and `ET`.

Data Inputs

- **IN** (BOOL): Input signal.
- **PT** (LTIME): Preset time.

Data Outputs

- **Q** (BOOL): Output signal, see Functionality.
- **ET** (LTIME): Elapsed time since the timing started.

Functionality

A rising edge of IN triggers a TRUE pulse of fixed duration PT on Q, regardless of how long IN stays TRUE. Internally, the block (analogous to `FB_TP`) holds the internal helper variables `MEM` and `StartTime` to track edge transitions of `IN` and the start time of the measurement — at `LTIME` resolution instead of `TIME`.

Technical Features

- **`LTIME` instead of `TIME`**: Provides 64-bit nanosecond resolution instead of the 32-bit millisecond resolution of `TIME`, relevant for very long or very precise timing.
- **Functionally identical to `FB_TP`**: Same timing behaviour, only the data type of `PT`/`ET` differs.

State Overview

See `FB_TP` — identical state behaviour, just with `LTIME` values instead of `TIME`.

Application Scenarios

- **Timing with very high precision or very long duration**, where the millisecond resolution or value range of `TIME` is insufficient.
- **Consistent `LTIME` usage** in applications that work with `LTIME` throughout, to avoid data type conversions.

Comparison with similar function blocks

- **`FB_TP`**: the same functionality with `TIME` instead of `LTIME`.

Conclusion

`FB_TP_LTIME` provides the same pulse functionality as `FB_TP`, but with `LTIME` resolution, and is suitable for applications working with high-resolution time values throughout.

Introduction

The IB (Input Byte) function block is a service interface function block for processing byte input data. It serves as an interface between an IEC 61499 control system and external input devices or resources that supply byte data.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block and configures the interface parameters
- **REQ**: Service Request - Requests current data input

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms successful initialization
- **CNF**: Service Acknowledgement - Confirms the requested service operations
- **IND**: Indication from Resource - Signals incoming data from the external resource

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - Controls the execution of events
- **PARAMS**: Service Parameters (STRING) - Configuration parameters for the interface

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - Status indicator for the output events
- **STATUS**: Service Status (STRING) - Status information about the current operation
- **IN**: Input data from the resource (BYTE) - The received byte data

Adapter

No adapter interfaces are available.

Functionality

The IB function block operates as a bidirectional interface for byte input data. During initialization (INIT), the interface parameters are configured. Data can be explicitly requested via REQ events, while IND events signal asynchronous data inputs. The received byte data is provided via the IN output.

Technical Features

- Supports both request-based (REQ/CNF) and event-based (IND) data acquisition
- BYTE data type for compact 8-bit data processing
- String-based parameter configuration for flexible customization
- Status feedback via SERVICE status output

State Overview

The function block goes through the following main states:

1. **Not Initialized**: Waiting for an INIT event
2. **Initialized**: Ready for data acquisition
3. **Data Request**: Processing REQ events
4. **Data Receive**: Processing incoming IND events

Application Scenarios

- Reading 8-bit sensor data

- Interface to simple digital input devices
- Communication with peripheral devices that provide byte data
- Protocol implementations with byte-oriented data formats

⚖️ Comparison with Similar Function Blocks

Compared to other input blocks:

- IB specialized for the BYTE data type (8-bit)
- Offers both polling (REQ) and interrupt-type (IND) operating modes
- Simpler than more complex protocol blocks, but more specific for byte data

🛠️ Related Exercises

- Exercise_006c
- Exercise_011a

Conclusion

The IB function block offers an efficient and flexible solution for integrating byte-based input data into IEC 61499 control systems. Its dual operating mode (request-based and event-driven) makes it versatile for various applications in industrial automation.

Introduction

The ID function block is an input service interface module for double-word (DWORD) input data. It serves as an interface between the control logic and external input devices or resources and enables the querying of 32-bit input data.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block and configures the parameters
- **REQ**: Service Request - Triggers a query of the input data

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms successful initialization
- **CNF**: Confirmation of Requested Service - Confirms a successful service request
- **IND**: Indication from Resource - Signals incoming data from the resource

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - Enables/disables the service
- **PARAMS**: Service Parameters (STRING) - Configuration parameters for the service

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - Status of the Service Output
- **STATUS**: Service status (STRING) - Status information about the service
- **IN**: Input data from the resource (DWORD) - The read 32-bit input data

Adapter

No adapter interfaces available.

Functionality

The ID block functions as a service interface for double-word input. During initialization (INIT), the service parameters are configured. Subsequently, input data can be selectively queried from the connected resource via REQ events. The block returns the read data via the IN outputs along with status information.

Technical Features

- Processes 32-bit data (DWORD)
- Supports both requested (REQ/CNF) and spontaneous (IND) data transmissions
- Flexible parameter configuration via STRING parameters
- Qualifier-based control (QI/QO) for service activation

State Overview

The function block goes through the following main states:

1. **Not Initialized**: Before INIT processing
2. **Initialized**: After successful INIT processing, ready for data queries
3. **Data Query**: During the processing of REQ events
4. **Data Reception**: During spontaneously received data (IND)

Application Scenarios

- Querying 32-bit sensor data
- Reading digital input signals in groups
- Communication with peripheral devices that provide double-word data
- Integration of external measurement systems into 4diac controllers

⚖️ Comparison with Similar Function Blocks

Compared to ID offers simpler input blocks:

- Extended status feedback
- Configurable service parameters
- Support for both operating modes (demand-driven and ad hoc)
- 32-bit data width instead of simple BOOL or BYTE values

Introduction

The IE (Input Event) function block is a service interface function block for processing event input data. It serves as an interface between the control logic and external input devices or signals and enables the initialization, querying, and indication of input events.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block with parameters
- **REQ**: Service Request - Triggers a query of the input state

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms successful initialization
- **CNF**: Service Acknowledgement - Confirms the processed service request
- **IND**: Resource Indication - Signals incoming events from the hardware

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/disables event processing
- **PARAMS** (STRING): Service Parameters - Configuration parameters for the service

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Status of the Event Processing
- **STATUS** (STRING): Service status - Feedback on the current operating state

Adapter

No adapter interfaces are available.

Functionality

The IE function block operates as a bidirectional interface for input events. During initialization (INIT), the service parameters are configured. Targeted queries of the input state can be performed via REQ events. Simultaneously, the block can asynchronously generate IND events when input events are spontaneously detected by the hardware.

Technical Features

- Supports both poll-based (REQ/CNF) and interrupt-based (IND) operating modes
- String-based parameter and status transmission for flexible configuration
- Separate qualifiers for input and output events (QI/QO)
- Robust error handling through STATUS feedback

State Overview

The function block goes through the following main states:

1. **Not Initialized**: Block waits for an INIT event
2. **Initialized**: Block is ready for operation and can process REQ and IND events
3. **Query Active**: Processing a REQ request
4. **Indication Active**: Processing a spontaneous input event

Application Scenarios

- Querying digital inputs (e.g., pushbuttons, switches)
- Monitoring sensor signals
- Interface to external input devices
- Event-driven control applications
- Hardware-level I/O management in automation systems

⚖️ Comparison with Similar building blocks

Compared to simpler input blocks, IE offers extended functionality:

- Compared to pure I/O blocks: Supports both poll-based and event-based queries
- Compared to static input blocks: Dynamic parameterization at runtime
- Enhanced status feedback for improved error diagnosis

Introduction

The IL (Input Long Word) function block is a Service Interface Function Block for processing long word input data. It serves as an interface between the control logic and external input devices or resources that provide 64-bit data values.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation
- **IND**: Indication from Resource

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Controls the execution of the service
- **PARAMS** (STRING): Service Parameters for Configuration

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Displays the status of the operation
- **STATUS** (STRING): Service Status Information
- **IN** (LWORD): Input Data from the Resource (64-bit value)

Adapters

No adapter interfaces are available.

Functionality

The IL block functions as an input service interface for long word data. Upon receiving the INIT event, the service is initialized and the configuration parameters are passed via PARAMS. The REQ event triggers a read operation, in which data is read from the connected resource. The block supports both requested reads (CNF) and spontaneous data updates (IND) from the resource.

Technical Features

- Processes 64-bit Long Word (LWORD) data types
- Supports both poll-based and event-based data queries
- Flexible parameter configuration via STRING parameters
- Status feedback via STATUS output

State Overview

The block goes through the following states:

1. **Not Initialized**: Before the INIT operation
2. **Initialized**: After successful INIT operation, ready for data queries
3. **Active**: During data querying or when receiving indications

Application Scenarios

- Reading 64-bit sensor data
- Communication with external devices that provide Long Word data
- High-precision data acquisition systems
- Control systems that need to process large numerical values

⚖️ Comparison with Similar Blocks

Compared to other input blocks such as IB (Byte), IW (Word), or ID (Double Word), IL processes the largest data size (64 bits). It thus offers the highest precision for numerical input values in the 4diac I/O library.

Conclusion

The IL function block provides a robust and flexible interface for processing 64-bit input data in IEC 61499 control systems. Its support for various operating modes (polling and event-driven) makes it versatile for use in a wide range of industrial applications.

2.11.5.7 IW

🎧 Podcast

- Miniware TS101: The Mobile Soldering All-Rounder – Strengths, Weaknesses, and the USB-C Revolution

Introduction

The IW (Input Word) function block is a service interface function block for processing word input data in 4diac systems. It serves as an interface between the control logic and external input devices or resources that provide word data (16-bit).

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block and configures the hardware parameters

- **REQ**: Service Request - Requests a current input from the connected device

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms completion of initialization
- **CNF**: Requested Service Acknowledgement - Acknowledges a successful REQ request
- **IND**: Resource Indication - Signals incoming data without a prior request

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - Enables/disables processing
- **PARAMS**: Service Parameters (STRING) - Configuration parameters for the hardware interface

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - Processing status
- **STATUS**: Service status (STRING) - Error messages or status information
- **IN**: Input data from the resource (WORD) - The read 16-bit data

Functionality

The IW block operates as a bidirectional interface for Word input data. During initialization (INIT), the hardware parameters are configured. The block can respond to explicit requests (REQ) as well as process asynchronous data indications (IND) from the connected resource. The read Word data is output to the IN output.

Technical Features

- Processes 16-bit WORD data types
- Supports both request-based (REQ/CNF) and event-based (IND) communication
- String-based parameter configuration for flexible hardware connectivity
- Comprehensive status feedback via STATUS output

State Overview

The block goes through the following main states:

- **Not Initialized**: Block waits for an INIT event
- **Initialized**: Block is ready and can process data
- **Data Request**: Processing a REQ request
- **Data Reception**: Processing incoming IND data

Application Scenarios

- Connecting 16-bit input devices (sensors, encoders, switch groups)
- Reading digital input words from process peripherals
- Interface to I/O modules with word-based inputs
- Monitoring status words from distributed systems

⚖️ Comparison with Similar Blocks

Compared to IB (Input Byte) IW processes 16-bit data instead of 8-bit data. Compared to ID (Input Double Word), IW offers a narrower data width. The block's structure is similar to other I/O interface blocks, but it is specifically optimized for WORD data types.

Conclusion

The IW function block provides a robust and flexible interface for processing 16-bit input data in 4diac systems. Its clear event structure and comprehensive status feedback make it a reliable solution for connecting word-based input devices in industrial automation applications.

2.11.5.8 IX

🎧 Podcast

- Infineon MOTIX BTM9020/9021EP: Datasheet Analysis for Automotive – Robust Motor Driver with Intelligent Diagnostics (HW vs. SPI)
- Integrated Full Bridge ICs MOTIX™ BTM9020EP

Introduction

The IX function block is a service interface function block for Boolean input data. It serves as an interface for communication with input devices and enables the querying and processing of digital input signals in 4diac systems.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block and configures the hardware parameters
- **REQ**: Service Request - Requests a query of the current input value

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms successful initialization
- **CNF**: Confirmation of Requested Service - Confirms a successful query
- **IND**: Indication from Resource - Signals a change in the input signal's state

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - Controls the activation of the service functionality
- **PARAMS**: Service Parameters (STRING) - Contains configuration parameters for the hardware interface

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - Displays the service execution status
- **STATUS**: Service status (STRING) - Provides status information about the service execution
- **IN**: Input data from the resource (BOOL) - Contains the current value of the digital input

Adapter

No adapter interfaces are available.

Functionality

The IX function block acts as an intermediary between the control logic and physical input devices. During initialization (INIT), the hardware parameters are configured. Subsequently, the current state of the input can be queried via REQ events. The block can process both poll-based queries (REQ/CNF) and event-based notifications (IND) upon state changes.

Technical Features

- Supports both request-based and event-driven operating modes
- Boolean data type for simple digital inputs
- Flexible parameter configuration via STRING parameters
- Comprehensive status feedback for fault diagnosis

State Overview

The function block goes through the following main states:

1. **Not Initialized**: Block is inactive
2. **Initialized**: Block is ready for operation after successful INIT processing
3. **Query Active**: Processing a REQ request
4. **Indication Ready**: Ready for event-driven notifications

Application Scenarios

- Querying digital sensors (limit switches, proximity switches)
- Monitoring push-button inputs
- Reading switch positions
- Digital signal processing in automation systems

⚖️ Comparison with Similar Blocks

Compared to other input blocks, IX offers an enhanced service interface with both poll-based and event-driven operating modes. While simpler input blocks often only provide direct values, IX offers additional status information and error handling.

2.11.5.9 QB

• – ◦ • – ◦ • – ◦ •

Introduction

The QB function block is an output service interface for byte output data. It serves as an interface between the control logic and physical output devices or resources, enabling the output of byte data to external hardware.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters for Configuration
- **OUT** (BYTE): Output Data for the Resource

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status Information

Adapters

No adapter interfaces are available.

Functionality

The QB block initializes itself with the corresponding PARAMS via the INIT event. After successful initialization, it confirms this with INITO. Byte data (OUT) can be output to the connected resource via the REQ event. Processing is acknowledged with the CNF event and status information.

Technical Features

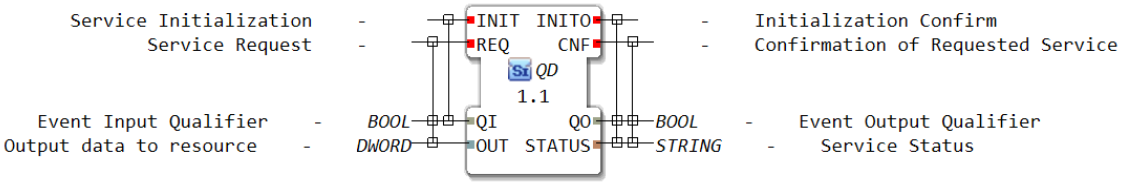
- Specialized for byte data output
- Supports configurable initialization
- Provides detailed status information via STRING output
- Uses qualifiers (QI/QO) for event control

State Overview

1. **Not Initialized**: Block awaits INIT event
2. **Initialized**: Block ready for REQ requests
3. **Active**: Processing output requests
4. **Error**: Status message in case of problems

Application Scenarios

- Controlling digital output modules
- Communication with byte-based peripherals
- Integration into I/O subsystems
- Controlling hardware with byte commands

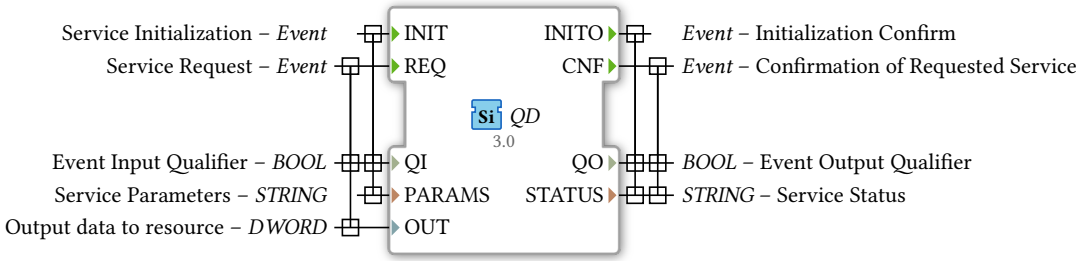


⚖️ Comparison with Similar Blocks

Compared to more general output blocks, QB is specifically optimized for byte data. Other blocks, such as WORD or DWORD output blocks, work with larger data types, while QB enables efficient processing of 8-bit data.

Conclusion

The QB function block offers a robust and standardized interface for byte output data in industrial control systems. Its clear event control and status feedback make it particularly suitable for reliable I/O operations in automated processes.



2.11.5.10 QD

• – ◦ • – ◦ • – ◦ •

Introduction

The QD function block is an output service interface component for outputting double-word (DWORD) data. It serves as an interface between the application logic and the physical output devices of a resource manager.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - initializes the function block with the required parameters
- **REQ**: Service Request - triggers data output to the resource

Event Outputs

- **INITO**: Initialization Acknowledgement - confirms completion of initialization
- **CNF**: Acknowledgement of Requested Service Execution - signals completion of data output

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - controls the execution of service requests
- **PARAMS**: Service Parameters (STRING) - configuration parameters for the service
- **OUT**: Output Data (DWORD) - the double-word data to be transmitted to the resource

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - status of the Service Execution
- **STATUS**: Service status (STRING) - detailed status information about service execution

Adapter

No adapter interfaces are available.

Functionality

The QD block operates as a cyclic service interface component. Upon receiving the INIT event, the block is initialized with the configuration data passed via PARAMS. The actual data output is triggered by the REQ event, whereby the DWORD data provided in the OUT input is transferred to the assigned resource. Each service request is acknowledged by corresponding confirmation events (INITO or CNF).

Technical Features

- Processes 32-bit data (DWORD)
- Supports configurable service configuration
- Provides detailed status feedback
- Works with qualifier flags for reliable service control

State Overview

The block goes through the following states:

1. **Not Initialized**: Block waits for an INIT event
2. **Initialized**: Block is ready for operation and waits for REQ events
3. **Service Execution**: Processing a REQ request
4. **Acknowledgement**: Feedback of the service result

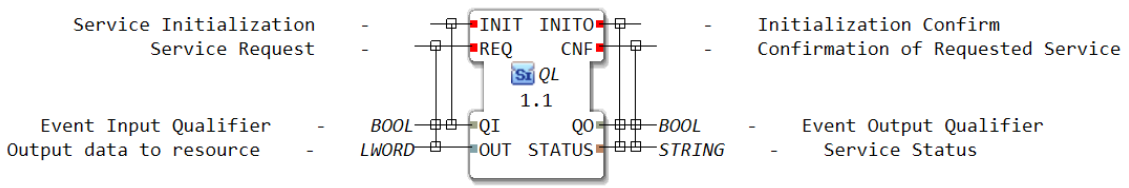
Application Scenarios

- Control of digital output modules with 32-bit data width
- Control of complex actuators with multiple parameter passing
- Integration into distributed control systems with resource management
- Applications with high output data integrity requirements

⚖️ Comparison with Similar Blocks

Compared to simpler output blocks, QD offers:

- Enhanced parameterization through STRING parameters
- DWORD data width instead of simple BOOL or BYTE values
- Detailed status feedback for fault diagnosis
- Complete service interface characteristics with initialization procedure

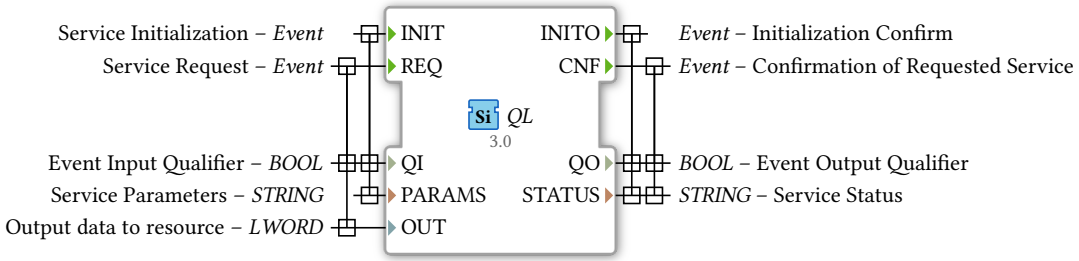


🛠️ Related Exercises

- Exercise_060

Conclusion

The QD function block represents a powerful and flexible solution for outputting double-word data in IEC 61499 systems. Its comprehensive parameterization and detailed status feedback make it particularly suitable for demanding automation applications that require reliable and configurable output services.



2.11.5.11 QL

• – ○ • – ○ • – ○ •

Introduction

The QL function block is an output service interface block for processing long-word output data. It serves as an interface between the control logic and external resources and enables the output of 64-bit data values.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **OUT** (LWORD): Output Data for the Resource (64-bit)

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status Information

Adapters

No adapter interfaces are available.

Functionality

The QL block processes two main operations: initialization and data output. During the INIT operation, the service parameters are configured and the connection to the resource is initialized. The REQ operation performs the actual data output of the LWORD value to the connected resource. Each operation is acknowledged by corresponding confirmation events.

Technical Features

- Processing of 64-bit data values (LWORD)
- String-based parameter configuration
- Status feedback via STRING variable
- Qualifier for event control (QI/QO)

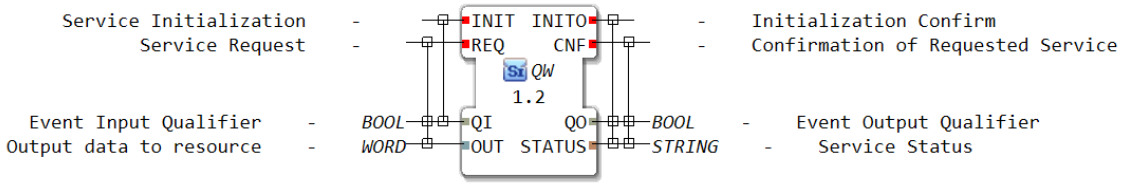
State Transitions

The block has two main states:

1. **Initialization State**: Processing the INIT request with PARAMS
2. **Operating State**: Processing REQ requests with OUT data

Application Scenarios

- Output of 64-bit control values to hardware interfaces
- Communication with external peripherals
- Integration into distributed control systems
- Connection to dedicated I/O modules

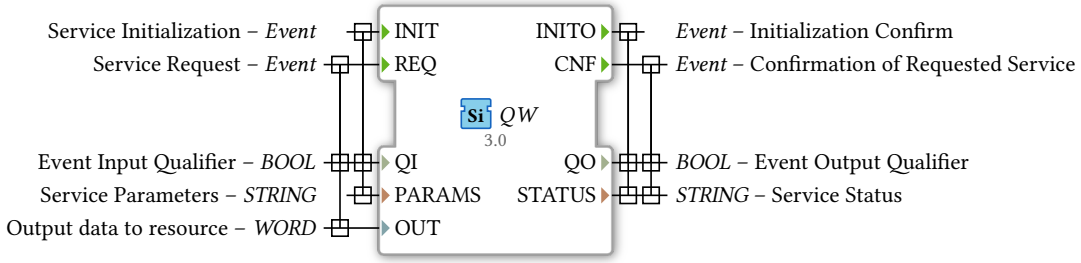


⚖️ Comparison with Similar Blocks

Compared to simpler output blocks, QL offers 64-bit data processing and extended parameter configuration. Compared to more general-purpose communication blocks, QL is specifically optimized for output functionality.

Conclusion

The QL function block provides a powerful interface for the output of long-word data and, through its structured event control and status feedback, offers a reliable basis for connecting external resources in automation systems.



2.11.5.12 QW

• – ◦ • – ◦ • – ◦ •

Introduction

The QW function block is an output service interface module for outputting Word data. It serves as an interface between the control logic and physical output devices or resources, enabling the secure transfer of 16-bit data to external hardware.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters for Configuration
- **OUT** (WORD): Output Data for the Resource

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status Information

Adapters

No adapter interfaces are present.

Functionality

Upon receiving the INIT event, the QW block initializes the hardware interface with the passed PARAMS. After successful initialization, it confirms this with INITO. A REQ request outputs the WORD data received by OUT to the configured resource. The operation is confirmed with CNF, where STATUS provides information about the success or failure of the operation.

Technical Features

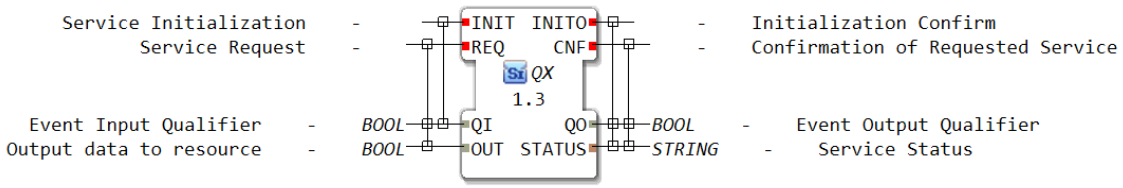
- Processes 16-bit WORD data
- String-based parameter configuration via PARAMS
- Status feedback via STRING variable
- Qualifier bits (QI/QO) for event control

State Overview

1. **Not Initialized**: Block awaits INIT event
2. **Initialized**: Block is ready and awaits REQ events
3. **Active**: Processes output requests and generates acknowledgments

Application Scenarios

- Control of digital output modules
- Communication with I/O systems
- Control of hardware with 16-bit data words
- Integration into distributed control systems

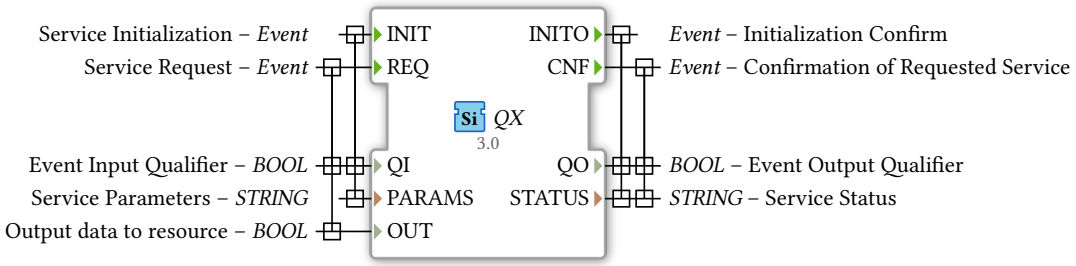


⚖️ Comparison with Similar Components

Compared to QB (byte output), QW processes 16-bit instead of 8-bit data. Compared to QD (double word), it offers a narrower data width with reduced resource requirements. The structure is similar to other I/O service blocks, but is specifically designed for WORD data.

Conclusion

The QW function block provides a robust and standardized interface for outputting 16-bit data to external resources. Its clear event handling and status feedback make it ideal for reliable real-time I/O operations in industrial control systems.



2.11.5.13 QX

• – ◦ • – ◦ • – ◦ •

Introduction

The QX function block is an output service interface function block for Boolean output data. It serves as an interface between the control logic and physical output devices and enables the output of digital signals to external resources.

Interface Structure

Event Inputs
- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs
- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs
- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters for Configuration
- **OUT** (BOOL): Output Data for the Resource

Data Outputs
- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status Information

Adapters
No adapter interfaces are available.

Functionality
The QX block processes two main operations: initialization and service requests. The INIT event initializes the service with the specified parameters. The REQ event outputs the Boolean OUT value to the connected resource. Each operation generates a corresponding acknowledgment (INITO or CNF) containing status information.

The INIT event initializes the service with the specified parameters.

Technical Features
- Specialized for Boolean output data
- Supports configurable service configuration
- Provides detailed status information via the STRING output STATUS
- Uses qualifiers (QI/QO) for event control

State Overview
The block cycles through the following states:

1. **Not Initialized**: Before the first INIT operation
2. **Initialized**: After successful INIT operation, ready for REQ operations
3. **Active**: During the processing of REQ operations

Application Scenarios
- Control of digital outputs (relays, LEDs, valves)
- Interface to actuators in automation systems
- Integration into I/O subsystems for distributed controllers
- Test and simulation environments for output signals

⚖️ Comparison with Similar Blocks
Compared to generic output blocks, QX offers specific service interface functionality with configurable settings and detailed status reporting. Other blocks, such as simple BOOL outputs, typically have fewer configuration options and less status information.

ADS_SERVER_CONFIG

• – ◦ • – ◦ • – ◦ •

Introduction

The ADS_SERVER_CONFIG function block is used to configure ADS server connections in 4diac systems. It enables the initialization and parameterization of connection settings for ADS communication, which can be used in downstream I/O function blocks.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event - Starts the configuration of the ADS server

Event Outputs

- **INITO**: Initialization Acknowledgement - Signals successful completion of the configuration

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/disables initialization
- **FRIENDLY_NAME** (WSTRING): User-friendly server name for use in I/O function blocks
- **SERVER_ADS_ADDRESS** (WSTRING): ADS address of the server
- **ADS_PORT** (UINT): ADS port of the server
- **SERVER_IPV4_OR_HOSTNAME** (WSTRING): IPv4 address or hostname of the ADS server

Data Outputs

- **QO** (BOOL): Event output qualifier - Indicates the initialization status
- **STATUS** (WSTRING): Service status information

Adapter

No adapter interfaces are available.

Functionality

The function block is activated by the INIT event and processes the provided configuration parameters. Upon successful processing, it outputs the INITO event and makes the configured parameters available to downstream ADS-IO function blocks. The STATUS output provides detailed information about the configuration process.

Technical Features

- Uses WSTRING data types for international character support
- Supports both IPv4 addresses and hostnames for maximum flexibility
- Separate parameters for ADS address and network address enable complex network configurations
- Port configuration as UINT for numeric port specification

State Overview

1. **Inactive**: Waiting for INIT event
2. **Configuration**: Processing input parameters
3. **Active**: Configuration completed successfully, parameters are available
4. **Error**: Configuration failed, STATUS contains error information

Application Scenarios

- Initial system configuration in ADS-based automation systems
- Central management of ADS server connection parameters
- Dynamic reconfiguration of network settings
- Integration into larger I/O management systems

⚖️ Comparison with Similar Blocks

Compared to simple ADS I/O blocks, ADS_SERVER_CONFIG provides a central configuration option for multiple downstream blocks. It separates the configuration logic from the actual data communication, thus enabling reusable server settings.

Conclusion

ADS_SERVER_CONFIG is an essential component for structured ADS communication in 4diac systems. Through centralized configuration management, it simplifies the maintenance and modification of network settings and promotes consistent connection parameters across various I/O function blocks.

SET_LOCAL_ADS_ADDRESS

• – ◦ • – ◦ • – ◦ •

Introduction

The SET_LOCAL_ADS_ADDRESS function block is a Service Interface Function Block for configuring the local ADS address. ADS (Automation Device Specification) is a communication protocol commonly used in automation technology. This block allows the dynamic setting of the local ADS address during runtime.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Starts the configuration process for the local ADS address

Event Outputs

- **INITO**: Initialization Confirmation - Signals the completion of the configuration process

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/disables the initialization process
- **PARAMS** (STRING): Local ADS address to be set

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Confirms the successful completion of the operation
- **STATUS** (WSTRING): Service Status - Contains status information about the performed operation
- **LOCAL_ADS_ADDRESS** (STRING): Resulting ADS Address - The actual ADS address set

Functionality

The function block is accessed by The INIT event is activated. Upon activation, it reads the PARAMS input, which contains the desired local ADS address in string format. The function block then configures the local ADS interface with the specified address. After completion, the INITO event is triggered, and the resulting ADS address and status information are made available at the outputs.

Technical Features

- Uses STRING data type for ADS addresses
- Provides comprehensive status information in WSTRING format

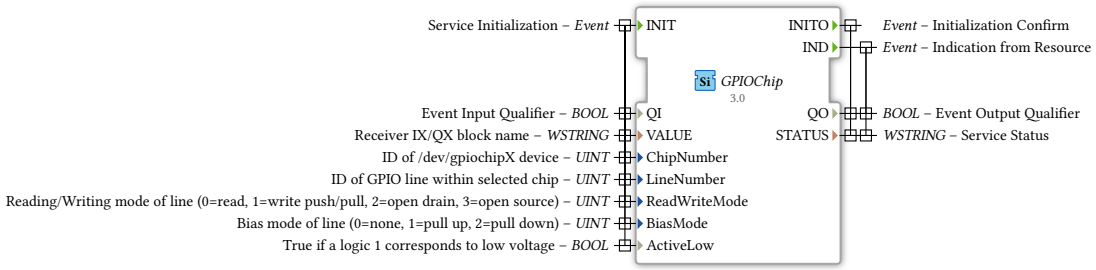
- Supports dynamic address configuration at runtime
- Implements a standardized initialization protocol

State Transitions

1. **Initial State**: Waits for INIT event
2. **Configuration State**: Processes the ADS address parameters
3. **Completion State**: Sends INITO event with result data

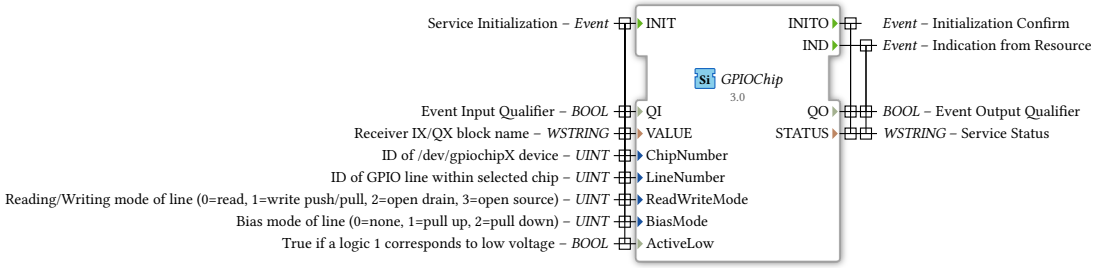
Application Scenarios

- Dynamic configuration of ADS devices in distributed automation systems
- Addressing of ADS components in flexible production facilities
- Integration into systems with variable network configurations
- Maintenance and commissioning of ADS-based controllers



⚖️ Comparison with Similar Blocks

Compared to static ADS configuration blocks, SET_LOCAL_ADS_ADDRESS enables dynamic address management at runtime. The function block also provides detailed status feedback, which simplifies troubleshooting.



Conclusion

The SET_LOCAL_ADS_ADDRESS function block offers a flexible solution for the dynamic configuration of ADS addresses in IEC 61499-based control systems. Its clear interface definition and comprehensive status feedback make it particularly suitable for applications requiring flexible network configuration.

2.11.5.15 GPIOChip

GPIOChip

• – ○ • – ○ • – ○ •

Introduction

The GPIOChip function block is a service interface function block for controlling GPIO chips under Linux systems. It enables access to GPIO lines via the Linux GPIO Character Device Interface (/dev/gpiochipX) and supports various operating modes for reading and writing GPIO signals.

Interface Structure

Event Inputs

- **INIT**: Service initialization event with the associated data QI, VALUE, ChipNumber, LineNumber, ReadWriteMode, BiasMode, and ActiveLow

Event Outputs

- **INITO**: Initialization confirmation with QO and STATUS
- **IND**: Resource indication with QO and STATUS

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **VALUE** (WSTRING): Receiver IX/QX block name
- **ChipNumber** (UINT): ID of the /dev/gpiochipX device (initial value: 0)
- **LineNumber** (UINT): ID of the GPIO line within the selected chip (initial value: 0)
- **ReadWriteMode** (UINT): Read/write mode of the line (0=read, 1=write) push/pull, 2=open drain, 3=open source) (Initial value: 0)
- **BiasMode** (UINT): Bias mode of the line (0=none, 1=pull up, 2=pull down) (Initial value: 0)
- **ActiveLow** (BOOL): True when logic 1 corresponds to low voltage (Initial value: 0)

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (WSTRING): Service Status

Adapter

No adapter interfaces available.

Functionality

Upon receiving the INIT event, the GPIOChip FB initializes a connection to a specific GPIO chip and a defined GPIO line. The configuration includes the operating mode (read/write), the bias mode, and the polarity setting (ActiveLow). After successful initialization, the block confirms with INITO+; in case of errors, it confirms with INITO- and a corresponding STATUS. ...

Technical Features

- Supports various GPIO operating modes: Read, Write (Push/Pull), Open Drain, and Open Source
- Configurable bias settings: None, Pull-Up, Pull-Down
- Active-Low mode for inverted logic
- Linux GPIO Character Device Interface based
- Automatic error handling with status feedback

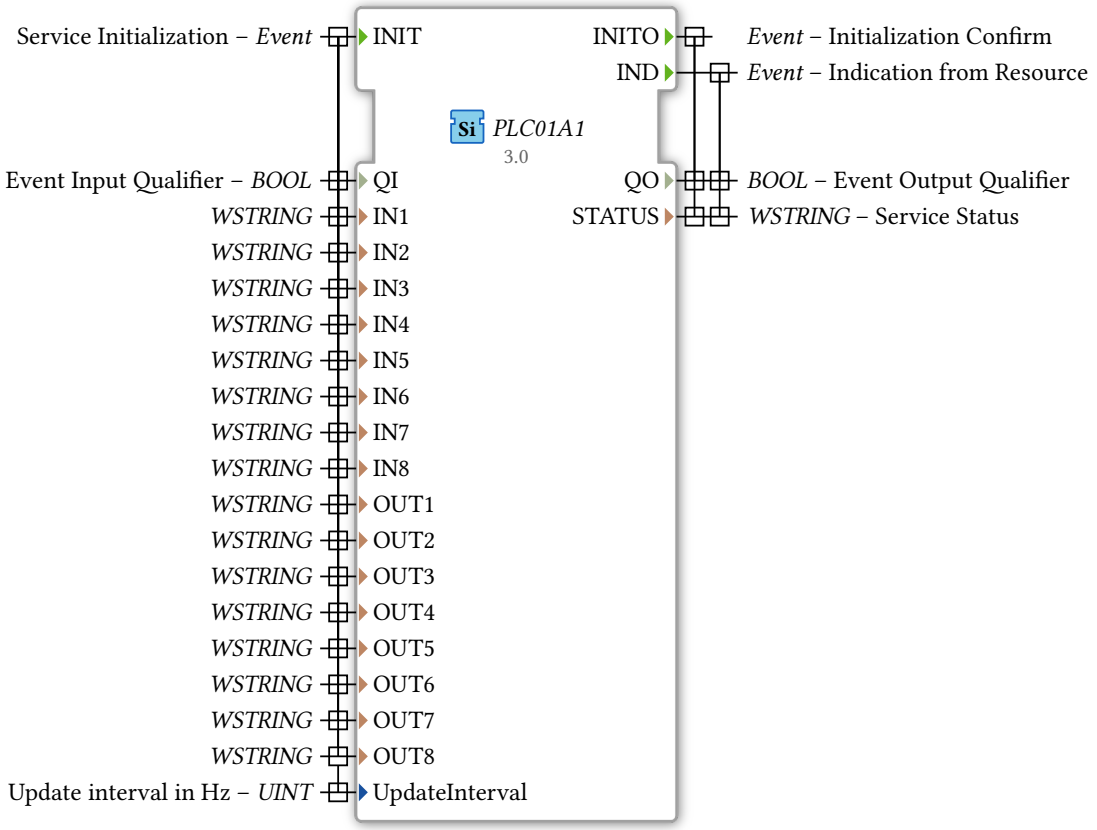
State Overview

The function block goes through the following states:

1. **Not Initialized**: Initial state before INIT
2. **Initialization**: During GPIO chip configuration
3. **Ready**: After successful initialization (INITO+)
4. **Error**: In case of initialization errors (INITO-)

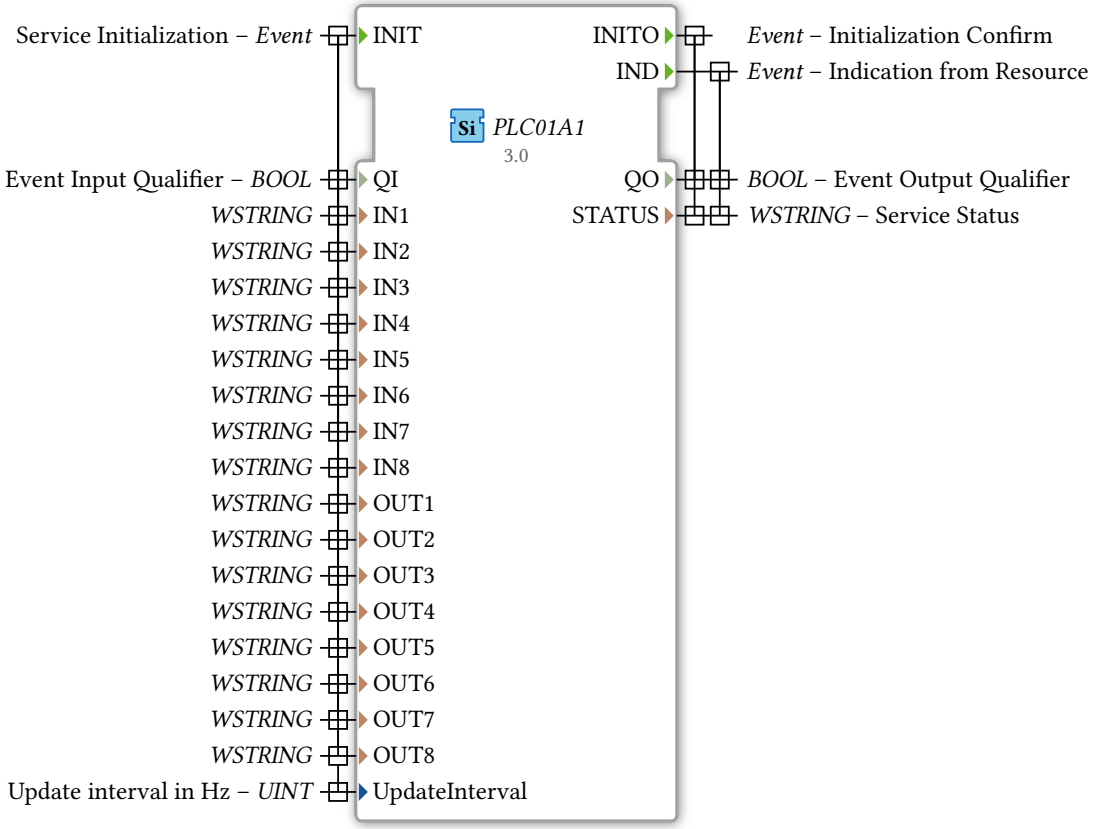
Application Scenarios

- Controlling GPIO pins in embedded Linux systems
- Low-level I/O operations in automation systems
- Interface to external sensors and actuators
- Prototyping and development of IoT devices
- Industrial control applications



⚖️ Comparison with similar Building Blocks

Compared to simple digital I/O blocks, GPIOChip offers advanced features such as configurable bias modes, various write modes, and direct access to the Linux GPIO subsystem. It is specifically designed for Linux systems with GPIOChip support.



Conclusion

The GPIOChip functional block provides a powerful interface for GPIO hardware control under Linux. Its extensive configurability and standardized service interface make it ideal for demanding embedded applications that require direct hardware access.

2.11.5.16 PLC01A1

PLC01A1

• – ◦ • – ◦ • – ◦ •

Introduction

The PLC01A1 function block serves as an interface for accessing the inputs and outputs of the PLC01A1 module. This block enables the control of 8 digital outputs and the reading of 8 digital inputs via a standardized 4diac interface.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- Linked to: QI, UpdateInterval, IN1-IN8, OUT1-OUT8

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **IND**: Resource Indication
- Linked to: QO, STATUS

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **IN1-IN8** (WSTRING): 8 Digital Inputs
- **OUT1-OUT8** (WSTRING): 8 Digital Outputs
- **UpdateInterval** (UINT): Update Interval in Hz (Initial Value: 25)

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (WSTRING): Service Status Information

Adapter

No adapter interfaces available.

Functionality

The PLC01A1 function block initializes the hardware interface upon receiving the INIT event. After successful initialization, the INITO event is output. The block continuously monitors inputs IN1-IN8 and updates outputs OUT1-OUT8 according to the configuration. The update interval can be adjusted using the UpdateInterval parameter.

Technical Features

- Uses WSTRING data type for all inputs/outputs
- Configurable update interval (default: 25 Hz)
- Separate initialization and operating states
- Status feedback via STATUS output

State Overview

1. **Not Initialized**: Waits for INIT event
2. **Initialization**: Processes INIT with configuration data
3. **Operation**: Monitors inputs and controls outputs
4. **Error**: Outputs error status via STATUS

Application Scenarios

- Connecting PLC01A1 hardware to 4diac controllers
- Digital signal processing in automation systems
- I/O management in distributed control systems
- Prototype development with PLC01A1 modules

⚖️ Comparison with Similar Components

Compared to generic I/O components, PLC01A1 offers specific customization for the PLC01A1 module with Eight predefined inputs and eight outputs. The use of WSTRING enables flexible data representation, but differs from typical BOOL-based I/O blocks.

Conclusion

The PLC01A1 function block provides a reliable and configurable interface for PLC01A1 hardware in 4diac-based control systems. Thanks to the clear separation of the initialization and operating phases, as well as the configurable update rate, the block is suitable for both real-time applications and general automation tasks.

2.11.5.17 PLCnext

PLCnextAXLSEDI16

• – ◦ • – ◦ • – ◦ •

Introduction

The PLCnextAXLSEDI16 is a Service Interface Function Block for connecting to PLCnext systems. This function block serves as an interface for digital inputs and enables communication with the PLCnext bus architecture. It supports 16 digital input channels and offers standardized initialization and status feedback.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block with the configured parameters

Event Outputs

- **INITO**: Initialization Confirm - Confirms successful initialization
- **IND**: Indication from Resource - Signals status changes or events from the resource

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Controls the initialization
- **DI_1 to DI_16** (STRING): Digital Input - 16 digital input channels for configuration

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Event output status
- **STATUS** (WSTRING): Service Status - Detailed status information

Adapters

- **BusAdapterOut** (Plug): Outgoing bus adapter for PLCnext Communication
- **BusAdapterIn** (Socket): Incoming bus adapter for PLCnext communication

Functionality

The function block initializes itself via the INIT event and configures the 16 digital input channels based on the DI_Parameters. After successful initialization, it confirms this via INITO. During operation, it continuously monitors the inputs and signals changes via the IND event. Communication with the PLCnext bus takes place via the integrated adapter interfaces.

Technical Features

- Supports 16 independent digital input channels
- String-based input configuration
- Unicode-enabled status feedback (WSTRING)
- Integrated PLCnext bus adapter communication
- Standard-compliant IEC 61499-2 implementation

State Overview

1. **Not Initialized**: Function block awaits INIT event
2. **Initialization**: Processing configuration parameters
3. **Ready for Operation**: Digital input monitoring active
4. **Fault State**: Status feedback issues

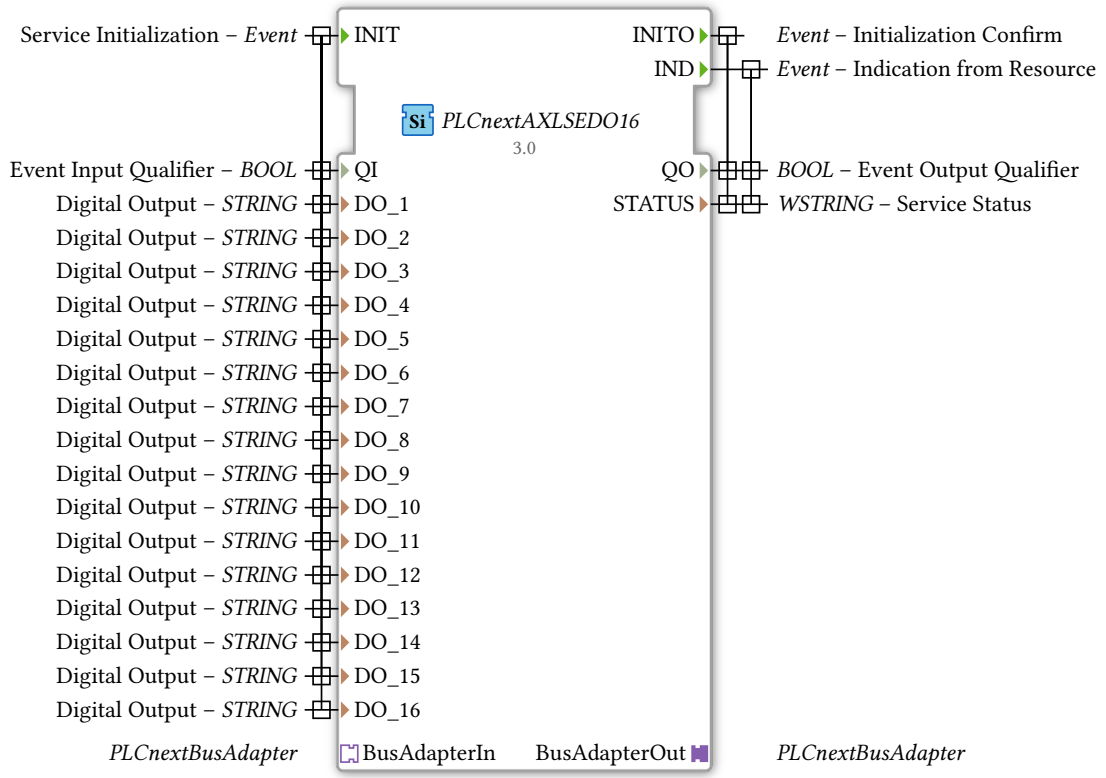
Application Scenarios

- Connecting digital sensors to PLCnext systems
- Industrial automation controllers
- Monitoring systems with multiple input signals
- PLCnext-based control architectures

⚖️ Comparison with Similar Blocks

Compared to simple digital input blocks, PLCnextAXLSEDI16 offers enhanced configurability through string parameters and integrated bus communication for PLCnext systems. The 16 channels enable a higher input density than standard modules.

Conclusion



The PLCnextAXLSEDI16 is a powerful function block for integrating digital inputs into PLCnext-based automation systems. Its flexible configuration and robust bus communication make it ideal for industrial applications with multiple digital signals.

PLCnextAXLSEDO16

• – ◦ • – ◦ • – ◦ •

Introduction

The PLCnextAXLSEDO16 is a Service Interface Function Block for controlling 16 digital outputs in PLCnext systems. This block serves as an interface between the IEC 61499-based control logic and the physical outputs of the PLCnext AXLSEDO16 module.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block and configures the digital outputs

Event Outputs

- **INITO**: Initialization Confirm - Confirms successful initialization
- **IND**: Indication from Resource - Signals status changes or errors from the resource adapter

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Controls the initialization
- **DO_1** to **DO_16** (STRING): Digital Outputs - Configure the respective output channels

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Status of the event output
- **STATUS** (WSTRING): Service Status - Detailed status information

Adapters

- **BusAdapterOut** (Plug): Outgoing bus adapter for the Communication with the Hardware
- **BusAdapterIn** (Socket): Incoming bus adapter for feedback from the hardware

Functionality

Upon receiving the INIT event, the module initializes the 16 digital outputs based on the configuration values in DO_1 to DO_16. Initialization is confirmed by INITO. During operation, status changes and errors can be reported via the IND event. Communication with the physical hardware occurs via the bus adapter interfaces.

Technical Features

- Supports 16 independent digital outputs
- Uses STRING type for output configuration, enabling flexible parameterization
- Integrates seamlessly into PLCnext systems via specific bus adapters
- Provides comprehensive status feedback via the WSTRING variable

State Overview

1. **Not Initialized**: Block is waiting for the INIT event
2. **Initialization in Progress**: Processing configuration parameters
3. **Ready for Operation**: Outputs are configured and ready for operation
4. **Fault State**: In case of problems, STATUS is populated with error information

Application Scenarios

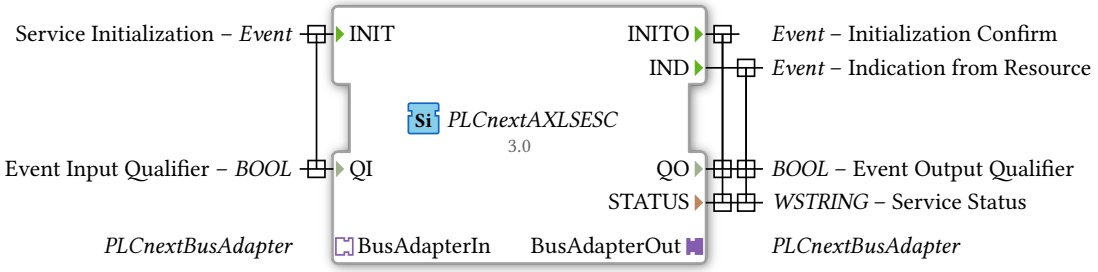
- Control of relays and actuators in automation systems
- Control of lighting systems
- Control of valves and motors
- Signal output in process control systems

⚖️ Comparison with Similar Blocks

Compared to simpler digital output blocks, PLCnextAXLSEDO16 offers:

- A higher number of channels (16 instead of the typical 16) 8)
- Specific integration for PLCnext hardware
- Extended status feedback
- Flexible string-based configuration

Conclusion



The PLCnextAXLSEDO16 is a powerful function block for controlling digital outputs in PLCnext environments. Its 16 channels, flexible configurability, and comprehensive status feedback make it ideal for complex automation tasks where multiple actuators need to be controlled simultaneously.

PLCnextAXLSESC

• – ◦ • – ◦ • – ◦ •

Introduction

The PLCnextAXLSESC is a Service Interface Function Block that serves as an interface for PLCnext bus systems. This block enables communication between the 4diac environment and PLCnext hardware components via special bus adapters.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the service with the qualifier QI

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms successful initialization with QO and STATUS
- **IND**: Resource Indication - Signals status changes with QO and STATUS

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Controls the service initialization

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Displays the status of the service output
- **STATUS** (WSTRING): Service Status - Contains detailed status information as a Unicode string

Adapters

- **BusAdapterOut** (Plug): Outgoing bus adapter for PLCnext communication
- **BusAdapterIn** (Socket): Incoming bus adapter for PLCnext communication

Functionality

The PLCnextAXLSESC function block acts as an intermediary between the 4diac controller and PLCnext hardware. Upon receiving an INIT event with QI enabled, the function block initializes communication via the bus adapters. Successful initialization is confirmed by the INITO event. During operation, status changes and indications from the hardware can be reported via the IND event.

Technical Features

- Uses WSTRING for STATUS output, supporting international character sets
- Implements a bidirectional adapter system for flexible bus communication
- Separate events for initialization and ongoing indications
- Qualifier bits (QI/QO) for reliable event control

State Overview

1. **Not Initialized**: Waits for an INIT event with QI=TRUE
2. **Initialization Phase**: Processes bus adapter communication
3. **Operational**: Sends INITO acknowledgment and is ready for IND events
4. **Active Operation**: Processes incoming indications and outputs STATUS

Application Scenarios

- Integration of PLCnext hardware into 4diac-based control systems
- Communication with PLCnext I/O modules and peripherals
- Monitoring and control of industrial automation processes
- Bridge functionality between 4diac and PLCnext Ecosystem

⚖️ Comparison with Similar Function Blocks

Compared to generic I/O blocks, PLCnextAXLSESC offers specific adaptations for the PLCnext platform, particularly through its integrated bus adapters. While standard I/O blocks provide general interfaces, this block is specifically optimized for the requirements of the PLCnext architecture.

Conclusion

The PLCnextAXLSESC function block provides a reliable and specialized interface for integrating PLCnext hardware into 4diac control systems. Its clear event structure and flexible adapter architecture enable robust communication in industrial automation applications.

PLCnextMaster

• – ◦ • – ◦ • – ◦ •

Introduction

The PLCnextMaster is a Service Interface Function Block that serves as the master component for communication with PLCnext systems. This block enables the initialization and control of bus communication in PLCnext-based automation solutions.

Interface Structure

Event Inputs
- **INIT**: Service Initialization
- Linked to: QI, SlaveUpdateInterval

Event Outputs
- **INITO**: Initialization Confirmation
- Linked to: QO, STATUS
- **IND**: Resource Indication
- Linked to: QO, STATUS

Data Inputs
- **QI** (BOOL): Event Input Qualifier - Controls service activation
- **SlaveUpdateInterval** (UINT): Update interval for slaves with an initial value of 25

Data Outputs
- **QO** (BOOL): Event Output Qualifier - Confirms the operation status
- **STATUS** (WSTRING): Status information as a Unicode string

Adapters
- **BusAdapterOut**: PLCnextBusAdapter for Bus Communication
- Type: eclipse4diac::io::plcnext::PLCnextBusAdapter

Functionality
The PLCnextMaster initializes and manages communication with PLCnext systems. The service starts when the INIT event is enabled with QI=TRUE. The SlaveUpdateInterval defines the update interval for connected slave components. After successful initialization, INITO confirms the operating state, while IND events indicate asynchronous status changes.

Technical Features
- Supports Unicode status messages (WSTRING)
- Configurable slave update interval
- Adapter-based bus communication
- Initial value for SlaveUpdateInterval set to 25

State Overview
1. **Inactive**: Before INIT activation
2. **Initialization**: During INIT processing
3. **Active**: After successful INITO confirmation
4. **Ready**: For IND events during active communication

Application Scenarios
- PLCnext-based automation systems
- Industry 4.0 applications
- Networked control systems
- IoT edge computing solutions

⚖️ Comparison with similar components
Compared to generic bus master components, the PLCnextMaster offers specific optimizations for PLCnext hardware and supports the specific bus architecture of PLCnext systems.

Conclusion
The PLCnextMaster is a specialized function block for integrating PLCnext systems into 4diac-based automation solutions. Its configurable parameters and adapter interface enable flexible and reliable communication in industrial control environments.

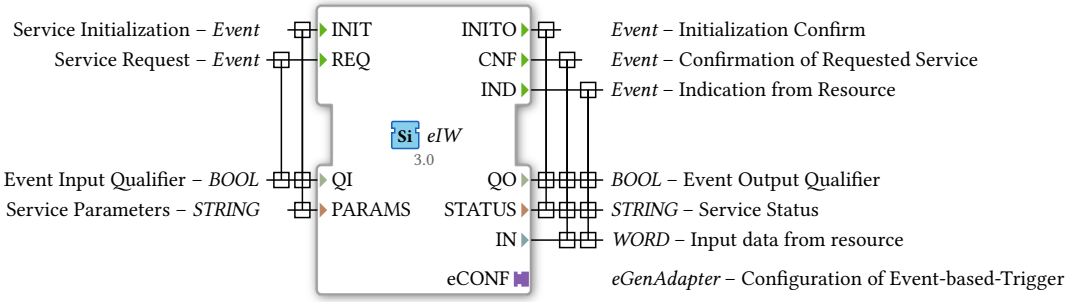
]



2.11.5.18 eIO

eIW

• – ◦ • – ◦ • – ◦ •

Introduction

The eIW function block is an input service interface for word input data (WORD) with event-based triggering. It serves as an interface between the control application and physical input devices and enables the querying of 16-bit data words.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - initializes the function block and configures the hardware parameters
- **REQ**: Service Request - triggers a query for the input data

Event Outputs

- **INITO**: Initialization Acknowledgement - confirms successful initialization
- **CNF**: Acknowledge of Requested Service Request - provides the requested input data
- **IND**: Indication from Resource - signals asynchronous state changes of the input data

Data Inputs

- **QI** (BOOL): Event Input Qualifier - controls the execution of service requests
- **PARAMS** (STRING): Service Parameters - configuration parameters for the hardware interface

Data Outputs

- **QO** (BOOL): Event Output Qualifier - indicates success or failure Operation at
- **STATUS** (STRING): Service status - detailed status information about the executed operation
- **IN** (WORD): Input data from the resource - the read 16-bit data

Adapter

- **eCONF** (eclipse4diac::io::eio::eGenAdapter): Configuration of event-based triggering - allows customization of the trigger behavior

Functionality

The eIW function block acts as an intermediary between the control application and physical input devices. During initialization (INIT), the hardware parameters are configured. Subsequently, input data can be selectively queried via REQ events. The block supports both synchronous queries (CNF) and asynchronous notifications for state changes (IND).

Technical Features

- Processes 16-bit word data (WORD data type)
- Supports event-based and polling-based query modes
- Provides detailed status feedback via the STATUS output

- Enables flexible hardware configuration via the PARAMS input
- Integrates an adapter interface for advanced trigger configuration

State Overview

The function block goes through the following states:

1. **Not Initialized**: Block is operational but not configured
2. **Initialized**: Hardware parameters are configured, block is operational
3. **Query Active**: Service request is being processed
4. **Data Available**: Input data is available and is being output

Application Scenarios

- Querying digital input groups (16-bit)
- Reading encoder values
- Monitoring status registers
- Acquiring sensor data words
- Interface to I/O modules with word access

⚖️ Comparison with Similar Devices Function Blocks

Compared to simple digital input blocks, eIW offers:

- Advanced 16-bit data processing
- Detailed status feedback
- Flexible configuration options
- Support for event-based and polling-based operating modes
- Adapter interface for extended functionality

Conclusion

The eIW function block provides a powerful and flexible interface for processing word input data in IEC 61499 control systems. Its combined support for synchronous queries and asynchronous notifications makes it particularly suitable for applications requiring both deterministic queries and time-critical state changes.

eIWconfig

• – ◦ • – ◦ • – ◦ •

Introduction

The eIWconfig function block serves as a service interface for configuring eIO instances. It allows you to set thresholds and gradients for industrial I/O operations.

Interface Structure

Event Inputs

- **CONF**: Configuration request - triggers the configuration of the eIO instance

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the configuration

Data Inputs

- **ST** (WORD): “Smaller than” - Lower threshold
- **BT** (WORD): “Bigger than” - Upper threshold
- **GRAD** (WORD): Gradient in percent - Steepness of the transitions

Data Outputs

- **STATUS** (WSTRING): Service status - feedback on the configuration process

Adapter

- **eIW**: Connection to the eIO instance (Type: eclipse4diac::io::eio::eGenAdapter)

Functionality

The function block receives via The CONF event is a configuration request along with the parameters ST, BT, and GRAD. These parameters are transmitted to the eIO instance via the eIW adapter. After successful configuration, the block confirms the process with the CNF event and provides status feedback via STATUS.

Conf event.

Technical Features

- Uses WORD data types for all numeric inputs
- STATUS output as WSTRING for detailed status information
- Adapter-based architecture for loose coupling to the eIO instance

State Overview

1. **Ready**: Waiting for CONF event
2. **Configuring**: Processing configuration parameters
3. **Acknowledging**: Sending CNF event with status information

Application Scenarios

- Configuration of I/O thresholds in automation systems
- Setting filter parameters for sensor signals
- Dynamic adjustment of limit values in control systems

⚖️ Comparison with Similar Blocks

Compared to simple I/O configuration blocks, eIWconfig offers extended functionality with gradient control and an adapter-based architecture for greater flexibility.

Conclusion

The eIWconfig function block provides a flexible and extensible solution for configuring eIO instances, distinguished by its adapter-based architecture and extensive parameterization options.

eIX

• – ◦ • – ◦ • – ◦ •

Introduction

The eIX function block is an input service interface for Boolean input data with event-based triggering. It serves as an interface between the control logic and physical input devices and enables the querying of digital input signals.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block with parameters
- **REQ**: Service Request - Triggers a query of the input signal

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms successful initialization
- **CNF**: Service Acknowledgement - Confirms the processed service request
- **IND**: Resource Indication - Signals a status change of the input

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/disables processing
- **PARAMS** (STRING): Service Parameters - Configuration parameters for the service

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Processing status
- **STATUS** (STRING): Service status - Error or status information
- **IN** (BOOL): Input data from the resource - Current value of the digital input

Adapter

- **eCONF**: Configuration of event-based triggering - Adapter for trigger configuration

Functionality

The eIX block acts as a service interface for digital inputs. During initialization (INIT), the service parameters are configured. Targeted queries of the input signal can be triggered via REQ events. The block returns the current input values via CNF and can report asynchronous status changes via IND.

Technical Features

- Event-based query mechanisms
- Separate initialization and operating modes
- String-based status feedback
- Adapter-based configuration of trigger logic
- Support for both requested and indexed operations

State Overview

1. **Not Initialized**: Block waits for INIT event
2. **Initialized**: Block is ready for operation and can process REQ events
3. **Active**: Processing service requests and providing feedback of input values
4. **Error**: In case of problems, STATUS is populated with error information

Application Scenarios

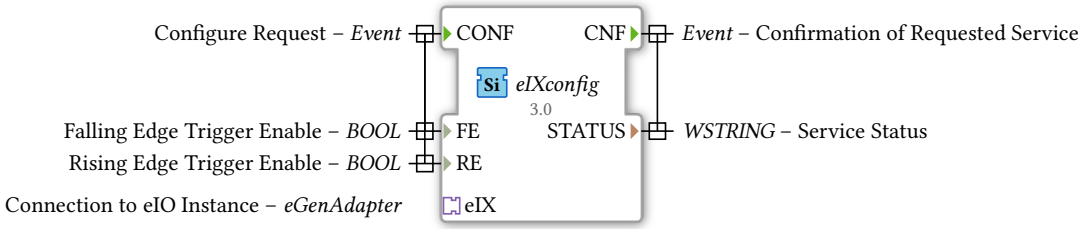
- Querying digital sensors (limit switches, proximity switches)
- Monitoring switching states
- Integration of pushbuttons and control elements
- Signal processing in automation systems
- Condition monitoring of machines and systems

⚖️ Comparison with Similar Blocks

Compared to simple digital input blocks, eIX offers extended functionality:

- Event-based instead of cyclic querying
- Detailed Status feedback
- Configurable trigger mechanisms
- Separate initialization and operating phases

Conclusion



The eIX function block represents a flexible and robust solution for integrating digital inputs into IEC 61499-based control systems. Its event-based architecture and comprehensive status feedback make it particularly suitable for applications requiring reliable and configurable input processing.

eIXconfig

• – ◦ • – ◦ • – ◦ •

Introduction

The eIXconfig function block serves as a Service Interface Function Block for configuring eIO instances. It allows you to set trigger properties for inputs and outputs and provides a connection to eIO instances via an adapter.

Interface Structure

Event Inputs

- **CONF**: Configuration Request - triggers the configuration of the eIO instance

Event Outputs

- **CNF**: Confirmation of the requested service - signals the completion of the configuration

Data Inputs

- **FE** (BOOL): Falling Edge Trigger Enable - enables edge triggering on a falling edge
- **RE** (BOOL): Rising Edge Trigger Enable - enables edge triggering on a rising edge

Data Outputs

- **STATUS** (WSTRING): Service Status - provides status information about the configuration process

Adapter

- **eIX**: Connection to the eIO instance - establishes communication with the eIO hardware

Functionality

The eIXconfig block receives a Configuration request. Along with the data inputs FE and RE, the trigger settings for the eIO instance are configured. After successful configuration, the CNF event is output with the corresponding status. Actual communication with the hardware takes place via the eIX adapter.

Technical Features

- Uses WSTRING for status outputs, enabling comprehensive status information
- Supports separate configuration of rising and falling edge detection
- Implemented as a Service Interface Function Block according to the IEC 61499-2 standard

State Transitions

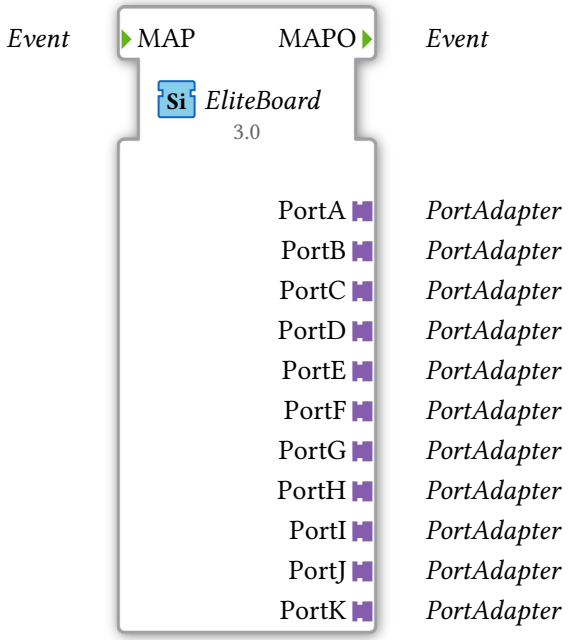
1. **Initialization State**: Block waits for a CONF event

2. **Configuration State**: Processes trigger settings and transmits them to the eIO instance
3. **Acknowledgement State**: Outputs CNF with status information

Application Scenarios

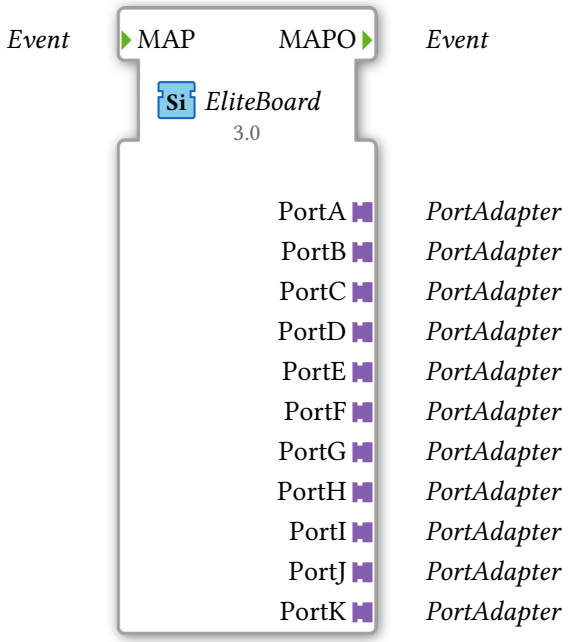
- Configuration of eIO hardware components in industrial control systems
- Setting trigger properties for digital inputs
- Integration into larger automation systems with eIO components

⚖️ Comparison with Similar Blocks



Compared to simple IO configuration blocks, eIXconfig offers specific eIO integration and advanced trigger configuration options. Using an adapter allows for a clean separation between functionality and hardware communication.

Conclusion



The eIXconfig function block represents a specialized solution for configuring eIO instances. Its clear separation of configuration logic and hardware communication, along with flexible trigger settings, makes it ideally suited for demanding industrial applications.

2.11.5.19 Eliteboard

eliteboard

EliteBoard

• – ◦ • – ◦ • – ◦ •

Introduction

The EliteBoard function block is a Service Interface Function Block Type that serves as an interface for the EliteBoard hardware. This block enables the connection and control of up to 11 different ports via standardized adapter interfaces.

Interface Structure

Event Inputs

- **MAP**: Initializes the mapping process for the configured ports

Event Outputs

- **MAPO**: Signals the successful completion of the mapping process

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

The function block has 11 adapter interfaces (plugs):

- **PortA** to **PortK**: Each of type `eclipse4diac::io::eliteboard::PortAdapter`

These adapters enable connection to various port interfaces of the EliteBoard hardware.

Functionality

Upon receiving the MAP event, the EliteBoard function block initializes the configured port adapters. After successful initialization of all connected ports, the MAPO event is triggered. Each port adapter (Port A to Port K) can be individually configured for specific input/output functions.

Technical Features

- Supports up to 11 independent port interfaces
- Uses standardized port adapter interfaces
- Simple initialization via a single event

- Robust error handling through centralized mapping

State Overview

1. **Initial State**: Waiting for MAP event
2. **Mapping State**: Initializing all configured port adapters
3. **Ready State**: All ports are initialized, MAPO event is triggered

Application Scenarios

- Control of EliteBoard hardware in industrial automation systems
- Connecting multiple input/output interfaces in embedded systems
- Integration into distributed control systems according to IEC 61499
- Hardware-level control tasks with modular port management

⚖️ Comparison with similar devices

Compared to simple I/O devices, EliteBoard offers structured management of multiple ports via standardized adapter interfaces. While simple I/O modules typically use direct data inputs/outputs, EliteBoard relies on an adapter-based architecture for improved modularity and reusability.

Conclusion

The EliteBoard function block provides a flexible and scalable solution for connecting EliteBoard hardware to 4diac-based control systems. By using standardized adapter interfaces and supporting multiple ports, it enables a modular and maintainable system architecture for industrial automation applications.

Introduction

The Port Function Block serves as a Service Interface Function Block for configuring and managing digital inputs/outputs on an EliteBoard system. It enables the mapping of pin names to physical ports via an adapter mechanism.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

- **Pin0** (STRING): Name of Pin 0
- **Pin1** (STRING): Name of Pin 1
- **Pin2** (STRING): Name of Pin 2
- **Pin3** (STRING): Name of Pin 3
- **Pin4** (STRING): Name of Pin 4
- **Pin5** (STRING): Name of Pin 5
- **Pin6** (STRING): Name of Pin 6
- **Pin7** (STRING): Name of Pin 7
- **Pin8** (STRING): Name of Pin 8
- **Pin9** (STRING): Name of Pin 9
- **Pin10** (STRING): Name Pin 10
- **Pin 11** (STRING): Name of Pin 11
- **Pin 12** (STRING): Name of Pin 12
- **Pin 13** (STRING): Name of Pin 13
- **Pin 14** (STRING): Name of Pin 14
- **Pin 15** (STRING): Name of Pin 15

Data Outputs

No data outputs available

Adapters

- **PortInAdapter** (eclipse4diac::io::eliteboard::PortAdapter): Socket adapter for communication with the port subsystem

Functionality

The Port FB serves as a configuration interface for up to 16 digital pins. Individual pin names can be assigned via the STRING inputs, which are then passed on to the underlying system via the PortAdapter. The function block itself does not perform any direct input/output operations, but merely provides the configuration parameters.

Technical Features

- Supports configuration of 16 digital pins
- Uses the STRING data type for pin names
- Implemented as a Service Interface Function Block
- Uses the adapter pattern for hardware abstraction
- Part of the eclipse4diac::io::eliteboard package

State Overview

Since this is a pure configuration block without event handling, the Port FB has no explicit states. The configuration is set statically via the data inputs.

Application Scenarios

- Configuration of digital inputs/outputs on EliteBoard systems
- Abstraction of hardware pins using logical names
- Integration into larger control systems with unified pin management
- Reusable pin configurations across various applications

⚖️ Comparison with similar components

Compared to direct GPIO components, the Port FB offers a higher level of abstraction by using logical pin names instead of direct hardware addressing. It primarily serves configuration purposes, while other components typically provide the actual input/output functionality.

Conclusion

The Port Function Block provides an elegant solution for configuration-based pin management in Eclipse 4diac systems. By using adapters, it enables a clear separation between configuration and hardware access, improving the maintainability and portability of control applications.

2.11.5.20 embrick

EBMaster

• – ◦ • – ◦ • – ◦ •

Introduction

The EBMaster function block is a Service Interface Function Block for communication with EtherBrick modules via SPI (Serial Peripheral Interface). It serves as the master component for controlling and configuring SPI bus communication with connected slave modules.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the SPI bus and configures the communication parameters

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms successful completion of initialization
- **IND**: Resource Indication - Signals status changes or events from the connected modules

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/Disables the function block
- **BusInterface** (UINT): ID of the SPI interface (initial value: 1)
- **BusSelectPin** (UINT): SPI Slave Select Pin (initial value: 49)
- **BusInitSpeed** (UDINT): SPI speed during initialization in Hz (initial value: 300000)
- **BusLoopSpeed** (UDINT): SPI speed during operation in Hz (initial value: 700000)
- **SlaveUpdateInterval** (UINT): Global update interval of the slave modules in Hz (initial value: 25)

Data Outputs

- **QO** (BOOL): Event Output Qualifier - status of the event output
- **STATUS** (WSTRING): Service Status - detailed status information

Adapters

- **BusAdapterOut**: Adapter for communication with the EtherBrick bus system

Functionality

The EBMaster manages SPI communication as the master component. During initialization (INIT event), it configures the SPI interface with the specified parameters. During operation, it controls the data transmission to the connected slave modules at the configured update interval. The block allows for different speeds during the initialization and operation phases.

Technical Features

- Support for various SPI speeds for initialization and operation
- Configurable slave select pins
- Adjustable global update interval for slave modules
- WSTRING-based status feedback for detailed fault diagnosis

State Overview

The function block goes through the following states:

1. **Not Initialized**: Waits for INIT event
2. **Initialization**: Configures SPI parameters upon INIT event
3. **Ready**: Sends INITO upon successful initialization
4. **Active**: Communicates with slaves according to the configured interval
5. **Fault**: Sends an IND event with STATUS information in case of problems

Application Scenarios

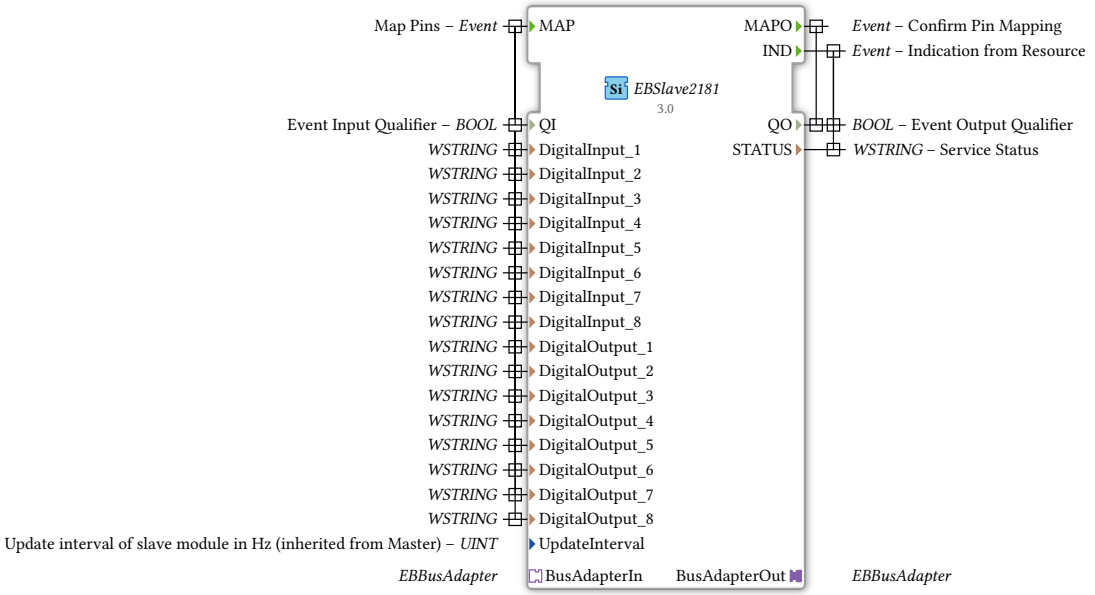
- Control of EtherBrick I/O modules in automation systems
- SPI-based communication in embedded systems

- Industrial controllers with modular I/O expansions
- Real-time data acquisition with configurable Update Rates

⚖️ Comparison with Similar Blocks

Compared to generic SPI master blocks, EBMaster offers specific optimizations for EtherBrick modules, including pre-configured parameter values and specialized bus adapter interfaces.

