Conclusion

AUDI_TO_AULI` is a practical composite function block for lossless conversion from UDINT to ULINT at the adapter level. It is simple, easy to understand, and ideal for clean interface separation in modular systems.

AULI_TO_AUDI

ULINT Adapter Input – *AULI* — *AUDI* – UDINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block **AULI_TO_AUDI** is a composite block that converts an AULI adapter (ULINT data) to an AUDI adapter (UDINT data). It serves as a unidirectional bridge between two different adapter types and enables the seamless integration of components based on different integer widths.

Interface Structure

Event Inputs

The function block does not have separate event inputs. The required event is received via the socket adapter:

- **E1** (in socket `AULI_IN`): Starts the conversion of a ULINT value.

Event Outputs

There are no direct event outputs. The event is output via the plug adapter:

- **E1** (in plug `AUDI_OUT`): Signals the completion of the conversion and the provision of the UDINT value.

Data Inputs

Data is provided exclusively via the socket adapter:

- **D1** (in socket `AULI_IN`): UDINT input value (64-bit unsigned integer).

Data Outputs

Data is output via the plug adapter:

- **D1** (in plug `AUDI_OUT`): UDINT output value (32-bit unsigned integer).

Adapter

- **Socket AULI_IN**

Type: `adapter::types::unidirectional::AULI`
Receives the ULINT value to be converted and the associated event.

- **Plug AUDI_OUT**

Type: `adapter::types::unidirectional::AUDI`
Provides the converted ULINT value and the completion event.

Functionality

The function block contains an internal network with a single conversion block, `F_ULINT_TO_UDINT` (from the IEC 61131 library).

1. An incoming event **E1** from socket `AULI_IN` triggers the conversion block via its `REQ` event.
2. Simultaneously, the ULINT value from `AULI_IN.D1` is forwarded to the input `IN` of the converter.
3. The converter transforms the 64-bit value into a 32-bit value and outputs the result to its output `OUT`.
4. After successful conversion, the converter sends an acknowledgment event (`CNF`), which is forwarded as **E1** to the plug `AUDI_OUT`.
5. The converted ULINT value is output to `AUDI_OUT.D1`.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite FB**: The function block itself does not have its own logic but uses a standardized IEC 61131 converter.
- **Adapter Conversion**: Enables the connection of components based on different adapter definitions without requiring manual conversion by the user.
- **Unidirectional Data Flow**: Conversion is only performed in one direction (ULINT → UDINT); reverse conversion is not supported.
- **No Data Range Check**: Since UDINT only comprises 32 bits, higher-order bits are lost for ULINT values > $2^{32}-1$.

State Overview

The Composite FB does not have its own state machine. Its behavior is entirely determined by the internal conversion block `F_ULINT_TO_UDINT`, which typically implements a simple wait/process state. After starting (`REQ`), it performs the conversion and acknowledges it with `CNF`.

Application Scenarios

- **Adapter Bridges**: When a system provides an AULI adapter (e.g., for large counters or timestamps), but a downstream component expects an AUDI adapter (e.g., for smaller control values).
- **Protocol or Interface Adaptation**: In heterogeneous automation networks where different integer sizes are used.
- **Data Reduction**: When only the lower 32 bits of a 64-bit size are relevant (e.g., for certain sensor values).

Comparison with Similar Function Blocks

- **Direct Type Conversions** (e.g., `F_ULINT_TO_UDINT`): These operate at the data level without adapters. AULI_TO_AUDI encapsulates the conversion in an adapter-based interface, which facilitates the exchange between different adapter types.
- **Bidirectional Converters**: Function blocks for the reverse conversion (UDINT → ULINT) also exist. This function block (FB) is specialized for one direction.
- **Composite Adapter**: Other composite FBs can contain multiple conversions or additional logic (e.g., range checking) – here, the focus is on simplicity and reusability.

Conclusion

The AULI_TO_AUDI is a compact, specialized composite block that cleanly encapsulates the conversion of an AULI (ULINT) to an AUDI adapter (UDINT). Thanks to the integration of the standardized converter, it is reliable and easy to integrate into existing 4diac projects. It is ideally suited for scenarios where different adapter definitions meet and contributes to the modularity and reusability of function blocks.

AUDI_TO_AUS

UDINT Adapter Input – *AUDI*

AUS – USINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_TO_AUS** serves as a composite block for converting a UDINT value (via the AUDI adapter) into a USINT value (via the AUS adapter). It encapsulates the conversion and allows for easy integration of components that expect different data types.

Interface Structure

Event Inputs

- **AUDI_IN.E1** (event from the AUDI adapter) – initiates the conversion of the incoming data value.

Event Outputs

- **AUS_OUT.E1** (event to the AUS adapter) – signals the completion of the conversion and the availability of the result.

Data Inputs

- **AUDI_IN.D1** (UDINT from the AUDI adapter) – the 32-bit value to be converted.

Data Outputs

- **AUS_OUT.D1** (USINT to the AUS adapter) – the converted 8-bit value.

Adapters

- **AUDI_IN** (Socket) – adapter of type `adapter::types::unidirectional::AUDI` (UDINT source).
- **AUS_OUT** (Plug) – adapter of type `adapter::types::unidirectional::AUS` (USINT sink).

Functionality

The module is implemented as a simple pass-through. In the FBNetwork, the incoming event pulse (`AUDI_IN.E1`) is forwarded directly to the internal conversion block `F_UDINT_TO_USINT`. Simultaneously, the data value `AUDI_IN.D1` is transferred to the input `IN` of the converter. After successful conversion, the converter sends the confirmation event (`CNF`) to the output adapter (`AUS_OUT.E1`) and the result (`OUT`) to the data output (`AUS_OUT.D1`). No intermediate storage or further logic takes place.

Technical Features

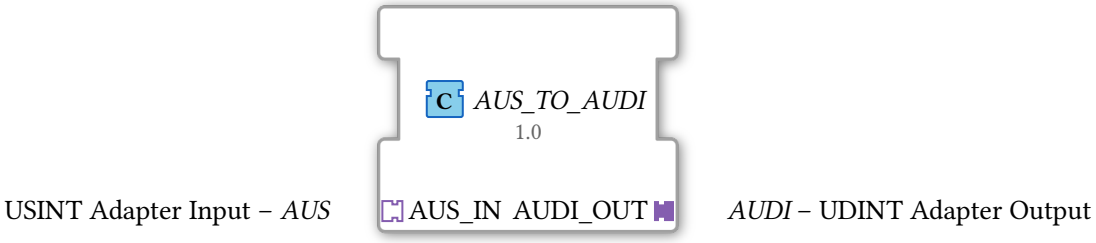
- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- Uses the standard conversion block `iec61131::conversion::F_UDINT_TO_USINT` from the IEC 61131 library.
- Pure event and data forwarding – no separate state machine required.
- The conversion is lossy: A UDINT (32-bit) is mapped to a USINT (8-bit), meaning higher-order bits are lost (values > 255 are truncated or handled according to the manufacturer's definition).

State Overview

The composite chip has no states of its own; it is entirely event-driven. The internal converter `F_UDINT_TO_USINT` operates according to the standard protocol (REQ/CNF). There are no additional locks or delays.

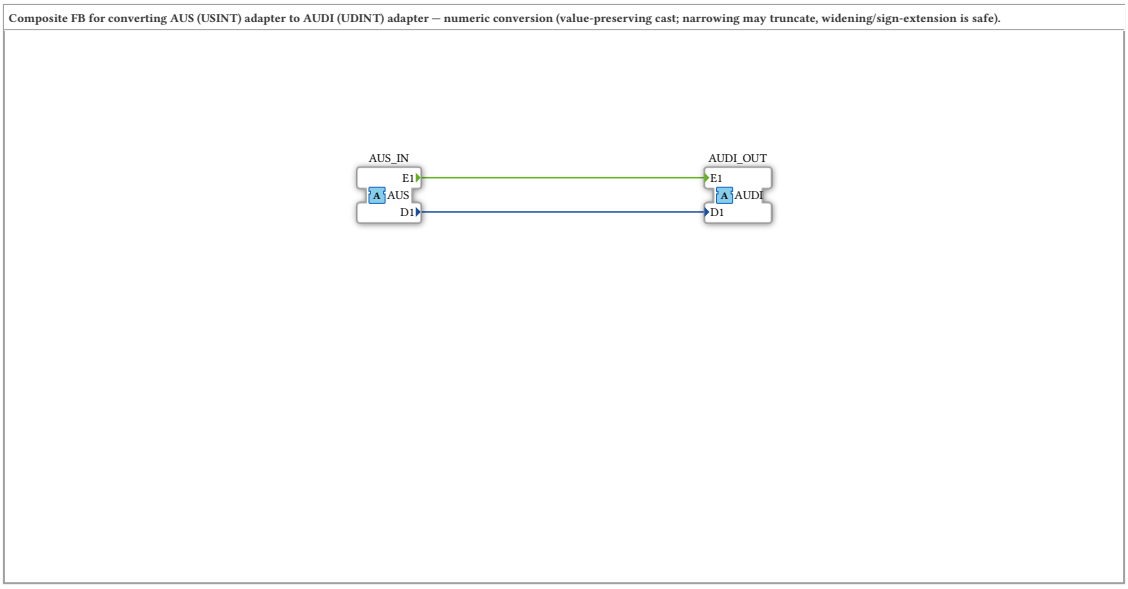
Application Scenarios

- Connecting a UDINT-based sensor to an actuator that only accepts a USINT value.
- Converting addresses or count values when only the lower-order part is needed.
- Interface adaptation in a mixed IEC 61499 environment where various data types are used.



Comparison with similar function blocks

- **AUDI_TO_AUDI** or **AUS_TO_AUS**: Would not perform any conversion, but only a simple forwarding.
- **F_UDINT_TO_USINT** (direct): This function block performs the same conversion, but does not offer an adapter interface. `AUDI_TO_AUS` encapsulates the adapter types and simplifies the network structure.
- If range checking or error handling is required, a separate function block would have to be created; this function block does not perform any plausibility checks.



Conclusion

AUDI_TO_AUS` is a simple yet useful strip-down function block for unidirectional UDINT-to-USINT conversion via adapters. It reduces complexity in the FB network by combining adapter coupling and conversion logic into a single block. Due to the lack of error handling, it is only suitable for applications where values > 255 do not occur or where their loss can be tolerated.

AUS_TO_AUDI

USINT Adapter Input – *AUS* *AUDI* – UDINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The composite function block **AUS_TO_AUDI** converts a unidirectional adapter of type **AUS** (based on USINT values) into an adapter of type **AUDI** (based on UDINT values). It is used to translate data between two different adapter interfaces without altering the underlying data logic. The block is implemented as a pure pass-through component, forwarding events and data directly from the input to the output side.

Interface Structure

Event Inputs

The block does not have its own event inputs. Events are provided via the connected **Socket Adapter** `AUS_IN`.

Event Outputs

This function block does not have its own event outputs. Events are passed on via the connected **Plug Adapter** `AUDI_OUT`.

Data Inputs

This function block does not have its own data inputs. Data is received via the **Socket Adapter** `AUS_IN`.

Data Outputs

This function block does not have its own data outputs. Data is output via the **Plug Adapter** `AUDI_OUT`.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AUS`	`AUS_IN`	Socket (Input)	Unidirectional adapter that provides data in USINT format (8 bits) and an event.
`adapter::types::unidirectional::AUDI`	`AUDI_OUT`	Plug (Output)	Unidirectional adapter that expects data in UDINT format (32 bits) and an event.

The internal network structure connects the event `E1` and the data value `D1` of the input adapter directly to the corresponding interfaces of the output adapter.

Functionality

This functional block operates as a simple pass-through. As soon as the event `E1` occurs at socket `AUS_IN`, it is immediately forwarded to plug `AUDI_OUT` as the event `E1`. Simultaneously, the data value `D1` (USINT) of the input adapter is transferred to the data value `D1` (UDINT) of the output adapter. A type conversion from USINT to UDINT occurs implicitly through the data connection (expansion from 8 bits to 32 bits). No validation or range check is performed.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-Based Interface**: The function block does not have traditional input/output variables, but uses only the standardized adapter types `AUS` and `AUDI` from the `adapter::types::unidirectional` package.
- **Simple Passthrough**: Event and data connections are implemented directly without additional logic.
- **Type Expansion**: Conversion from USINT (0–255) to UDINT (0–4294967295) is lossless, as the entire USINT value range can be mapped to the UDINT range.
- **No State Storage**: The function block is stateless; all processing occurs in the same execution instance.

State Overview

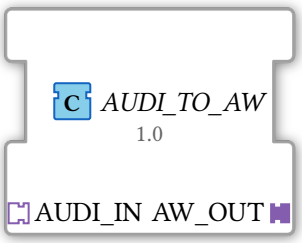
The function block does not have an internal state machine. The functionality is limited to a direct 1:1 connection between the input and output adapters. A state description is therefore not required.

Application Scenarios

- **Adapter Bridge**: Used in systems that utilize the AUS adapter (e.g., for simple byte values) but expect an AUDI interface (e.g., for 32-bit counters or addresses).
- **Protocol Conversion**: Used within composite function blocks to mediate between different adapter versions within a device family.
- **Data Preparation**: Prepares USINT data for function blocks that accept only UDINT inputs.

Comparison with Similar Function Blocks

- **INT_TO_DINT**: A standard function block for converting INTEGER types, but with independent input/output variables. `AUS_TO_AUDI`, on the other hand, operates at the adapter level and is optimized for integration into adapter-based architectures.
- **AUS_TO_AUDI (simple)**: Alternative implementations could include additional overflow checks or filter functions; this function block is limited to simple pass-through.



Conclusion

AUS_TO_AUDI` is a compact, specialized composite function block for lossless conversion between the unidirectional adapters OFF (USINT) and AUDI (UDINT). Thanks to the direct pass-through of events and data without additional logic, it is ideally suited as a building block in adapter-based control networks where simple type conversion at the communication layer is required.

AUDI_TO_AW

UDINT Adapter Input – *AUDI*

AW – WORD Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The **AUDI_TO_AW** function block is a composite function block for converting an **AUDI adapter** (UDINT) to an **AW adapter** (WORD). It serves as a unidirectional bridge between different data types and enables the seamless integration of components based on different adapter interfaces. The block encapsulates the conversion logic and is typically used in automation projects according to IEC 61499 that require the adaptation of data types between adapters.

Interface Structure

Event Inputs

Name	Type	Description
(via AUDI_IN.E1)	EVENT	Event that triggers the conversion (provided by the connected AUDI adapter)

Event Outputs

Name	Type	Description
(via AW_OUT.E1)	EVENT	Output event after successful conversion (provided by the AW adapter)

Data Inputs

Name	Type	Description
(via AUDI_IN.D1)	UDINT	32-bit unsigned integer to be converted (provided by the AUDI adapter)

Data Outputs

Name	Type	Description
(via AW_OUT.D1)	WORD	16-bit unsigned integer (result of the conversion, provided by the AW adapter)

Adapter

Name	Type	Direction	Description

AUDI_IN	adapter::types::unidirectional::AUDI	Socket (Input)	Receives the UDINT signal and its associated event
AW_OUT	adapter::types::unidirectional::AW	Plug (Output)	Passes on the converted WORD signal and its output event

Functionality

The function block operates as a **Composite FB** containing a single IEC 61131 conversion block `F_UDINT_TO_WORD`. Processing proceeds as follows:

1. The socket `AUDI_IN` receives an event at its event input `E1` and the corresponding data value `D1` (UDINT).
2. This event is internally forwarded to the `REQ` input of the conversion block, while the UDINT value is passed to the `IN` input.
3. The conversion block converts the UDINT value into a WORD and signals completion via its `CNF` output. 4. The `CNF` event is passed to the event output `E1` of plug `AW_OUT`, and the converted WORD is output to its data output `D1`.

The entire process is **event-driven** and takes place within a single execution step.

Technical Features

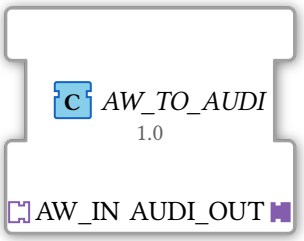
- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Unidirectional Data Flow**: The function block converts exclusively from AUDI (UDINT) to AW (WORD); reverse conversion is not supported.
- **Composite Architecture**: The internal logic is fully implemented by a single standard conversion block, making the function block easy to understand and maintain.
- **Use of IEC 61131 libraries**: The function block `F_UDINT_TO_WORD` is derived from the `iec61131::conversion` library, ensuring high portability and standards compliance.
- **No dedicated state machine**: The function block does not have an ECC (Execution Control Chart) and operates purely in a data flow-oriented manner.

State overview

The function block does **not have a state machine**. Processing is event-driven and deterministic according to the internal wiring. There are no internal states or latencies.

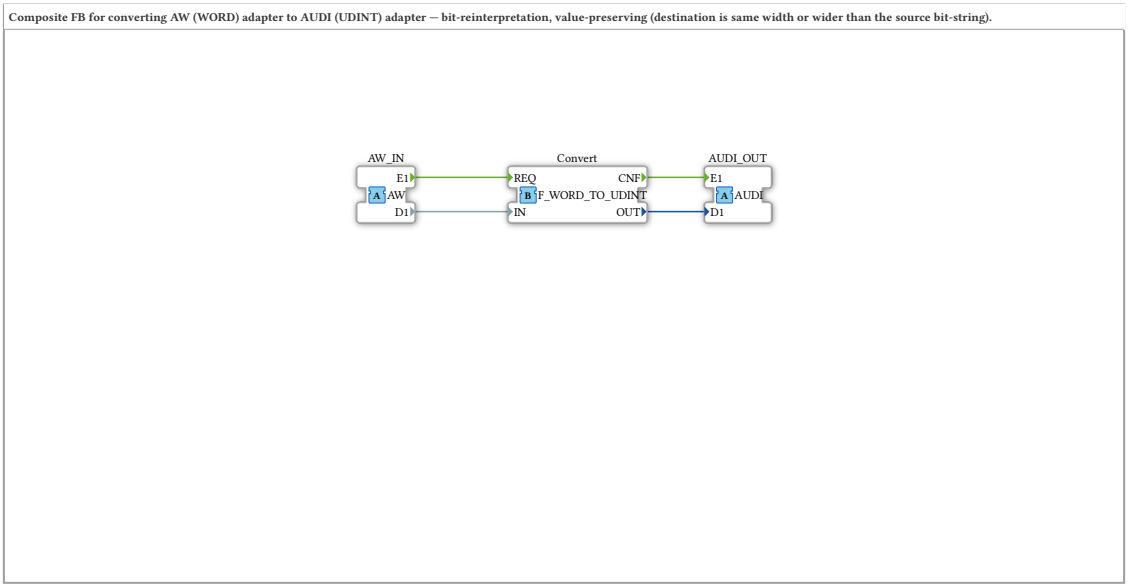
Application scenarios

- **Interface adaptation**: A system provides data via an AUDI adapter (UDINT), but a subsequent function block expects an AW adapter (WORD). The AUDI_TO_AW adapter converts the data without manual programming.
- **Data consolidation**: In a controller, multiple sensor data from different adapter types need to be combined. This function block serves as a conversion element.
- **Legacy Integration**: Older components based on UDINT are to be integrated into a modern WORD-based architecture.



Comparison with Similar Function Blocks

- **F_WORD_TO_UDINT** (analogous, but in reverse): Converts WORD to UDINT and expects an AW input and an AUDI output.
- **General Conversion Function Blocks** such as `F_UDINT_TO_DINT` or `F_UDINT_TO_REAL` offer similar functionality but work with different data types and without adapter connections.
- **Custom Adapter Converters** can be implemented by combining several conversion function blocks and adapters, but are less encapsulated than this composite function block.



Conclusion

The **AUDI_TO_AW** is a specialized but essential component for adapter-based communication in IEC 61499 systems. By using a standardized conversion block and encapsulating it in a composite function block, it offers a clean, reusable, and testable solution for converting UDINT to WORD data within a unidirectional adapter path.

AW_TO_AUDI

WORD Adapter Input – *AW* *AUDI* – UDINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AW_TO_AUDI` is a composite block that converts a data value received via a WORD adapter (`AW`) into a UDINT value and outputs it via a UDINT adapter (`AUDI`). The conversion is performed using the internally used block `F_WORD_TO_UDINT` from the IEC 61131 library. The function block encapsulates the adapter interfaces and enables a clean separation between different data formats within a system.

Interface Structure

Event Inputs

- **AW_IN.E1** (via socket `AW_IN`): Trigger for conversion. An incoming event starts the conversion of the current WORD value.
- **Custom Event Inputs**: None – the function block receives events exclusively via the adapter `AW_IN`.

Event Outputs

- **AUDI_OUT.E1** (via plug `AUDI_OUT`): Acknowledgement after successful conversion. The outgoing event signals that a new UDINT value is available at the data output.
- **Custom Event Outputs**: None – the function block forwards events exclusively via the adapter `AUDI_OUT`.

Data Inputs

- **AW_IN.D1** (via socket `AW_IN`): The WORD value to be converted (16-bit).
- **Custom Data Inputs**: None.

Data Outputs

- **AUDI_OUT.D1** (via plug `AUDI_OUT`): The converted UDINT value (32-bit, unsigned).
- **Custom Data Outputs**: None.

Adapters

- **Socket `AW_IN`**: Expects an instance of adapter type `adapter::types::unidirectional::AW`. This adapter provides the event and data interface for the WORD input.
- **Plug `AUDI_OUT`**: Provides an instance of the adapter type `adapter::types::unidirectional::AUDI`. This adapter provides the event- and data-side interface for the UDINT output.

Functionality

1. The function block waits for an event at **AW_IN.E1**.
2. Upon receiving the event, the current value of **AW_IN.D1** (WORD) is passed to the embedded function block `F_WORD_TO_UDINT`.
3. `F_WORD_TO_UDINT` performs the conversion and places the result (UDINT) at its output `OUT`.
4. Once the conversion is complete, an event is sent via `Convert.CNF` to **AUDI_OUT.E1**, and the converted value is output via **AUDI_OUT.D1**.

Data flow and event control are synchronous: Each incoming event generates exactly one outgoing event with the updated data value.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Composite Function Block**: The function block consists entirely of an internal network and has no state logic of its own.
- **Adapter Encapsulation**: All communication takes place via the standardized unidirectional adapters `AW` and `AUDI`. This allows the function block to be integrated into any system that supports these adapter interfaces.
- **Reuse**: The internally used conversion function `F_WORD_TO_UDINT` is part of the IEC 61131 library and ensures standards-compliant type conversion.
- **No Side Effects**: The function block (FB) does not perform any state changes or have any side effects outside of the actual conversion.

State Overview

The FB `AW_TO_AUDI` does not have its own state machine. Sequence control is implemented by the internal block `F_WORD_TO_UDINT`, which exhibits simple REQ/CNF behavior:

- **Wait** (before REQ): No event at `AW_IN.E1` ⟶ no action.
- **Processing** (after REQ, before CNF): The conversion is running; the output is not updated.
- **Finished** (according to CNF): A new value is received at `AUDI_OUT.D1`, and an event is sent to `AUDI_OUT.E1`.

The overall function block reflects this behavior externally.

Application Scenarios

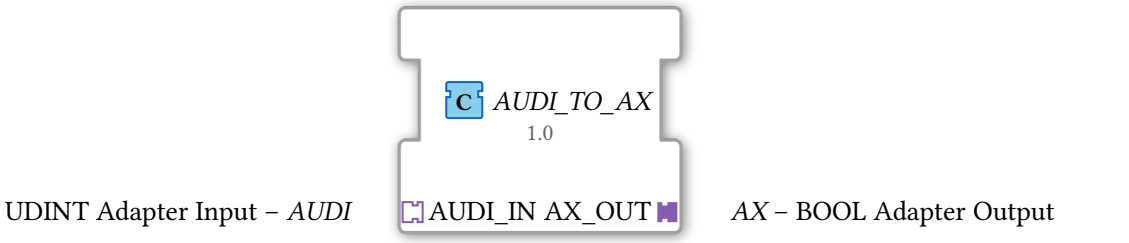
- **Integration of Subsystems with Different Data Types**: A sensor delivers its values as WORD (e.g., a 16-bit counter) via an AW adapter, while a control unit expects UDINT values (32-bit) via an AUDI adapter.
- **Interface Adaptation in Modular Automation Systems**: Use in a component that communicates via an adapter but requires the actual data conversion from WORD to UDINT.
- **Creation of Conversion Cascades**: Together with other modules that use, for example, DINT or REAL adapters, any data format adaptations can be created.

Comparison with Similar Modules

Module	Input Adapter	Output Adapter	Conversion	Note
`AW_TO_AUDI`	`AW` (WORD)	`AUDI` (UDINT)	WORD ⟶ UDINT	Composite, encapsulated `F_WORD_TO_UDINT`

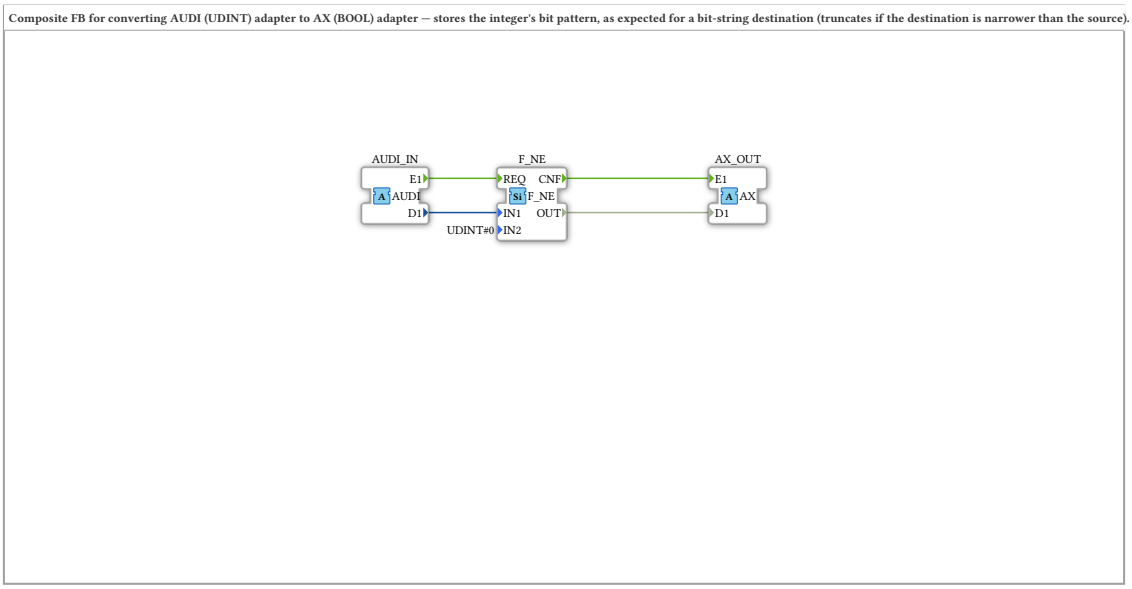
Direct use of `F_WORD_TO_UDINT`	No adapters	No adapter	WORD → UDINT	Standard Function Block without Adapter Interfaces
`AW_TO_ADINT` (hypothetical)	`AW` (WORD)	`ADINT` (DINT)	WORD → DINT	Signed Analog Conversion

The `AW_TO_AUDI` differs from directly using the conversion function by integrating adapters, making it immediately usable for adapter-based systems.



Conclusion

The `AW_TO_AUDI` function block offers a simple and clean way to convert between two unidirectional adapters of types WORD and UDINT. By encapsulating the IEC conversion function and clearly defining the interfaces, it increases reusability and facilitates integration into existing adapter architectures. It is ideal for applications where different data widths or formats need to be exchanged via standardized adapters.



Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AUDI_TO_AX

UDINT Adapter Input – *AUDI* *AX* – BOOL Adapter Output

• – ◦ • – ◦ • – ◦ •

The function block `AUDI_TO_AX` is a composite function block that converts an **AUDI** adapter (UDINT data) into an **AX** adapter (BOOL data). It serves as a unidirectional converter for applications where an integer value (e.g., from a counter) needs to be mapped to a binary signal – specifically, it checks whether the input value is non-zero. The function block is implemented as a pure network connection using IEC 61131-compliant components. The function block does not have its own event inputs. The event to start processing is provided via the socket adapter `AUDI_IN` (see section Adapters).

The FB has no built-in event outputs. The result event is output via the plug adapter `AX_OUT` (see section Adapters).

The FB has no built-in data inputs. The UDINT value to be processed is provided via the socket adapter `AUDI_IN` (see section Adapters).