Conclusion



The EBMaster function block provides a robust and configurable solution for SPI master communication with EtherBrick modules. By separating initialization and operating speeds and offering a configurable update interval, it enables optimal adaptation to various application requirements.

EBSlave2181

• – ◦ • – ◦ • – ◦ •

Introduction

The EBSlave2181 is a Service Interface Function Block for communication with EtherBrick slave modules. This function block enables the configuration and monitoring of the digital inputs and outputs of an EtherBrick slave module and serves as an interface between the control logic and the physical fieldbus communication.

Interface Structure

Event Inputs

- **MAP**: Used to configure pin assignments. Triggers the assignment of digital inputs and outputs.

Event Outputs

- **MAPO**: Confirms successful pin assignment.
- **IND**: Indicates status changes or errors from the slave module.

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/disables the function block
- **DigitalInput_1** to **DigitalInput_8** (WSTRING): Configuration of digital inputs 1-8
- **DigitalOutput_1** to **DigitalOutput_8** (WSTRING): Configuration of digital outputs 1-8
- **UpdateInterval** (UINT): Update interval of the slave module in Hz (inherited from the master)

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Status of the function block
- **STATUS** (WSTRING): Service Status - Contains status information or error messages

Adapters

- **BusAdapterOut** (Plug): Outgoing bus adapter for EtherBrick communication
- **BusAdapterIn** (Socket): Incoming bus adapter for EtherBrick communication

Functionality

The The EBSlave2181 acts as an intermediary between the IEC 61499 control logic and an EtherBrick slave module. Upon receiving the MAP event, the configured digital inputs and outputs are assigned to the slave module. The MAPO event confirms the successful completion of this assignment. The IND event signals status changes or error states of the slave module.

Technical Features

- Supports 8 digital inputs and 8 digital outputs
- Uses WSTRING data type for pin configuration
- Enables configurable update intervals
- Integrates into the EtherBrick architecture via standardized bus adapters
- Implements qualifier patterns (QI/QO) for reliable status management

State Overview

The function block has the following operating states:

- **Inactive**: QI = FALSE, function block does not respond to events
- **Configuring**: Processing the MAP event and assigning pins
- **Active**: Successfully configured, waiting for IND events from the slave
- **Error**: STATUS contains error information, QO can be FALSE

Application Scenarios

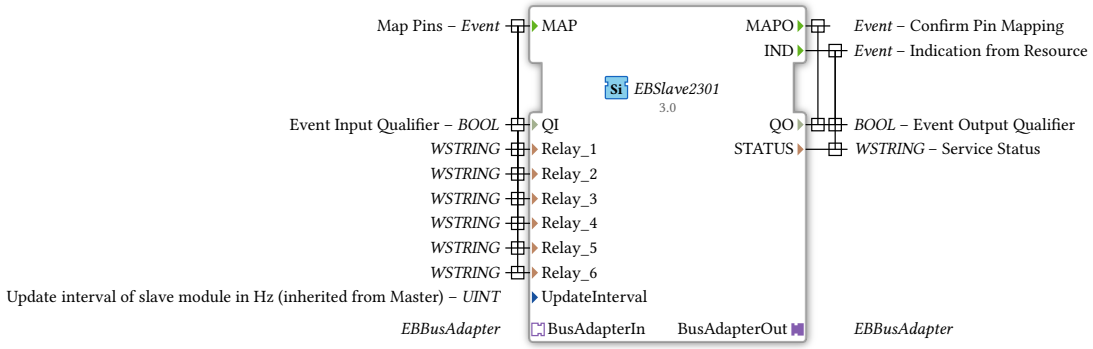
- Connecting EtherBrick slave modules in distributed automation systems
- Configuring digital I/O modules in industrial plants
- Integration into control systems with EtherBrick Fieldbus Communication

Real-time Monitoring and Diagnostics of Slave Modules

⚖️ Comparison with Similar Components

Compared to generic I/O function blocks, the EBSlave2181 offers specific integration for EtherBrick systems with predefined bus adapter interfaces. It specializes in the configuration and monitoring of slave modules and provides direct support for EtherBrick communication protocols.

Conclusion



The EBSlave2181 is a specialized service interface function block that provides a reliable and standardized interface for integrating EtherBrick slave modules into IEC 61499-based control systems. Its structured interface and clear state management make it a robust solution for industrial fieldbus communication.

EBSlave2301

• – ◦ • – ◦ • – ◦ •

Introduction

The EBSlave2301 is a Service Interface Function Block for communication with an EtherBrick slave module. This function block serves as an interface for configuring and controlling up to six relay outputs via an EtherBrick bus system.

Interface Structure

Event Inputs

- **MAP**: Triggered to configure the pin assignments. Accompanied by the data variables Relay_1 to Relay_6 and QI.

Event Outputs

- **MAPO**: Confirms successful pin assignment. Outputs with QO.
- **IND**: Message from the resource interface. Outputs with QO and STATUS.

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/disables the function block
- **Relay_1** to **Relay_6** (WSTRING): Relay pin configuration
- **UpdateInterval** (UINT): Slave module update interval in Hz (inherited from the master)

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Operation status
- **STATUS** (WSTRING): Service status information

Adapters

- **BusAdapterOut** (Plug): Outgoing bus adapter of type EBBusAdapter
- **BusAdapterIn** (Socket): Incoming bus adapter of type EBBusAdapter

Functionality

The EBSlave2301 allows the configuration of up to six relay outputs via the MAP event. When activated by QI, the relay parameters are transmitted to the EtherBrick system via the bus adapters. The MAPO event confirms successful configuration, while IND events provide status information from the resource interface.

Technical Features

- Supports WSTRING data types for relay configuration
- Uses an adapter-based bus system for communication
- UpdateInterval is inherited from the master system
- Provides qualified event control via QI and QO

State Overview

The function block toggles between the following states:

- Inactive: QI = FALSE
- Configuration mode: On MAP event with QI = TRUE
- Ready for operation: After successful MAPO acknowledgment
- Fault state: On IND event with status information

Application Scenarios

- Control of relay-based actuators in automation systems
- Integration into EtherBrick-based I/O systems
- Distributed control system with master-slave architecture

- Applications with configurable relay assignments

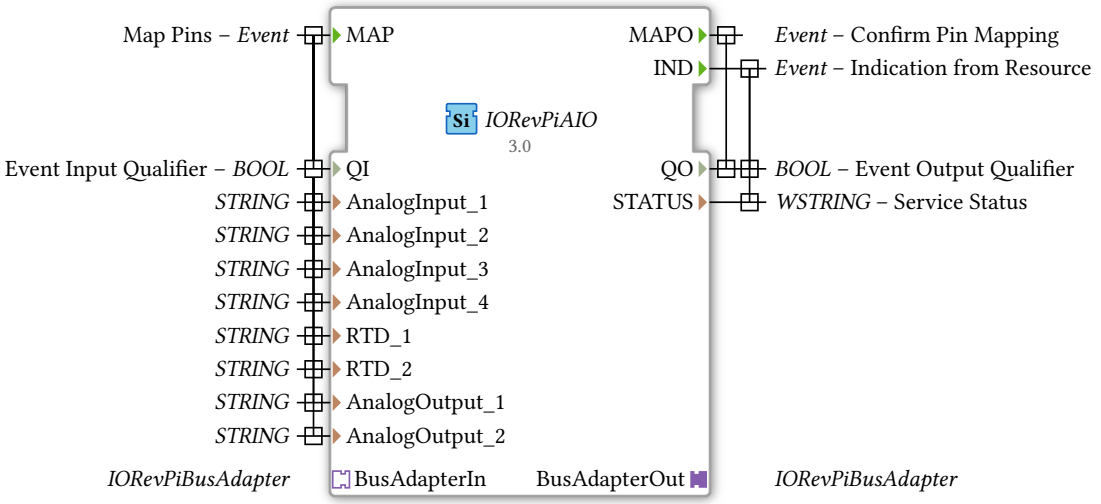
⚖️ Comparison with Similar Devices

Compared to simple digital output devices, the EBSlave2301 offers:

- Configurable pin assignments for Runtime
- Adapter-based bus communication
- Qualified event control
- Status feedback from the resource interface

Conclusion

The EBSlave2301 is a specialized function block for the flexible control of relay outputs in EtherBrick systems. Its configurable interfaces and adapter-based architecture make it particularly suitable for demanding automation applications with dynamic I/O configurations.



2.11.5.21 revpi

🔌 IORevPiAIO

• – ◦ • – ◦ • – ◦ •

Introduction

The IORevPiAIO function block provides an interface for the analog I/O module of the Revolution Pi from KUNBUS GmbH. This module enables the control and reading of analog inputs and outputs, as well as RTD (Resistance Temperature Detector) sensors, via the Revolution Pi system.

Interface Structure

Event Inputs

- **MAP**: Starts the pin mapping for all configured analog inputs and outputs

Event Outputs

- **MAPO**: Confirms successful pin mapping
- **IND**: Displays status information from the resource manager

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/Disables the function block
- **AnalogInput_1** (STRING): Configuration for analog input 1
- **AnalogInput_2** (STRING): Configuration for analog input 2
- **AnalogInput_3** (STRING): Configuration for analog input 3
- **AnalogInput_4** (STRING): Configuration for analog input 4
- **RTD_1** (STRING): Configuration for RTD sensor 1
- **RTD_2** (STRING): Configuration for RTD Sensor 2

- **AnalogOutput_1** (STRING): Configuration for Analog Output 1
- **AnalogOutput_2** (STRING): Configuration for Analog Output 2

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Operation Status
- **STATUS** (WSTRING): Detailed Service Status Information

Adapters

- **BusAdapterIn** (Socket): Input adapter for Revolution Pi bus communication
- **BusAdapterOut** (Plug): Output adapter for Revolution Pi bus communication

Functionality

The IORevPiAIO function block manages communication with the Revolution Pi Analog I/O module. Upon receiving the MAP event, all configured analog inputs and outputs, as well as RTD sensors, are initialized and assigned according to the string parameters. The block uses dedicated bus adapters for communication with the Revolution Pi hardware.

Technical Features

- Supports up to 4 analog inputs
- Supports up to 2 analog outputs
- Integrated RTD sensor support (2 channels)
- String-based pin mapping configuration
- Bus adapter architecture for low-level communication

State Overview

The function block has the following operating states:

- **Inactive**: QI = FALSE, no operations
- **Ready**: QI = TRUE, waiting for MAP event
- **Mapping**: Processes pin mapping after MAP event
- **Active**: Successfully configured, ready for data operations

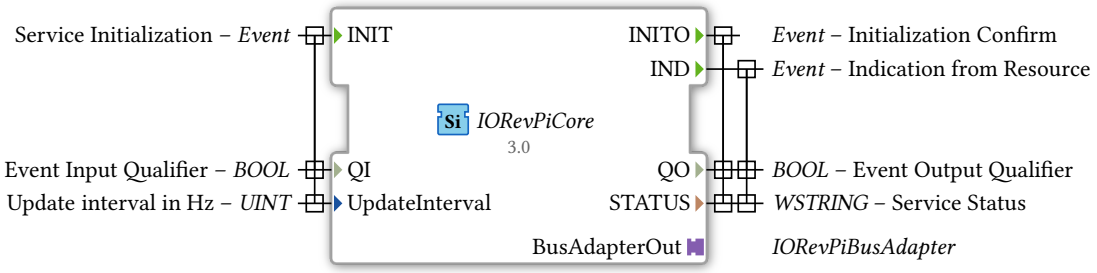
Application Scenarios

- Industrial process automation with analog sensors
- Temperature measurement with RTD sensors
- Analog signal processing in control systems
- Revolution Pi-based automation solutions

⚖️ Comparison with Similar Blocks

Compared to generic analog I/O blocks, IORevPiAIO offers specific integration for Revolution Pi hardware and additionally supports RTD temperature sensors. The bus adapter architecture enables efficient communication with the Revolution Pi system.

Conclusion



The IORevPiAIO function block offers a reliable and specialized interface for analog I/O operations on Revolution Pi systems. With its integrated support for RTD sensors and flexible configuration via string parameters, it is particularly well-suited for industrial automation applications with analog measurement and control tasks.

🔌 IORevPiCore

• – ◦ • – ◦ • – ◦ •

Introduction

The IORevPiCore function block serves as the core module for the Revolution Pi hardware from KUNBUS GmbH. It enables basic communication and configuration of the Revolution Pi I/O modules within a 4diac-based control application.

Interface Structure

Event Inputs

- **INIT**: Initialization event to activate the function block

Event Outputs

- **INITO**: Confirmation of successful initialization
- **IND**: Indication event for status changes of resources

Data Inputs

- **QI** (BOOL): Event input qualifier
- **UpdateInterval** (UINT): Update interval in Hz (default: 25)

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (WSTRING): Service status as a Unicode string

Adapters

- **BusAdapterOut**: Output adapter for Revolution Pi bus communication (Type: eclipse4diac::io::revpi::IORevPiBusAdapter)

Functionality

The The IORevPiCore block initiates communication with the Revolution Pi hardware upon receiving the INIT event. After successful initialization, INITO is output with the corresponding status. The block continuously monitors the hardware state and outputs IND events when changes occur. The UpdateInterval determines the sampling rate for hardware monitoring.

Technical Features

- Standard update interval of 25 Hz
- Unicode string output for status information
- Integration via a specific bus adapter for Revolution Pi hardware
- Automatic hardware detection and initialization

State Overview

1. **Inactive**: Block awaits INIT event
2. **Initialization**: Processing configuration parameters
3. **Active**: Monitoring Revolution Pi hardware and outputting IND events upon status changes

Application Scenarios

- Controlling Revolution Pi I/O modules in industrial automation solutions
- Integrating Revolution Pi hardware into 4diac-based control systems
- Monitoring and diagnostics of Revolution Pi components

⚖️ Comparison with Similar Blocks

Compared to generic I/O blocks, IORevPiCore offers specific optimizations for the Revolution Pi hardware platform, including specialized bus communication and hardware-level configuration parameters.

Conclusion

The IORevPiCore function block provides a reliable and easy-to-configure interface for integrating Revolution Pi hardware into 4diac-based automation solutions. Its standardized interface and flexible configuration options enable efficient integration of industrial I/O components.

🔌 IORevPiDIO

• – ◦ • – ◦ • – ◦ •

Introduction

The IORevPiDIO function block is a digital input/output module for Revolution Pi systems from KUNBUS GmbH. It enables the control and monitoring of digital inputs and outputs via the Revolution Pi system and serves as an interface between the 4diac IDE and the Revolution Pi hardware.

Interface Structure

Event Inputs

- **MAP**: Event for mapping the pins with all Digital Input and Digital Output data variables, as well as QI

Event Outputs

- **MAPO**: Confirmation event for successful pin mapping with QO
- **IND**: Indication event from the resource with QO and STATUS

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **DigitalInput_1** to **DigitalInput_14** (STRING): Configuration of digital inputs 1-14
- **DigitalOutput_1** to **DigitalOutput_14** (STRING): Configuration of digital outputs 1-14

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (WSTRING): Service Status

Adapter

- **BusAdapterOut** (Plug): Outgoing bus adapter of type IORevPiBusAdapter
- **BusAdapterIn** (Socket): Incoming bus adapter of type IORevPiBusAdapter

Functionality

This function block enables the configuration and control of up to 14 digital inputs and 14 digital outputs of a Revolution Pi system. The MAP event transmits the pin configurations, which are confirmed with MAPO. The IND output signals status changes and error states. Communication with the hardware occurs via the IORevPiBusAdapter interface.

Technical Features

- Supports up to 14 digital inputs and 14 digital outputs
- Uses STRING type for pin configuration
- Integrated bus adapter for Revolution Pi communication
- Provides comprehensive status feedback via WSTRING

State Transitions

1. **Initialization**: Waits for a MAP event with configuration data
2. **Configuration**: Processes pin assignments and confirms via MAPO
3. **Operation**: Monitors digital inputs/outputs and signals via IND
4. **Fault Handling**: Provides status messages in case of communication problems with the hardware

Application Scenarios

- Industrial automation with Revolution Pi
- Digital signal processing in control systems
- Connecting sensors and actuators to 4diac-based controllers
- Prototyping and development of IoT solutions

⚖️ Comparison with Similar Devices

Compared to other I/O devices, IORevPiDIO offers specific support for Revolution Pi hardware with a large number of configurable Inputs/Outputs. The integrated bus adapter enables direct communication with the Revolution Pi platform.

Conclusion

The IORevPiDIO function block provides a powerful interface for digital inputs/outputs in Revolution Pi systems and allows for easy integration into 4diac-based automation solutions. Its extensive configuration options and reliable status feedback make it a robust solution for industrial applications.

2.11.5.22 wago

Wago1405_6

• – ◦ • – ◦ • – ◦ •

Introduction

The Wago1405_6 is a Service Interface Function Block for connecting to Wago bus systems. This function block serves as an interface for configuring and controlling the digital inputs of a Wago I/O system and enables communication via special bus adapters.

Interface Structure

Event Inputs

- **MAP**: Map Pins - Used to configure pin assignments for digital inputs

Event Outputs

- **MAPO**: Confirm Pin Mapping - Confirms successful pin mapping
- **IND**: Indication from Resource - Message from the resource interface

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - Qualifies the event inputs
- **DigitalInput_1** to **DigitalInput_16**: Pin Configuration (STRING) - Assigns digital inputs 1-16

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - Qualifies the event outputs
- **STATUS**: Service Status (WSTRING) - Status information of the service interface

Adapters

- **BusAdapterOut**: Outgoing bus adapter (plug) of type eclipse4diac::io::wago::WagoBusAdapter
- **BusAdapterIn**: Incoming bus adapter (socket) of type eclipse4diac::io::wago::WagoBusAdapter

Functionality

The Wago1405_6 function block allows the configuration of 16 digital inputs via the MAP event. When the MAP event is activated, the pin assignments are configured using the DigitalInput_x parameters. Successful configuration is confirmed via the MAPO event. The IND event is used for asynchronous communication with the underlying resource interface and provides status information.

Technical Features

- Supports 16 digital inputs
- Uses STRING type for pin configuration
- Implements bidirectional bus adapter communication
- Provides comprehensive status feedback via WSTRING

State Overview

The function block operates with the following main states:

1. **Inactive**: Waiting for MAP event
2. **Configuration**: Processing pin assignments
3. **Acknowledge**: Sending MAPO acknowledgement
4. **Operation**: Asynchronous status messages via IND

Application Scenarios

- Connecting Wago 750-1405/750-1406 I/O systems
- Configuring digital inputs in automation systems
- Integration into distributed control systems with 4diac
- Industrial I/O configuration and monitoring

⚖️ Comparison with Similar Blocks

Compared to generic I/O function blocks, the Wago1405_6 offers specific Adaptations for Wago bus systems and more extensive configuration options for digital inputs. The integration of the bus adapters enables seamless integration into Wago-specific communication architectures.

Conclusion

The Wago1405_6 function block represents a specialized solution for connecting and configuring Wago I/O systems. With its extensive configuration options for 16 digital inputs and the integrated bus adapter interface, it offers an efficient solution for industrial automation applications using Wago components.

Wago1504_5

• – ◦ • – ◦ • – ◦ •

Introduction

The Wago1504_5 is a Service Interface Function Block for controlling the digital outputs of a Wago 750-1504/005-000 module. This function block enables the configuration and control of 16 digital outputs via a bus adapter interface.

Interface Structure

Event Inputs

- **MAP**: Map Pins - Initializes the pin mapping of the digital outputs

Event Outputs

- **MAPO**: Confirm Pin Mapping - Confirms successful pin mapping
- **IND**: Indication from Resource - Message from the resource adapter

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - Qualifies the event inputs
- **DigitalOutput_1** to **DigitalOutput_16** (STRING) - Configuration strings for the respective digital outputs

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - Qualifies the event outputs
- **STATUS**: Service Status (WSTRING) - Service status information

Adapters

- **BusAdapterOut** (Plug): Outgoing WagoBusAdapter
- **BusAdapterIn** (Socket): Incoming WagoBusAdapter

Functionality

The Wago1504_5 function block serves as an interface between the 4diac controller and the Wago 750-1504/005-000 I/O module. Upon receiving the MAP event, the 16 digital outputs are assigned according to the transmitted string configuration. Successful assignment is confirmed by the MAPO event. The IND output is used to provide feedback of status information from the resource adapter.

Technical Features

- Supports 16 independent digital outputs
- Uses string-based configuration for pin assignment
- Implements bus adapter communication for connection to Wago hardware

- Provides status feedback via WSTRING data type

State Overview

The function block cycles through the following states:

1. **Inactive**: Waiting for MAP event
2. **Mapping**: Processing pin assignment
3. **Acknowledge**: Sends MAPO upon successful assignment
4. **Ready**: Ready for IND messages

Application Scenarios

- Control of relays and actuators in automation systems
- Digital signal output in process controllers
- Integration of Wago 750-1504/005-000 modules into 4diac-based controllers
- Industrial automation with distributed I/O systems

⚖️ **Comparison with Similar Function Blocks**

Compared to generic digital The Wago1504_5 output block offers:

- Specific adaptation for Wago hardware
- Extended configuration options via string parameters
- Integrated bus adapter communication
- Status feedback with detailed information

Conclusion

The Wago1504_5 function block provides a reliable and specialized interface for controlling Wago 750-1504/005-000 digital output modules. Its structured event control and comprehensive status feedback make it particularly suitable for robust industrial automation solutions.

Wago1506

• – ◦ • – ◦ • – ◦ •

Introduction

The Wago1506 is a Service Interface Function Block for controlling Wago 750-1506 I/O modules. This function block enables the configuration and control of digital inputs and outputs via a bus adapter and serves as an interface between the control logic and the physical hardware.

Interface Structure

Event Inputs

- **MAP**: Used to configure the pin assignment. Triggers the mapping of the digital inputs and outputs.

Event Outputs

- **MAPO**: Confirms successful pin mapping.
- **IND**: Displays status information from the resource.

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/disables the function block
- **DigitalInput_1** to **DigitalInput_8** (STRING): Configuration of digital inputs 1-8
- **DigitalOutput_1** to **DigitalOutput_8** (STRING): Configuration of digital outputs 1-8

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Operation status
- **STATUS** (WSTRING): Detailed service status information

Adapters

- **BusAdapterOut** (Plug): Outgoing bus adapter for Wago communication
- **BusAdapterIn** (Socket): Incoming bus adapter for Wago communication

Functionality

The Wago1506 FB manages communication with a Wago 750-1506 I/O module. Upon receiving the MAP event, the configured pin assignments are passed to the bus adapter interface. The function block monitors the hardware status and outputs IND events with corresponding status information when changes occur.

Technical Features

- Supports 8 digital inputs and 8 digital outputs
- Uses STRING types for pin configuration, enabling flexible addressing
- Integrates specific Wago bus adapters for reliable hardware communication
- Provides comprehensive status feedback via WSTRING

Status Overview

1. **Inactive**: QI = FALSE, FB awaits activation
2. **Configured**: After a MAP event with successful pin assignment
3. **Active**: QI = TRUE, FB communicates with hardware
4. **Error**: In case of communication problems or invalid configurations

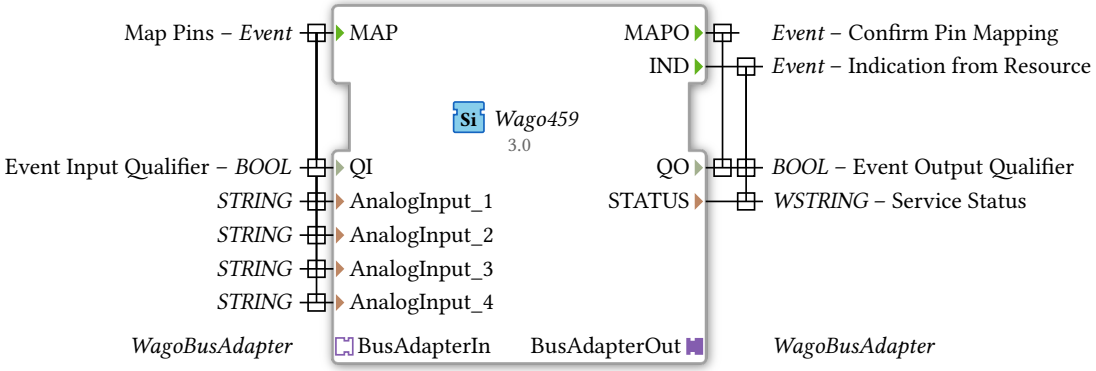
Application Scenarios

- Control of Wago 750-1506 digital I/O modules
- Industrial automation applications
- Machine control with digital signals
- Process automation with distributed I/Os

⚖️ Comparison with Similar Function Blocks

Compared to generic I/O function blocks, the Wago1506 offers specific optimizations for Wago hardware, specifically for the 750-1506 module. The integration of dedicated bus adapters ensures more reliable communication than universal solutions.

Conclusion



The Wago1506 function block represents a robust and specialized solution for controlling Wago 750-1506 I/O modules. Its clear separation of configuration (MAP) and operation (IND), along with comprehensive status feedback, makes it ideally suited for industrial automation projects with high reliability requirements.

Wago459

• – ◦ • – ◦ • – ◦ •

Introduction

The Wago459 is a Service Interface Function Block for connecting Wago-750-459 analog input modules in 4diac systems. This function block enables the configuration and monitoring of up to four analog input channels and establishes communication with the Wago bus system.

Interface Structure

Event Inputs

- **MAP**: Initiates the pin assignment for the analog inputs. Linked to the data variables AnalogInput_1 to AnalogInput_4 and QI.

Event Outputs

- **MAPO**: Confirms successful pin assignment. Linked to QO.
- **IND**: Provides status information from the resource manager. Linked to QO and STATUS.

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Controls the activation of the function block
- **AnalogInput_1** (STRING): Configuration for analog input 1
- **AnalogInput_2** (STRING): Configuration for analog input 2
- **AnalogInput_3** (STRING): Configuration for analog input 3

- **AnalogInput_4** (STRING): Configuration for analog input 4

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Indicates the operating status
- **STATUS** (WSTRING): Detailed status information of the service

Adapters

- **BusAdapterOut** (Plug): Outgoing bus adapter connection of type WagoBusAdapter
- **BusAdapterIn** (Socket): Incoming bus adapter connection of type WagoBusAdapter

Functionality

The Wago459 function block serves as Interface between the 4diac controller and the Wago 750-459 analog input module. Upon receiving the MAP event, the configured pin assignments (AnalogInput_1 to AnalogInput_4) are transmitted to the bus system. The block confirms successful assignments via MAPO and continuously provides status information via IND events.

Technical Features

- Supports up to four analog input channels
- Uses STRING data types for flexible pin configuration
- Provides comprehensive status feedback via WSTRING
- Implements a bidirectional adapter system for bus communication
- Includes qualifier variables (QI/QO) for reliable state management

State Overview

The function block has the following operating states:

- Inactive: Waits for a MAP event with QI enabled
- Configuration: Processes pin assignments after a MAP event
- Operational: Continuously monitors the module status and sends IND events
- Error: In case of problems, STATUS is populated with error information

Application Scenarios

- Connecting Wago 750-459 analog input modules in automation systems
- Acquiring data from analog sensors (0-10V, 0-20mA, 4-20mA)
- Process monitoring in industrial control systems
- Integration into distributed systems Peripheral Systems with Wago Bus Architecture

⚖️ Comparison with Similar Modules

Compared to generic I/O function blocks, Wago459 offers:

- Specific optimization for Wago-750-459 hardware
- Pre-configured adapters for Wago bus systems
- Direct support for all four channels of the module
- Integrated status monitoring and error handling

Conclusion

The Wago459 function block represents a reliable and specialized solution for integrating Wago-750-459 analog input modules into 4diac-based control systems. Its clear interface definition and comprehensive status feedback enable efficient implementation of analog measurement processing in industrial automation projects.

WagoMaster

- – ◦ • – ◦ • – ◦ •

Introduction

The WagoMaster is a Service Interface Function Block for controlling and monitoring Wago bus systems. This block serves as the master component for communication with Wago I/O systems and enables the initialization and management of the bus connection.

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- Linked to: QI, UpdateInterval

Event Outputs

- **INITO**: Initialization Confirmation
- Linked to: QO, STATUS
- **IND**: Indication Event
- Linked to: STATUS, QO

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Controls service activation
- **UpdateInterval** (UINT): Defines the update interval for bus communication

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Displays the service execution status
- **STATUS** (WSTRING): Service Status - Contains status information and error messages

Adapters

- **BusAdapterOut**: WagoBusAdapter - Establishes the connection to the Wago bus system

Functionality

The WagoMaster initializes and manages communication with Wago bus systems. Upon activation via the INIT event, the service is started, and bus communication is performed periodically according to the defined UpdateInterval. The function block reports successful initialization via INITO and continuously provides status information via IND events.

Technical Features

- Supports WSTRING for detailed status messages
- Configurable update interval for flexible adaptation to various application requirements
- Integrated qualifier variables (QI/QO) for reliable service control
- Specialized WagoBusAdapter for optimized bus communication

State Overview

The function block goes through the following states:

1. **Inactive**: Before initialization
2. **Initialization**: Upon INIT event with QI=TRUE
3. **Active**: After successful initialization (QO=TRUE)
4. **Error**: In case of communication problems (STATUS with error message)

Application Scenarios

- Control of Wago 750 series I/O modules

- Integration into automation systems with Wago controllers
- Monitoring and diagnostics of Wago bus networks
- Industry 4.0 applications with distributed Wago I/O systems

⚖️ Comparison with Similar Function Blocks

Compared to generic The WagoMaster bus master module offers specific optimizations for Wago bus systems and integrated status diagnostics via WSTRING. Its specialized adapter interface enables more efficient communication than universal bus adapters.

Conclusion

The WagoMaster is a reliable and specialized module for integrating Wago bus systems into 4diac-based control systems. Its configurable parameters and detailed status feedback make it particularly suitable for demanding industrial automation applications.

Esp32EthernetKitIO

• – ◦ • – ◦ • – ◦ •

Introduction

The Esp32EthernetKitIO function block serves as a template for modular input/output operations with the Esp32EthernetKit board. This block enables the control and monitoring of various hardware components of the board via a standardized interface.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - triggers the initialization process of the function block

Event Outputs

- **INITO**: Initialization Confirmation - signals successful completion of initialization

Data Inputs

- **QI** (BOOL): Event Input Qualifier - controls the execution of the function block
- **LED0** (STRING): Configuration for LED0
- **SW0** (STRING): Configuration for Switch SW0
- **ADC_CH_0** (STRING): Configuration for Analog-to-Digital Converter Channel 0
- **PWM** (STRING): Configuration for Pulse Width Modulation
- **UpdateInterval** (TIME): Update interval with a default value of 40 ms

Data Outputs

- **QO** (BOOL): Event Output Qualifier - status of the function block execution
- **STATUS** (STRING): Service status - provides detailed status information

Adapter

No adapter interfaces available.

Functionality

The Esp32EthernetKitIO chip initializes and manages the hardware components of the Esp32EthernetKit board. Upon receiving the INIT event, the configured input/output components (LEDs, switches, ADC, PWM) are set up according to the passed string parameters. The update interval determines how frequently the input/output states are updated.

Technical Features

- Uses string parameters for flexible configuration of hardware components
- Supports mixed signal types (digital, analog, PWM)
- Provides a configurable update interval for real-time applications
- Implemented in the Zephyr RTOS framework

State Transitions

1. **Initialization State**: Waits for an INIT event
2. **Activation State**: Processes INIT with configuration parameters
3. **Operating State**: Performs continuous I/O operations
4. **Status Message**: Sends INITO with status information

Application Scenarios

- Control of lighting systems with LEDs
- Capture of user input via pushbuttons/switches
- Measurement of analog sensor data via ADC
- Control of motors or actuators using PWM
- IoT devices with the ESP32 Ethernet Kit board

⚖️ Comparison with Similar Building Blocks

Compared to simple I/O blocks, it offers Esp32EthernetKitIO is an integrated solution for the specific hardware board, supporting various signal types and configurable update intervals.

Conclusion

The Esp32EthernetKitIO function block provides a flexible and powerful solution for controlling Esp32EthernetKit boards in 4diac-based control systems. Its modular configuration via string parameters enables versatile use in various industrial and IoT applications.

ZephyrIO

• – ◦ • – ◦ • – ◦ •

Introduction

The ZephyrIO function block serves as a template for modular input/output functionality with boards that use the Zephyr operating system. This block enables the initialization and configuration of I/O services in distributed automation systems.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- Linked to: QI, UpdateInterval

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Controls the execution of the initialization process
- **UpdateInterval** (TIME): Update interval for the service (default: T#40ms)

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Displays the initialization status
- **STATUS** (STRING): Service status information

Adapters

No adapter interfaces available.

Functionality

The ZephyrIO function block initializes I/O services for Zephyr-based hardware. Upon receiving the INIT event, the service is started with the configured update interval. After successful initialization, the INITO event is output with corresponding status information.

Technical Features

- Specifically optimized for Zephyr RTOS
- Configurable update interval for periodic operations
- Standard update interval of 40 milliseconds
- Status feedback via STRING variable

Status Overview

1. **Not Initialized**: Waiting for INIT event
2. **Initialization in progress**: Processing INIT with QI=true
3. **Initialized**: Sending INITO with status information

Application Scenarios

- Integration of Zephyr-based I/O boards into 4diac systems
- Modular I/O extensions for embedded systems
- Hardware-level real-time control with Zephyr RTOS

⚖️ Comparison with similar components

Compared to generic I/O components, ZephyrIO offers specific optimizations for the Zephyr operating system and enables seamless integration of Zephyr-based hardware into 4diac environments.

Conclusion

The ZephyrIO function block represents a specialized solution for integrating Zephyr-based I/O components into IEC 61499 systems and offers a standardized interface for modular hardware extensions.

2.11.6.2 CLIENT_0

• – ◦ • – ◦ • – ◦ •

Introduction

The CLIENT_0 function block is used to communicate with a SERVER_0 block via a network connection. It enables the establishment and closure of connections. Unlike CLIENT_1, there is no explicit data exchange via data inputs/outputs; synchronization occurs primarily through events.

•

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE)
- **REQ**: Requests interaction with the server

Event Outputs

- **INITO**: Confirms that a new connection has been established (QI = TRUE) or that a connection has been closed (QI = FALSE)
- **CNF**: Confirms that the request has been executed

Data Inputs

- **QI** (BOOL): Controls the connection status (TRUE = open connection, FALSE = close connection)
- **ID** (WSTRING): Identifier for the connection

Data Outputs

- **QO** (BOOL): Connection status (TRUE = connected, FALSE = disconnected)
- **STATUS** (WSTRING): Status information about The Connection

Adapter

No adapter interfaces are available.

Functionality

The CLIENT_0 block initializes a network connection to the SERVER_0 block via the INIT event. Upon successful connection, the INITO event is triggered with QO=TRUE. Interaction with the server can be initiated via the REQ event, the completion of which is confirmed by CNF.

Technical Features

- No data inputs/outputs (SD_x, RD_x) available
- WSTRING data type for ID and STATUS
- Generic implementation via GEN_CLIENT class name

State Overview

1. **Not connected**: Initial state, QO = FALSE
2. **Connection Established**: INIT processed with QI = TRUE
3. **Connected**: INITO confirmed with QO = TRUE
4. **Interaction**: REQ/CNF cycle
5. **Connection Disconnected**: INIT processed with QI = FALSE

Application Scenarios

- Pure event synchronization between systems
- "Heartbeat" monitoring without user data
- Trigger signals over network

2.11.6.3 CLIENT_0_1

• – ◦ • – ◦ • – ◦ •

Introduction

The CLIENT_0_1 function block is used to communicate with a corresponding server block (e.g., SERVER_1_0) via a network connection. It is specifically designed to **receive** data from the server without sending any data itself (Receive Only Client).

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE)
- **REQ**: Requests data from the server

Event Outputs

- **INITO**: Confirms that a new connection has been established (QI = TRUE) or that a connection has been closed (QI = FALSE)
- **CNF**: Signals that new data has been received from the server and is available at RD_1

Data Inputs

- **QI** (BOOL): Controls the connection status (TRUE = open connection, FALSE = close connection)
- **ID** (WSTRING): Identifier for the connection

Data Outputs

- **QO** (BOOL): Connection status (TRUE = connected, FALSE = disconnected)
- **STATUS** (WSTRING): Connection status information
- **RD_1** (ANY): Data received from the server

Adapter

No adapter interfaces are available.

Functionality

The CLIENT_0_1 block establishes a connection via INIT. It requests data from the server using the REQ event. When the server responds, the data is provided at output RD_1, and the CNF event is triggered. There is no data input for sending user data.

Technical Features

- Unidirectional data transmission (receive)
- Use of the ANY data type for RD_1 enables flexible data types
- WSTRING data type for ID and STATUS

Application Scenarios

- Querying sensor values or status information from a remote system
- Monitoring systems that only read data

2.11.6.4 CLIENT_0_10

• – ◦ • – ◦ • – ◦ •

Introduction

The `CLIENT_0_10` function block is the generic client variant with 0 send and 10 receive data fields for communicating with a matching SERVER_10_0 block. It receives 10 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`) from the server without sending any payload itself. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`CLIENT_0_10` transmits no payload data with `REQ`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.
- **RD_5** (ANY): Receive value 5, delivered by the server with `CNF`.
- **RD_6** (ANY): Receive value 6, delivered by the server with `CNF`.
- **RD_7** (ANY): Receive value 7, delivered by the server with `CNF`.
- **RD_8** (ANY): Receive value 8, delivered by the server with `CNF`.
- **RD_9** (ANY): Receive value 9, delivered by the server with `CNF`.
- **RD_10** (ANY): Receive value 10, delivered by the server with `CNF`.

Functionality

`CLIENT_0_10` initializes a connection to the matching `SERVER_10_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, a request without payload is sent. Once response data (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`) is available, the block triggers `CNF` and provides `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`.

Technical Features

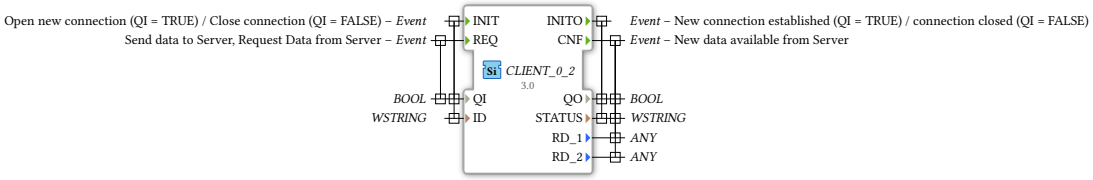
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_10_0`**: `CLIENT_0_10` is only functionally compatible with a `SERVER_10_0` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 10 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_10_0` with the matching field count.



Comparison with similar function blocks

- **SERVER_10_0**: the direct counterpart on the server side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_0_10` provides the generic client variant of the `GEN_CLIENT` family tailored to 0 send and 10 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.5 CLIENT_0_2

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_0_2` function block is the generic client variant with 0 send and 2 receive data fields for communicating with a matching SERVER_2_0 block. It receives 2 data values (`RD_1` `RD_2`) from the server without sending any payload itself. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1` `RD_2`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`CLIENT_0_2` transmits no payload data with `REQ`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.

Functionality

`CLIENT_0_2` initializes a connection to the matching `SERVER_2_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, a request without payload is sent. Once response data (`RD_1` `RD_2`) is available, the block triggers `CNF` and provides `RD_1` `RD_2`.

Technical Features

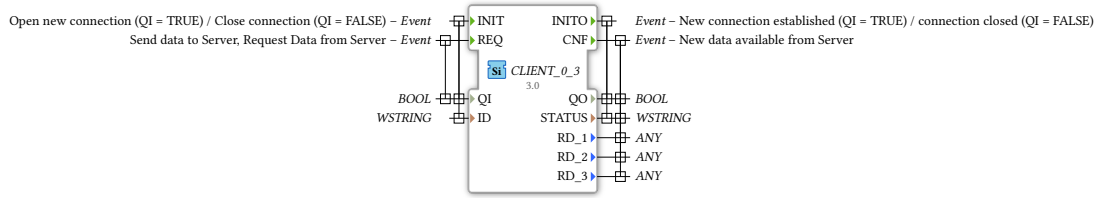
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_2_0`**: `CLIENT_0_2` is only functionally compatible with a `SERVER_2_0` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 2 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_2_0` with the matching field count.



Comparison with similar function blocks

- SERVER_2_0: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_0_2` provides the generic client variant of the `GEN_CLIENT` family tailored to 0 send and 2 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.6 CLIENT_0_3

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_0_3 function block is the generic client variant with 0 send and 3 receive data fields for communicating with a matching SERVER_3_0 block. It receives 3 data values (RD_1 RD_2 RD_3) from the server without sending any payload itself. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS and RD_1 RD_2 RD_3.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (CLIENT_0_3 transmits no payload data with REQ, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with CNF.
- **RD_2** (ANY): Receive value 2, delivered by the server with CNF.
- **RD_3** (ANY): Receive value 3, delivered by the server with CNF.

Functionality

CLIENT_0_3 initializes a connection to the matching SERVER_3_0 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, a request without payload is sent. Once response data (RD_1 RD_2 RD_3) is available, the block triggers CNF and provides RD_1 RD_2 RD_3.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_3_0**: CLIENT_0_3 is only functionally compatible with a SERVER_3_0 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

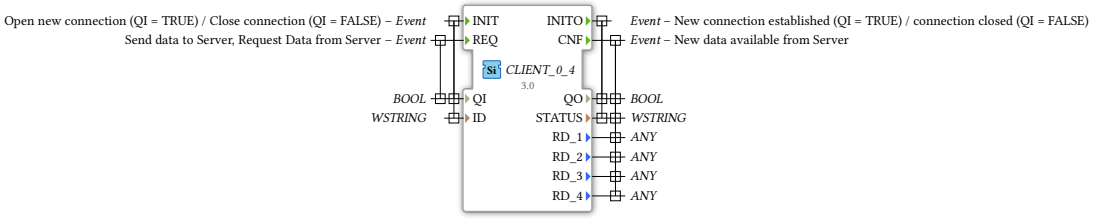
State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 3 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_3_0 with the matching field count.

Comparison with similar function blocks



- **SERVER_3_0**: the direct counterpart on the server side, with send/receive field counts swapped.

- **CLIENT_1 / SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_0_3` provides the generic client variant of the `GEN_CLIENT` family tailored to 0 send and 3 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.7 CLIENT_0_4

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_0_4` function block is the generic client variant with 0 send and 4 receive data fields for communicating with a matching SERVER_4_0 block. It receives 4 data values (`RD_1 RD_2 RD_3 RD_4`) from the server without sending any payload itself. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1 RD_2 RD_3 RD_4`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`CLIENT_0_4` transmits no payload data with `REQ`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.

Functionality

`CLIENT_0_4` initializes a connection to the matching `SERVER_4_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, a request without payload is sent. Once response data (`RD_1 RD_2 RD_3 RD_4`) is available, the block triggers `CNF` and provides `RD_1 RD_2 RD_3 RD_4`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.

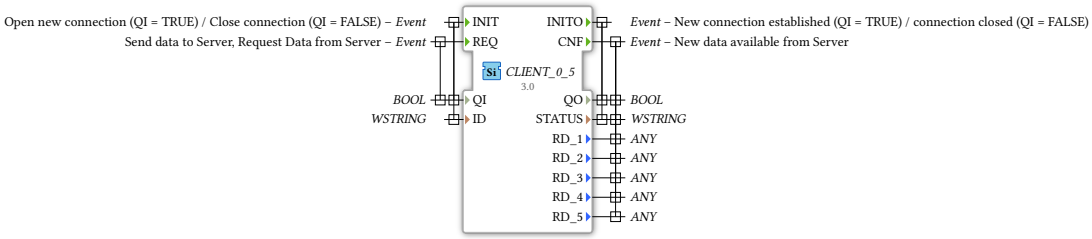
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_4_0**: CLIENT_0_4 is only functionally compatible with a SERVER_4_0 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 4 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_4_0 with the matching field count.



Comparison with similar function blocks

- SERVER_4_0: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

CLIENT_0_4 provides the generic client variant of the GEN_CLIENT family tailored to 0 send and 4 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.8 CLIENT_0_5

• — ○ • — ○ • — ○ •

Introduction

The CLIENT_0_5 function block is the generic client variant with 0 send and 5 receive data fields for communicating with a matching SERVER_5_0 block. It receives 5 data values (RD_1 RD_2 RD_3 RD_4 RD_5) from the server without sending any payload itself. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS and RD_1 RD_2 RD_3 RD_4 RD_5.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).

- No send fields (`CLIENT_0_5` transmits no payload data with `REQ`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.
- **RD_5** (ANY): Receive value 5, delivered by the server with `CNF`.

Functionality

`CLIENT_0_5` initializes a connection to the matching `SERVER_5_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, a request without payload is sent. Once response data (`RD_1 RD_2 RD_3 RD_4 RD_5`) is available, the block triggers `CNF` and provides `RD_1 RD_2 RD_3 RD_4 RD_5`.

Technical Features

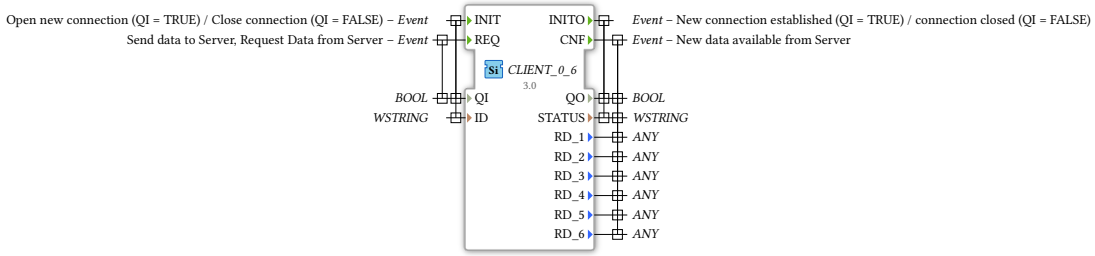
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_5_0`**: `CLIENT_0_5` is only functionally compatible with a `SERVER_5_0` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 5 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_5_0` with the matching field count.



Comparison with similar function blocks

- SERVER_5_0: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_0_5` provides the generic client variant of the `GEN_CLIENT` family tailored to 0 send and 5 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.9 CLIENT_0_6

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_0_6 function block is the generic client variant with 0 send and 6 receive data fields for communicating with a matching SERVER_6_0 block. It receives 6 data values (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6) from the server without sending any payload itself. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS and RD_1 RD_2 RD_3 RD_4 RD_5 RD_6.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (CLIENT_0_6 transmits no payload data with REQ, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with CNF.
- **RD_2** (ANY): Receive value 2, delivered by the server with CNF.
- **RD_3** (ANY): Receive value 3, delivered by the server with CNF.
- **RD_4** (ANY): Receive value 4, delivered by the server with CNF.
- **RD_5** (ANY): Receive value 5, delivered by the server with CNF.
- **RD_6** (ANY): Receive value 6, delivered by the server with CNF.

Functionality

CLIENT_0_6 initializes a connection to the matching SERVER_6_0 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, a request without payload is sent. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6) is available, the block triggers CNF and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_6_0**: CLIENT_0_6 is only functionally compatible with a SERVER_6_0 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

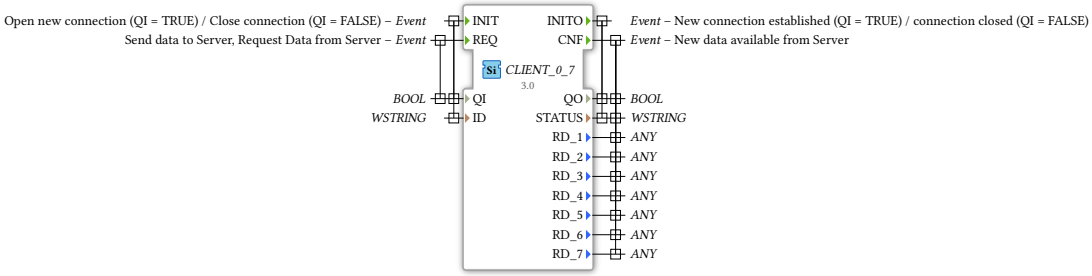
State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 6 values, without carrying unused surplus data fields.

- **Client-side connection** to a communication partner already laid out as a `SERVER_6_0` with the matching field count.



Comparison with similar function blocks

- **SERVER_6_0**: the direct counterpart on the server side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_0_6` provides the generic client variant of the `GEN_CLIENT` family tailored to 0 send and 6 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.10 CLIENT_0_7

• – ◦ • – ◦ • – ◦ •

Introduction

The `CLIENT_0_7` function block is the generic client variant with 0 send and 7 receive data fields for communicating with a matching SERVER_7_0 block. It receives 7 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7`) from the server without sending any payload itself. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`CLIENT_0_7` transmits no payload data with `REQ`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.
- **RD_5** (ANY): Receive value 5, delivered by the server with `CNF`.
- **RD_6** (ANY): Receive value 6, delivered by the server with `CNF`.
- **RD_7** (ANY): Receive value 7, delivered by the server with `CNF`.

Functionality

CLIENT_0_7 initializes a connection to the matching SERVER_7_0 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, a request without payload is sent. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7) is available, the block triggers CNF and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7.

Technical Features

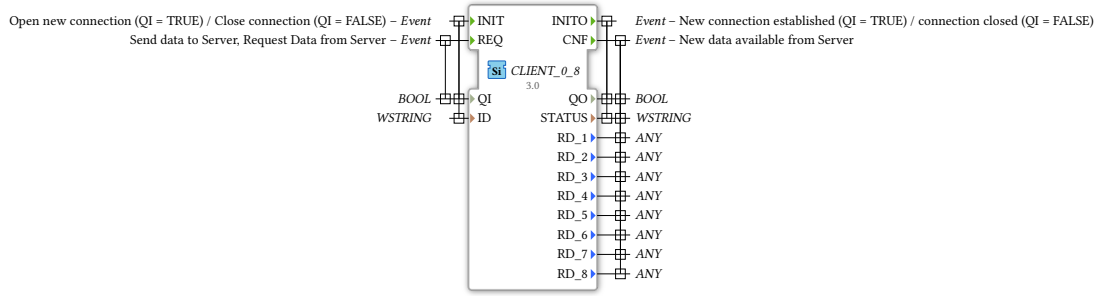
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_7_0**: CLIENT_0_7 is only functionally compatible with a SERVER_7_0 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 7 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_7_0 with the matching field count.



Comparison with similar function blocks

- SERVER_7_0: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

CLIENT_0_7 provides the generic client variant of the GEN_CLIENT family tailored to 0 send and 7 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.11 CLIENT_0_8

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_0_8 function block is the generic client variant with 0 send and 8 receive data fields for communicating with a matching SERVER_8_0 block. It receives 8 data values (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8) from the server without sending any payload itself. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`CLIENT_0_8` transmits no payload data with `REQ`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.
- **RD_5** (ANY): Receive value 5, delivered by the server with `CNF`.
- **RD_6** (ANY): Receive value 6, delivered by the server with `CNF`.
- **RD_7** (ANY): Receive value 7, delivered by the server with `CNF`.
- **RD_8** (ANY): Receive value 8, delivered by the server with `CNF`.

Functionality

`CLIENT_0_8` initializes a connection to the matching `SERVER_8_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, a request without payload is sent. Once response data (`RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8`) is available, the block triggers `CNF` and provides `RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_8_0`**: `CLIENT_0_8` is only functionally compatible with a `SERVER_8_0` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

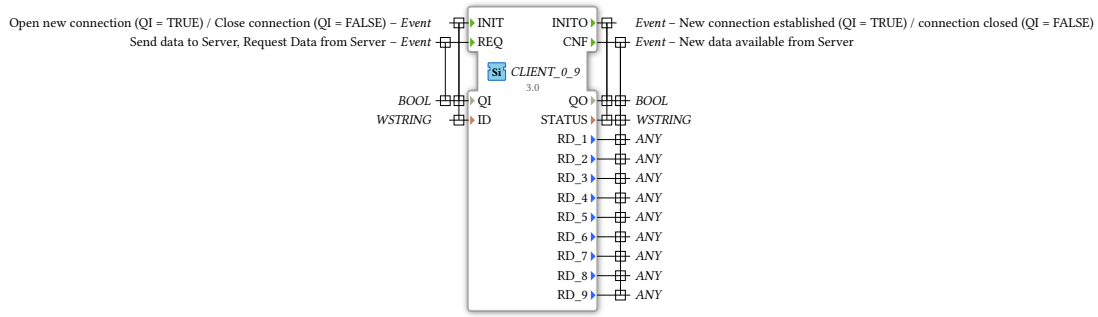
State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 8 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_8_0` with the matching field count.

Comparison with similar function blocks



- **SERVER_8_0**: the direct counterpart on the server side, with send/receive field counts swapped.

- **CLIENT_1 / SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_0_8` provides the generic client variant of the `GEN_CLIENT` family tailored to 0 send and 8 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.12 CLIENT_0_9

• – ◦ • – ◦ • – ◦ •

Introduction

The `CLIENT_0_9` function block is the generic client variant with 0 send and 9 receive data fields for communicating with a matching SERVER_9_0 block. It receives 9 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9`) from the server without sending any payload itself. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`CLIENT_0_9` transmits no payload data with `REQ`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.
- **RD_5** (ANY): Receive value 5, delivered by the server with `CNF`.
- **RD_6** (ANY): Receive value 6, delivered by the server with `CNF`.
- **RD_7** (ANY): Receive value 7, delivered by the server with `CNF`.
- **RD_8** (ANY): Receive value 8, delivered by the server with `CNF`.
- **RD_9** (ANY): Receive value 9, delivered by the server with `CNF`.

Functionality

CLIENT_0_9 initializes a connection to the matching SERVER_9_0 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, a request without payload is sent. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9) is available, the block triggers CNF and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_9_0**: CLIENT_0_9 is only functionally compatible with a SERVER_9_0 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

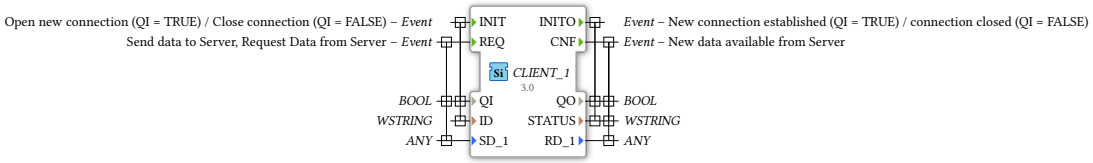
Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 9 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_9_0 with the matching field count.

Comparison with similar function blocks

- SERVER_9_0: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion



CLIENT_0_9 provides the generic client variant of the GEN_CLIENT family tailored to 0 send and 9 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.13 CLIENT_1

• – ◦ • – ◦ • – ◦ •

Introduction

The CLIENT_1 function block is used to communicate with a SERVER_1 block via a network connection. It enables the establishment and closure of connections as well as data exchange between client and server.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE)
- **REQ**: Sends data to the server and requests data from the server

Event Outputs

- **INITO**: Confirms the establishment of a new connection (QI = TRUE) or the closing of a connection (QI = FALSE)
- **CNF**: Signals that new data is available from the server

Data Inputs

- **QI** (BOOL): Controls the connection status (TRUE = open connection, FALSE = close connection)
- **ID** (WSTRING): Identifier for the connection
- **SD_1** (ANY): Data to be sent to the server

Data Outputs

- **QO** (BOOL): Connection status (TRUE = connected, FALSE = disconnected)
- **STATUS** (WSTRING): Connection status information
- **RD_1** (ANY): Data received from the server

Adapter

No adapter interfaces are present.

Functionality

The CLIENT_1 block initializes a network connection to the SERVER_1 block via the INIT event. Upon successful connection, the INITO event is triggered with QO=TRUE. Data can be sent to and requested from the server via the REQ event. Received data is made available via the CNF event using the corresponding data outputs.

Technical Features

- Use of the ANY data type for SD_1 and RD_1 enables flexible data types
- WSTRING data type for ID and STATUS supports Unicode characters
- Generic implementation through GEN_CLIENT class names

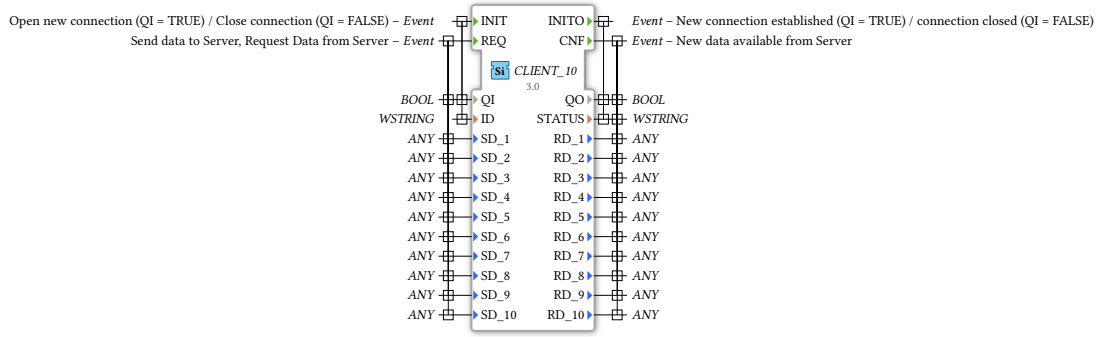
State Overview

1. **Not connected**: Initial state, QO = FALSE
2. **Connection establishing**: INIT processed with QI = TRUE
3. **Connected**: INITO confirmed with QO = TRUE
4. **Data transmission**: REQ/CNF cycle for data exchange
5. **Connection disconnection**: INIT processed with QI = FALSE

Application Scenarios

- Communication between distributed control systems
- Data exchange in Industry 4.0 applications
- Client-server architectures in automation systems
- Networked control components via TCP/IP or other protocols

⚖️ Comparison with similar modules



Compared to simpler communication modules, this offers CLIENT_1:

- Bidirectional data exchange in a single transaction
- Flexible data types through ANY type
- Explicit connection control
- Detailed status feedback

Conclusion

The CLIENT_1 function block provides a robust solution for client-server communication in distributed automation systems. Its flexible interface and explicit connection control make it particularly suitable for demanding network applications in industrial environments.

2.11.6.14 CLIENT_10

• – ◦ • – ◦ • – ◦ •

Introduction

The `CLIENT_10` function block is the generic client variant with 10 send and 10 receive data fields for communicating with a matching SERVER_10 block. It transmits 10 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9` `SD_10`) to the server and receives 10 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`) back. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9` `SD_10`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.
- **SD_3** (ANY): Send value 3, transmitted to the server with `REQ`.
- **SD_4** (ANY): Send value 4, transmitted to the server with `REQ`.
- **SD_5** (ANY): Send value 5, transmitted to the server with `REQ`.
- **SD_6** (ANY): Send value 6, transmitted to the server with `REQ`.
- **SD_7** (ANY): Send value 7, transmitted to the server with `REQ`.
- **SD_8** (ANY): Send value 8, transmitted to the server with `REQ`.
- **SD_9** (ANY): Send value 9, transmitted to the server with `REQ`.
- **SD_10** (ANY): Send value 10, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.
- **RD_5** (ANY): Receive value 5, delivered by the server with `CNF`.
- **RD_6** (ANY): Receive value 6, delivered by the server with `CNF`.

- **RD_7** (ANY): Receive value 7, delivered by the server with CNF.
- **RD_8** (ANY): Receive value 8, delivered by the server with CNF.
- **RD_9** (ANY): Receive value 9, delivered by the server with CNF.
- **RD_10** (ANY): Receive value 10, delivered by the server with CNF.

Functionality

CLIENT_10 initializes a connection to the matching SERVER_10 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 SD_10 are transmitted to the server. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9 RD_10) is available, the block triggers CNF and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9 RD_10.

Technical Features

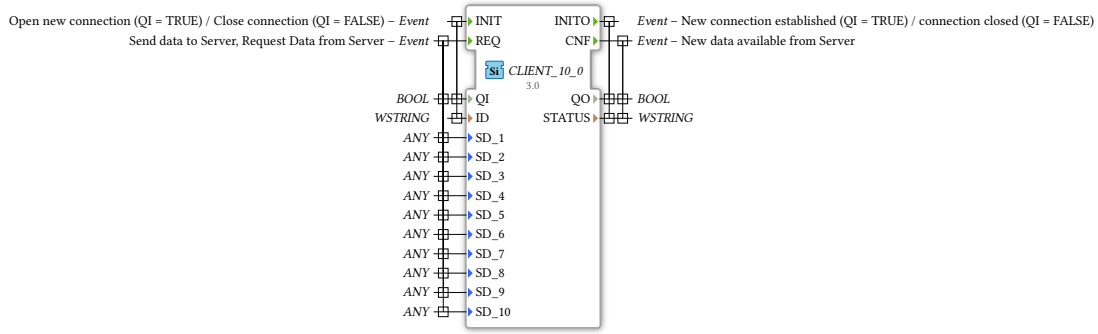
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_10**: CLIENT_10 is only functionally compatible with a SERVER_10 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 10 values and receive exactly 10 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_10 with the matching field count.



Comparison with similar function blocks

- **SERVER_10**: the direct counterpart on the server side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

CLIENT_10 provides the generic client variant of the GEN_CLIENT family tailored to 10 send and 10 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.15 CLIENT_10_0

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_10_0 function block is the generic client variant with 10 send and 0 receive data fields for communicating with a matching SERVER_0_10 block. It transmits 10 data values (SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 SD_10) to the server without receiving any data back. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 SD_10.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with REQ.
- **SD_2** (ANY): Send value 2, transmitted to the server with REQ.
- **SD_3** (ANY): Send value 3, transmitted to the server with REQ.
- **SD_4** (ANY): Send value 4, transmitted to the server with REQ.
- **SD_5** (ANY): Send value 5, transmitted to the server with REQ.
- **SD_6** (ANY): Send value 6, transmitted to the server with REQ.
- **SD_7** (ANY): Send value 7, transmitted to the server with REQ.
- **SD_8** (ANY): Send value 8, transmitted to the server with REQ.
- **SD_9** (ANY): Send value 9, transmitted to the server with REQ.
- **SD_10** (ANY): Send value 10, transmitted to the server with REQ.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (CLIENT_10_0 receives no payload data via CNF, only connection/status information).

Functionality

CLIENT_10_0 initializes a connection to the matching SERVER_0_10 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 SD_10 are transmitted to the server. Once a response is available, the block triggers CNF.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_0_10**: CLIENT_10_0 is only functionally compatible with a SERVER_0_10 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.

5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

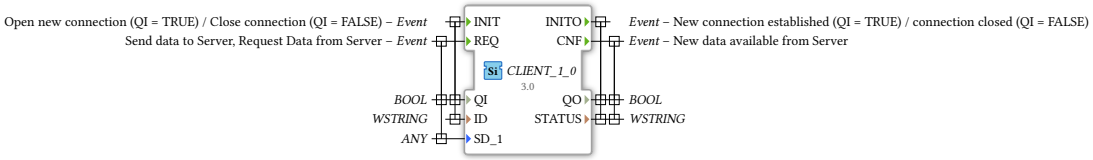
Application Scenarios

- **Communication between distributed control systems** that need to send exactly 10 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_0_10` with the matching field count.

Comparison with similar function blocks

- **SERVER_0_10**: the direct counterpart on the server side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion



`CLIENT_10_0` provides the generic client variant of the `GEN_CLIENT` family tailored to 10 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.16 CLIENT_1_0

• – ◦ • – ◦ • – ◦ •

Introduction

The CLIENT_1_0 function block is used to communicate with a corresponding server block (e.g., SERVER_0_1) via a network connection. It is specifically designed for **sending** data to the server without receiving any data (Send Only Client).

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE)
- **REQ**: Sends the data present at SD_1 to the server

Event Outputs

- **INITO**: Confirms that a new connection has been established (QI = TRUE) or that a connection has been closed (QI = FALSE)
- **CNF**: Confirms that the data was sent successfully

Data Inputs

- **QI** (BOOL): Controls the connection status (TRUE = open connection, FALSE = close connection)
- **ID** (WSTRING): Identifier for the connection
- **SD_1** (ANY): Data to be sent to the server

Data Outputs

- **QO** (BOOL): Connection status (TRUE = connected, FALSE = disconnected)
- **STATUS** (WSTRING): Status information about the connection

Adapter

No adapter interfaces are available.

Functionality

The CLIENT_1_0 block establishes a connection via INIT. When the REQ event is triggered, the block sends the value of SD_1 to the server. Successful transmission is confirmed by the CNF event. There is no data output for received data.

Technical Features

- Unidirectional data transmission (sending)
- Use of the ANY data type for SD_1 enables flexible data types
- WSTRING data type for ID and STATUS

Application Scenarios

- Sending control commands or setpoints to a remote system (without a direct response as data)
- Logging clients that push data to a central server

2.11.6.17 CLIENT_2

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_2` function block is the generic client variant with 2 send and 2 receive data fields for communicating with a matching SERVER_2 block. It transmits 2 data values (`SD_1` `SD_2`) to the server and receives 2 data values (`RD_1` `RD_2`) back. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1` `SD_2`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1` `RD_2`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.

Functionality

`CLIENT_2` initializes a connection to the matching `SERVER_2` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, the values `SD_1` `SD_2` are transmitted to the server. Once response data (`RD_1` `RD_2`) is available, the block triggers `CNF` and provides `RD_1` `RD_2`.

Technical Features

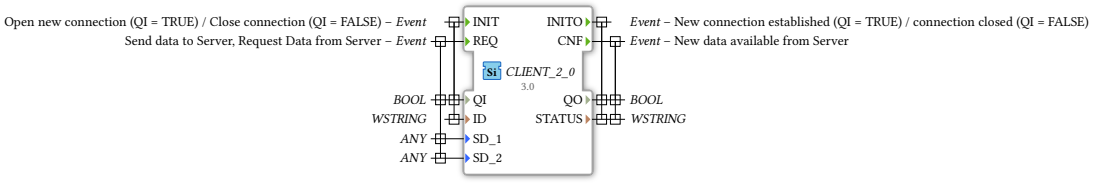
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_2`**: `CLIENT_2` is only functionally compatible with a `SERVER_2` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 2 values and receive exactly 2 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_2` with the matching field count.



Comparison with similar function blocks

- SERVER_2: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_2` provides the generic client variant of the `GEN_CLIENT` family tailored to 2 send and 2 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.18 CLIENT_2_0

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_2_0` function block is the generic client variant with 2 send and 0 receive data fields for communicating with a matching SERVER_0_2 block. It transmits 2 data values (`SD_1` `SD_2`) to the server without receiving any data back. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1` `SD_2`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`CLIENT_2_0` receives no payload data via `CNF`, only connection/status information).

Functionality

`CLIENT_2_0` initializes a connection to the matching `SERVER_0_2` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, the values `SD_1` `SD_2` are transmitted to the server. Once a response is available, the block triggers `CNF`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_0_2`**: `CLIENT_2_0` is only functionally compatible with a `SERVER_0_2` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

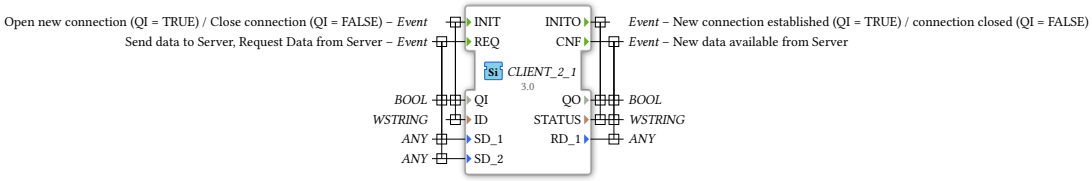
Application Scenarios

- **Communication between distributed control systems** that need to send exactly 2 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_0_2` with the matching field count.

Comparison with similar function blocks

- SERVER_0_2: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion



`CLIENT_2_0` provides the generic client variant of the `GEN_CLIENT` family tailored to 2 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.19 CLIENT_2_1

• – ◦ • – ◦ • – ◦ •

Introduction

The CLIENT_2_1 function block is used to communicate with a SERVER_1_2 block via a network connection. It enables the establishment and termination of connections as well as data exchange between client and server.

Interface Structure

Event Inputs

- **INIT**: Initialization event to open (QI = TRUE) or close (QI = FALSE) a connection
- **REQ**: Request event to send data to the server and request data from the server

Event Outputs

- **INITO**: Acknowledge event for connection establishment (QI = TRUE) or connection termination (QI = FALSE)
- **CNF**: Acknowledge event when new data is available from the server

Data Inputs

- **QI** (BOOL): Quality indicator for the INIT event (TRUE = open connection, FALSE = close connection)
- **ID** (WSTRING): Identifier for the connection
- **SD_1** (ANY): First data transmission block to the server
- **SD_2** (ANY): Second data transmission block to the Server

Data Outputs

- **QO** (BOOL): Quality indicator for output events
- **STATUS** (WSTRING): Status information about the connection or operation
- **RD_1** (ANY): Data block received from the server

Adapter

No adapter interfaces available.

Functionality

The CLIENT_2_1 block manages the entire client side of client-server communication. With INIT and QI=TRUE, a new connection to the specified server is established. With INIT and QI=FALSE, an existing connection is closed. The REQ event simultaneously triggers the sending of data SD_1 and SD_2 to the server and the request for data from the server. Upon successful operation, the received data is output via RD_1.

Technical Features

- Supports the ANY data type for flexible data transfer
- Uses WSTRING for status messages and connection IDs
- Provides bidirectional data exchange in a single operation
- Implements complete connection management (establishment/disconnection)

State Overview

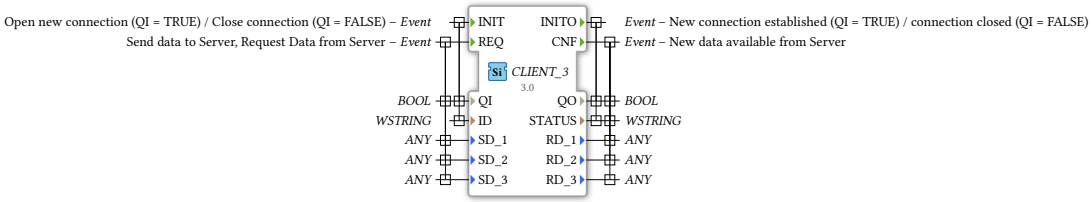
The block can assume the following states:

- Not connected (initial state)
- Establishing connection
- Connected and ready for operation
- Disconnecting connection in progress

Application Scenarios

- Industrial automation systems with distributed control

- IoT applications with client-server architecture
- Data exchange between different control levels
- Remote monitoring and control of devices



⚖️ Comparison with Similar Blocks

Compared to simpler client blocks, CLIENT_2_1 offers the ability to send two different data blocks simultaneously and receive one data block at a time. The integration of connection management and data exchange into a single block simplifies the application logic.

Conclusion

The CLIENT_2_1 function block represents a powerful solution for client-server communication in distributed automation systems. By combining connection management and bidirectional data exchange in a single block, it enables efficient and transparent network applications.

2.11.6.20 CLIENT_3

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_3` function block is the generic client variant with 3 send and 3 receive data fields for communicating with a matching SERVER_3 block. It transmits 3 data values (`SD_1` `SD_2` `SD_3`) to the server and receives 3 data values (`RD_1` `RD_2` `RD_3`) back. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1` `SD_2` `SD_3`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.
- **SD_3** (ANY): Send value 3, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.

Functionality

CLIENT_3 initializes a connection to the matching SERVER_3 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, the values SD_1 SD_2 SD_3 are transmitted to the server. Once response data (RD_1 RD_2 RD_3) is available, the block triggers CNF and provides RD_1 RD_2 RD_3.

Technical Features

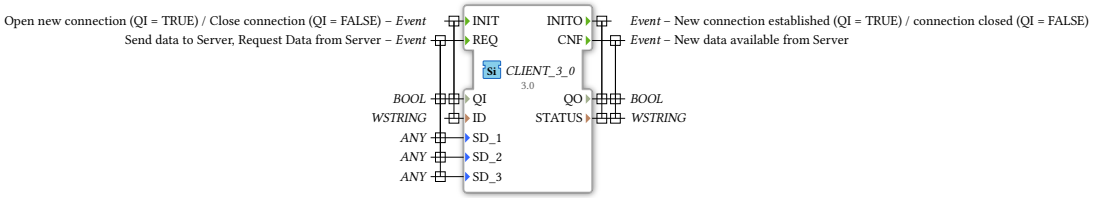
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_3**: CLIENT_3 is only functionally compatible with a SERVER_3 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 3 values and receive exactly 3 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_3 with the matching field count.



Comparison with similar function blocks

- SERVER_3: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

CLIENT_3 provides the generic client variant of the GEN_CLIENT family tailored to 3 send and 3 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.21 CLIENT_3_0

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_3_0 function block is the generic client variant with 3 send and 0 receive data fields for communicating with a matching SERVER_0_3 block. It transmits 3 data values (SD_1 SD_2 SD_3) to the server without receiving any data back. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.

- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1` `SD_2` `SD_3`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.
- **SD_3** (ANY): Send value 3, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`CLIENT_3_0` receives no payload data via `CNF`, only connection/status information).

Functionality

`CLIENT_3_0` initializes a connection to the matching `SERVER_0_3` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, the values `SD_1` `SD_2` `SD_3` are transmitted to the server. Once a response is available, the block triggers `CNF`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_0_3`**: `CLIENT_3_0` is only functionally compatible with a `SERVER_0_3` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

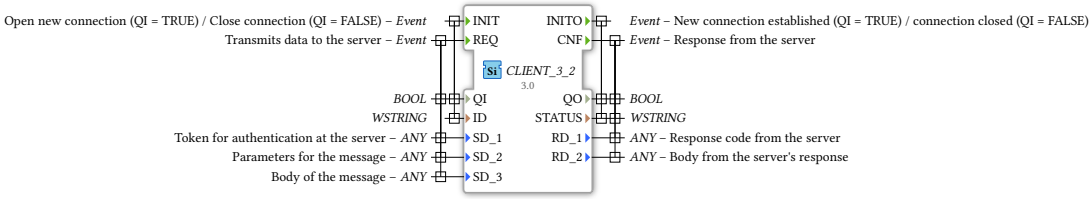
Application Scenarios

- **Communication between distributed control systems** that need to send exactly 3 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_0_3` with the matching field count.

Comparison with similar function blocks

- SERVER_0_3: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion



`CLIENT_3_0` provides the generic client variant of the `GEN_CLIENT` family tailored to 3 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.22 CLIENT_3_2

• – ◦ • – ◦ • – ◦ •

Introduction

The CLIENT_3_2 is a function block for HTTP communication, designed as a client with three inputs and two outputs. It enables communication with a server via the HTTP protocol and supports both opening and closing connections as well as sending requests and receiving responses.

Interface Structure

Event Inputs

- **INIT** (Type: EInit) - Opens a new connection (QI = TRUE) or closes a connection (QI = FALSE)
- **REQ** (Type: Event) - Sends data to the server

Event Outputs

- **INITO** (Type: EInit) - Signals that a new connection has been established (QI = TRUE) or a connection has been closed (QI = FALSE)
- **CNF** (Type: Event) - Response from the server

Data Inputs

- **QI** (BOOL) - Quality indicator for INIT and REQ events
- **ID** (WSTRING) - Connection identifier
- **SD_1** (ANY) - Token for authentication with the server
- **SD_2** (ANY) - Parameter for the Message
- **SD_3** (ANY) - Message Body

Data Outputs

- **QO** (BOOL) - Quality indicator for INITO and CNF events
- **STATUS** (WSTRING) - Status information
- **RD_1** (ANY) - Server response code
- **RD_2** (ANY) - Server response body

Adapter

No adapter interfaces available.

Functionality

The CLIENT_3_2 function block operates in two main phases: connection management and data transmission. The INIT event establishes or closes a connection to the server. After a successful connection, data can be sent to the server via the REQ event. The server response is reported back via the CNF event.

Technical Features

- Use of WSTRING for ID and STATUS for international character set support
- ANY type for SD_1, SD_2, SD_3, RD_1, and RD_2 enables flexible data types
- Separate quality indicators for inputs (QI) and outputs (QO)
- Support for authentication tokens (SD_1)

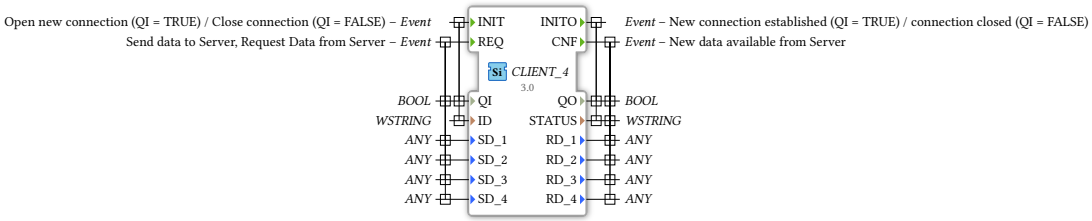
State Overview

1. **Initialization State**: Waiting for INIT event
2. **Connection Establishment**: Processing INIT with QI=TRUE
3. **Ready**: Connection established, waiting for REQ events
4. **Data Transfer**: Sending REQ and waiting for CNF
5. **Connection Termination**: Processing INIT with QI=FALSE

Application Scenarios

- HTTP REST API communication in automation systems

- Web service integration in industrial controllers
- Data exchange with cloud services
- Authenticated communication with Backend Servers



⚖️ Comparison with Similar Modules

Compared to simpler client modules, CLIENT_3_2 offers enhanced functionality through three separate data inputs (SD_1-3) and two data outputs (RD_1-2), enabling structured transmission of authentication data, parameters, and message content.

Conclusion

CLIENT_3_2 is a versatile HTTP client module that, thanks to its flexible data interface and comprehensive status feedback, enables robust communication with HTTP servers in industrial automation environments.

2.11.6.23 CLIENT_4

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_4` function block is the generic client variant with 4 send and 4 receive data fields for communicating with a matching SERVER_4 block. It transmits 4 data values (`SD_1` `SD_2` `SD_3` `SD_4`) to the server and receives 4 data values (`RD_1` `RD_2` `RD_3` `RD_4`) back. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.
- **SD_3** (ANY): Send value 3, transmitted to the server with `REQ`.
- **SD_4** (ANY): Send value 4, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.

Functionality

CLIENT_4 initializes a connection to the matching SERVER_4 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, the values SD_1 SD_2 SD_3 SD_4 are transmitted to the server. Once response data (RD_1 RD_2 RD_3 RD_4) is available, the block triggers CNF and provides RD_1 RD_2 RD_3 RD_4.

Technical Features

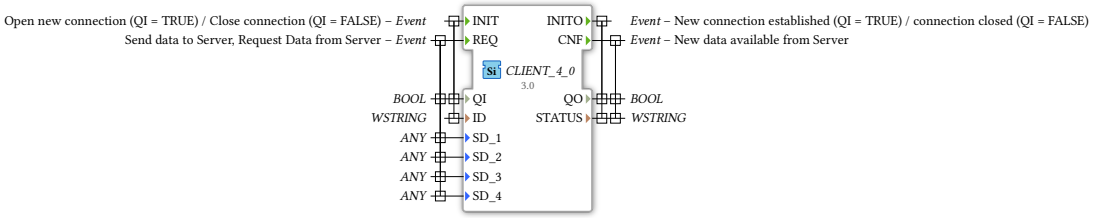
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_4**: CLIENT_4 is only functionally compatible with a SERVER_4 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 4 values and receive exactly 4 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_4 with the matching field count.



Comparison with similar function blocks

- SERVER_4: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

CLIENT_4 provides the generic client variant of the GEN_CLIENT family tailored to 4 send and 4 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.24 CLIENT_4_0

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_4_0 function block is the generic client variant with 4 send and 0 receive data fields for communicating with a matching SERVER_0_4 block. It transmits 4 data values (SD_1 SD_2 SD_3 SD_4) to the server without receiving any data back. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.
- **SD_3** (ANY): Send value 3, transmitted to the server with `REQ`.
- **SD_4** (ANY): Send value 4, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`CLIENT_4_0` receives no payload data via `CNF`, only connection/status information).

Functionality

`CLIENT_4_0` initializes a connection to the matching `SERVER_0_4` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, the values `SD_1` `SD_2` `SD_3` `SD_4` are transmitted to the server. Once a response is available, the block triggers `CNF`.

Technical Features

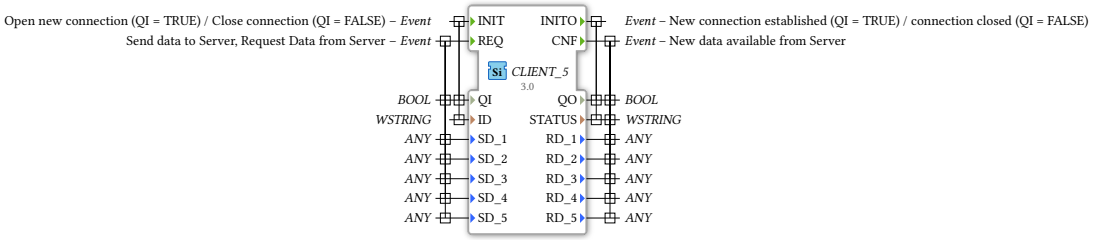
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_0_4`**: `CLIENT_4_0` is only functionally compatible with a `SERVER_0_4` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 4 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_0_4` with the matching field count.



Comparison with similar function blocks

- **SERVER_0_4**: the direct counterpart on the server side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_4_0` provides the generic client variant of the `GEN_CLIENT` family tailored to 4 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.25 CLIENT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The `CLIENT_5` function block is the generic client variant with 5 send and 5 receive data fields for communicating with a matching SERVER_5 block. It transmits 5 data values (`SD_1 SD_2 SD_3 SD_4 SD_5`) to the server and receives 5 data values (`RD_1 RD_2 RD_3 RD_4 RD_5`) back. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1 SD_2 SD_3 SD_4 SD_5`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1 RD_2 RD_3 RD_4 RD_5`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.
- **SD_3** (ANY): Send value 3, transmitted to the server with `REQ`.
- **SD_4** (ANY): Send value 4, transmitted to the server with `REQ`.
- **SD_5** (ANY): Send value 5, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.
- **RD_5** (ANY): Receive value 5, delivered by the server with `CNF`.

Functionality

`CLIENT_5` initializes a connection to the matching `SERVER_5` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, the values `SD_1 SD_2 SD_3 SD_4 SD_5` are transmitted to the server. Once response data (`RD_1 RD_2 RD_3 RD_4 RD_5`) is available, the block triggers `CNF` and provides `RD_1 RD_2 RD_3 RD_4 RD_5`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.

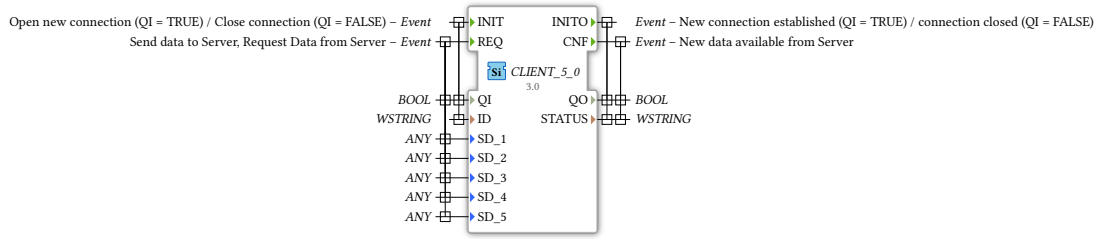
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_5**: CLIENT_5 is only functionally compatible with a SERVER_5 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 5 values and receive exactly 5 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_5 with the matching field count.



Comparison with similar function blocks

- SERVER_5: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

CLIENT_5 provides the generic client variant of the GEN_CLIENT family tailored to 5 send and 5 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.26 CLIENT_5_0

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_5_0 function block is the generic client variant with 5 send and 0 receive data fields for communicating with a matching SERVER_0_5 block. It transmits 5 data values (SD_1 SD_2 SD_3 SD_4 SD_5) to the server without receiving any data back. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).

- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with REQ.
- **SD_2** (ANY): Send value 2, transmitted to the server with REQ.
- **SD_3** (ANY): Send value 3, transmitted to the server with REQ.
- **SD_4** (ANY): Send value 4, transmitted to the server with REQ.
- **SD_5** (ANY): Send value 5, transmitted to the server with REQ.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (CLIENT_5_0 receives no payload data via CNF, only connection/status information).

Functionality

CLIENT_5_0 initializes a connection to the matching SERVER_0_5 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, the values SD_1 SD_2 SD_3 SD_4 SD_5 are transmitted to the server. Once a response is available, the block triggers CNF.

Technical Features

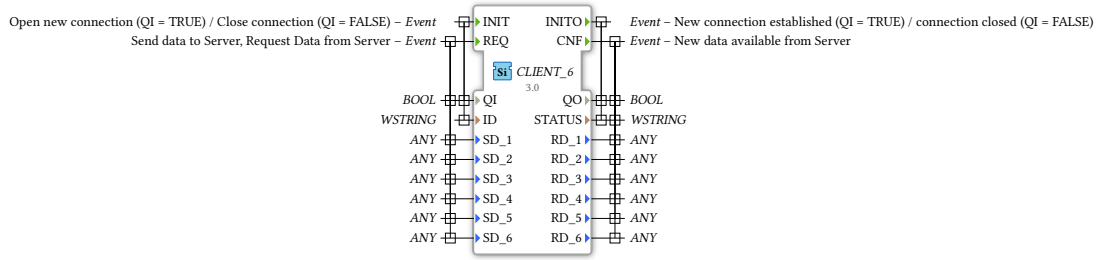
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_0_5**: CLIENT_5_0 is only functionally compatible with a SERVER_0_5 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 5 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_0_5 with the matching field count.



Comparison with similar function blocks

- SERVER_0_5: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

CLIENT_5_0 provides the generic client variant of the GEN_CLIENT family tailored to 5 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.27 CLIENT_6

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_6 function block is the generic client variant with 6 send and 6 receive data fields for communicating with a matching SERVER_6 block. It transmits 6 data values (SD_1 SD_2 SD_3 SD_4 SD_5 SD_6) to the server and receives 6 data values (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6) back. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS and RD_1 RD_2 RD_3 RD_4 RD_5 RD_6.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with REQ.
- **SD_2** (ANY): Send value 2, transmitted to the server with REQ.
- **SD_3** (ANY): Send value 3, transmitted to the server with REQ.
- **SD_4** (ANY): Send value 4, transmitted to the server with REQ.
- **SD_5** (ANY): Send value 5, transmitted to the server with REQ.
- **SD_6** (ANY): Send value 6, transmitted to the server with REQ.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with CNF.
- **RD_2** (ANY): Receive value 2, delivered by the server with CNF.
- **RD_3** (ANY): Receive value 3, delivered by the server with CNF.
- **RD_4** (ANY): Receive value 4, delivered by the server with CNF.
- **RD_5** (ANY): Receive value 5, delivered by the server with CNF.
- **RD_6** (ANY): Receive value 6, delivered by the server with CNF.

Functionality

CLIENT_6 initializes a connection to the matching SERVER_6 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 are transmitted to the server. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6) is available, the block triggers CNF and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_6**: CLIENT_6 is only functionally compatible with a SERVER_6 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

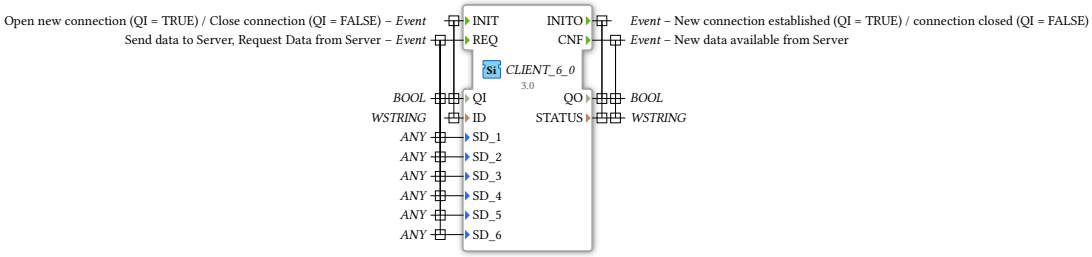
State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.

4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 6 values and receive exactly 6 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_6 with the matching field count.



Comparison with similar function blocks

- SERVER_6: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

CLIENT_6 provides the generic client variant of the GEN_CLIENT family tailored to 6 send and 6 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.28 CLIENT_6_0

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_6_0 function block is the generic client variant with 6 send and 0 receive data fields for communicating with a matching SERVER_0_6 block. It transmits 6 data values (SD_1 SD_2 SD_3 SD_4 SD_5 SD_6) to the server without receiving any data back. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with REQ.
- **SD_2** (ANY): Send value 2, transmitted to the server with REQ.
- **SD_3** (ANY): Send value 3, transmitted to the server with REQ.
- **SD_4** (ANY): Send value 4, transmitted to the server with REQ.
- **SD_5** (ANY): Send value 5, transmitted to the server with REQ.
- **SD_6** (ANY): Send value 6, transmitted to the server with REQ.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`CLIENT_6_0` receives no payload data via `CNF`, only connection/status information).

Functionality

`CLIENT_6_0` initializes a connection to the matching `SERVER_0_6` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, the values `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` are transmitted to the server. Once a response is available, the block triggers `CNF`.

Technical Features

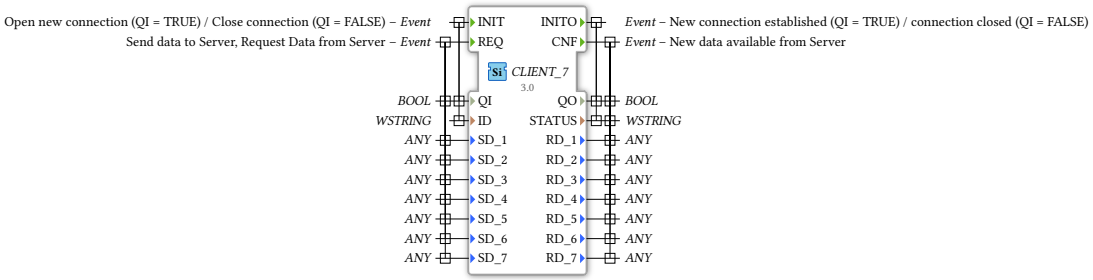
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_0_6`**: `CLIENT_6_0` is only functionally compatible with a `SERVER_0_6` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 6 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_0_6` with the matching field count.



Comparison with similar function blocks

- SERVER_0_6: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_6_0` provides the generic client variant of the `GEN_CLIENT` family tailored to 6 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.29 CLIENT_7

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_7` function block is the generic client variant with 7 send and 7 receive data fields for communicating with a matching SERVER_7 block. It transmits 7 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7`) to the server and receives 7 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7`) back. Like

all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS and RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with REQ.
- **SD_2** (ANY): Send value 2, transmitted to the server with REQ.
- **SD_3** (ANY): Send value 3, transmitted to the server with REQ.
- **SD_4** (ANY): Send value 4, transmitted to the server with REQ.
- **SD_5** (ANY): Send value 5, transmitted to the server with REQ.
- **SD_6** (ANY): Send value 6, transmitted to the server with REQ.
- **SD_7** (ANY): Send value 7, transmitted to the server with REQ.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with CNF.
- **RD_2** (ANY): Receive value 2, delivered by the server with CNF.
- **RD_3** (ANY): Receive value 3, delivered by the server with CNF.
- **RD_4** (ANY): Receive value 4, delivered by the server with CNF.
- **RD_5** (ANY): Receive value 5, delivered by the server with CNF.
- **RD_6** (ANY): Receive value 6, delivered by the server with CNF.
- **RD_7** (ANY): Receive value 7, delivered by the server with CNF.

Functionality

CLIENT_7 initializes a connection to the matching SERVER_7 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 are transmitted to the server. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7) is available, the block triggers CNF and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7.

Technical Features

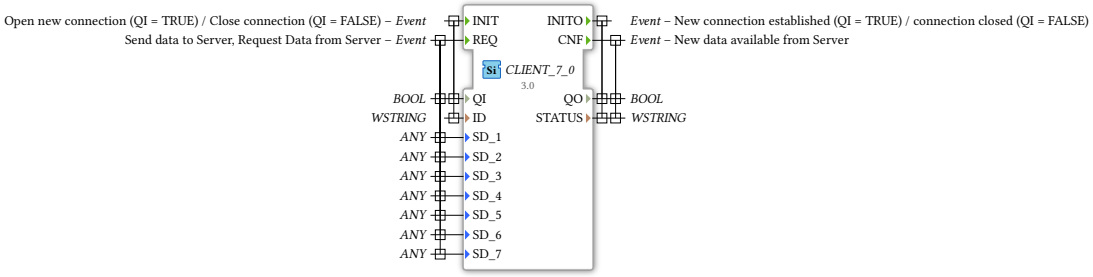
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_7**: CLIENT_7 is only functionally compatible with a SERVER_7 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 7 values and receive exactly 7 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_7` with the matching field count.



Comparison with similar function blocks

- SERVER_7: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_7` provides the generic client variant of the `GEN_CLIENT` family tailored to 7 send and 7 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.30 CLIENT_7_0

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_7_0` function block is the generic client variant with 7 send and 0 receive data fields for communicating with a matching SERVER_0_7 block. It transmits 7 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7`) to the server without receiving any data back. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.
- **SD_3** (ANY): Send value 3, transmitted to the server with `REQ`.
- **SD_4** (ANY): Send value 4, transmitted to the server with `REQ`.
- **SD_5** (ANY): Send value 5, transmitted to the server with `REQ`.
- **SD_6** (ANY): Send value 6, transmitted to the server with `REQ`.
- **SD_7** (ANY): Send value 7, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.

- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`CLIENT_7_0` receives no payload data via `CNF`, only connection/status information).

Functionality

`CLIENT_7_0` initializes a connection to the matching `SERVER_0_7` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, the values `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` are transmitted to the server. Once a response is available, the block triggers `CNF`.

Technical Features

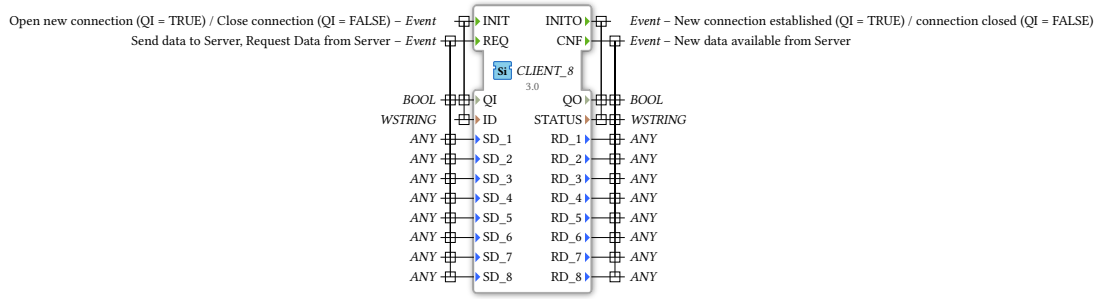
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_0_7`**: `CLIENT_7_0` is only functionally compatible with a `SERVER_0_7` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 7 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_0_7` with the matching field count.



Comparison with similar function blocks

- SERVER_0_7: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_7_0` provides the generic client variant of the `GEN_CLIENT` family tailored to 7 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.31 CLIENT_8

• — ○ • — ○ • — ○ •

Introduction

The `CLIENT_8` function block is the generic client variant with 8 send and 8 receive data fields for communicating with a matching SERVER_8 block. It transmits 8 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8`) to the server and receives 8 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8`) back. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS` and `RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.
- **SD_2** (ANY): Send value 2, transmitted to the server with `REQ`.
- **SD_3** (ANY): Send value 3, transmitted to the server with `REQ`.
- **SD_4** (ANY): Send value 4, transmitted to the server with `REQ`.
- **SD_5** (ANY): Send value 5, transmitted to the server with `REQ`.
- **SD_6** (ANY): Send value 6, transmitted to the server with `REQ`.
- **SD_7** (ANY): Send value 7, transmitted to the server with `REQ`.
- **SD_8** (ANY): Send value 8, transmitted to the server with `REQ`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with `CNF`.
- **RD_2** (ANY): Receive value 2, delivered by the server with `CNF`.
- **RD_3** (ANY): Receive value 3, delivered by the server with `CNF`.
- **RD_4** (ANY): Receive value 4, delivered by the server with `CNF`.
- **RD_5** (ANY): Receive value 5, delivered by the server with `CNF`.
- **RD_6** (ANY): Receive value 6, delivered by the server with `CNF`.
- **RD_7** (ANY): Receive value 7, delivered by the server with `CNF`.
- **RD_8** (ANY): Receive value 8, delivered by the server with `CNF`.

Functionality

`CLIENT_8` initializes a connection to the matching `SERVER_8` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, the values `SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8` are transmitted to the server. Once response data (`RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8`) is available, the block triggers `CNF` and provides `RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8`.

Technical Features

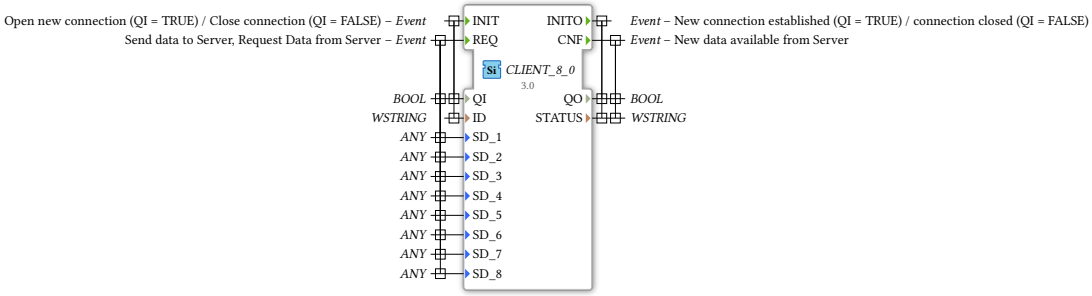
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_8`**: `CLIENT_8` is only functionally compatible with a `SERVER_8` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 8 values and receive exactly 8 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_8 with the matching field count.



Comparison with similar function blocks

- SERVER_8: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

CLIENT_8 provides the generic client variant of the GEN_CLIENT family tailored to 8 send and 8 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.32 CLIENT_8_0

• – ○ • – ○ • – ○ •

Introduction

The CLIENT_8_0 function block is the generic client variant with 8 send and 0 receive data fields for communicating with a matching SERVER_0_8 block. It transmits 8 data values (SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8) to the server without receiving any data back. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with REQ.
- **SD_2** (ANY): Send value 2, transmitted to the server with REQ.
- **SD_3** (ANY): Send value 3, transmitted to the server with REQ.
- **SD_4** (ANY): Send value 4, transmitted to the server with REQ.
- **SD_5** (ANY): Send value 5, transmitted to the server with REQ.
- **SD_6** (ANY): Send value 6, transmitted to the server with REQ.
- **SD_7** (ANY): Send value 7, transmitted to the server with REQ.
- **SD_8** (ANY): Send value 8, transmitted to the server with REQ.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`CLIENT_8_0` receives no payload data via `CNF`, only connection/status information).

Functionality

`CLIENT_8_0` initializes a connection to the matching `SERVER_0_8` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `REQ`, the values `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` are transmitted to the server. Once a response is available, the block triggers `CNF`.

Technical Features

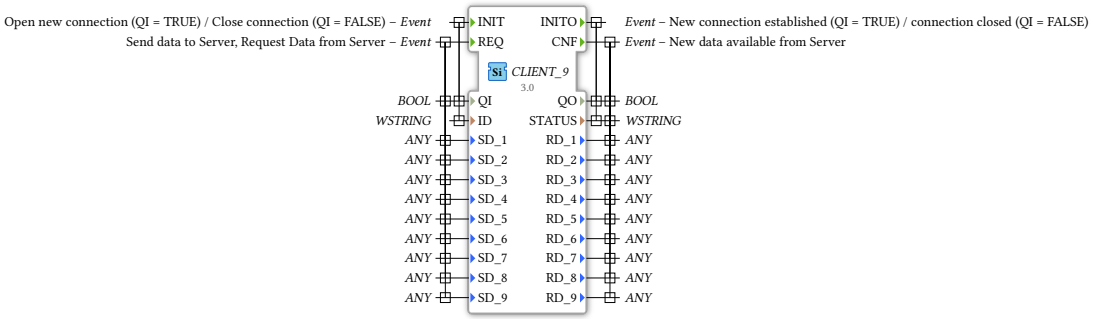
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_CLIENT'`, the same C++ base as all other `CLIENT_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `SERVER_0_8`**: `CLIENT_8_0` is only functionally compatible with a `SERVER_0_8` block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 8 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_0_8` with the matching field count.



Comparison with similar function blocks

- SERVER_0_8: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_8_0` provides the generic client variant of the `GEN_CLIENT` family tailored to 8 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.33 CLIENT_9

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_9` function block is the generic client variant with 9 send and 9 receive data fields for communicating with a matching SERVER_9 block. It transmits 9 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9`) to the server and receives 9 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8`

RD_9) back. Like all CLIENT_* blocks, it is based on the generic GEN_CLIENT implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries QI and ID.
- **REQ**: Sends data to the server and requests data from the server, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **CNF**: Signals that new data is available from the server, carries QO, STATUS and RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with REQ.
- **SD_2** (ANY): Send value 2, transmitted to the server with REQ.
- **SD_3** (ANY): Send value 3, transmitted to the server with REQ.
- **SD_4** (ANY): Send value 4, transmitted to the server with REQ.
- **SD_5** (ANY): Send value 5, transmitted to the server with REQ.
- **SD_6** (ANY): Send value 6, transmitted to the server with REQ.
- **SD_7** (ANY): Send value 7, transmitted to the server with REQ.
- **SD_8** (ANY): Send value 8, transmitted to the server with REQ.
- **SD_9** (ANY): Send value 9, transmitted to the server with REQ.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the server with CNF.
- **RD_2** (ANY): Receive value 2, delivered by the server with CNF.
- **RD_3** (ANY): Receive value 3, delivered by the server with CNF.
- **RD_4** (ANY): Receive value 4, delivered by the server with CNF.
- **RD_5** (ANY): Receive value 5, delivered by the server with CNF.
- **RD_6** (ANY): Receive value 6, delivered by the server with CNF.
- **RD_7** (ANY): Receive value 7, delivered by the server with CNF.
- **RD_8** (ANY): Receive value 8, delivered by the server with CNF.
- **RD_9** (ANY): Receive value 9, delivered by the server with CNF.

Functionality

CLIENT_9 initializes a connection to the matching SERVER_9 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 are transmitted to the server. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9) is available, the block triggers CNF and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9.

Technical Features

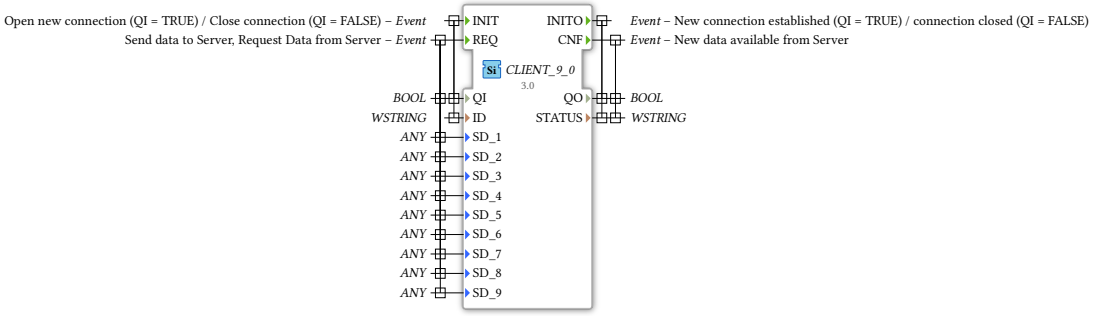
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_9**: CLIENT_9 is only functionally compatible with a SERVER_9 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `REQ`/`CNF` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 9 values and receive exactly 9 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a `SERVER_9` with the matching field count.



Comparison with similar function blocks

- SERVER_9: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`CLIENT_9` provides the generic client variant of the `GEN_CLIENT` family tailored to 9 send and 9 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.34 CLIENT_9_0

• – ○ • – ○ • – ○ •

Introduction

The `CLIENT_9_0` function block is the generic client variant with 9 send and 0 receive data fields for communicating with a matching SERVER_0_9 block. It transmits 9 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9`) to the server without receiving any data back. Like all `CLIENT_*` blocks, it is based on the generic `GEN_CLIENT` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Opens a new connection (QI = TRUE) or closes an existing connection (QI = FALSE), carries `QI` and `ID`.
- **REQ**: Sends data to the server and requests data from the server, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **CNF**: Signals that new data is available from the server, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the server with `REQ`.

- **SD_2** (ANY): Send value 2, transmitted to the server with REQ.
- **SD_3** (ANY): Send value 3, transmitted to the server with REQ.
- **SD_4** (ANY): Send value 4, transmitted to the server with REQ.
- **SD_5** (ANY): Send value 5, transmitted to the server with REQ.
- **SD_6** (ANY): Send value 6, transmitted to the server with REQ.
- **SD_7** (ANY): Send value 7, transmitted to the server with REQ.
- **SD_8** (ANY): Send value 8, transmitted to the server with REQ.
- **SD_9** (ANY): Send value 9, transmitted to the server with REQ.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (CLIENT_9_0 receives no payload data via CNF, only connection/status information).

Functionality

CLIENT_9_0 initializes a connection to the matching SERVER_0_9 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via REQ, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 are transmitted to the server. Once a response is available, the block triggers CNF.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_CLIENT', the same C++ base as all other CLIENT_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart SERVER_0_9**: CLIENT_9_0 is only functionally compatible with a SERVER_0_9 block on the server side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: REQ/CNF cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

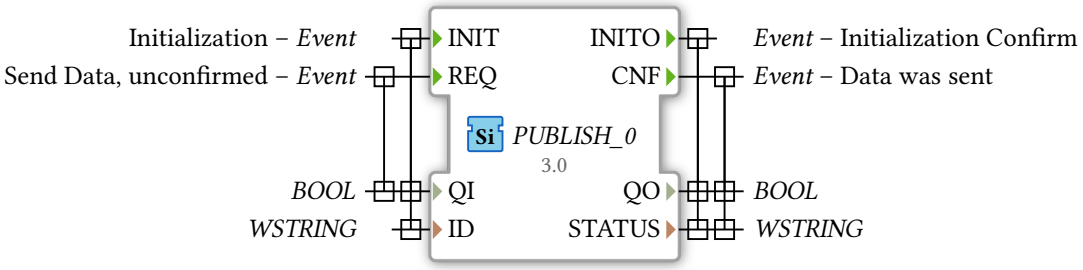
Application Scenarios

- **Communication between distributed control systems** that need to send exactly 9 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Client-side connection** to a communication partner already laid out as a SERVER_0_9 with the matching field count.

Comparison with similar function blocks

- SERVER_0_9: the direct counterpart on the server side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion



CLIENT_9_0 provides the generic client variant of the GEN_CLIENT family tailored to 9 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.35 PUBLISH_0

• − ◦ • − ◦ • − ◦ •

Introduction

The PUBLISH_0 function block is used to publish data to one or more SUBSCRIBE_0 blocks. It enables unacknowledged communication between different components in a 4diac system.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **REQ**: Data transmission request (unacknowledged) with associated data QI

Event Outputs

- **INITO**: Initialization acknowledgment with associated data QO and STATUS
- **CNF**: Data transmission acknowledgment with associated data QO and STATUS

Data Inputs

- **QI** (BOOL): Block activation quality indicator
- **ID** (WSTRING): Communication identification string

Data Outputs

- **QO** (BOOL): Block output quality indicator
- **STATUS** (WSTRING): Status information about the executed operation

Adapters

No adapter interfaces available.

How it Works

The PUBLISH_0 block enables the publication of data via a publish-subscribe pattern. Upon initialization (INIT), the block is configured with a specific ID. Upon a send request (REQ), the data is distributed to all registered subscribers. Communication is unacknowledged, meaning no response is expected from the recipients.

Technical Features

- Uses WSTRING data types for ID and STATUS for international character support
- Implements unconfirmed communication
- Supports multiple subscribers via a single Publish instance
- Generic implementation as GEN_PUBLISH

State Overview

The block goes through the following main states:

1. **Uninitialized**: Block is operational but not configured
2. **Initialized**: Block is configured and ready to send
3. **Ready to Send**: Block can distribute data to subscribers

Application Scenarios

- Distribution of sensor data to multiple processing nodes
- Broadcast of system status information
- Distribution of control commands to multiple actuators
- Data exchange in distributed control systems

⚖️ Comparison with Similar Blocks

Compared to confirmed communication blocks, PUBLISH_0 offers:

- Higher performance through unconfirmed transmission
- Lower latency
- Simpler implementation
- No guarantee of Delivery

Conclusion

The PUBLISH_0 block is an efficient tool for unacknowledged communication in distributed control systems. Its simple interface and support for multiple receivers make it ideal for scenarios where performance is more important than guaranteed delivery.

2.11.6.36 PUBLISH_1

• – ◦ • – ◦ • – ◦ •

Introduction

The PUBLISH_1 function block is used to send data to one or more SUBSCRIBE_1 blocks. It implements a publish-subscribe communication pattern, in which data is distributed to all subscribed recipients without acknowledgment.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **REQ**: Data send request (unacknowledged) with associated data QI and SD_1

Event Outputs

- **INITO**: Initialization acknowledgement with associated data QO and STATUS
- **CNF**: Data sent acknowledgement with associated data QO and STATUS

Data Inputs

- **QI** (BOOL): Qualifier for initialization and operation
- **ID** (WSTRING): Publish channel identifier
- **SD_1** (ANY): Data to be sent (any data type)

Data Outputs

- **QO** (BOOL): Output status qualifier
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

No adapter interfaces are available.

Functionality

The PUBLISH_1 block enables the distribution of data to multiple recipients via a publish-subscribe mechanism. Upon initialization (INIT event), the block is configured with a specific ID. Upon receiving a REQ event, the data passed to SD_1 is sent to all SUBSCRIBE_1 blocks with the same ID. Communication is unacknowledged, meaning no response is expected from the recipients.

Technical Features

- Using the ANY data type for SD_1 allows sending arbitrary data structures
- The WSTRING data type for ID and STATUS supports international character sets
- Unacknowledged communication for reduced latency
- Generic implementation via the GenericClassName attribute

State Overview

1. **Not Initialized**: Block awaits INIT event
2. **Initialized**: Block ready to receive REQ events
3. **Send Active**: Processing REQ events and distributing data

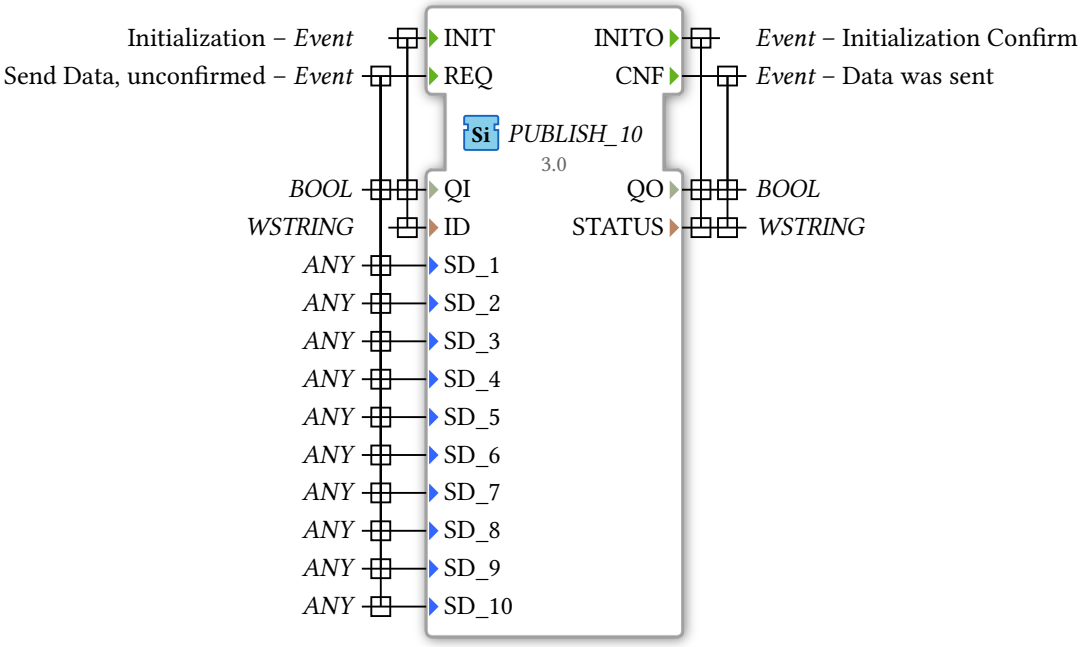
Application Scenarios

- Distributing sensor data to multiple processing nodes
- Broadcasting system status information
- Distributing configuration data to multiple controllers
- Multi-cast communication in distributed automation systems

⚖️ Comparison with Similar Blocks

Compared to acknowledged communication blocks, PUBLISH_1 offers reduced latency through unacknowledged transmission. Compared to point-to-point connections, it enables efficient one-to-many communication without explicitly establishing connections to each recipient.

Conclusion



The PUBLISH_1 block is an efficient tool for unacknowledged one-to-many communication in distributed automation systems. Its flexible data type support and simple configuration make it ideal for scenarios where data needs to be distributed to multiple recipients without requiring acknowledgments.

2.11.6.37 PUBLISH_10

• – ◦ • – ◦ • – ◦ •

Introduction

The PUBLISH_10 function block is used to distribute data to one or more SUBSCRIBE_10 blocks. It enables the unacknowledged transmission of up to 10 different data values using a publish-subscribe communication pattern.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **REQ**: Send request for unacknowledged data transmission with 10 data variables

Event Outputs

- **INITO**: Acknowledgement of initialization with status information
- **CNF**: Acknowledgement that data has been sent

Data Inputs

- **QI** (BOOL): Qualifier for initialization (TRUE = enable, FALSE = disable)
- **ID** (WSTRING): Identification string for the communication channel
- **SD_1** to **SD_10** (ANY): 10 different data values of any type to be sent

Data Outputs

- **QO** (BOOL): Qualifier output (TRUE = successful, FALSE = failed)
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

No adapter interfaces are available.

Functionality

The PUBLISH_10 block operates according to the publish-subscribe principle. After successful initialization with the INIT event, up to 10 different data values can be distributed simultaneously to all registered subscribers via the REQ event. Data transmission is unacknowledged, meaning that the block does not expect any feedback from the recipients.

Technical Features

- Supports up to 10 different data sources simultaneously
- Uses the generic data type ANY for maximum flexibility
- Unicode string support for ID and STATUS
- Unacknowledged communication for reduced latency
- Generic implementation via the GEN_PUBLISH base class

State Overview

1. **Not Initialized**: Block is inactive
2. **Initialized**: Block is ready for data distribution
3. **Ready to Send**: Processes REQ events and distributes data

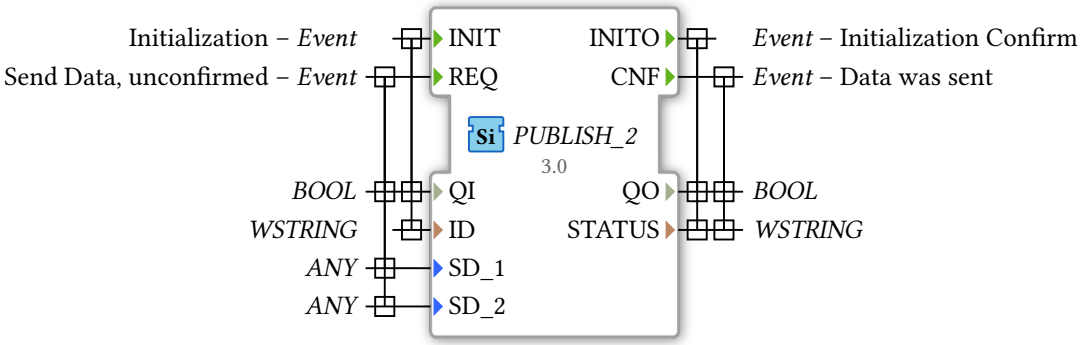
Application Scenarios

- Distribution of sensor data to multiple consumers
- Broadcast communication in distributed systems
- Data distribution in real-time control systems
- Multi-consumer data pipeline architectures

⚖️ Comparison with Similar Blocks

Compared to acknowledged communication blocks, PUBLISH_10 offers reduced latency through unacknowledged transmission. Compared to blocks with fewer data channels, it enables the simultaneous distribution of multiple data streams.

Conclusion



The PUBLISH_10 function block is a powerful solution for unacknowledged multi-data publish-subscribe communication in IEC 61499 systems. Its flexibility in data acquisition and support for up to 10 parallel data channels make it ideal for complex data distribution tasks in industrial automation systems.

2.11.6.38 PUBLISH_2

• – ◦ • – ◦ • – ◦ •

Introduction

The PUBLISH_2 function block is used to send data to one or more SUBSCRIBE_2 blocks. It enables unacknowledged communication between different components in a distributed system.

Interface Structure

Event Inputs

- **INIT**: Initialization event with the associated data QI and ID
- **REQ**: Request event to send data with the associated data QI, SD_1, and SD_2

Event Outputs

- **INITO**: Confirmation of initialization with the associated data QO and STATUS
- **CNF**: Confirmation that data has been sent, with the associated data QO and STATUS

Data Inputs

- **QI** (BOOL): Qualifier for initialization and operation
- **ID** (WSTRING): Identifier for communication
- **SD_1** (ANY): First data value to be sent (any data type)
- **SD_2** (ANY): Second data value to be sent (any data type)

Data Outputs

- **QO** (BOOL): Qualifier for the output state

- **STATUS** (WSTRING): Status information about the operating state

Adapters

No adapters available.

Functionality

The PUBLISH_2 block initializes itself via the INIT event and then sends data via the REQ event. The data SD_1 and SD_2 are distributed to all connected SUBSCRIBE_2 blocks. Communication is unacknowledged, meaning that no response is expected from the receivers.

Technical Features

- Supports any data type for SD_1 and SD_2
- Uses WSTRING for ID and STATUS for international character support
- Unacknowledged communication mode (Publish/Subscribe pattern)
- Flexible data transmission with two separate data channels

State Overview

1. **Not Initialized**: Block waits for INIT event
2. **Initialized**: Block is ready and can process REQ events
3. **Ready to Send**: Processes REQ events and sends data to the subscriber

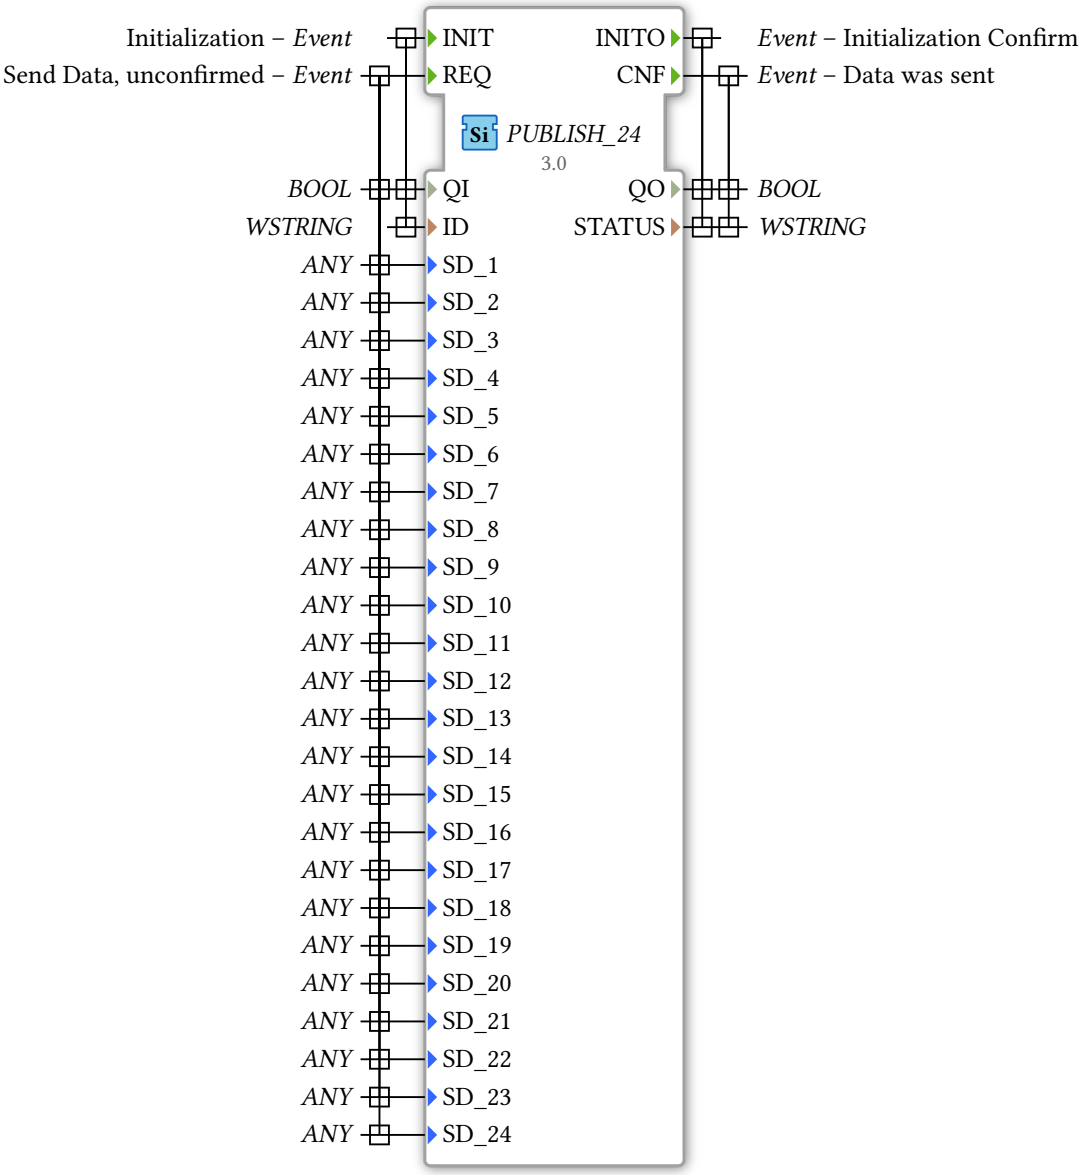
Application Scenarios

- Distributed systems with multiple data receivers
- Real-time data distribution without an acknowledgment mechanism
- Systems with variable data types
- Communication between different control components

⚖️ Comparison with Similar Blocks

Compared to acknowledged communication blocks, PUBLISH_2 offers higher performance but lower reliability. Its support for any data type makes it more flexible than type-specific communication blocks.

Conclusion



The PUBLISH_2 block is an efficient tool for unacknowledged data distribution in distributed systems. Its flexibility in data type support and ease of use make it ideal for scenarios where performance is more important than guaranteed delivery.

2.11.6.39 PUBLISH_24

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `PUBLISH_24` distributes data to one or more `SUBSCRIBE_24` blocks. It allows the unconfirmed transmission of up to 24 data values using a publish-subscribe communication pattern.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation. Associated with `QI`, `ID`.
- **REQ**: send data, unconfirmed. Associated with `QI`, `SD_1` to `SD_24`.

Event Outputs

- **INITO** (`EInit`): initialisation confirm. Associated with `QO`, `STATUS`.
- **CNF**: data was sent. Associated with `QO`, `STATUS`.

Data Inputs

- **QI** (`BOOL`): event input qualifier
- **ID** (`WSTRING`): identification string of the communication channel
- **SD_1** to **SD_24** (`ANY`): data values of any type to send

Data Outputs

- **QO** (`BOOL`): event output qualifier
- **STATUS** (`WSTRING`): status information

Adapters

No adapter interfaces available.

Functionality

After initialisation with `INIT`, `REQ` distributes up to 24 data values to all registered subscribers. The transmission is unconfirmed; `CNF` only reports that the data was sent.

Technical Details

- Generic block (generic class `GEN_PUBLISH`): the number of data ports is 24 here, their types (`ANY`) are fixed at instantiation
- Unicode strings (`WSTRING`) for `ID` and `STATUS`
- Counterpart: `SUBSCRIBE_24` with `RD_1` to `RD_24`

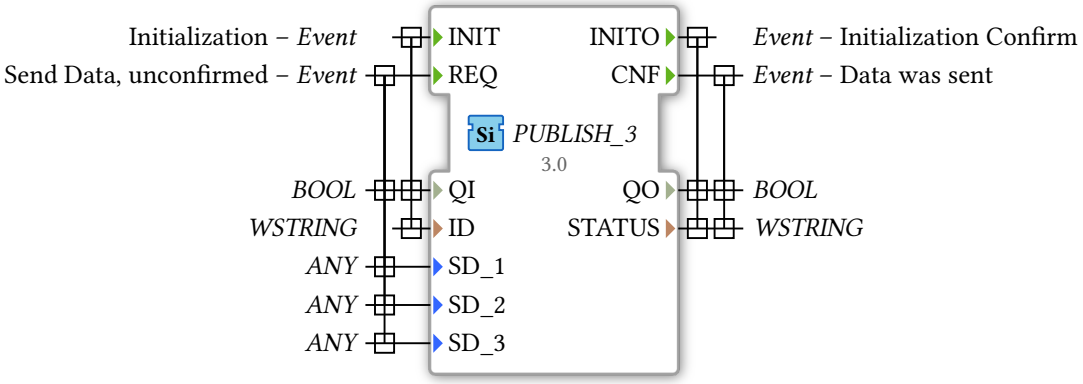
Application Scenarios

- Distributing many related values (e.g. measured values or states) with a single event to other applications or devices

⚖ Comparison with Similar Building Blocks

`PUBLISH_10` transmits up to 10 data values, `PUBLISH_24` up to 24.

Conclusion



`PUBLISH_24` is the unconfirmed publish variant for up to 24 data values.

2.11.6.40 PUBLISH_3

• – ◦ • – ◦ • – ◦ •

Introduction

The PUBLISH_3 function block is used to distribute data to one or more SUBSCRIBE_3 blocks. It enables the unacknowledged transmission of up to three different data values to subscribers in a distributed system.

Interface Structure

Event Inputs

- **INIT**: Initialization event with the associated data QI and ID
- **REQ**: Send request for data (unacknowledged) with the associated data QI, SD_1, SD_2, and SD_3

Event Outputs

- **INITO**: Acknowledgement of initialization with the associated data QO and STATUS
- **CNF**: Acknowledgement that data has been sent, with the associated data QO and STATUS

Data Inputs

- **QI** (BOOL): Qualifier for initialization and send operations
- **ID** (WSTRING): Publisher identifier
- **SD_1** (ANY): First data value to be sent (any data type)

- **SD_2** (ANY): Second data value to be sent (Any data type)
- **SD_3** (ANY): Third data value to be sent (any data type)

Data Outputs

- **QO** (BOOL): Qualifier for output events
- **STATUS** (WSTRING): Status information about the executed operation

Adapters

No adapter interfaces are available.

Functionality

The PUBLISH_3 block is first initialized via the INIT event, where the ID parameter defines the unique identifier for this publisher. After successful initialization, the block acknowledges with INITO. Data can then be sent via the REQ event, with up to three different data values (SD_1, SD_2, SD_3) being transmitted simultaneously. The transmission is unacknowledged, but the block issues a CNF event after sending.

Technical Features

- Supports the ANY data type for all three data channels, offering maximum flexibility in the types of data to be transmitted
- Uses WSTRING for ID and STATUS, thus enabling international character sets
- Unacknowledged communication for reduced latency
- Can distribute data to multiple subscribers simultaneously

State Overview

1. **Not Initialized**: Block is operational but not configured for data exchange
2. **Initialized**: Block is configured and ready to send data
3. **Sending**: Block is processing a send request
4. **Ready**: Block has successfully sent data and is ready for further requests

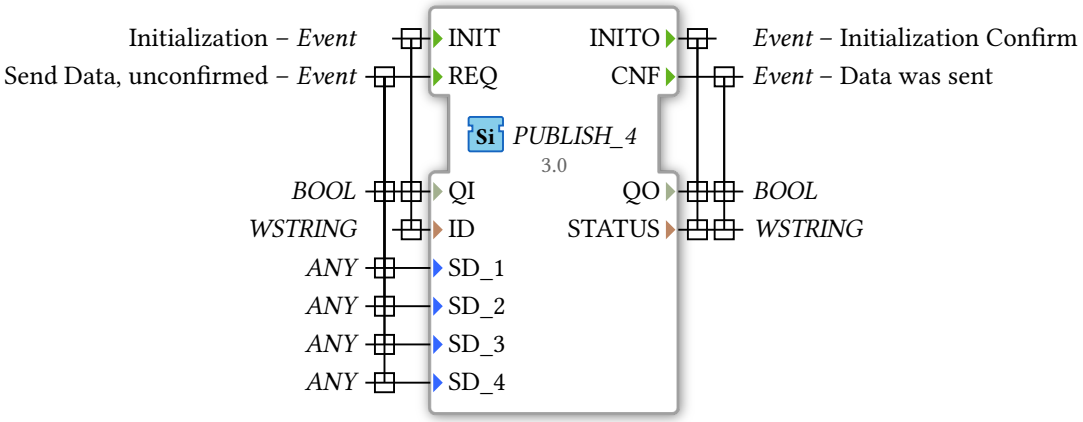
Application Scenarios

- Distribution of sensor data to multiple processing nodes
- Broadcast of control information in distributed systems
- Data distribution in production facilities with multiple consumers
- Measurement distribution in monitoring systems

⚖️ Comparison with Similar Blocks

Compared to simpler PUBLISH blocks, PUBLISH_3 offers the ability to send up to three different data values simultaneously This increases efficiency in systems with multiple related data points. Using ANY data types offers greater flexibility than type-specific implementations.

Conclusion



The PUBLISH_3 function block is a powerful solution for distributing data in distributed automation systems. Its ability to transfer up to three different data values simultaneously, combined with the flexibility of ANY data types, makes it particularly suitable for complex applications where multiple related pieces of information need to be distributed efficiently.

2.11.6.41 PUBLISH_4

• – ◦ • – ◦ • – ◦ •

Introduction

The PUBLISH_4 function block is used to publish data to one or more SUBSCRIBE_4 blocks. It enables the unacknowledged transmission of up to four different data values using a publish-subscribe communication pattern.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **REQ**: Data send request (unacknowledged) with associated data QI, SD_1, SD_2, SD_3, and SD_4

Event Outputs

- **INITO**: Initialization acknowledgement with associated data QO and STATUS
- **CNF**: Data sent acknowledgement with associated data QO and STATUS

Data Inputs

- **QI** (BOOL): Qualifier for initialization and send operations
- **ID** (WSTRING): Identification string for communication
- **SD_1** (ANY): First data value to be sent (any data type)
- **SD_2** (ANY): Second data value to be sent (Any data type)
- **SD_3** (ANY): Third data value to be sent (any data type)
- **SD_4** (ANY): Fourth data value to be sent (any data type)

Data Outputs

- **QO** (BOOL): Qualifier for output events
- **STATUS** (WSTRING): Status information as a wide string

Adapters

No adapter interfaces are available.

Functionality

The PUBLISH_4 block initializes itself via the INIT event and confirms this with INITO. After successful initialization, up to four different data values (SD_1 to SD_4) can be sent simultaneously to all connected SUBSCRIBE_4 blocks via the REQ event. Data transmission is unacknowledged; the block only confirms that the data was sent (CNF), not that it was received.

Technical Features

- Supports any data type (ANY) for all four data channels
- Uses wide strings (WSTRING) for ID and STATUS
- Unacknowledged send mode (fire-and-forget)
- Maximum capacity of four simultaneous data values
- Generic implementation as GEN_PUBLISH

State Overview

1. **Not Initialized**: Block awaits INIT event
2. **Initialized**: Block ready to receive REQ events
3. **Send Active**: Processing REQ events and triggering CNF

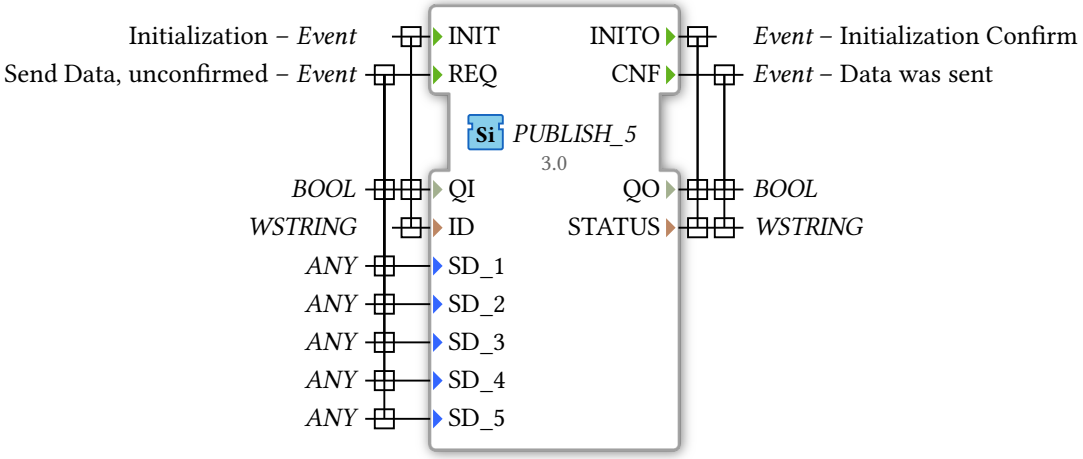
Application Scenarios

- Distributed systems with a publish-subscribe architecture
- Real-time data distribution to multiple receivers
- Systems with unidirectional data communication
- Applications requiring simultaneous transmission of multiple data values

⚖️ Comparison with Similar Blocks

Compared to acknowledged communication blocks, PUBLISH_4 offers lower latency due to its unacknowledged send mode. Compared to blocks with fewer data channels, it enables the simultaneous transmission of up to four different data values.

Conclusion



The PUBLISH_4 function block is an efficient solution for unacknowledged data distribution in distributed systems. Its flexibility in supporting any data type and the ability to send four data values in parallel make it particularly suitable for complex communication scenarios in industrial automation systems.

2.11.6.42 PUBLISH_5

• − ◦ • − ◦ • − ◦ •

Introduction

The PUBLISH_5 function block is used to publish data to one or more SUBSCRIBE_5 blocks. It allows the transmission of up to five different data values using a publish-subscribe communication pattern.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **REQ**: Request event to send data (unacknowledged) with associated data QI, SD_1 to SD_5

Event Outputs

- **INITO**: Acknowledgement of initialization with associated data QO and STATUS
- **CNF**: Acknowledgement that data has been sent with associated data QO and STATUS

Data Inputs

- **QI** (BOOL): Qualifier for initialization/operation
- **ID** (WSTRING): Identifier for the publish channel
- **SD_1** (ANY): First data value to be sent
- **SD_2** (ANY): Second data value to be sent
- **SD_3** (ANY): Third data value to be sent Data Value
- **SD_4** (ANY): Fourth data value to be sent
- **SD_5** (ANY): Fifth data value to be sent

Data Outputs

- **QO** (BOOL): Qualifier for output status
- **STATUS** (WSTRING): Status information about the operation

Adapters

No adapter interfaces are available.

Functionality

The PUBLISH_5 block initializes itself via the INIT event and configures the publish channel with the specified ID. After successful initialization, data can be sent to all connected SUBSCRIBE_5 blocks via the REQ event. Data SD_1 to SD_5 is transmitted simultaneously. Each transmission is acknowledged by a CNF event.

Technical Features

- Supports the ANY data type for maximum flexibility in the data to be sent
- Uses WSTRING for status messages and channel IDs
- Implements an unconfirmed sending procedure
- Provides space for up to five different data values per send

State Overview

1. **Not Initialized**: Block waits for INIT event
2. **Initialized**: Block is ready for REQ events
3. **Send**: Processes REQ and sends data to subscriber
4. **Confirm**: Sends CNF after successful data transmission

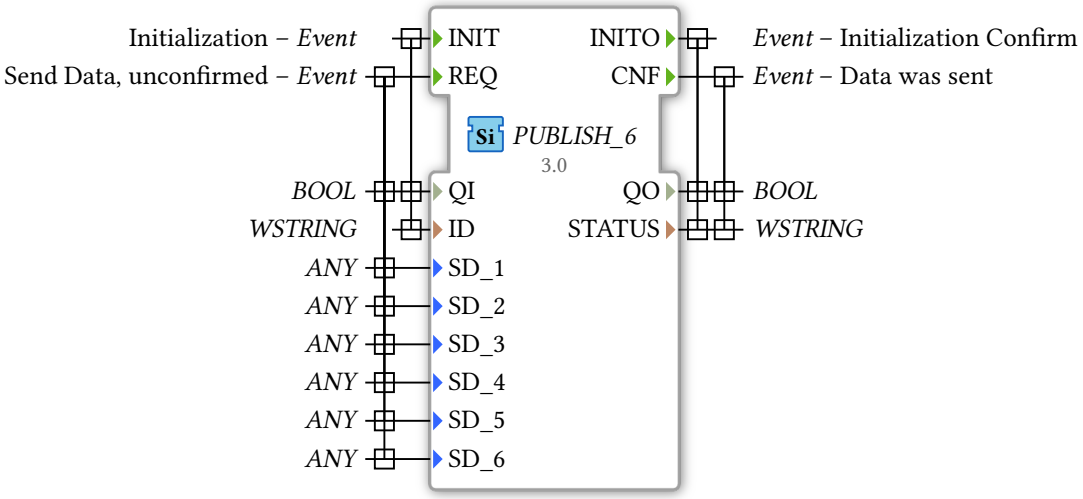
Application Scenarios

- Distributed systems with publisher-subscriber architecture
- Data distribution to multiple receivers in real-time systems
- Flexible messaging between different control components
- Systems with variable data structures (through ANY type support)

⚖️ Comparison with Similar Blocks

Compared to simpler PUBLISH blocks, PUBLISH_5 offers the Ability to send up to five different data values simultaneously. The use of the ANY data type allows for greater flexibility than type-specific publish blocks.

Conclusion



The PUBLISH_5 function block is a powerful solution for publish-subscribe communication in distributed automation systems. Its flexibility, thanks to the ANY data type and the ability to send multiple data values simultaneously, makes it particularly suitable for complex data distribution tasks in industrial control systems.

2.11.6.43 PUBLISH_6

• – ○ • – ○ • – ○ •

Introduction

The PUBLISH_6 function block is used to publish data to one or more SUBSCRIBE_6 blocks. It allows the transmission of up to six different data values via a publish-subscribe communication pattern and offers both acknowledged and unacknowledged send operations.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **REQ**: Data transmission request (unacknowledged) with associated data QI and SD_1 to SD_6

Event Outputs

- **INITO**: Initialization acknowledgment with associated data QO and STATUS
- **CNF**: Acknowledgement that data has been sent, with associated data QO and STATUS

Data Inputs

- **QI** (BOOL): Quality indicator for initialization and transmission operations
- **ID** (WSTRING): Identifier for the communication channel
- **SD_1** to **SD_6** (ANY): Six different data values of any type to be sent

Data Outputs

- **QO** (BOOL): Quality indicator for Output Operations
- **STATUS** (WSTRING): Status information about the executed operation

Adapter

No adapter interfaces are available.

Functionality

The PUBLISH_6 block initializes itself via the INIT event and confirms the initialization with INITO. Data can be sent via the REQ event, with up to six different data values (SD_1 to SD_6) being transmitted simultaneously. A CNF event is issued after successful data transmission. The block supports the publish-subscribe pattern, allowing multiple subscribers to receive the sent data.

Technical Features

- Support for up to six different data values of any type (ANY)
- Use of WSTRING for status messages and channel identification
- Unacknowledged send operations (REQ) with subsequent acknowledgment (CNF)
- Generic implementation for flexible reuse

State Overview

1. **Not Initialized**: Block waits for INIT event
2. **Initialized**: Block ready to receive REQ events
3. **Send Operation**: Processing the send request and data transmission
4. **Acknowledgement**: Output of CNF after successful transmission

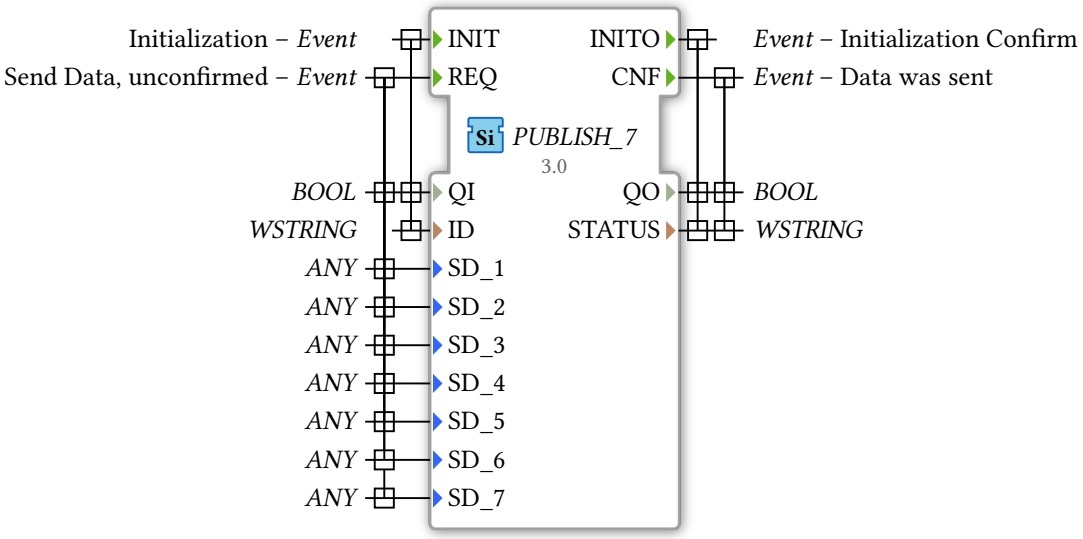
Application Scenarios

- Distribution of sensor data to multiple processing nodes
- Broadcast communication in distributed control systems
- Data distribution in production facilities with multiple consumers
- Flexible messaging in IoT applications

⚖️ Comparison with Similar Blocks

Compared to simpler Publish blocks, PUBLISH_6 offers the ability to simultaneously publish up to six different data values This increases efficiency when transmitting related data. The use of the ANY data type allows for maximum flexibility in the data formats to be transmitted.

Conclusion



The PUBLISH_6 function block is a powerful tool for publish-subscribe communication in distributed automation systems. Its ability to transmit multiple data values simultaneously makes it particularly efficient for applications where related datasets need to be distributed. Flexible type support and robust error handling through status messages make it a reliable solution for industrial communication requirements.

2.11.6.44 PUBLISH_7

• – ◦ • – ◦ • – ◦ •

Introduction

The PUBLISH_7 function block is used to distribute data to one or more SUBSCRIBE_7 blocks. It enables the unacknowledged transmission of up to seven different data values via a publish-subscribe architecture.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **REQ**: Send request for data (unacknowledged) with seven data variables

Event Outputs

- **INITO**: Initialization acknowledgement with QO and STATUS
- **CNF**: Acknowledgement that data has been sent with QO and STATUS

Data Inputs

- **QI** (BOOL): Quality indicator for initialization
- **ID** (WSTRING): Identifier for the publish channel
- **SD_1** to **SD_7** (ANY): Seven different data values of any type

Data Outputs

- **QO** (BOOL): Quality indicator for output state
- **STATUS** (WSTRING): Status information as a Unicode string

Adapter

No adapter interfaces available.

Functionality

The PUBLISH_7 block initializes itself via the INIT event with a specific channel ID. After successful initialization, up to seven data values (SD_1 to SD_7) can be distributed simultaneously to all connected SUBSCRIBE_7 blocks via the REQ event. Data transmission is unacknowledged; the CNF output only confirms that the data was sent, not that it was received.

Technical Features

- Supports the ANY data type for maximum flexibility
- Uses WSTRING for ID and STATUS for international character set support
- Provides seven independent data channels
- Implemented according to the IEC 61499-2 standard
- Uses GenericClassName 'GEN_PUBLISH' for generic implementation

State Overview

1. **Not Initialized**: Block awaits INIT event
2. **Initialized**: Block ready for REQ events
3. **Ready to Send**: Processes REQ events and distributes data

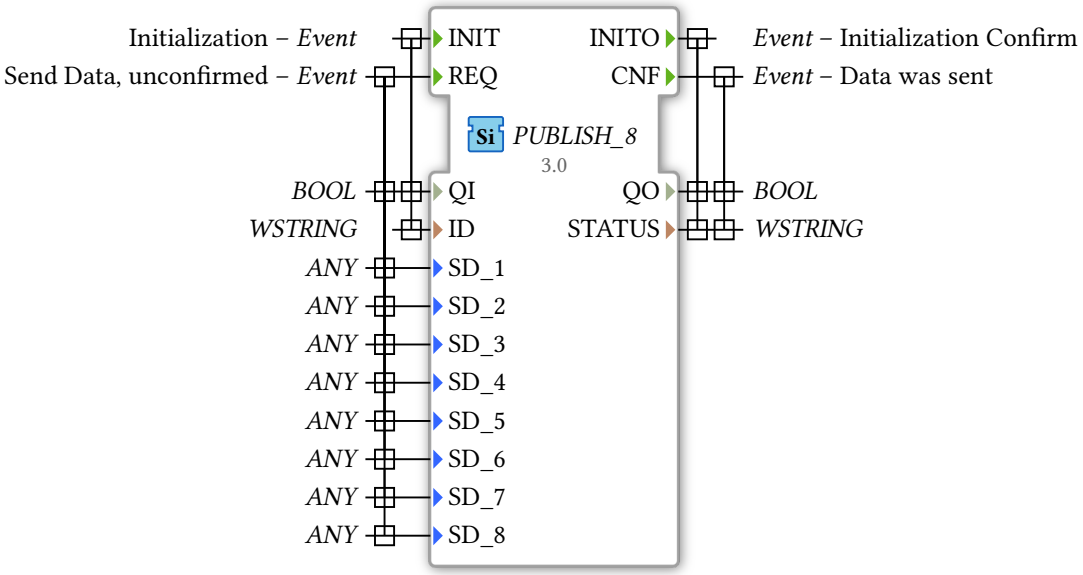
Application Scenarios

- Distribution of sensor data to multiple consumers
- Broadcast communication in distributed systems
- Data distribution in production facilities
- Measurement distribution in monitoring systems

⚖️ Comparison with Similar Blocks

Compared to simpler PUBLISH blocks, PUBLISH_7 offers the ability to distribute seven different data values in parallel, while simpler variants typically support only one or a few data channels.

Conclusion



The PUBLISH_7 function block is a powerful solution for publish-subscribe communication in IEC 61499 systems, which, thanks to its seven parallel data channels and flexibility in data types, is particularly suitable for complex data distribution tasks.

2.11.6.45 PUBLISH_8

• − ◦ • − ◦ • − ◦ •

Introduction

The PUBLISH_8 function block is used to send data to one or more SUBSCRIBE_8 blocks. It implements a publisher-subscriber communication pattern and allows the distribution of up to eight different data values to subscribed recipients.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **REQ**: Send request for data (unacknowledged) with all eight SD_x data values

Event Outputs

- **INITO**: Initialization acknowledgment with QO and STATUS
- **CNF**: Acknowledgement that data has been sent, with QO and STATUS

Data Inputs

- **QI** (BOOL): Qualifier for initialization
- **ID** (WSTRING): Identifier for communication
- **SD_1** to **SD_8** (ANY): Eight different send data of any type

Data Outputs

- **QO** (BOOL): Qualifier for output state
- **STATUS** (WSTRING): Status information

Adapter

No adapter interfaces are available.

Functionality

The PUBLISH_8 block enables data distribution via a publisher-subscriber model. Upon receiving a REQ event, all eight SD_x data values are sent to all subscribed SUBSCRIBE_8 blocks. The INIT initialization configures the block for communication, with the ID parameter serving to identify the publisher.

Technical Features

- Supports up to eight different data values of any type (ANY)
- Uses Wide-String (WSTRING) for ID and STATUS for international character support
- Implements unacknowledged communication (REQ without direct acknowledgment)
- Generic implementation based on GEN_PUBLISH

State Overview

The block has two main states:

1. **Not Initialized**: Block is operational but not configured for communication
2. **Initialized**: Block is configured and can distribute data to subscribers

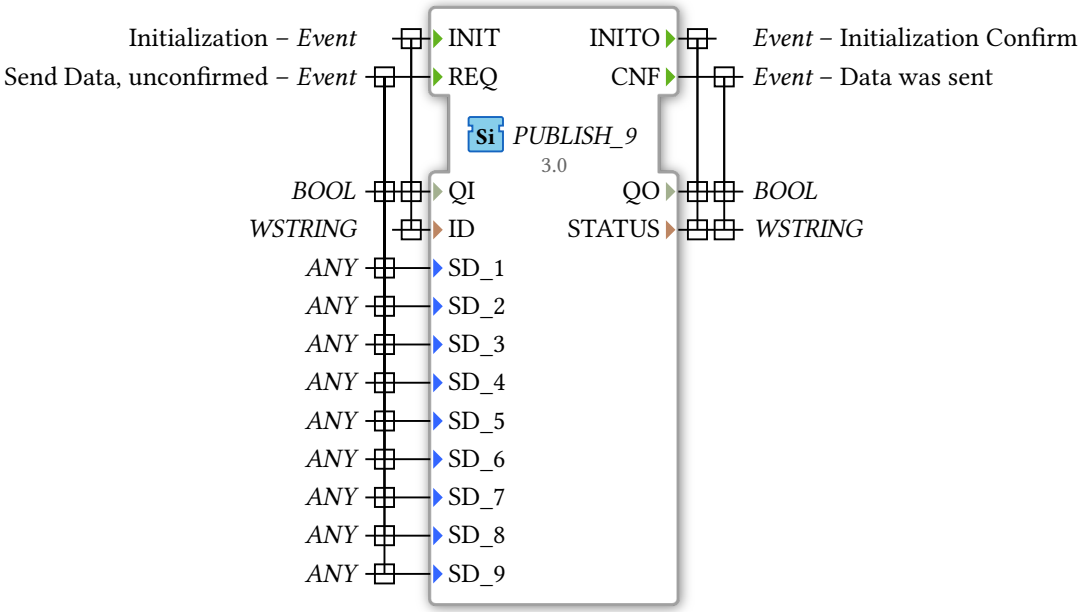
Application Scenarios

- Distribution of process data to multiple display or control systems
- Implementation of data broadcasting in distributed systems
- Use in PLC systems for machine-to-machine communication
- Use in Industry 4.0 applications for flexible data distribution

⚖️ Comparison with Similar Blocks

Compared to simpler PUBLISH blocks, PUBLISH_8 offers the ability to process up to eight different data values in parallel. Distributing data allows for a higher data density per communication cycle. The use of ANY data types offers maximum flexibility in the types of data to be transmitted.

Conclusion



The PUBLISH_8 function block is a powerful solution for distributing multiple data values in distributed automation systems. Its flexibility in data types and support for eight parallel data channels make it ideal for complex communication scenarios in industrial applications.

2.11.6.46 PUBLISH_9

• – ◦ • – ◦ • – ◦ •

Introduction

The PUBLISH_9 function block is used to publish data to one or more SUBSCRIBE_9 blocks. It enables the unacknowledged transmission of up to nine different data values over a communication network.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **REQ**: Send request for unacknowledged data transmission with nine data values

Event Outputs

- **INITO**: Initialization acknowledgment with QO and STATUS
- **CNF**: Acknowledgement that data has been sent, with QO and STATUS

Data Inputs

- **QI** (BOOL): Qualifier for initialization (TRUE = enable, FALSE = disable)
- **ID** (WSTRING): Identifier for the communication channel
- **SD_1** to **SD_9** (ANY): Nine different data values of any type to be sent

Data Outputs

- **QO** (BOOL): Qualifier for output state
- **STATUS** (WSTRING): Status information about the operating state

Adapter

No adapter interfaces are available.

Functionality

The PUBLISH_9 block is first initialized via the INIT event, where the ID parameter defines the communication channel. With the QI input enabled (TRUE), data can be sent via the REQ event. The block transmits all nine SD_x data values simultaneously to all connected SUBSCRIBE_9 blocks. The transmission is unacknowledged, but the CNF event signals successful processing of the send request.

Technical Features

- Supports up to nine different data values of any type (ANY)
- Unacknowledged communication (fire-and-forget principle)
- WSTRING-based channel identification for flexible addressing
- Generic implementation via the GEN_PUBLISH base class

State Overview

The block has two main states: initialized and uninitialized. After successful initialization (INIT with QI=TRUE), the block switches to the active state and can send data. Upon deactivation (INIT with QI=FALSE), the block is deinitialized.

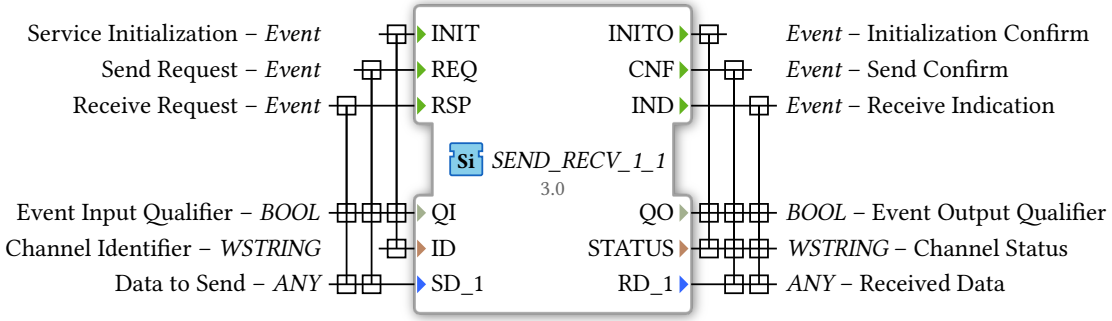
Application Scenarios

- Distributed systems with publisher-subscriber architecture
- Data exchange between different control components
- Broadcast communication in automation networks
- Systems with one-to-many communication relationships

⚖️ Comparison with similar blocks

Compared to acknowledged communication blocks, PUBLISH_9 offers reduced latency by eliminating the need for acknowledgments. Compared to blocks with fewer data channels, it enables the simultaneous transmission of multiple data values, thus increasing system efficiency.

Conclusion



The PUBLISH_9 function block is a powerful solution for unacknowledged multiple data transmissions in distributed automation systems. Its data transmission flexibility and support for nine different data values make it ideal for complex communication scenarios in industrial control systems.

2.11.6.47 SEND_RECV_1_1

• – ◦ • – ◦ • – ◦ •

Introduction

The SEND_RECV_1_1 function block implements a duplex communication interface for bidirectional data exchange over communication channels. The block enables both sending and receiving data over a shared channel and supports generic data types for maximum flexibility.

Interface Structure

Event Inputs
- **INIT**: Service initialization with associated data QI and ID
- **REQ**: Send request with associated data QI and SD_1
- **RSP**: Receive request with associated data QI and SD_1

Event Outputs
- **INITO**: Initialization acknowledgment with QO and STATUS
- **CNF**: Send acknowledgment with QO, STATUS, and RD_1
- **IND**: Receive indication with QO, STATUS, and RD_1

Data Inputs
- **QI** (BOOL): Event input qualifier
- **ID** (WSTRING): Channel identifier
- **SD_1** (ANY): Data to be sent (generic) Data Type)

Data Outputs
- **QO** (BOOL): Event Output Qualifier
- **STATUS** (WSTRING): Channel Status Information
- **RD_1** (ANY): Received Data (generic data type)

Adapter
No adapter interfaces are available.

Functionality
The function block operates as a bidirectional communication interface, initialized via the INIT event input. After successful initialization, data can be sent via REQ and received via RSP. Communication occurs via a channel identified by its ID. The generic ANY data type allows the transmission of any data structure.