The FB has no built-in data outputs. The result (BOOL) is output via the plug adapter `AX_OUT` (see section Adapters).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Name	Type	Adapter Type	Direction	Comment
AUDI_IN	adapter::types::unidirectional::AUDI	Socket	Input	Provides the UDINT value (D1) and the associated event (E1)
AX_OUT	adapter::types::unidirectional::AX	Plug	Output	Provides the BOOL value (D1) and the acknowledgment event (E1)

Functionality

The internal process is divided into three steps:

1. **Event Reception:** The event `E1` of the socket adapter `AUDI_IN` triggers the processing.
2. **Comparison:** The received UDINT value (`AUDI_IN.D1`) is compared in the function block `F_NE` (IEC 61131-3: *not equal*) with the constant value `UDINT#0`.
3. **Result Output:** The result of the comparison (`F_NE.OUT`) – a BOOL – is placed on the output data port `AX_OUT.D1`. Simultaneously, the event `F_NE.CNF` is forwarded to the event input `AX_OUT.E1`, so that the output adapter signals the result.
4. **Result Output:** The result of the comparison (`F_NE.OUT`) – a BOOL – is placed on the output data port `AX_OUT.D1`. **Context:**

- If the input value is not equal to 0 ⟶ Output `TRUE`
- If the input value is equal to 0 ⟶ Output `FALSE`
- **Library Used:** The core consists of the IEC 61131 function block `F_NE` (non-equal comparison). This is imported from the library `iec61131::comparison::F_NE`.
- **No Dedicated ECC:** As a composite function block, `AUDI_TO_AX` does not have its own execution state – the entire logic is purely data flow-driven.
- **Unidirectional Adapters:** Both the input and output adapters are designed as *unidirectional*, meaning they only support a defined data and event flow from the source to the sink.
- – **Parameterization:** The comparison value is fixed at `UDINT#0` and cannot be externally parameterized.

The function block (FB) does not have its own state machine. Its behavior is entirely determined by incoming events: Every event at socket `AUDI_IN.E1` triggers an execution of the internal logic and an output at plug `AX_OUT`.

- **Binary Threshold Output:** A counter value (e.g., number of parts detected) should be passed on to a downstream controller as a switching signal (`TRUE` if present, `FALSE` if zero).
- **Network Simplification:** The function block encapsulates the non-zero logic, thereby reducing the complexity of higher-level function plans.

- **`AUDI_TO_BOOL` (hypothetical):** Would offer the same functionality, but without the adapter concept – possibly with direct data inputs/outputs.
- **Direct Comparison `F_NE`:** A single function block that performs the comparison, but without adapter adaptation.

The advantage of `AUDI_TO_AX` lies in its seamless integration into an adapter-based architecture, as is common in the 4diac IDE. It avoids additional conversion steps between different interface types.

The `AUDI_TO_AX` function block is a specialized yet highly useful converter for the unidirectional transfer of a UDINT value to a BOOL signal. By clearly encapsulating the comparison logic and using standard adapters, it simplifies the signal chain in IEC 61499-based automation systems. It is robust, easy to understand, and requires no complex configuration – ideal for common tasks such as binary meter reading.

AX_TO_AUDI

BOOL Adapter Input – *AX* *AUDI* – UDINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The **AX_TO_AUDI** function block is a composite function block (FB) that converts a Boolean value (BOOL) provided via an AX adapter into an unsigned double-word value (UDINT) and outputs it via an AUDI adapter. It is used to convert signals between adapter interfaces, with the actual conversion performed by an internal IEC 61131 conversion block.

Interface Structure

Event Inputs

- **AX_IN.E1** (via socket adapter AX_IN): Event that triggers the conversion.

Event Outputs

- **AUDI_OUT.E1** (via plug adapter AUDI_OUT): Confirmation event after successful conversion.

Data Inputs

- **AX_IN.D1** (via socket adapter AX_IN, data type **BOOL**): The Boolean value to be converted.

Data Outputs

- **AUDI_OUT.D1** (via plug adapter AUDI_OUT, data type **UDINT**): The converted integer value (0 or 1).

Adapters

- **AX_IN** – Socket adapter of type `adapter::types::unidirectional::AX`

Accepts a Boolean value (and an associated event).

- **AUDI_OUT** – Plug adapter of type `adapter::types::unidirectional::AUDI`

Provides the converted UDINT value (and an acknowledgment event).

Functionality

The function block operates in an event-driven manner:

1. An event at the event input **AX_IN.E1** triggers the internal conversion block `F_BOOL_TO_UDINT` via its event input **REQ**.
2. The data value **AX_IN.D1** (BOOL) is forwarded to the data input **IN** of the conversion block.
3. The conversion block converts the Boolean value into a UDINT (FALSE ⟶ 0, TRUE ⟶ 1) and outputs the result at its output **OUT**.
4. The result is passed to the data output **AUDI_OUT.D1**.
5. After the conversion is complete, the acknowledgment event of the conversion block (**CNF**) is passed to the event output **AUDI_OUT.E1**.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Composite block (FB)** according to IEC 61499-2.
- Uses the internal FB `iec61131::conversion::F_BOOL_TO_UDINT` for the actual conversion.
- The adapter interfaces (`AX` and `AUDI`) enable modular and standardized integration with other blocks.
- The block is open source and licensed under the Eclipse Public License 2.0.

State Overview

The block does not have its own state machines. The behavior is entirely determined by the sequential processing of the internal conversion block:

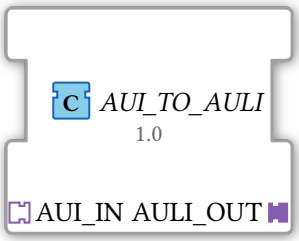
- **Idle**: Waiting for an event at **AX_IN.E1**.
- **Conversion active**: After receiving the event, the conversion is performed; no further events are processed during this time (single execution).
- **Completion**: The output event is sent, after which the block returns to the idle state.

Application Scenarios

- Conversion of a digital sensor signal (e.g., limit switch) into a numerical value for further processing in a PLC.
- Adaptation between different adapter interfaces in IEC 61499-based automation systems.
- Use in systems where only Boolean values are available via an AX interface, but a UDINT interface is required (e.g., for diagnostic or counting purposes).

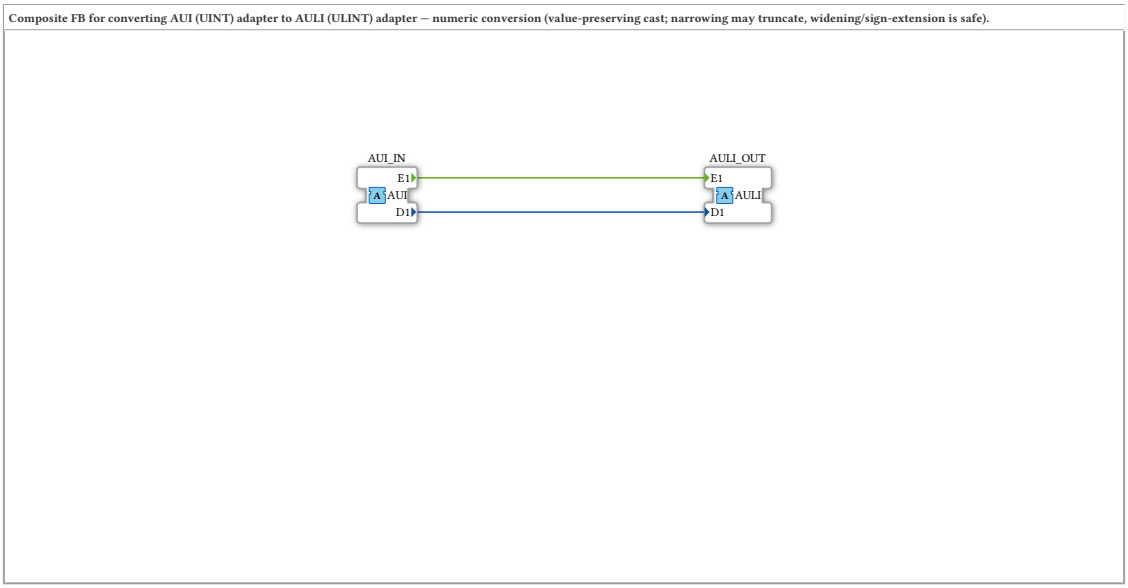
Comparison with Similar Function Blocks

- **F_BOOL_TO_UDINT** (direct): Performs the same conversion but requires separate event and data connections. **AX_TO_AUDI** encapsulates this logic in an adapter-based interface.
- AX_TO_ *function blocks**: Analogous to this function block, but with different target data types (e.g., INT, DINT). This function block is based on the UDINT variant.
- **Adapter coupler**: Pure pass-through function blocks without conversion – unlike **AX_TO_AUDI**, which performs an active type conversion.



Conclusion

The **AX_TO_AUDI** function block provides a simple yet useful bridge between Boolean and integer adapter interfaces. By encapsulating the conversion in a composite block, the design becomes clearer and reusability is increased. It is particularly suitable for standard conversion tasks in IEC 61499 projects that use modular adapter interfaces.



Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AUI_TO_AULI

UINT Adapter Input – *AUI* *AULI* – ULINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AUI_TO_AULI` is a composite function block for converting a unidirectional AUI adapter (data type `UINT`) into a unidirectional AULI adapter (data type `ULINT`). It serves as a simple type converter

between the two adapter interfaces, transparently passing on both the event signal and the data value. The function block enables seamless integration of components that use different addressing widths.

Interface Structure

The function block does not have its own event or data inputs/outputs, but uses only adapter interfaces. The following sections describe the signals that are routed externally via the adapters used.

Event Inputs

Signal	Description
(E1 via AUI_IN)	Event input of the connected AUI adapter (socket). An incoming event is forwarded directly to the AULI adapter.

Event Outputs

Signal	Description
(E1 via AULI_OUT)	Event output of the connected AULI adapter (plug). The event received from the AUI adapter is output here.

Data Inputs

Signal	Data Type	Description
(D1 via AUI_IN)	`UINT` (16 bits)	Data input of the AUI adapter. The incoming value is interpreted as a 16-bit integer.

Data Outputs

Signal	Data Type	Description
(D1 via AULI_OUT)	`ULINT` (64 bits)	Data output of the AULI adapter. The value received from the AUI adapter is output as a 64-bit unsigned integer.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AUI`	`AUI_IN`	Socket (Input)	Adapter for receiving events and data in the format `UINT`.
`adapter::types::unidirectional::AULI`	`AULI_OUT`	Plug (Output)	Adapter for sending events and data in the format `ULINT`.

Functionality

This function block forwards incoming events and data from the input adapter `AUI_IN` unchanged to the output adapter `AULI_OUT`. The data type `UINT` is implicitly converted to `ULINT` (the value remains the same; only the bit width is increased from 16 to 64 bits). The connection is established in the FB network of the composite module by directly wiring the respective event and data channels (`E1` and `D1`). No additional logic or state storage is performed.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Implicit Type Conversion:** The conversion from `UINT` to `ULINT` is performed automatically by the 4diac IDE and does not require an explicit conversion module. The value range from 0 to 65535 (UINT) is mapped to the corresponding ULINT range.
- **Implicit Type Conversion:** - **Pass-Through Behavior:** Events and data are transmitted without delay or buffering. The output event occurs simultaneously with the input event.

- **Unidirectional Adapters:** The module supports only one direction of data flow (from the AUI input to the AULI output). Reverse communication is not supported.

State Overview

The module does not have its own states, as it consists exclusively of direct connections. The behavior is purely combinatorial: An event at the input immediately generates an event at the output, and the data value is transmitted continuously.

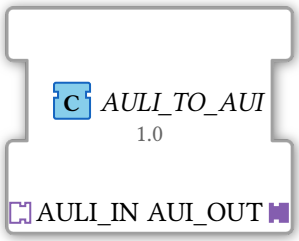
Application Scenarios

- **Systems with Mixed Address Width:** When a sensor or component delivers data in the format `UINT` (e.g., a 16-bit counter value), but a downstream controller or bus interface only accepts `ULINT` (64-bit).
- **Adapter Coupling:** Used as an intermediary between two different adapter types in a modular control architecture based on the 61499 standard.
- **Prototype Development:** Rapid integration of library blocks that use different adapter interfaces without manual conversion.

Comparison with Similar Blocks

- **INT_TO_LINT / UINT_TO_ULINT (Direct Data Converters):** These blocks operate on pure data levels without event forwarding and require separate event processing. `AUI_TO_AULI` combines event and data conversion in a single adapter interface.
- **Adapter-Adapter Connector:** Other composite blocks that connect two similar adapters (e.g., AUI_TO_AUI) – they differ only in the absence of type conversion.
- **Explicit Multi-Channel Conversion Blocks:** More complex blocks that convert multiple signals simultaneously are overkill for simple point-to-point connections like this one.

Conclusion



AUI_TO_AULIis a lean, specialized composite block for converting an AUI adapter to an AULI adapter. It simplifies type conversion between 16-bit and 64-bit addressing in IEC 61499 systems by automatically converting and forwarding both event and data paths. Thanks to the implicit type conversion fromUINTtoULINT`, manual implementation of conversion logic is eliminated, facilitating the design of modular and reusable control applications.

AULI_TO_AUI

ULINT Adapter Input – *AULI*

AUI – UINT Adapter Output

• — ○ • — ○ • — ○ •

Introduction

The function block **AULI_TO_AUI** is a composite function block (FB) that converts an **AULI** adapter (based on the data type `ULINT`) into an **AUI** adapter (based on the data type `UINT`). It is used when a 64-bit unsigned integer interface (`ULINT`) needs to be mapped to a 16-bit unsigned integer interface (`UINT`), for example, when connecting different sensor or actuator components in automation technology.

Interface Structure

Event Inputs

An event of type `AULI_IN` is provided via the adapter socket. This is forwarded internally to the conversion module.

Event Outputs

An event of type `AUI_OUT` is output via the adapter plug as soon as the conversion is complete.

Data Inputs

A data value of type `D1` (corresponding to `ULINT`) is received via the adapter socket `AULI_IN`.

Data Outputs

The adapter plug `AUI_OUT` outputs a data value of type `D1` (equivalent to `UINT`).

Adapter

Name	Direction	Type
AULI_IN	Socket	`adapter::types::unidirectional::AULI`
AUI_OUT	Plug	`adapter::types::unidirectional::AUI`

Functionality

The function block operates in an event-driven manner:

1. An event at input `AULI_IN.E1` triggers the internal function block `F_ULINT_TO_UINT` via its input `REQ`.
2. The data value `AULI_IN.D1` is directly passed to the conversion block as input `IN`.
3. The conversion block converts the `ULINT` value into a `UINT` value.
4. After the conversion is complete, the output `CNF` of the conversion block signals an event, which is then forwarded to the output `AUI_OUT.E1`.
5. Simultaneously, the converted value is transferred from the `OUT` output of the conversion module to the `AUI_OUT.D1` output.

The conversion is performed according to IEC 61131 standard `F_ULINT_TO_UINT`. Values greater than `65535` (maximum `UINT` value) may result in an overflow, which must be handled by the application.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Adapter-Based Encapsulation**: The module allows for the seamless replacement of adapters in the 4diac IDE without changing the logic of the surrounding network.
- **Reuse of IEC standard conversion**: The actual type conversion is performed by the standardized IEC function block `F_ULINT_TO_UINT`, ensuring portability and correctness.
- **No state storage**: The function block is purely combinatorial – after each execution, the current result is available at the output.

State overview

The function block does not have its own finite state machine. The internal conversion is event-driven and without internal states. The runtime is determined solely by the underlying `F_ULINT_TO_UINT` function block.

Application scenarios

- **Sensor integration**: A 64-bit sensor (e.g., high-resolution displacement measurement) is connected to a controller that only accepts 16-bit inputs.
- **Communication Gateway**: Adapter interfaces between bus systems (e.g., CANopen with 64-bit data to PROFINET I device with 16-bit data).
- **Data Reduction**: Targeted reduction of the resolution for subsequent processing steps (e.g., display or simple threshold logic).

Comparison with similar components

Component	Input type	Output type	Special feature
`AULI_TO_AUI`	`ULINT`	`UINT`	Adapter Wrapper, Event-Driven
`F_ULINT_TO_UINT`	`ULINT`	`UINT`	Pure Function, No Adapter
`AUI_TO_AULI`	`UINT`	`ULINT`	Reverse Direction (Not Available)

Unlike a bare IEC function, this block offers an adapter-compliant input and output interface, thus enabling easy integration into adapter-based architectures.

Conclusion

The **AULI_TO_AUI** block is a practical solution for mapping 64-bit UINT data to 16-bit UINT data using a standardized adapter mechanism. It combines the robustness of IEC conversion functionality with the flexibility of 4diac adapters and is particularly well-suited for heterogeneous automation systems where different data types interact.

AUI_TO_AUS

UINT Adapter Input – *AUI*

AUS – USINT Adapter Output

• – ○ • – ○ • – ○ •

The function block **AUI_TO_AUS** serves as a composite module for converting an AUI adapter (data type UINT) into an AUS adapter (data type USINT). It is typically used to mediate between different adapter types in the 4diac IDE when a reduction in the value range or a type conversion is required. The module encapsulates the conversion logic and enables seamless integration into existing runtime environments.

No separate event inputs. Event control is handled via the connected adapters.
No separate event outputs. Event propagation is handled via the connected adapters.
No separate data inputs. Data input is via the connected adapters.
No separate data outputs. Data output is via the connected adapters.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Direction	Name	Type	Description
Socket	**AUI_IN**	adapter::types::unidirectional::AUI	UINT input adapter (source)
Plug	**AUS_OUT**	adapter::types::unidirectional::AUS	USINT output adapter (destination)

The socket `AUI_IN` accepts the UINT value (16-bit unsigned) and the corresponding event signal. The plug `AUS_OUT` outputs the converted USINT value (8 unsigned bits) along with the corresponding event.

Functionality

The function block operates as a simple pass-through element with type conversion:

1. **Event Reception**: An incoming event at socket `AUI_IN.E1` triggers processing.
2. **Data Acquisition**: The corresponding data value `AUI_IN.D1` (type UINT) is read.
3. **Conversion**: Internally, the function `F_UINT_TO_USINT` from the IEC 61131 library is called. This function converts the UINT value into a USINT value. If the USINT value range (0…255) is exceeded, the value is truncated or handled according to the underlying implementation (usually capped at 255).
4. **Output**: The converted value is made available on `AUS_OUT.D1` (type USINT), and the output event `AUS_OUT.E1` is sent.

All coupling occurs via the event and data connections in the FB network of the composite block.

- **Range Limitation**: Converting UINT (0…65535) to USINT (0…255) inevitably results in information loss if the input value is greater than 255. Users must ensure that the input value range meets expectations.
- **No State Storage**: The FB is stateless – all processing occurs independently of previous conversions.
- **Reusability**: The function block is designed as an encapsulated component and can be used in different projects without having to reimplement the conversion logic.
- **Compatibility**: The availability of the library `iec61131::conversion::F_UINT_TO_USINT` is required.

The function block does not have an explicit state machine. However, the internal process can be described as two-step:

- **Ready (Idle)**: The function block waits for an incoming event at the socket.
- **Processing (Convert)**: After the event is received, the conversion is performed and the output event is triggered. The function block then immediately returns to the ready state.

A detailed state graph is not required, as the function block does not have any delays or multi-stage steps.

- **Sensor Connection**: A sensor delivers values in UINT format that must be passed to subsequent logic with a USINT request.
- **Device Coupling**: Seamless communication is established between two devices or components that use different adapter types.
- **Data Reduction**: In cases where the higher resolution of a UINT is not required, conversion to USINT can offer storage and bandwidth advantages.
- **System Migration**: When switching from older to newer adapter protocols, this function block can serve as a temporary or permanent bridge.

Other conversion function blocks exist in the 4diac library, e.g., `F_UINT_TO_USINT`, which directly maps a UINT input to a USINT output. The **AUI_TO_AUS** described here differs in that it uses adapters (AUI and AUS) instead of basic data inputs. This allows it to encapsulate the entire interface, including event control, simplifying its use in complex, adapter-based architectures. A pure function block like `F_UINT_TO_USINT`, on the other hand, requires separate event and data connections.

The **AUI_TO_AUS** is a compact and focused function block for adapter-based conversion from UINT to USINT. Its composite structure facilitates integration into existing 4diac projects, reduces wiring effort, and improves clarity. Its simple functionality and clear interface make it a useful tool for all applications requiring type conversion at the adapter level.

AUS_TO_AUI

• – ○ • – ○ • – ○ •

Introduction

The **AUS_TO_AUI** function block is a composite component that performs an interface conversion from an AUS adapter (USINT data type) to an AUI adapter (UINT data type). It serves as a simple passthrough, where both the event and the data value are transferred directly from the input to the output adapter. The implicit type conversion from USINT (8-bit unsigned) to UINT (16-bit unsigned) is performed automatically by the runtime environment.

Interface Structure

Event Inputs

Name	Data Type	Description
E1	Event	Event input of the AUS adapter; passed unchanged to the output.

Event Outputs

Name	Data Type	Description

E1	Event	Event output of the AUI adapter; receives the event from the input.

Data Inputs

Name	Data Type	Description
D1	USINT	Data value (8-bit) from the AUS adapter; converted to UINT and passed on.

Data Outputs

Name	Data Type	Description
D1	UINT	Data value (16-bit) of the AUI adapter; contains the converted USINT value.

Adapter

Type	Name	Direction	Description
adapter::types::unidirectional::AUS	AUS_IN	Socket (Input)	Out adapter with USINT data and one event.
adapter::types::unidirectional::AUI	AUI_OUT	Plug (Output)	AUI adapter with UINT data and one event.

Functionality

The function block operates as a simple passthrough:

- An incoming event at `AUS_IN.E1` is passed directly to `AUI_OUT.E1`.
- The incoming data value from `AUS_IN.D1` (USINT) is passed to `AUI_OUT.D1` without any additional logic. The type conversion from USINT to UINT is performed automatically by the 4diac IDE or the target platform.

There are no internal function blocks or algorithms that manipulate the signal.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Function Block**: It does not contain its own function block instances, but simply connects the adapter ports directly.
- **Implicit Type Conversion**: The conversion from USINT to UINT is not explicitly implemented in the function block, but is supported by the runtime system. The 8-bit value is transferred to the less significant part of the 16-bit word.
- **Unidirectional Adapters**: Both AUS and AUI are defined as unidirectional adapters, meaning data flows are only intended to occur in one direction.

State Overview

The function block has no states of its own, as it contains no internal logic or state machines. It reacts exclusively to input events and forwards them immediately.

Application Scenarios

- **System Integration**: When a control system (e.g., field devices) delivers data in USINT format, but a downstream module expects UINT.
- **Adapter Switching**: In a PLC or distributed control environment, standard adapters of different types can be coupled using such a conversion function block.
- **Prototyping**: Rapid adaptation of interfaces during the development phase without changing the underlying adapters.

Comparison with Similar Function Blocks

- **INT_TO_UINT**: Converts an integer data type to an unsigned integer – also available as a composite or basic function block.
- **AUS_TO_AUI** is specifically designed for the adapter types AUS (USINT) and AUI (UINT). Other function blocks, such as `SINT_TO_USINT`, use analogous passthroughs for other data types.
- Unlike function blocks with arithmetic or logical processing, this function block is limited to pure conversion and event forwarding.

Conclusion

The **AUS_TO_AUI** function block is a streamlined tool for adapting adapter interfaces between USINT and UINT. Its simple passthrough structure makes it performant and easy to understand. It is particularly suitable for integration tasks where existing components with different data widths need to be connected. Due to the lack of internal logic, it is robust and requires no parameterization.

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AUI_TO_AW

UINT Adapter Input – *AUI*

AW – WORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block `AUI_TO_AW` is a composite module that converts an AUI adapter (data type UINT) into an AW adapter (data type WORD). It encapsulates the type conversion and provides it as a standardized adapter interface, enabling seamless integration of system components with different data types.

Interface Structure

Event Inputs

Name	Type	Comment
AUI_IN.E1	Event (via adapter)	Trigger to convert the incoming UINT value

Event Outputs

Name	Type	Comment
AW_OUT.E1	Event (via adapter)	Confirmation that the converted WORD value has been provided

Data Inputs

Name	Data Type	Comment
AUI_IN.D1	UINT (via adapter)	The input value to be converted

Data Outputs

Name	Data Type	Comment
AW_OUT.D1	WORD (via adapter)	Converted Output Value

Adapter

Direction	Name	Type	Comment
Socket (Input)	AUI_IN	adapter::types::unidirectional::AUI	UINT adapter as source
Plug (Output)	AW_OUT	adapter::types::unidirectional::AW	WORD adapter as sink

Functionality

This function block responds to an event on socket AUI_IN.E1. The current value of AUI_IN.D1 (data type UINT) is then forwarded to the internal conversion block F_UINT_TO_WORD. This block converts the value to the WORD data type according to IEC 61131. Once the conversion is complete, the result is passed to the plug AW_OUT.D1, and an acknowledgment event is triggered on AW_OUT.E1.

The interaction of event and data flow ensures secure and deterministic data transmission.

Technical Features

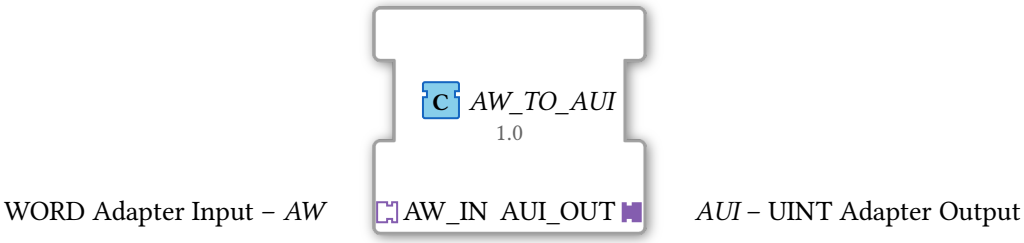
- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Structure:** The block encapsulates the complete conversion logic in a single function block, eliminating the need for any further conversion steps in the application.
- **Type Conversion:** Conversion is performed using the standardized IEC 61131 function block F_UINT_TO_WORD. UINT and WORD are bit-compatible, so no data loss occurs.
- **Adapter Interface:** The use of adapters enables loose coupling of the components. The function block can be directly integrated into adapter-based networks.
- **No States:** The function block has no state behavior (ECC). It operates purely event-driven and performs an immediate conversion upon each trigger.

State Overview

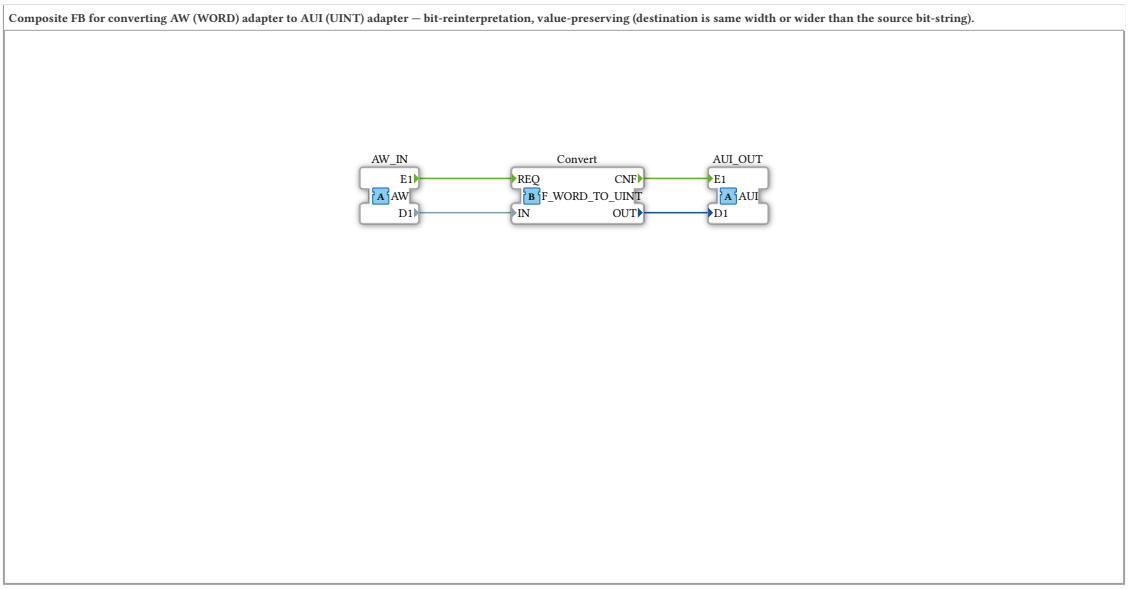
The function block does not contain its own state machine (ECC). Sequence control is handled solely through the event connections in the composite network. After startup, the function block is immediately ready to process incoming events and perform the conversion.

Application Scenarios

- **Adapter Bridge:** If one system component communicates only via an AUI adapter (UINT), but another component expects an AW adapter (WORD), `AUI_TO_AW` can be used as an intermediary.
- **Data Type Adaptation:** In Industry 4.0 or IIoT environments where devices use different data types, this component harmonizes the interfaces.
- **Modular Chaining:** The component can be easily inserted into a chain of adapters to ensure compatibility between components.



Comparison with Similar Components



- **Direct Use of `F_UINT_TO_WORD`:** Instead of the composite component, `F_UINT_TO_WORD` could be used directly, and the adapters connected separately. The composite block simplifies cabling and increases reusability.
- **Analog converters (e.g., `AWORD_TO_AUINT`):** Corresponding modules exist for the reverse direction. `AUI_TO_AW` focuses specifically on the conversion from UINT to WORD and offers a clearly named, targeted solution.

Conclusion

The `AUI_TO_AW` function block provides a compact and robust solution for converting a UINT adapter signal to a WORD adapter signal. By encapsulating the standard conversion and using the adapter interface, integration into existing systems is facilitated, and network readability is improved. The module is ideally suited to reconcile data type differences between components without compromising application clarity.

AW_TO_AUI

• – ○ • – ○ • – ○ •

Introduction

The function block **AW_TO_AUI** is a composite function block (FB) that converts an **AW (WORD)** adapter into an **AUI (UINT)** adapter. It enables the seamless integration of components that use different

data types via unidirectional adapters. Internally, it uses the standard conversion block `F_WORD_TO_UINT` for type conversion.