Technical Features
- Support for generic data types (ANY) for maximum flexibility
- Bidirectional communication over a shared channel
- Unicode string support for channel IDs and status messages
- Separate qualifiers for input and output events
- Status feedback via WSTRING for detailed error information

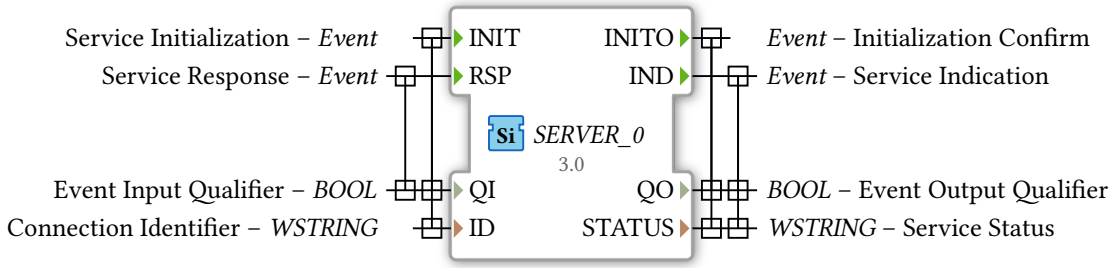
State Overview
The function block goes through the following states:

1. **Not Initialized**: Before INIT call
2. **Initialized**: After successful INIT/INITO sequence
3. **Send Operation**: During REQ/CNF operation
4. **Receive Operation**: During RSP/IND operation

Application Scenarios
- Client-server communication in distributed systems
- Bidirectional data transmission between control components
- Protocol implementations with request-response patterns
- Network communication in industrial automation systems

⚖️ Comparison with Similar Blocks
Compared to simple SEND or SEND_RECV_1_1 offers RECV blocks the combined functionality of both operations in a single block. Its duplex capability distinguishes it from simplex communication blocks and enables more efficient communication patterns.

Conclusion



The SEND_RECV_1_1 function block provides a versatile solution for bidirectional communication requirements in distributed automation systems. By supporting generic data types and offering combined send/receive functionality, it provides an efficient foundation for various communication scenarios.

2.11.6.48 SERVER_0

• – ◦ • – ◦ • – ◦ •

Introduction

The SERVER_0 function block serves as the counterpart to a CLIENT_0 block. It enables the establishment of a server-client connection without exchanging user data via data inputs/outputs.

Interface Structure

Event Inputs

- **INIT** (Type: Event) - Enables the server for a client connection (QI = TRUE) or shuts down the server (QI = FALSE)
- **RSP** (Type: Event) - Sends a response/acknowledgment to the client

Event Outputs

- **INITO** (Type: Event) - Signals readiness for a client connection (QI = TRUE) or a closed state (QI = FALSE)
- **IND** (Type: Event) - Indicates that a request has been received from the client

Data Inputs

- **QI** (BOOL) - Qualifier for the INIT operation
- **ID** (WSTRING) - Identifier for the server instance

Data Outputs

- **QO** (BOOL) - Qualifier for status output
- **STATUS** (WSTRING) - Status Information

Functionality

The SERVER_0 block manages the connection.

1. **Initialization**: Activation via INIT.
2. **Synchronization**:

- When the client sends a request (REQ), the IND event is triggered on the server.
- The server can then respond with RSP, which triggers the CNF event on the client.

No user data (SD_x, RD_x) is transmitted during this process.

Technical Features

- No data inputs/outputs available
- WSTRING type for ID and STATUS
- Generic implementation via the 'GEN_SERVER' class attribute

State Overview

- **Not Initialized**: Server inactive

- **Initialized**: Server ready
- **Indication (IND)**: Client has requested
- **Response (RSP)**: Server responding

Application Scenarios

- Event synchronization
- Signaling of states without data content

2.11.6.49 SERVER_0_1

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_0_1` function block is the generic server variant with 0 send and 1 receive data fields for communicating with a matching CLIENT_1_0 block. It receives 1 data values (`RD_1`) from the client without sending any payload itself. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`SERVER_0_1` transmits no payload data with `RSP`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.

Functionality

SERVER_0_1 initializes a connection to the matching CLIENT_1_0 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, a request without payload is sent. Once response data (RD_1) is available, the block triggers IND and provides RD_1.

Technical Features

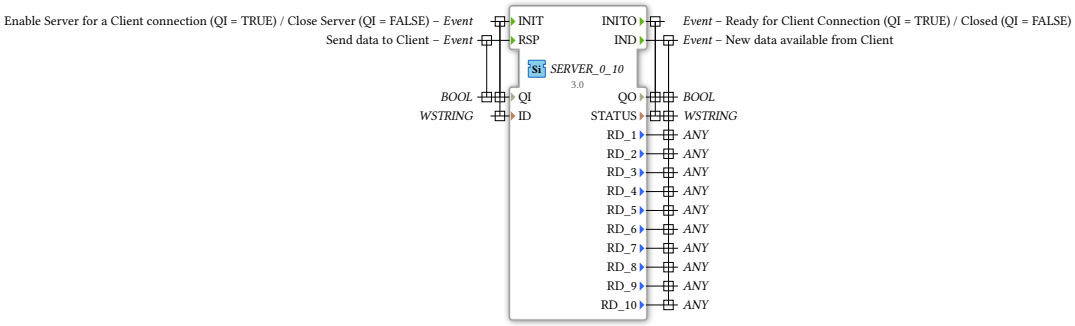
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_1_0**: SERVER_0_1 is only functionally compatible with a CLIENT_1_0 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 1 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_1_0 with the matching field count.



Comparison with similar function blocks

- CLIENT_1_0: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_0_1 provides the generic server variant of the GEN_SERVER family tailored to 0 send and 1 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.50 SERVER_0_10

• – ○ • – ○ • – ○ •

Introduction

The SERVER_0_10 function block is the generic server variant with 0 send and 10 receive data fields for communicating with a matching CLIENT_10_0 block. It receives 10 data values (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9 RD_10) from the client without sending any payload itself. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`SERVER_0_10` transmits no payload data with `RSP`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.
- **RD_4** (ANY): Receive value 4, delivered by the client with `IND`.
- **RD_5** (ANY): Receive value 5, delivered by the client with `IND`.
- **RD_6** (ANY): Receive value 6, delivered by the client with `IND`.
- **RD_7** (ANY): Receive value 7, delivered by the client with `IND`.
- **RD_8** (ANY): Receive value 8, delivered by the client with `IND`.
- **RD_9** (ANY): Receive value 9, delivered by the client with `IND`.
- **RD_10** (ANY): Receive value 10, delivered by the client with `IND`.

Functionality

`SERVER_0_10` initializes a connection to the matching `CLIENT_10_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, a request without payload is sent. Once response data (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`) is available, the block triggers `IND` and provides `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`.

Technical Features

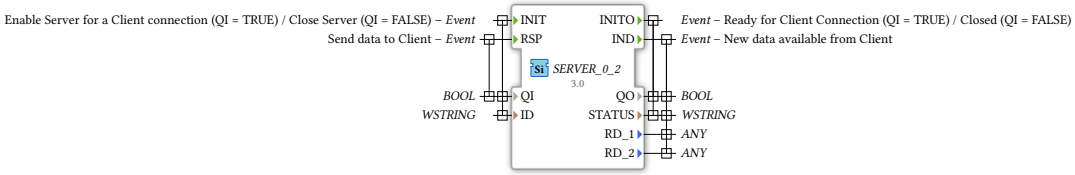
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_10_0`**: `SERVER_0_10` is only functionally compatible with a `CLIENT_10_0` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 10 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_10_0` with the matching field count.



Comparison with similar function blocks

- **CLIENT_10_0**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_0_10 provides the generic server variant of the GEN_SERVER family tailored to 0 send and 10 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.51 SERVER_0_2

• – ○ • – ○ • – ○ •

Introduction

The SERVER_0_2 function block is the generic server variant with 0 send and 2 receive data fields for communicating with a matching CLIENT_2_0 block. It receives 2 data values (RD_1 RD_2) from the client without sending any payload itself. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **IND**: Signals that new data is available from the client, carries QO, STATUS and RD_1 RD_2.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (SERVER_0_2 transmits no payload data with RSP, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with IND.
- **RD_2** (ANY): Receive value 2, delivered by the client with IND.

Functionality

SERVER_0_2 initializes a connection to the matching CLIENT_2_0 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, a request without payload is sent. Once response data (RD_1 RD_2) is available, the block triggers IND and provides RD_1 RD_2.

Technical Features

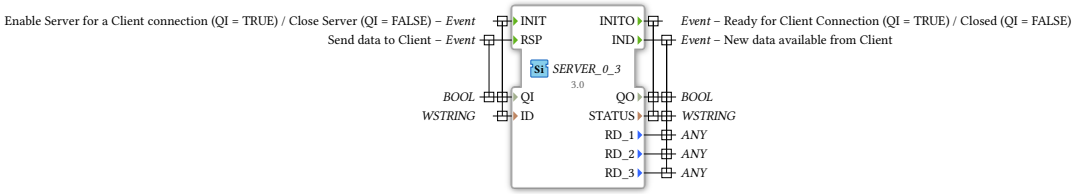
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_2_0**: SERVER_0_2 is only functionally compatible with a CLIENT_2_0 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 2 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_2_0` with the matching field count.



Comparison with similar function blocks

- **CLIENT_2_0**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_0_2` provides the generic server variant of the `GEN_SERVER` family tailored to 0 send and 2 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.52 SERVER_0_3

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_0_3` function block is the generic server variant with 0 send and 3 receive data fields for communicating with a matching CLIENT_3_0 block. It receives 3 data values (`RD_1 RD_2 RD_3`) from the client without sending any payload itself. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1 RD_2 RD_3`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`SERVER_0_3` transmits no payload data with `RSP`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.

- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.

Functionality

`SERVER_0_3` initializes a connection to the matching `CLIENT_3_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, a request without payload is sent. Once response data (`RD_1 RD_2 RD_3`) is available, the block triggers `IND` and provides `RD_1 RD_2 RD_3`.

Technical Features

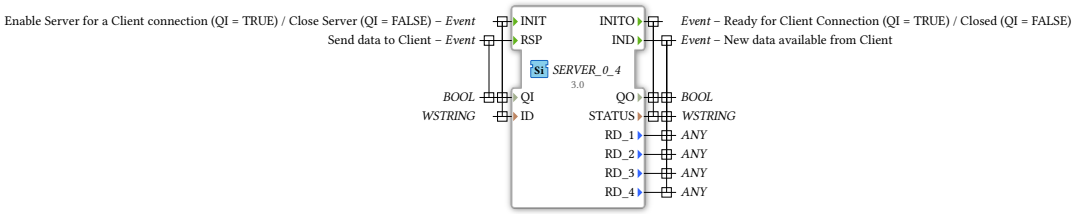
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_3_0`**: `SERVER_0_3` is only functionally compatible with a `CLIENT_3_0` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 3 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_3_0` with the matching field count.



Comparison with similar function blocks

- CLIENT_3_0: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_0_3` provides the generic server variant of the `GEN_SERVER` family tailored to 0 send and 3 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.53 SERVER_0_4

• – ◦ • – ◦ • – ◦ •

Introduction

The `SERVER_0_4` function block is the generic server variant with 0 send and 4 receive data fields for communicating with a matching CLIENT_4_0 block. It receives 4 data values (`RD_1 RD_2 RD_3 RD_4`) from the client without sending any payload itself. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.

- **RSP**: Sends data to the client, carries QI.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **IND**: Signals that new data is available from the client, carries QO, STATUS and RD_1 RD_2 RD_3 RD_4.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (SERVER_0_4 transmits no payload data with RSP, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with IND.
- **RD_2** (ANY): Receive value 2, delivered by the client with IND.
- **RD_3** (ANY): Receive value 3, delivered by the client with IND.
- **RD_4** (ANY): Receive value 4, delivered by the client with IND.

Functionality

SERVER_0_4 initializes a connection to the matching CLIENT_4_0 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, a request without payload is sent. Once response data (RD_1 RD_2 RD_3 RD_4) is available, the block triggers IND and provides RD_1 RD_2 RD_3 RD_4.

Technical Features

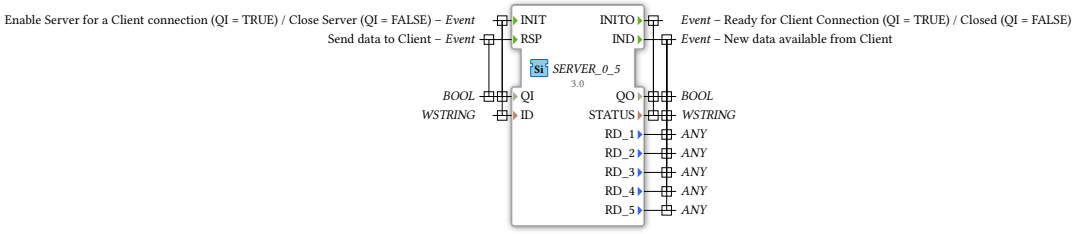
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_4_0**: SERVER_0_4 is only functionally compatible with a CLIENT_4_0 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 4 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_4_0 with the matching field count.



Comparison with similar function blocks

- CLIENT_4_0: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_0_4 provides the generic server variant of the GEN_SERVER family tailored to 0 send and 4 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.54 SERVER_0_5

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_0_5` function block is the generic server variant with 0 send and 5 receive data fields for communicating with a matching CLIENT_5_0 block. It receives 5 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5`) from the client without sending any payload itself. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`SERVER_0_5` transmits no payload data with `RSP`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.
- **RD_4** (ANY): Receive value 4, delivered by the client with `IND`.
- **RD_5** (ANY): Receive value 5, delivered by the client with `IND`.

Functionality

`SERVER_0_5` initializes a connection to the matching `CLIENT_5_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, a request without payload is sent. Once response data (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5`) is available, the block triggers `IND` and provides `RD_1` `RD_2` `RD_3` `RD_4` `RD_5`.

Technical Features

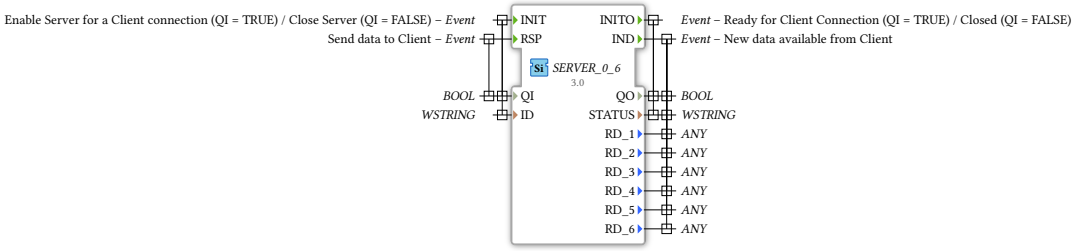
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_5_0`**: `SERVER_0_5` is only functionally compatible with a `CLIENT_5_0` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 5 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_5_0` with the matching field count.



Comparison with similar function blocks

- **CLIENT_5_0**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_0_5` provides the generic server variant of the `GEN_SERVER` family tailored to 0 send and 5 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.55 SERVER_0_6

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_0_6` function block is the generic server variant with 0 send and 6 receive data fields for communicating with a matching CLIENT_6_0 block. It receives 6 data values (`RD_1 RD_2 RD_3 RD_4 RD_5 RD_6`) from the client without sending any payload itself. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1 RD_2 RD_3 RD_4 RD_5 RD_6`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`SERVER_0_6` transmits no payload data with `RSP`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.

- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.
- **RD_4** (ANY): Receive value 4, delivered by the client with `IND`.
- **RD_5** (ANY): Receive value 5, delivered by the client with `IND`.
- **RD_6** (ANY): Receive value 6, delivered by the client with `IND`.

Functionality

`SERVER_0_6` initializes a connection to the matching `CLIENT_6_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, a request without payload is sent. Once response data (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6`) is available, the block triggers `IND` and provides `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6`.

Technical Features

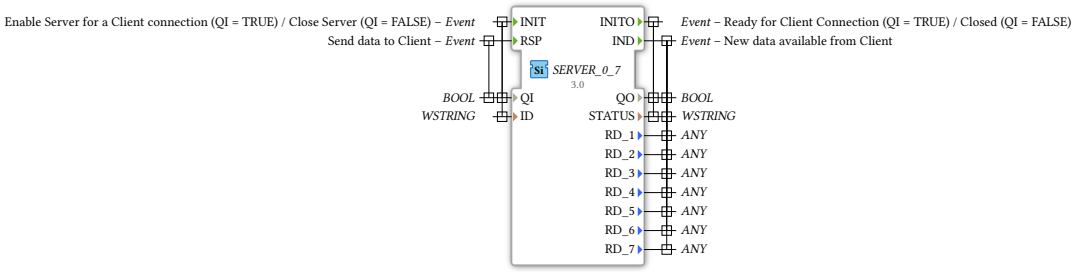
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_6_0`**: `SERVER_0_6` is only functionally compatible with a `CLIENT_6_0` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 6 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_6_0` with the matching field count.



Comparison with similar function blocks

- **CLIENT_6_0**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_0_6` provides the generic server variant of the `GEN_SERVER` family tailored to 0 send and 6 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.56 SERVER_0_7

• – ○ • – ○ • – ○ •

Introduction

The SERVER_0_7 function block is the generic server variant with 0 send and 7 receive data fields for communicating with a matching CLIENT_7_0 block. It receives 7 data values (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7) from the client without sending any payload itself. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **IND**: Signals that new data is available from the client, carries QO, STATUS and RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (SERVER_0_7 transmits no payload data with RSP, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with IND.
- **RD_2** (ANY): Receive value 2, delivered by the client with IND.
- **RD_3** (ANY): Receive value 3, delivered by the client with IND.
- **RD_4** (ANY): Receive value 4, delivered by the client with IND.
- **RD_5** (ANY): Receive value 5, delivered by the client with IND.
- **RD_6** (ANY): Receive value 6, delivered by the client with IND.
- **RD_7** (ANY): Receive value 7, delivered by the client with IND.

Functionality

SERVER_0_7 initializes a connection to the matching CLIENT_7_0 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, a request without payload is sent. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7) is available, the block triggers IND and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_7_0**: SERVER_0_7 is only functionally compatible with a CLIENT_7_0 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

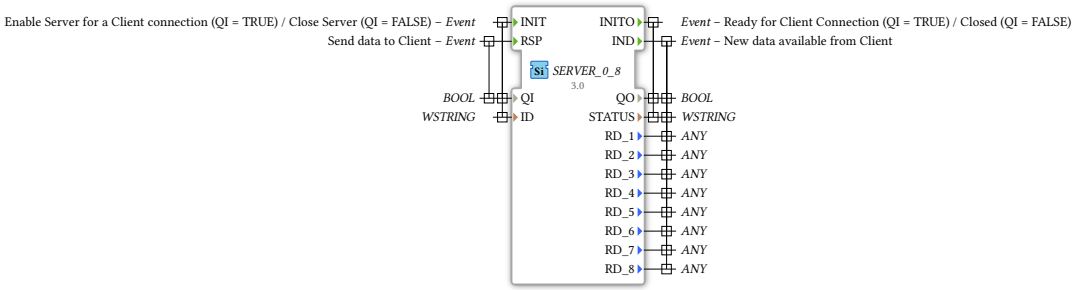
State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 7 values, without carrying unused surplus data fields.

- **Server-side connection** to a communication partner already laid out as a `CLIENT_7_0` with the matching field count.



Comparison with similar function blocks

- **CLIENT_7_0**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_0_7` provides the generic server variant of the `GEN_SERVER` family tailored to 0 send and 7 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.57 SERVER_0_8

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_0_8` function block is the generic server variant with 0 send and 8 receive data fields for communicating with a matching CLIENT_8_0 block. It receives 8 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8`) from the client without sending any payload itself. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`SERVER_0_8` transmits no payload data with `RSP`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.
- **RD_4** (ANY): Receive value 4, delivered by the client with `IND`.
- **RD_5** (ANY): Receive value 5, delivered by the client with `IND`.
- **RD_6** (ANY): Receive value 6, delivered by the client with `IND`.
- **RD_7** (ANY): Receive value 7, delivered by the client with `IND`.
- **RD_8** (ANY): Receive value 8, delivered by the client with `IND`.

Functionality

SERVER_0_8 initializes a connection to the matching CLIENT_8_0 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, a request without payload is sent. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8) is available, the block triggers IND and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8.

Technical Features

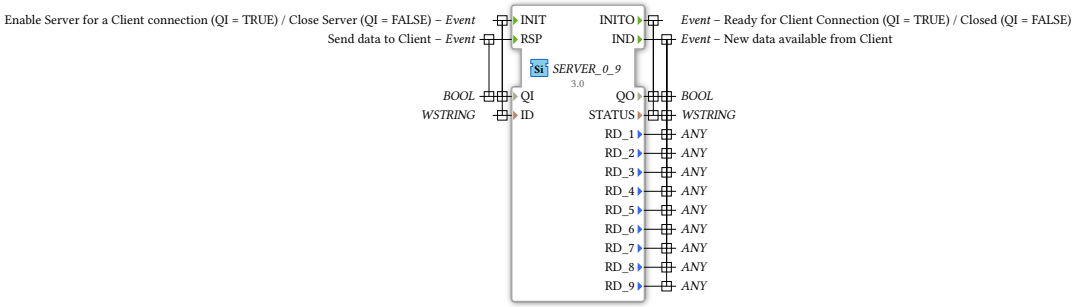
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_8_0**: SERVER_0_8 is only functionally compatible with a CLIENT_8_0 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 8 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_8_0 with the matching field count.



Comparison with similar function blocks

- CLIENT_8_0: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_0_8 provides the generic server variant of the GEN_SERVER family tailored to 0 send and 8 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.58 SERVER_0_9

• – ◦ • – ◦ • – ◦ •

Introduction

The SERVER_0_9 function block is the generic server variant with 0 send and 9 receive data fields for communicating with a matching CLIENT_9_0 block. It receives 9 data values (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9) from the client without sending any payload itself. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- No send fields (`SERVER_0_9` transmits no payload data with `RSP`, only connection control).

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.
- **RD_4** (ANY): Receive value 4, delivered by the client with `IND`.
- **RD_5** (ANY): Receive value 5, delivered by the client with `IND`.
- **RD_6** (ANY): Receive value 6, delivered by the client with `IND`.
- **RD_7** (ANY): Receive value 7, delivered by the client with `IND`.
- **RD_8** (ANY): Receive value 8, delivered by the client with `IND`.
- **RD_9** (ANY): Receive value 9, delivered by the client with `IND`.

Functionality

`SERVER_0_9` initializes a connection to the matching `CLIENT_9_0` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, a request without payload is sent. Once response data (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9`) is available, the block triggers `IND` and provides `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_9_0`**: `SERVER_0_9` is only functionally compatible with a `CLIENT_9_0` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

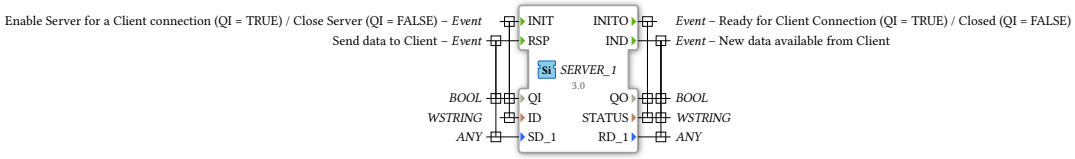
- **Communication between distributed control systems** that need to send exactly 0 values and receive exactly 9 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_9_0` with the matching field count.

Comparison with similar function blocks

- **CLIENT_9_0**: the direct counterpart on the client side, with send/receive field counts swapped.

- **CLIENT_1 / SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion



`SERVER_0_9` provides the generic server variant of the `GEN_SERVER` family tailored to 0 send and 9 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.59 SERVER_1

• – ○ • – ○ • – ○ •

Introduction

The SERVER_1 function block communicates with a CLIENT_1 block and enables the establishment of a server-client connection. The block can receive data from and send data to clients, providing a flexible communication interface for various use cases.

Interface Structure

Event Inputs

- **INIT** (Type: EInit) - Enables the server for a client connection (QI = TRUE) or shuts down the server (QI = FALSE)
- **RSP** (Type: Event) - Sends data to the client

Event Outputs

- **INITO** (Type: EInit) - Signals readiness for a client connection (QI = TRUE) or a closed state (QI = FALSE)
- **IND** (Type: Event) - Displays newly available data from the client

Data Inputs

- **QI** (BOOL) - Qualifier for the INIT operation
- **ID** (WSTRING) - Identifier for the server instance
- **SD_1** (ANY) - Sends data to the client

Data Outputs

- **QO** (BOOL) - Qualifier for status output
- **STATUS** (WSTRING) - Status information
- **RD_1** (ANY) - Data received from the client

Functionality

The SERVER_1 block manages server-client connections through two main operations:

1. **Initialization/Deactivation**: The INIT event with the corresponding QI value activates or deactivates the server. Upon successful operation, INITO is triggered with status information.
2. **Data Communication**:

- Receiving: Incoming data from the client triggers the IND event and is available via RD_1.
- Sending: The RSP event enables sending data via SD_1 to the connected client.

Technical Features

- Using the ANY data type for SD_1 and RD_1 allows for flexible data formats.
- The WSTRING type for ID and STATUS supports Unicode strings.
- Generic implementation via the 'GEN_SERVER' class attribute.
- Package membership: iec61499::net

State Overview

The block can assume the following states:

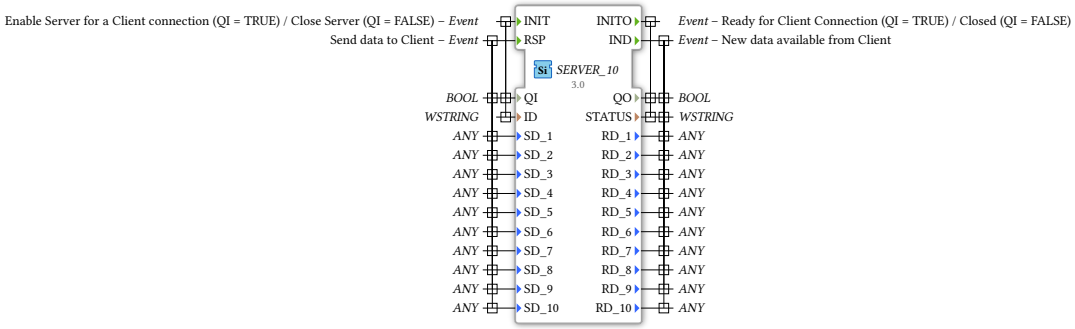
- **Not Initialized**: Server not operational.

- **Initialized**: Server ready for client connections.
- **Data Receiving**: Processing incoming data.
- **Data Sending**: Sending data to the client.

Application Scenarios

- Industrial Automation Systems
- Networked Control Systems
- IoT Communication Applications
- Distributed Control Systems (DCS)
- Machine-to-Machine Communication

⚖️ Comparison with Similar Blocks



Compared to other communication blocks, SERVER_1 offers:

- Specific server functionality for CLIENT_1 blocks
- Flexible data transmission via ANY type
- Explicit initialization and deactivation control
- Status feedback for improved error detection

Conclusion

The SERVER_1 function block represents a robust and flexible solution for server-client communication in distributed automation systems. Its clear interface definition and flexible data type support make it particularly suitable for a wide variety of industrial communication requirements.

2.11.6.60 SERVER_10

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_10` function block is the generic server variant with 10 send and 10 receive data fields for communicating with a matching CLIENT_10 block. It transmits 10 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9` `SD_10`) to the client and receives 10 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`) back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9` `SD_10`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9` `RD_10`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.
- **SD_4** (ANY): Send value 4, transmitted to the client with `RSP`.
- **SD_5** (ANY): Send value 5, transmitted to the client with `RSP`.
- **SD_6** (ANY): Send value 6, transmitted to the client with `RSP`.
- **SD_7** (ANY): Send value 7, transmitted to the client with `RSP`.
- **SD_8** (ANY): Send value 8, transmitted to the client with `RSP`.
- **SD_9** (ANY): Send value 9, transmitted to the client with `RSP`.
- **SD_10** (ANY): Send value 10, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.
- **RD_4** (ANY): Receive value 4, delivered by the client with `IND`.
- **RD_5** (ANY): Receive value 5, delivered by the client with `IND`.
- **RD_6** (ANY): Receive value 6, delivered by the client with `IND`.
- **RD_7** (ANY): Receive value 7, delivered by the client with `IND`.
- **RD_8** (ANY): Receive value 8, delivered by the client with `IND`.
- **RD_9** (ANY): Receive value 9, delivered by the client with `IND`.
- **RD_10** (ANY): Receive value 10, delivered by the client with `IND`.

Functionality

`SERVER_10` initializes a connection to the matching `CLIENT_10` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 SD_10` are transmitted to the client. Once response data (`RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9 RD_10`) is available, the block triggers `IND` and provides `RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9 RD_10`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_10`**: `SERVER_10` is only functionally compatible with a `CLIENT_10` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

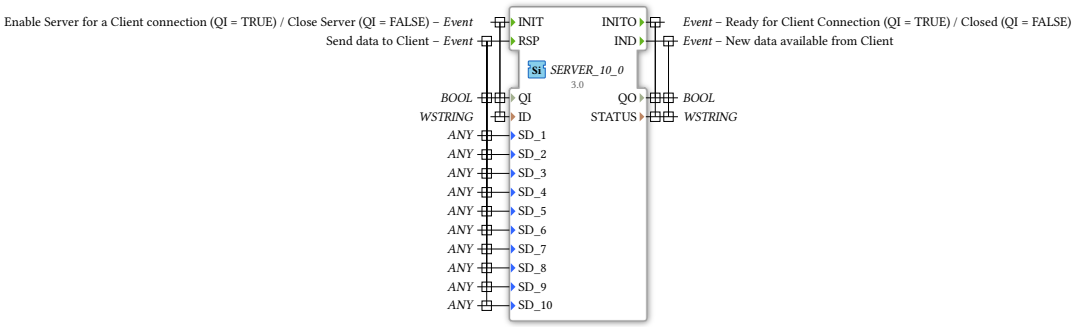
State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 10 values and receive exactly 10 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_10` with the matching field count.

Comparison with similar function blocks



- **CLIENT_10**: the direct counterpart on the client side, with send/receive field counts swapped.

- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_10 provides the generic server variant of the GEN_SERVER family tailored to 10 send and 10 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.61 SERVER_10_0

• – ○ • – ○ • – ○ •

Introduction

The SERVER_10_0 function block is the generic server variant with 10 send and 0 receive data fields for communicating with a matching CLIENT_0_10 block. It transmits 10 data values (SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 SD_10) to the client without receiving any data back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 SD_10.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **IND**: Signals that new data is available from the client, carries QO, STATUS.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with RSP.
- **SD_2** (ANY): Send value 2, transmitted to the client with RSP.
- **SD_3** (ANY): Send value 3, transmitted to the client with RSP.
- **SD_4** (ANY): Send value 4, transmitted to the client with RSP.
- **SD_5** (ANY): Send value 5, transmitted to the client with RSP.
- **SD_6** (ANY): Send value 6, transmitted to the client with RSP.
- **SD_7** (ANY): Send value 7, transmitted to the client with RSP.
- **SD_8** (ANY): Send value 8, transmitted to the client with RSP.
- **SD_9** (ANY): Send value 9, transmitted to the client with RSP.
- **SD_10** (ANY): Send value 10, transmitted to the client with RSP.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (SERVER_10_0 receives no payload data via IND, only connection/status information).

Functionality

SERVER_10_0 initializes a connection to the matching CLIENT_0_10 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 SD_10 are transmitted to the client. Once a response is available, the block triggers IND.

Technical Features

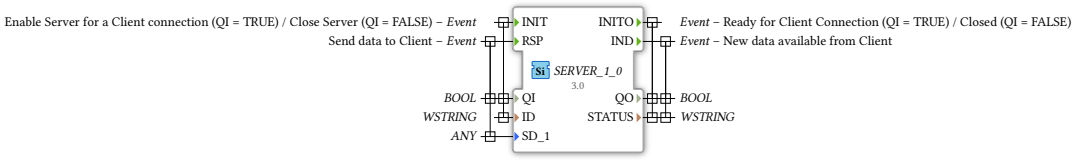
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_0_10**: SERVER_10_0 is only functionally compatible with a CLIENT_0_10 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 10 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_0_10 with the matching field count.



Comparison with similar function blocks

- CLIENT_0_10: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_10_0 provides the generic server variant of the GEN_SERVER family tailored to 10 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.62 SERVER_1_0

• – ○ • – ○ • – ○ •

Introduction

The SERVER_1_0 function block is the generic server variant with 1 send and 0 receive data fields for communicating with a matching CLIENT_0_1 block. It transmits 1 data values (SD_1) to the client without receiving any data back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI and SD_1.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`SERVER_1_0` receives no payload data via `IND`, only connection/status information).

Functionality

`SERVER_1_0` initializes a connection to the matching `CLIENT_0_1` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1` are transmitted to the client. Once a response is available, the block triggers `IND`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_0_1`**: `SERVER_1_0` is only functionally compatible with a `CLIENT_0_1` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

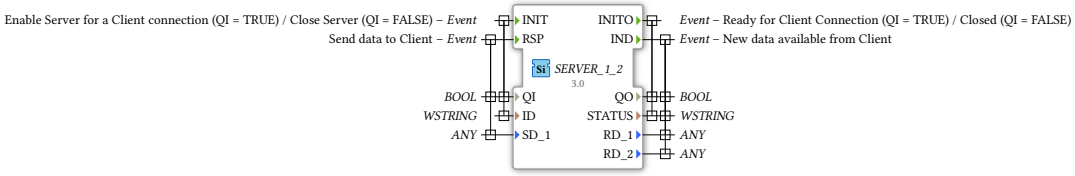
Application Scenarios

- **Communication between distributed control systems** that need to send exactly 1 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_0_1` with the matching field count.

Comparison with similar function blocks

- **CLIENT_0_1**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion



`SERVER_1_0` provides the generic server variant of the `GEN_SERVER` family tailored to 1 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.63 SERVER_1_2

• – ◦ • – ◦ • – ◦ •

Introduction

The SERVER_1_2 function block communicates with a CLIENT_2_1 block and enables the creation of a server-client connection. The block can receive and send data, as well as initialize and terminate the connection.

Interface Structure

Event Inputs

- **INIT**: Initializes the server for a client connection (QI = TRUE) or shuts down the server (QI = FALSE)
- **RSP**: Sends data to the client

Event Outputs

- **INITO**: Signals readiness for a client connection (QI = TRUE) or a closed state (QI = FALSE)
- **IND**: Displays newly available data from the client

Data Inputs

- **QI** (BOOL): Qualifier for the INIT event (TRUE = enable, FALSE = disable)
- **ID** (WSTRING): Identification string for the server instance
- **SD_1** (ANY): Data to be sent to the client

Data Outputs

- **QO** (BOOL): Status output (TRUE = active, FALSE = inactive) (inactive)
- **STATUS** (WSTRING): Status information as a string
- **RD_1** (ANY): Data received from the client (Channel 1)
- **RD_2** (ANY): Data received from the client (Channel 2)

Functionality

The SERVER_1_2 block operates as a server in a client-server architecture. Upon initialization (INIT with QI=TRUE), the server is made available for incoming connections. When data is received from the client, the IND event is triggered, and the received data is made available via RD_1 and RD_2. Data can be sent back to the client via the RSP event.

Technical Features

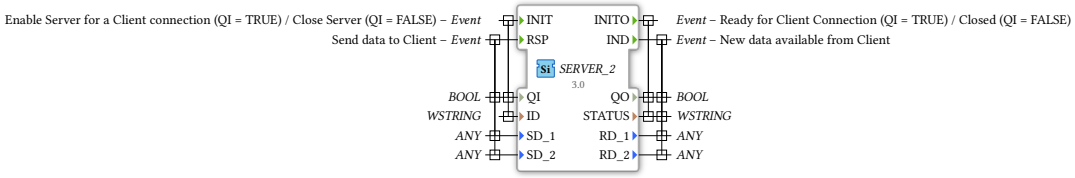
- Supports the ANY data type for flexible data transmission
- Uses WSTRING for status messages and identification
- Provides two separate data channels for receiving (RD_1 and RD_2)
- Implemented as a generic server block

Status Overview

- **Inactive**: Server not initialized (QO = FALSE)
- **Active**: Server ready for client connections (QO = TRUE)
- **Data Receive**: New data available from the client (IND event)
- **Data Send**: Data is being sent to the client (RSP event)

Application Scenarios

- Network communication in distributed automation systems
- Data exchange between different control components
- Implementation of server services in IEC 61499-based systems
- Bidirectional communication in industrial networks



⚖️ Comparison with Similar Blocks

Compared to simpler communication blocks, SERVER_1_2 offers a complete server implementation with Initialization and status management. The two separate receive channels enable structured data processing.

Conclusion

The SERVER_1_2 function block represents a robust solution for server-based communication in IEC 61499 systems. Its flexible data type support and clear state management make it ideally suited for various industrial communication scenarios.

2.11.6.64 SERVER_2

• – ◦ • – ◦ • – ◦ •

Introduction

The `SERVER_2` function block is the generic server variant with 2 send and 2 receive data fields for communicating with a matching CLIENT_2 block. It transmits 2 data values (`SD_1` `SD_2`) to the client and receives 2 data values (`RD_1` `RD_2`) back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1` `SD_2`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1` `RD_2`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.

Functionality

`SERVER_2` initializes a connection to the matching `CLIENT_2` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1` `SD_2` are transmitted to the client. Once response data (`RD_1` `RD_2`) is available, the block triggers `IND` and provides `RD_1` `RD_2`.

Technical Features

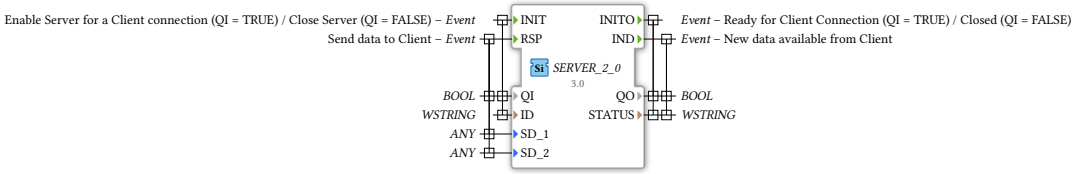
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_2`**: `SERVER_2` is only functionally compatible with a `CLIENT_2` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 2 values and receive exactly 2 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_2` with the matching field count.



Comparison with similar function blocks

- CLIENT_2: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_2` provides the generic server variant of the `GEN_SERVER` family tailored to 2 send and 2 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.65 SERVER_2_0

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_2_0` function block is the generic server variant with 2 send and 0 receive data fields for communicating with a matching CLIENT_0_2 block. It transmits 2 data values (`SD_1` `SD_2`) to the client without receiving any data back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1` `SD_2`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`SERVER_2_0` receives no payload data via `IND`, only connection/status information).

Functionality

SERVER_2_0 initializes a connection to the matching CLIENT_0_2 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 are transmitted to the client. Once a response is available, the block triggers IND.

Technical Features

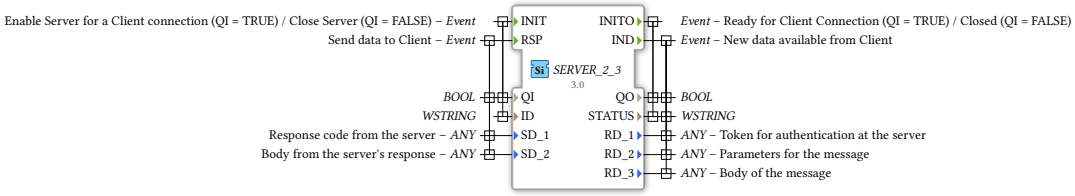
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_0_2**: SERVER_2_0 is only functionally compatible with a CLIENT_0_2 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 2 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_0_2 with the matching field count.



Comparison with similar function blocks

- CLIENT_0_2: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_2_0 provides the generic server variant of the GEN_SERVER family tailored to 2 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.66 SERVER_2_3

• – ○ • – ○ • – ○ •

Introduction

The SERVER_2_3 function block is the generic server variant with 2 send and 3 receive data fields for communicating with a matching CLIENT_3_2 block. It transmits 2 data values (SD_1 SD_2) to the client and receives 3 data values (RD_1 RD_2 RD_3) back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI and SD_1 SD_2.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.

Functionality

`SERVER_2_3` initializes a connection to the matching `CLIENT_3_2` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1` `SD_2` are transmitted to the client. Once response data (`RD_1` `RD_2` `RD_3`) is available, the block triggers `IND` and provides `RD_1` `RD_2` `RD_3`.

Technical Features

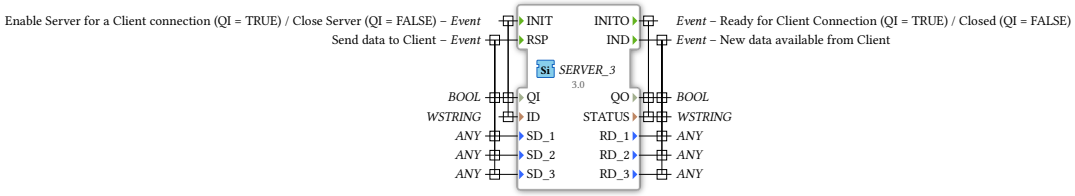
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_3_2`**: `SERVER_2_3` is only functionally compatible with a `CLIENT_3_2` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 2 values and receive exactly 3 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_3_2` with the matching field count.



Comparison with similar function blocks

- CLIENT_3_2: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_2_3` provides the generic server variant of the `GEN_SERVER` family tailored to 2 send and 3 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.67 SERVER_3

• – ◦ • – ◦ • – ◦ •

Introduction

The SERVER_3 function block is the generic server variant with 3 send and 3 receive data fields for communicating with a matching CLIENT_3 block. It transmits 3 data values (SD_1 SD_2 SD_3) to the client and receives 3 data values (RD_1 RD_2 RD_3) back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI and SD_1 SD_2 SD_3.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **IND**: Signals that new data is available from the client, carries QO, STATUS and RD_1 RD_2 RD_3.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with RSP.
- **SD_2** (ANY): Send value 2, transmitted to the client with RSP.
- **SD_3** (ANY): Send value 3, transmitted to the client with RSP.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with IND.
- **RD_2** (ANY): Receive value 2, delivered by the client with IND.
- **RD_3** (ANY): Receive value 3, delivered by the client with IND.

Functionality

SERVER_3 initializes a connection to the matching CLIENT_3 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 SD_3 are transmitted to the client. Once response data (RD_1 RD_2 RD_3) is available, the block triggers IND and provides RD_1 RD_2 RD_3.

Technical Features

- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_3**: SERVER_3 is only functionally compatible with a CLIENT_3 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

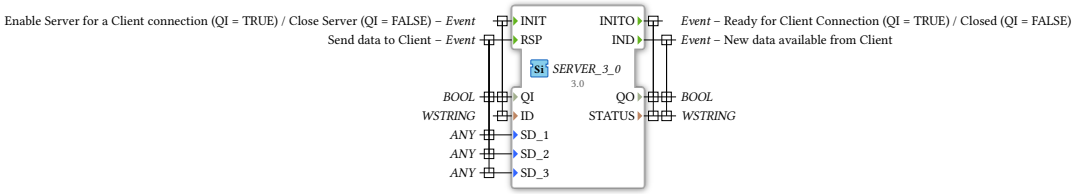
State Overview

1. **Disconnected**: Initial state, QO = FALSE.

2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 3 values and receive exactly 3 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_3` with the matching field count.



Comparison with similar function blocks

- CLIENT_3: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_3` provides the generic server variant of the `GEN_SERVER` family tailored to 3 send and 3 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.68 SERVER_3_0

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_3_0` function block is the generic server variant with 3 send and 0 receive data fields for communicating with a matching CLIENT_0_3 block. It transmits 3 data values (`SD_1 SD_2 SD_3`) to the client without receiving any data back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1 SD_2 SD_3`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`SERVER_3_0` receives no payload data via `IND`, only connection/status information).

Functionality

SERVER_3_0 initializes a connection to the matching CLIENT_0_3 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 SD_3 are transmitted to the client. Once a response is available, the block triggers IND.

Technical Features

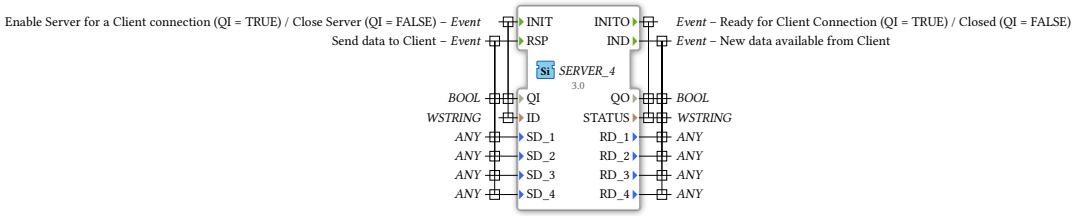
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_0_3**: SERVER_3_0 is only functionally compatible with a CLIENT_0_3 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 3 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_0_3 with the matching field count.



Comparison with similar function blocks

- CLIENT_0_3: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_3_0 provides the generic server variant of the GEN_SERVER family tailored to 3 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.69 SERVER_4

• – ○ • – ○ • – ○ •

Introduction

The SERVER_4 function block is the generic server variant with 4 send and 4 receive data fields for communicating with a matching CLIENT_4 block. It transmits 4 data values (SD_1 SD_2 SD_3 SD_4) to the client and receives 4 data values (RD_1 RD_2 RD_3 RD_4) back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI and SD_1 SD_2 SD_3 SD_4.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.
- **SD_4** (ANY): Send value 4, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.
- **RD_4** (ANY): Receive value 4, delivered by the client with `IND`.

Functionality

`SERVER_4` initializes a connection to the matching `CLIENT_4` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1` `SD_2` `SD_3` `SD_4` are transmitted to the client. Once response data (`RD_1` `RD_2` `RD_3` `RD_4`) is available, the block triggers `IND` and provides `RD_1` `RD_2` `RD_3` `RD_4`.

Technical Features

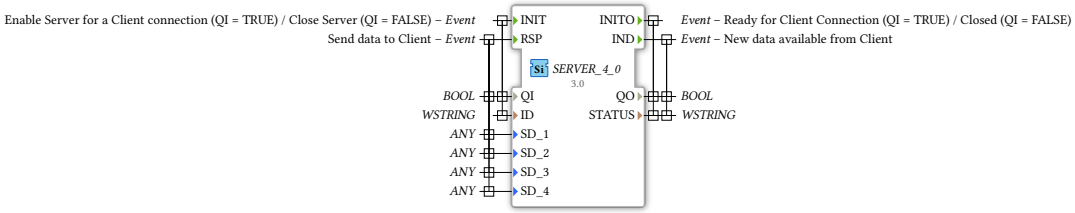
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_4`**: `SERVER_4` is only functionally compatible with a `CLIENT_4` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 4 values and receive exactly 4 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_4` with the matching field count.



Comparison with similar function blocks

- `CLIENT_4`: the direct counterpart on the client side, with send/receive field counts swapped.
- `CLIENT_1` / `SERVER_1`: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_4` provides the generic server variant of the `GEN_SERVER` family tailored to 4 send and 4 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.70 SERVER_4_0

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_4_0` function block is the generic server variant with 4 send and 0 receive data fields for communicating with a matching CLIENT_0_4 block. It transmits 4 data values (`SD_1 SD_2 SD_3 SD_4`) to the client without receiving any data back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1 SD_2 SD_3 SD_4`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.
- **SD_4** (ANY): Send value 4, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`SERVER_4_0` receives no payload data via `IND`, only connection/status information).

Functionality

`SERVER_4_0` initializes a connection to the matching `CLIENT_0_4` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1 SD_2 SD_3 SD_4` are transmitted to the client. Once a response is available, the block triggers `IND`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_0_4`**: `SERVER_4_0` is only functionally compatible with a `CLIENT_0_4` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

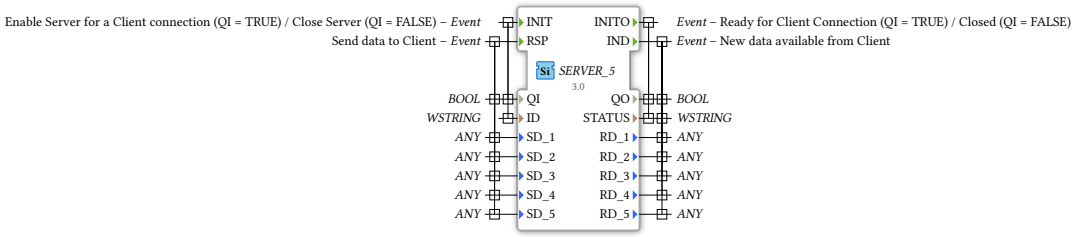
State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.

4. **Data exchange**: `RSP/IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 4 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_0_4` with the matching field count.



Comparison with similar function blocks

- **CLIENT_0_4**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_4_0` provides the generic server variant of the `GEN_SERVER` family tailored to 4 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.71 SERVER_5

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_5` function block is the generic server variant with 5 send and 5 receive data fields for communicating with a matching CLIENT_5 block. It transmits 5 data values (`SD_1 SD_2 SD_3 SD_4 SD_5`) to the client and receives 5 data values (`RD_1 RD_2 RD_3 RD_4 RD_5`) back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1 SD_2 SD_3 SD_4 SD_5`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1 RD_2 RD_3 RD_4 RD_5`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.
- **SD_4** (ANY): Send value 4, transmitted to the client with `RSP`.
- **SD_5** (ANY): Send value 5, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.

- **RD_2** (ANY): Receive value 2, delivered by the client with IND.
- **RD_3** (ANY): Receive value 3, delivered by the client with IND.
- **RD_4** (ANY): Receive value 4, delivered by the client with IND.
- **RD_5** (ANY): Receive value 5, delivered by the client with IND.

Functionality

SERVER_5 initializes a connection to the matching CLIENT_5 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 SD_3 SD_4 SD_5 are transmitted to the client. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5) is available, the block triggers IND and provides RD_1 RD_2 RD_3 RD_4 RD_5.

Technical Features

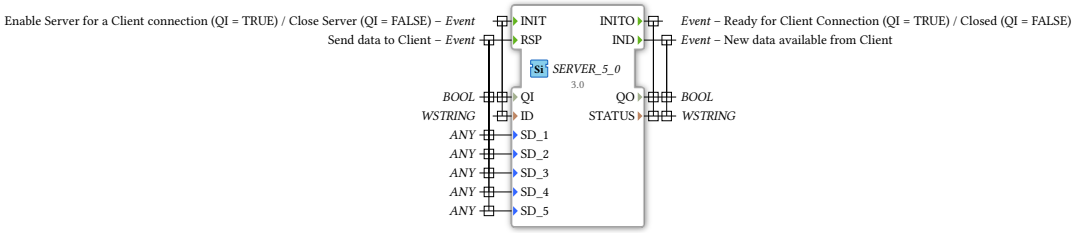
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_5**: SERVER_5 is only functionally compatible with a CLIENT_5 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 5 values and receive exactly 5 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_5 with the matching field count.



Comparison with similar function blocks

- CLIENT_5: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_5 provides the generic server variant of the GEN_SERVER family tailored to 5 send and 5 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.72 SERVER_5_0

• – ○ • – ○ • – ○ •

Introduction

The SERVER_5_0 function block is the generic server variant with 5 send and 0 receive data fields for communicating with a matching CLIENT_0_5 block. It transmits 5 data values (SD_1 SD_2 SD_3 SD_4 SD_5) to the client without receiving any data back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4` `SD_5`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.
- **SD_4** (ANY): Send value 4, transmitted to the client with `RSP`.
- **SD_5** (ANY): Send value 5, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`SERVER_5_0` receives no payload data via `IND`, only connection/status information).

Functionality

`SERVER_5_0` initializes a connection to the matching `CLIENT_0_5` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` are transmitted to the client. Once a response is available, the block triggers `IND`.

Technical Features

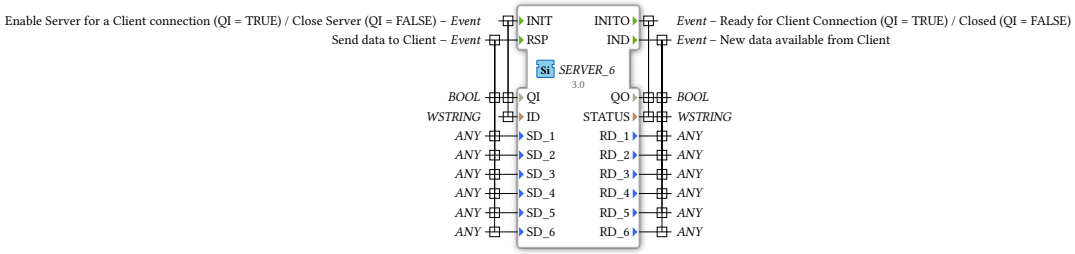
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_0_5`**: `SERVER_5_0` is only functionally compatible with a `CLIENT_0_5` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 5 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_0_5` with the matching field count.



Comparison with similar function blocks

- **CLIENT_0_5**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_5_0` provides the generic server variant of the `GEN_SERVER` family tailored to 5 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.73 SERVER_6

• – ○ • – ○ • – ○ •

Introduction

The SERVER_6 function block is the generic server variant with 6 send and 6 receive data fields for communicating with a matching CLIENT_6 block. It transmits 6 data values (SD_1 SD_2 SD_3 SD_4 SD_5 SD_6) to the client and receives 6 data values (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6) back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **IND**: Signals that new data is available from the client, carries QO, STATUS and RD_1 RD_2 RD_3 RD_4 RD_5 RD_6.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with RSP.
- **SD_2** (ANY): Send value 2, transmitted to the client with RSP.
- **SD_3** (ANY): Send value 3, transmitted to the client with RSP.
- **SD_4** (ANY): Send value 4, transmitted to the client with RSP.
- **SD_5** (ANY): Send value 5, transmitted to the client with RSP.
- **SD_6** (ANY): Send value 6, transmitted to the client with RSP.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with IND.
- **RD_2** (ANY): Receive value 2, delivered by the client with IND.
- **RD_3** (ANY): Receive value 3, delivered by the client with IND.
- **RD_4** (ANY): Receive value 4, delivered by the client with IND.
- **RD_5** (ANY): Receive value 5, delivered by the client with IND.
- **RD_6** (ANY): Receive value 6, delivered by the client with IND.

Functionality

SERVER_6 initializes a connection to the matching CLIENT_6 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 are transmitted to the client. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6) is available, the block triggers IND and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6.

Technical Features

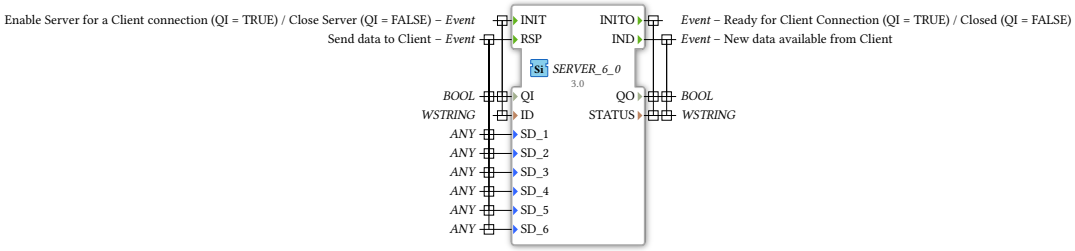
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_6`**: `SERVER_6` is only functionally compatible with a `CLIENT_6` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 6 values and receive exactly 6 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_6` with the matching field count.



Comparison with similar function blocks

- CLIENT_6: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_6` provides the generic server variant of the `GEN_SERVER` family tailored to 6 send and 6 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.74 SERVER_6_0

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_6_0` function block is the generic server variant with 6 send and 0 receive data fields for communicating with a matching CLIENT_0_6 block. It transmits 6 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6`) to the client without receiving any data back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with RSP.
- **SD_2** (ANY): Send value 2, transmitted to the client with RSP.
- **SD_3** (ANY): Send value 3, transmitted to the client with RSP.
- **SD_4** (ANY): Send value 4, transmitted to the client with RSP.
- **SD_5** (ANY): Send value 5, transmitted to the client with RSP.
- **SD_6** (ANY): Send value 6, transmitted to the client with RSP.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (SERVER_6_0 receives no payload data via IND, only connection/status information).

Functionality

SERVER_6_0 initializes a connection to the matching CLIENT_0_6 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 are transmitted to the client. Once a response is available, the block triggers IND.

Technical Features

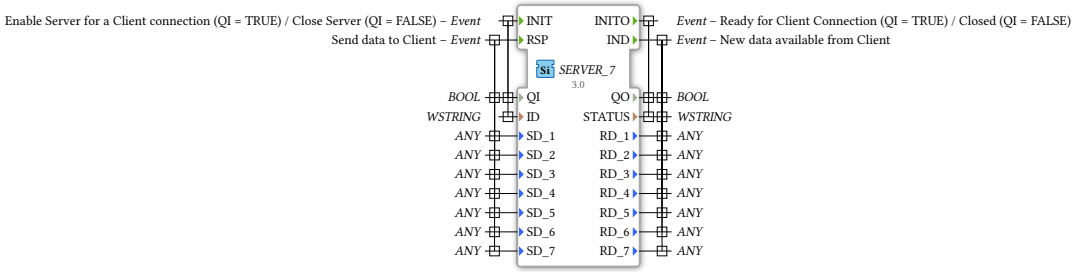
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_0_6**: SERVER_6_0 is only functionally compatible with a CLIENT_0_6 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 6 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_0_6 with the matching field count.



Comparison with similar function blocks

- **CLIENT_0_6**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_6_0 provides the generic server variant of the GEN_SERVER family tailored to 6 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.75 SERVER_7

• – ○ • – ○ • – ○ •

Introduction

The `SERVER_7` function block is the generic server variant with 7 send and 7 receive data fields for communicating with a matching CLIENT_7 block. It transmits 7 data values (`SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7`) to the client and receives 7 data values (`RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7`) back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.
- **SD_4** (ANY): Send value 4, transmitted to the client with `RSP`.
- **SD_5** (ANY): Send value 5, transmitted to the client with `RSP`.
- **SD_6** (ANY): Send value 6, transmitted to the client with `RSP`.
- **SD_7** (ANY): Send value 7, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.
- **RD_4** (ANY): Receive value 4, delivered by the client with `IND`.
- **RD_5** (ANY): Receive value 5, delivered by the client with `IND`.
- **RD_6** (ANY): Receive value 6, delivered by the client with `IND`.
- **RD_7** (ANY): Receive value 7, delivered by the client with `IND`.

Functionality

`SERVER_7` initializes a connection to the matching `CLIENT_7` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7` are transmitted to the client. Once response data (`RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7`) is available, the block triggers `IND` and provides `RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7`.

Technical Features

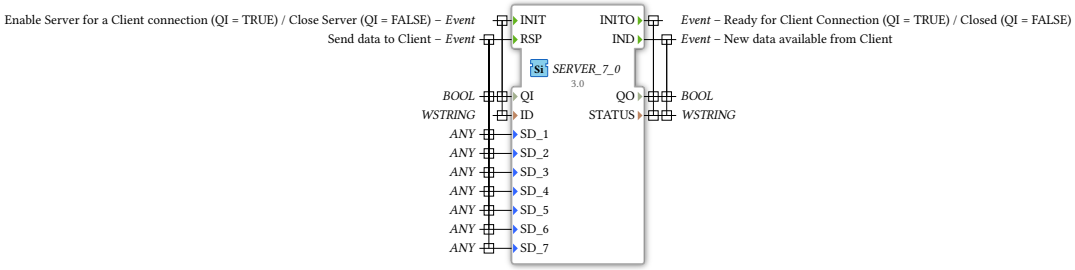
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_7`**: `SERVER_7` is only functionally compatible with a `CLIENT_7` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 7 values and receive exactly 7 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_7` with the matching field count.



Comparison with similar function blocks

- CLIENT_7: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_7` provides the generic server variant of the `GEN_SERVER` family tailored to 7 send and 7 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.76 SERVER_7_0

• – ◦ • – ◦ • – ◦ •

Introduction

The `SERVER_7_0` function block is the generic server variant with 7 send and 0 receive data fields for communicating with a matching CLIENT_0_7 block. It transmits 7 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7`) to the client without receiving any data back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with RSP.
- **SD_2** (ANY): Send value 2, transmitted to the client with RSP.
- **SD_3** (ANY): Send value 3, transmitted to the client with RSP.
- **SD_4** (ANY): Send value 4, transmitted to the client with RSP.
- **SD_5** (ANY): Send value 5, transmitted to the client with RSP.
- **SD_6** (ANY): Send value 6, transmitted to the client with RSP.
- **SD_7** (ANY): Send value 7, transmitted to the client with RSP.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (SERVER_7_0 receives no payload data via IND, only connection/status information).

Functionality

SERVER_7_0 initializes a connection to the matching CLIENT_0_7 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 are transmitted to the client. Once a response is available, the block triggers IND.

Technical Features

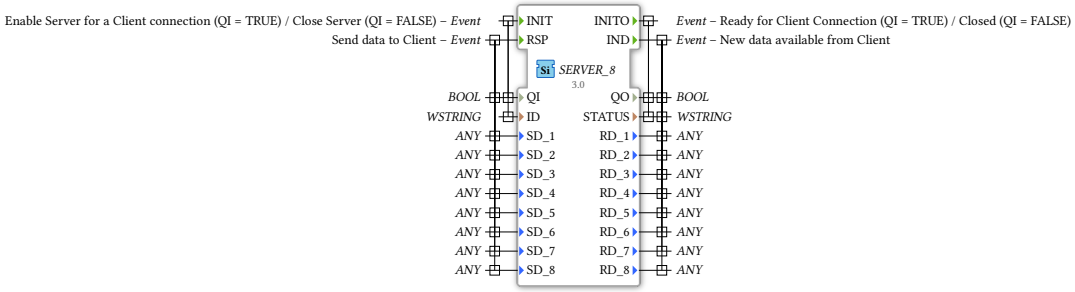
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_0_7**: SERVER_7_0 is only functionally compatible with a CLIENT_0_7 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 7 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_0_7 with the matching field count.



Comparison with similar function blocks

- CLIENT_0_7: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_7_0 provides the generic server variant of the GEN_SERVER family tailored to 7 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.77 SERVER_8

• – ○ • – ○ • – ○ •

Introduction

The SERVER_8 function block is the generic server variant with 8 send and 8 receive data fields for communicating with a matching CLIENT_8 block. It transmits 8 data values (SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8) to the client and receives 8 data values (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8) back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries QO and STATUS.
- **IND**: Signals that new data is available from the client, carries QO, STATUS and RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8.

Data Inputs

- **QI** (BOOL): Controls the connection state (TRUE = open connection, FALSE = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with RSP.
- **SD_2** (ANY): Send value 2, transmitted to the client with RSP.
- **SD_3** (ANY): Send value 3, transmitted to the client with RSP.
- **SD_4** (ANY): Send value 4, transmitted to the client with RSP.
- **SD_5** (ANY): Send value 5, transmitted to the client with RSP.
- **SD_6** (ANY): Send value 6, transmitted to the client with RSP.
- **SD_7** (ANY): Send value 7, transmitted to the client with RSP.
- **SD_8** (ANY): Send value 8, transmitted to the client with RSP.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with IND.
- **RD_2** (ANY): Receive value 2, delivered by the client with IND.
- **RD_3** (ANY): Receive value 3, delivered by the client with IND.
- **RD_4** (ANY): Receive value 4, delivered by the client with IND.
- **RD_5** (ANY): Receive value 5, delivered by the client with IND.
- **RD_6** (ANY): Receive value 6, delivered by the client with IND.
- **RD_7** (ANY): Receive value 7, delivered by the client with IND.
- **RD_8** (ANY): Receive value 8, delivered by the client with IND.

Functionality

SERVER_8 initializes a connection to the matching CLIENT_8 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 SD_3 SD_4 SD_5

SD_6 SD_7 SD_8 are transmitted to the client. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8) is available, the block triggers IND and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8.

Technical Features

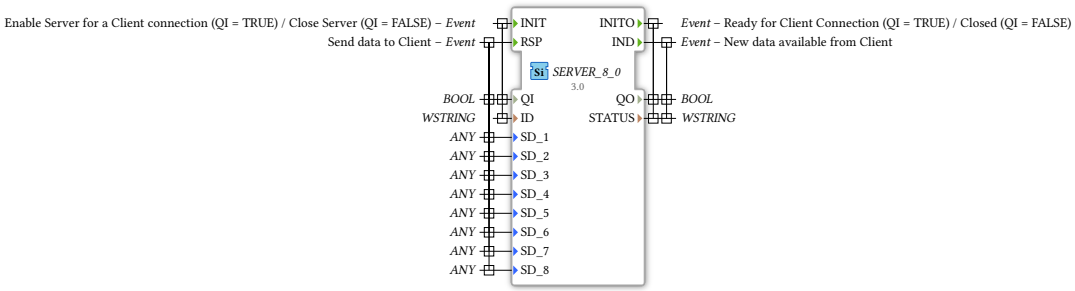
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_8**: SERVER_8 is only functionally compatible with a CLIENT_8 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 8 values and receive exactly 8 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_8 with the matching field count.



Comparison with similar function blocks

- CLIENT_8: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_8 provides the generic server variant of the GEN_SERVER family tailored to 8 send and 8 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.78 SERVER_8_0

• – ○ • – ○ • – ○ •

Introduction

The SERVER_8_0 function block is the generic server variant with 8 send and 0 receive data fields for communicating with a matching CLIENT_0_8 block. It transmits 8 data values (SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8) to the client without receiving any data back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries QI and ID.
- **RSP**: Sends data to the client, carries QI and SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.
- **SD_4** (ANY): Send value 4, transmitted to the client with `RSP`.
- **SD_5** (ANY): Send value 5, transmitted to the client with `RSP`.
- **SD_6** (ANY): Send value 6, transmitted to the client with `RSP`.
- **SD_7** (ANY): Send value 7, transmitted to the client with `RSP`.
- **SD_8** (ANY): Send value 8, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`SERVER_8_0` receives no payload data via `IND`, only connection/status information).

Functionality

`SERVER_8_0` initializes a connection to the matching `CLIENT_0_8` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` are transmitted to the client. Once a response is available, the block triggers `IND`.

Technical Features

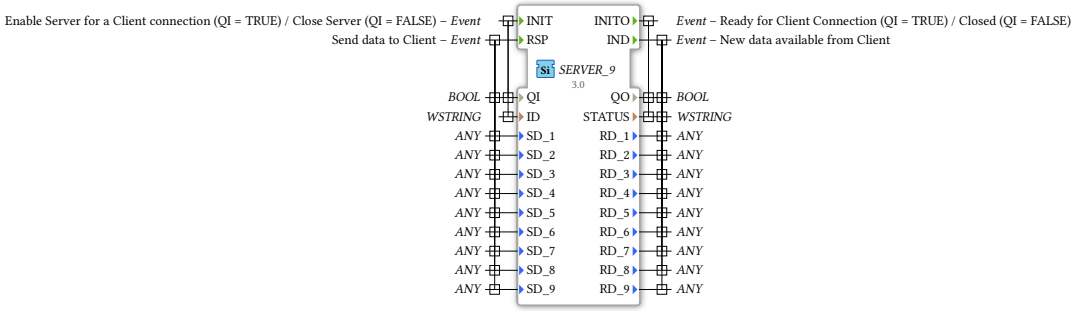
- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_0_8`**: `SERVER_8_0` is only functionally compatible with a `CLIENT_0_8` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 8 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_0_8` with the matching field count.



Comparison with similar function blocks

- **CLIENT_0_8**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion

`SERVER_8_0` provides the generic server variant of the `GEN_SERVER` family tailored to 8 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.79 SERVER_9

• – ◦ • – ◦ • – ◦ •

Introduction

The `SERVER_9` function block is the generic server variant with 9 send and 9 receive data fields for communicating with a matching CLIENT_9 block. It transmits 9 data values (`SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9`) to the client and receives 9 data values (`RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9`) back. Like all `SERVER_*` blocks, it is based on the generic `GEN_SERVER` implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS` and `RD_1` `RD_2` `RD_3` `RD_4` `RD_5` `RD_6` `RD_7` `RD_8` `RD_9`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.
- **SD_4** (ANY): Send value 4, transmitted to the client with `RSP`.
- **SD_5** (ANY): Send value 5, transmitted to the client with `RSP`.
- **SD_6** (ANY): Send value 6, transmitted to the client with `RSP`.
- **SD_7** (ANY): Send value 7, transmitted to the client with `RSP`.
- **SD_8** (ANY): Send value 8, transmitted to the client with `RSP`.
- **SD_9** (ANY): Send value 9, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- **RD_1** (ANY): Receive value 1, delivered by the client with `IND`.
- **RD_2** (ANY): Receive value 2, delivered by the client with `IND`.
- **RD_3** (ANY): Receive value 3, delivered by the client with `IND`.
- **RD_4** (ANY): Receive value 4, delivered by the client with `IND`.
- **RD_5** (ANY): Receive value 5, delivered by the client with `IND`.
- **RD_6** (ANY): Receive value 6, delivered by the client with `IND`.
- **RD_7** (ANY): Receive value 7, delivered by the client with `IND`.
- **RD_8** (ANY): Receive value 8, delivered by the client with `IND`.
- **RD_9** (ANY): Receive value 9, delivered by the client with `IND`.

Functionality

SERVER_9 initializes a connection to the matching CLIENT_9 block via INIT (when QI = TRUE) or closes it (when QI = FALSE); completion is confirmed via INITO. Via RSP, the values SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9 are transmitted to the client. Once response data (RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9) is available, the block triggers IND and provides RD_1 RD_2 RD_3 RD_4 RD_5 RD_6 RD_7 RD_8 RD_9.

Technical Features

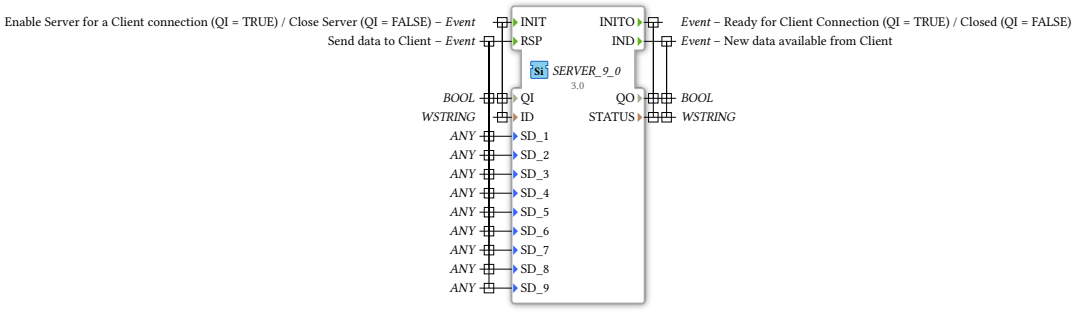
- **Generic implementation**: eclipse4diac::core::GenericClassName = 'GEN_SERVER', the same C++ base as all other SERVER_* variants; the number and type (ANY) of send/receive fields are fixed per instantiation via the type definition.
- **ANY data fields**: All SD_i/RD_i are generically (ANY) typed and adapt to whichever data type is wired to them.
- **Counterpart CLIENT_9**: SERVER_9 is only functionally compatible with a CLIENT_9 block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, QO = FALSE.
2. **Connecting**: INIT with QI = TRUE is processed.
3. **Connected**: INITO with QO = TRUE confirms the connection.
4. **Data exchange**: RSP/IND cycle for send/receive data.
5. **Disconnecting**: INIT with QI = FALSE is processed.

Application Scenarios

- **Communication between distributed control systems** that need to send exactly 9 values and receive exactly 9 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a CLIENT_9 with the matching field count.



Comparison with similar function blocks

- CLIENT_9: the direct counterpart on the client side, with send/receive field counts swapped.
- CLIENT_1 / SERVER_1: the same generic implementation with one send and one receive field each.

Conclusion

SERVER_9 provides the generic server variant of the GEN_SERVER family tailored to 9 send and 9 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.80 SERVER_9_0

• – ○ • – ○ • – ○ •

Introduction

The SERVER_9_0 function block is the generic server variant with 9 send and 0 receive data fields for communicating with a matching CLIENT_0_9 block. It transmits 9 data values (SD_1 SD_2 SD_3 SD_4 SD_5 SD_6 SD_7 SD_8 SD_9) to the client without receiving any data back. Like all SERVER_* blocks, it is based on the generic GEN_SERVER implementation — the same C++ base as CLIENT_1/SERVER_1 only the number of send/receive fields differs per instantiation.

Interface Structure

Event Inputs

- **INIT**: Enables the server for a client connection (QI = TRUE) or closes it (QI = FALSE), carries `QI` and `ID`.
- **RSP**: Sends data to the client, carries `QI` and `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9`.

Event Outputs

- **INITO**: Confirms connection setup/teardown, carries `QO` and `STATUS`.
- **IND**: Signals that new data is available from the client, carries `QO`, `STATUS`.

Data Inputs

- **QI** (BOOL): Controls the connection state (`TRUE` = open connection, `FALSE` = close connection).
- **ID** (WSTRING): Connection identifier (e.g. target address/port).
- **SD_1** (ANY): Send value 1, transmitted to the client with `RSP`.
- **SD_2** (ANY): Send value 2, transmitted to the client with `RSP`.
- **SD_3** (ANY): Send value 3, transmitted to the client with `RSP`.
- **SD_4** (ANY): Send value 4, transmitted to the client with `RSP`.
- **SD_5** (ANY): Send value 5, transmitted to the client with `RSP`.
- **SD_6** (ANY): Send value 6, transmitted to the client with `RSP`.
- **SD_7** (ANY): Send value 7, transmitted to the client with `RSP`.
- **SD_8** (ANY): Send value 8, transmitted to the client with `RSP`.
- **SD_9** (ANY): Send value 9, transmitted to the client with `RSP`.

Data Outputs

- **QO** (BOOL): Current connection status.
- **STATUS** (WSTRING): Status information about the connection.
- No receive fields (`SERVER_9_0` receives no payload data via `IND`, only connection/status information).

Functionality

`SERVER_9_0` initializes a connection to the matching `CLIENT_0_9` block via `INIT` (when `QI = TRUE`) or closes it (when `QI = FALSE`); completion is confirmed via `INITO`. Via `RSP`, the values `SD_1` `SD_2` `SD_3` `SD_4` `SD_5` `SD_6` `SD_7` `SD_8` `SD_9` are transmitted to the client. Once a response is available, the block triggers `IND`.

Technical Features

- **Generic implementation**: `eclipse4diac::core::GenericClassName = 'GEN_SERVER'`, the same C++ base as all other `SERVER_*` variants; the number and type (`ANY`) of send/receive fields are fixed per instantiation via the type definition.
- **`ANY` data fields**: All `SD_i`/`RD_i` are generically (`ANY`) typed and adapt to whichever data type is wired to them.
- **Counterpart `CLIENT_0_9`**: `SERVER_9_0` is only functionally compatible with a `CLIENT_0_9` block on the client side — the number of send fields on one side must match the number of receive fields on the other.

State Overview

1. **Disconnected**: Initial state, `QO = FALSE`.
2. **Connecting**: `INIT` with `QI = TRUE` is processed.
3. **Connected**: `INITO` with `QO = TRUE` confirms the connection.
4. **Data exchange**: `RSP`/`IND` cycle for send/receive data.
5. **Disconnecting**: `INIT` with `QI = FALSE` is processed.

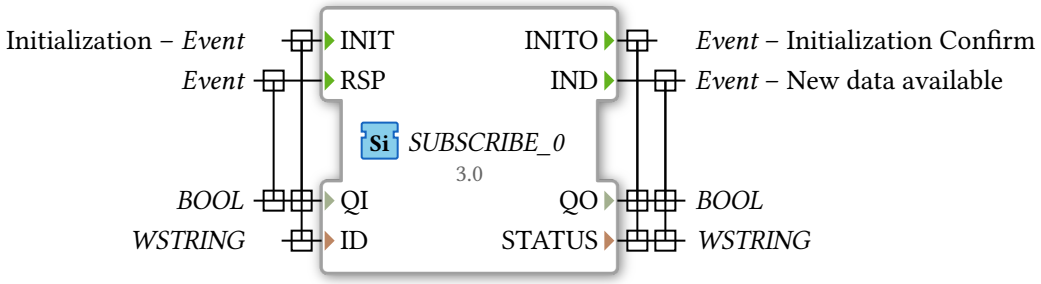
Application Scenarios

- **Communication between distributed control systems** that need to send exactly 9 values and receive exactly 0 values, without carrying unused surplus data fields.
- **Server-side connection** to a communication partner already laid out as a `CLIENT_0_9` with the matching field count.

Comparison with similar function blocks

- **CLIENT_0_9**: the direct counterpart on the client side, with send/receive field counts swapped.
- **CLIENT_1** / **SERVER_1**: the same generic implementation with one send and one receive field each.

Conclusion



`SERVER_9_0` provides the generic server variant of the `GEN_SERVER` family tailored to 9 send and 0 receive fields, suiting network connections whose payload count differs from the standard single-field variant.

2.11.6.81 SUBSCRIBE_0

• – ◦ • – ◦ • – ◦ •

Introduction

The SUBSCRIBE_0 function block is used to subscribe to data from a PUBLISH_0 block. It enables communication between different components in a distributed automation system by receiving data from a publisher and triggering events when new data is available.

Interface Structure

Event Inputs

- **INIT** (Type: EInit) - Initialization Event
- Linked to: QI, ID
- **RSP** (Type: Event) - Response Event
- Linked to: QI

Event Outputs

- **INITO** (Type: EInit) - Initialization Confirmation
- Linked to: QO, STATUS
- **IND** (Type: Event) - Indication of New Available Data
- Linked to: QO, STATUS

Data Inputs

- **QI** (Type: BOOL) - Qualifier for Initialization
- **ID** (Type: WSTRING) - Subscription Connection Identifier

Data Outputs

- **QO** (Type: BOOL) - Qualifier for Initial State
- **STATUS** (Type: WSTRING) - Status Information

Adapter

No adapter interfaces are present.