Interface Structure

Event Inputs
The FB does not have its own independent event inputs. The event `E1` is provided via the **socket (input adapter) `AW_IN`** and triggers the data conversion.

Event Outputs
The FB does not have any standalone event outputs. The event `E1` is output via the **plug (output adapter) `AUI_OUT`** after successful conversion.

Data Inputs
The FB does not have any standalone data inputs. The date `D1` of type `WORD` is provided via the **socket `AW_IN`**.

Data Outputs
The FB does not have any standalone data outputs. The date `D1` of type `UINT` is output via the **plug `AUI_OUT`**.

Adapter

Name	Direction	Type	Description
`AW_IN`	Input	`adapter::types::unidirectional::AW`	WORD Adapter Input (Socket)
`AUI_OUT`	Output	`adapter::types::unidirectional::AUI`	UINT Adapter Output (Plug)

Functionality
This function block acts as a conversion layer between two different adapter types. Internally, a single function block, `F_WORD_TO_UINT`, is embedded:

1. **Event Control**:

- An incoming event at socket `AW_IN.E1` triggers the conversion process (`Convert.REQ`).
- After the conversion is complete, the internal block generates an acknowledgment event (`Convert.CNF`), which is forwarded to plug `AUI_OUT.E1`.

1. **Data Flow**:

- The value `WORD`, provided by socket `AW_IN.D1`, is passed to input `Convert.IN`.
- The output `Convert.OUT` returns the converted `UINT` value, which is then passed to the plug `AUI_OUT.D1`.

The conversion is performed according to the IEC 61131-3 standard conversion `WORD_TO_UINT`.

Technical Features
- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Pure Composite Structure**: The function block (FB) does not have its own state machine or logic, but delegates all functionality to the embedded standard function block.
- **Unidirectional Adapters**: Both the input and output adapters are designed as unidirectional types, enabling simple and directional data transfer.
- **Reusability**: The function block can be used in projects where interface adaptation between WORD- and UINT-based components is required.

State Overview
Since this is a composite function block without its own state machine, there are no internal states. The function block behaves strictly event-driven: Every input event is followed—after conversion is complete—by an output event.

Application Scenarios

- **System Integration**: Connecting a component that provides data as `WORD` via an AW adapter to another component that expects `UINT` via an AUI adapter.
- **Protocol Adaptation**: Use in middleware or gateway functions to harmonize different data formats within a control architecture.
- **Modular Extension**: Easy integration into existing 4diac networks without requiring changes to adjacent function blocks.

Comparison with Similar Modules

Other conversion modules (e.g., `F_WORD_TO_DWORD` or `F_INT_TO_UINT`) operate directly on data ports. In contrast, `AW_TO_AUI` is specifically designed for adapter-based communication and encapsulates both the type conversion and the adapter logic in a single unit. This simplifies the handling of adapter interfaces and keeps network design clear.

Conclusion

The `AW_TO_AUI` function block offers a compact and reliable solution for adapter conversion from `WORD` to `UINT`. Thanks to the use of a standardized IEC 61131 conversion module and clear event control, it is easy to understand and maintain. It is particularly suitable for projects that require a clean separation between different data types at the adapter level.

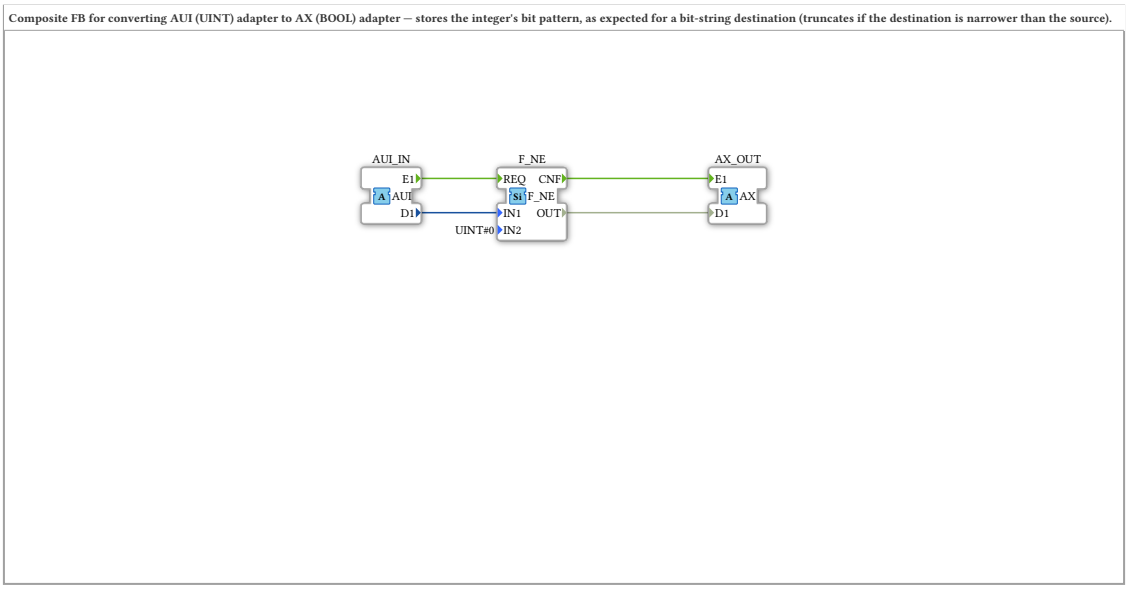
Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AUI_TO_AX

UINT Adapter Input – *AUI*

AX – BOOL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AUI_TO_AX** function block is a composite block that converts an AUI adapter (type *AUI* with a UINT value) into an AX adapter (type *AX* with a BOOL value). It serves as a bidirectional conversion interface between two different adapter types and is typically used to provide digital comparison results for further processing in BOOL-based adapters.

Interface Structure

Event Inputs

No direct event inputs. Event control is handled exclusively via the **AUI_IN** socket adapter.

Event Outputs

No direct event outputs. The result event is passed on via the **AX_OUT** plug adapter.

Data Inputs

No direct data inputs. The UINT value to be processed is provided via the socket adapter **AUI_IN**.

Data Outputs

No direct data outputs. The BOOL result is output via the plug adapter **AX_OUT**.

Adapter

- **AUX_IN (Socket)** – Type: *adapter::types::unidirectional::AUI*
- Event: E1 (triggering event for the comparison)
- Data: D1 (UINT value compared to 0)
- **AX_OUT (Plug)** – Type: *adapter::types::unidirectional::AX*
- Event: E1 (confirmation event after successful comparison)
- Data: D1 (BOOL result: TRUE if D1 ≠ 0, otherwise FALSE)

Functionality

The function block internally contains an instance of the comparison function block *iec61131::comparison::F_NE* (inequality). The process is as follows:

1. An event on socket **AUI_IN.E1** triggers the input **REQ** of the F_NE function block.
2. The UINT value supplied by the socket via **AUI_IN.D1** is compared to the constant *UINT#0*.
3. The comparison result (BOOL) is provided at output **F_NE.OUT**.
4. The result event **F_NE.CNF** is forwarded to plug **AX_OUT.E1**.
5. The BOOL result is simultaneously transmitted to **AX_OUT.D1** via the data connection.

Therefore:

- AUI_IN.D1 = 0 ⟶ AX_OUT.D1 = FALSE
- AUI_IN.D1 ≠ 0 ⟶ AX_OUT.D1 = TRUE

Technical Specifications

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **License:** Eclipse Public License 2.0 (EPL-2.0)
- **Author:** Franz Höpfinger, HR Agrartechnik GmbH
- **Package:** `adapter::conversion::unidirectional`
- **Internal Block:** `iec61131::comparison::F_NE` with parameter `IN2 = UINT#0`
- The block is a pure composite and does not contain its own state machine. All logic is implemented by the embedded F_NE.

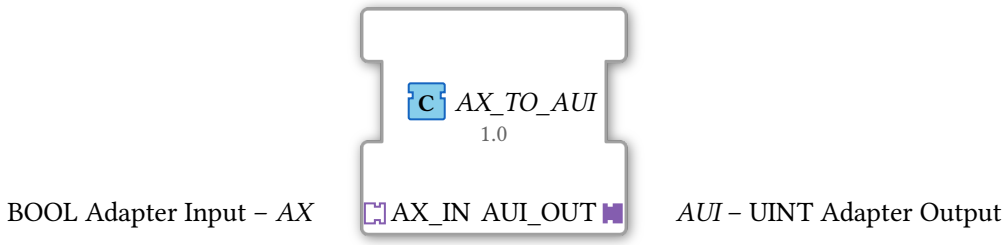
State Overview

Since this is a composite block without its own ECC (Execution Control Chart), there is no explicit state machine. The behavior is entirely determined by the internal F_NE block, which performs a simple comparison without intermediate storage. The block is therefore stateless.

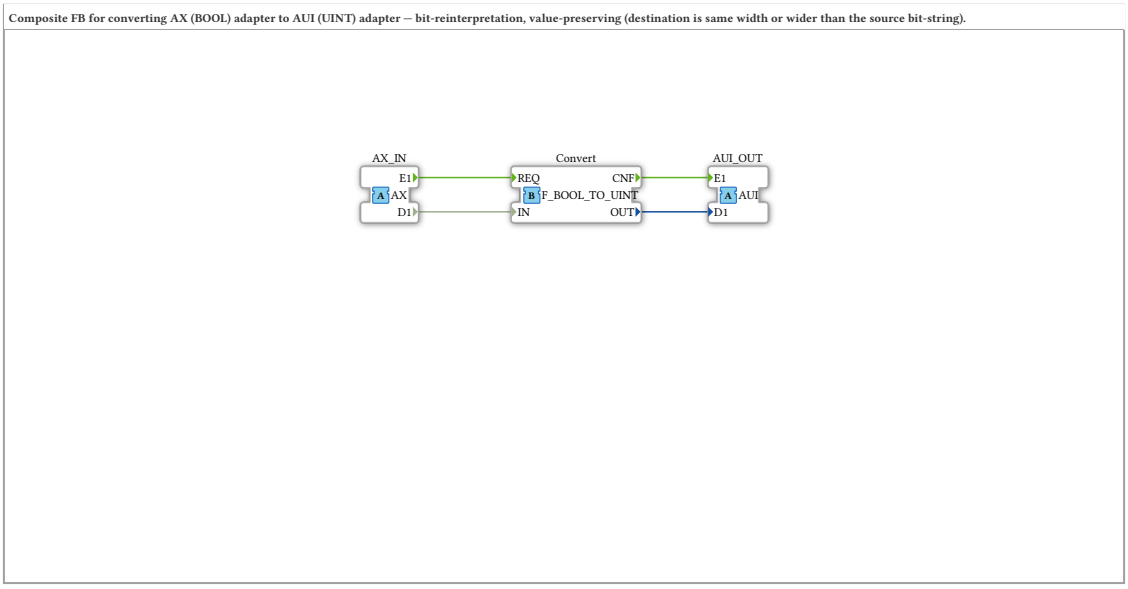
Application Scenarios

- **Threshold Detection:** Converting an analog (UINT) sensor value into a digital signal (BOOL), e.g., “non-zero value” as an alarm or control signal.
- **Adapter Conversion:** Use in systems that employ different adapter standards (AUI ↔ AX) to ensure compatibility between components.
- **Simple Logic Chaining:** Use as a binary decision stage in larger composite function blocks.

Comparison with Similar Blocks



Block	Input Type	Output Type	Function
AUI_TO_AX	AUI (UINT)	AX (BOOL)	Inequality with Zero
AUI_TO_AX_INV (hypothetical)	AUI (UINT)	AX (BOOL)	Equality with Zero (inverted)
CONV_UINT_TO_BOOL (direct)	UINT (Data)	BOOL (Data)	Direct data converter, no adapter



This function block stands out from simple data converters due to its full adapter compliance and integrated event handling.

Conclusion

AUI_TO_AX is a compact, purpose-built composite function block for converting a UINT-based AUI adapter into a BOOL-based AX adapter. Thanks to the use of the standardized F_NE comparison, the function is reliable and easy to understand. The component is particularly suitable for integration into adapter-based automation architectures where a simple zero comparison needs to be elevated to the signal level.

AX_TO_AUI

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_TO_AUI is a composite function block (FB) that converts a BOOL value from an AX adapter into a UINT value for an AUI adapter. It encapsulates the conversion logic and enables seamless integration between unidirectional adapters of different data types. The conversion is event-driven via an internal IEC 61131 conversion block.

Interface Structure

The block has no direct event or data interfaces, but only adapter interfaces. The following list describes the signals provided or required by the adapters.

Event Inputs

- **AX_IN.E1** (Event from the connected AX adapter): Triggers the conversion of the provided BOOL value.

Event Outputs

- **AUI_OUT.E1** (Event for the connected AUI adapter): Signals that the converted UINT value is present.

Data Inputs

- **AX_IN.D1** (BOOL): Boolean input value (e.g., 0 or 1) to be converted to a UINT value.

Data Outputs

- **AUI_OUT.D1** (UINT): Integer output value (0 or 1) corresponding to the converted BOOL input.

Adapter

- **AX_IN** (Socket) – Type: `adapter::types::unidirectional::AX` (BOOL)
- **AUI_OUT** (Plug) – Type: `adapter::types::unidirectional::AUI` (UINT)

Functionality

The function block operates as a simple pipeline: An incoming event at socket AX_IN.E1 triggers the internal function block `F_BOOL_TO_UINT`. This block reads the current value from AX_IN.D1, converts it to a UINT value (BOOL FALSE $\longrightarrow$ 0, BOOL TRUE $\longrightarrow$ 1), and places the result at AUI_OUT.D1. Upon completion, an event is output via AUI_OUT.E1. The entire process is atomic and event-driven; there is no internal state.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- The function block is implemented as a composite function block, meaning... It consists of a network of subordinate FB instances (here only `F_BOOL_TO_UINT`).
- The conversion follows the IEC 61131-3 conversion rule: BOOL FALSE = 0, BOOL TRUE = 1.
- The use of adapters enables loose coupling between components of different domains (BOOL control and UINT communication).
- The FB does not have its own state machine; execution is purely event-driven.

State Overview

Since this is a composite FB without its own ECC (Execution Control Chart), there are no explicit states. Its functionality is limited to the event-driven execution of the internal FB.

Application Scenarios

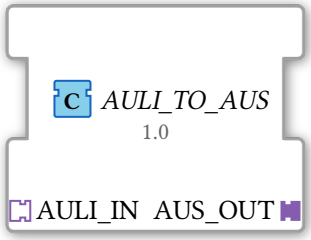
- **Control Interface**: A BOOL signal (e.g., switch on/off) is converted into a numerical value to be sent to a higher-level controller via an AUI adapter.
- **Protocol Adaptation**: Connecting a BOOL-based sensor to a system that expects UINT values (e.g., for further processing in arithmetic blocks).
- **Standardization of Adapter Interfaces**: The function block acts as an adapter between two different unidirectional adapter types, avoiding redundant development.