Functionality

The SUBSCRIBE_0 block initializes itself via the INIT event and establishes a connection to a PUBLISH_0 block, which is identified by the ID parameter. After successful initialization, the block confirms this via the INITO event. When new data is received from the publisher, the IND event is triggered, informing the application about available data.

Technical Features

- Uses WSTRING data types for ID and STATUS for international character support
- Implements a qualification model with QI and QO for state management
- Provides status feedback via the STATUS output

State Overview

1. **Not Initialized**: Initial state before INIT
2. **Initialization Phase**: During INIT processing
3. **Ready**: Successfully initialized and waiting for data
4. **Data Receiving**: Processes incoming data and triggers IND

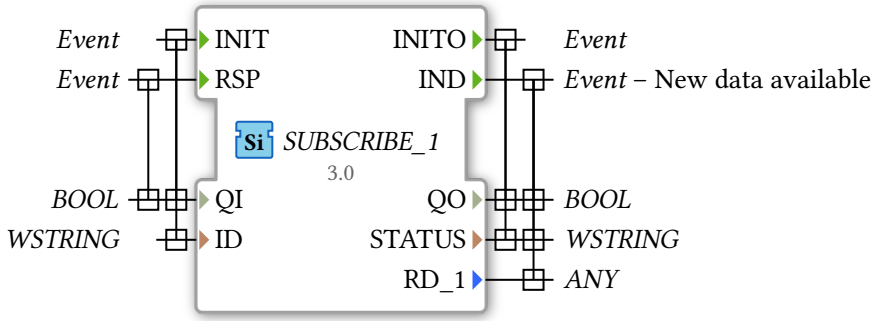
Application Scenarios

- Distributed automation systems with data distribution
- IoT applications with a publisher-subscriber pattern
- Monitoring systems that collect status data from various sources
- Control systems with decoupled communication between components

⚖️ Comparison with Similar Blocks

Compared to other communication blocks, SUBSCRIBE_0 focuses specifically on the publisher-subscriber pattern and provides a simple interface for subscribing to data streams. Unlike client-server modules, it operates asynchronously and is push-based.

Conclusion



The SUBSCRIBE_0 function block offers a robust solution for subscribing to data in distributed automation systems. Its clear interface and established publisher-subscriber pattern make it a reliable choice for loosely coupled communication scenarios.

2.11.6.82 SUBSCRIBE_1

• – ◦ • – ◦ • – ◦ •

Introduction

The SUBSCRIBE_1 function block is used to subscribe to data from a PUBLISH_1 block. It enables communication between different components in a distributed system by receiving data from a publisher and making it available when new data is available.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **RSP**: Response event with associated data QI

Event Outputs

- **INITO**: Initialization output with associated data QO and STATUS
- **IND**: Indication event when new data is available with associated data QO, STATUS, and RD_1

Data Inputs

- **QI** (BOOL): Qualifier Input - Controls block activation
- **ID** (WSTRING): Identifier - Unique ID for the subscription connection

Data Outputs

- **QO** (BOOL): Qualifier Output - Block execution status
- **STATUS** (WSTRING): Status information as Unicode String

- **RD_1** (ANY): Received Data - Can contain any data type

Adapter

No adapter interfaces are available.

Functionality

The SUBSCRIBE_1 block initializes itself via the INIT event and subscribes to data from a PUBLISH_1 block with the specified ID. Upon successful initialization, it confirms this via INITO. When new data is available from the publisher, the IND event is triggered, and the received data is made available via RD_1. The STATUS output provides status information about the subscription process.

Technical Features

- Uses WSTRING for ID and STATUS for Unicode compatibility
- RD_1 supports the ANY data type for maximum flexibility in received data
- Two separate event paths for initialization and data reception
- Qualifier inputs (QI) and outputs (QO) for reliable state control

State Overview

1. **Not Initialized**: Block waits for INIT event
2. **Initialized**: Subscription active, waits for data from the publisher
3. **Data Reception**: Processes incoming data and triggers IND event

Application Scenarios

- Distributed control systems with data distribution
- IoT applications with publisher-subscriber architecture
- Industry 4.0 communication structures
- Real-time data exchange between different control components

⚖️ Comparison with Similar Blocks

Compared to other communication blocks, SUBSCRIBE_1 offers a specialized solution for the publisher-subscriber pattern with a focus on Flexibility is enhanced by the ANY data type and Unicode support.

Conclusion

The SUBSCRIBE_1 function block is an essential building block for distributed systems in 4diac, enabling robust and flexible communication between different components. Its simple interface and support for any data type make it versatile for use in various automation applications.

2.11.6.83 SUBSCRIBE_10

• – ◦ • – ◦ • – ◦ •

Introduction

The SUBSCRIBE_10 function block acts as a subscriber in a publish-subscribe communication pattern and allows data to be received from a PUBLISH_10 block. The block can receive and process up to 10 different data values simultaneously.

Interface Structure

Event Inputs

- **INIT** (Type: EInit) - Initialization Event
- Linked to: QI, ID
- **RSP** (Type: Event) - Response Event
- Linked to: QI

Event Outputs

- **INITO** (Type: EInit) - Initialization Output
- Linked to: QO, STATUS
- **IND** (Type: Event) - Indication Event (New Data Available)
- Linked to: QO, STATUS, RD_1 to RD_10

Data Inputs

- **QI** (BOOL) - Qualified Input (Activation)
- **ID** (WSTRING) - Identification String for the Connection

Data Outputs

- **QO** (BOOL) - Qualified Output (Status)
- **STATUS** (WSTRING) - Status Information
- **RD_1** to **RD_10** (ANY) - Received Data Values 1-10

Adapter

No adapter interfaces available.

Functionality

The SUBSCRIBE_10 block initializes via the INIT event and connects to a corresponding PUBLISH_10 block based on the specified ID. As soon as new data is available from the publisher, the IND event is triggered, and the received data is made available via the RD_1 to RD_10 outputs.

Technical Features

- Supports the ANY data type for all received data, offering maximum flexibility in data types
- Can receive up to 10 different data values in parallel
- Uses WSTRING for status and identification information

- Implements a reliable publish-subscribe communication pattern

State Overview

1. **Not Initialized**: Block is inactive
2. **Initialized**: Connection to the publisher established, waiting for data
3. **Data Receiving**: Receives and processes incoming data
4. **Error State**: In case of connection problems or errors

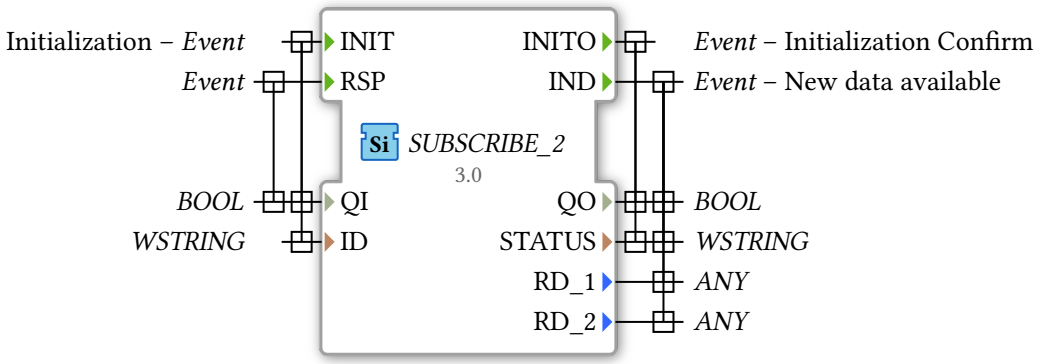
Application Scenarios

- Distributed control systems
- Data distribution in automation networks
- Communication between different control components
- Monitoring systems with multiple data sources

⚖️ Comparison with Similar Blocks

Compared to simpler subscribe blocks, SUBSCRIBE_10 offers the ability to receive up to 10 different data values simultaneously, making it suitable for more complex applications with multiple data points.

Conclusion



The SUBSCRIBE_10 function block is a powerful tool for distributed communication in IEC 61499 systems. Its ability to process up to 10 different data values and its flexible ANY data type support make it particularly suitable for complex automation applications with extensive data exchange requirements.

2.11.6.84 SUBSCRIBE_2

• – ◦ • – ◦ • – ◦ •

Introduction

The SUBSCRIBE_2 function block acts as a subscriber for a PUBLISH_2 block and enables the receipt of data via a publish-subscribe communication pattern. The block can receive and process two different data values from a publisher.

Interface Structure

Event Inputs

- **INIT**: Initialization event with the associated data QI and ID
- **RSP**: Response event with the associated data value QI

Event Outputs

- **INITO**: Initialization confirmation with the data QO and STATUS
- **IND**: Indication event when new data is available with QO, STATUS, RD_1, and RD_2

Data Inputs

- **QI** (BOOL): Qualifier Input - Controls block activation
- **ID** (WSTRING): Identification string for assignment to the corresponding publisher

Data Outputs

- **QO** (BOOL): Qualifier Output - Block operation status
- **STATUS** (WSTRING): Status information as a Unicode string
- **RD_1** (ANY): Received Data 1 (any data type)
- **RD_2** (ANY): Received Data 2 (any data type)

Adapter

No adapter interfaces are available.

Functionality

The SUBSCRIBE_2 block initializes itself via the INIT event and subscribes to a specific publisher using the ID identifier. After successful initialization, the block confirms this via INITO. When data is received from the publisher, the block triggers the IND event and makes the received data available via RD_1 and RD_2.

Technical Features

- Supports receiving two different data values simultaneously
- Uses WSTRING for status and identification information
- Implements generic data types (ANY) for maximum flexibility
- Based on the GEN_SUBSCRIBE generic template

State Overview

The block goes through the following main states:

1. **Not Initialized**: Block waits for the INIT event
2. **Initialized**: Block is ready to receive data
3. **Data Receipt**: Processing incoming data and triggering IND

Application Scenarios

- Distributed control systems with data distribution
- IoT applications with publisher-subscriber architecture
- Industrial automation with decentralized data communication
- Systems with flexible data type requirements

⚖️ Comparison with Similar Blocks

Compared to simpler SUBSCRIBE blocks, SUBSCRIBE_2 offers the ability to receive two different data values in parallel. The use of ANY data types allows for greater flexibility compared to type-specific implementations.

Conclusion

The SUBSCRIBE_2 block represents an enhanced solution for publish-subscribe communication in 4diac systems, offering exceptional flexibility through its support for two data channels and generic data types.

2.11.6.85 SUBSCRIBE_24

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SUBSCRIBE_24` subscribes to a `PUBLISH_24` block and provides the received data (up to 24 values) at its outputs.

Interface Structure

Event Inputs

- **INIT** (`EInit`): initialisation. Associated with `QI`, `ID`.
- **RSP**: response to an indication. Associated with `QI`.

Event Outputs

- **INITO** (`EInit`): initialisation confirm. Associated with `QO`, `STATUS`.
- **IND**: new data available. Associated with `QO`, `STATUS`, `RD_1` to `RD_24`.

Data Inputs

- **QI** (`BOOL`): event input qualifier
- **ID** (`WSTRING`): identification string of the communication channel (must match that of the `PUBLISH_24`)

Data Outputs

- **QO** (`BOOL`): event output qualifier
- **STATUS** (`WSTRING`): status information

- **RD_1** to **RD_24** (ANY): received data values

Adapters

No adapter interfaces available.

Functionality

After initialisation with INIT, the block signals IND whenever new data is received and provides the values RD_1 to RD_24. The service is implemented as a service interface (APPLICATION ↔ RESOURCE); RSP answers the indication.

Technical Details

- Generic block (generic class GEN_SUBSCRIBE): the number of data ports is 24 here, their types (ANY) are fixed at instantiation
- Unicode strings (WSTRING) for ID and STATUS
- Counterpart: PUBLISH_24 with SD_1 to SD_24

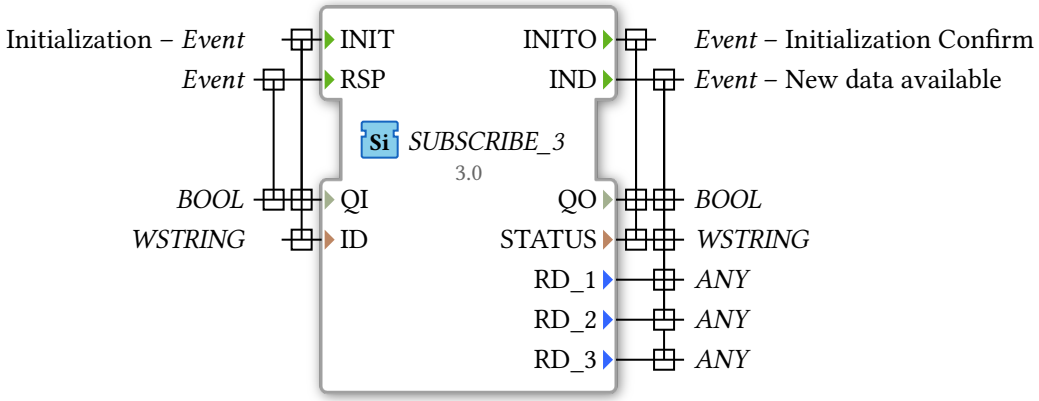
Application Scenarios

- Receiving many related values that a PUBLISH_24 sends elsewhere

⚖️ Comparison with Similar Building Blocks

SUBSCRIBE_10 receives up to 10 data values, SUBSCRIBE_24 up to 24.

Conclusion



SUBSCRIBE_24 is the receiving counterpart of PUBLISH_24 for up to 24 data values.

2.11.6.86 SUBSCRIBE_3

• – ◦ • – ◦ • – ◦ •

Introduction

The SUBSCRIBE_3 function block is used to subscribe to data from a PUBLISH_3 block. It enables the reception of three different data streams over a network connection and provides a standardized mechanism for communication between distributed system components.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **RSP**: Response event with associated data QI

Event Outputs

- **INITO**: Initialization confirmation with associated data QO and STATUS
- **IND**: Data availability event with associated data QO, STATUS, RD_1, RD_3, and RD_2

Data Inputs

- **QI** (BOOL): Qualifier for initialization and operation
- **ID** (WSTRING): Identification string for the connection

Data Outputs

- **QO** (BOOL): Qualifier for output state
- **STATUS** (WSTRING): Connection status information
- **RD_1** (ANY): Received data type 1
- **RD_2** (ANY): Received data type 2
- **RD_3** (ANY): Received data type 3

Adapter

No adapter interfaces available.

Functionality

The SUBSCRIBE_3 block initializes itself via the INIT event and establishes a connection to a corresponding PUBLISH_3 block. After successful initialization, it confirms this via INITO. When data is received from the publisher, the IND event is triggered, and the received data is output via RD_1, RD_2, and RD_3. The STATUS parameter provides information about the connection status.

Technical Features

- Supports three independent data channels (RD_1, RD_2, RD_3) with ANY data type
- Uses WSTRING for ID and STATUS for international character support
- Implements a reliable initialization protocol with QI/QO handshake
- Generic implementation via the GEN_SUBSCRIBE base class

State Overview

1. **Not Initialized**: Block waits for INIT event
2. **Initialization**: Processing INIT with ID parameter
3. **Ready**: Successful connection to the publisher
4. **Data Receiving**: Processing incoming data with IND trigger

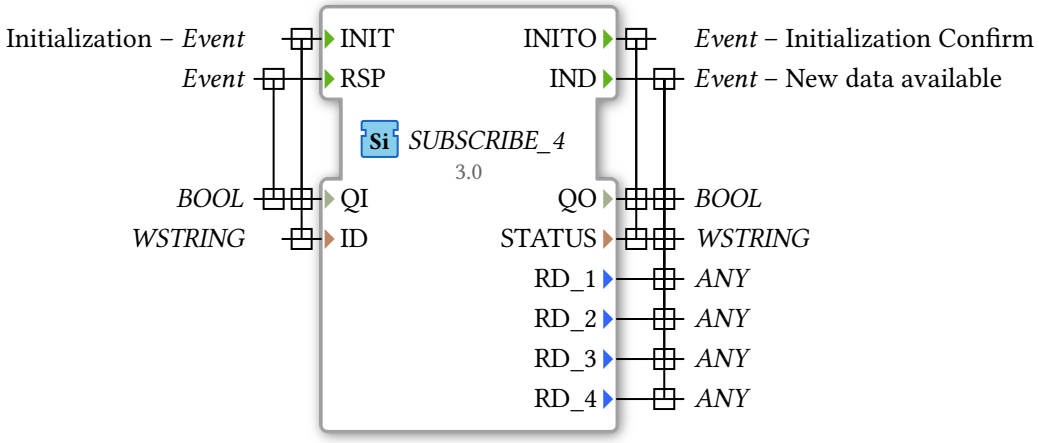
Application Scenarios

- Distributed control systems in automation technology
- Data distribution in IoT applications
- Communication between different control levels
- Machine-to-machine communication in Industry 4.0 environments

⚖️ Comparison with Similar Blocks

Compared to simpler SUBSCRIBE blocks, this offers SUBSCRIBE_3 offers the ability to receive three different data streams in parallel. The use of ANY data types allows for greater flexibility in the transmitted data formats.

Conclusion



The SUBSCRIBE_3 function block represents a powerful solution for communication in distributed automation systems. Its support for multiple data channels and flexible data types makes it particularly suitable for complex applications where multiple data sources need to be monitored simultaneously.

2.11.6.87 SUBSCRIBE_4

• − ○ • − ○ • − ○ •

Introduction

The SUBSCRIBE_4 function block is used to subscribe to data from a PUBLISH_4 block. It allows the receipt of up to four different data points via a communication link and makes them available when they become available.

Interface Structure

Event Inputs

- **INIT** (Type: EInit) - Initialization Event
- Linked to: QI, ID
- **RSP** (Type: Event) - Response Event
- Linked to: QI

Event Outputs

- **INITO** (Type: EInit) - Initialization Acknowledgement
- Linked to: QO, STATUS
- **IND** (Type: Event) - Data Availability Message
- Linked to: QO, STATUS, RD_1, RD_3, RD_2, RD_4

Data Inputs

- **QI** (BOOL) - Qualified Input (Activation/Deactivation)
- **ID** (WSTRING) - Identifier for the Communication Connection

Data Outputs

- **QO** (BOOL) - Qualified Output (Status Feedback)
- **STATUS** (WSTRING) - Status Information
- **RD_1** (ANY) - Received Data 1
- **RD_2** (ANY) - Received Data 2
- **RD_3** (ANY) - Received Data 3
- **RD_4** (ANY) - Received Data 4

Adapters

No adapter interfaces are available.

Functionality

Upon receiving the INIT event, the SUBSCRIBE_4 block initializes a subscription connection to a PUBLISH_4 block using the specified ID. After successful initialization, it confirms this with INITO. When new data is available from the publisher, the IND event is triggered, and the received data is made available via the RD_1 to RD_4 outputs.

Technical Features

- Supports receiving up to four different data types (ANY type)
- Uses WSTRING for status and identification information
- Generic implementation via the GEN_SUBSCRIBE base class
- Robust error handling via STATUS output

State Overview

1. **Inactive**: Block is not initialized

2. **Initialized**: Subscription active, waiting for data
3. **Data Receiving**: Processes incoming data and outputs an IND event

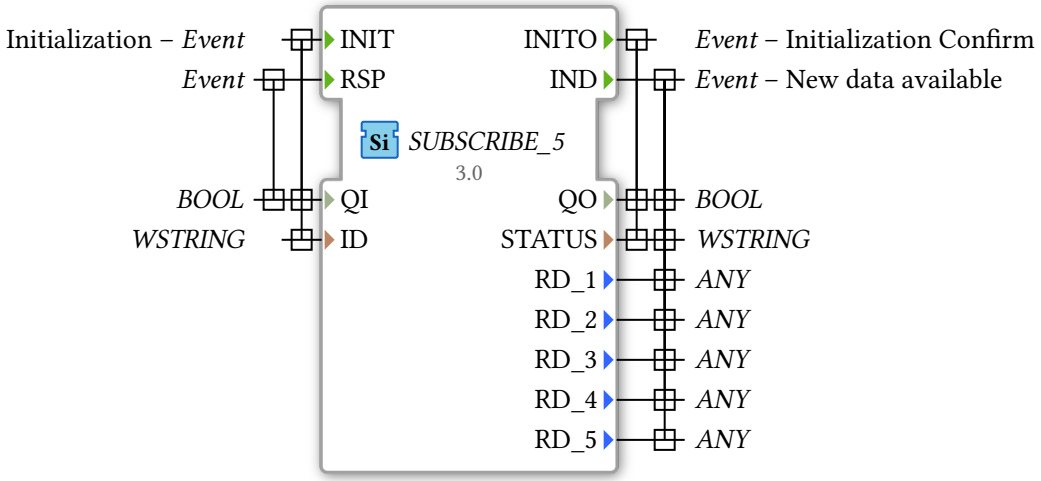
Application Scenarios

- Distributed automation systems
- Data distribution in decentralized controllers
- Communication between different control components
- Monitoring systems with data subscription

⚖ Comparison with Similar Blocks

Compared to simpler SUBSCRIBE blocks, SUBSCRIBE_4 offers the ability to receive up to four different data points simultaneously. This enhanced functionality makes it particularly suitable for more complex communication scenarios where multiple data sources need to be consolidated.

Conclusion



The SUBSCRIBE_4 function block represents a powerful solution for subscription-based communication in IEC 61499 systems. Its ability to manage multiple data points in parallel makes it a flexible choice for demanding automation applications with distributed data communication.

2.11.6.88 SUBSCRIBE_5

• − ◦ • − ◦ • − ◦ •

Introduction

The SUBSCRIBE_5 function block is used to subscribe to data from a PUBLISH_5 block. It allows the reception of up to five different data points over a network connection and provides a standardized interface for communication between distributed automation components.

Interface Structure

Event Inputs

- **INIT**: Initialization event with the associated data QI and ID
- **RSP**: Response event with the associated data point QI

Event Outputs

- **INITO**: Initialization confirmation with the data QO and STATUS
- **IND**: Indication event when new data is available with QO, STATUS, and the five data points RD_1 to RD_5

Data Inputs

- **QI** (BOOL): Qualifier for initialization - activates/deactivates the block
- **ID** (WSTRING): Identification string for assignment to the corresponding PUBLISH_5 block

Data Outputs

- **QO** (BOOL): Qualifier output - indicates the operating status
- **STATUS** (WSTRING): Status Information and Error Messages
- **RD_1** to **RD_5** (ANY): Received data points 1 to 5 with any data type

Adapter

No adapter interfaces are available.

Functionality

The SUBSCRIBE_5 block initializes itself via the INIT event and then establishes a connection to the corresponding PUBLISH_5 block. Upon successful initialization, it confirms this via INITO. As soon as new data is available from the publisher, it is output via the IND event using the corresponding data outputs RD_1 to RD_5. The STATUS output provides information about the connection status and any errors.

Technical Features

- Supports up to five different data points simultaneously
- Uses WSTRING for ID and STATUS for international character set support
- ANY type for data outputs enables flexible data types
- Generic implementation via the GEN_SUBSCRIBE base class

State Overview

1. **Not Initialized**: Block waits for INIT event
2. **Initialization Phase**: Processing INIT with ID parameter
3. **Connected**: Successful connection to the publisher, ready to receive data
4. **Data Reception**: Processing incoming data and output via IND

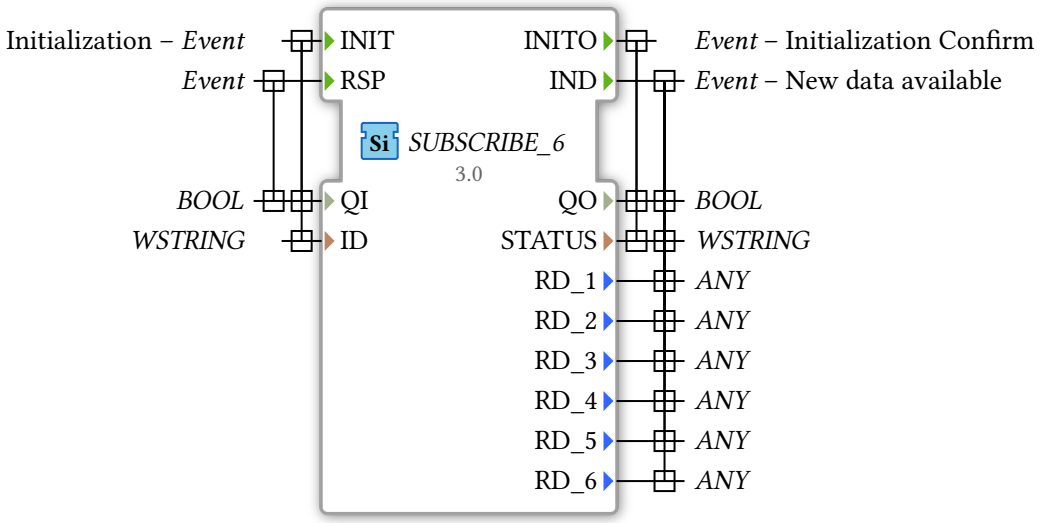
Application Scenarios

- Distributed automation systems
- Data distribution in production plants
- Machine-to-machine communication
- Monitoring systems with multiple sensor data
- SCADA systems with decentralized data sources

⚖️ Comparison with Similar Blocks

Compared to simpler SUBSCRIBE blocks, SUBSCRIBE_5 offers the ability to process up to five different data points in parallel. received. The use of ANY types makes it more flexible than type-specific subscribe blocks, but requires a correct type mapping to the corresponding publisher.

Conclusion



The SUBSCRIBE_5 function block represents a powerful and flexible solution for receiving multiple data streams in distributed automation systems. Its generic implementation and support for various data types make it particularly suitable for complex applications with variable data structures.

2.11.6.89 SUBSCRIBE_6

• − ◦ • − ◦ • − ◦ •

Introduction

The SUBSCRIBE_6 function block is used to subscribe to data from a PUBLISH_6 block. It allows the receipt of up to six different data values via a network connection and makes them available for further processing in an IEC 61499 system.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **RSP**: Response event with associated data QI

Event Outputs

- **INITO**: Initialization confirmation with associated data QO and STATUS
- **IND**: Indication event for newly available data with associated data QO, STATUS, and RD_1 to RD_6

Data Inputs

- **QI** (BOOL): Qualifier Input - Controls block activation
- **ID** (WSTRING): Identification string for assignment to the corresponding PUBLISH_6 block

Data Outputs

- **QO** (BOOL): Qualifier Output - Block operation status
- **STATUS** (WSTRING): Status information as a Unicode string
- **RD_1** to **RD_6** (ANY): Received data values (up to 6 different data types)

Functionality

The SUBSCRIBE_6 block initializes itself via the INIT event and establishes a connection to a PUBLISH_6 block with the specified ID. Upon successful initialization, it confirms this with INITO. As soon as new data is available from the PUBLISH_6 block, the SUBSCRIBE_6 block triggers the IND event and makes the received data available via the RD_1 to RD_6 outputs.

Technical Features

- Supports up to six different data values simultaneously
- Uses WSTRING for status messages and identification
- Flexible data types through ANY type for received data
- Network-based communication between distributed systems

State Overview

The block goes through the following main states:

1. **Not Initialized**: Block is inactive
2. **Initialization**: Processing the INIT event
3. **Connected**: Successful connection to the publisher
4. **Data Reception**: Receives and processes incoming data

Application Scenarios

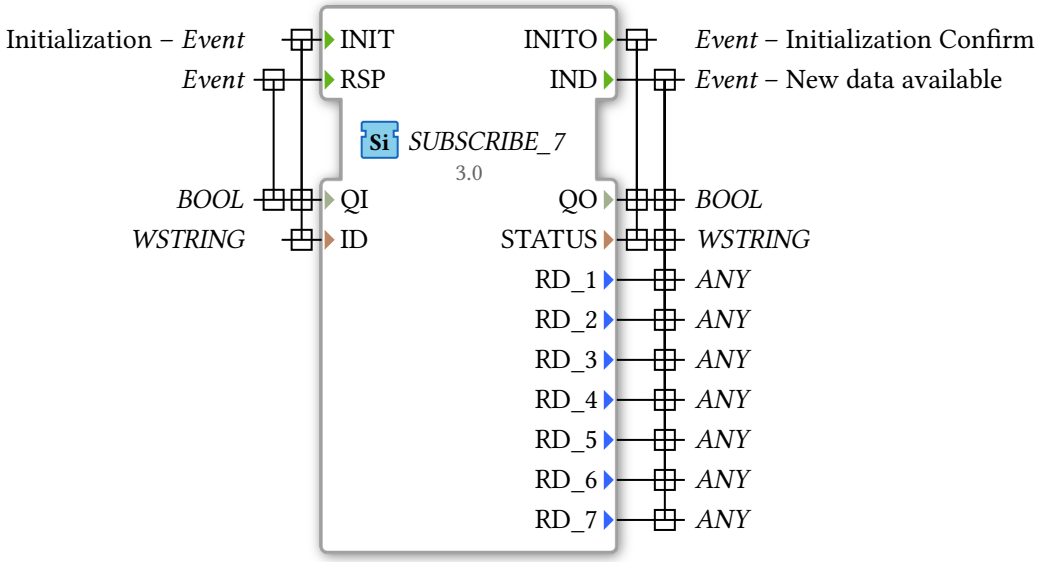
- Distributed control systems with data distribution

- Monitoring systems with centralized data acquisition
- Industry 4.0 applications with machine data
- SCADA systems with decentralized data sources

⚖️ Comparison with Similar Blocks

Compared to simpler Subscribe blocks, SUBSCRIBE_6 offers the ability to receive up to six different data values in parallel, enabling higher data throughput capacity. Using WSTRING for status messages allows for more detailed error information.

Conclusion



The SUBSCRIBE_6 function block is a powerful solution for distributed systems that require the simultaneous reception of multiple data streams. Its flexible architecture and support for various data types make it ideal for complex industrial automation applications.

2.11.6.90 SUBSCRIBE_7

• – ◦ • – ◦ • – ◦ •

Introduction

The SUBSCRIBE_7 function block acts as a subscriber for data from a PUBLISH_7 block. It enables the reception of up to seven different data points over a single communication link. This block is part of the IEC 61499 network communication functionality and is used in distributed automation systems.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **RSP**: Response event with associated data QI

Event Outputs

- **INITO**: Initialization confirmation with associated data QO and STATUS
- **IND**: Indication event when new data is available with associated data QO, STATUS, and RD_1 to RD_7

Data Inputs

- **QI** (BOOL): Qualifier for initialization
- **ID** (WSTRING): Identifier for the connection

Data Outputs

- **QO** (BOOL): Qualifier for output state
- **STATUS** (WSTRING): Connection status information

- **RD_1** to **RD_7** (ANY): Received data points 1 to 7

Adapter

No adapter interfaces available.

Functionality

The SUBSCRIBE_7 block initializes itself via the INIT event and establishes a connection to a corresponding PUBLISH_7 block. After successful initialization, it confirms this via INITO. When data is received from the publisher, the IND event is triggered, and the received data is output via RD_1 to RD_7. The RSP input allows for the handling of reply messages.

Technical Features

- Supports up to seven different data points simultaneously
- Uses WSTRING for status and identification information
- ANY data type for received data enables flexible data types
- Generic implementation via the GEN_SUBSCRIBE base class

State Overview

1. **Not Initialized**: Block waits for INIT event
2. **Initialization**: Processing the INIT request
3. **Ready**: Successfully connected, waiting for data
4. **Data Receiving**: Processing incoming data with IND trigger

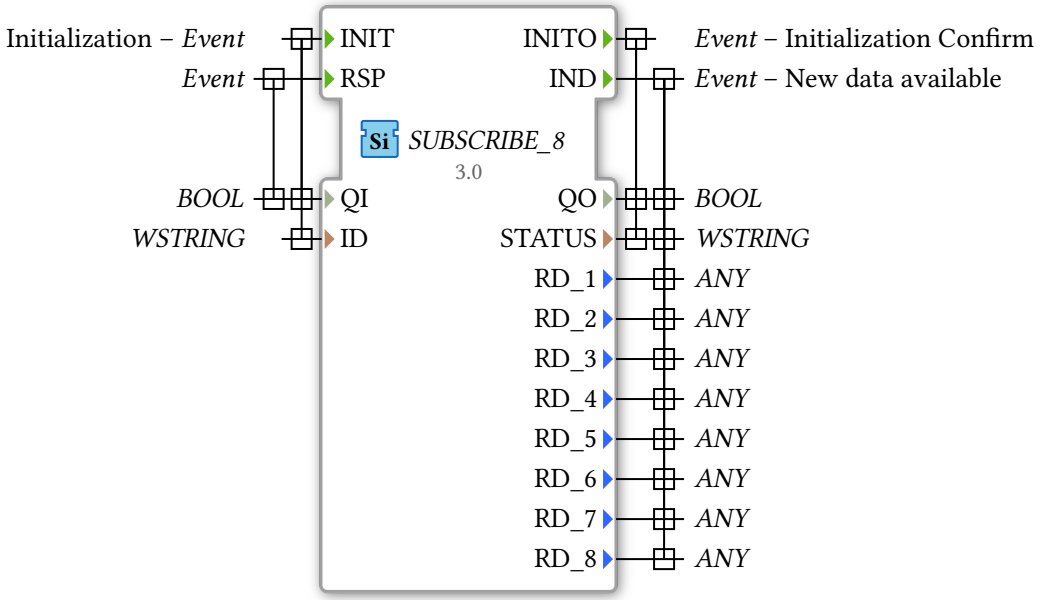
Application Scenarios

- Distributed automation system with data distribution
- Machine networking in Industry 4.0 environments
- Data exchange between different control components
- Monitoring systems with centralized data collection

⚖️ Comparison with Similar Blocks

Compared to simpler SUBSCRIBE blocks, SUBSCRIBE_7 offers the ability to receive up to seven data points in parallel. Compared to individual communication solutions, it offers standardized IEC 61499 interfaces and simplified configuration.

Conclusion



The SUBSCRIBE_7 block is a powerful communication module for distributed automation systems. Its flexible data transmission and standardized interfaces provide a reliable foundation for industrial communication applications.

2.11.6.91 SUBSCRIBE_8

• – ◦ • – ◦ • – ◦ •

Introduction

The SUBSCRIBE_8 function block acts as a subscriber for a PUBLISH_8 block and allows the receipt of up to 8 different data values over a single communication link. The block implements a publish-subscribe communication pattern and is part of the iec61499::net package.

Interface Structure

Event Inputs

- **INIT** - Initialization Event
- Linked to: QI, ID
- **RSP** - Response Event
- Linked to: QI

Event Outputs

- **INITO** - Initialization Confirmation
- Linked to: QO, STATUS
- **IND** - Indication Event for New Data
- Linked to: QO, STATUS, RD_1 to RD_8

Data Inputs

- **QI** (BOOL) - Qualified Input for Initialization
- **ID** (WSTRING) - Identification String for the Connection

Data Outputs

- **QO** (BOOL) - Qualified Output
- **STATUS** (WSTRING) - Status Information
- **RD_1** to **RD_8** (ANY) - Received Data Values 1 to 8

Adapter

No adapter interfaces available.

Functionality

The SUBSCRIBE_8 block initializes itself via the INIT event and establishes a connection to a corresponding PUBLISH_8 block. After successful initialization, it confirms this with the INITO event. When data is received from the publisher, the IND event is triggered, and the received data is made available via the RD_1 to RD_8 outputs.

Technical Features

- Supports the ANY data type for all data outputs, enabling maximum flexibility in the transmitted data types
- Uses WSTRING for status messages and identification
- Implements a reliable initialization protocol with qualification bits
- Can receive up to 8 different data values in parallel

State Overview

1. **Not Initialized** - Block waiting for INIT event
2. **Initialization** - Processing the INIT event
3. **Ready** - Successfully initialized, waiting for data
4. **Data Receiving** - Processing incoming data with IND triggering

Application Scenarios

- Distributed control systems with data distribution
- Monitoring systems with centralized data acquisition
- Communication between different control components
- Systems with a publish-subscribe architecture

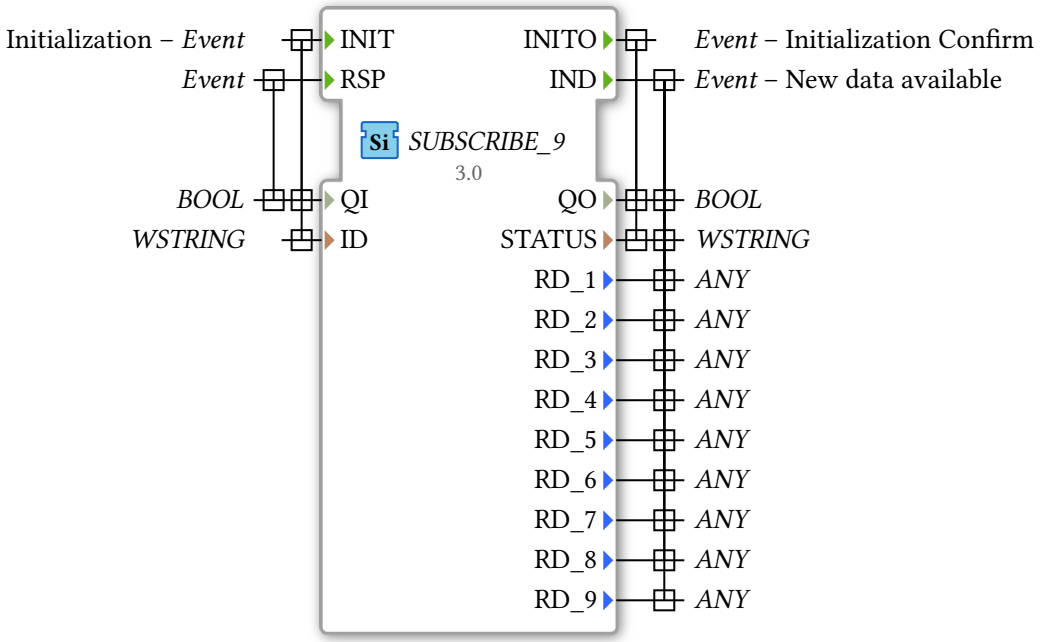
⚖️ Comparison with Similar Blocks

Compared to simpler subscribe blocks, SUBSCRIBE_8 offers the ability to receive up to 8 different data values in parallel. Using the ANY data type offers greater flexibility than type-specific subscribe blocks.

Conclusion

The SUBSCRIBE_8 function block provides a powerful and flexible solution for publish-subscribe communication in distributed automation systems. Its ability to receive multiple data values of different types makes it particularly suitable for complex communication scenarios in industrial control systems.

2.11.6.92 SUBSCRIBE_9



• – ◦ • – ◦ • – ◦ •

Introduction

The SUBSCRIBE_9 function block is used to subscribe to data from a PUBLISH_9 block. It allows the receipt of up to 9 different data points via a network connection and makes them available for further processing in the control system.

• – ◦ • – ◦ • – ◦

The SUBSCRIBE_9 function block is used to subscribe to data from a PUBLISH_9 block. It enables the reception of up to 9 different data points via a network connection and makes them available for further processing in the control system.

Interface Structure

Event Inputs

- **INIT**: Initialization event with associated data QI and ID
- **RSP**: Response event with associated data QI

Event Outputs

- **INITO**: Initialization confirmation with QO and STATUS
- **IND**: Indication event when new data is available with QO, STATUS, and all 9 RD_x data outputs

Data Inputs

- **QI** (BOOL): Qualifier for initialization (TRUE = enable, FALSE = disable)
- **ID** (WSTRING): Identification string for the connection to the publisher

Data Outputs

- **QO** (BOOL): Qualifier output for operating status
- **STATUS** (WSTRING): Status information as Unicode String
- **RD_1** to **RD_9** (ANY): Received data points 1-9 with any data type

Adapter

No adapter interfaces available.

Functionality

Upon receiving the INIT event, the SUBSCRIBE_9 block initializes a connection to a PUBLISH_9 block based on the specified ID. After successful initialization, it confirms this with the INITO event. When data is received from the publisher, the IND event is triggered, and the data is made available via the RD_1 to RD_9 outputs.

Technical Features

- Supports up to 9 different data points in parallel
- Uses WSTRING for status and identification information
- ANY data types for the received data enable flexible data types
- Generic implementation as GEN_SUBSCRIBE

State Overview

1. **Not Initialized**: Block waits for INIT event
2. **Initialized**: Connection to the publisher established, ready to receive data
3. **Data Receiving**: Processes incoming data and triggers IND event

Application Scenarios

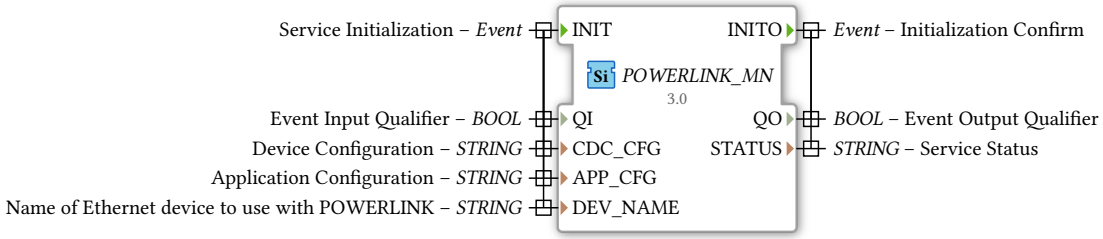
- Distributed control systems with data distribution
- Machine networking in Industry 4.0 environments
- Monitoring systems with centralized data collection
- Systems with multiple decentralized sensor nodes

⚖️ Comparison with Similar Blocks

Compared to simpler SUBSCRIBE blocks, SUBSCRIBE_9 offers the ability to receive up to 9 different data points simultaneously, increasing efficiency in more complex network structures.

Conclusion

The SUBSCRIBE_9 function block is a powerful solution for receiving multiple data streams in distributed automation systems and is particularly suitable for applications with high data throughput.



2.11.7 powerlink

2.11.7.1 POWERLINK_MN

• – ◦ • – ◦ • – ◦ •

Introduction

The POWERLINK_MN function block is used to configure the openPOWERLINK fieldbus. It acts as a Managing Node (MN) and initializes the network.

Interface Structure

Event Inputs

- **INIT**: Initializes the service. Starts the configuration process.

Event Outputs

- **INITO**: Confirms initialization. Indicates whether the start was successful.

Data Inputs

- **QI** (BOOL): Qualifier for the INIT input (TRUE = Start, FALSE = Stop).
- **CDC_CFG** (STRING): Device Configuration.
- **APP_CFG** (STRING): Application Configuration.
- **DEV_NAME** (STRING): Name of the Ethernet device to be used for POWERLINK (e.g., “eth0”).

Data Outputs

- **QO** (BOOL): Qualifier for the INITO output.
- **STATUS** (STRING): Service status information.

Functionality

This block initializes the openPOWERLINK stack on the specified Ethernet interface (`DEV_NAME`). The configuration files for the device (`CDC_CFG`) and application (`APP_CFG`) are loaded.

Application Scenarios

- Central control of a POWERLINK network.
- Master component in a real-time Ethernet system.

2.11.7.2 X20AI2622

• – ◦ • – ◦ • – ◦ •

Introduction

The X20AI2622 function block provides an interface for analog inputs in the openPOWERLINK fieldbus. It corresponds to the B&R X20AI2622 module.

Interface Structure

Event Inputs

- **INIT**: Service initialization.
- **REQ**: Request to update input data.

Event Outputs

- **INITO**: Initialization confirmation.
- **CNF**: Request to update the input data.

Data Inputs

- **QI** (BOOL): Qualifier for INIT and REQ.
- **CNID** (USINT): Client Node ID (address of the node in the POWERLINK network).
- **MODID** (UINT): Module ID (position of the module in the node).

Data Outputs

- **QO** (BOOL): Qualifier for outputs.
- **CNIDO** (USINT): Confirmed Client Node ID.
- **STATUS** (STRING): Network status.
- **AI01** (INT): Analog input 01.
- **AI02** (INT): Analog input 02.

Functionality

After initialization with `CNID` and `MODID`, the function block outputs the current analog values of the physical module at outputs `AIxx` every `REQ`.

2.11.7.3 X20AI4622

• – ◦ • – ◦ • – ◦ •

Introduction

The X20AI4622 function block provides an interface for analog inputs in the openPOWERLINK fieldbus. It corresponds to the B&R X20AI4622 module with 4 analog inputs.

Interface Structure

Event Inputs

- **INIT**: Service initialization.
- **REQ**: Request to update input data.

Event Outputs

- **INITO**: Initialization confirmation.
- **CNF**: Request to update the input data.

Data Inputs

- **QI** (BOOL): Qualifier for INIT and REQ.
- **CNID** (USINT): Client Node ID.
- **MODID** (UINT): Module ID.

Data Outputs

- **QO** (BOOL): Qualifier for outputs.
- **CNIDO** (USINT): Confirmed Client Node ID.
- **STATUS** (STRING): Network status.
- **AI01** (INT): Analog input 01.
- **AI02** (INT): Analog input 02.
- **AI03** (INT): Analog input 03.
- **AI04** (INT): Analog input 04.

Functionality

After initialization, the module provides the current analog values of the four channels.

2.11.7.4 X20AO4622

• – ◦ • – ◦ • – ◦ •

Introduction

The X20AO4622 function block is used to control analog outputs via the openPOWERLINK fieldbus. It corresponds to the B&R X20AO4622 module (4 outputs).

Interface Structure

Event Inputs

- **INIT**: Initialization.
- **REQ**: Writes the values of the inputs `AOxx` to the module.

Event Outputs

- **INITO**: Initialization confirmed.
- **CNF**: Write operation confirmed.

Data Inputs

- **QI** (BOOL): Qualifier.
- **CNID** (USINT): Client Node ID.
- **MODID** (UINT): Module ID.
- **AO01** (INT): Analog value for output 01.
- **AO02** (INT): Analog value for output 02.
- **AO03** (INT): Analog value for output 03.
- **AO04** (INT): Analog value for output 04.

Data Outputs

- **QO** (BOOL): Qualifier.
- **CNIDO** (USINT): Confirmed Node ID.
- **STATUS** (STRING): Status.

Functionality

The integer values present at inputs `AO01-AO04` are sent to the output module when the `REQ` event is triggered.

2.11.7.5 X20AT2402

• – ◦ • – ◦ • – ◦ •

Introduction

The X20AT2402 function block is used to read temperature values via the openPOWERLINK fieldbus. It corresponds to the B&R X20AT2402 temperature input module (2 channels).

Interface Structure

Event Inputs

- **INIT**: Initialization.
- **REQ**: Request data update.

Event Outputs

- **INITO**: Initialization confirmed.
- **CNF**: New temperature data available.

Data Inputs

- **QI** (BOOL): Qualifier.
- **CNID** (USINT): Client Node ID.
- **MODID** (UINT): Module ID.

Data Outputs

- **QO** (BOOL): Qualifier.
- **CNIDO** (USINT): Confirmed Node ID.
- **STATUS** (STRING): Status.
- **T01** (REAL): Temperature input 01 (typically in °C, depending on module configuration).
- **T02** (REAL): Temperature input 02.

Functionality

Reads temperature values from the physical module and provides them as REAL values.

2.11.7.6 X20AT4222

• – ◦ • – ◦ • – ◦ •

Introduction

The X20AT4222 function block is used to read temperature values via the openPOWERLINK fieldbus. It corresponds to the B&R X20AT4222 temperature input module (4 channels).

Interface Structure

Event Inputs

- **INIT**: Initialization.
- **REQ**: Request data update.

Event Outputs

- **INITO**: Initialization confirmed.
- **CNF**: New temperature data available.

Data Inputs

- **QI** (BOOL): Qualifier.
- **CNID** (USINT): Client Node ID.
- **MODID** (UINT): Module ID.

Data Outputs

- **QO** (BOOL): Qualifier.
- **CNIDO** (USINT): Confirmed Node ID.
- **STATUS** (STRING): Status.
- **T01** (REAL): Temperature Input 01.
- **T02** (REAL): Temperature Input 02.
- **T03** (REAL): Temperature Input 03.
- **T04** (REAL): Temperature Input 04.

Functionality

Reads temperature values from the physical module and provides them as real values.

2.11.7.7 X20DI4653

• – ◦ • – ◦ • – ◦ •

Introduction

The X20DI4653 function block is used to read digital signals via the openPOWERLINK fieldbus. It corresponds to the B&R X20DI4653 digital input module (4 channels).

Interface Structure

Event Inputs

- **INIT**: Initialization.
- **REQ**: Update input data.

Event Outputs

- **INITO**: Initialization confirmed.
- **CNF**: New data available.

Data Inputs

- **QI** (BOOL): Qualifier.
- **CNID** (USINT): Client Node ID.
- **MODID** (UINT): Module ID.

Data Outputs

- **QO** (BOOL): Qualifier.

- **CNIDO** (USINT): Confirmed Node ID.
- **STATUS** (STRING): Status.
- **DI01** (BOOL): Digital Input 01.
- **DI02** (BOOL): Digital Input 02.
- **DI03** (BOOL): Digital Input 03.
- **DI04** (BOOL): Digital Input 04.

Functionality

Reads the state of the digital inputs from the module and provides them as Boolean values.

2.11.7.8 X20DI9371

• – ◦ • – ◦ • – ◦ •

Introduction

The X20DI9371 function block is used to read digital signals via the openPOWERLINK fieldbus. It corresponds to the B&R X20DI9371 digital input module (12 channels).

Interface Structure

Event Inputs

- **INIT**: Initialization.
- **REQ**: Update input data.

Event Outputs

- **INITO**: Initialization confirmed.
- **CNF**: New data available.

Data Inputs

- **QI** (BOOL): Qualifier.
- **CNID** (USINT): Client Node ID.
- **MODID** (UINT): Module ID.

Data Outputs

- **QO** (BOOL): Qualifier.
- **CNIDO** (USINT): Confirmed Node ID.
- **STATUS** (STRING): Status.
- **DI01** - **DI12** (BOOL): Digital Inputs 01 to 12.

Functionality

Reads the status of the 12 digital inputs from the module.

2.11.7.9 X20DI9372

• – ◦ • – ◦ • – ◦ •

Introduction

The X20DI9372 function block is used to read digital signals via the openPOWERLINK fieldbus. It corresponds to the B&R X20DI9372 digital input module (12 channels).

Interface Structure

Event Inputs

- **INIT**: Initialization.
- **REQ**: Update input data.

Event Outputs

- **INITO**: Initialization confirmed.
- **CNF**: New data available.

Data Inputs

- **QI** (BOOL): Qualifier.
- **CNID** (USINT): Client Node ID.
- **MODID** (UINT): Module ID.

Data Outputs

- **QO** (BOOL): Qualifier.
- **CNIDO** (USINT): Confirmed Node ID.
- **STATUS** (STRING): Status.
- **DI01** - **DI12** (BOOL): Digital Inputs 01 to 12.

Functionality

Reads the status of the 12 digital inputs from the module.

2.11.7.10 X20DO4623

• – ◦ • – ◦ • – ◦ •

Introduction

The X20DO4623 function block is used to control digital outputs via the openPOWERLINK fieldbus. It corresponds to the B&R X20DO4623 digital output module (4 channels).

Interface Structure

Event Inputs

- **INIT**: Initialization.
- **REQ**: Write outputs.

Event Outputs

- **INITO**: Initialization confirmed.
- **CNF**: Write operation confirmed.

Data Inputs

- **QI** (BOOL): Qualifier.
- **CNID** (USINT): Client Node ID.
- **MODID** (UINT): Module ID.
- **DO01** (BOOL): Digital Output 01.
- **DO02** (BOOL): Digital Output 02.
- **DO03** (BOOL): Digital Output 03.
- **DO04** (BOOL): Digital Output 04.

Data Outputs

- **QO** (BOOL): Qualifier.
- **CNIDO** (USINT): Confirmed Node ID.
- **STATUS** (STRING): Status.

Functionality

Sets the digital outputs on the module according to the input values `DO01-DO04`.

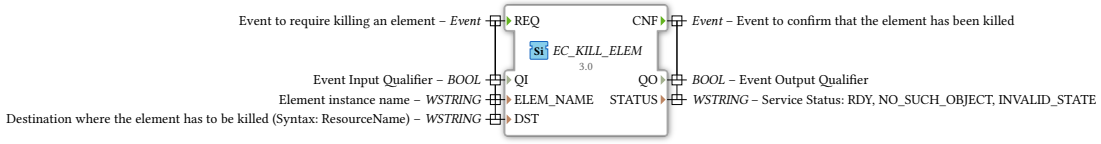
2.11.8 reconfiguration



2.11.8.1 EC_KILL_ELEM

• — ○ • — ○ • — ○ •

Introduction

The EC_KILL_ELEM function block is used to terminate instances according to the state machine of IEC 61499 function blocks. It enables the targeted termination of function block instances, connections (event/data), resources, or devices within a 4diac system.

Interface Structure

Event Inputs
- **REQ**: Event to request the termination of an element

Event Outputs
- **CNF**: Event to confirm that the element has been terminated

Data Inputs
- **QI** (BOOL): Event input qualifier
- **ELEM_NAME** (WSTRING): Name of the element instance
- **DST** (WSTRING): Destination where the element must be terminated (Syntax: ResourceName)

Data Outputs
- **QO** (BOOL): Event output qualifier
- **STATUS** (WSTRING): Service status (RDY, NO_SUCH_OBJECT, INVALID_STATE)

Adapters
No adapter interfaces are available.

Functionality
The function block responds to the REQ event and attempts to terminate the specified element (function block, connection, resource, or device) at the specified target resource. Upon execution, the CNF event is output with the corresponding status.

Technical Features
- Supports terminating various element types (FBs, connections, resources, devices)
- Uses WSTRING data types for element names and targets
- Provides detailed status feedback on the termination process
- Implemented according to IEC 61499 Execution Control Services

Status Overview
The function block has several service sequences:

- **normal_establishment**: Successful initialization
- **unsuccessful_establishment**: Failed initialization
- **request_confirm**: Successful termination request
- **request_inhibited**: Suppressed termination request
- **request_error**: Failed termination request
- **application_initiated_termination**: Application-initiated termination
- **resource_initiated_termination**: Resource-initiated termination

Application Scenarios
- Dynamic reconfiguration of automation systems
- Targeted termination of faulty components
- Resource management in distributed systems
- System maintenance and -Updates
- Error Handling and System Recovery

⚖️ Comparison with Similar Blocks
Compared to other execution control blocks, EC_KILL_ELEM offers specific functions for terminating element instances, while similar blocks often provide creation or management functions. Its ability to handle various element types (FBs, connections, resources, devices) makes it particularly versatile.

Conclusion
EC_KILL_ELEM is an essential building block for reconfiguration tasks in IEC 61499-based systems. Its ability to selectively terminate elements enables dynamic system adjustments and robust error handling strategies in industrial automation solutions.

2.11.8.2 EC_SET_EVT

• — ○ • — ○ • — ○ •

Introduction

The EC_SET_EVT function block is used to set event inputs or outputs of a function block instance. It enables the targeted triggering of events in other function blocks and can be used, for example, as an event sniffer. This function block belongs to the category of reconfiguration services according to the IEC 61499-1 standard.

Interface Structure

Event Inputs

- **REQ**: Service Request - triggers the execution of the setting operation

Event Outputs

- **CNF**: Acknowledgement of the requested service operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier - enables/disables the service
- **FB_NAME** (WSTRING): Name of the function block instance
- **FB_EVENT_IO** (WSTRING): Name of the event to be set
- **DST** (WSTRING): Destination where the event is to be set (Syntax: ResourceName)

Data Outputs

- **QO** (BOOL): Event Output Qualifier - indicates the status of the service execution
- **STATUS** (WSTRING): Service status (RDY, NO_SUCH_OBJECT, INVALID_STATE)

Adapter

No adapter interfaces are available.

Functionality

The EC_SET_EVT function block receives a request via the REQ event to set a specific event in another function block instance. The input data specifies the target function block instance (FB_NAME), the event to be set (FB_EVENT_IO), and the destination (DST). After successful execution, the CNF event is returned with the corresponding status.

…

Technical Features

- Implementation in C++ for GCC compiler version 3.0 and later
- Supports wide-string data types for international character sets
- Provides detailed status feedback for troubleshooting
- Operates as a reconfiguration service between the application and the resource

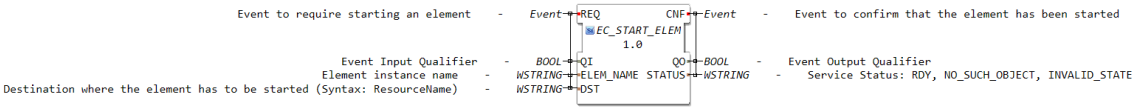
State Overview

The function block supports several service sequences:

- **normal_establishment**: Successful initialization
- **unsuccessful_establishment**: Failed initialization
- **request_confirm**: Successful service execution
- **request_inhibited**: Suppressed service request
- **request_error**: Failed service execution
- **application_initiated_termination**: Application-side termination
- **resource_initiated_termination**: Resource-side termination

Application Scenarios

- Debugging and monitoring of event flows
- Automated test environments
- Dynamic reconfiguration of control systems
- Event-based diagnostic functions
- Simulation of external Events

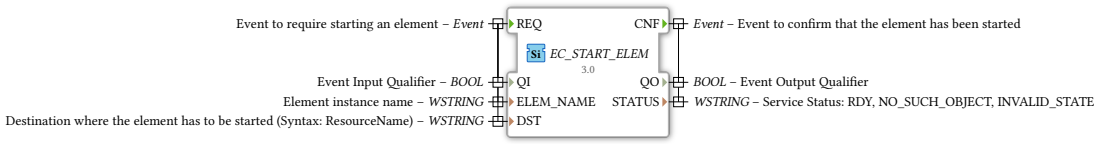


⚖️ Comparison with Similar Function Blocks

Compared to standard function blocks, EC_SET_EVT offers special reconfiguration capabilities that go beyond normal event processing. It allows external access to events in other function blocks, which is particularly valuable for diagnostic and testing purposes.

Conclusion

The EC_SET_EVT function block is a powerful tool for advanced control applications, especially for debugging, testing, and dynamic reconfiguration. Its ability to selectively set events in other function block instances makes it a valuable component for complex automation systems.



2.11.8.3 EC_START_ELEM

• — ○ • — ○ • — ○ •

Introduction

The EC_START_ELEM function block is used to start instances according to the state machine definition of IEC 61499 function blocks. It enables the targeted starting of function block instances, connections (event/data), resources, or devices within a distributed automation system.

Interface Structure

Event Inputs

- **REQ**: Event to request the start of an element. Associated with the data ELEM_NAME, DST, and QI.

Event Outputs

- **CNF**: Event to confirm that the element has been started. Associated with the data STATUS and QO.

Data Inputs

- **QI** (BOOL): Event input qualifier for controlling the request
- **ELEM_NAME** (WSTRING): Name of the element instance to be started
- **DST** (WSTRING): Destination where the element must be started (Syntax: ResourceName)

Data Outputs

- **QO** (BOOL): Event output qualifier for status feedback
- **STATUS** (WSTRING): Service status with possible values: RDY, NO_SUCH_OBJECT, INVALID_STATE

Adapters

No adapter interfaces are available.

Operation

The function block responds to the REQ event and attempts to start the specified element (function block, connection, resource, or device) at the specified destination. The start process follows the IEC 61499 state machine. Upon successful startup, the CNF event is returned with the status “RDY”. In case of errors, corresponding status messages such as “NO_SUCH_OBJECT” or “INVALID_STATE” are returned.

Technical Features

- Supports wide-string data types for element names and destinations
- Implements a qualifier system to control execution logic
- Provides detailed status feedback for various error states
- Complies with the IEC 61499 standard for execution control services

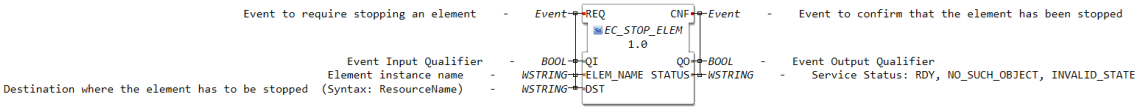
State Overview

The function block has several service sequences:

- **normal_establishment**: Successful initialization
- **unsuccessful_establishment**: Failed initialization
- **request_confirm**: Successful request processing
- **request_inhibited**: Suppressed request
- **request_error**: Failed request processing
- **application_initiated_termination**: Application-side termination
- **resource_initiated_termination**: Resource-side termination

Application Scenarios

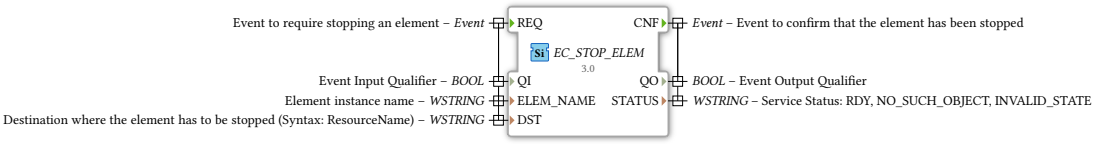
- Dynamically starting function blocks in running systems
- Reconfiguring automation systems at runtime
- Distributed management of resources and devices
- Fault-tolerant systems with restart functionality



⚖️ Comparison with similar function blocks

Compared to simple start function blocks, EC_START_ELEM offers extended functionality for distributed systems with specific destination specification and detailed status feedback. It is part of the reconfiguration services and supports various element types beyond those of simple function blocks.

Conclusion



EC_START_ELEM is a powerful function block for the dynamic control of automation system components. Its ability to start various element types at specific destinations makes it particularly valuable for reconfigurable and adaptive control systems according to IEC 61499.

2.11.8.4 EC_STOP_ELEM

Introduction

The EC_STOP_ELEM function block is used to stop instances according to the state machine of IEC 61499 function blocks. It can stop function block instances, connections (event/data), resources, or devices. This block belongs to the category of reconfiguration services and implements an execution control service according to IEC 61499-1.

Interface Structure

Event Inputs

- **REQ**: Event to request that an element be stopped

Event Outputs

- **CNF**: Event to confirm that the element has been stopped

Data Inputs

- **QI** (BOOL): Event input qualifier
- **ELEM_NAME** (WSTRING): Element instance name
- **DST** (WSTRING): Destination where the element must be stopped (Syntax: ResourceName)

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (WSTRING): Service status: RDY, NO_SUCH_OBJECT, INVALID_STATE

Adapters

No adapter interfaces are available.

Functionality

The EC_STOP_ELEM function block processes stop requests for various elements within an IEC 61499 system. Upon receipt of a REQ event with an enabled QI input, the stop process for the specified element is initiated. After completion of the stop process, a CNF event is output with the corresponding status.

Technical Features

- Supports stopping various element types: FBs, connections, resources, and devices
- Uses WSTRING data types for element names and targets
- Provides detailed status feedback on possible error states
- Implemented according to the IEC 61499-1 standard for execution control services

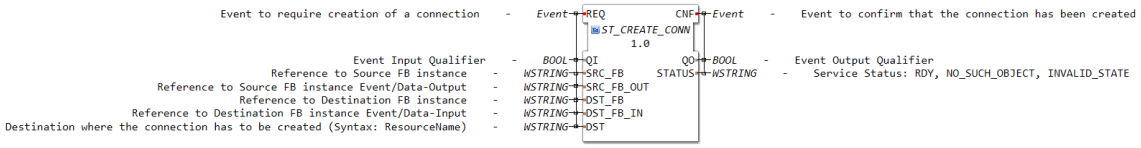
State Overview

The function block has several service sequences:

- **normal_establishment**: Successful initialization
- **unsuccessful_establishment**: Failed initialization
- **request_confirm**: Successful stop request
- **request_inhibited**: Suppressed stop request
- **request_error**: Failed stop request
- **application_initiated_termination**: Application-initiated termination
- **resource_initiated_termination**: Resource-initiated termination

Application Scenarios

- Dynamic reconfiguration of control systems
- Planned shutdown of system components
- Error handling Targeted stopping of faulty components
- Maintenance work on running systems

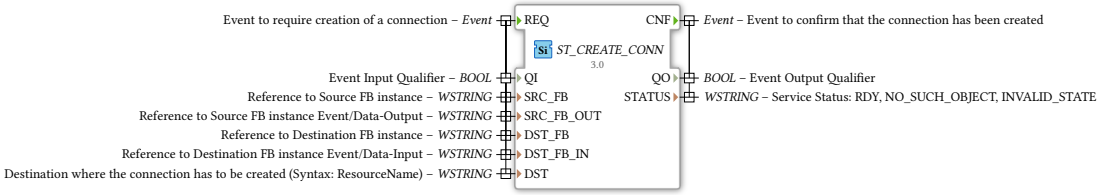


⚖️ Comparison with similar function blocks

Compared to other reconfiguration function blocks, EC_STOP_ELEM offers a specialized function for the targeted stopping of individual system components. While general reconfiguration function blocks often support more complex operations, this function block focuses on the specific task of controlled stopping.

Conclusion

EC_STOP_ELEM is an essential function block for dynamic control systems that require runtime reconfiguration. Its clear interface and reliable status feedback make it a valuable tool for developing maintainable and flexible automation solutions according to IEC 61499.



2.11.8.5 ST_CREATE_CONN

• — ○ • — ○ • — ○ •

Introduction

The ST_CREATE_CONN function block is used to create event or data connections between two function block instances at runtime. This component enables the dynamic reconfiguration of connections in a 4diac system and is classified as a structural service.

Interface Structure

Event Inputs

- **REQ**: Event requesting the creation of a connection

Event Outputs

- **CNF**: Event confirming that the connection has been created

Data Inputs

- **QI** (BOOL): Event input qualifier
- **SRC_FB** (WSTRING): Reference to the source FB instance
- **SRC_FB_OUT** (WSTRING): Reference to the event/data output of the source FB instance
- **DST_FB** (WSTRING): Reference to the target FB instance
- **DST_FB_IN** (WSTRING): Reference to the event/data input of the target FB instance
- **DST** (WSTRING): Destination where the connection must be created (Syntax: ResourceName)

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (WSTRING): Service status (RDY, NO_SUCH_OBJECT, INVALID_STATE)

Adapter

No adapter interfaces are available.

Functionality

The function block establishes a connection between a source and a target function block instance upon request (REQ event). The connection can be used for both events and data streams. After successful processing, an acknowledgment (CNF event) is issued with the corresponding status.

Technical Features

- Supports dynamic reconfiguration at runtime
- Uses wide-string data types for all references
- Provides detailed status feedback
- Implemented as a structured service according to IEC 61499-1

State Overview

The function block supports several service sequences:

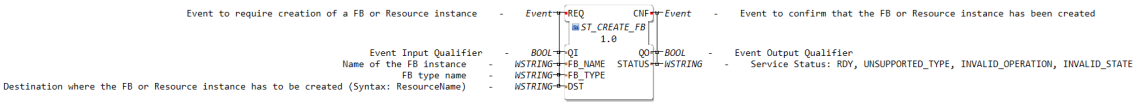
- Normal connection creation
- Failed connection creation
- Request acknowledgment cycle
- Request prevention
- Error handling
- Application- and resource-initiated termination

Application Scenarios

- Dynamic system reconfiguration
- Runtime adaptation of control logic
- Flexible connection management in distributed systems
- Adaptive automation systems

⚖️ Comparison with Similar Function Blocks

Unlike statically configured connections, ST_CREATE_CONN enables the dynamic creation of connections at runtime. Other reconfiguration function blocks typically focus on creating or deleting FB instances, while this function block is specifically optimized for connection management.

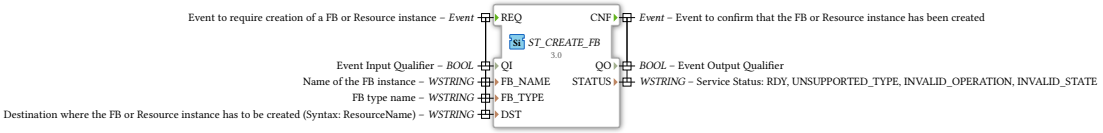


Conclusion

ST_CREATE_CONN is an essential building block for systems requiring dynamic reconfiguration. Its ability to create connections between function blocks at runtime makes it particularly valuable for adaptive and flexible automation solutions.

🌐 Related topic subpages on ms-muc-docs.de

- 🌐 Eclipse 4diac IDE & Color Reference on ms-muc-docs.de



2.11.8.6 ST_CREATE_FB

• — ○ • — ○ • — ○ •

Introduction

The ST_CREATE_FB function block is used to dynamically create function block or resource instances during the runtime of an IEC 61499 system. This block enables the reconfiguration of automation systems by generating new function blocks based on specific FB types.

Interface Structure

Event Inputs

- **REQ**: Event requesting the creation of a function block (FB) or resource instance

Event Outputs

- **CNF**: Event confirming that the FB or resource instance has been created

Data Inputs

- **QI** (BOOL): Event input qualifier
- **FB_NAME** (WSTRING): Name of the FB instance to be created
- **FB_TYPE** (WSTRING): FB type name

- **DST** (WSTRING): Destination where the FB or resource instance should be created (Syntax: Resource-Name)

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (WSTRING): Service status (RDY, UNSUPPORTED_TYPE, INVALID_OPERATION, INVALID_STATE)

Adapter

No adapter interfaces are available.

Functionality

The ST_CREATE_FB function block receives a request to create a new function block instance via the REQ event. The required parameters (FB_NAME, FB_TYPE, DST) are included in the request. After successful processing of the request, the function block returns a confirmation via the CNF event, which contains the status of the operation in the STATUS output.

Technical Features

- Supports dynamic reconfiguration of IEC 61499 systems
- Uses WSTRING data types for international character set support
- Provides detailed status feedback for fault diagnosis
- Implemented as a structural service according to the IEC 61499-1 standard

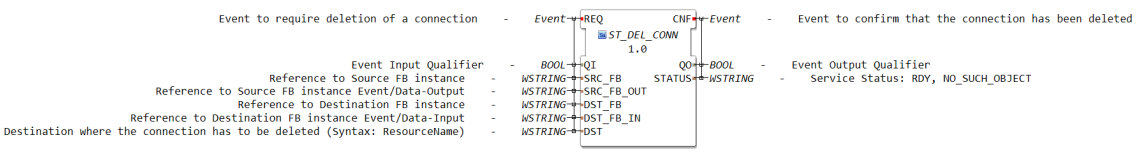
Status Overview

The function block has several service sequences:

- **normal_establishment**: Successful initialization
- **unsuccessful_establishment**: Failed initialization
- **request_confirm**: Successful request processing
- **request_inhibited**: Suppressed request
- **request_error**: Failed request processing
- **application_initiated_termination**: Application-initiated termination
- **resource_initiated_termination**: Resource-initiated termination

Application Scenarios

- Dynamic expansion of automation systems
- Adaptive control systems that adjust to changing production requirements
- Modular systems Architectures where components are added at runtime
- Reconfigurable manufacturing systems

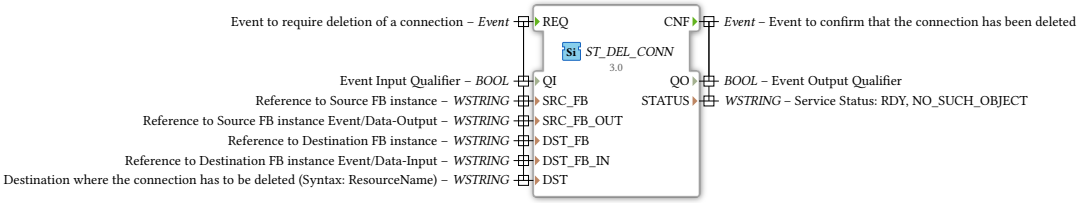


⚖️ Comparison with similar function blocks

Compared to static function blocks, ST_CREATE_FB offers the unique ability to create instances at runtime. While standard function blocks are defined at compile time, this block enables a flexible system architecture.

Conclusion

The ST_CREATE_FB function block is an essential tool for developing dynamic and reconfigurable automation systems according to IEC 61499. Its ability to create function block instances at runtime makes it particularly valuable for applications requiring adaptability and flexibility.



2.11.8.7 ST_DEL_CONN

• — ○ • — ○ • — ○ •

Introduction

The ST_DEL_CONN function block is used to delete event or data connections between two function block instances within a 4diac system. It enables the dynamic reconfiguration of connections at runtime and belongs to the category of structural services according to IEC 61499-1.

Interface Structure

Event Inputs

- **REQ**: Event to request the deletion of a connection

Event Outputs

- **CNF**: Event confirming that the connection has been deleted

Data Inputs

- **QI** (BOOL): Event input qualifier
- **SRC_FB** (WSTRING): Reference to the source FB instance
- **SRC_FB_OUT** (WSTRING): Reference to the event/data output of the source FB instance
- **DST_FB** (WSTRING): Reference to the target FB instance
- **DST_FB_IN** (WSTRING): Reference to the event/data input of the target FB instance
- **DST** (WSTRING): Destination where the connection must be deleted (Syntax: ResourceName)

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (WSTRING): Service Status: RDY, NO_SUCH_OBJECT

Adapters

No adapter interfaces are available.

Functionality

When the REQ event is triggered, the specified connection between the indicated function block instances is deleted. The block expects complete references for both the source and target function block instances, including their inputs and outputs. After successful processing, the CNF event is output with the corresponding status.

Technical Features

- Supports the deletion of both event and data connections
- Works with wide-string data types for all reference parameters
- Provides status feedback on successful or failed operations
- Implemented according to the IEC 61499-1 standard for structured services

State Overview

The function block supports various service sequences:

- Normal initialization (INIT+ ⟶ INITO+)
- Failed initialization (INIT+ ⟶ INITO-)
- Successful request (REQ+ ⟶ CNF+)
- Suppressed request (REQ- ⟶ CNF-)
- Failed request (REQ+ ⟶ CNF-)
- Application- and resource-side termination

Application Scenarios

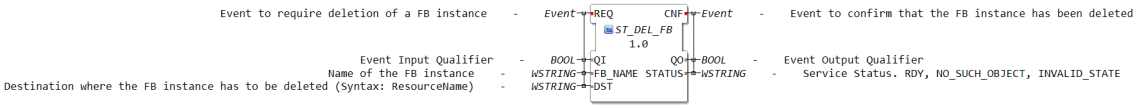
- Dynamic reconfiguration of control systems

- Removal of connections at runtime
- Error handling for connection problems
- Adaptive systems that need to adjust to changing requirements

⚖️ Comparison with Similar Blocks

Specialized compared to other reconfiguration blocks ST_DEL_CONN focuses exclusively on deleting connections, while other function blocks may support creating or modifying connections.

Conclusion



ST_DEL_CONN is an essential function block for systems requiring dynamic reconfiguration. Its clear interface definition and reliable status feedback make it a dependable tool for managing connections in IEC 61499-based control systems.

2.11.8.8 ST_DEL_FB

• — ○ • — ○ • — ○ •

Introduction

The ST_DEL_FB function block is used to delete a function block instance of a specific function block type. This function block belongs to the category of reconfiguration services and enables the dynamic management of function block instances at runtime.

Interface Structure

Event Inputs

- **REQ**: Event to request the deletion of a function block instance

Event Outputs

- **CNF**: Event confirming that the function block instance has been deleted

Data Inputs

- **QI** (BOOL): Event input qualifier
- **FB_NAME** (WSTRING): Name of the function block instance to be deleted
- **DST** (WSTRING): Destination where the function block instance must be deleted (Syntax: Resource-Name)

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (WSTRING): Service status (RDY, NO_SUCH_OBJECT, INVALID_STATE)

Adapter

No adapter interfaces are available.

Functionality

The ST_DEL_FB function block responds to the REQ event and attempts to delete the specified function block instance at the indicated destination. Upon successful execution, a CNF event with the corresponding status is output. The block supports various operating states and error handling.

Technical Features

- Supports dynamic reconfiguration of function blocks
- Uses WSTRING data types for international character sets
- Provides detailed status feedback on the deletion process
- Implemented according to the IEC 61499-1 standard for structured services

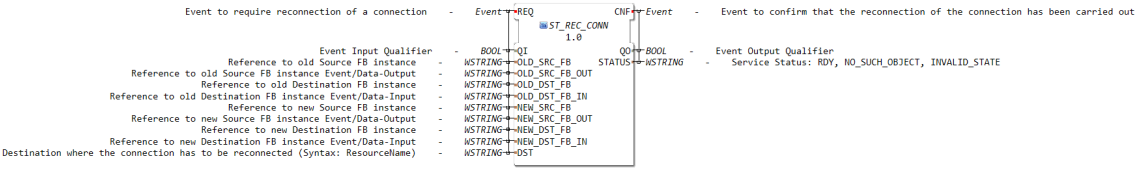
State Overview

The function block supports several service sequences:

- Normal Establishment
- Unsuccessful Establishment
- Request Confirmation
- Suppressed Request Inhibited
- Request Error
- Application-Initiated Termination
- Resource-Initiated Termination

Application Scenarios

- Dynamic reconfiguration of control systems
- Resource management in distributed automation systems
- Runtime adaptation of function block architectures
- Maintenance and updates of automation systems

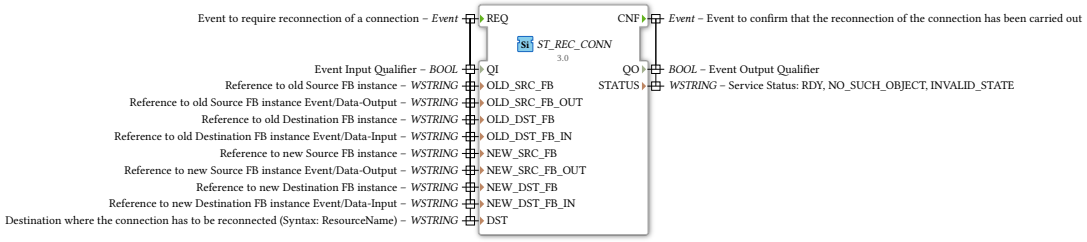


⚖️ Comparison with similar Function Blocks

Compared to static function blocks, ST_DEL_FB enables the dynamic management of function block instances at runtime. It differs from creation blocks through its specific deletion functionality, thus offering complementary functionality for complete lifecycle management.