Comparison with Similar Function Blocks

- **AX_TO_AUI** converts BOOL to UINT.

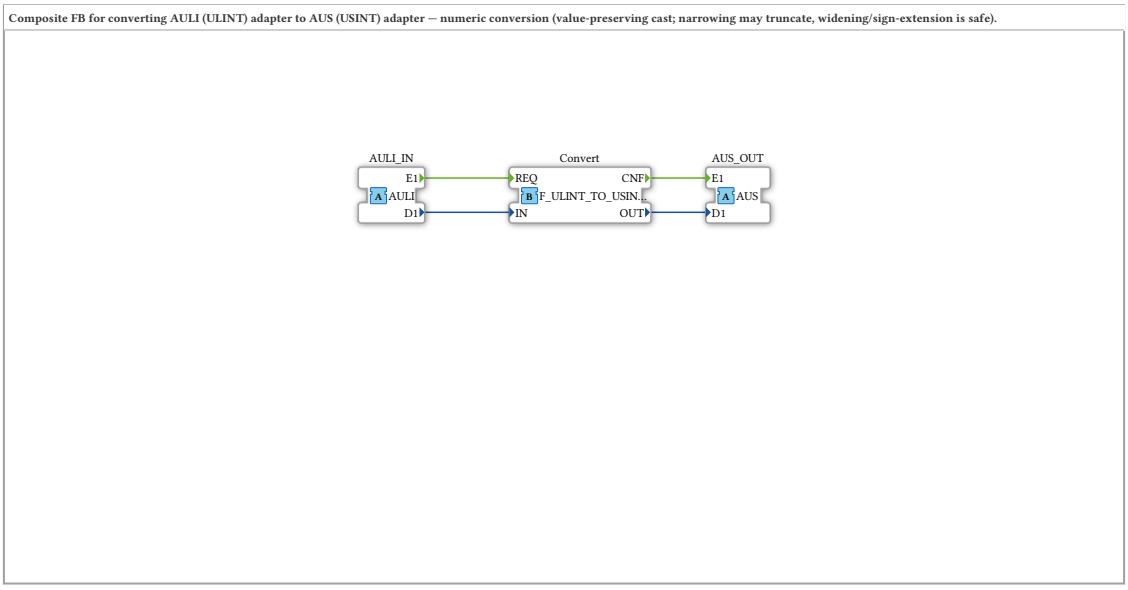
- **AX_TO_ASI** would convert BOOL to SINT, **AX_TO_ADI** BOOL to DINT – all follow the same pattern, but with different target types.
- Unlike a generic `F_BOOL_TO_UINT`, this function block offers an encapsulated adapter interface and can be directly integrated into adapter-based architectures.

Conclusion



The AX_TO_AUI is a small, specialized function block for converting BOOL to UINT data via adapter interfaces. It fulfills a typical integration task in IEC 61499-based systems, where different data types need to be connected via unidirectional adapters. Its composite structure makes the implementation transparent and extensible.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AULI_TO_AUS

ULINT Adapter Input – *AULI*

AUS – USINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AULI_TO_AUS** function block is a composite function block that performs a conversion from an **AULI adapter** (ulint, 64-bit unsigned) to an **AUS adapter** (usint, 8-bit unsigned). It encapsulates the IEC 61131 function **F_ULINT_TO_USINT** in an adapter-based environment, enabling data exchange via standardized adapters.

Interface Structure

The function block has no direct event or data inputs/outputs at the FB level. All communication takes place via the two adapters.

Event Inputs

- via **Socket AULI_IN** (Type AULI): Event **E1** – initiates data transfer and conversion.

Event Outputs

- via **Plug AUS_OUT** (Type AUS): Event **E1** – is triggered as soon as the converted value is present at the output.

Data Inputs

- via **Socket AULI_IN** (Type AULI): Data input **D1** (ULINT) – the 64-bit value to be converted.

Data Outputs

- via **Plug AUS_OUT** (Type AUS): Data output **D1** (USINT) – the converted 8-bit value.

Adapter

Name	Type	Direction	Description
AULI_IN	AULI	Socket	Input adapter for ULINT data
AUS_OUT	AUS	Plug	Output adapter for USINT data

Functionality

1. The FB receives an event at **E1** via the **AULI_IN** socket. Simultaneously, the corresponding ULINT value is provided at **D1**.
2. This event is forwarded to the internal function block **F_ULINT_TO_USINT** (name: `Convert`) (via the event connection `REQ`).
3. The ULINT value is passed to the **IN** data input of the converter.
4. After the conversion is complete, the converter generates the **CNF** event.
5. This event is transferred to the **AUS_OUT** plug at its **E1** event input, while the converted USINT value is transferred from the **OUT** output of the converter to the **D1** data output of the plug.
6. The connected receiver can now process the event and the USINT value.

Technical Features

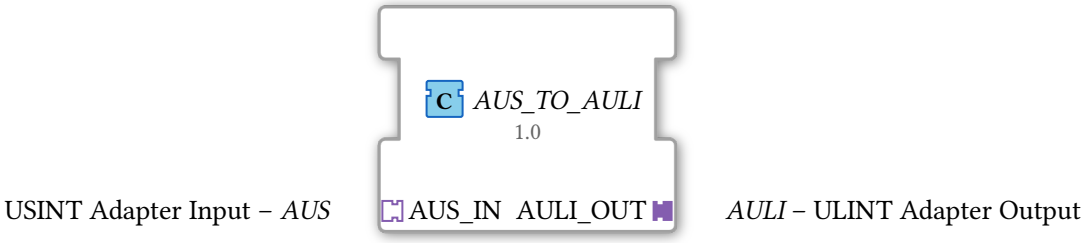
- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Block** – It contains an internal instance of **F_ULINT_TO_USINT** from the IEC 61131 library.
- **Adapter-Based Communication** – No direct data/events at the top-level function block; input/output is handled exclusively via the supplied adapters (AULI / AUS).
- **Data loss possible** – Since the USINT data type only comprises 8 bits, values > 255 are lost (truncated or wrapped around, depending on the converter implementation).
- **No dedicated state machine** – The function block (FB) is a pure network of existing blocks and does not have its own state machine.

State overview

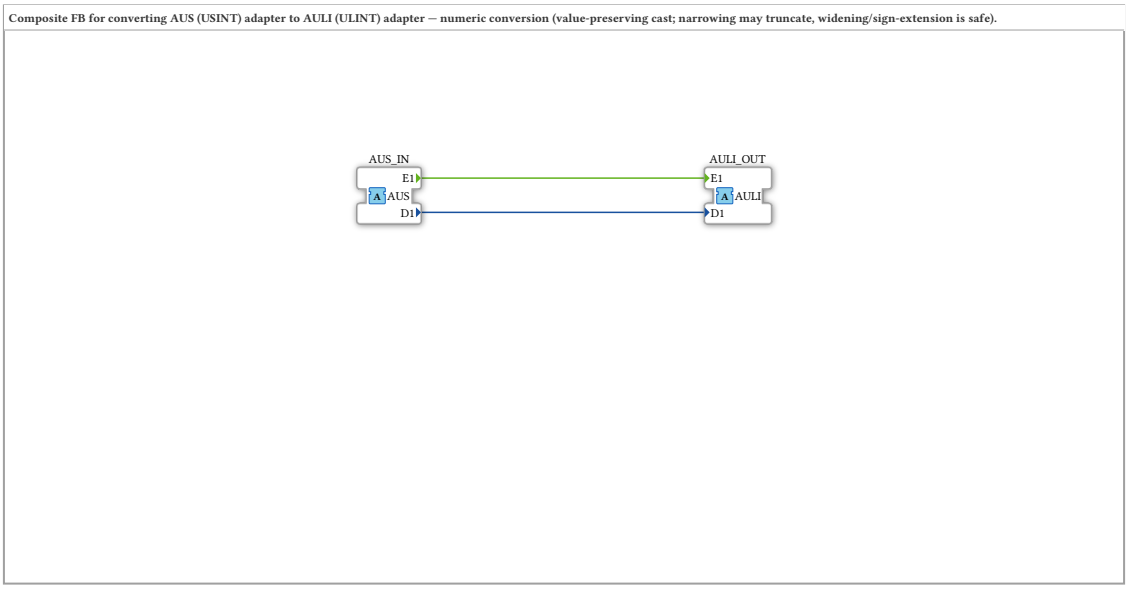
Due to its composite nature and the lack of a dedicated state machine, a state overview is not available. Its behavior is entirely determined by the internal FB **F_ULINT_TO_USINT**.

Application scenarios

- **Integration of ULINT data sources** (e.g., high-resolution counters, timestamps, or large sensor data) into an automation system that can only process USINT values due to memory or protocol limitations.
- **Adapter conversion** in a distributed application to mediate between two different adapter types (AULI ↔ AUS) without changing the underlying logic.
- **Prototypical conversions** from 64-bit to 8-bit data paths during development.



Comparison with similar components



Similar components such as **AULI_TO_AINT** (ULINT → AINT) or **AULI_TO_AWORD** (ULINT → AWORD) implement analogous conversions for other output types. This component specializes in **USINT** – a particularly memory-efficient target variable. Unlike direct application-level data conversion, the adapter-based approach offers a structured, reusable interface encapsulation that facilitates the exchange of data streams in standardized industrial protocols.

Conclusion

AULI_TO_AUS is a practical composite component that embeds an IEC 61131 conversion function in an adapter-based environment. It enables the transparent conversion of ULINT to USINT values via the corresponding adapters and is particularly suitable for scenarios where high accuracy or large value ranges need to be reduced to a smaller data format. The component is easy to use but requires attention to potential data loss.

AUS_TO_AULI

• – ○ • – ○ • – ○ •

Introduction

The function block `AUS_TO_AULI` is a composite block for converting an AUS adapter (UNSIGNED SHORT INTEGER) to an AULI adapter (UNSIGNED LONG INTEGER). It enables the direct forwarding of events and data between these two unidirectional adapter types, with an implicit type conversion from USINT to ULINT.

Interface Structure

Event Inputs

- **E1** (via `AUS_IN`): Event input of the connected AUS adapter. Passed directly to the output.

Event Outputs

- **E1** (via `AULI_OUT`): Event output of the AULI adapter. Corresponds to the incoming event of `AUS_IN.E1`.

Data Inputs

- **D1** (via `AUS_IN`): Data input of type **USINT** (OFF adapter). The value is transferred to the output.

Data Outputs

- **D1** (via `AULI_OUT`): Data output of type **ULINT** (AULI adapter). Contains the converted value of the input.

Adapters

- **OFF_IN** (Socket): Input interface for an OFF adapter (data type USINT, event E1, data D1).
- **AULI_OUT** (Plug): Output interface for an AULI adapter (data type ULINT, event E1, data D1).

Functionality

This function block directly connects the elements of the incoming OFF adapter with the corresponding elements of the outgoing AULI adapter:

- An incoming event at `AUS_IN.E1` is immediately passed on to `AULI_OUT.E1`.
- The data value `AUS_IN.D1` (USINT) is mapped to `AULI_OUT.D1` (ULINT) without any additional logic. The type conversion is implicit through the different adapter definitions; a USINT value is expanded to the corresponding ULINT value.

Technical Features

- **Numeric conversion**: value-preserving cast (narrowing may truncate, widening/sign-extension is safe).
- **Composite Function Block**: The function block does not contain its own ECC (Execution Control Chart) or state logic, but consists solely of an event and data connection.
- **Implicit Type Conversion**: The conversion from USINT to ULINT is provided by the adapter definitions in the `adapter::types::unidirectional` library. Explicit type conversion in the function block (FB) is not required.
- **Unidirectionality**: The FB only supports one direction of data flow (from AUS to AULI). Reverse conversion is not supported.

State Overview

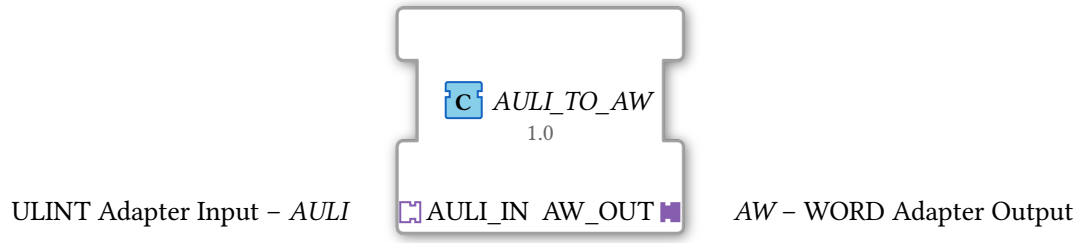
The function block does not have its own state machine. It operates purely event-driven and combinatorially: With each incoming event, the current data value is immediately forwarded. No internal states are stored.

Application Scenarios

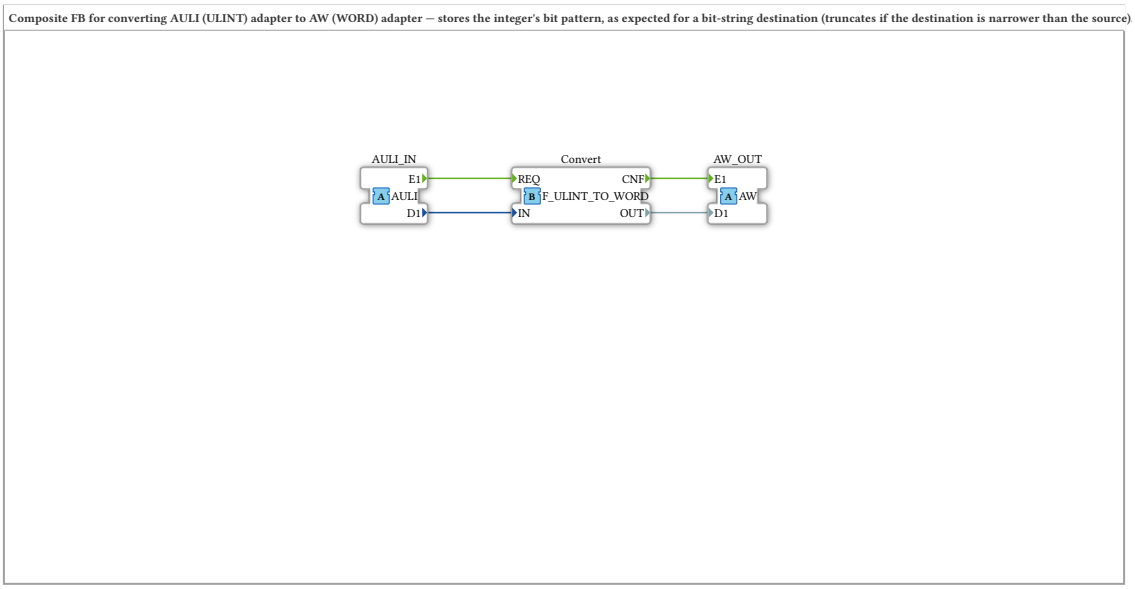
- **Adapter Integration**: If an existing module (e.g., a sensor) outputs an AUS adapter, but a subsequent module (e.g., a controller) expects an AULI adapter, this FB can be used as a conversion intermediary layer.
- **System Expansion**: Easy upgrade from USINT-based interfaces to ULINT without changing the surrounding logic.
- **Test Environments**: As a placeholder or bridge in adapter-based test structures.