Conclusion

The ST_DEL_FB function block is an essential tool for systems requiring dynamic reconfiguration. Its robust error handling and detailed status feedback make it a reliable solution for managing function block instances in complex automation environments.



2.11.8.9 ST_REC_CONN

• — ○ • — ○ • — ○ •

Introduction

The ST_REC_CONN function block is used for the dynamic reconfiguration of connections between function blocks in 4diac systems. It enables the redirection of event or data connections from existing source and target function blocks to new instances during runtime.

Interface Structure

Event Inputs

- **REQ**: Starts the reconfiguration process for a connection

Event Outputs

- **CNF**: Confirms whether the connection reconfiguration was successful or failed

Data Inputs

- **QI** (BOOL): Qualifies the event input
- **OLD_SRC_FB** (WSTRING): Reference to the old source FB instance
- **OLD_SRC_FB_OUT** (WSTRING): Reference to the old source FB output (event/data)
- **OLD_DST_FB** (WSTRING): Reference to the old target FB instance
- **OLD_DST_FB_IN** (WSTRING): Reference to the old target FB input (event/data)
- **NEW_SRC_FB** (WSTRING): Reference to the new Source FB Instance
- **NEW_SRC_FB_OUT** (WSTRING): Reference to the new source FB output (event/data)
- **NEW_DST_FB** (WSTRING): Reference to the new target FB instance
- **NEW_DST_FB_IN** (WSTRING): Reference to the new target FB input (event/data)
- **DST** (WSTRING): Destination for reconfiguration (Syntax: ResourceName)

Data Outputs

- **QO** (BOOL): Qualifies the event output
- **STATUS** (WSTRING): Service status (RDY, NO_SUCH_OBJECT, INVALID_STATE)

Adapters

No adapter interfaces are available.

Functionality

Upon arrival of the REQ event, the function block analyzes the passed parameters and performs the following steps:

1. Identifies the existing connection between OLD_SRC_FB and OLD_DST_FB
2. Disconnects the existing connection
3. Establishes a new connection between NEW_SRC_FB and NEW_DST_FB
4. Provides feedback on the operation status via the CNF event

The QI input controls the execution: If FALSE, the operation is not performed.

Technical Features

- Supports both event and data connections
- Uses WSTRING data types for all reference parameters
- Works with resource-specific target specifications
- Provides detailed status feedback
- Implemented according to the IEC 61499-1 standard for reconfiguration

State Overview

The function block operates according to a simple request-acknowledgment principle:

- Waiting state: No active operation
- Execution state: Processing the REQ request
- Completion state: Sending the CNF acknowledgment

Application Scenarios

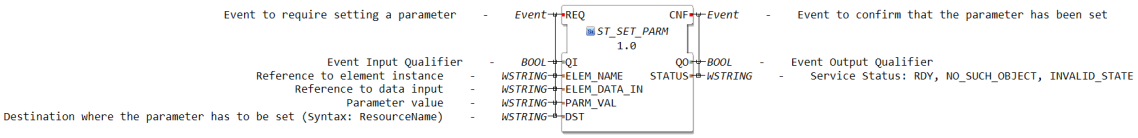
- Dynamic system reconfiguration during operation
- Hot-swapping of function blocks
- Load balancing through connection redirection
- Fault-tolerant systems with redundant components
- Adaptive control systems with changing operating modes

⚖️ Comparison with similar blocks

Unlike static connections in 4diac, ST_REC_CONN enables:

- Dynamic adjustment of connections at runtime
- Greater flexibility in Adaptive Systems
- More complex reconfiguration scenarios compared to simple connection blocks

Conclusion



ST_REC_CONN is an essential component for flexible and adaptive automation systems that require dynamic reconfiguration during operation. Its comprehensive parameterization enables precise control of connection changes, while status feedback ensures reliable monitoring of the reconfiguration processes.

2.11.8.10 ST_SET_PARM

• – ○ • – ○ • – ○ •

Introduction

The ST_SET_PARM function block is used to set parameters for data inputs of function blocks, resources, or device instances within a 4diac system. This function block enables the dynamic configuration of system parameters at runtime.

Interface Structure

Event Inputs

- **REQ**: Starts the process of setting a parameter. Associated with the data ELEM_NAME, ELEM_DATA_IN, PARM_VAL, DST, and QI.

Event Outputs

- **CNF**: Confirms that the parameter was set successfully. Associated with the data STATUS and QO.

Data Inputs

- **QI** (BOOL): Event input qualifier
- **ELEM_NAME** (WSTRING): Reference to element instance
- **ELEM_DATA_IN** (WSTRING): Reference to data input
- **PARM_VAL** (WSTRING): Parameter value

- **DST** (WSTRING): Destination where the parameter must be set (Syntax: ResourceName)

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (WSTRING): Service status (RDY, NO_SUCH_OBJECT, INVALID_STATE)

Adapters

No adapters available.
Data Inputs

Functionality

Upon arrival of the REQ event, the ST_SET_PARM function block attempts to set the specified parameter value (PARM_VAL) for the specified data input (ELEM_DATA_IN) of the target instance (ELEM_NAME) at the specified destination (DST). Upon completion of the process, the CNF event is output with the corresponding status.

Technical Features

- Supports wide-string data types for all text-based parameters
- Provides detailed status feedback on the success or failure of the operation
- Enables configuration across resource boundaries
- Implemented as a reconfiguration service according to the IEC 61499-1 standard

State Overview

1. **Idle State**: Waits for a REQ event
2. **Processing State**: Sets the parameter based on the input data
3. **Acknowledgement State**: Sends a CNF event with status information

Application Scenarios

- Dynamic adjustment of system parameters during operation
- Configuration of function block parameters in distributed systems
- Automated parameterization in production plants
- Maintenance and optimization of control systems

⚖️ Comparison with Similar Function Blocks

Compared to static parameterization methods, ST_SET_PARM offers the ability to change parameters at runtime, enabling greater flexibility in adaptive control systems. Other configuration blocks typically only operate during the initialization phase.

Conclusion

The ST_SET_PARM function block is an essential tool for the dynamic reconfiguration of 4diac systems. Its ability to set parameters at runtime makes it particularly valuable for applications requiring adaptability and flexibility. The clear interface definition and detailed status feedback ensure reliable integration into complex automation systems.

2.11.9 rtevents

2.11.9.1 RT_Bridge_1

• – ◦ • – ◦ • – ◦ •

Introduction

The RT_Bridge_1 function block serves as a decoupling bridge for a data connection between real-time event chains. It enables secure data exchange between different execution contexts.

Interface Structure

Event Inputs

- **RD**: Read data from the bridge.
- **WR**: Write data to the bridge.

Event Outputs

- **RDO**: Notification of read data.

Data Inputs

- **SD_1** (ANY): Data to be written to the bridge.

Data Outputs

- **RD_1** (ANY): Data read from the bridge.

Functionality

The module temporarily stores the data received via `WR` and makes it available at the output at `RD`. This decouples the write and read processes in terms of timing.

2.11.9.12 RT_E_CYCLE

• – ◦ • – ◦ • – ◦ •

Introduction

The RT_E_CYCLE function block implements periodic event generation (cycle) with real-time capabilities. It allows you to define deadlines and execution times (WCET).

Interface Structure

Event Inputs

- **START**: Starts the cycle.
- **STOP**: Stops the cycle.

Event Outputs

- **EO**: The cyclically generated event.

Data Inputs

- **DT** (TIME): Cycle time (delay time).
- **Deadline** (TIME): Deadline for event processing.
- **WCET** (TIME): Worst-case execution time.

Data Outputs

- **QO** (BOOL): Status indicator.

Functionality

After the `START` event, the `EO` event is triggered periodically at time `DT`. The parameters `Deadline` and `WCET` are used for real-time scheduling and monitoring.

2.11.9.13 RT_E_DELAY

• – ◦ • – ◦ • – ◦ •

Introduction

The RT_E_DELAY function block delays an event by a defined time (DT) while adhering to real-time requirements.

Interface Structure

Event Inputs

- **INIT**: Initialization.
- **START**: Starts the delay.
- **STOP**: Stops the delay.

Event Outputs

- **INITO**: Initialization acknowledged.
- **EO**: The delayed event.

Data Inputs

- **QI** (BOOL): Qualifier.
- **DT** (TIME): Delay time.
- **Tmin** (TIME): Minimum time.
- **Deadline** (TIME): Deadline.
- **WCET** (TIME): Worst-case execution time.

Data Outputs

- **QO** (BOOL): Status.

2.11.9.14 RT_E_DEMUX

• – ◦ • – ◦ • – ◦ •

Introduction

Real-time version of the E_DEMUX block. Forwards an input event to one of several outputs.

Interface

Event inputs

Event	Associated variables	Description
INIT	QI, Tmin, Deadline0..Deadline3, WCET0..WCET3	Initialization
EI	K	Event to demultiplex

Event outputs

Event	Associated variables	Description
INITO	QO	Confirmation of the initialization
EO0..EO3	-	Output events (the number of outputs is implementation dependent)

Input variables

Name	Type	Description
QI	BOOL	Initialization input
K	UINT	Event index, the maximum is implementation dependent
Tmin	TIME	Timing parameter of the real-time variant (not further commented in the source)
Deadline0..Deadline3	TIME	Timing parameter of the real-time variant (not further commented in the source), per output EO0..EO3
WCET0..WCET3	TIME	Timing parameter of the real-time variant (not further commented in the source), per output EO0..EO3

Output variables

Name	Type	Description
QO	BOOL	Initialization output (with INITO)

2.11.9.15 RT_E_EC_COUPLER

• – ◦ • – ◦ • – ◦ •

Introduction

Couples event chains with real-time parameters.

Interface Structure

Event Inputs

- **INIT**: Initialization, carries `QI`, `Tmin`, `Deadline` and `WCET`.
- **EI**: Event input (start of the coupling); carries no data.

Event Outputs

- **INITO**: Confirms the initialization, carries `QO`.
- **EO**: Event output (continuation of the event chain); carries no data.

Data Inputs

- **QI** (`BOOL`): Qualifier for the initialization.
- **Tmin** (`TIME`): Real-time parameter (minimum distance).
- **Deadline** (`TIME`): Real-time parameter (deadline).
- **WCET** (`TIME`): Real-time parameter (worst-case execution time).

Data Outputs

- **QO** (`BOOL`): Output qualifier of the initialization.

2.11.9.18 RT_E_PERMIT

• – ◦ • – ◦ • – ◦ •

Introduction

Real-time version of the E_PERMIT block. Allows an event only if the condition (PERMIT) is true.

Interface Structure

Event Inputs

- **INIT**: Initialization, carries `QI`, `Tmin`, `Deadline` and `WCET`.
- **EI**: Event input, carries `PERMIT`.

Event Outputs

- **INITO**: Confirms the initialization, carries `QO`.
- **EO**: Event output; carries no data.

Data Inputs

- **QI** (`BOOL`): Qualifier for the initialization.
- **PERMIT** (`BOOL`): Permission condition for propagating the event.
- **Tmin** (`TIME`): Real-time parameter (minimum distance).
- **Deadline** (`TIME`): Real-time parameter (deadline).
- **WCET** (`TIME`): Real-time parameter (worst-case execution time).

Data Outputs

- **QO** (`BOOL`): Output qualifier of the initialization.

2.11.9.20 RT_E_R_TRIG

• – ◦ • – ◦ • – ◦ •

Introduction

Real-time variant of the E_R_TRIG function block (rising edge).

Interface

Event inputs

Event	Associated variables	Description
INIT	QI, Tmin, Deadline, WCET	Initialization
EI	QI	Event input

Event outputs

Event	Associated variables	Description
INITO	QO	Confirmation of the initialization
EO	-	Event output

Input variables

Name	Type	Description
QI	BOOL	Input (with INIT: initialization; with EI: value to be evaluated)
Tmin	TIME	Timing parameter of the real-time variant (not further commented in the source)
Deadline	TIME	Timing parameter of the real-time variant (not further commented in the source)
WCET	TIME	Timing parameter of the real-time variant (not further commented in the source)

2.11.9.21 RT_E_SELECT

• – ○ • – ○ • – ○ •

Introduction

Real-time version of the E_SELECT block. Selects one of two input events based on a selector.

Interface Structure

Event Inputs

- **INIT**: Initialization, carries `QI`, `Tmin`, `Deadline` and `WCET`.
- **EI0**: Input event, selected when `G` = 0; carries `G`.
- **EI1**: Input event, selected when `G` = 1; carries `G`.

Event Outputs

- **INITO**: Confirms the initialization, carries `QO`.
- **EO**: Output event; carries no data.

Data Inputs

- **QI** (`BOOL`): Qualifier for the initialization.
- **G** (`BOOL`): Selector: `EI0` when `G` = 0, `EI1` when `G` = 1.
- **Tmin** (`TIME`): Real-time parameter (minimum distance).
- **Deadline** (`TIME`): Real-time parameter (deadline).
- **WCET** (`TIME`): Real-time parameter (worst-case execution time).

Data Outputs

- **QO** (`BOOL`): Output qualifier of the initialization.

2.11.9.23 RT_E_SWITCH

• – ◦ • – ◦ • – ◦ •

Introduction

Real-time version of the E_SWITCH block. Routes the input event EI to one of the two outputs EO1/EO2 depending on G.

Interface

Event inputs

Event	Associated variables	Description
INIT	QI, Tmin, Deadline_EO1, WCET_EO1, Deadline_EO2, WCET_EO2	Initialization
EI	G	Input event

Event outputs

Event	Associated variables	Description
INITO	QO	Confirmation of the initialization
EO1	-	First output event
EO2	-	Second output event

Input variables

Name	Type	Description
QI	BOOL	Initialization input
G	BOOL	Switching condition, associated with EI
Tmin	TIME	Timing parameter of the real-time variant (not further commented in the source)
Deadline_EO1, Deadline_EO2	TIME	Timing parameter of the real-time variant (not further commented in the source), per output
WCET_EO1, WCET_EO2	TIME	Timing parameter of the real-time variant (not further commented in the source), per output

Output variables

Name	Type	Description
QO	BOOL	Initialization output (with INITO)

2.11.9.24 RT_E_TRAIN

• – ○ • – ○ • – ○ •

Introduction

Real-time version of the E_TRAIN block. Generates a sequence of events.

Interface Structure

Event Inputs

- **START**: Starts the event train, carries `DT`, `N`, `Deadline` and `WCET`.
- **STOP**: Stops the event train; carries no data.

Event Outputs

- **EO**: `N` events at period `DT`, starting `DT` after `START`; carries `CV`.

Data Inputs

- **DT** (`TIME`): Period between events.
- **N** (`UINT`): Number of events to generate.
- **Deadline** (`TIME`): Real-time parameter (deadline).
- **WCET** (`TIME`): Real-time parameter (worst-case execution time).

Data Outputs

- **CV** (`UINT`): Index of the current `EO` (0 to N-1).

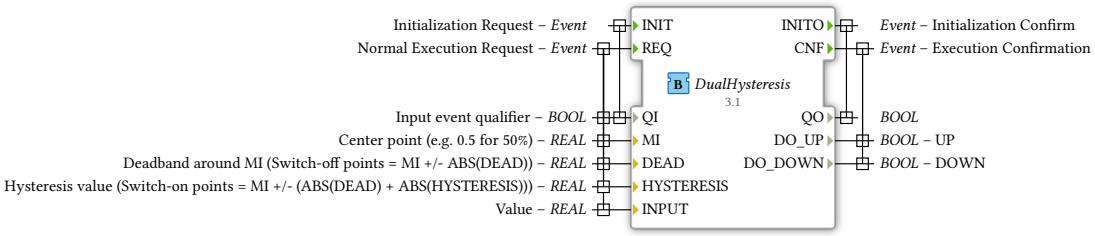
2.11.10 signal processing

...



2.11.10.1 DualHysteresis

• – ○ • – ○ • – ○ •

Introduction

The DualHysteresis function block enables bidirectional conversion of analog to digital signals using hysteresis. It is particularly useful in control applications where reliable switching point conversion with deadband and hysteresis is required.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with `QI`)
- `REQ`: Normal Execution Request (with `QI`, `MI`, `DEAD`, `INPUT`, `HYSTERESIS`)

Event Outputs

- `INITO`: Initialization Acknowledgement (with `QO`)
- `CNF`: Execution Confirmation (with `DO_UP`, `DO_DOWN`)

Data Inputs

- `QI` (BOOL): Input Event Qualifier
- `MI` (REAL, Initial Value: 0.5): Average Setting (e.g., 0.5 for 50%)
- `DEAD` (REAL, Initial Value: 0.1): Dead Band around MI (e.g., 0.1 for 10%)
- `HYSTERESIS` (REAL, Initial Value: 0.1): Hysteresis (e.g., 0.1 for 10%)
- `INPUT` (REAL): Input value

Data Outputs

- `QO` (BOOL): Output event qualifier
- `DO_UP` (BOOL): Upward signal
- `DO_DOWN` (BOOL): Downward signal

Adapters

No adapters available.

Functionality

The function block goes through various states:

1. **Initialization**: Sets the outputs to safe values
2. **Neutral**: Waits for valid input values
3. **UP/DOWN**: Activates the corresponding outputs when the threshold values are exceeded
4. **Deinitialization**: Returns to the safe state

Hysteresis prevents excessive switching for small signal changes around the threshold value.

Technical Features

- Uses a deadband (DEAD) around the mean (MI)
- Implements symmetrical hysteresis (HYSTERESIS)
- All parameters are configurable
- Safe state upon deactivation (QI=FALSE)

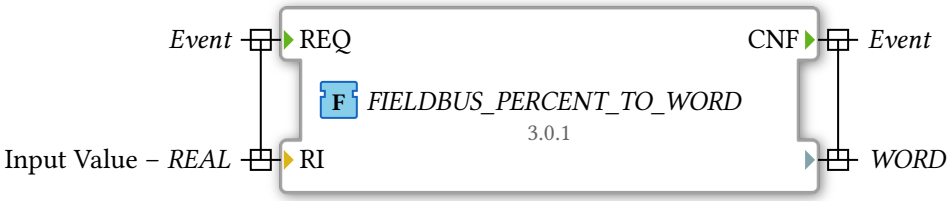
State Overview

1. **START → Init** (when INIT with QI=TRUE)
2. **Init → Neutral** (when REQ)
3. **Neutral → UP** (when INPUT ≥ MI + DEAD + HYSTERESIS)
4. **Neutral → DOWN** (when INPUT ≤ MI - DEAD - HYSTERESIS)
5. **UP/DOWN → Neutral** (when returning to the deadband range)

6. **Neutral → DeInit** (when INIT with QI=FALSE)
7. **DeInit → START** (automatic)

Application Scenarios

- Position control with deadband
- Temperature monitoring with hysteresis
- Level detection with different switching points for filling/emptying
- General signal conditioning with noise suppression



⚖️ **Comparison with similar components**

- Simple hysteresis blocks typically only have one switching output
- Standard comparators do not offer deadband or hysteresis functionality
- This block combines both directions in a single component with configurable parameters

Conclusion

The DualHysteresis block offers a flexible solution for applications requiring reliable signal conversion with deadband and hysteresis in both directions. Its clear state machine and configurable parameters make it particularly versatile.

2.11.10.2 FIELDBUS_PERCENT_TO_WORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FIELDBUS_PERCENT_TO_WORD` converts a REAL value in the range of 0.0 to 100.0 into a WORD value in the range of 0 to FAFF (hexadecimal). This function block is particularly suitable for signal processing in fieldbus systems according to the SAE J1939 and ISO 11783 standards.

Interface Structure

Event Inputs

- `REQ`: Trigger event for the conversion. Linked to the input value `RI`.

Event Outputs

- `CNF`: Confirmation event triggered after successful conversion.

Data Inputs

- `RI` (REAL): Input value in the range 0.0 to 100.0 to be converted.

Data Outputs

- (WORD): The converted output value in the range 0 to FAFF (hexadecimal).

Adapters

No adapters available.

Functionality

The function block performs the following steps:

1. Multiplication of the input REAL value (`RI`) by the converted maximum valid signal value (`FIELDBUS_SIGNAL::VALID_SIGNAL_W`).
2. Conversion of the result to a UDINT value.
3. Converting the UDINT value to the final WORD output value.

The conversion is performed using the following formula:
FIELDBUS_PERCENT_TO_WORD = UDINT_TO_WORD(REAL_TO_UDINT(RI * UDINT_TO_REAL(WORD_TO_UDINT(FIELDBUS_SIGNAL::VALID_SIGNAL_W))))

Technical Features

- Uses special type conversion functions (REAL_TO_UDINT, UDINT_TO_WORD, etc.)
- Works with the constant value `FIELDBUS_SIGNAL::VALID_SIGNAL_W` as the maximum limit
- Embedded in the package `eclipse4diac::signalprocessing`

State Overview

1. Wait state: Waits for the `REQ` event
2. Process state: Conversion is performed upon `REQ` input
3. Output state: `CNF` is triggered after successful conversion

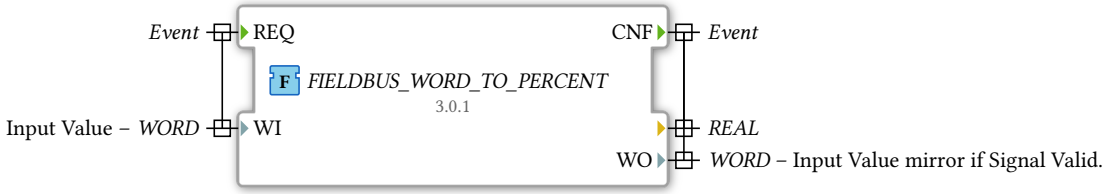
Application Scenarios

- Signal processing in agricultural machinery
- Vehicle control systems
- Industrial automation with fieldbus communication
- Process data conversion between different systems

⚖️ Comparison with similar modules

- Specialized to the specific requirements of SAE J1939 and ISO 11783
- Offers more precise control over the value range than generic conversion blocks
- Optimized for use in signal processing

Conclusion



The `FIELDBUS_PERCENT_TO_WORD` function block is a specialized tool for the precise conversion of percentage values into fieldbus-specific WORD values. Its clear interface and efficient implementation make it particularly suitable for applications in mobile machine control and industrial automation.

]

2.11.10.3 FIELDBUS_WORD_TO_PERCENT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FIELDBUS_WORD_TO_PERCENT` converts a REAL value in the range of 0.0 to 100.0 into a WORD value in the range of 0 to FAFF (hexadecimal). This is particularly useful for signal processing in fieldbus systems that operate according to the SAE J1939 and ISO 11783 standards.

Interface Structure

Event Inputs

- **REQ**: Starts the conversion. Linked to the data input `WI`.

Event Outputs

- **CNF**: Confirms the completion of the conversion. Outputs the converted value via the data output `WO`.

Data Inputs

- **WI** (WORD): The input value to be converted.

Data Outputs

- **WO** (WORD): A mirror image of the input value `WI`, if the signal is valid.
- **(REAL)**: The converted REAL value in the range of 0.0 to 100.0.

Functionality

The function block first checks whether the input value `WI` is less than or equal to the defined `VALID_SIGNAL_W`. If so, the value is mirrored (`WO := WI`) and then converted into a REAL value between 0.0 and 100.0. The conversion is performed by dividing the converted WORD value by the maximum valid signal value (`VALID_SIGNAL_W`).

Technical Features

- The block supports the SAE J1939 and ISO 11783 standards.
- Conversion only occurs if the input signal is valid (`WI <= VALID_SIGNAL_W`).
- The output `WO` is used to validate the input signal.

State Overview

1. **Initialization**: The block waits for a `REQ` event.
2. **Processing**: Upon `REQ`, `WI` is checked and converted if necessary.
3. **Output**: Upon successful conversion, `CNF` is triggered and the results are output.

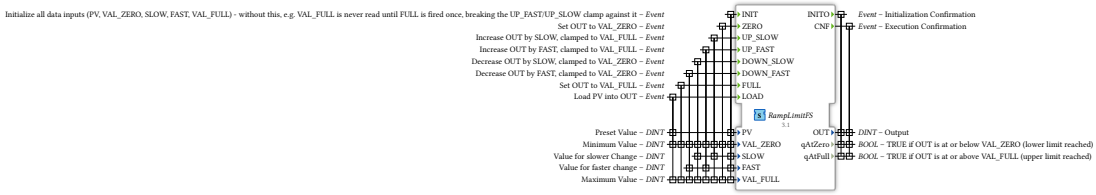
Application Scenarios

- Signal processing in agricultural machinery (ISO 11783).
- Control systems in commercial vehicles (SAE J1939).
- General fieldbus communication where WORD-to-REAL conversions are required.

⚖️ Comparison with Similar Blocks

- Unlike generic conversion blocks, `FIELDBUS_WORD_TO_PERCENT` is specifically optimized for the requirements of SAE J1939 and ISO 11783.
- Other blocks may not offer direct mirroring of the input signal for validation.

Conclusion



The `FIELDBUS_WORD_TO_PERCENT` block is a specialized converter for signal processing in fieldbus systems. Its simple interface and robust functionality make it ideal for applications that require reliable conversion from WORD to REAL values.

2.11.10.4 RampLimitFS

• — ○ • — ○ • — ○ •

Introduction

The `RampLimitFS` function block incrementally increases or decreases an output value at different speeds (fast/slow), similar to a cruise control function in vehicles. It also allows you to set minimum and maximum values and load a predefined value.

Interface Structure

Event Inputs

- `INIT`: Initializes all data inputs (`PV`, `VAL_ZERO`, `SLOW`, `FAST`, `VAL_FULL`) together and sets `OUT` to `VAL_ZERO`. **Must be fired once before any other event** — without `INIT`, e.g. `VAL_FULL` stays at its default value of 0 until `FULL` itself has fired once, which breaks the clamp in `UP_SLOW`/`UP_FAST` (see Technical Details).

- ZERO: Sets the output OUT to the value of VAL_ZERO.
- UP_SLOW: Increments OUT by the value of SLOW.
- UP_FAST: Increments OUT by the value of FAST.
- DOWN_SLOW: Decrements OUT by the value of SLOW.
- DOWN_FAST: Decrements OUT by the value of FAST.
- FULL: Sets OUT to the value of VAL_FULL.
- LOAD: Loads the value of PV into OUT.

Event Outputs

- INITO: Confirms initialization (response to INIT) and outputs the current value of OUT.
- CNF: Confirms execution and outputs the current value of OUT.

Data Inputs

- PV (DINT): Preset value, loaded with LOAD.
- VAL_ZERO (DINT): Minimum value for OUT.
- SLOW (DINT): Step size for slow changes.
- FAST (DINT): Step size for fast changes.
- VAL_FULL (DINT): Maximum value for OUT.

Data Outputs

- OUT (DINT): Current output value.
- qAtZero (BOOL): TRUE if OUT is at or below VAL_ZERO (lower limit reached).
- qAtFull (BOOL): TRUE if OUT is at or above VAL_FULL (upper limit reached).

Adapters

No adapters available.

Functionality

This function block allows for incremental adjustment of the output value OUT through various events:

- **Incremental Increase/Decrease**:
  - UP_SLOW/DOWN_SLOW: Changes OUT by the SLOW value.
  - UP_FAST/DOWN_FAST: Changes OUT by the FAST value.
- **Direct Value Assignment**:
  - ZERO sets OUT to VAL_ZERO.
  - FULL sets OUT to VAL_FULL.
  - LOAD loads the value of PV into OUT.

The output value is always clamped to the boundaries VAL_ZERO (minimum) and VAL_FULL (maximum).

Technical Details

- **Output Value Limitation**: The value of OUT is automatically clamped to the defined limits (VAL_ZERO, VAL_FULL) if the step sizes (SLOW, FAST) would exceed them.
- **Flexible Step Sizes**: Different rates of change via SLOW and FAST.
- **INIT is mandatory before the first event**: Each event only reads the data inputs it needs for its own calculation, as declared via its WITH list. Since every event recomputes qAtZero/qAtFull at the end, every WITH list carries both VAL_ZERO and VAL_FULL — e.g. UP_SLOW reads SLOW, VAL_FULL (for the actual clamp) **and** VAL_ZERO (only for qAtZero), while DOWN_SLOW reads SLOW, VAL_ZERO (clamp) **and** VAL_FULL (only for qAtFull). Without a preceding INIT call, these values have never been assigned a valid value and sit at their default of 0 — usually unnoticed for VAL_ZERO, but for VAL_FULL every UP_SLOW/UP_FAST step then immediately clamps to 0.
- **Limit detection via qAtZero/qAtFull**: Every event (including INIT) recomputes qAtZero := OUT <= VAL_ZERO and qAtFull := OUT >= VAL_FULL after the actual value change and outputs both alongside INITO/CNF. A calling block therefore doesn't need to check the limits itself - useful e.g. to hide a control when a limit is reached (see ScrollFS/ScrollFS_PHYS_Softkey in isobus::UT::Q, which use exactly this for the scroll arrow buttons).

State Overview

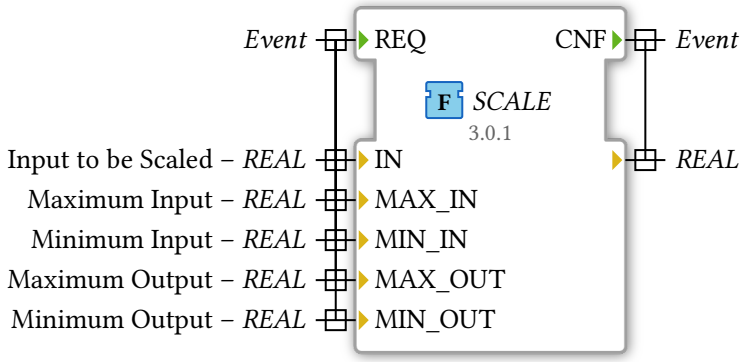
The function block has no internal state. Each event immediately triggers its corresponding calculation and output. The one exception: `INIT` must run once before all other events, so that `VAL_ZERO`/`VAL_FULL`/`SLOW`/`FAST`/`PV` have a defined value in the block at all.

Application Scenarios

- **Cruise Control**: Stepwise speed adjustment with slow/fast key presses.
- **Process Control**: Limited setpoint specification with manual fine-tuning.
- **Parameter Loading**: Loading predefined values (e.g., from non-volatile memory).

⚖️ Comparison with Similar Blocks

- **Comparison with Standard Ramp Functions**: `RampLimitFS` additionally offers the option to switch between fast and slow step sizes and assign direct values (min/max).
- **Flexibility**: Unlike simple counters, this function block allows for dynamic adjustment of step sizes and limits.



🛠️ Related Exercises

- Exercise_009a

Conclusion

The `RampLimitFS` function block is ideal for applications where a value needs to be adjusted stepwise within defined limits. By differentiating between fast and slow changes and offering the ability to load direct values, it provides a high degree of flexibility for various control tasks.

2.11.10.5 SCALE

• – ◦ • – ◦ • – ◦ •

Introduction

The SCALE function block is used to scale an input value from an input range to an output range. This is particularly useful in signal processing when values from one measurement range need to be transformed into another.

Interface Structure

Event Inputs

- **REQ**: Starts the scaling operation. It is linked to the data inputs IN, MAX_IN, MIN_IN, MAX_OUT, and MIN_OUT.

Event Outputs

- **CNF**: Signals the completion of the scaling operation.

Data Inputs

- **IN**: The input value to be scaled (REAL).
- **MAX_IN**: The maximum value of the input range (REAL).

- **MIN_IN**: The minimum value of the input range (REAL).
- **MAX_OUT**: The maximum value of the output range (REAL).
- **MIN_OUT**: The minimum value of the output range (REAL).

Data Outputs

- **(unnamed)**: The scaled output value (REAL).

Adapters

No adapters available.

Functionality

The SCALE function block calculates the scaled value using the following formula:
SCALE := (IN - MIN_IN) * (MAX_OUT - MIN_OUT) / (MAX_IN - MIN_IN) + MIN_OUT; This formula linearly transforms the input value from the input range [MIN_IN, MAX_IN] to the output range [MIN_OUT, MAX_OUT].

Technical Features

- The function block is implemented in ST (Structured Text).
- The calculation is performed in a single step, ensuring high efficiency.
- No state management is required, as this is a static transformation.

State Overview

The function block has no internal states. The operation is re-executed with each REQ event.

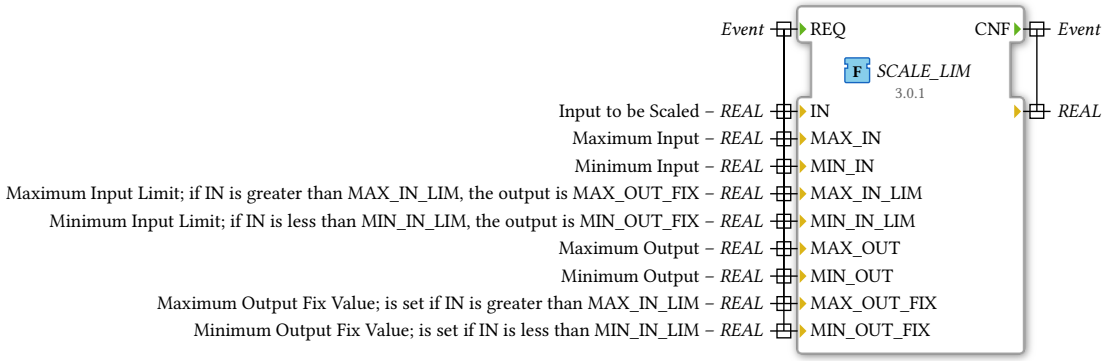
Application Scenarios

- Scaling of sensor values (e.g., from 4-20 mA to 0-100%).
- Transformation of measured values for display or further processing.
- General signal processing in industrial control systems.

⚖️ Comparison with Similar Function Blocks

- Compared to other scaling function blocks, SCALE is particularly easy and straightforward to use.
- No additional parameters or complex settings are required.

Ideal for simple linear scaling without additional logic.



🛠️ Related Exercises

- Exercise_042

Conclusion

The SCALE function block offers an efficient and simple solution for linear scaling tasks. Its clear interface and direct implementation make it a valuable component in signal processing.

2.11.10.6 SCALE_LIM

• – ◦ • – ◦ • – ◦ •

Introduction

The SCALE_LIM function block is a scaling module with additional limiting functions. It enables the linear scaling of an input value within a defined range and also offers the option of fixing output values when certain input limits are exceeded.

Interface Structure

Event Inputs

- **REQ**: Starts the scaling operation. It is linked to all data inputs.

Event Outputs

- **CNF**: Signals the completion of the scaling operation.

Data Inputs

- **IN** (REAL): Input value to be scaled
- **MAX_IN** (REAL): Maximum input value for scaling
- **MIN_IN** (REAL): Minimum input value for scaling
- **MAX_IN_LIM** (REAL): Upper input limit, above which MAX_OUT_FIX is output
- **MIN_IN_LIM** (REAL): Lower input limit, below which MIN_OUT_FIX is output
- **MAX_OUT** (REAL): Maximum output value for scaling
- **MIN_OUT** (REAL): Minimum output value for scaling
- **MAX_OUT_FIX** (REAL): Fixed output value if MAX_IN_LIM is exceeded
- **MIN_OUT_FIX** (REAL): Fixed output value if MIN_IN_LIM is not reached

Data Outputs

- (REAL): Scaled output value

Adapters

No adapters available.

Functionality

The function block performs the following operations:

1. Checks whether the input value IN exceeds the defined limits MIN_IN_LIM or MAX_IN_LIM
2. If IN exceeds MAX_IN_LIM: Outputs MAX_OUT_FIX
3. In normal operating range: Linear scaling of the input value according to the formula:

(IN - MIN_IN) * (MAX_OUT - MIN_OUT) / (MAX_IN - MIN_IN) + MIN_OUT

Technical Features

- Implemented in Structured Text (ST)
- Supports both scaling and limiting
- Part of the `eclipse4diac::signalprocessing` package

State Overview

The function block (FB) has a simple state machine:

1. Waits for a REQ event
2. Performs scaling/limiting
3. Sends a CNF event

Application Scenarios

- Signal processing in control systems
- Scaling of sensor values with limit monitoring
- Process control with defined operating ranges

⚖️ Comparison with Similar Function Blocks

Compared to simple scaling function blocks, SCALE_LIM additionally offers:

- Limit monitoring
- Option to output fixed values when a limit is exceeded

- More flexible definition of scaling ranges

🛠️ Related Exercises

- Exercise_043

Conclusion

SCALE_LIM is a versatile function block for applications that require both scaling and limiting values. Its additional limit functions make it particularly suitable for safety-critical applications where defined responses to limit violations are necessary.

2.11.10.7 distance

RangeBasedPulse

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `RangeBasedPulse` is a distance-based pulse generator that controls a Boolean output (Q) based on the distance traveled (DIST_IN). The function block is started with a HIGH pulse and periodically generates output pulses according to the configured distance values for HIGH and LOW phases.

Interface Structure

Event Inputs

- `REQ`: Normal execution request. Linked to the input data DIST_IN, DIST_OFF, DIST_HIGH, and DIST_LOW.

Event Outputs

- `CNF`: Execution confirmation. Linked to output Q.

Data Inputs

- `DIST_IN` (UDINT): Distance traveled
- `DIST_OFF` (UDINT): Distance offset
- `DIST_HIGH` (UDINT): Distance for HIGH output
- `DIST_LOW` (UDINT): Distance for LOW output

Data Outputs

- `Q` (BOOL): Output signal

Adapters

No adapters included.

Functionality

The function block calculates the remainder (DIST_REMAINDER) of the sum of the distance traveled (DIST_IN) and the offset (DIST_OFF) modulo the sum of DIST_HIGH and DIST_LOW. The output Q is set to HIGH if DIST_REMAINDER is greater than or equal to DIST_HIGH; otherwise, it remains LOW.

Technical Features

- Uses UDINT (unsigned double integer) for distance calculations
- Implements a simple modulo operation for periodic pulse generation
- Supports an offset value for flexible start positions

State Overview

- `REQ`: The only state that executes the algorithm and sends the CNF acknowledgment

Application Scenarios

- Control of machines with distance-based switching operations
- Generation of periodic signals based on distances
- Position-dependent control in vehicle or conveyor systems

⚖️ Comparison with Similar Function Blocks

Unlike simple timers, this function block works with distance values instead of time intervals. It offers greater flexibility through the offset parameter and allows the definition of individual HIGH and LOW phases.

🛠️ Related Exercises

- Exercise_071b
- Exercise_072b

Conclusion

The RangeBasedPulse FB is a specialized function block for applications requiring distance-based control signals. Its simple configuration and flexible offset setting make it well-suited for various industrial control tasks.

2.11.12 utils

2.11.12.1 CSV_WRITER_1

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `CSV_WRITER_1` serves as a service interface for writing data to a CSV file. It enables the initialization of the write operation and the controlled writing of data to a file with status feedback.

Interface Structure

Event Inputs

- **INIT**: Initializes the write service. Triggered by the variables `QI` (qualifier) and `FILE_NAME` (filename).
- **REQ**: Requests the writing of data. Triggered by the variables `QI` and `SD_1` (data to be written).

Event Outputs

- **INITO**: Confirms initialization. Returns `QO` (qualifier) and `STATUS` (initialization state).
- **CNF**: Confirms completion of the write operation. Returns `QO` and `STATUS` (write operation state).

Data Inputs

- **QI**: Boolean qualifier for events.
- **FILE_NAME**: String specifying the name of the file to be written.
- **SD_1**: Data of type `ANY` to be written to the CSV file.

Data Outputs

- **QO**: Boolean qualifier for output events.
- **STATUS**: String returning the file access status.

Adapters

No adapters available.

Functionality

1. **Initialization**: The `INIT` event initializes the write service with the specified filename (`FILE_NAME`). The status is returned via `INITO`.
2. **Write Data**: The `REQ` event triggers the data write operation (`SD_1`). Success or failure is reported via `CNF` and `STATUS`.

Technical Features

- Supports generic data types (`ANY`) for the data to be written.
- Status feedback as a string for detailed error analysis.

Status Overview

- **Initialization State**: Set by `INIT` and confirmed by `INITO`.
- **Write State**: Activated by `REQ` and completed by `CNF`.

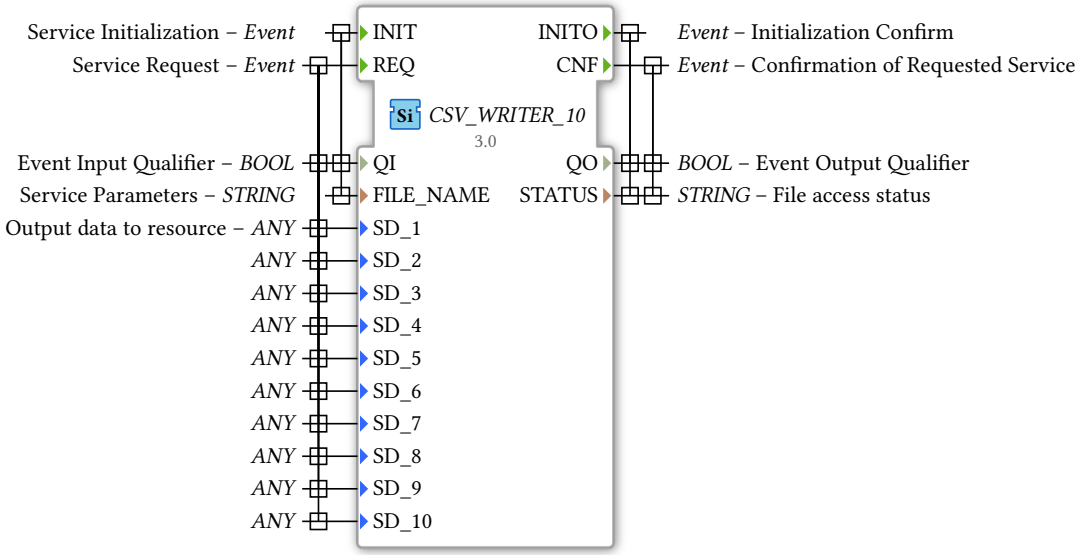
Application Scenarios

- Logging of process data to CSV files.
- Export of measurement data for further analysis.
- Automated data storage in industrial control systems.

⚖️ Comparison with Similar Blocks

- Compared to simple file write blocks, `CSV_WRITER_1` offers detailed status feedback and support for generic data types.
- Other blocks might be limited to specific data types or offer less feedback.

Conclusion



The `CSV_WRITER_1` is a flexible and reliable function block for writing data to CSV files, ideal for applications that require robust logging and data export functionality.

2.11.12.2 CSV_WRITER_10

• – ◦ • – ◦ • – ◦ •

Introduction

The CSV_WRITER_10 function block is used to write data to a CSV file. It allows you to save up to 10 different data values in a structured text file. This block is particularly useful for data collection, logging, and exchanging data with other systems.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block and specifies the file name (using QI and FILE_NAME)
- **REQ**: Triggers the write operation (using QI and SD_1 to SD_10)

Event Outputs

- **INITO**: Confirms initialization (using QO and STATUS)
- **CNF**: Confirms the write operation (using QO and STATUS)

Data Inputs

- **QI**: BOOL - Qualifies the event inputs
- **FILE_NAME**: STRING - Name of the CSV file
- **SD_1 to SD_10**: ANY - Data values to be written (any type)

Data Outputs

- **QO**: BOOL - Qualifies the Event Outputs
- **STATUS**: STRING - File access status message

Adapter

No adapters available.

Functionality

1. **Initialization**: INIT with a valid FILE_NAME prepares the CSV file.
2. **Write Data**: REQ writes the current values from SD_1 to SD_10 as a new line to the file.
3. **Status Feedback**: Each action generates a status message (successful/failed).

Technical Features

- Supports any data type (ANY) for the values to be written.
- Automatic conversion of data to text format.
- Thread-safe file access.
- Maximum capacity of 10 data values per line.

Status Overview

1. **Not Initialized**: Before INIT.
2. **Ready**: After successful initialization.
3. **Error**: In case of file access problems.

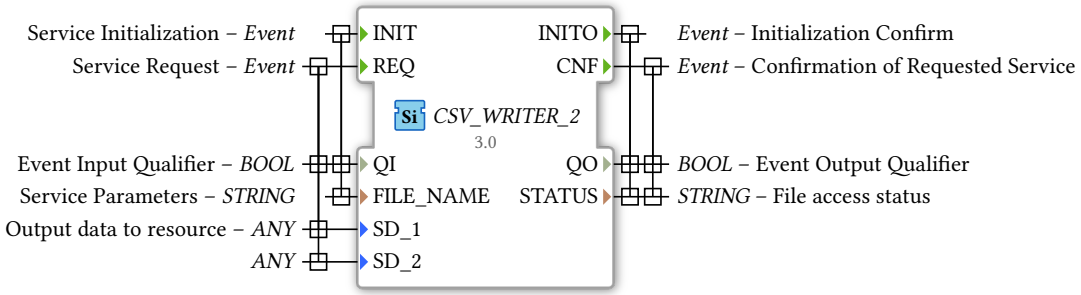
Application Scenarios

- Data acquisition of process values.
- Creation of log files.
- Export of measurement data for external analysis.
- Interface to spreadsheet programs.

⚖️ Comparison with Similar Modules

- Compared to simpler This block offers CSV writers greater flexibility through 10 data channels.
- Unlike hard-typed writers, it supports any data type.
- Provides more detailed status feedback than basic versions.

Conclusion



The CSV_WRITER_10 is a powerful function block for structured data storage, particularly well-suited for applications with multiple values to be logged simultaneously. Its flexible type support and detailed status feedback make it a robust solution for industrial data acquisition tasks.

2.11.12.3 CSV_WRITER_2

• – ◦ • – ◦ • – ◦ •

Introduction

The CSV_WRITER_2 is a function block used to write data to a CSV file. It provides a simple interface for initialization and the writing process, supporting two different data fields. This function block is particularly useful for applications where data needs to be stored persistently or exported for further analysis.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block and configures the filename for the CSV file.
- Input data: `QI` (BOOL), `FILE_NAME` (STRING)
- **REQ**: Starts the data writing process to the CSV file.
- Input data: `QI` (BOOL), `SD_1` (ANY), `SD_2` (ANY)

Event Outputs

- **INITO**: Confirms the initialization of the function block.
- Output data: `QO` (BOOL), `STATUS` (STRING)
- **CNF**: Confirms the successful completion of the write operation.

- Output data: `QO` (BOOL), `STATUS` (STRING)

Data Inputs

- **QI**: Qualifies the event (TRUE for valid, FALSE for invalid).
- **FILE_NAME**: The name of the CSV file to be written to.
- **SD_1**: The first data field to be written to the CSV file (any data type).
- **SD_2**: The second data field to be written to the CSV file (any data type).

Data Outputs

- **QO**: Qualifies the output event (TRUE for success, FALSE for failure).
- **STATUS**: Returns the status of the file access (e.g., success message or error description).

Adapters

This function block has no adapters.

Operation

1. **Initialization**: Sending a `INIT` event with the desired file name (`FILE_NAME`) initializes the function block. The initialization status is reported via `INITO`.
2. **Write Data**: The `REQ` event triggers the write operation. The data `SD_1` and `SD_2` are written to the CSV file. The success or failure of the write operation is reported via `CNF`.

Technical Features

- Supports any data type for the data to be written (`SD_1` and `SD_2`).
- The status (`STATUS`) provides detailed information about the success or failure of the file access.
- The function block is part of the `eclipse4diac::utils` package.

Status Overview

1. **Inactive**: The function block is waiting for initialization.
2. **Initialized**: The function block is ready to write data.
3. **Write Operation**: The function block is writing data to the CSV file.

Application Scenarios

- Logging process data to a CSV file for later analysis.
- Exporting measurement data for external evaluation.
- Storing configuration data in a readable format.

⚖️ Comparison with Similar Function Blocks

- Compared to simpler write function blocks, `CSV_WRITER_2` supports two data fields and provides detailed status feedback.
- Other CSV write function blocks may be less flexible in their data type support or may not provide status feedback.

Conclusion

The `CSV_WRITER_2` function block is a flexible and reliable function block for writing data to CSV files. Its support for arbitrary data types and detailed status feedback make it ideal for applications that require persistent data storage.

2.11.12.4 CSV_WRITER_3

• – ◦ • – ◦ • – ◦ •

Introduction

The CSV_WRITER_3 is a function block used to write data to a CSV file. It supports writing up to three different data fields to a file, specified via the parameter `FILE_NAME`. This function block is particularly useful for logging and data storage in automation systems.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block. Triggered with the data `QI` (Qualifier Input) and `FILE_NAME` (Filename).
- **REQ**: Starts the write operation. Triggered with the data `QI`, `SD_1`, `SD_2`, and `SD_3` (the data to be written).

Event Outputs

- **INITO**: Confirms initialization. Returns `QO` (Qualifier Output) and `STATUS` (Initialization Status).
- **CNF**: Confirms completion of the write operation. Returns `QO` and `STATUS`.

Data Inputs

- **QI**: Boolean value indicating the quality of the event input.
- **FILE_NAME**: String specifying the name of the CSV file.
- **SD_1**, **SD_2**, **SD_3**: Data fields of type `ANY` that are written to the CSV file.

Data Outputs

- **QO**: Boolean value indicating the quality of the event output.
- **STATUS**: String indicating the status of the file access.

Adapters

No adapters available.

Functionality

The function block initializes upon receiving the `INIT` event and acknowledges this with `INITO`. Upon receiving the `REQ` event, the data `SD_1`, `SD_2`, and `SD_3` are written to the specified CSV file. The write status is reported via `CNF`.

Technical Features

- Supports writing to up to three different data fields.
- The data type of the data to be written is `ANY`, allowing for high flexibility.
- Detailed file access status is reported.

State Overview

1. **Initialization State**: Waiting for the `INIT` event.
2. **Ready State**: After successful initialization, waits for the `REQ` event.
3. **Write State**: Writes data to the CSV file and reports the status back.

Application Scenarios

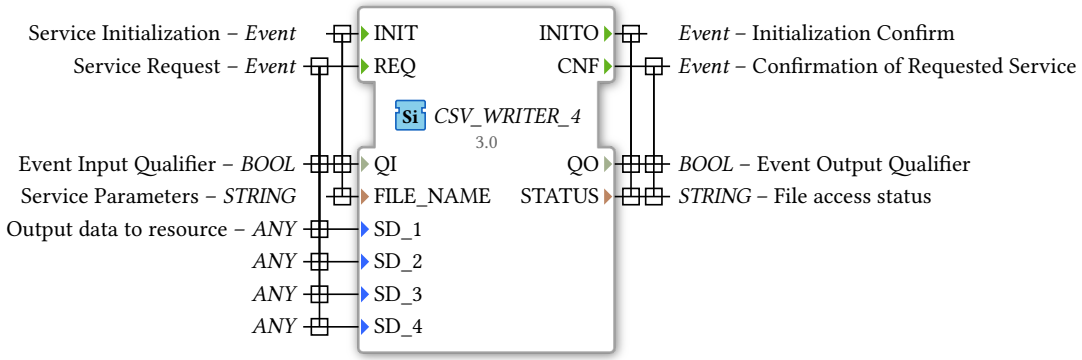
- Logging sensor data to a CSV file.
- Storing process data for later analysis.
- Exchanging data with other systems via CSV files.

⚖️ Comparison with Similar Function Blocks

- Compared to simpler CSV writer function blocks, `CSV_WRITER_3` supports writing to multiple data fields (`SD_1`, `SD_2`, `SD_3`).

Other function blocks might be restricted to specific data types, while `CSV_WRITER_3` uses the `ANY` type.

Conclusion



The `CSV_WRITER_3` is a flexible and powerful function block for storing data in CSV files. Its support for multiple data fields and the `ANY` data type makes it particularly versatile.

2.11.12.5 CSV_WRITER_4

• – ◦ • – ◦ • – ◦ •

Introduction

The CSV_WRITER_4 function block is used to write data to a CSV file. It supports saving up to four different data values in a structured format. The function block is particularly useful for data acquisition and logging in automation applications.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block and configures the output file. It links to data in `QI` and `FILE_NAME`.
- **REQ**: Triggers the write operation. Linked to `QI` and the data values `SD_1` through `SD_4`.

Event Outputs

- **INITO**: Confirms initialization. Returns `QO` and `STATUS`.
- **CNF**: Confirms the write operation is complete. Returns `QO` and `STATUS`.

Data Inputs

- **QI** (BOOL): Qualifies the INIT and REQ events.
- **FILE_NAME** (STRING): Name of the CSV file.
- **SD_1** to **SD_4** (ANY): The data values to be written (up to 4 different ones).

Data Outputs

- **QO** (BOOL): Qualifies the output events.
- **STATUS** (STRING): Status message about file access.

Adapters

No adapters available.

Functionality

1. **Initialization**: The INIT event with `QI` active prepares the CSV file with the specified `FILE_NAME`.
2. **Write Data**: The REQ event with `QI` active triggers the write operation. The values from `SD_1` to `SD_4` are written to the file.
3. **Confirmation**: After each operation (INIT or REQ), the status is reported via `INITO` or `CNF`.

Technical Features

- Supports generic data types (ANY) for the data to be written.
- The function block is part of the `eclipse4diac::utils` package.
- The generic class is defined as `GEN_CSV_WRITER`.

Status Overview

1. **Inactive**: Waiting for initialization.
2. **Initialized**: File is ready, waiting for write requests.
3. **Writing**: Processing a write request.

Application Scenarios

- Logging of process data.
- Data acquisition for analysis purposes.
- Export of measured values to a standardized format.

⚖️ Comparison with Similar Function Blocks

- Compared to simpler write function blocks, CSV_WRITER_4 offers the ability to store multiple data values simultaneously.
- The use of ANY types makes it more flexible than function blocks with fixed data types.

Conclusion

CSV_WRITER_4 is a versatile function block for data acquisition, particularly well-suited for applications that require logging structured data. Its flexibility and ease of integration make it a practical solution for many automation tasks.

2.11.12.6 CSV_WRITER_5

• – ◦ • – ◦ • – ◦ •

Introduction

The CSV_WRITER_5 is a function block for outputting data to a CSV file. It allows you to write up to five different data points to a user-defined file. This function block is particularly useful for data acquisition and logging applications.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block and opens the specified CSV file.
- Linked Data: QI (BOOL), FILE_NAME (STRING)
- **REQ**: Triggers the write operation.

- Linked Data: QI (BOOL), SD_1 to SD_5 (ANY)

Event Outputs

- **INITO**: Confirms initialization.
- Linked Data: QO (BOOL), STATUS (STRING)
- **CNF**: Confirms successful write operation.
- Linked Data: QO (BOOL), STATUS (STRING)

Data Inputs

- **QI**: Qualifies the event (TRUE for active, FALSE for inactive).
- **FILE_NAME**: Name of the CSV file to be written to.
- **SD_1 to SD_5**: The data to be written (any type).

Data Outputs

- **QO**: Returns the status of the function block (TRUE for successful, FALSE for error).
- **STATUS**: Contains a status message about the last operation.

Adapters

No adapters available.

Functionality

1. **Initialization**: The INIT event opens the CSV file with the specified name. If the file does not exist, it will be created.
2. **Write Data**: The REQ event triggers the write operation. Data SD_1 to SD_5 is written as a single line to the CSV file.
3. **Acknowledge**: After each write operation, the CNF event is triggered, which returns the status of the operation.

Technical Features

- Supports any data type for the output data (ANY).
- The status output (STATUS) returns detailed error messages.
- Initialization can be repeated if necessary to open a new file.

Status Overview

- **Inactive**: Waiting for initialization.
- **Ready**: File is open and ready for write operations.
- **Error**: An error has occurred (e.g., file access denied).

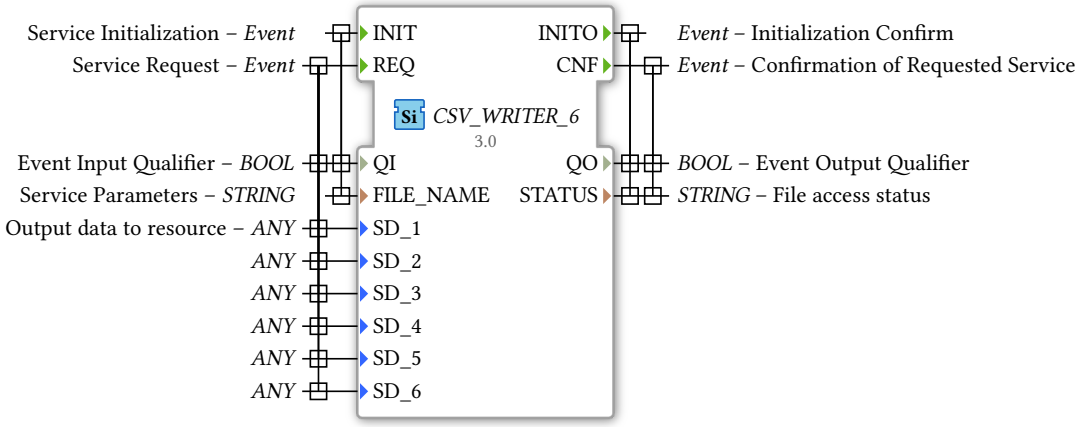
Application Scenarios

- Logging sensor data.
- Storing process data for later analysis.
- Export of data to a table-based format.

⚖️ Comparison with similar building blocks

- Compared to simpler CSV writer blocks, CSV_WRITER_5 offers greater flexibility by supporting five data points and any data type.
- Other blocks might be limited to specific data types or support fewer data points.

Conclusion



CSV_WRITER_5 is a powerful and flexible function block for data collection and logging. Its support for any data type and multiple data points makes it ideal for complex applications.

2.11.12.7 CSV_WRITER_6

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `CSV_WRITER_6` is used to write data to a CSV file. It allows the storage of up to six different data values in a comma-separated format. The block is particularly useful for data acquisition and logging in automation systems.

Interface Structure

Event Inputs

- `INIT`: Initializes the function block. Triggered by the variables `QI` and `FILE_NAME`.
- `REQ`: Starts the write operation. Triggered by the variables `QI`, `SD_1` through `SD_6`.

Event Outputs

- `INITO`: Confirms initialization. Returns `QO` and `STATUS`.
- `CNF`: Confirms successful write operation. Returns `QO` and `STATUS`.

Data Inputs

- `QI` (BOOL): Qualifies the event (e.g., whether the write operation should be activated).
- `FILE_NAME` (STRING): Name of the CSV file to be written to.
- `SD_1` to `SD_6` (ANY): The data values to be written.

Data Outputs

- `QO` (BOOL): Qualifies the output event (e.g., whether the operation was successful).
- `STATUS` (STRING): File access status message.

Adapters

No adapters available.

Functionality

1. **Initialization**: The `INIT` event initializes the function block with the file name (`FILE_NAME`). The status is reported via `INITO`.
2. **Write Operation**: The `REQ` event triggers the write operation. The data `SD_1` to `SD_6` are written to the CSV file. Success is confirmed via `CNF`.

Technical Features

- Supports any data type (`ANY`) for the data to be written.
- The status (`STATUS`) provides detailed information about whether the file access was successful or failed.

State Overview

1. **Initialization State**: Waiting for the `INIT` event.
2. **Ready State**: After successful initialization, waits for the `REQ` event.
3. **Write State**: Processes the data and writes it to the file.

Application Scenarios

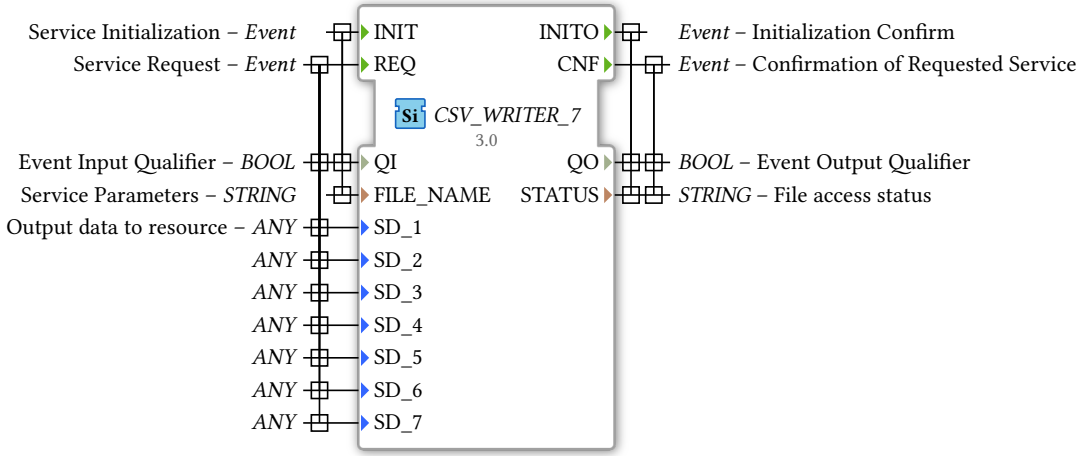
- Real-time logging of sensor data.

- Storage of process data for later analysis.
- Data acquisition in test and validation environments.

⚖️ Comparison with Similar Blocks

- Compared to simpler CSV writer blocks, `CSV_WRITER_6` offers the ability to store up to six different data values simultaneously.
- Other blocks may be limited to specific data types, while this block supports `ANY` types.

Conclusion



The `CSV_WRITER_6` is a flexible and powerful function block for storing data in CSV files. Its support for various data types and the ability to store multiple values simultaneously make it ideal for complex data collection tasks.

2.11.12.8 CSV_WRITER_7

• – ◦ • – ◦ • – ◦ •

Introduction

The CSV_WRITER_7 is a function block that writes data to a CSV file. It supports writing up to seven different data fields to a specified file. This function block is particularly useful for logging and data storage in automation applications.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block. Used with the variables `QI` (Qualifier Input) and `FILE_NAME` (CSV file name).
- **REQ**: Starts the write operation. Used with the variables `QI` and the seven data fields `SD_1` to `SD_7`.

Event Outputs

- **INITO**: Confirms initialization. Returns `QO` (qualifier output) and `STATUS` (initialization status).
- **CNF**: Confirms the write operation is complete. Returns `QO` and `STATUS`.

Data Inputs

- **QI**: Boolean qualifier indicating whether the operation should be performed.
- **FILE_NAME**: Name of the CSV file to which data should be written.
- **SD_1** to **SD_7**: Data fields that are written to the CSV file. Each field can have any data type (`ANY`).

Data Outputs

- **QO**: Boolean qualifier indicating the success or failure of the operation.
- **STATUS**: String describing the status of the file access.

Adapters

No adapters are present.

Operation

1. **Initialization**: The function block is initialized by the `INIT` event. The filename (`FILE_NAME`) is passed to this event.
2. **Write Operation**: The `REQ` event triggers the write operation. The data `SD_1` to `SD_7` will be written to the specified CSV file.
3. **Confirmation**: Upon completion of the operation, the `CNF` event is triggered, which returns the status of the operation.

Technical Features

- Supports writing to up to seven different data fields.
- The data fields can be of any data type (`ANY`).
- The file access status is returned in detail.

State Overview

1. **Initialization State**: Waiting for the `INIT` event.
2. **Ready**: After successful initialization, the function block waits for the `REQ` event.
3. **Write Operation**: The function block is active during the write operation.
4. **Completed**: The `CNF` event is triggered after the write operation is complete.

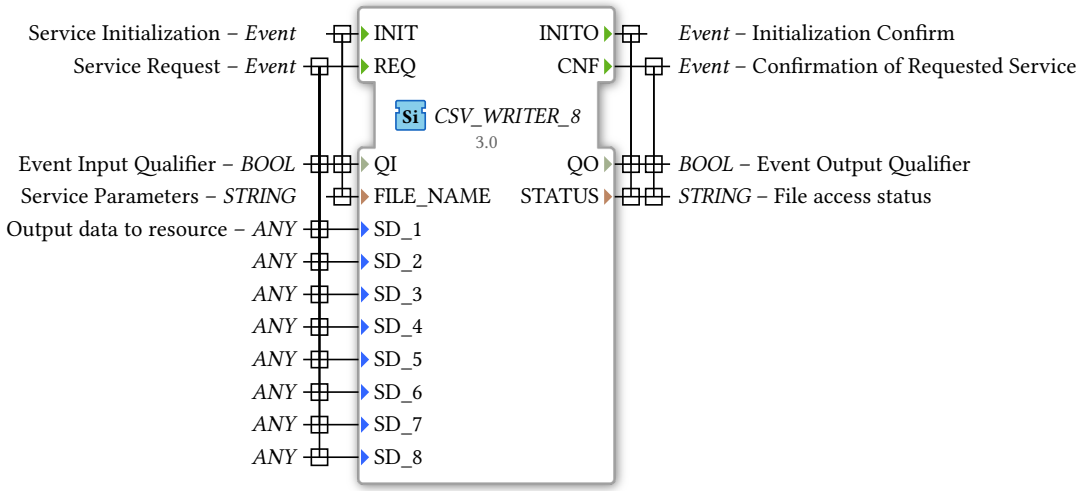
Application Scenarios

- Logging of process data in industrial automation.
- Storage of measurement data for later analysis.
- Data acquisition in real-time systems.

⚖️ Comparison with Similar Function Blocks

- **CSV_WRITER_5**: Supports only five data fields.
- **FILE_WRITER**: More general function block that is not specifically optimized for CSV files.

Conclusion



The CSV_WRITER_7 is a powerful function block for storing data in CSV files. Its flexibility in supporting various data types and its detailed status feedback make it an ideal choice for many automation applications.

2.11.12.9 CSV_WRITER_8

• – ◦ • – ◦ • – ◦ •

Introduction

The CSV_WRITER_8 is a function block for outputting data to a CSV file. It allows you to write up to 8 different data values to a specified file. This function block is part of the eclipse4diac::utils package family and is particularly suitable for data acquisition and logging tasks.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block. It uses the variables QI (Qualifier) and FILE_NAME (Filename).
- **REQ**: Triggers a write operation. It uses QI and the data variables SD_1 to SD_8.

Event Outputs

- **INITO**: Confirms initialization. Returns QO (qualifier) and STATUS (status message).
- **CNF**: Confirms the completion of the write operation. Also returns QO and STATUS.

Data Inputs

- **QI**: Boolean qualifier for events.
- **FILE_NAME**: String specifying the path and name of the CSV file.
- **SD_1 to SD_8**: Data variables of type ANY to be written to the CSV file.

Data Outputs

- **QO**: Boolean qualifier for output events.
- **STATUS**: String describing the status of the file access.

Functionality

The function block initializes itself upon receiving the INIT event and confirms this with INITO. The REQ event writes the current values of SD_1 to SD_8 to the specified CSV file. After the write operation is complete, the CNF event is triggered.

Technical Features

- Supports generic data types (ANY) for output data.
- Provides status messages for successful and failed operations.
- Part of the eclipse4diac::utils package.

State Overview

1. **Initialization State**: Waiting for the INIT event.
2. **Ready**: After successful initialization.
3. **Write Operation**: Active during the REQ event.
4. **Acknowledgement**: Sends CNF upon completion.

Application Scenarios

- Logging of process data.
- Data acquisition for analysis purposes.
- Export of control data in CSV format.

⚖️ Comparison with Similar Blocks

Compared to simpler CSV writer blocks, CSV_WRITER_8 offers the ability to write up to 8 different data values simultaneously and process generic data types.

Conclusion

CSV_WRITER_8 is a powerful function block for data acquisition and logging in CSV files. Its data processing flexibility and detailed status messages make it a good choice for complex applications.

2.11.12.10 CSV_WRITER_9

• – ◦ • – ◦ • – ◦ •

Introduction

The CSV_WRITER_9 is a function block for creating CSV files. It allows you to write up to nine different data points to a CSV file. This function block is part of the eclipse4diac::utils package and is suitable for applications that need to store data in a standardized format.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block and sets the file name. Used with `QI` and `FILE_NAME`.
- **REQ**: Starts the writing process to the CSV file. Used with `QI` and data points `SD_1` through `SD_9`.

Event Outputs

- **INITO**: Confirms initialization and returns the status. Used with `QO` and `STATUS`.
- **CNF**: Confirms successful or failed write operation. Used with `QO` and `STATUS`.

Data Inputs

- **QI**: Boolean qualifier for event inputs.
- **FILE_NAME**: String specifying the name of the CSV file.
- **SD_1** to **SD_9**: Data points of type `ANY`, which are written to the CSV file.

Data Outputs

- **QO**: Boolean qualifier for event outputs.
- **STATUS**: String indicating the status of file access.

Adapters

No adapters are defined.

Functionality

1. **Initialization**: The function block is initialized by the `INIT` event. The filename is set via `FILE_NAME`.
2. **Write Operation**: The `REQ` event triggers the write operation. Data points `SD_1` to `SD_9` are written to the CSV file.
3. **Confirmation**: The status of the operation is returned via `INITO` or `CNF`.

Technical Features

- Supports up to nine data points (`SD_1` to `SD_9`) of type `ANY`.
- The file access status is returned via the `STATUS` output.
- This function block is part of the eclipse4diac::utils package and is subject to the Eclipse Public License 2.0.

Status Overview

- **Initialization**: Successful (`INITO+`) or failed (`INITO-`).

- **Write Operation**: Successful (`CNF+`) or failed (`CNF-`).

Application Scenarios

- Data acquisition and storage in industrial control systems.
- Logging of process data to a standardized CSV file.
- Integration into larger automation solutions for data processing.

⚖️ Comparison with Similar Function Blocks

- Compared to simpler CSV writer function blocks, CSV_WRITER_9 offers the ability to write up to nine data points simultaneously.
- Other function blocks may offer less flexibility in data types due to the use of `ANY`.

Conclusion

The CSV_WRITER_9 is a powerful function block for creating CSV files in the 4diac IDE. Its flexibility in data ingestion and clear status feedback make it a good choice for applications that require structured data storage.

2.11.12.11 FB_RANDOM

• – ○ • – ○ • – ○ •

Introduction

The FB_RANDOM function block generates a random REAL number between 0 and 1.

Interface Structure

Event Inputs

- **INIT**: Initializes the random number generator with a seed.
- **REQ**: Calculates a new random number.

Event Outputs

- **INITO**: Initialization complete.
- **CNF**: Calculation complete, new value available.

Data Inputs

- **SEED** (UINT): The seed value for the random number generator. A value of 0 uses the current system time.

Data Outputs

- **VAL** (REAL): The generated random number.

2.11.12.12 GetInstancePath

• – ◦ • – ◦ • – ◦ •

The function block `GetInstancePath` is used to determine the instance path of the function block within the 4diac IDE. This path can be used, for example, for diagnostic purposes or for dynamic configuration. The function block is particularly useful in complex applications where precise identification of the instance location is required.

- **REQ**: Service request. Triggers the determination of the instance path.
- **CNF**: Acknowledgement of the service request. Signals successful determination of the instance path.
- **Sep**: Separator character (CHAR) for the generated path. The default value is `'/'`.
- **Path**: The determined instance path as a STRING.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

No adapters available.

Functionality

1. Upon receiving the `REQ` event, the function block begins determining its own instance path.
2. The path is formatted with the specified separator character (`Sep`).
3. The `CNF` event is triggered, and the determined path is output via the `Path` output.

- The function block uses a service interface to communicate with the resource level.
- **Idle**: Waiting for a `REQ` request.
- **Processing**: Determines the instance path and outputs it via `CNF`.
- Diagnostics and Logging: Identifying the exact location of a function block instance in a complex application.
- Dynamic Configuration: Using the path to dynamically adjust parameters or behaviors.
- Unlike static path specifications, `GetInstancePath` allows for dynamic path determination, which is particularly advantageous in reusable or nested components.

The `GetInstancePath`-FB is a useful tool for dynamically determining the instance path in 4diac applications. Its simple interface and flexible configuration make it ideal for diagnostic and configuration purposes.

2.11.12.13 GetInstancePathAndName

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `GetInstancePathAndName` is used to retrieve the instance path and instance name from the runtime environment. This is particularly useful for debugging purposes or for dynamic configurations where the exact path of an instance is required.

Interface Structure

Event Inputs

- **REQ**: Service request that triggers the retrieval of the instance path and name. Concatenated with the separator character `Sep`.

Event Outputs

- **CNF**: Acknowledgement of the requested service request. The output variables `Path` (instance path) and `Name` (instance name) are linked.

Data Inputs

- **Sep** (CHAR): Separator character for the generated output path. The default value is `'/'`.

Data Outputs

- **Path** (STRING): The instance path of the function block.
- **Name** (STRING): The instance name of the function block.

Adapters

No adapters are available.

Functionality

1. The function block is activated upon receiving a `REQ` event.
2. The function block determines the current instance path and instance name from the runtime environment.
3. The instance path is formatted with the specified separator character `Sep`.
4. The `CNF` event is triggered, and the determined values for `Path` and `Name` are output.

Technical Features

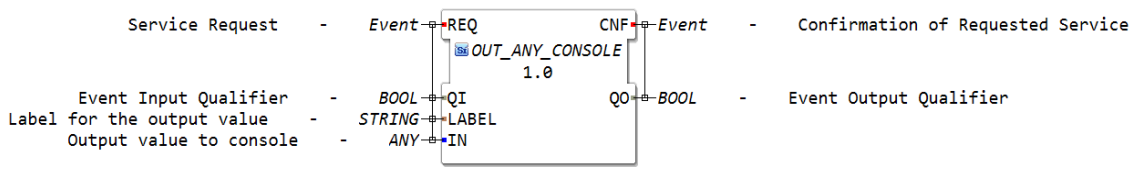
- The default separator for the path is `'/'`, but it can be changed via the input `Sep`.
- The output variables `Path` and `Name` are of type `STRING` and contain the complete path and the instance name, respectively.

State Overview

The function block has no internal state. It reacts exclusively to the `REQ` event and immediately outputs the corresponding data.

Application Scenarios

- **Debugging**: Determining the exact path of an instance for troubleshooting.
- **Dynamic Configuration**: Using the instance path for dynamic configurations or logging.
- **System Monitoring**: Monitoring and logging instance paths in complex systems.

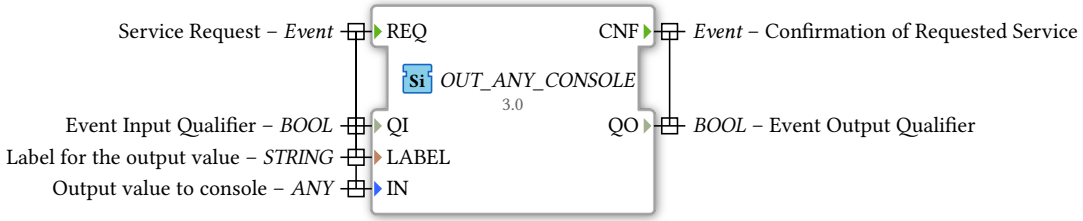


⚖️ Comparison with Similar Blocks

- Compared to other function blocks that provide similar information, `GetInstancePathAndName` offers the flexibility to customize the path separator.
- Other blocks might only provide the path or only the name, while this function block combines both.

Conclusion

The `GetInstancePathAndName` function block is a simple yet powerful tool for retrieving instance information from the runtime environment. Its flexibility and simplicity make it ideal for debugging and dynamic configurations.



2.11.12.14 OUT_ANY_CONSOLE

• — ○ • — ○ • — ○ •

Introduction

The **OUT_ANY_CONSOLE** function block is a universal debugging tool for outputting variable values to the system console, developed under the EPL 2.0 license (version 3.0). The block supports outputting any data type for development and diagnostic purposes.

Interface Structure

Event Inputs

- `REQ`: Trigger for console output (with qualifier `QI`, value `IN`, and optional `LABEL`)

Event Outputs

- `CNF`: Acknowledgement of the output operation

Data Inputs

Parameter	Type	Description
`QI`	BOOL	Enables output when TRUE
`LABEL`	STRING	Optional description text
`IN`	ANY	Any value to be output

Data Outputs

Parameter	Type	Description
QO	BOOL	Confirms successful output

Functionality

1. **Triggering**:

- The REQ event with QI=TRUE starts output
- The combination of LABEL and IN is formatted

1. **Execution**:

- The value is written to standard output
- Automatic type conversion for ANY

1. **Confirmation**:

- CNF with QO=TRUE on success
- CNF with QO=FALSE on errors

Technical Features

✓ **Universal Type Support** (ANY data type) ✓ **Flexible labeling** with LABEL parameters ✓ **Eclipse 4diac integration** (Package: eclipse4diac::utils) ✓ **Platform-independent** for various target systems

Application Scenarios

- **Debugging**: Runtime variable inspection
- **Logging**: Event tracking
- **System diagnostics**: Condition monitoring
- **Development**: Rapid algorithm testing

Example outputs

LABEL	IN (value)	Console output
“Temperature”	23.5	“Temperature: 23.5”
“Status”	TRUE	“Status: TRUE”
““	42	“42”

⚖️ **Comparison with similar building blocks**

Feature	OUT_ANY_CONSOLE	Standard debugging	Extended logging
Data types	Any	Limited	Limited
Labeling	Optional	No	Yes
Integration	4diac-specific	System-dependent	Framework-dependent
Real-time capable	Yes	Partially	No

Conclusion

The OUT_ANY_CONSOLE block is an indispensable tool for development:

- **Flexible**: Supports all data types
- **Easy**: Quick integration into existing systems
- **Powerful**: Suitable for real-time debugging

Ideal for:

- Prototype development
- System testing
- Error analysis

- Live diagnostics

The Swiss Army knife for developers in Eclipse 4diac environments

2.11.12.15 STEST_END

• – ◦ • – ◦ • – ◦ •

Introduction

The STEST_END function block is a Service Interface Function Block that serves as an endpoint for service requests. It is typically used in conjunction with other service function blocks to implement a service-oriented architecture in the 4diac IDE.

Service Request – *Event*

Interface Structure

Event Inputs

- **REQ**: Service Request - Triggered to initiate a service request.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

No adapters available.

Functionality

The STEST_END function block serves as an endpoint for service requests. When the REQ input is triggered, the service request is processed. Since it is an endpoint, there are no other event or data outputs.

Technical Features

- Implemented as a Service Interface Function Block.
- Supports communication between RESOURCE and APPLICATION interfaces.

State Overview

The function block has no complex states. It simply responds to and processes the REQ request.

Application Scenarios

- As an endpoint in a service-oriented architecture.
- In test environments to simulate or terminate service requests.

⚖️ Comparison with Similar Function Blocks

Compared to other service function blocks, STEST_END has no outputs or additional interfaces, making it ideal as an endpoint.

Conclusion

The STEST_END function block is a simple yet essential building block for service-oriented architectures in the 4diac IDE. Its simplicity makes it a reliable endpoint for service requests.

2.11.12.16 TEST_CONDITION

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `TEST_CONDITION` is used to check a condition and signals whether it is met or not. It is typically used in test environments to validate specific conditions.

Interface Structure

Event Inputs

- **REQ**: Starts the condition check. When this input is triggered, the function block begins evaluating the data input `check`.

Event Outputs

- **CNF**: Signals the completion of the check. This event is triggered after the condition has been evaluated.

Data Inputs

- **Check**: A Boolean value (`BOOL`) representing the condition to be checked.
- If `check == TRUE`, the condition is considered fulfilled (test passed).
- If `check == FALSE`, the condition is considered not fulfilled (test failed).

Data Outputs

- None present.

Adapters

- None present.

Functionality

1. The function block is activated by the event `REQ`.
2. The value of the data input `check` is evaluated.
3. The result of the evaluation is processed internally (no direct feedback via data outputs).
4. The event `CNF` is triggered to signal the completion of the check.

Technical Features

- The function block has a simple structure and does not contain any complex state machines.
- No data outputs are provided, as the result of the check is processed internally only.

State Overview

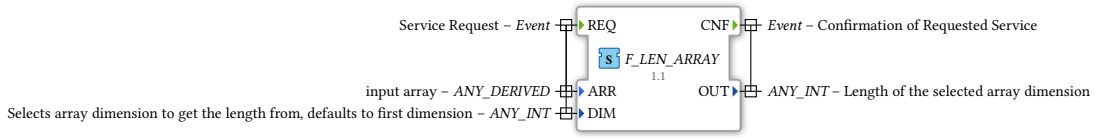
The function block has a simple sequence:

1. **Idle State**: Waits for the `REQ` event.
2. **Evaluation State**: Evaluates `check` and triggers `CNF`.
3. Returns to the **Idle State**.

Application Scenarios

- **Test Automation**: Checking conditions in automated test sequences.
- **Fault Detection**: Validating system states or input data.
- **Prototypical Implementation**: Rapid integration into test environments for logic validation.

⚖️ Comparison with Similar Function Blocks



- Compared to other test blocks, `TEST_CONDITION` offers a minimalist interface and is specialized for evaluating a single condition.
- More complex test blocks might support additional features such as time monitoring or multiple conditions.

Conclusion

The `TEST_CONDITION` function block is a simple yet effective tool for checking conditions in test environments. Its streamlined interface makes it easy to integrate, while its functionality is sufficient for basic validations. However, for more complex requirements, more advanced test blocks should be considered.

2.11.12.17 Arrays

F_LEN_ARRAY

• – ◦ • – ◦ • – ◦ •

Introduction

`F_LEN_ARRAY` is a simple function block that returns the length (element count) of a selected dimension of an array of arbitrary type. It complements the standard functions `UPPER_BOUND`/`LOWER_BOUND` with a directly usable length calculation.

Interface Structure

Event Inputs

- **REQ**: Triggers the calculation, carries `ARR` and `DIM`.

Event Outputs

- **CNF**: Confirms completion, carries `OUT`.

Data Inputs

- **ARR** (ANY_DERIVED): The array whose length is to be determined.
- **DIM** (ANY_INT, default `DINT#1`): The array dimension to consider (for multi-dimensional arrays).

Data Outputs

- **OUT** (ANY_INT): The length of the selected dimension, i.e. the element count.

Functionality

The block is implemented as a `SimpleFB` with a single ECC state. On `REQ`, the algorithm's ST statement computes `OUT := ADD(SUB(UPPER_BOUND(ARR, DIM), LOWER_BOUND(ARR, DIM)), 1)` — i.e. the upper minus the lower index bound of the selected dimension, plus 1 (since both bounds are inclusive). `CNF` is then triggered.

Technical Features

- **`ANY_DERIVED` input**: `ARR` accepts arrays of any element type and any dimensionality.
- **Dimension selection via `DIM`**: For multi-dimensional arrays, `DIM` selects which dimension's length to query; the default is the first dimension (`DINT#1`).
- **Based on `UPPER_BOUND`/`LOWER_BOUND`**: The block is a direct combination of these two IEC 61131-3 standard functions, saving the manual arithmetic.

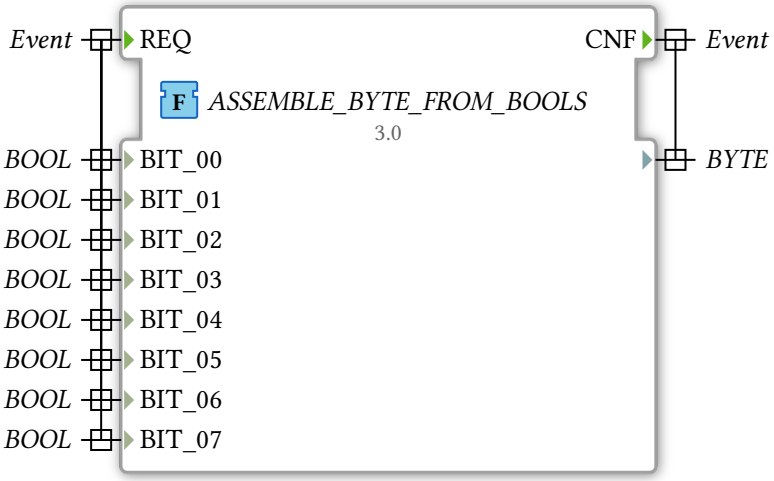
State Overview

Stateless: every `REQ` immediately results in the calculation and `CNF`.

Application Scenarios

- **Dynamic array processing**: Looping over an array whose actual size is only known at runtime (e.g. depending on the caller).
- **Sanity checking**: Comparing the actual array length against an expected size before accessing individual elements.

Comparison with similar function blocks



- **`UPPER_BOUND`/`LOWER_BOUND`**: the two standard functions `F_LEN_ARRAY` combines to perform its calculation.

Conclusion

`F_LEN_ARRAY` provides a simple, directly usable length calculation for arrays of arbitrary type and a selectable dimension, without requiring `UPPER_BOUND`/`LOWER_BOUND` to be combined manually.

2.11.12.18 assembling

ASSEMBLE_BYTE_FROM_BOOLS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_BYTE_FROM_BOOLS` combines eight Boolean input values into a single byte. Each Boolean input represents one bit of the resulting byte. This block is particularly useful when individual Boolean signals need to be combined into a compact byte value.

Interface Structure

Event Inputs

- `REQ`: Starts processing the Boolean inputs and generates the resulting byte.

Event Outputs

- `CNF`: Signals successful aggregation of the Boolean values into a single byte.

Data Inputs

- `BIT_00` to `BIT_07`: Eight Boolean inputs, each corresponding to one bit of the resulting byte.

Data Outputs

- `BYTE`: The composite byte generated from the eight Boolean inputs.

Adapters

No adapters are included.

Functionality

This function block combines the eight Boolean inputs (`BIT_00` to `BIT_07`) into a single byte. Each Boolean value is mapped to the corresponding bit of the byte:

- `BIT_00` corresponds to bit 0 (LSB)
- `BIT_01` corresponds to bit 1
- ...
- `BIT_07` corresponds to bit 7 (MSB)

When the event `REQ` is triggered, the current values of the Boolean inputs are read and combined into a byte. The result is output at the data output, and the event `CNF` signals successful processing.

Technical Features

- The function block is implemented in ST (Structured Text).
- Bit mapping is performed directly by assigning the Boolean values to the corresponding bits of the byte.

State Overview

1. **Idle State**: Waits for the `REQ` event.
2. **Processing State**: Reads the Boolean inputs and assembles the byte.
3. **Acknowledge State**: Outputs the resulting byte and signals `CNF`.

Application Scenarios

- Summarizing 8 individual switch states into one byte for communication with other systems.
- Compressing Boolean status information for more efficient data transmission.
- Use in control systems where multiple Boolean signals need to be processed as a single byte.

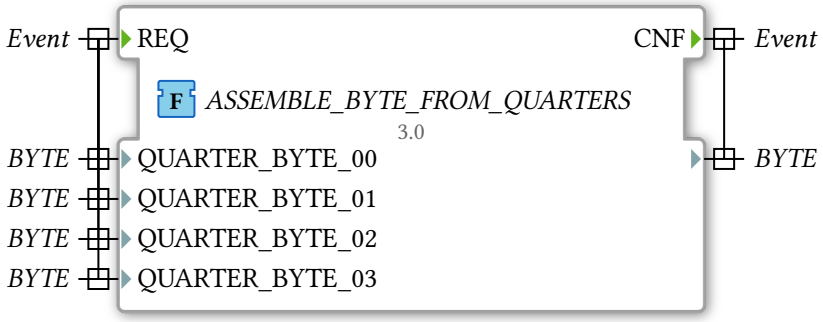
⚖️ Comparison with Similar Function Blocks

- Compared to manual bit operations in ST or other languages, this function block offers a predefined and maintainable solution.

Similar function blocks might have fewer inputs or offer additional features like inverted logic, which is not the case here.

🛠️ Related Exercises

- Exercise_035a1b_AX
- Exercise_053



Conclusion

The `ASSEMBLE_BYTE_FROM_BOOLS` function block is a simple and efficient solution for combining eight Boolean values into one byte. Its clear interface and direct implementation make it ideal for applications that require compact processing of Boolean signals.

ASSEMBLE_BYTE_FROM_QUARTERS

🎧 Podcast

- QUARTER

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_BYTE_FROM_QUARTERS` combines four individual quarter bytes into a complete byte. This is particularly useful in scenarios where data needs to be transmitted or processed in parts and then reassembled.

Interface Structure

Event Inputs

- `REQ`: Starts combining the quarter bytes into one byte. It is linked to the four quarter bytes (`QUARTER_BYTE_00` to `QUARTER_BYTE_03`).

Event Outputs

- `CNF`: Signals successful concatenation of the quarter bytes into a single byte.

Data Inputs

- `QUARTER_BYTE_00`: First quarter byte (least significant bits).
- `QUARTER_BYTE_01`: Second quarter byte.
- `QUARTER_BYTE_02`: Third quarter byte.
- `QUARTER_BYTE_03`: Fourth quarter byte (most significant bits).

Data Outputs

- `BYTE`: The concatenated byte resulting from the combination of the four quarter bytes.

Adapters

No adapters available.

Functionality

The function block accepts four quarter bytes and combines them into a complete byte. The individual quarter bytes are shifted to the correct position in the resulting byte using bit shift operations (`SHL`) and joined together using logical OR operations (`OR`). The precise shifts are defined by constants (`quarterconst::SHIFT_QUARTER_00` to `quarterconst::SHIFT_QUARTER_03`).

Technical Features

- Uses bit shift operations (`SHL`) and logical OR operations (`OR`) to combine the quarter bytes.
- The shift positions are defined as constants, allowing for flexible adjustment.

State Overview

1. **Initialization**: The function block is initialized and waits for the `REQ` event.
2. **Processing**: Upon receiving `REQ`, the four quarter bytes are processed and combined into the resulting byte.
3. **Acknowledgement**: After successful combination, the `CNF` event is triggered, and the resulting byte is output.

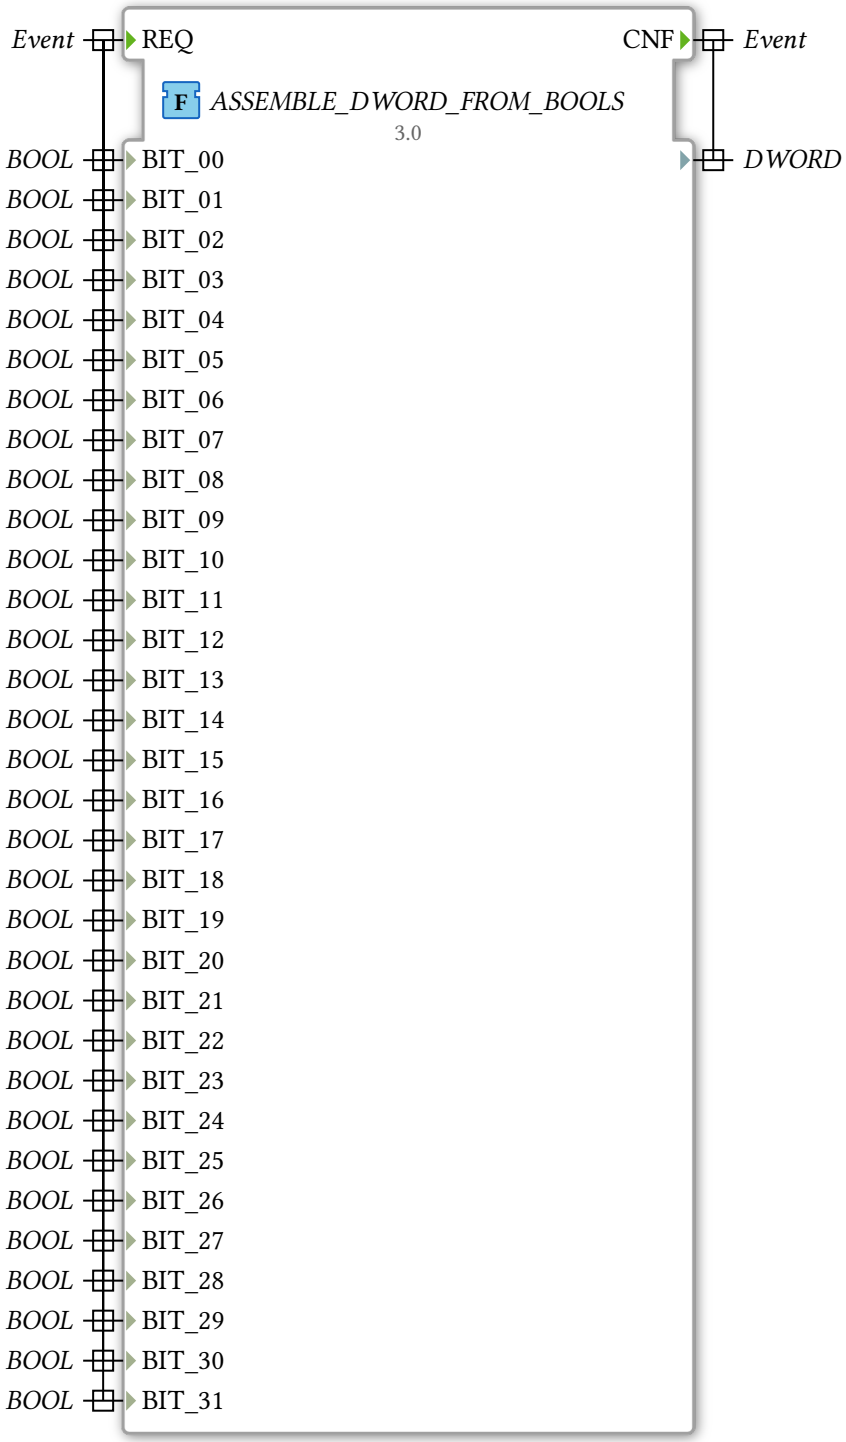
Application Scenarios

- **Data Communication**: Combining partially transmitted data into a complete byte.

- **Data Processing**: Processing data that exists in smaller units but is required as a whole.

⚖️ Comparison with Similar Blocks

- Compared to generic bit manipulation function blocks, `ASSEMBLE_BYTE_FROM_QUARTERS` offers a specialized and optimized solution for combining quarter bytes.
- Other blocks may offer similar functionality, but are often less specific and require more configuration.



🛠️ Related Exercises

- Exercise_056

Conclusion

The `ASSEMBLE_BYTE_FROM_QUARTERS` function block is an efficient and specialized solution for combining four quarter bytes into a complete byte. By using bit-shift and logical operations, it offers a high-performance and flexible way to process data in relevant application scenarios.

ASSEMBLE_DWORD_FROM_BOOLS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_DWORD_FROM_BOOLS` combines 32 individual BOOL values into a single DWORD value. This is particularly useful when multiple binary states need to be processed or transmitted in a compact form.

Interface Structure

Event Inputs

- `REQ`: Trigger event that starts processing the input data. It is linked to all 32 bit inputs.

Event Outputs

- `CNF`: Confirmation event that is output after successful combination of the BOOL values into a DWORD.

Data Inputs

32 BOOL inputs (`BIT_00` to `BIT_31`), each representing one bit in the resulting DWORD:

- `BIT_00`: Bit 0 (least significant bit)
- `BIT_01`: Bit 1
- ...
- `BIT_31`: Bit 31 (most significant bit)

Data Outputs

- `OUT`: DWORD composed of the 32 input BOOLs.

Adapters

No adapters included.

Functionality

When the `REQ` event is triggered, the function block combines the 32 BOOL inputs into a DWORD. Each BOOL input corresponds to one bit in the DWORD:

- `BIT_00` becomes bit 0 (LSB)
- `BIT_31` becomes bit 31 (MSB)

After successful combination, the `CNF` event is output.

Technical Features

- The function block is implemented in ST (Structured Text).
- Bit mapping is performed directly by assigning the BOOL values to the corresponding bit positions of the DWORD.
- No buffering or state storage: Processing occurs anew with each `REQ` event.

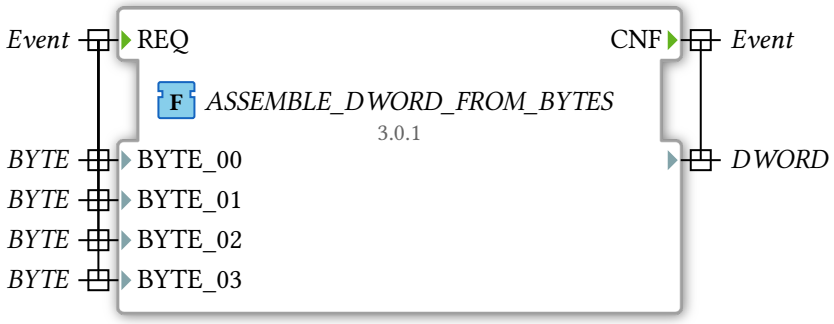
State Overview

The function block has no internal state. Processing is purely event-driven:

1. Receive `REQ` ⟶ Start processing.
2. Read BOOL values and combine them into a DWORD.
3. Output `CNF`.

Application Scenarios

- Compression of multiple binary signals for transmission via communication protocols.
- Storage of multiple switching states in a single register.
- Efficient processing of bitmasks in control algorithms.



⚖️ Comparison with Similar Function Blocks

- Compared to manual bit operations in ST or other FB types, this function block offers a predefined, error-free solution for combining BOOLs into a DWORD.
- Similar function blocks might process fewer bits or offer additional functions such as bit shifts.

Conclusion

The `ASSEMBLE_DWORD_FROM_BOOLS` function block is an efficient and reliable solution for combining 32 binary inputs into a single DWORD. Its simple and clear interface makes it ideal for applications requiring compact representations of multiple binary states.

ASSEMBLE_DWORD_FROM_BYTES

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_DWORD_FROM_BYTES` combines four BYTE values into a single DWORD value. This is particularly useful when data from multiple sources needs to be merged for processing or storage as a single unit.

Interface Structure

Event Inputs

- **REQ**: Initiates the combination of the BYTE values into a DWORD. This is linked to the data inputs `BYTE_00`, `BYTE_01`, `BYTE_02`, and `BYTE_03`.

Event Outputs

- **CNF**: Signals the successful combination of the BYTE values into a DWORD. The combined DWORD value is available at the data output.

Data Inputs

- **BYTE_00**: First byte of the DWORD to be combined.
- **BYTE_01**: Second byte of the DWORD to be combined.
- **BYTE_02**: Third byte of the DWORD to be combined.
- **BYTE_03**: Fourth byte of the DWORD to be combined.

Data Outputs

- **(unnamed)**: The combined DWORD value created from the four input bytes.

Adapters

No adapters available.

Functionality

The function block accepts four BYTE values and combines them into a single DWORD value. The combination is achieved by directly assigning the individual bytes to the corresponding positions in the DWORD:

- `BYTE_00` is assigned to the least significant byte (B0) of the DWORD.
- `BYTE_01` is assigned to the next byte (B1).
- `BYTE_02` is assigned to the next byte (B2).
- `BYTE_03` is assigned to the most significant byte (B3).

Technical Features

- The function block is implemented in the ST (Structured Text) language.
- The bytes are assigned directly using the `%B0` to `%B3` syntax, which accesses the individual bytes of the DWORD.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Upon receiving `REQ`, the input bytes are combined and the DWORD value is calculated.

3. **Completed**: Sends the `CNF` event with the combined DWORD value.

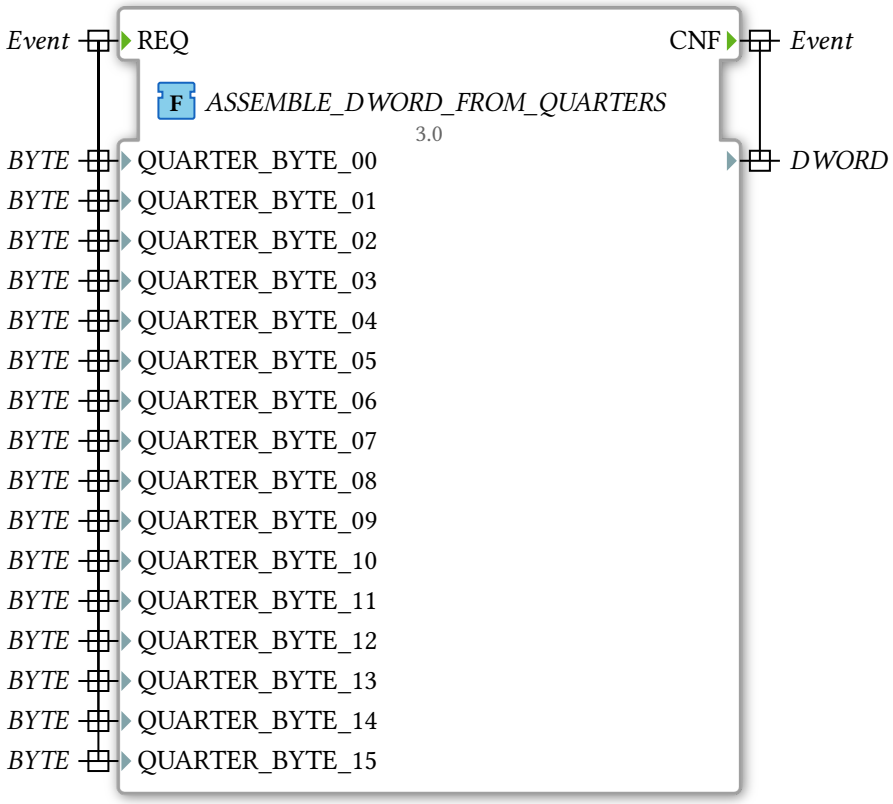
Application Scenarios

- Combining data from multiple sensors or sources into a single value.
- Preprocessing data for transmission or storage.
- Use in protocol implementations where data needs to be segmented into bytes and later reassembled.

⚖️ Comparison with Similar Building Blocks

- Similar function blocks might combine individual bytes into other data types (e.g., WORD).

Unlike manual combinations in ST code, this block offers a predefined and reusable solution.



Conclusion

The `ASSEMBLE_DWORD_FROM_BYTES` function block provides a simple and efficient way to combine four byte values into a DWORD. Its clear interface and direct implementation make it a useful tool in various use cases.

ASSEMBLE_DWORD_FROM_QUARTERS

🎧 Podcast

- QUARTER

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_DWORD_FROM_QUARTERS` combines 16 quarter bytes (4 bits each) into a DWORD (32 bits). This is particularly useful when data exists in smaller units and needs to be combined into a larger unit.

Interface Structure

Event Inputs
- `REQ`: Starts combining the quarter bytes into a DWORD. All 16 quarter bytes are combined.

Event Outputs
- `CNF`: Signals the successful combination of the quarter bytes into a DWORD.

Data Inputs
- `QUARTER_BYTE_00` to `QUARTER_BYTE_15`: 16 inputs of type `BYTE`, each containing one quarter byte (4 bits).

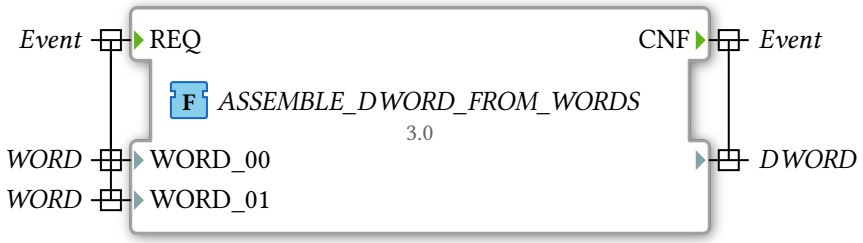
Data Outputs
- (Unnamed): One output of type `DWORD` containing the combined result.

Adapters
No adapters are present.

Operation
The function block accepts 16 quarter bytes and combines them into a 32-bit DWORD. Each quarter byte is shifted according to its position in the DWORD and then concatenated with the others. The shifting is performed using constants (`quarterconst::SHIFT_QUARTER_XX`) that define the position of each quarter byte in the DWORD.

Technical Features
- Uses bit shifts (`SHL`) and logical OR operations (`OR`) to correctly combine the quarter bytes.
- The conversion from `BYTE` to `DWORD` is performed using `BYTE_TO_DWORD`.

State Overview
1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Processes the quarter bytes and combines them into a DWORD.
3. **Complete**: Sends the `CNF` event and provides the combined DWORD.



Application Scenarios
- Data compression: Combining multiple small data packets into one larger one.
- Communication protocols: Processing data transmitted in smaller units.
- Signal processing: Summarizing parts of a signal into a complete value.

⚖️ Comparison with similar building blocks
- Similar building blocks could be `BYTE_TO_WORD` or `WORD_TO_DWORD`, but these offer less flexibility as they only combine fixed values.
- `ASSEMBLE_DWORD_FROM_QUARTERS` offers more control over the position of each individual bit in the resulting DWORD.

🛠️ Related Exercises
- Exercise_060

Conclusion
The `ASSEMBLE_DWORD_FROM_QUARTERS` function block is a powerful tool for combining 16 quarter-bytes into a DWORD. Its flexible and precise operation makes it ideal for applications where data exists in smaller units and needs to be combined into a larger unit.

ASSEMBLE_DWORD_FROM_WORDS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_DWORD_FROM_WORDS` combines two 16-bit words (WORD) into a 32-bit double word (DWORD). This functionality is particularly useful when data from two separate sources needs to be merged.

Interface Structure

Event Inputs

- `REQ`: Starts the processing of the function block. Must be linked to the data inputs `WORD_00` and `WORD_01`.

Event Outputs

- `CNF`: Signals successful processing and output of the combined DWORD.

Data Inputs

- `WORD_00`: First 16-bit word (WORD) inserted into the resulting DWORD.
- `WORD_01`: Second 16-bit word (WORD) inserted into the resulting DWORD.

Data Outputs

- (no name): The combined 32-bit double word (DWORD) consisting of the two input words.

Adapters

This function block does not use adapters.

Functionality

The function block receives the two 16-bit input words (`WORD_00` and `WORD_01`) and combines them into a single 32-bit double word (DWORD). `WORD_00` is placed in the lower 16 bits and `WORD_01` in the upper 16 bits of the resulting DWORD.

Technical Details

- The implementation is in Structured Text (ST).
- The function block is part of the `eclipse4diac::utils::assembling` package.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Processes the input words and creates the DWORD.
3. **Complete**: Sends the `CNF` event with the combined DWORD.

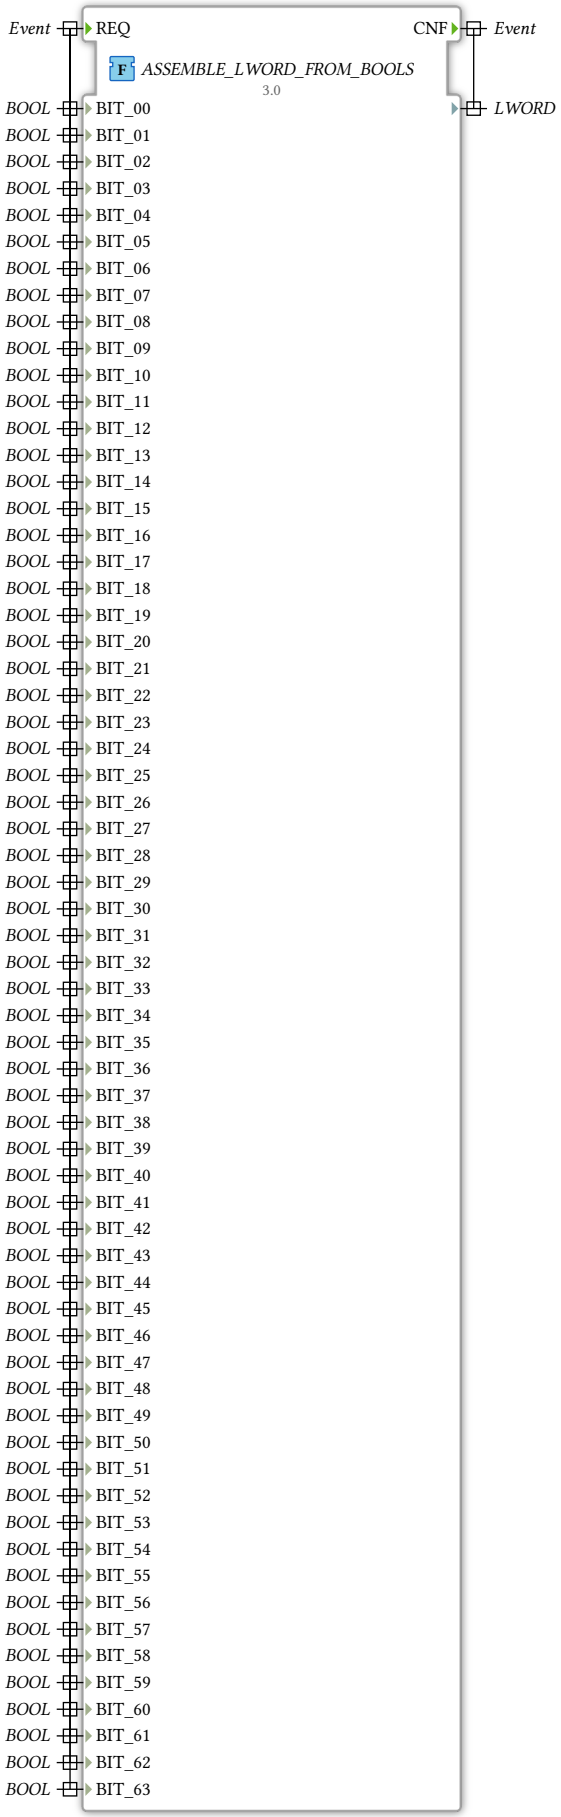
Application Scenarios

- Combining two 16-bit sensor data points into a 32-bit value.
- Processing data from two separate communication channels.
- Extending 16-bit data to 32 bits for further processing.

⚖️ Comparison with Similar Blocks

- Unlike simple bit operations, this function block offers a clearly defined interface and is integrated into the 4diac IDE.
- Similar functionality could be achieved with basic operations, but this block simplifies handling.

Conclusion



The `ASSEMBLE_DWORD_FROM_WORDS` function block provides a simple and efficient way to combine two 16-bit words into a 32-bit double word. Its clear interface and direct integration with 4diac make it particularly useful for applications that work with combined word data.

LWORD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_LWORD_FROM_BOOLS` combines 64 individual BOOL values into a single LWORD data type. This is particularly useful when multiple binary states need to be processed or transmitted in a compact form.

Interface Structure

Event Inputs

- `REQ`: Starts combining the 64 BOOL inputs into an LWORD.

Event Outputs

- `CNF`: Signals the successful combination of the BOOL values into an LWORD.

Data Inputs

64 BOOL inputs (`BIT_00` to `BIT_63`), each representing one bit in the resulting LWORD.

Data Outputs

- One LWORD composed of the 64 BOOL inputs.

Adapters

No adapters included.

Operation

The function block assigns each of the 64 bits of the LWORD output to a corresponding BOOL input. Upon triggering the `REQ` event, all BOOL inputs are read and inserted into the LWORD. The `CNF` event signals the completion of this process.

Technical Features

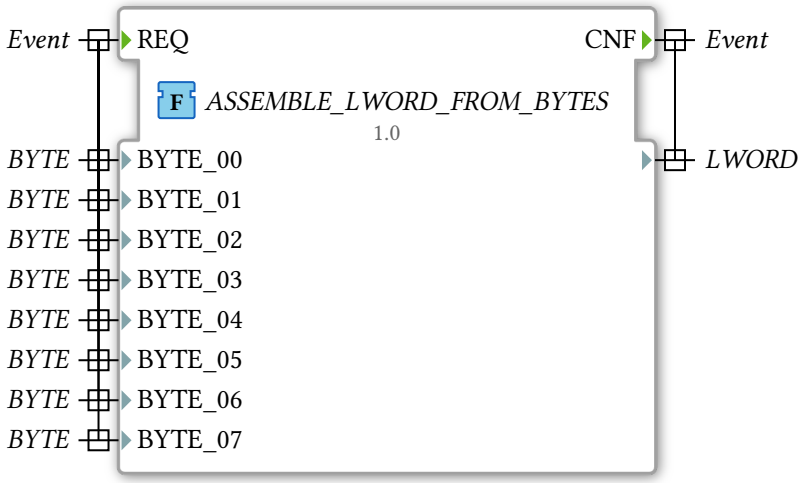
- Processes 64 BOOL inputs in parallel.
- Direct bit mapping without additional calculations.
- Efficient implementation through direct bit assignment.

State Overview

1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Combines the BOOL values into an LWORD.
3. **Complete**: Sends the `CNF` event and outputs the combined LWORD.

Application Scenarios

- Compressing multiple binary signals for transmission.
- Processing bitmasks in control applications.
- Efficient storage of binary states.



⚖️ Comparison with Similar Function Blocks

- Similar to `BOOL_TO_*` function blocks, but optimized for 64 bits.
- Offers more flexibility than hard-coded bit operations.

Conclusion

The `ASSEMBLE_LWORD_FROM_BOOLS` function block is an efficient tool for combining multiple BOOL values into a single LWORD data type, ideal for applications with high bit density.

ASSEMBLE_LWORD_FROM_BYTES

• – ◦ • – ◦ • – ◦ •

Introduction

The function `ASSEMBLE_LWORD_FROM_BYTES` combines eight BYTE values into a single LWORD value. It is useful when data from several byte sources (e.g. protocol fields) has to be assembled into a 64-bit unit.

Interface Structure

Event Inputs

- **REQ**: Initiates the combination of the BYTE values into an LWORD. Linked to `BYTE_00` to `BYTE_07`.

Event Outputs

- **CNF**: Signals the completed combination. The LWORD value is available at the data output.

Data Inputs

- **BYTE_00**: Least significant byte (B0) of the LWORD.
- **BYTE_01**: Byte B1.
- **BYTE_02**: Byte B2.
- **BYTE_03**: Byte B3.
- **BYTE_04**: Byte B4.
- **BYTE_05**: Byte B5.
- **BYTE_06**: Byte B6.
- **BYTE_07**: Most significant byte (B7) of the LWORD.

Data Outputs

- **(unnamed)**: The assembled LWORD value (return value of the function).

Adapters

No adapters available.

Functionality

The function assigns each input byte directly to the corresponding byte of the return value:

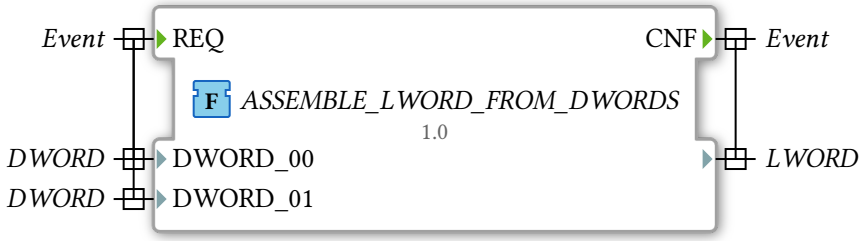
- `BYTE_00` ⟶ `%B0` (least significant)
- `BYTE_01` ⟶ `%B1`
- `BYTE_02` ⟶ `%B2`
- `BYTE_03` ⟶ `%B3`
- `BYTE_04` ⟶ `%B4`
- `BYTE_05` ⟶ `%B5`
- `BYTE_06` ⟶ `%B6`
- `BYTE_07` ⟶ `%B7` (most significant)

Technical Details

- Implemented as a function (`FUNCTION ... : LWORD`) in ST (Structured Text), package `eclipse4diac::utils::assembling`.
- Individual bytes are accessed with the partial access syntax `%B0` to `%B7`.
- No state of its own.

Application Scenarios

- Assembling 64-bit values from individual bytes, e.g. in protocol implementations or CAN data.



⚖ Comparison with Similar Building Blocks

- ASSEMBLE_DWORD_FROM_BYTES assembles four bytes into a DWORD, ASSEMBLE_LWORD_FROM_WORDS four words into an LWORD.

Conclusion

`ASSEMBLE_LWORD_FROM_BYTES` assembles eight BYTE values byte by byte into an LWORD.

ASSEMBLE_LWORD_FROM_DWORDS

• – ◦ • – ◦ • – ◦ •

Introduction

The function `ASSEMBLE_LWORD_FROM_DWORDS` combines two 32-bit double words (`DWORD`) into one 64-bit long word (`LWORD`).

Interface Structure

Event Inputs

- `REQ`: Starts the processing. Associated data: `DWORD_00`, `DWORD_01`

Event Outputs

- `CNF`: Signals the processing and the output of the combined `LWORD`.

Data Inputs

- `DWORD_00`: Double word 0 (`DWORD`), lowest 32 bits of the result
- `DWORD_01`: Double word 1 (`DWORD`), highest 32 bits (bits 32 to 63)

Data Outputs

- (no name): The combined 64-bit long word (`LWORD`), also the return value of the function

Adapters

This function does not use any adapters.

How it works

The function assigns the two input values to the return value via the partial access `.%D0` and `.%D1`:

```
ASSEMBLE_LWORD_FROM_DWORDS.%D0 := DWORD_00;
ASSEMBLE_LWORD_FROM_DWORDS.%D1 := DWORD_01;
```

`DWORD_00` thus forms the least significant and `DWORD_01` the most significant double word of the `LWORD`.

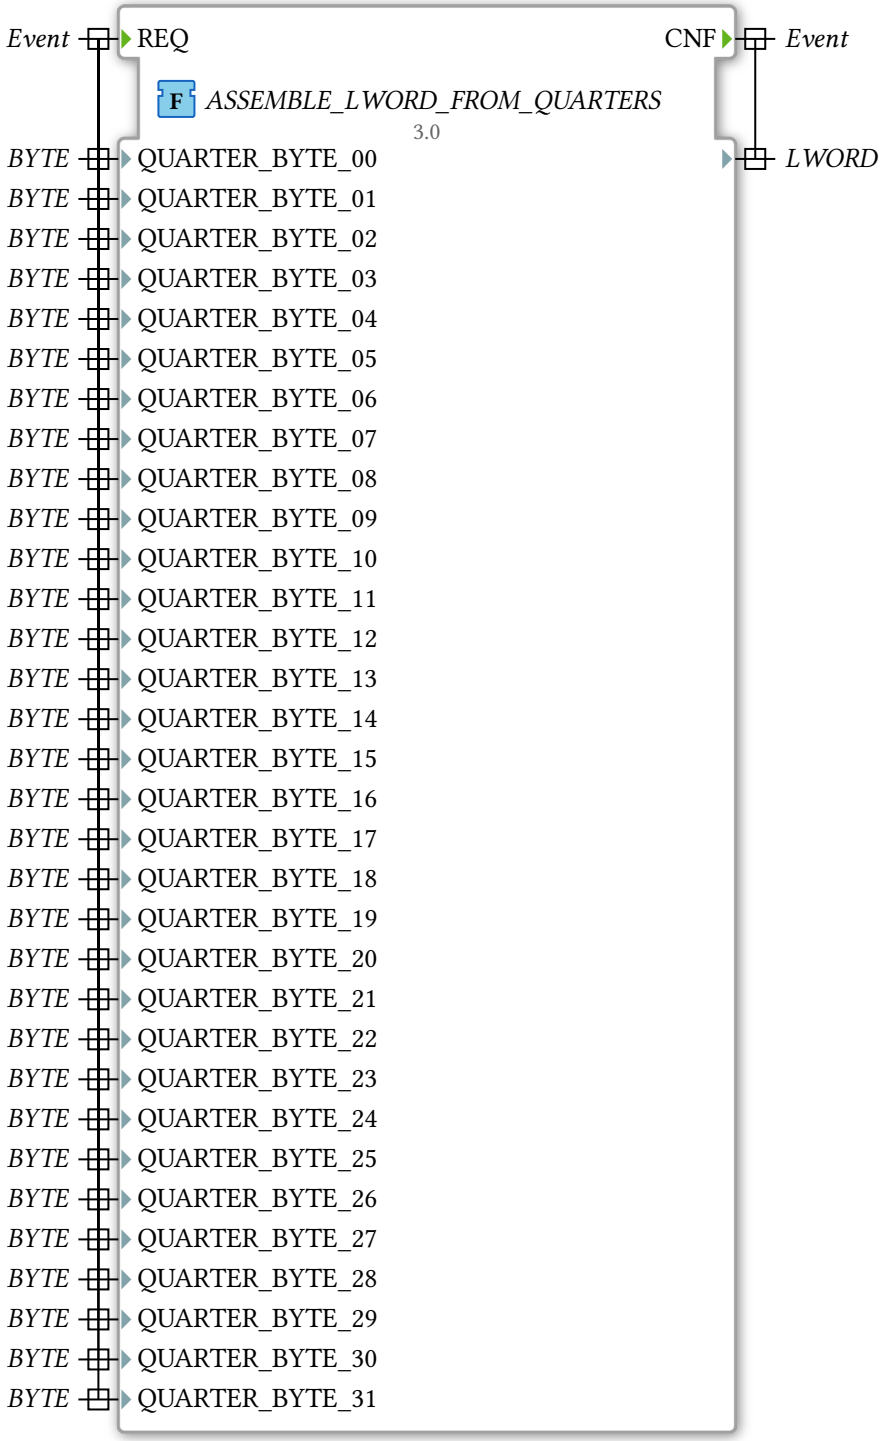
Technical Details

- Implemented in Structured Text (ST) as a `FUNCTION` without internal state

- Part of the package `eclipse4diac::utils::assembling`
- The inverse function is `SPLIT_LWORD_INTO_DWORDS`
- Version 1.0 (2026-05-16)

Application Scenarios

- Assembling a 64-bit value from two 32-bit registers (e.g. fieldbus data)
- Generating 64-bit bit patterns from two double words



Summary

`ASSEMBLE_LWORD_FROM_DWORDS` assembles two `DWORD` values, starting with the least significant one, into an `LWORD`.

ASSEMBLE_LWORD_FROM_QUARTERS

🎧 Podcast

- QUARTER

• – ◦ • – ◦ • – ◦

Introduction

The function block `ASSEMBLE_LWORD_FROM_QUARTERS` combines 32 byte values (QUARTER_BYTE_00 to QUARTER_BYTE_31) into a 64-bit LWORD value. This is particularly useful when data is in smaller units and needs to be combined into a larger data word.

Interface Structure

Event Inputs

- `REQ`: Starts the processing and combines the 32 byte inputs into an LWORD.

Event Outputs

- `CNF`: Signals the successful merging of the bytes into an LWORD.

Data Inputs

- `QUARTER_BYTE_00` to `QUARTER_BYTE_31` (32 inputs of type `BYTE`): The individual byte values that are combined into an LWORD.

Data Outputs

- (Unnamed, type `LWORD`): The combined 64-bit value that is created from the 32 byte inputs.

Adapters

No adapters are present.

Functionality

The function block receives the 32 byte inputs and combines them into a 64-bit LWORD. Each byte value is shifted to a specific position in the LWORD (using the `SHL` operation) and then logically combined with the current LWORD value (`OR` operation). The shifting is performed according to predefined constants (`quarterconst::SHIFT_QUARTER_XX`) that define the exact position of each byte in the LWORD.

Technical Features

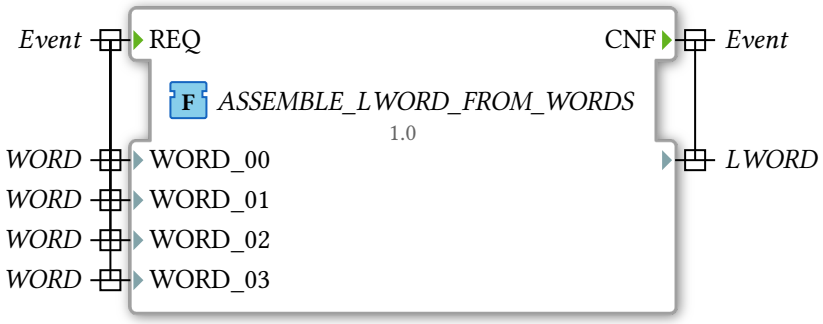
- Uses bitwise operations (`SHL`, `OR`) for efficient byte combination.
- The combination order ranges from `QUARTER_BYTE_31` (most significant byte) to `QUARTER_BYTE_00` (least significant byte).
- The function block is implemented in ST (Structured Text) and uses a library (`quarterconst`) for the shift constants.

State Overview

The function block has no internal states. Processing occurs directly upon receiving the `REQ` event, and the result is immediately output via `CNF`.

Application Scenarios

- Reassembling data that has been transmitted or stored in smaller units (bytes).
- Processing protocols or data formats that transmit large values in segmented form.
- Use in systems that work with 64-bit data but only have 8-bit interfaces available.



⚖️ Comparison with Similar Blocks

- Similar function blocks could be... For example, `ASSEMBLE_DWORD_FROM_BYTES`, which only combines 32-bit values.
- Unlike manual implementations, this function block offers a standardized and optimized solution for combining 32 bytes into a 64-bit LWORD.

Conclusion

The `ASSEMBLE_LWORD_FROM_QUARTERS` function block provides an efficient and reliable method for combining 32-byte values into a 64-bit LWORD. By using bitwise operations and predefined shift constants, the solution is performant and easily integrated into existing systems. Ideal for applications that work with large, segmented datasets.

ASSEMBLE_LWORD_FROM_WORDS

• – ◦ • – ◦ • – ◦ •

Introduction

The function `ASSEMBLE_LWORD_FROM_WORDS` combines four 16-bit words (`WORD`) into one 64-bit long word (`LWORD`).

Interface Structure

Event Inputs

- `REQ`: Starts the processing. Associated data: `WORD_00`, `WORD_01`, `WORD_02`, `WORD_03`

Event Outputs

- `CNF`: Signals the processing and the output of the combined `LWORD`.

Data Inputs

- `WORD_00`: Word 0 (`WORD`), lowest 16 bits of the result
- `WORD_01`: Word 1 (`WORD`), bits 16 to 31
- `WORD_02`: Word 2 (`WORD`), bits 32 to 47
- `WORD_03`: Word 3 (`WORD`), highest 16 bits (bits 48 to 63)

Data Outputs

- (no name): The combined 64-bit long word (`LWORD`), also the return value of the function

Adapters

This function uses no adapters.

How it works

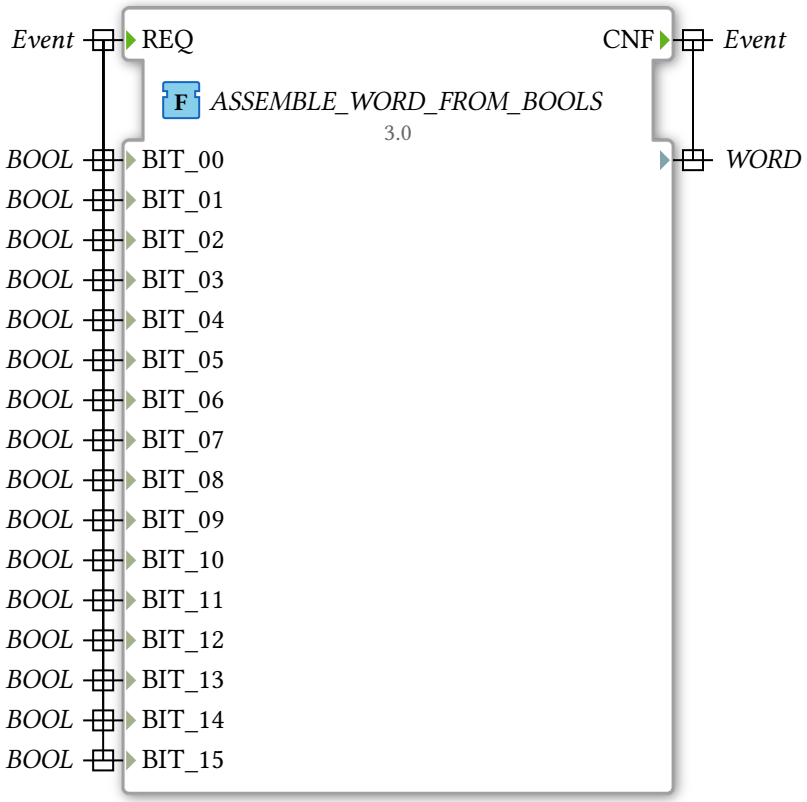
The function assigns the four input words to the return value via the partial access `.%W0` to `.%W3`:

```
ASSEMBLE_LWORD_FROM_WORDS.%W0 := WORD_00;
ASSEMBLE_LWORD_FROM_WORDS.%W1 := WORD_01;
ASSEMBLE_LWORD_FROM_WORDS.%W2 := WORD_02;
ASSEMBLE_LWORD_FROM_WORDS.%W3 := WORD_03;
```

`WORD_00` thus forms the least significant and `WORD_03` the most significant word of the `LWORD`.

Technical Details

- Implemented in Structured Text (ST) as a `FUNCTION` without internal state
- Part of the package `eclipse4diac::utils::assembling`
- The inverse is `SPLIT_LWORD_INTO_DWORDS` or the respective `SPLIT_*` functions in the package `splitting`



Application Scenarios

- Assembling a 64-bit value from four 16-bit registers (e.g. fieldbus/Modbus data)
- Creating 64-bit bit patterns from individual words

Summary

`ASSEMBLE_LWORD_FROM_WORDS` assembles four `WORD` values, starting with the least significant, into an `LWORD`.

ASSEMBLE_WORD_FROM_BOOLS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_WORD_FROM_BOOLS` combines 16 Boolean input values into a single WORD output value. Each Boolean input represents a single bit in the resulting WORD.

Interface Structure

Event Inputs

- `REQ`: Starts processing and takes all current values from the Boolean inputs.

Event Outputs

- `CNF`: Signals the successful combination of the Boolean values into a WORD.

Data Inputs

16 Boolean inputs (BIT_00 to BIT_15), each corresponding to one bit in the resulting WORD:

- `BIT_00` to `BIT_15` (BOOL): Individual bits for the WORD to be assembled

Data Outputs

- `(Unbenannt)` (WORD): The resulting WORD, assembled from the 16 Boolean inputs.

Adapters

No adapters are available.

Operation

When the `REQ` event is triggered, all 16 Boolean input values are read and combined into a 16-bit WORD. Here, the following correspond to:

- `BIT_00` corresponds to bit 0 (LSB)
- `BIT_15` corresponds to bit 15 (MSB)

The assignment is performed directly via bitwise operations, where each Boolean input value is mapped to the corresponding bit in the WORD.

Technical Features

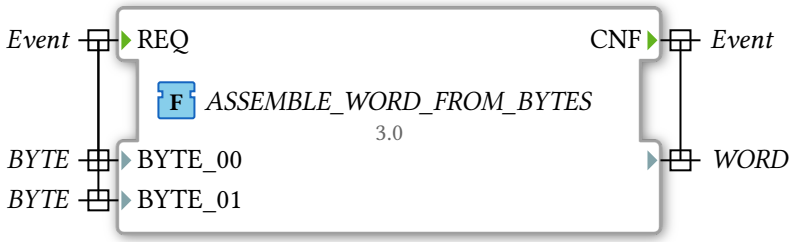
- The bit order is fixed (BIT_00 = LSB, BIT_15 = MSB)
- The block does not perform any additional calculations or transformations
- The operation is atomic and occurs in one step

State Overview

1. **Idle**: Waits for the `REQ` event
2. **Processing**: Processes the inputs and assembles the WORD
3. **Output**: Sends `CNF` with the resulting WORD

Application Scenarios

- Combining individual switching states into a compact data word
- Preparing data for communication with devices that expect WORD data
- Bitwise control of hardware registers



⚖️ Comparison with Similar Function Blocks

- Unlike general combination blocks, this function block is specifically optimized for converting BOOL to WORD
- Offers a more direct and efficient Solution than using multiple individual blocks
- Similar to BIT_TO_* blocks, but with a fixed 16-bit WORD output

Conclusion

The `ASSEMBLE_WORD_FROM_BOOLS` function block provides an efficient and direct method to convert 16 Boolean signals into a single WORD. Its simple and deterministic operation makes it particularly suitable for applications where individual bits need to be combined into compact data words.

ASSEMBLE_WORD_FROM_BYTES

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASSEMBLE_WORD_FROM_BYTES` combines two byte values into a single word (WORD). This is particularly useful when data from two separate byte sources needs to be concatenated into a single 16-bit value.

Interface Structure

Event Inputs

- **REQ**: Starts processing. The input data `BYTE_00` and `BYTE_01` are passed with this event.

Event Outputs

- **CNF**: Signals successful merging of the bytes into a WORD.

Data Inputs

- **BYTE_00**: The least significant byte (LSB) of the resulting WORD.
- **BYTE_01**: The most significant byte (MSB) of the resulting WORD.

Data Outputs

- **(no name)**: The resulting WORD, composed of `BYTE_00` (LSB) and `BYTE_01` (MSB).

Adapters

No adapters are used.

Functionality

The function block combines the two input bytes `BYTE_00` and `BYTE_01` into a 16-bit WORD. The least significant byte (LSB) is `BYTE_00` and the most significant byte (MSB) is `BYTE_01`. The operation occurs immediately after the `REQ` event arrives, and the result is output with the `CNF` event.

Technical Features

- The concatenation is performed directly by assigning the bytes to the corresponding positions in the WORD.
- The block is optimized for use in real-time systems and has a deterministic runtime.

State Overview

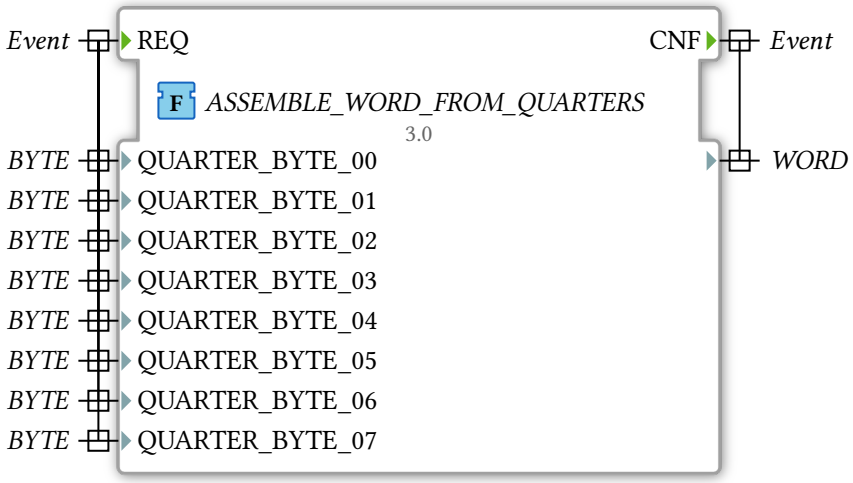
1. **Idle**: Waits for the `REQ` event.
2. **Processing**: Processes the input data and creates the WORD.
3. **Output**: Sends the `CNF` event along with the resulting WORD.

Application Scenarios

- Combining sensor values stored as separate bytes.
- Processing communication protocols where data is transmitted in byte pairs.
- General data manipulation in control systems.

⚖️ Comparison with Similar Blocks

- Compared to generic computing blocks, `ASSEMBLE_WORD_FROM_BYTES` is specialized and more efficient for this specific task.
- Similar blocks might offer additional features such as byte swapping or error handling, but they are more complex.



Conclusion

The `ASSEMBLE_WORD_FROM_BYTES` function block is a simple and efficient block for combining two bytes into a WORD. It is particularly suitable for applications where performance and simplicity are paramount.

ASSEMBLE_WORD_FROM_QUARTERS

🎧 Podcast

- QUARTER

• – ◦ • – ◦ • – ◦ •

Introduction

The function block ASSEMBLE_WORD_FROM_QUARTERS combines 8 quarter bytes into a WORD. This is particularly useful when data is in smaller units and needs to be combined into a larger unit.

Interface Structure

Event Inputs

- REQ: Starts the processing and combines the 8 quarter bytes into a WORD.

Event Outputs

- CNF: Signals the successful combination of the quarter bytes into a WORD.

Data Inputs

- QUARTER_BYTE_00 to QUARTER_BYTE_07 (Type: BYTE): The 8 quarter bytes that are combined to form a WORD.

Data Outputs

- OUT (Type: WORD): The resulting WORD composed of the 8 quarter bytes.

Adapters

No adapters are available.

Functionality

The function block receives 8 quarter bytes and combines them into a WORD. Each quarter byte is moved to a specific position within the WORD and concatenated using logical OR operations. The exact shifts are defined by constants (quarterconst::SHIFT_QUARTER_00 to quarterconst::SHIFT_QUARTER_07).

Technical Features

- Uses bitwise operations (SHL and OR) to combine the bytes.
- The shift positions are defined by constants, allowing for flexible adjustment.

State Overview

1. **Idle**: Waits for the REQ event.
2. **Processing**: Combines the quarter bytes into a WORD.
3. **Complete**: Sends the CNF event along with the resulting WORD.

Application Scenarios

- Data compression: Combining smaller data units into larger ones.
- Communication protocols: Composing data packets from individual bytes.
- Signal processing: Combining signal segments into a complete signal.

⚖️ Comparison with similar function blocks

- Similar function blocks could be BYTE_TO_WORD or SHL; however, ASSEMBLE_WORD_FROM_QUARTERS offers a specialized function for combining eight quarter bytes into a WORD.
- Unlike generic combination function blocks, this function block is optimized for the specific requirement of combining quarter bytes.

Conclusion

The ASSEMBLE_WORD_FROM_QUARTERS function block is an efficient tool for combining eight quarter bytes into a WORD. By using bitwise operations and defined shift positions, it provides a reliable and flexible solution for this specific task.

2.11.12.20 selection

F_SEL_E_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SEL_E_2` is an event-based selector that selects between two input variables. It belongs to the category of standard selection functions according to IEC 61131-3 and is typically used in control applications where conditional selection between two input signals is required.

Interface Structure

Event Inputs

- `REQ0`: Event input that triggers the selection of the first input variable (`IN0`).
- `REQ1`: Event input that triggers the selection of the second input variable (`IN1`).

Event Outputs

- `CNF`: Confirmation event that is output after an input variable is selected. This event is linked to the output variable `OUT`.

Data Inputs

- `IN0`: First selectable input variable (Type: `ANY`).
- `IN1`: Second selectable input variable (Type: `ANY`).

Data Outputs

- `OUT`: Selected input variable (type: `ANY`). The value corresponds to either `IN0` or `IN1`, depending on the triggering event (`REQ0` or `REQ1`).

Adapters

- This function block has no adapters.

Functionality

The function block `F_SEL_E_2` selects between two input variables based on the incoming events:

- If the event `REQ0` is triggered, the value of `IN0` is passed to `OUT`.
- When the event `REQ1` is triggered, the value of `IN1` is passed to `OUT`.
- After selection, the confirmation event `CNF` is issued to signal successful selection.

Technical Features

- The function block supports the data type `ANY`, meaning it is compatible with various data types.
- Selection is exclusively event-driven; that is, the logical condition for selection is controlled by external events.

State Overview

1. **Initial State**: The function block waits for an event (`REQ0` or `REQ1`).
2. **Selection State**:

- `REQ0` selects `IN0`.
- `REQ1` selects `IN1`.

1. **Confirmation State**: After selection, `CNF` is output, and the block returns to its initial state.

Application Scenarios

- Selection between two sensor data points based on external conditions.
- Switching between two operating modes in a controller.
- Dynamic selection of input signals depending on process events.

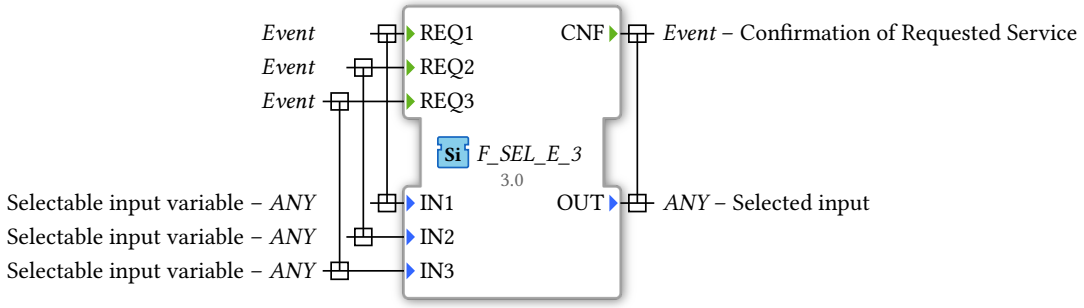
⚖️ Comparison with Similar Components

- Compared to other selection blocks (e.g., `SEL` in IEC 61131-3), `F_SEL_E_2` is purely event-driven and does not require any additional logical condition for selection.
- Similar blocks, such as `MUX` (multiplexer), allow selection from multiple inputs but are often data-flow driven and not event-based.

🛠️ Related Exercises

- Exercise_019
- Exercise_074

Conclusion



The `F_SEL_E_2` is a flexible and easy-to-use function block for applications requiring event-based selection between two input variables. Its compatibility with the `ANY` data type makes it particularly versatile.

F_SEL_E_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_SEL_E_3` is an event-based selector that selects one of three input variables based on the triggering event and passes it to the output. It is part of the `eclipse4diac::utils::selection` package and complies with the IEC 61131-3 standard for standard selection functions.

Interface Structure

Event Inputs

- `REQ0`: Selects the input variable `IN0`
- `REQ1`: Selects the input variable `IN1`
- `REQ2`: Selects the input variable `IN2`

Event Outputs

- `CNF`: Confirms the execution of the selection and returns the selected value

Data Inputs

- `IN0`: First selectable input variable (Type: ANY)
- `IN1`: Second selectable input variable (Type: ANY)
- `IN2`: Third selectable input variable (Type: ANY)

Data Outputs

- `OUT`: Selected input variable (Type: ANY)

Adapters

No adapters available.

Functionality

The function block waits for an incoming event (`REQ0`, `REQ1`, or `REQ2`). Upon the occurrence of such an event, the corresponding input variable (`IN0`, `IN1`, or `IN2`) is selected and forwarded to the output `OUT`. Simultaneously, the acknowledgment event `CNF` is triggered.

When such an event occurs, the corresponding input variable (`IN0`, `IN1`, or `IN2`) is selected and forwarded to the output `OUT`.

Technical Features

- Supports the ANY data type for maximum flexibility
- Event-based triggering for deterministic behavior
- Simple and direct selection without additional logic

State Overview

1. Waiting state: No active event
2. Selection state: Event received, corresponding input selected
3. Acknowledgement state: Output updated and CNF event triggered

Application Scenarios

- Selection between different sensor data streams
- Switching between operating modes
- Multiplexing of data sources in control systems
- Implementation of priority logic

⚖️ Comparison with Similar Function Blocks

- Unlike `F_SEL_E_2`, this function block offers three inputs instead of two
- Similar to `F_MUX`, but with event-based instead of data-driven selection
- More complex than simple gates, but more specialized for selection tasks

🛠️ Related Exercises

- Exercise_015a
- Exercise_016a

Conclusion

The `F_SEL_E_3` is an efficient and flexible component for applications that require event-driven switching between three different data sources. Its simple interface and support for any data type make it a versatile tool in automation technology.

F_SEL_E_4

• – ◦ • – ◦ • – ◦ •

Introduction

The F_SEL_E_4 function block is an event-based selector that selects one input from up to four inputs and forwards it to the output. It is classified according to the IEC 61131-3 standard and serves as a standard selection function in automation systems.

Interface Structure

Event Inputs

- **REQ0**: Event that selects the value of IN0.
- **REQ1**: Event that selects the value of IN1.
- **REQ2**: Event that selects the value of IN2.
- **REQ3**: Event that selects the value of IN3.

Event Outputs

- **CNF**: Confirmation event triggered as soon as an input is selected and the value is passed to OUT.

Data Inputs

- **IN0**: First selectable input (Type: ANY).
- **IN1**: Second selectable input (Type: ANY).
- **IN2**: Third selectable input (Type: ANY).
- **IN3**: Fourth selectable input (Type: ANY).

Data Outputs

- **OUT**: Selected input (Type: ANY).

Adapters

No adapters available.

Functionality

Based on the triggering event (REQ0 to REQ3), F_SEL_E_4 selects the corresponding input (IN0 to IN3) and passes the value to OUT. The CNF event confirms the successful selection and transmission.

Technical Features

- Supports the ANY data type, enabling flexible use with various data types.
- Event-based selection, allowing for precise control.

State Overview

The function block has no internal states. Selection and transmission occur immediately upon the arrival of the corresponding REQ event.

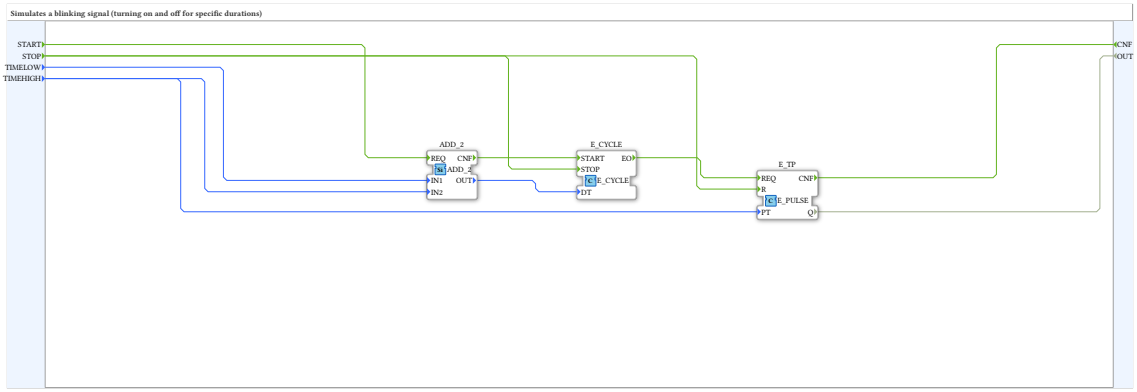
Application Scenarios

- Selection between different sensor data in a controller.
- Multiplexing of control signals in automation systems.
- Flexible data transmission depending on external events.

⚖️ Comparison with Similar Function Blocks

- Compared to other selectors, F_SEL_E_4 offers event-based control, enabling more precise selection than time- or state-based alternatives.
- Support for the ANY data type makes it more flexible than type-specific selectors.

🛠️ Related Exercises

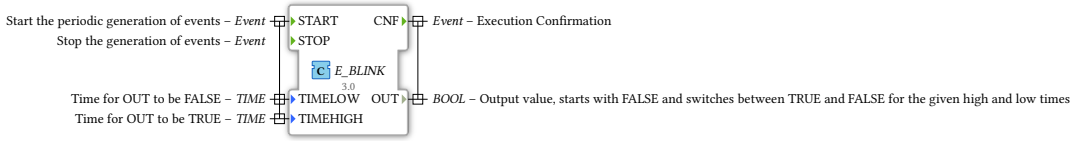


- Exercise_019a
- Exercise_019b
- Exercise_019c

Conclusion

The F_SEL_E_4 is a versatile and flexible function block for event-based data selection in automation systems. Its simple interface and support for various data types make it a practical solution for many use cases.

2.11.12.21 signals



E_BLINK

• – ○ • – ○ • – ○ •

Introduction

The E_BLINK function block simulates a flashing signal that alternates between the states TRUE and FALSE. The duration of each state can be configured individually. Unlike similar implementations, this function block always returns to FALSE upon the STOP event.

Interface Structure

Event Inputs

- **START**: Starts the periodic generation of events. Uses the data `TIMELOW` and `TIMEHIGH`.
- **STOP**: Stops the generation of events and sets the output to FALSE.

Event Outputs

- **CNF**: Acknowledges execution and returns the current output value `OUT`.

Data Inputs

- **TIMELOW**: Time in milliseconds during which the output is FALSE.
- **TIMEHIGH**: Time in milliseconds during which the output is TRUE.

Data Outputs

- **OUT**: The output value that toggles between TRUE and FALSE.

Adapters

No adapters available.

Functionality

The E_BLINK function block internally uses an E_PULSE timer and an E_CYCLE generator to implement the periodic state changes. During the START event, the times for TRUE and FALSE are added and used as the cycle time for E_CYCLE. The E_PULSE timer then controls the duration of the TRUE state, while the time difference determines the FALSE state.

Technical Features

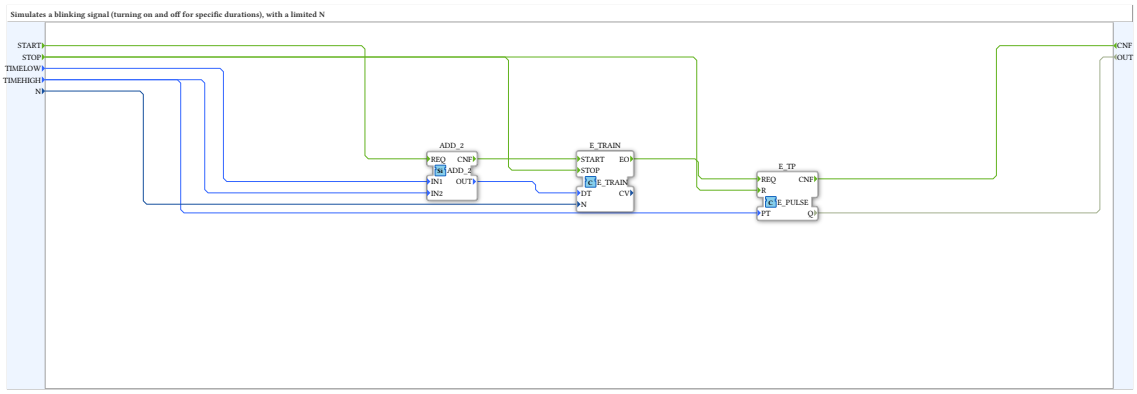
- The function block always resets the output to FALSE upon the STOP event.
- The implementation differs from similar solutions like CODESYS BLINK, which retain the last state.

State Overview

1. **Inactive**: Output is FALSE.
2. **Active**: Output toggles periodically between TRUE and FALSE.
3. **Stopped**: Output is set to FALSE.

Application Scenarios

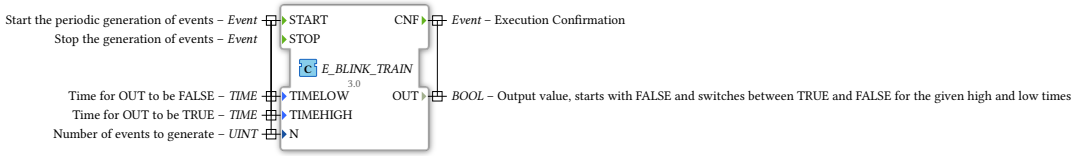
- Controlling flashing warning lights
- Generating clock signals for testing purposes
- Visualizing state changes in user interfaces



⚖️ Comparison with Similar Function Blocks

Compared to the CODESYS BLINK function block, E_BLINK offers simplified handling due to the automatic reset to FALSE upon stopping. The functionality is similar, but the behavior during a STOP event is more consistent.

Conclusion



The E_BLINK function block offers a simple and reliable way to generate periodic signals with configurable on and off times. The clear definition of the STOP behavior makes it particularly suitable for safety-critical applications.

E_BLINK_TRAIN

• – ○ • – ○ • – ○ •

The function block `E_BLINK_TRAIN` simulates a flashing signal that is switched on and off for specific time intervals. The number of flash cycles can be limited. Unlike similar flashing function blocks, this FB always returns to the state `FALSE` when stopped.

- `START`: Starts the periodic generation of events. Linked to the data inputs `TIMELOW`, `TIMEHIGH`, and `N`.
- `STOP`: Stops event generation.
- `CNF`: Acknowledges execution and returns the current output value `OUT`.
- `TIMELOW` (TIME): Time during which `OUT` has the value `FALSE`.
- `N` (UINT): Number of blink cycles to generate.
- `OUT` (BOOL): Output value that alternates between `TRUE` and `FALSE`. Starts with `FALSE`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Functionality

1. Upon a `START` event, the sum of `TIMELOW` and `TIMEHIGH` is calculated and used as the period for the blink cycle.
2. The function block generates `N` blink cycles, where `OUT` is set to `TRUE` for `TIMEHIGH` and to `FALSE` for `TIMELOW`.
3. Upon a `STOP` event, generation is terminated and `OUT` is reset to `FALSE`.
4. Each state change is confirmed via the `CNF` event.

- Uses internal function blocks `E_PULSE` (for timing) and `E_TRAIN` (for cycle limiting).
- The period duration is determined by adding `TIMELOW` and `TIMEHIGH`.
- Unlike some other blink function blocks, `FALSE` is always output upon stopping.

1. **Inactive**: `OUT` = `FALSE` (initial state or after `STOP`).
2. **Active**: Generates blink cycles according to the set times and number of cycles.

- `OUT` toggles between `TRUE` (`TIMEHIGH`) and `FALSE` (`TIMELOW`).
- Display of warning or status lights with a defined blink frequency.
- Control of periodic signals in industrial automation processes.
- Simulation of blink patterns for testing purposes.
- **CODESYS BLINK FB**: Retains the last state when stopped, while `E_BLINK_TRAIN` always reverts to `FALSE`.
- **Simple Timer FBs**: Do not offer an integrated limit on the number of cycles (`N`).
- Exercise_035a3

The `E_BLINK_TRAIN` is a versatile function block for generating blinking signals with configurable times and a limited number of cycles. Its unique feature is that it reverts to `FALSE` when stopped, making it ideal for safety-critical applications. The clear interface structure and the internal use of proven timer FBs make it reliable and easy to use.

SPLIT_BYTE_INTO_BOOLS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_BYTE_INTO_BOOLS` is used to split a byte into its individual bits and output them as separate BOOL values. This is particularly useful when working with hardware that evaluates or sets individual bits of a byte.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. When this event is triggered, the bits of the current byte value are evaluated at `IN`.

Event Outputs

- **CNF**: Confirms the execution of the function block. This event is triggered after all bits have been evaluated and forwarded to the corresponding outputs.

Data Inputs

- **IN**: The byte to be split into its individual bits. The data type is `BYTE`.

Data Outputs

- **BIT_00** to **BIT_07**: The individual bits of the byte, where `BIT_00` represents the least significant bit (LSB) and `BIT_07` represents the most significant bit (MSB). The data type of all outputs is `BOOL`.

Adapters

This function block does not use adapters.

Operation

This function block splits the incoming byte `IN` into its 8 bits and assigns them to the corresponding BOOL outputs. Each bit is extracted directly from the byte and output as a separate BOOL value. Evaluation occurs with each `REQ` event.

Technical Features

- Bit extraction is performed directly via the access notation `IN.%X0` to `IN.%X7`, enabling efficient and fast processing.
- The function block is implemented in the ST (Structured Text) programming language.

State Overview

The function block has no internal states. Execution occurs immediately upon receiving the `REQ` event, and the results are immediately available via the `CNF` event and the data outputs.

Application Scenarios

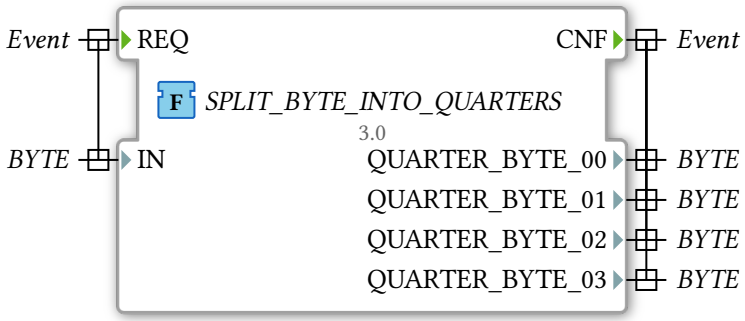
- **Hardware Control**: When controlling digital inputs and outputs organized as bytes, individual bits can be easily evaluated.
- **Data Processing**: When processing byte data where individual bits have a specific meaning (e.g., status flags).

⚖️ Comparison with Similar Blocks

- Compared to generic bit manipulation functions, this block offers a specialized and simple solution for decomposing a byte into bits.
- Other blocks might require more complex operations such as bit shifts or masks, while this block enables direct bit extraction.

🛠️ Related Exercises

- Exercise_053



Conclusion

The `SPLIT_BYTE_INTO_BOOLS` function block is a simple and efficient tool for decomposing a byte into its individual bits. It is particularly suitable for applications requiring fast and direct bit extraction. Its clear interface and simple operation make it easy to integrate into existing systems.

SPLIT_BYTE_INTO_QUARTERS

🎧 Podcast

- QUARTER

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_BYTE_INTO_QUARTERS` is used to split a byte into four quarter bytes. This function is particularly useful when individual parts of a byte need to be processed separately, for example, when decoding data or manipulating bits.

Interface Structure

Event Inputs

- `REQ`: Starts the processing of the input byte. It is linked to the data input `IN`.

Event Outputs

- `CNF`: Signals the completion of processing and provides the four quarter bytes. It is linked to the data outputs `QUARTER_BYTE_00`, `QUARTER_BYTE_01`, `QUARTER_BYTE_02`, and `QUARTER_BYTE_03`.

Data Inputs

- `IN` (BYTE): The input byte to be split into four quarter bytes.