Comparison with Similar Function Blocks

- **AUS_TO_AULI vs. Generic Type Converters**: Unlike a universal converter, this function block is specifically designed for AUS/AULI adapters and requires no additional parameterization. It is more compact and faster to develop.
- **AUS_TO_AULI vs. Manual Adapter Programming**: Instead of programming an adapter-to-adapter converter yourself, this ready-made function block offers an immediately usable, tested solution.



Conclusion



The FB `AUS_TO_AULI` is a simple yet effective composite function block for converting an AUS adapter (USINT) to an AULI adapter (ULINT). Through its direct passing of events and data, as well as implicit type conversion, it represents a clean and maintainable solution for the integration of different adapter interfaces.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AULI_TO_AW

• – ○ • – ○ • – ○ •

Introduction

The function block **AULI_TO_AW** is a composite function block (FB) that converts a ULINT adapter interface (AULI) to a WORD adapter interface (AW). It is used where a unidirectional data type conversion from unsigned 64-bit integer to 16-bit word is required.

Interface Structure

Event Inputs

Name	Type	Comment
E1 (via AULI_IN)	Event	Starts the conversion

Event Outputs

Name	Type	Comment
E1 (via AW_OUT)	Event	Signals completion of conversion

Data Inputs

Name	Type	Comment
D1 (via AULI_IN)	ULINT	ULINT input value

Data Outputs

Name	Type	Comment

D1 (via AW_OUT)	WORD	WORD output value

Adapters

Type	Role	Name	Comment
adapter::types::unidirectional::AULI	Socket	AULI_IN	ULINT Adapter Input
adapter::types::unidirectional::AW	Plug	AW_OUT	WORD Adapter Output

Functionality

The function block internally uses the IEC 61131 function **F_ULINT_TO_WORD** to convert the incoming ULINT value (via the AULI_IN adapter) into a WORD value. The process is purely event-driven:

1. An incoming event at the AULI_IN adapter (E1) triggers the conversion.
2. The ULINT value (D1) is passed to the function block **F_ULINT_TO_WORD**.
3. After the conversion is complete, the output event is sent at the AW_OUT adapter (E1), and the WORD value is available at the output data point (D1).

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Unidirectional Adapters**: Both AULI_IN and AW_OUT are unidirectional adapters, meaning data flow is only in one direction.
- **Composition**: The function block is built from a single integrated conversion function block, making it easy to understand and maintain.
- **Type Conversion**: The conversion from ULINT (64-bit) to WORD (16-bit) results in an overflow for values greater than 65535 – the user must ensure that the input value is in the range 0…65535.

State Overview

Since this is a pure composite function block without its own state machine, there are no internal states. All logic is implemented by the embedded function block **F_ULINT_TO_WORD**, which has simple, event-driven function execution.

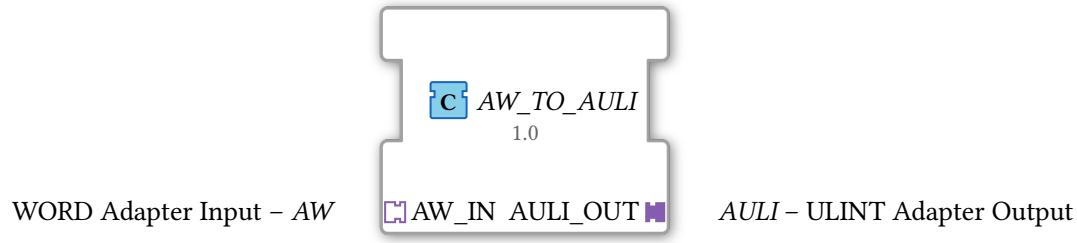
Application Scenarios

- **Interface Adaptation**: When an AULI adapter (e.g., from a sensor unit) needs to be integrated into a system that only supports Word adapter (AW) interfaces.
- **Data Reduction**: Reducing the data width from 64 bits to 16 bits for subsequent processing steps.
- **Legacy Integration**: Integrating older components that only work with 16-bit data into a modern environment that provides ULINT.

Comparison with Similar Function Blocks

Comparable function blocks include **ULINT_TO_INT** and **ULINT_TO_DWORD**, which offer different target formats. **AULI_TO_AW** is specifically tailored to the unidirectional adapter types of the 4diac world. Unlike a simple type conversion, this function block also handles event and adapter linking, significantly simplifying integration into adapter-based architectures.

Conclusion



AULI_TO_AW is a practical, compact conversion function block that bridges the gap between ULINT and WORD adapter interfaces. By encapsulating the IEC function in a composite function block, the user is relieved of adapter details and receives a clean, event-driven transformation solution. This function block is particularly suitable for scenarios where data widths need to be reduced while maintaining the adapter structure.

AW_TO_AULI

WORD Adapter Input – *AW*

AULI – ULINT Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The composite function block `AW_TO_AULI` converts a unidirectional adapter of type `AW` (WORD data format) into an adapter of type `AULI` (ULINT data format). The conversion is performed internally using the standard function block `F_WORD_TO_ULINT` from the IEC 61131 library.

Interface Structure

Event Inputs

- **AW_IN.E1** – Event input via socket `AW_IN`. Triggers the conversion.

Event Outputs

- **AULI_OUT.E1** – Event output via plug `AULI_OUT`. Signals the completion of the conversion.

Data Inputs

- **AW_IN.D1** – Data input of type WORD (via socket `AW_IN`).

Data Outputs

- **AULI_OUT.D1** – Data output of type ULINT (via plug `AULI_OUT`).

Adapter

- **Socket:** `AW_IN` (Type: `adapter::types::unidirectional::AW`)
- **Plug:** `AULI_OUT` (Type: `adapter::types::unidirectional::AULI`)

Functionality

As soon as an event arrives at event input `AW_IN.E1`, the internal function block `F_WORD_TO_ULINT` is called. This block reads the current value of the data input `AW_IN.D1` (WORD) and converts it into a ULINT

value. After successful conversion, an event is output at event output `AULI_OUT.E1`, and the converted value is made available at data output `AULI_OUT.D1`.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- The function block (FB) is implemented as a composite and fully encapsulates the conversion logic.
- The conversion function used, `F_WORD_TO_ULINT`, complies with the IEC 61131-3 standard.
- The interfaces are based on unidirectional adapters – event and data flow is one-way only.
- The FB does not have a state machine; its functionality is purely event-driven.

State Overview

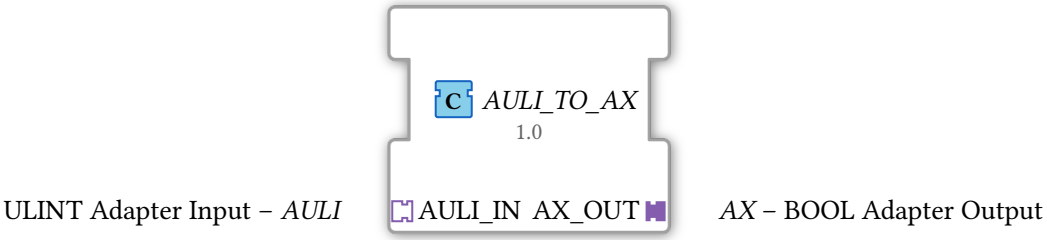
The FB does not contain any explicit states. Processing is linear: Event ⟶ Conversion ⟶ Output.

Application Scenarios

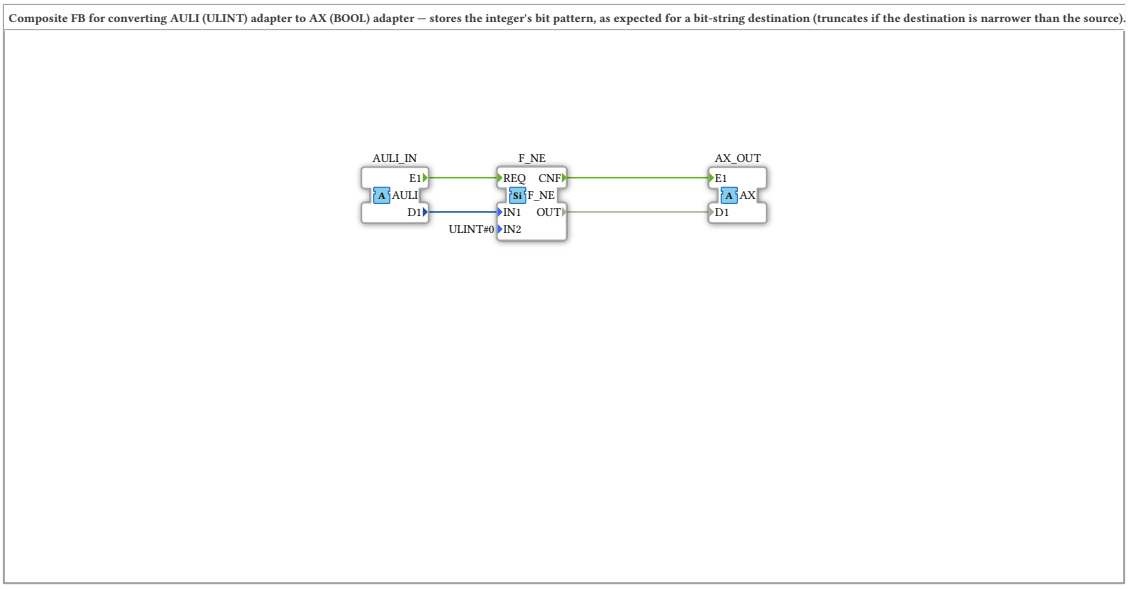
- Integration of sensors or actuators that deliver WORD data into systems that expect ULINT values.
- Adapter-based protocol conversion in automation technology (e.g., agricultural engineering).
- Reusable encapsulation of the standard conversion function for modular control projects.

Comparison with Similar Function Blocks

- **Direct use of `F_WORD_TO_ULINT`:** Requires manual wiring of event and data lines. The composite function block `AW_TO_AULI` simplifies integration into adapter-oriented architectures.
- **Other conversion adapters** (e.g., `AW_TO_ADINT` for DINT or `AW_TO_ABOOL` for BOOL): Offer analogous conversions for other target data types.



Conclusion



AW_TO_AULI` is a practical and easy-to-use component for converting WORD to ULINT data. The use of standardized adapter interfaces and the IEC conversion function ensures compatibility and reliability. The function block is particularly suitable for modular, adapter-based automation solutions.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AULI_TO_AX

• — ○ • — ○ • — ○ •

Introduction

The **AULI_TO_AX** function block serves as a composite block for converting an **AULI** adapter (data type ULINT) into an **AX** adapter (data type BOOL). It allows the connection of an unsigned integer from an adapter socket to a Boolean adapter plug, where the value 0 is interpreted as FALSE and any other value as TRUE.

Interface Structure

Event Inputs

The function block does not have direct event inputs. The triggering event is provided via the **AULI_IN** adapter:

- **AULI_IN.E1**: Event for processing the ULINT value and triggering the output on the AX adapter.

Event Outputs

Event output is also handled via the adapter:

- **AX_OUT.E1**: Acknowledgement event that, after successful conversion, forwards the new BOOL value to the connected receiver.

Data Inputs

All data inputs are part of the adapter socket:

- **AULI_IN.D1** (ULINT): The input value to be converted.

Data Outputs

Data output is handled via the adapter plug:

- **AX_OUT.D1** (BOOL): Conversion result – TRUE if the input value is not equal to 0, otherwise FALSE.

Adapter

- **AULI_IN** (Socket, Type: `adapter::types::unidirectional::AULI`): Receives the ULINT value and the associated event.
- **AX_OUT** (Plug, Type: `adapter::types::unidirectional::AX`): Provides the converted BOOL value and the output event.

Functionality

The function block (FB) operates purely event-driven and internally uses the comparison block **F_NE** (IEC 61131-3, “not equal”). An incoming event on **AULI_IN.E1** triggers the execution of the FB **F_NE**

by triggering its input **REQ**. The comparison block checks the ULINT value present at **IN1** against the constant value **ULINT#0** (parameter **IN2**). The result **OUT** (BOOL) is forwarded to the data output **AX_OUT.D1**. Once the comparison is complete, **F_NE** generates an acknowledgment event on **CNF**, which is passed to **AX_OUT.E1** to signal the availability of the new value to the connected receiver.

F_NE** is not a validation event.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Function Block**: Functionality is achieved through internal interconnection of standard function blocks – in this case, only a single comparison block.
- **Adapter Encapsulation**: Inputs and outputs are defined exclusively via adapters, enabling uniform and modular connectivity in adapter-based architectures.
- **Use of IEC 61131 Library**: The **F_NE** function block used is from the IEC 61131-3 library, promoting compatibility and reusability.
- **Constant Comparison Reference**: The limit value is fixed at 0; parameterization is not provided.

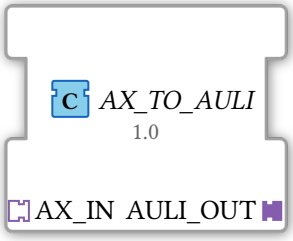
State Overview

As a composite function block, **AULI_TO_AX** does not have its own states in the sense of a state machine. The sequence is controlled purely by event chaining:

1. **Waiting** for an event at **AULI_IN.E1**.
2. **Processing** by **F_NE** (comparison) – quasi-static, no delay.
3. **Output** of the result to **AX_OUT** (event and data).