Data Outputs

- `QUARTER_BYTE_00` (BYTE): The first quarter byte (bits 0-1).
- `QUARTER_BYTE_01` (BYTE): The second quarter byte (bits 2-3).
- `QUARTER_BYTE_02` (BYTE): The third quarter byte (bits 4-5).
- `QUARTER_BYTE_03` (BYTE): The fourth quarter byte (bits 6-7).

Adapters

No adapters are used.

Functionality

The function block extracts the four quarter bytes from the input byte `IN` using bitwise operations:

1. Each quarter byte is isolated using a bitwise AND operation with a corresponding mask.
2. The result is then shifted into the correct position using a right shift (`SHR`).
3. The masks and shift values used are defined in the constant file `quarterconst`.

Technical Features

- The bitwise operations are efficient and fast because they are performed directly at the processor level.
- The use of constants (`quarterconst`) allows for flexible adjustment of masks and shift values.

State Overview

The function block has no internal state. Processing occurs exclusively when the `REQ` event occurs.

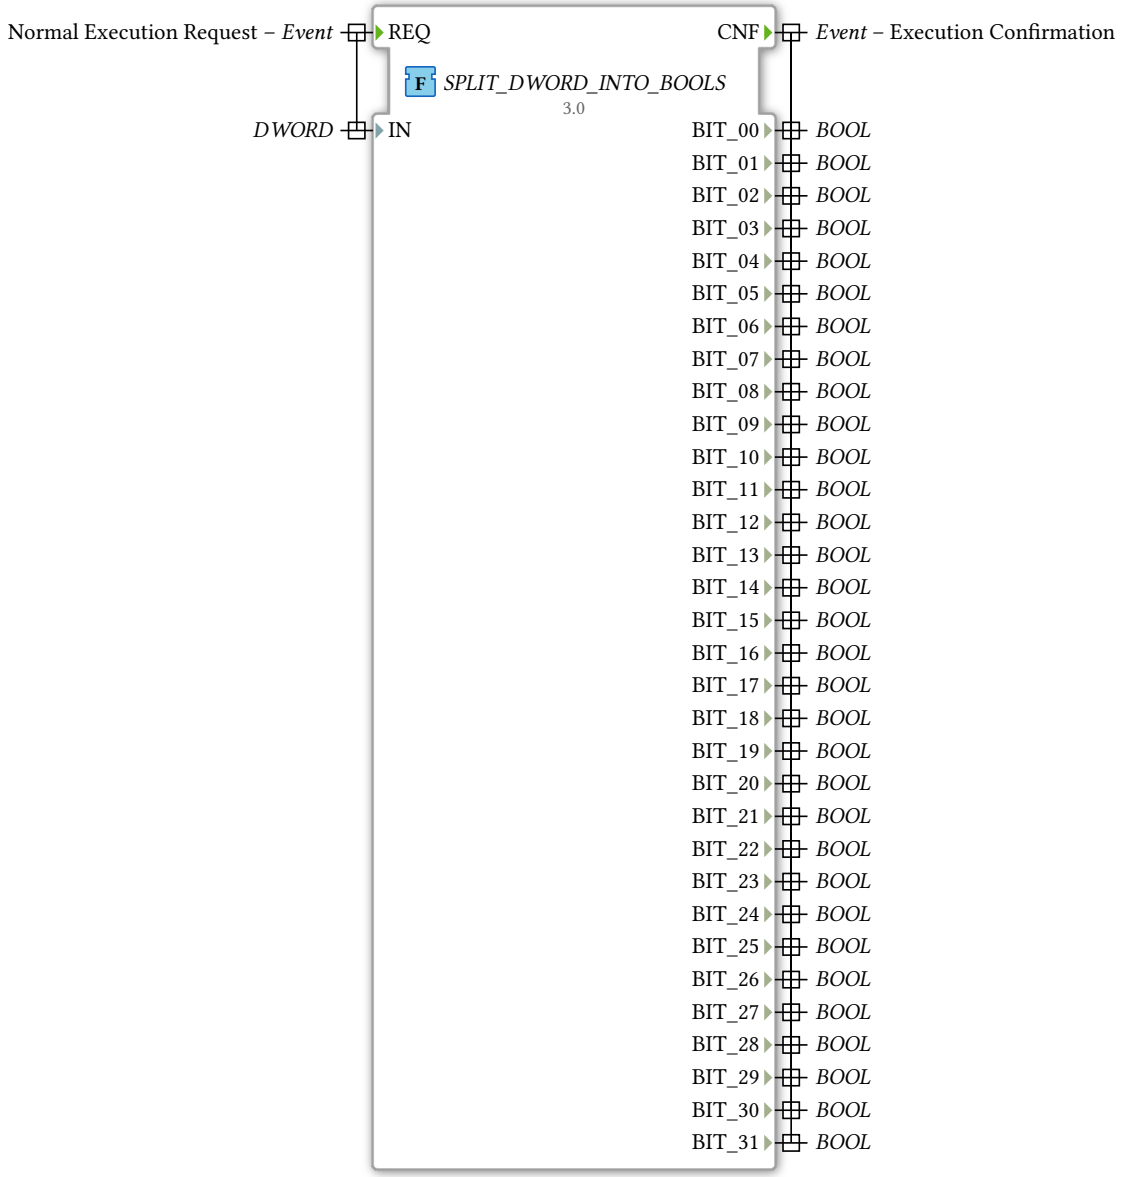
Application Scenarios

- Decoding data packed into a byte.
- Extracting individual control bits from a status byte.
- Processing data in communication protocols where information is encoded in quarter bytes.

⚖️ Comparison with Similar Function Blocks

- Compared to generic bit manipulation function blocks, `SPLIT_BYTE_INTO_QUARTERS` offers a specialized and optimized solution for splitting a byte into four parts.

Other blocks, such as `EXTRACT_BITS` or `BIT_SLICE`, are more general but require more configuration and may be less efficient.



🛠️ Related Exercises

- Exercise_056

Conclusion

The `SPLIT_BYTE_INTO_QUARTERS` function block is an efficient and specialized solution for splitting a byte into four quarter bytes. Its use of bitwise operations and constants makes it fast and flexible. It is ideal for applications where data is in a compact form and needs to be processed separately.

SPLIT_DWORD_INTO_BOOLS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_DWORD_INTO_BOOLS` is used to split a 32-bit DWORD into its individual bits and output them as separate BOOL values. This is particularly useful when compressed data needs to be processed in a controller and the individual bits need to be addressed separately.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. When this input is activated, the bits of the input DWORD are evaluated and made available at the outputs.

Event Outputs

- **CNF**: Confirms the successful execution of the function block. This event is triggered along with the updated BOOL outputs.

Data Inputs

- **IN**: The input DWORD to be split into 32 individual bits.

Data Outputs

- **BIT_00** to **BIT_31**: The 32 individual bits of the input DWORD, each output as a BOOL value. Each output represents one bit of the DWORD, where `BIT_00` corresponds to the least significant bit (LSB) and `BIT_31` to the most significant bit (MSB).

Adapters

This function block does not use adapters.

Operation

The function block extracts each bit of the input DWORD `IN` and assigns it to the corresponding BOOL outputs. The mapping is direct:

- `BIT_00` = Bit 0 (LSB)
- `BIT_01` = Bit 1
- ...
- `BIT_31` = Bit 31 (MSB)

When the `REQ` event is triggered, all bits are evaluated, and the `CNF` event is triggered as soon as the outputs are updated.

Technical Features

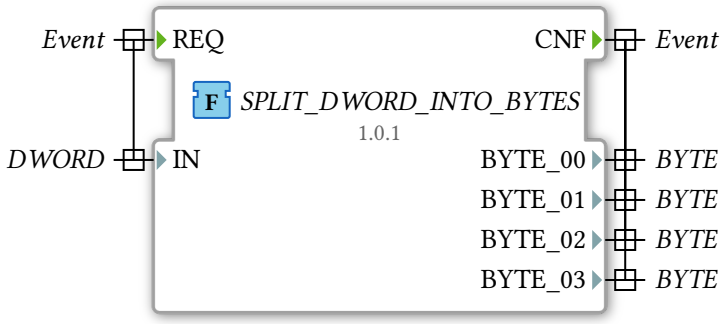
- The function block is implemented in ST (Structured Text) and uses direct bit access to the DWORD (`IN.%X0` to `IN.%X31`).
- The outputs are updated synchronously with the `CNF` event, enabling deterministic processing.

State Overview

The function block has no internal state. The outputs are recalculated with each `REQ` event.

Application Scenarios

- Processing compressed status information, e.g., from a fieldbus or interface.
- Decoding bitmasks in control applications.
- Splitting DWORD values for individual bit manipulation.



⚖ Comparison with Similar Function Blocks

- Compared to generic bit manipulation functions, this function block offers a direct and efficient method for extracting all bits of a DWORD.
- Similar function blocks might only process parts of a DWORD or contain additional logic, which is not the case here.

Conclusion

The `SPLIT_DWORD_INTO_BOOLS` function block is a specialized tool for efficiently splitting a DWORD into its individual bits. Its simple and deterministic operation makes it ideal for applications requiring bit manipulation.

SPLIT_DWORD_INTO_BYTES

• – ◦ • – ◦ • – ◦ •

Introduction

The function SPLIT_DWORD_INTO_BYTES splits a DWORD value into its four BYTE parts. It is the counterpart of ASSEMBLE_DWORD_FROM_BYTES.

Interface Structure

Event Inputs

- **REQ**: starts the split. Associated data: IN.

Event Outputs

- **CNF**: signals the completed split. Associated data: BYTE_00 to BYTE_03.

Data Inputs

- **IN** (DWORD): value to split

Data Outputs

- **BYTE_00** (BYTE): least significant byte (%B0)
- **BYTE_01** (BYTE): byte %B1
- **BYTE_02** (BYTE): byte %B2
- **BYTE_03** (BYTE): most significant byte (%B3)

Adapters

No adapters available.

Functionality

The function assigns each output the corresponding byte of the input:

- BYTE_00 := IN.%B0
- BYTE_01 := IN.%B1
- BYTE_02 := IN.%B2
- BYTE_03 := IN.%B3

Technical Details

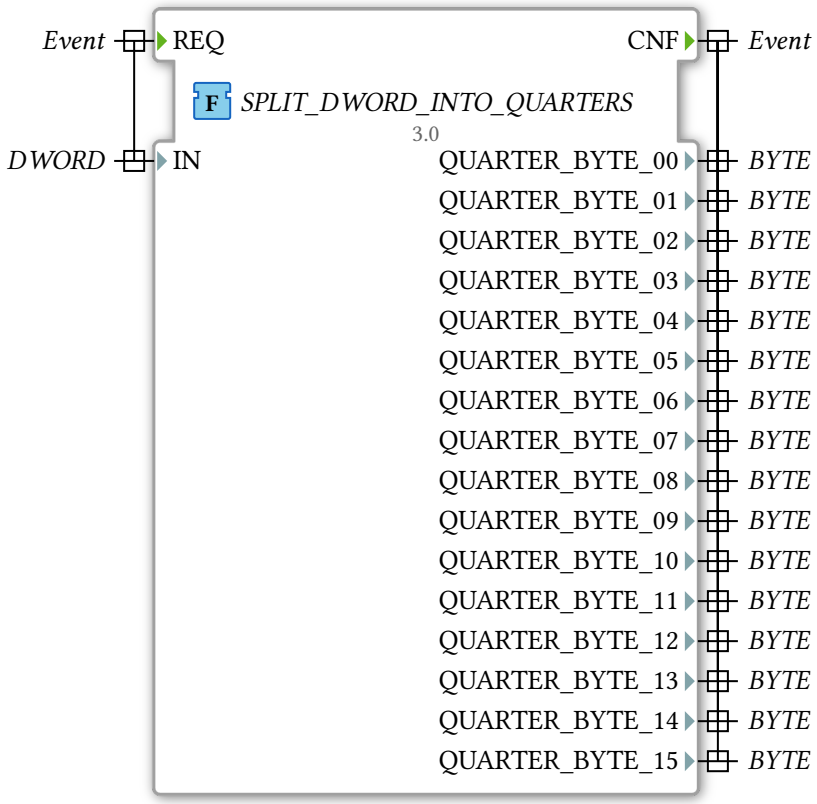
- Implemented as an ST function (FUNCTION) with VAR_OUTPUT, package eclipse4diac::utils::splitting
- Individual bytes are accessed with the partial access syntax %B0 to %B3
- No state of its own

Application Scenarios

- Splitting 32-bit values into individual bytes, e.g. for protocols or CAN data

⚖️ Comparison with Similar Building Blocks

- SPLIT_WORD_INTO_BYTES splits a WORD into two bytes, SPLIT_DWORD_INTO_WORDS a DWORD into two words.



Conclusion

SPLIT_DWORD_INTO_BYTES splits a DWORD byte by byte into four BYTE outputs.

SPLIT_DWORD_INTO_QUARTERS

🎧 Podcast

- QUARTER

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_DWORD_INTO_QUARTERS` is used to split a 32-bit word (DWORD) into its 16 individual 4-bit blocks (QUARTER_BYTE). Each of these 4-bit blocks is output as a separate BYTE variable. This block is particularly useful when individual parts of a DWORD need to be processed or analyzed separately.

Interface Structure

Event Inputs

- `REQ`: Starts processing the input DWORD.

Event Outputs

- `CNF`: Signals successful processing and provision of all 16 QUARTER_BYTE outputs.

Data Inputs

- `IN`: The input DWORD, which is split into 16 QUARTER_BYTE.

Data Outputs

- `QUARTER_BYTE_00` to `QUARTER_BYTE_15`: The 16 individual 4-bit blocks of the input DWORD, each output as a BYTE.

Adapters

No adapters are available.

Functionality

The function block extracts the 16 QUARTER_BYTE from the input DWORD using bitwise operations. Each QUARTER_BYTE is isolated using a combination of bitwise AND operation and right shift, and then converted into a BYTE value. The constants used (`DWORD_QUARTER_XX` and `SHIFT_QUARTER_XX`) are defined in a separate constant file (`quarterconst`).

Technical Features

- The block uses bitwise operations to isolate the individual 4-bit blocks.
- The output values are defined as BYTES, even though they only contain 4 bits. Therefore, the upper 4 bits of each BYTE are always 0.
- The use of predefined constants (`quarterconst`) allows for flexible adjustment of the bit positions.

State Overview

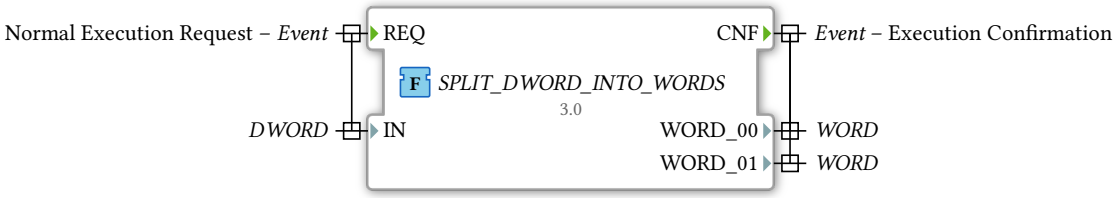
The function block has no internal state. Processing is repeated with each `REQ` event.

Application Scenarios

- Processing data packets where individual 4-bit blocks of a DWORD need to be evaluated.
- Decoding status or control information encoded in a DWORD.
- Splitting data for further processing in downstream systems.

⚖️ Comparison with Similar Blocks

- Compared to generic bit manipulation blocks, `SPLIT_DWORD_INTO_QUARTERS` offers specialized functionality for splitting a DWORD into 4-bit blocks.
- Other blocks, such as `SPLIT_DWORD_INTO_BYTES`, split a DWORD into 8-bit blocks, while this block offers finer granularity.



🛠️ Related Exercises

- Exercise_060

Conclusion

The `SPLIT_DWORD_INTO_QUARTERS` function block is a specialized tool for splitting a 32-bit word into 16 individual 4-bit blocks. Its simple and efficient implementation makes it ideal for applications requiring detailed analysis or processing of DWORD data.

SPLIT_DWORD_INTO_WORDS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_DWORD_INTO_WORDS` is used to split a 32-bit DWORD into two 16-bit WORDs. This functionality is particularly useful when working with data that is stored as a DWORD but needs to be further processed in separate WORD parts.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. It is linked to the data input `IN`.

Event Outputs

- **CNF**: Signals the successful execution of the function block. Linked to the data outputs `WORD_00` and `WORD_01`.

Data Inputs

- **IN**: DWORD (32-bit) to be split into two WORDs.

Data Outputs

- **WORD_00**: First WORD (16-bit) of the DWORD.
- **WORD_01**: Second WORD (16-bit) of the DWORD.

Adapters

This function block does not use adapters.

Functionality

The function block takes a DWORD as input and splits it into two WORDs:

- `WORD_00` contains the lower 16 bits of the DWORD (`IN.%W0`).
- `WORD_01` contains the upper 16 bits of the DWORD (`IN.%X1`).

The split occurs with each `REQ` event, and the result is confirmed with the `CNF` event.

Technical Details

- The implementation is in Structured Text (ST).
- The function block is part of the `eclipse4diac::utils::splitting` package.

State Overview

The function block has no internal state. Processing occurs immediately with each `REQ` event.

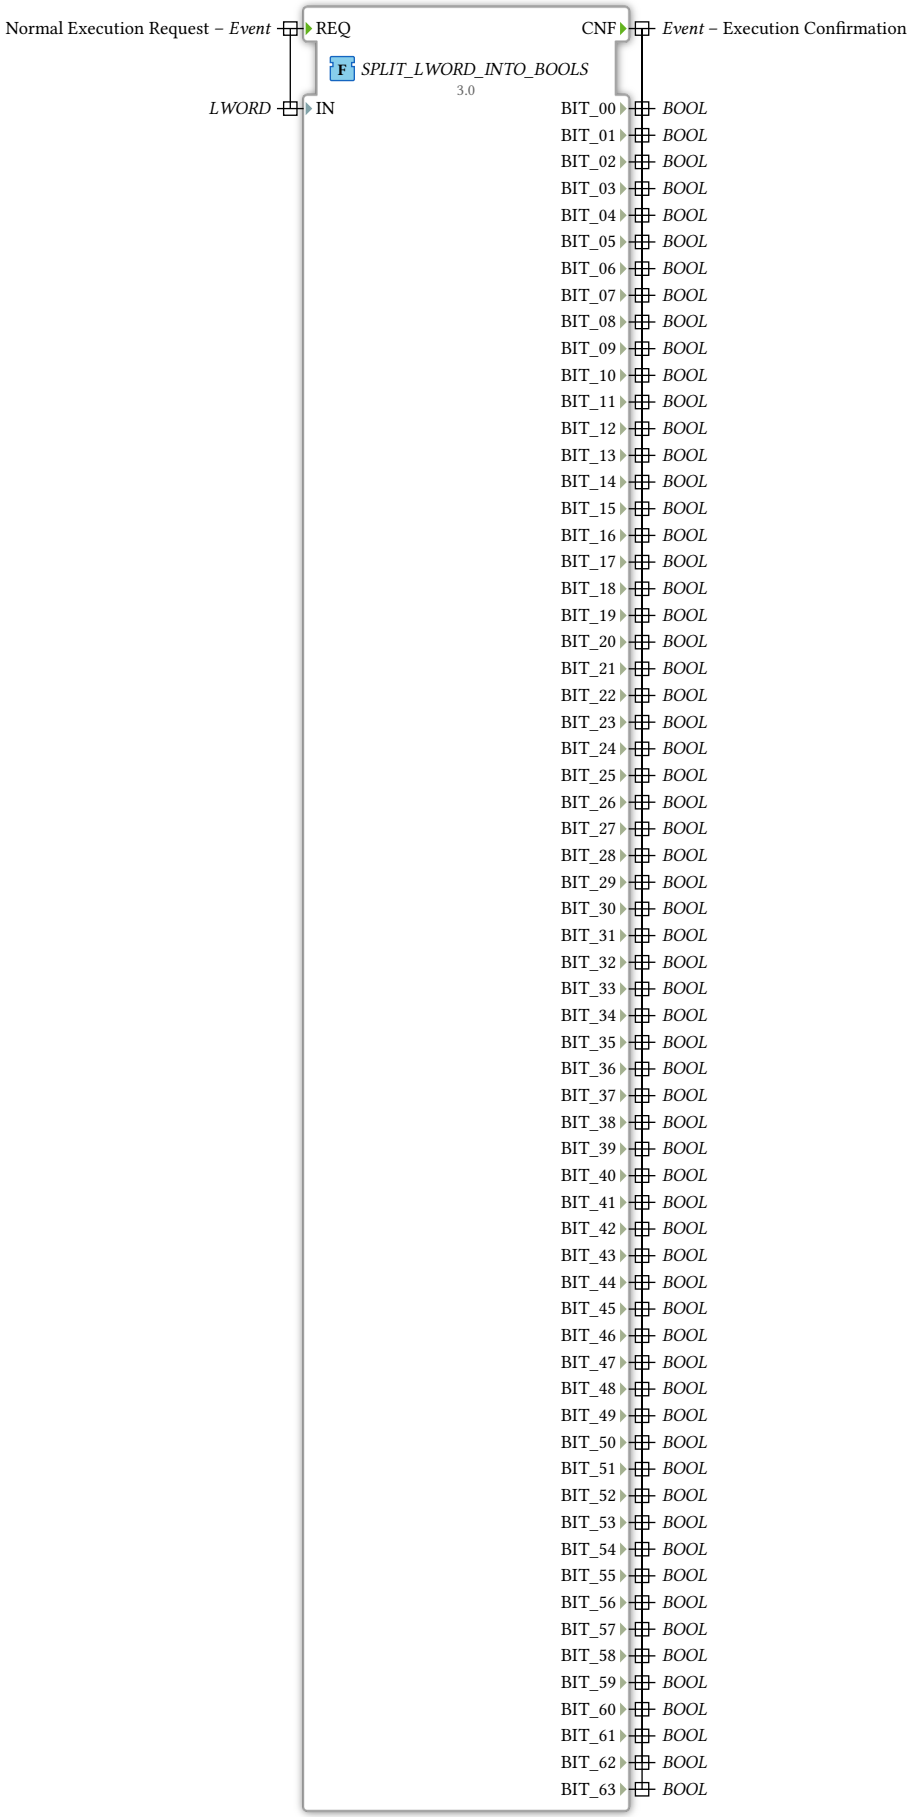
Application Scenarios

- Processing DWORD data originating from hardware registers or communication protocols.
- Splitting 32-bit values for further processing in 16-bit systems.

⚖️ Comparison with similar blocks

- Unlike generic bit manipulation blocks, `SPLIT_DWORD_INTO_WORDS` specializes in splitting DWORDs into WORDs.
- Similar blocks might offer additional flexibility, such as selecting which bits to extract, but are often more complex to use.

Conclusion



The `SPLIT_DWORD_INTO_WORDS` function block provides a simple and efficient way to split DWORD data into its WORD components. Its specialized functionality makes it particularly useful for applications that regularly perform such data conversions.

Introduction

The function block `SPLIT_LWORD_INTO_BOOLS` is used to decompose a 64-bit LWORD data type into its individual bits. Each bit is provided as a separate BOOL output. This block is particularly useful when individual bits of a long word need to be evaluated or processed.

Interface Structure

Event Inputs

- `REQ` (Event): Starts the decomposition of the LWORD into individual bits. It is linked to the input `IN`.

Event Outputs

- `CNF` (Event): Confirms the successful decomposition of the LWORD. Linked to all 64 BOOL outputs.

Data Inputs

- `IN` (LWORD): The 64-bit word to be split into individual bits.

Data Outputs

- `BIT_00` to `BIT_63` (BOOL): The individual bits of the input LWORD, where `BIT_00` is the least significant bit (LSB) and `BIT_63` is the most significant bit (MSB).

Adapters

No adapters are included.

Functionality

The function block extracts each bit of the input LWORD (`IN`) and assigns it to the corresponding BOOL outputs. Extraction is performed via direct bit accesses (`IN.%X0` to `IN.%X63`). Upon triggering the `REQ` event, all bits are updated, and the `CNF` event confirms successful processing.

Technical Features

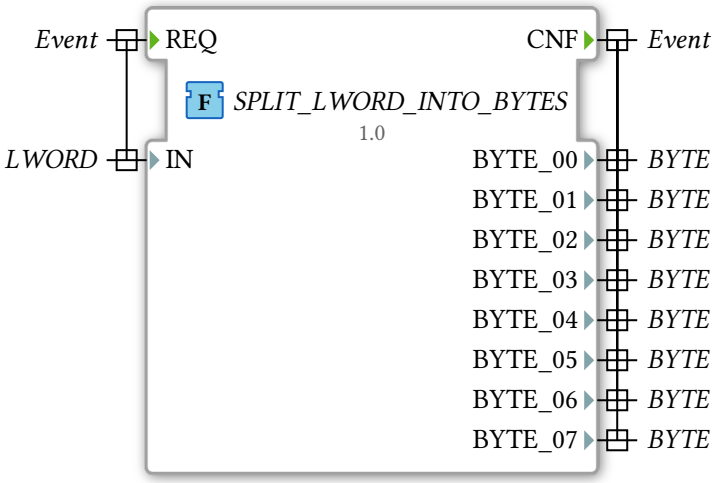
- Processes 64-bit data (LWORD).
- Each bit is output individually as a BOOL.
- No additional logic or filtering – direct bit mapping.

State Overview

The block has no internal state. The decomposition is performed anew with each `REQ` event.

Application Scenarios

- Evaluation of bitmasks or status registers.
- Processing of digital signals encoded as LWORDs.
- Debugging or monitoring individual bits in long data words.



⚖️ Comparison with similar blocks

- Similar blocks like `SPLIT_WORD_INTO_BOOLS` or `SPLIT_DWORD_INTO_BOOLS` work with shorter data types (WORD and DWORD, respectively).
- This block is specifically optimized for 64-bit data.

Conclusion

The `SPLIT_LWORD_INTO_BOOLS` block is an efficient tool for decomposing 64-bit data into individual bits. Its simple and direct operation makes it ideal for applications requiring detailed bit analysis.

SPLIT_LWORD_INTO_BYTES

• – ◦ • – ◦ • – ◦ •

Introduction

The function `SPLIT_LWORD_INTO_BYTES` splits a 64-bit long word (`LWORD`) into its eight bytes (`BYTE`).

Interface Structure

Event Inputs

- `REQ`: Starts the processing. Associated data: `IN`

Event Outputs

- `CNF`: Signals the processing. Associated data: `BYTE_00` to `BYTE_07`

Data Inputs

- `IN`: The long word to be split (`LWORD`)

Data Outputs

- `BYTE_00`: Byte 0 (`BYTE`), least significant byte (bits 0 to 7)
- `BYTE_01`: Byte 1 (`BYTE`), bits 8 to 15
- `BYTE_02`: Byte 2 (`BYTE`), bits 16 to 23
- `BYTE_03`: Byte 3 (`BYTE`), bits 24 to 31
- `BYTE_04`: Byte 4 (`BYTE`), bits 32 to 39
- `BYTE_05`: Byte 5 (`BYTE`), bits 40 to 47
- `BYTE_06`: Byte 6 (`BYTE`), bits 48 to 55
- `BYTE_07`: Byte 7 (`BYTE`), most significant byte (bits 56 to 63)

Adapters

This function does not use any adapters.

How it works

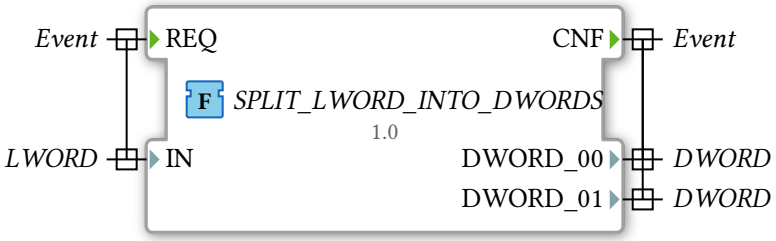
The function reads the eight bytes from the input `IN` via the partial access `.%B0` to `.%B7`:

```
BYTE_00 := IN.%B0;
BYTE_01 := IN.%B1;
BYTE_02 := IN.%B2;
BYTE_03 := IN.%B3;
BYTE_04 := IN.%B4;
BYTE_05 := IN.%B5;
BYTE_06 := IN.%B6;
BYTE_07 := IN.%B7;
```

`BYTE_00` is thus the least significant and `BYTE_07` the most significant byte of the `LWORD`.

Technical Details

- Implemented in Structured Text (ST) as a `FUNCTION` without internal state
- Part of the package `eclipse4diac::utils::splitting`
- Version 1.0 (2026-05-16)



Application Scenarios

- Splitting a 64-bit value into individual bytes, e.g. for telegrams or bus messages (CAN: 8 data bytes)
- Byte-wise analysis of 64-bit bit patterns

Summary

`SPLIT_LWORD_INTO_BYTES` extracts the eight bytes of an `LWORD`, starting with the least significant one.

SPLIT_LWORD_INTO_DWORDS

• – ◦ • – ◦ • – ◦ •

Introduction

The function `SPLIT_LWORD_INTO_DWORDS` extracts the two 32-bit double words (`DWORD`) from a 64-bit long word (`LWORD`).

Interface Structure

Event Inputs

- `REQ`: Starts the processing. Associated data: `IN`

Event Outputs

- `CNF`: Signals the processing. Associated data: `DWORD_00`, `DWORD_01`

Data Inputs

- `IN` (`LWORD`): Long word to be split

Data Outputs

- `DWORD_00` (`DWORD`): Least significant double word (bits 0 to 31)
- `DWORD_01` (`DWORD`): Most significant double word (bits 32 to 63)

Adapters

This function uses no adapters.

How it works

The function assigns the parts via partial access:

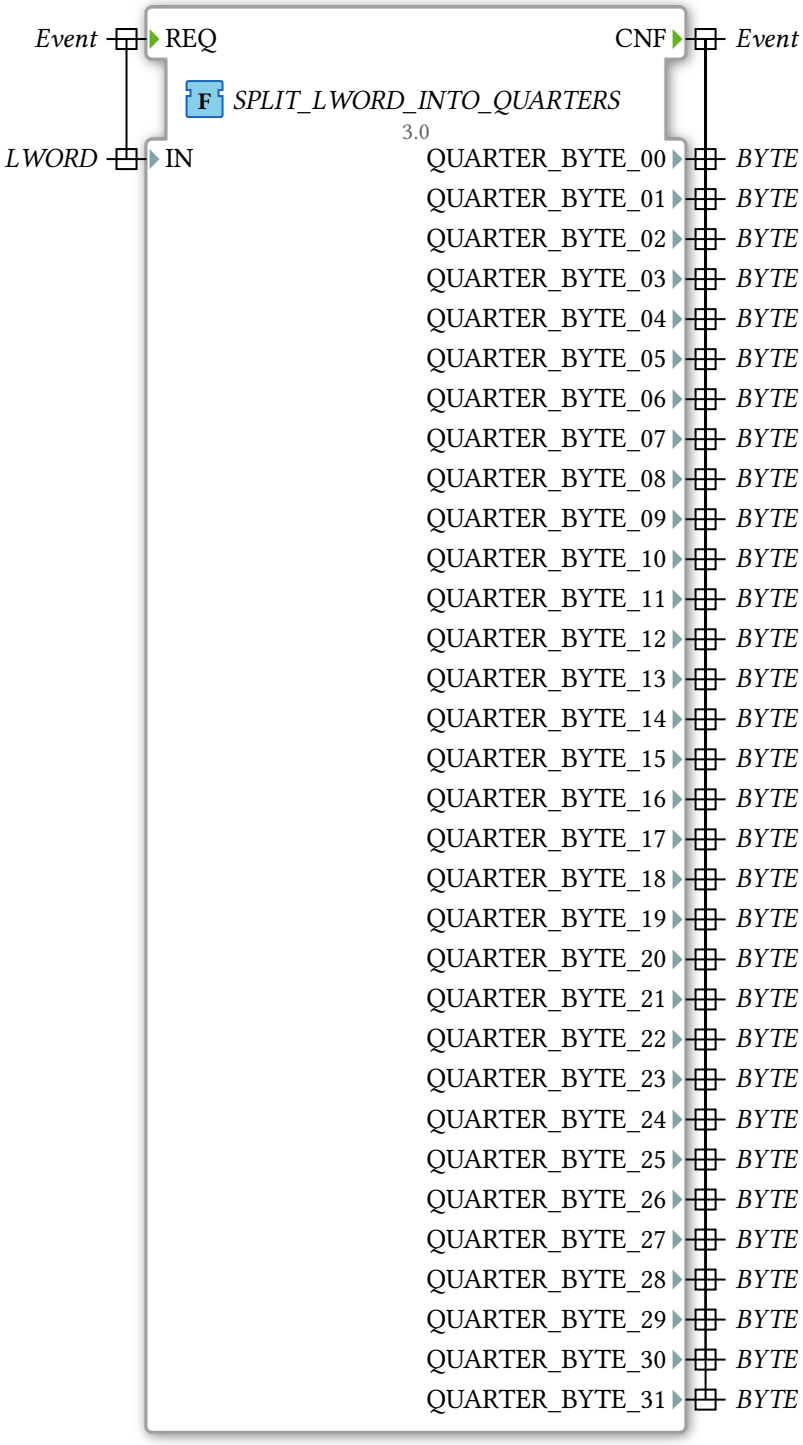
```
DWORD_00 := IN.%D0;
DWORD_01 := IN.%D1;
```

Technical Details

- Implemented in Structured Text (ST) as a `FUNCTION` without internal state
- Part of the package `eclipse4diac::utils::splitting`
- The inverse is formed by the `ASSEMBLE_*` functions in the package `assembling` (e.g. `ASSEMBLE_LWORD_FROM_WORDS` for `WORD` parts).

Application Scenarios

- Splitting a 64-bit value into two 32-bit values, e.g. for fieldbus or register access



Summary

`SPLIT_LWORD_INTO_DWORDS` splits an `LWORD` into its least significant and its most significant `DWORD`.

SPLIT_LWORD_INTO_QUARTERS

Podcast

- QUARTER

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_LWORD_INTO_QUARTERS` extracts the 32 quarter bytes (8 bits each) from a 64-bit LWORD. This allows for the targeted processing of individual byte segments within a long word.

Interface Structure

Event Inputs

- `REQ`: Starts processing the input value `IN`.

Event Outputs

- `CNF`: Confirms successful processing and returns all 32 quarter bytes.

Data Inputs

- `IN` (LWORD): The 64-bit input word to be split into quarter bytes.

Data Outputs

32 outputs of type BYTE:

- `QUARTER_BYTE_00` to `QUARTER_BYTE_31`: The extracted 8-bit segments of the input word.

Adapters

No adapters available.

Adapters ## Functionality

The function block uses bitwise operations (AND and right shift) in combination with constants (`quarterconst::LWORD_QUARTER_xx` and `quarterconst::SHIFT_QUARTER_xx`) to isolate each of the 32 quarter bytes from the input LWORD. Each quarter byte is then written to a separate BYTE output.

Technical Features

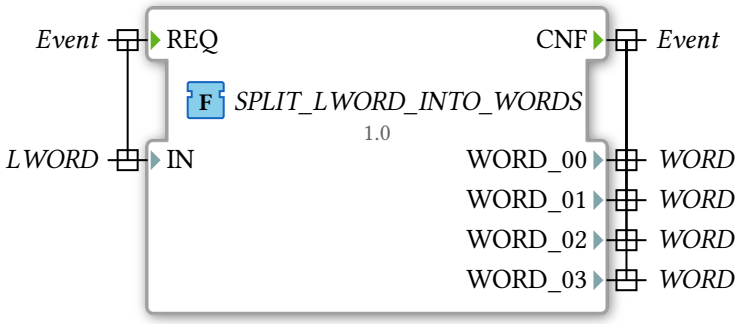
- Uses special bitmasks and shift constants for precise extraction
- Works with the largest IEC data type, LWORD (64-bit)
- Delivers all 32 quarter bytes in parallel in a single pass

State Overview

1. **Idle**: Waits for REQ event
2. **Processing**: Extracts all quarter bytes
3. **Output**: Triggers CNF event with all output values

Application Scenarios

- Processing long data words in communication protocols
- Extracting individual parameters from packed data structures
- Bitwise analysis of sensor or control data



⚖️ Comparison with Similar Function Blocks

- Unlike simple BYTE extraction blocks, this function block can process all 32 segments simultaneously
- More efficient than multiple cascaded extraction blocks
- Specialized in processing LWORD data types

Conclusion

The The `SPLIT_LWORD_INTO_QUARTERS` function block offers a highly optimized solution for splitting 64-bit words into their individual byte components. Its parallel processing of all segments makes it particularly suitable for applications requiring efficient processing of large data words.

SPLIT_LWORD_INTO_WORDS

• – ◦ • – ◦ • – ◦ •

Introduction

The function `SPLIT_LWORD_INTO_WORDS` extracts the four `WORD` values from a `LWORD`. It is useful when a 64-bit value (e.g. from a communication protocol) has to be split into 16-bit parts.

Interface Structure

Event Inputs

- **REQ**: starts the processing (associated with `IN`)

Event Outputs

- **CNF**: signals completion (associated with `WORD_00`..`WORD_03`)

Data Inputs

- **IN** (LWORD): 64-bit value to be split

Data Outputs

- **WORD_00** (WORD): first word, bits 0-15 (`IN.%W0`)
- **WORD_01** (WORD): second word, bits 16-31 (`IN.%W1`)
- **WORD_02** (WORD): third word, bits 32-47 (`IN.%W2`)
- **WORD_03** (WORD): fourth word, bits 48-63 (`IN.%W3`)

Adapters

No adapters are used.

Functionality

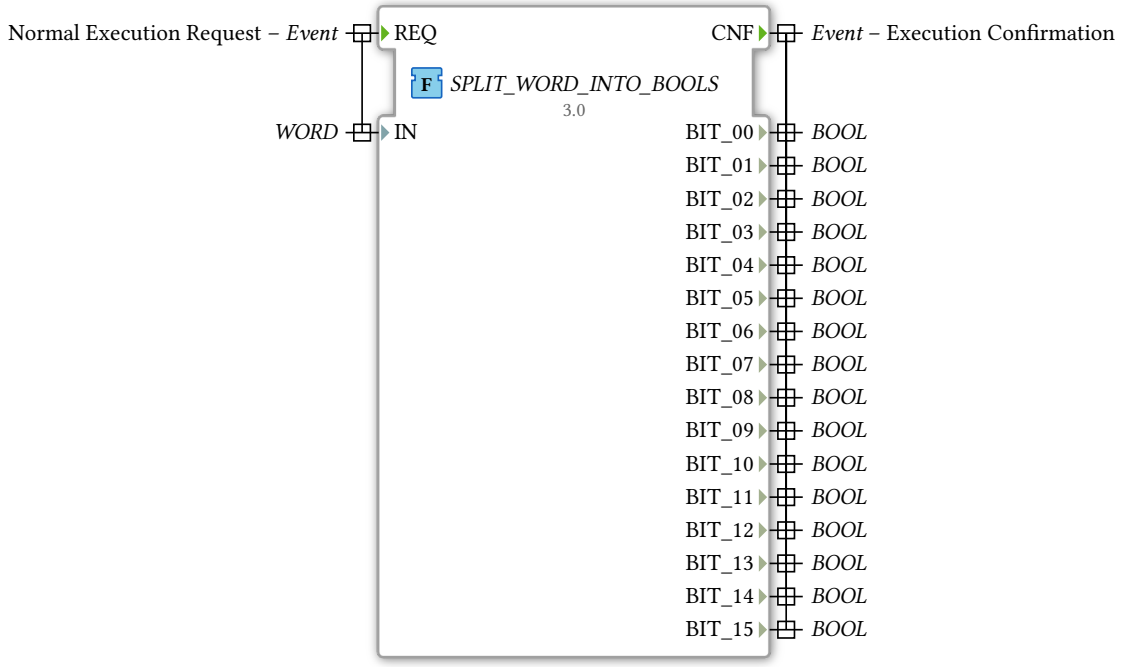
The function assigns the four words by partial access: `WORD_00 := IN.%W0;`, `WORD_01 := IN.%W1;`, `WORD_02 := IN.%W2;`, `WORD_03 := IN.%W3;`.

Technical Details

- Pure bit accesses without calculation effort; no states
- Package `eclipse4diac::utils::splitting`, version 1.0 (2026-05-16)

Application Scenarios

- Splitting 64-bit values (e.g. from OPC-UA or CAN data) into 16-bit registers



⚖️ Comparison with Similar Blocks

Analogous blocks split smaller values, such as `SPLIT_BYTE_INTO_QUARTERS` (byte into four quarter bytes) or `SPLIT_DWORD_INTO_BOOLS`.

Conclusion

`SPLIT_LWORD_INTO_WORDS` splits a `LWORD` into four `WORD` values and delivers them with a single `CNF` event.

SPLIT_WORD_INTO_BOOLS

• – ◦ • – ◦ • – ◦ •

The function block `SPLIT_WORD_INTO_BOOLS` is used to decompose a 16-bit word into its individual bits. Each bit of the input word is mapped to a separate BOOL output. This is particularly useful when individual bits of a word need to be further processed or monitored.

- `REQ` (Normal Execution Request): Starts the decomposition of the input word. It is linked to the data input `IN`.
- `CNF` (Execution Confirmation): Confirms successful word decomposition. Linked to all 16 BOOL outputs.
- `IN` (WORD): The 16-bit word to be decomposed into individual bits.
- `BIT_00` to `BIT_15` (BOOL): The individual bits of the input word, where `BIT_00` represents the least significant bit (LSB) and `BIT_15` represents the most significant bit (MSB).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

- No adapters available.

The function block parses the input word `IN` into its 16 individual bits and assigns them to the corresponding BOOL outputs. The assignment is done directly via the bit addressing of the WORD data type (e.g., `IN.%X0` for the first bit). When the `REQ` event is triggered, all bits are extracted, and the `CNF` event confirms successful execution.

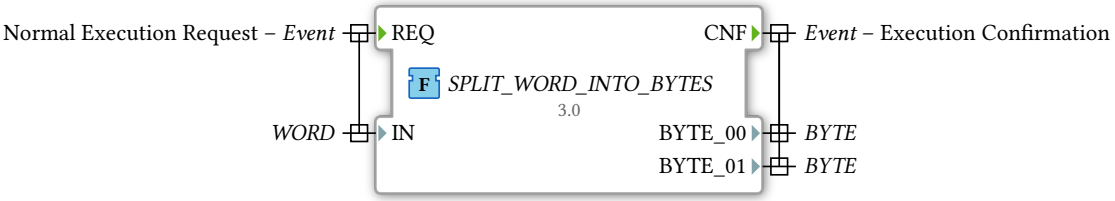
- Bit extraction is performed directly via low-level hardware bit addressing, enabling efficient processing.
- The function block is deterministic and has no internal states.
- **Idle**: Waiting for the `REQ` event.
- **Processing**: Parses the word and updates the outputs.
- **Complete: `Löst das` CNF` event and returns to the idle state.

- Processing of digital input signals transmitted as WORDs.
- Decoding of status or control words in control systems.
- Interface between word-based and bit-based system components.
- Compared to generic bit manipulation functions, this block offers a specialized and simple interface for decomposing words.
- Similar blocks might support a flexible number of bits, which is not the case here.

The `SPLIT_WORD_INTO_BOOLS` function block is a simple and efficient block for decomposing 16-bit words into individual bits. It is particularly suitable for applications where clear and direct bit extraction is required.

Functionality

Technical Features



State Overview

Application Scenarios

Conclusion

SPLIT_WORD_INTO_BYTES

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_WORD_INTO_BYTES` is used to split a 16-bit word (WORD) into its two 8-bit bytes. This is particularly useful when working with data that is transmitted as a WORD but needs to be processed byte by byte.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. When this event input is triggered, processing of the input value `IN` begins.

Event Outputs

- **CNF**: Signals the successful completion of processing. This event is triggered along with the two output bytes `BYTE_00` and `BYTE_01`.

Data Inputs

- **IN**: The 16-bit word (WORD) to be split into two bytes.

Data Outputs

- **BYTE_00**: The least significant byte (bits 0 to 7) of the input word `IN`.
- **BYTE_01**: The most significant byte (bits 8 to 15) of the input word `IN`.

Adapters

No adapters available.

Adapters ## Functionality

The function block extracts the two bytes from the input word `IN` and outputs them via the outputs `BYTE_00` (lower-order byte) and `BYTE_01` (higher-order byte). Extraction is performed by direct access to the bytes of the WORD data type (`IN.%B0` for the lower-order byte and `IN.%B1` for the higher-order byte).

Technical Features

- The function block is implemented in the ST (Structured Text) programming language.
- Processing occurs synchronously with the triggering of the `REQ` event.
- The bytes are output along with the `CNF` event.

State Overview

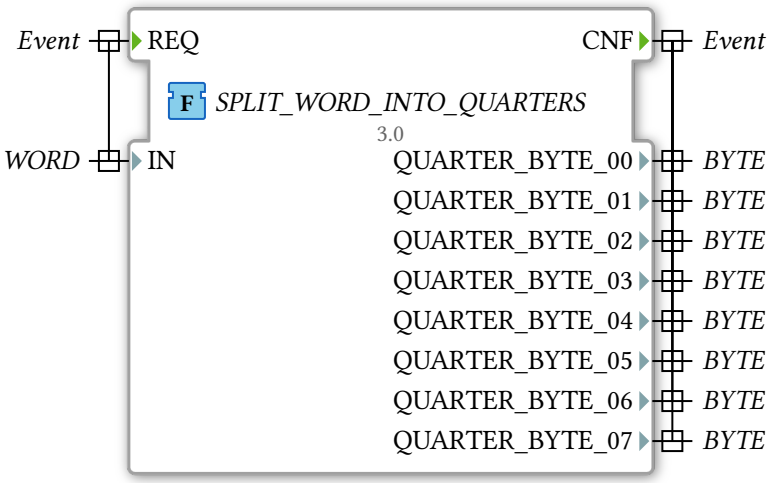
1. **Idle State**: Waiting for the `REQ` event.
2. **Processing State**: When `REQ` is triggered, the bytes are extracted.
3. **Output State**: The extracted bytes are output with the `CNF` event, and the block returns to the idle state.

Application Scenarios

- **Data Communication**: When processing network data transmitted as WORDs but requiring byte-by-byte interpretation.
- **Low-Hardware Programming**: When working with register contents read as WORDs but containing individual bytes.
- **Data Conversion**: When converting WORD data into two separate BYTE data for further processing.

⚖️ Comparison with Similar Building Blocks

- Compared to generic extraction functions, `SPLIT_WORD_INTO_BYTES` offers a specialized and optimized solution for splitting WORD data into bytes.
- Other building blocks might offer additional features such as sign handling or bit extraction, but are less efficient for this specific task.



Conclusion

The `SPLIT_WORD_INTO_BYTES` function block is a simple yet effective building block for splitting 16-bit words into their individual bytes. Its clear interface and efficient implementation make it ideal for applications requiring this functionality.

SPLIT_WORD_INTO_QUARTERS

🎧 Podcast

- QUARTER

• – ◦ • – ◦ • – ◦ •

Introduction

The function block SPLIT_WORD_INTO_QUARTERS is used to split a 16-bit word into eight 2-bit quarter bytes. This is particularly useful when processing compressed data or extracting specific bit patterns.

Interface Structure

Event Inputs

- REQ: Starts processing the input word. Linked to the data input IN.

Event Outputs

- CNF: Signals the completion of processing. It is linked to all eight quarter-byte outputs.

Data Inputs

- IN (WORD): The 16-bit input word, which is split into quarter bytes.

Data Outputs

- QUARTER_BYTE_00 to QUARTER_BYTE_07 (BYTE): The eight extracted 2-bit quarter bytes. Each output contains one of the quarter bytes of the input word.

Adapters

No adapters are available.

Operation

The function block uses bitmasks and shift operations to extract the individual 2-bit segments from the input word. Each quarter byte is isolated using a bitwise AND operation with a specific mask and then shifted to the corresponding position to be output as a byte.

Technical Features

- Uses constants (quarterconst::WORD_QUARTER_XX and quarterconst::SHIFT_QUARTER_XX) for the masks and shift positions.
- Extraction is performed by combining AND operations and right shifts.

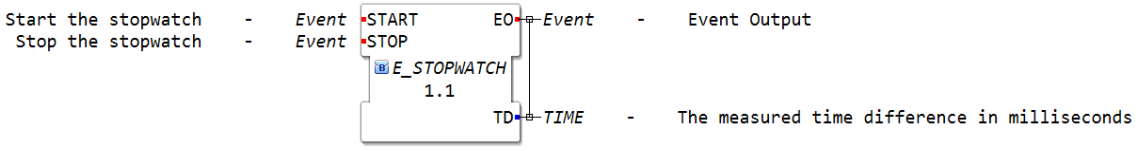
State Overview

1. **Idle**: Waits for the REQ event.
2. **Processing**: Extracts the quarter bytes from the input word.
3. **Completion**: Sends the CNF event and outputs the quarter bytes.

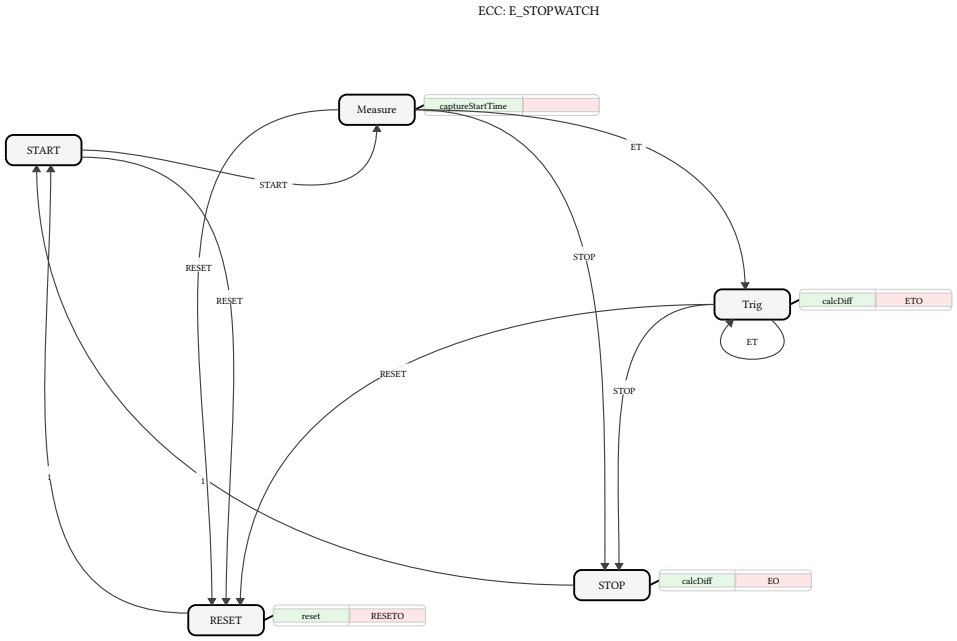
Application Scenarios

- Decoding compressed data.
- Extraction of control bits from a status word.
- Processing of coded sensor data.

⚖️ Comparison with similar function blocks



- **SPLIT_WORD_INTO_BYTES**: Splits a word into two bytes, not eight quarter-bytes.
- **BIT_EXTRACT**: Extracts individual bits or groups of bits, but is less specialized for quarter-bytes.

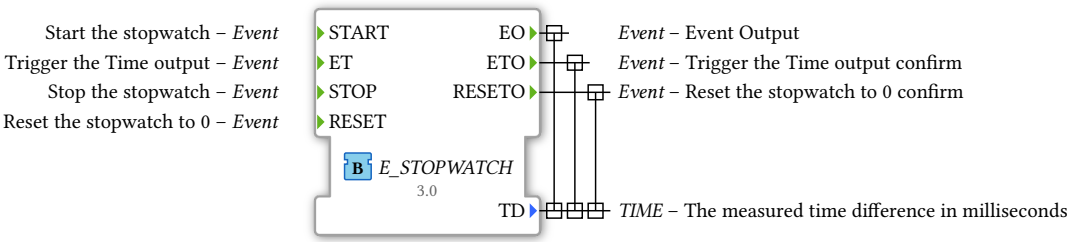


Conclusion

The SPLIT_WORD_INTO_QUARTERS function block is a specialized tool for efficiently extracting 2-bit data from a 16-bit word. Its clear interface and efficient implementation make it ideal for applications working with compressed or bit-coded data.

2.11.12.23 timing

E_STOPWATCH



• – ○ • – ○ • – ○ •

Introduction

The **E_STOPWATCH** function block is a high-precision timing module compliant with the IEC 61499-2 standard, developed under the EPL 2.0 license. The module enables millisecond-accurate timing measurements between events in real-time systems.

Interface Structure

Event Inputs

- `START`: Starts timing
- `ET`: Triggers intermediate output of the measured time
- `STOP`: Ends timing and outputs the result
- `RESET`: Resets the stopwatch

Event Outputs

- `EO`: Outputs time difference after STOP
- `ETO`: Outputs time difference after ET trigger
- `RESETO`: Confirms the reset operation

Data Outputs

Parameter	Type	Description	Accuracy
`TD`	TIME	Measured time difference	1 ms

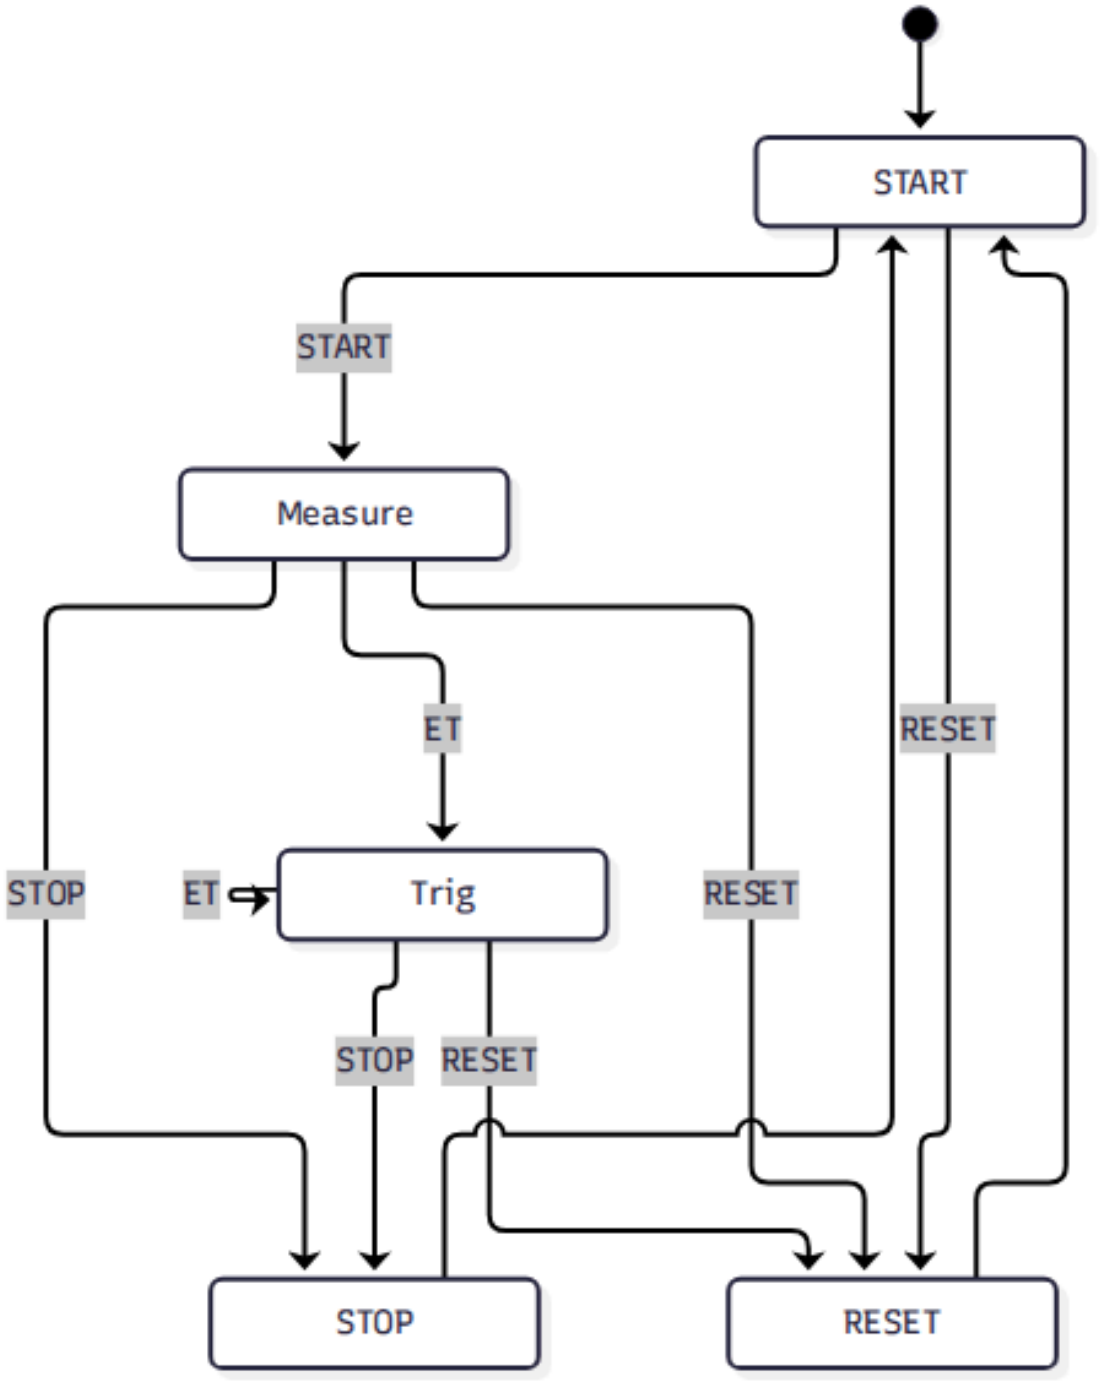
Functionality

1. **Start Phase**:

- `START` initializes the time measurement
- Monotone system time is recorded (`NOW_MONOTONIC`)

1. **Measurement Phase**:

- `ET` delivers intermediate results without stopping the measurement
- Multiple triggers are possible



1. **Closing Phase**:

- `STOP` ends the measurement and outputs the final result
- `RESET` resets all values

Technical Features

✓ IEC 61499-2 compliant ✓ Monotone time measurement (no system time adjustments) **✓ Millisecond accuracy ✓ Multiple triggers possible** during the measurement **✓ Eclipse 4diac integration** (Package: eclipse4diac::utils::timing)

State Machine (ECC)

Application Scenarios

- **Performance Measurement**: Algorithm Runtimes
- **Process Control**: Time-Critical Processes
- **System Diagnostics**: Response Times
- **Production**: Cycle Time Measurement

Example Values

Operation	Result (TD)
START -> STOP after 1.5s	T#1s500ms

START -> ET after 750ms -> STOP after 1.5s	T#750ms (ETO), T#1s500ms (EO)
RESET during measurement	T#0s

⚖️ Comparison with Similar Components

Feature	E_STOPWATCH	Standard Timer	High-Res Timer
Accuracy	1 ms	10 ms	1 µs
Trigger during run	Yes	No	Yes
Monotonous timer	Yes	No	Yes
Reset function	Yes	Partially	Yes

🛠️ Related Exercises

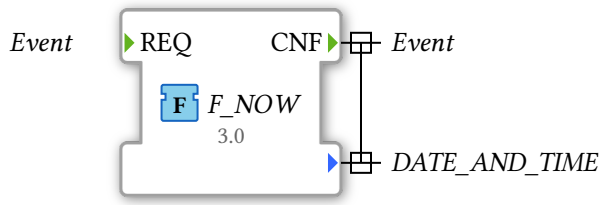
- Exercise_020i
- Exercise_020i_AX

Conclusion

The E_STOPWATCH module is the precise instrument for time measurements:

- **Reliable**: Monotonous time base prevents measurement errors
- **Flexible**: Intermediate outputs without interrupting the measurement
- **Simple**: Intuitive operation with Start/Stop/Reset

Ideal for:



- Performance optimizations
- Real-time systems
- Process analyses
- Benchmark tests

The precise stopwatch for industrial control systems

F_NOW

• – ◦ • – ◦ • – ◦ •

Introduction

The **F_NOW** function is an IEC 61499-1 compliant helper function for querying the current local date and time, developed under the EPL-2.0 license (version 3.0). The function serves as a wrapper for the ST function NOW().

Interface Structure

Event Inputs

- `REQ`: Triggers the time query

Event Outputs

- `CNF`: Acknowledges the time query

Data Outputs

Parameter	Type	Description	Format
(implicit)	DATE_AND_TIME	Current timestamp	DT#2025-04-14-15:30:45

Functionality

1. **Query**:

- `REQ` triggers the time query
- System time is captured in the local time zone

1. **Output**:

- `CNF` returns the result in DATE_AND_TIME format
- Contains date and time with second accuracy

Technical Features

✓ **IEC 61499-1 compliant** ✓ **Local time zone support** (including daylight saving time) ✓ **Easy integration** as a NOW() wrapper ✓ **Eclipse 4diac integration**

Application Scenarios

- **Logging**: Timestamps for events
- **Reports**: Generation with creation date
- **Time-controlled processes**: Current time check
- **Diagnostics**: Time-based error analysis

Example Values

Call time	Return value
14.04.2025 15:30:45	DT#2025-04-14-15:30:45
31.12.2024 23:59:59	DT#2024-12-31-23:59:59

⚖️ **Comparison with similar functions**

Feature	F_NOW	NOW	TIME()
Return type	DATE_AND_TIME	DATE_AND_TIME	TIME
Time zone	Local	Local	System
Accuracy	Seconds	Seconds	Milliseconds
Daylight Saving Time	Yes	Yes	No

Limitations

⚠️ **Time jumps possible** with:

- Daylight Saving Time
- Manual time adjustments
- NTP synchronization

Conclusion

The F_NOW function offers easy access to the system time:

- **Practical**: Quick integration of existing NOW functions
- **Localized**: Automatic time zone adjustment
- **Standards compliant**: IEC-compatible implementation

Ideal for:

- Event logging
- Time-controlled processes
- Diagnostic functions
- Report generation

The simple solution for time-critical applications in 4diac

F_NOW_MONOTONIC

• – ◦ • – ◦ • – ◦ •

Introduction

F_NOW_MONOTONIC is an IEC 61499-compliant function that returns a monotonic timestamp. Unlike the system time (NOW`), this time is independent of external changes (e.g., time zones or NTP updates) and is therefore ideally suited for time-critical control applications or performance measurements.

The function serves as a wrapper for the ST function `NOW_MONOTONIC()`.

Interface Structure

Event Inputs

- **REQ** (Trigger):

Starts the execution of the function. Upon receipt of this event, the current monotonic timestamp is calculated and output via `CNF`.

Event Outputs

- **CNF** (Acknowledgement):

Signals the completion of the operation. The event is output along with the calculated time value (`TIME`).

Data Inputs

- *None* – The function requires no additional input parameters.

Data Outputs

- **TIME** (Output Variable):

Return value of type `TIME`, representing the current value of the monotonic clock.

Example: `T#123456ms` (depending on the hardware/OS reference point).

Operation

1. **Initialization**:

The function is activated by the event `REQ`. Resources are not persistently stored, as this is a stateless computation.

1. **Macro Execution**:

- Calls the system-level function `NOW_MONOTONIC()`.
- Assigns the return value to the output variable `TIME`.

- Triggers the event `CNF`.

1. **Error Handling**:

- No specific error handling, as the function has no external dependencies.
- In case of hardware/OS errors, the return value is undefined.

–

Technical Features

- **Monotonic Time**:

Guaranteed continuously increasing values, even with system time changes.
Note: The reference point is hardware-dependent (e.g., system startup).

- **License**: Eclipse Public License 2.0 (EPL-2.0).

Return Codes

- **Success**: Valid `TIME` value (e.g., `T#42s`).
- **Error**: No explicit error codes, but undefined values in case of system errors.

–

Application Scenarios

1. **Real-time Measurements**: Runtime analysis of control cycles unaffected by system time changes.
2. **Synchronization**: Timestamps for logging in distributed systems.
3. **Timeout Control**:

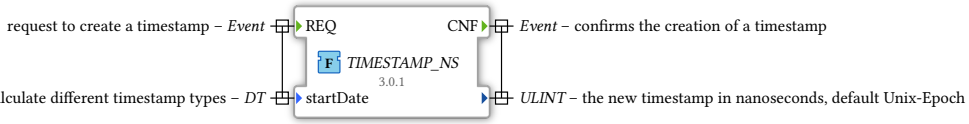
Reliable timers for critical processes.
–

⚖️ Comparison with Similar Function Blocks

Function	`F_NOW_MONOTONIC`	`NOW()`	`NOW_SYSTEM()`
Time Source	Monotonous (Hardware)	System Time	System Time (UTC)
Influenceable	No	Yes (NTP, Time Zone)	Yes (NTP)
Use Case	Real-time Measurements	General Timestamps	Global Timestamps

---

Conclusion



F_NOW_MONOTONIC` is a lean yet essential component for applications requiring a reliable and monotonous time source.
Its close connection to the hardware and its independence from system time changes make it particularly suitable for industrial real-time applications.
Integration with Eclipse 4diac ensures compatibility with modern automation solutions.
Note: For absolute time references, `NOW_SYSTEM()` should be used.

TIMESTAMP_NS

• – ◦ • – ◦ • – ◦ •

Introduction

The **TIMESTAMP_NS** is an IEC 61499-compliant function block for generating high-resolution timestamps in nanoseconds. By default, it generates Unix epoch timestamps (from January 1, 1970), but supports alternative time references by adjusting the start date (`startDate`).

Developed under the EPL 2.0 license.

–

Interface Structure

Event Inputs

- **REQ** (Trigger):

Starts the timestamp calculation. Must be linked to the input parameter `startDate`.
Example: `REQ(startDate := DT#2000-01-01-00:00:00)`

Event Outputs

- **CNF** (Acknowledgement):

Signals the completion of the calculation. The generated timestamp is then available as the value `ULINT`.

Data Inputs

- **startDate** (DT):

Start date for the timestamp calculation.
Default: `DT#1970-01-01-00:00:00` (Unix epoch).
Note: Other values allow user-defined references (e.g., system startup).

Data Outputs

- **ULINT** (Output Variable):

Timestamp in nanoseconds since the defined `startDate`.
Example: `1680000000000000000` (1.68e18 ns ≈ 2023-03-28).

Functionality

1. **Initialization**:

- Activated by the `REQ` event.
- Uses the current system time (`NOW()`).

1. **Calculation**:

- Subtracts `startDate` from the current system time.
- Converts the difference to nanoseconds via `TIME_IN_NS_TO_ULINT()`.
- Outputs the result as `ULINT` and triggers `CNF`.

1. **Error Handling**:

- No explicit error message, but overflow is possible in the case of:
- Extremely large time differences (>584 years).
- Invalid `startDate` (e.g., future date).

–

Technical Features

- **Nanosecond Precision**: 64-bit counter (`ULINT`) prevents overflow up to 584 years.
- **Flexible References**: Any starting date (e.g., `DT#2000-01-01` for Y2K reference).
- **License**: Eclipse Public License 2.0 (EPL-2.0).

–

Return Codes

- **Success**: Valid `ULINT` value (nanoseconds).
- **Errors**: No explicit codes, but:
- `0` for invalid calculations (e.g., `startDate > NOW()`).
- Overflow for differences >26 ns.

–

Application Scenarios

1. **High-Performance Logging**:

Synchronization of events in distributed systems.

1. **Real-Time Measurements**:

Runtime analysis with nanosecond precision.

1. **User-Defined Time Periods**:

Calculation of intervals from arbitrary reference points.

–

⚖️ Comparison with Similar Building Blocks

Function	`TIMESTAMP_NS`	`NOW()`	`F_NOW_MONOTONIC`
Output Format	Nanoseconds (ULINT)	Time Interval (TIME)	Time Interval (TIME)
Reference Point	Configurable	System Startup	Hardware Dependent
Precision	1 ns	1 ms	1 ns (typical)
Use Case	Absolute Timestamps	Relative Time Measurement	Monotonical Measurement

---

Conclusion

TIMESTAMP_NS` is an essential component for applications requiring highly precise and flexible timestamps. Its support for user-defined start dates and nanosecond precision makes it ideal for:

- **Industrial Data Recording**
- **Real-Time Controls**
- **Scientific Measurement Systems**

Note: For monotonous time measurements, `F_NOW_MONOTONIC` should be preferred.

2.12 ⚖️ Comparison with other standards

This section presents concepts and building blocks from other standards, particularly **IEC 61131-3**, to highlight differences and similarities with IEC 61499.

2.12.1 IEC 61131-3 (Old Standard)

This section describes function blocks according to the "classic" PLC standard **IEC 61131-3**. These blocks serve as a reference and basis for comparison with the IEC 61499 concepts. !!! Warning "Important Note" These function blocks comply with **IEC 61131-3**. Behaviors, particularly regarding execution and events, may differ in IEC 61499.

2.12.1.1 Timers

2.12.1.2 Bistable Elements (Flip-Flops)

2.12.1.3 RS (Bistable, Priority Reset) - IEC 61131-3

The function block **RS** is a bistable element (flip-flop) where resetting takes precedence over setting.

Interface

Type	Name	Data Type	Description
Input	S	BOOL	Set Input (Set)
Input	R1	BOOL	Reset Input (Reset)

Output	Q1	BOOL	Output State

Function

The behavior corresponds to **Table 43** (Standard Bistable Function Blocks) of the DIN EN 61131-3 standard.

The logic is described by the following truth table:

S	R1	Q1 (current)	Description
0	0	Q1 (old)	Hold state
0	1	0	Reset
1	0	1	Set
1	1	0	**Priority Reset**

Note: The initial state of the output variable `Q1` is `0` (FALSE) by default.

Logical Equation

According to the function block body in the standard (Table 43, 2a):

Q1 := NOT R1 AND (S OR Q1); If `R1` is TRUE, the expression `NOT R1` becomes FALSE, and thus `Q1` inevitably becomes `FALSE` (0), regardless of the state of `S`. This implements reset dominance.

See also

- E_RS (IEC 61499): The event-driven equivalent in IEC 61499. Note that there is no guaranteed "dominance" for concurrent events.

2.12.1.4 SR (Bistable, Set Priority) - IEC 61131-3

The function block **SR** is a bistable element (flip-flop) where setting takes precedence over resetting.

Interface

Type	Name	Data Type	Description
Input	S1	BOOL	Set Input
Input	R	BOOL	Reset Input
Output	Q1	BOOL	Output State

Function

The behavior corresponds to **Table 43** (Standard Bistable Function Blocks) of the DIN EN 61131-3 standard.

The logic is described by the following truth table:

S1	R	Q1 (current)	Description
0	0	Q1 (old)	Hold state
0	1	0	Reset
1	0	1	Set
1	1	1	**Priority Set**

Note: The initial state of the output variable `Q1` is `0` (FALSE) by default.

Logical Equation

In graphical representations (FBS), this is often depicted as an OR gate at the set input and a memory element, but logically, the state corresponds to:

Q1 := S1 OR (Q1 AND NOT R); *(Taking into account the dominance of S1 during simultaneous activation)*

More precisely according to the normative framework (Table 43, 1a):

(Table 43, 1a):

*(Table 43, 1a):```text Q1 := S1 OR (NOT R AND Q1); If `S1` is TRUE, then `Q1` is TRUE, regardless of whether `R` is true.

See also

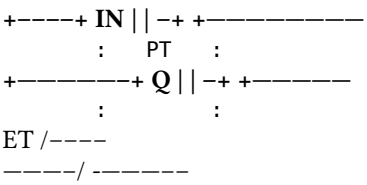
- E_SR (IEC 61499): The event-driven equivalent in IEC 61499. Note that there is no guaranteed "dominance" for concurrent events.

]

2.12.1.5 TOF (Timer Off-Delay) - IEC 61131-3

The function block **TOF** (Timer Off-Delay) implements a timer off. The output remains active for a defined period after the input signal ceases.

Interface



Type	Name	Data Type	Description
Input	IN	BOOL	Start Signal
Input	PT	TIME	Preset Time (Delay Time)
Output	Q	BOOL	Output Signal
Output	ET	TIME	Elapsed Time (Time Elapsed Since Falling Edge)

Function

The behavior corresponds to **Table 46** (Standard Function Blocks Timers) and **Figure 15 c)** (Turn-off Delay (TOF) Time Behavior) of the standard DIN EN 61131-3.

- **Activation:** When `IN` is `TRUE`, the output `Q` is immediately set to `TRUE`, and `ET` is held at 0.
- **Start Delay:** When `IN` transitions from `TRUE` to `FALSE` (falling edge), the time measurement `ET` starts. `Q` remains `TRUE`.
- **Process:** When `ET` reaches the value of `PT`, the output `Q` is set to `FALSE`.
- **Reset:** If `IN` becomes `TRUE` again before the time expires, `ET` is reset to 0, and `Q` remains `TRUE`.

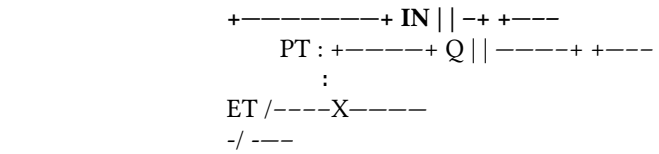
Time Diagram (Principle)

2.12.1.6 TON (On-Delay) - IEC 61131-3

The **TON** (Timer On-Delay) function block implements an on-delay. The output is only activated when the input signal is present for a defined period.

Interface

Type	Name	Data Type	Description
Input	IN	BOOL	Start Signal
Input	PT	TIME	Preset Time (Delay Time)
Output	Q	BOOL	Output Signal
Output	ET	TIME	Elapsed Time



Output

Function

The behavior corresponds to **Table 46** (Standard Function Blocks Timers) and **Figure 15 b)** (Turn-on Delay (TON) Time Behavior) of the standard DIN EN 61131-3.

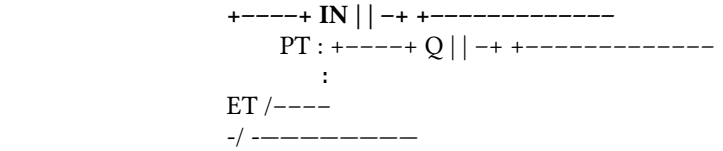
- **Start:** When `IN` equals `TRUE`, the time measurement begins at `ET`.
- **Sequence:** When `ET` reaches the value of `PT` and `IN` is still `TRUE`, the output `Q` is set to `TRUE`.
- **Hold:** `Q` remains `TRUE` as long as `IN` is `TRUE`.
- **Abort:** When `IN` changes to `FALSE` (before or after `PT` expires), `ET` is reset to 0 and `Q` becomes `FALSE`.

Time Diagram (Principle)

2.12.1.7 TP (Pulse) - IEC 61131-3

The **TP** (Timer Pulse) function block implements a pulse generator (monoflop). It generates an output pulse of defined duration.

Interface



Type	Name	Data Type	Description
Input	IN	BOOL	Start signal (rising edge triggers pulse)
Input	PT	TIME	Preset Time (pulse duration)
Output	Q	BOOL	Output signal
Output	ET	TIME	Elapsed Time (time elapsed since pulse start)

Function

The behavior corresponds to **Table 46** (Standard Function Blocks Timers) and **Figure 15 a)** (Pulse (TP) Timing Behavior) of the standard DIN EN 61131-3.

- **Start:** When `IN` changes from `FALSE` to `TRUE` (rising edge), the output `Q` is set to `TRUE` and the timing measurement `ET` starts.
- **Duration:** The output `Q` remains at `TRUE` for the duration `PT`, regardless of whether `IN` changes back to `FALSE` during that time.
- **Reset:** After the time `PT` has elapsed (i.e., `ET >= PT`), `Q` reverts to `FALSE`.
- **Re-Trigger:** The pulse is **not** retriggerable. Edges at the input `IN` during pulse output (as long as `ET < PT` and `Q = TRUE`) are ignored.
- **Initialization:** `ET` is reset when `IN` `FALSE` and the timer has expired or has not yet started.

Timing Diagram (Principle)

3.1 Fonts

3.1.1 TGL Normschrift – _std Font Variants

3.1.1.1 Overview

The `_std` variants of the TGL Normschrift fonts fix the **U+0023 (#)** glyph, which in the original fonts incorrectly contains a "m/m" (millimeters) symbol instead of the standard number sign / hash character.

This makes the fonts usable in contexts where a proper # is required (e.g. programming, technical documentation, IEC 61499 function block diagrams).

3.1.1.2 Fonts

File	Style	Based on
`TGL 0-16_std.ttf`	Italic (75° slant)	TGL 0-16
`TGL 0-17_std.ttf`	Upright	TGL 0-17
`TGL 0-17 alt_std.ttf`	Upright (alternate)	TGL 0-17 Alt

3.1.1.3 Changes

New glyph at U+0023 (#)

A number sign was designed from scratch to match each font's style:

- **Stroke width** matches the font (207–208 units)
- **Round stroke caps** using the same quadratic Bézier curve pattern as the original glyphs (I, l, hyphen)
- **Height** is approximately 2/3 of the capital letter height, consistent with typical number sign proportions
- **TGL 0-16_std** (italic): vertical strokes are slanted at 75° from the baseline, matching the font's standard lean angle per DIN/TGL specification for slanted Normschrift
- **TGL 0-17_std / TGL 0-17 alt_std** (upright): all strokes are perpendicular to each other
- The glyph is constructed as a single non-overlapping outer contour with one inner counter (hole), avoiding rendering artifacts from overlapping paths

Original m/m glyph preserved at U+E000

The original "m/m" symbol that previously occupied the # position has been moved to **U+E000** (Unicode Private Use Area) so it remains accessible if needed.

Internal font names

All internal name table entries (family name, full name, PostScript name, unique ID) have `_std` appended to avoid conflicts when both original and modified fonts are installed on the same system.

3.1.1.4 Technical Details

- Format: TrueType (.ttf)
- Units per em: 2048
- Modified using Python `fonttools` library
- No other glyphs were changed
- All original font metrics, hinting, and licensing information are preserved

3.1.1.5 License

The original TGL Normschrift fonts are Copyright (c) 2010 by Peter Wiegel, released under GPL with font exception and OFL (Open Font License). The `_std` modifications are distributed under the same terms.