Application Scenarios

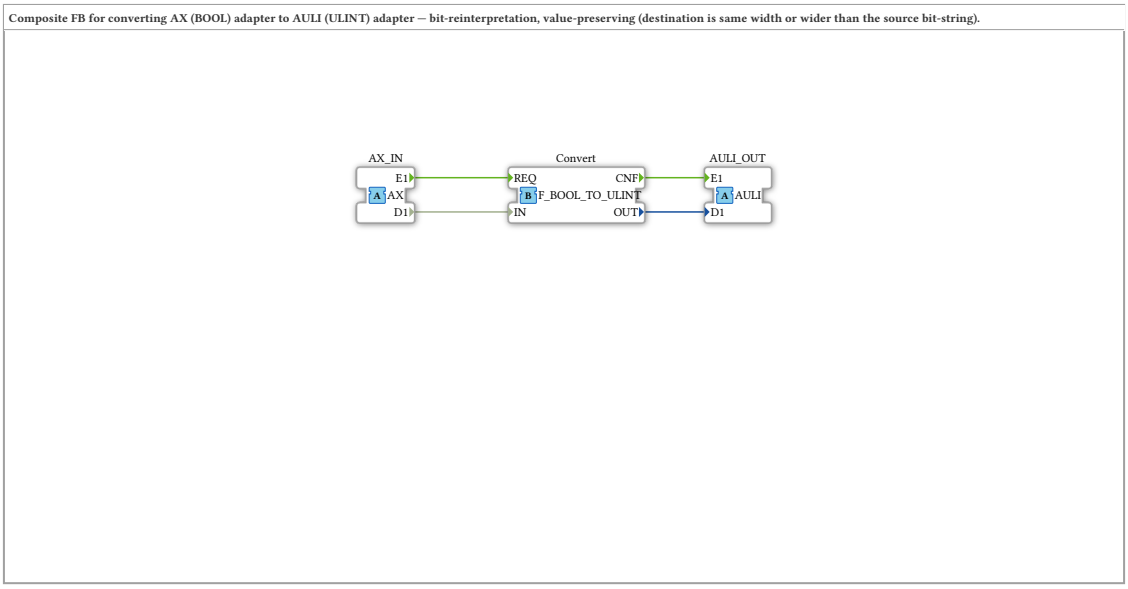
- **Limit Logic**: Converts a ULINT counter reading (e.g., quantity, fill level) into a simple Boolean signal indicating whether the value deviates from zero.
- **Adapter Conversion**: Replaces direct type conversion in adapter-based control architectures when only Boolean processing is required.
- **Signal Simplification**: Reduces complex numerical information to a binary state for alarm or status messages.



Comparison with Similar Function Blocks

Unlike general comparison function blocks (e.g., **GT**, **EQ**), **AULI_TO_AX** is specifically designed for adapter conversion and does not have configurable comparison operators or variable thresholds. A direct comparison with 0 is hard-coded. Function blocks like **ULINT_TO_BOOL** (without adapters) require their own event and data connections, whereas this function block integrates all adapter handling.

Conclusion



AULI_TO_AX is a compact and specialized composite function block for the simple conversion of a ULINT adapter signal to a Boolean adapter signal. It reduces wiring effort in adapter-based projects and ensures clear, maintainable structures when only the "non-zero" state needs to be evaluated. Implementation using a standardized comparison function block guarantees reliable and resource-efficient execution.

AX_TO_AULI

BOOL Adapter Input – *AX*

AULI – ULINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_TO_AULI** is a composite block for converting a BOOL adapter signal (type `AX`) into a ULINT adapter signal (type `AULI`). It encapsulates the type-safe conversion of a binary value into an unsigned 64-bit integer, thus enabling the easy integration of BOOL interfaces into ULINT-based control logic.

The function block is provided in the package `adapter::conversion::unidirectional` and is based on the standardized conversion function block `F_BOOL_TO_ULINT` from the IEC 61131 library.

Interface Structure

Event Inputs

No dedicated event inputs.

Event control is handled via the connected adapters (see section **Adapters**).

Event Outputs

No dedicated event outputs.

Result events are provided via the output adapter (see section **Adapters**).

Data Inputs

No dedicated data inputs.

The data to be converted is received via the input adapter (see section **Adapters**).

Data Outputs

No dedicated data outputs.

The converted result is provided via the output adapter (see section **Adapters**).

No dedicated data outputs.

Adapter

Direction	Name	Type	Description
Socket	`AX_IN`	`adapter::types::unidirectional::AX`	BOOL adapter input. Provides input data via the event `E1` and the date `D1` (BOOL value).
Plug	`AULI_OUT`	`adapter::types::unidirectional::AULI`	ULINT adapter output. Outputs the conversion result via the event `E1` and the date `D1` (ULINT value).

Functionality

The function block contains an internal network consisting of a single instance of the conversion function block `F_BOOL_TO_ULINT`.

The connections are as follows:

1. **Event Handling**:

- The event `AX_IN.E1` (from the input adapter) is passed to the event input `Convert.REQ` and starts the conversion.
- After the conversion is complete, the event `Convert.CNF` is passed to the event output `AULI_OUT.E1` to finally update the output adapter.

1. **Data Flow**:

- The Boolean value of `AX_IN.D1` is mirrored to the data input `Convert.IN`.
- The converted ULINT value of `Convert.OUT` is transferred to `AULI_OUT.D1`.

Thus, on each rising edge of the input event, the current BOOL value is converted to a ULINT value (BOOL $\longrightarrow$ 0 $\longrightarrow$ 0 ULINT, BOOL $\longrightarrow$ 1 $\longrightarrow$ 1 ULINT) and made available via the output adapter.

Technical Specifications

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **License**: The source code is licensed under the Eclipse Public License 2.0 (EPL-2.0).
- **Author**: Developed by **Franz Höpfinger** for **HR Agrartechnik GmbH** (Version 1.0, dated 2026-02-17).
- **Package Structure**: The module is organized in the package `adapter::conversion::unidirectional`.
- **Dependencies**: It imports the module `iec61131::conversion::F_BOOL_TO_ULINT`.
- **Type Safety**: The use of adapters ensures strict type checking at design time.

State Overview

The composite module does not have its own state machine.

The entire sequence control is implemented by the internal module `F_BOOL_TO_ULINT`, which implements a simple event-driven state machine:

- In its idle state, it waits for a `REQ` event.
- Upon arrival of the event, the conversion is performed and the output is immediately confirmed with `CNF`.

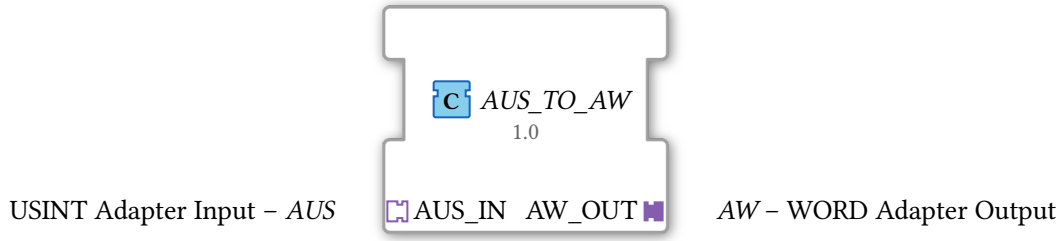
Application Scenarios

- **Integration of binary sensors** into controllers that expect ULINT values (e.g., counter registers, addressing logic).
- **Adapter bridging** in heterogeneous systems where a BOOL adapter (e.g., from a switch) needs to be adapted to a ULINT adapter (e.g., a profile/parameter interface).
- **Type-safe conversion** in composite function blocks to standardize the handling of different data types in an application.

Comparison with Similar Function Blocks

- **F_BOOL_TO_ULINT**: The underlying basic function block – it offers pure conversion without adapter encapsulation.
- **AX_TO_UDINT**, **AX_TO_DINT**: Analogously structured composite function blocks for other target data types (UDINT, DINT).
- **Direct Type Conversion**: Numerous standard conversion function blocks exist in the IEC 61131 environment; this one specializes in the adapter interface.

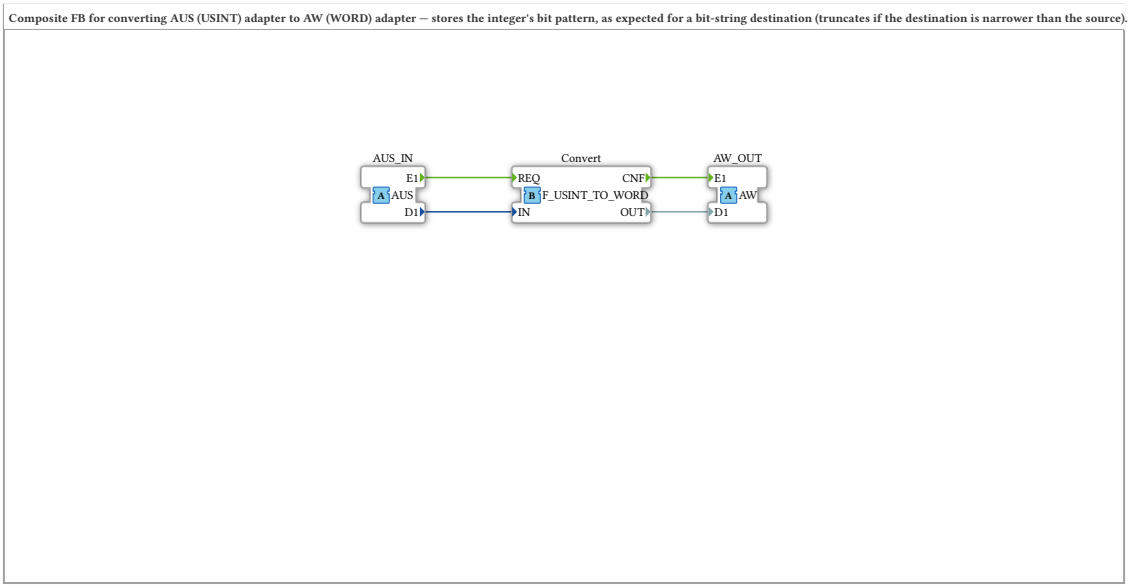
Conclusion



The **AX_TO_AULI** function block is a compact, type-safe, and easily reusable solution for converting a BOOL adapter to a ULINT adapter.

It simplifies the hierarchical structuring of applications and enables a clear separation between data sources and sinks. Thanks to its EPL 2.0 licensing, it can be freely integrated into custom projects.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AUS_TO_AW

USINT Adapter Input – *AUS*

AW – WORD Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AUS_TO_AW** function block is a composite function block that enables the simple and standardized conversion of a **USINT** value (0–255) to a **WORD** value (16 bits) via adapter interfaces. It acts as an intermediary between systems that provide or expect different data types via unidirectional adapters.

Interface Structure

The function block itself has no direct inputs or outputs. All communication takes place via the two integrated adapters.

Event Inputs

No direct event inputs are available. Event control is implemented via the **AUS_IN** adapter. This provides an event input **E1**, the activation of which starts the conversion process.

Event Outputs

No direct event outputs are available. An event is output via the **AW_OUT** adapter after successful conversion (event output **E1**).

Data Inputs

No direct data inputs are available. The USINT value to be converted is read via the **D1** data input of the **AUS_IN** adapter (type: USINT).

Data Outputs

No direct data outputs are available. The converted WORD value is output via the **D1** data output of the **AW_OUT** adapter (type: WORD).

Adapters

- **AUS_IN** (Socket): Unidirectional adapter of type `adapter::types::unidirectional::AUS`. Expects a USINT value and an event to trigger the conversion.
- **AW_OUT** (Plug): Unidirectional adapter of type `adapter::types::unidirectional::AW`. Provides the WORD value and a confirmation event after successful conversion.

Functionality

1. An external event at the **E1** input of the **AUS_IN** adapter triggers execution.
2. The internal function block **F_USINT_TO_WORD** (from the IEC 61131 library) takes the USINT value present at **AUS_IN.D1** and converts it to a WORD value.
3. After the conversion is complete, the WORD value at the **OUT** output of **F_USINT_TO_WORD** is forwarded to **AW_OUT.D1**.
4. Simultaneously, an event is generated at the **CNF** output of **F_USINT_TO_WORD**, which signals externally via **AW_OUT.E1** that the converted value is available.

Technical Features

- **Stores the integer's bit pattern**, as expected for a bit-string destination (truncates if the destination is narrower than the source).
- **Composite Block**: The conversion logic is encapsulated in its own network, promoting reuse and clarity.
- **Unidirectional Adapters**: The **OFF** and **AW** adapters are designed as pure data and event pipelines – reverse communication is not supported.
- **Standard Conversion**: The actual type conversion is based on the tested block `F_USINT_TO_WORD` from the IEC 61131 library.
- **No Internal State Logic**: The block delegates all control to the internal converter and the adapter interfaces.

State Overview

The block does not have its own state machine. The process is event-driven and strictly sequential:

- **Idle**: Waiting for an event at the OFF_IN adapter.
- **Conversion active**: Internal **F_USINT_TO_WORD** is executed. Upon completion, the function block automatically returns to the idle state.
- **Output**: The confirmation event is sent via the AW_OUT adapter.

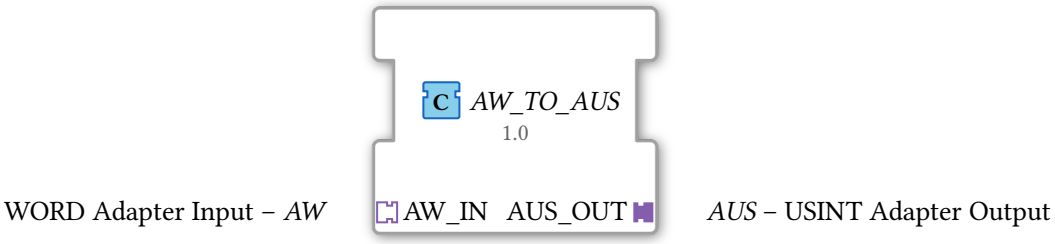
Application Scenarios

- **System Integration**: A sensor delivers measured values as USINT via a unidirectional AUS adapter, but the controller expects WORD values via an AW adapter.
- **Data Preparation**: Simple type conversion without additional logic is required in an adapter-based communication chain.
- **Prototype Development**: Rapid coupling of two components using different data types without modifying the existing adapter structure.

Comparison with Similar Function Blocks

- **F_USINT_TO_WORD** (direct): Provides pure conversion without adapter integration – suitable for internal flows within a device.
- **AUS_TO_AW**: Extends the conversion process with unidirectional adapters, enabling loose coupling between independent systems.
- **Other adapter converters (e.g., INT_TO_DWORD)**: Follow the same pattern but with different target types. **AUS_TO_AW** is specifically optimized for the USINT → WORD pairing.

Conclusion



AUS_TO_AW is a compact, reliable composite component that standardizes the conversion of USINT to WORD data via unidirectional adapters and can be seamlessly integrated into existing 4diac projects. It reduces development effort and increases reusability in modular automation systems.

]

AW_TO_AUS

• – ◦ • – ◦ • – ◦ •

Introduction

The composite function block `AW_TO_AUS` converts a `WORD` adapter signal into a `USINT` adapter signal. It encapsulates the IEC 61131-3 standard function `F_WORD_TO_USINT` in an adapter-coupled environment, thus enabling seamless integration between different adapter types.

Interface Structure

The function block has no independent event or data ports at the function block interface level. All communication takes place exclusively via the two adapters.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket (Input)	AW_IN	adapter::types::unidirectional::AW	Expects a WORD value via data port D1 and an event via E1.
Plug (Output)	AUS_OUT	adapter::types::unidirectional::AUS	Returns the converted USINT value via data port D1 and an acknowledgment event via E1.

Functionality

1. An incoming event at the adapter socket AW_IN.E1 triggers the internal conversion module Convert (type F_WORD_TO_USINT) via its event input REQ.
2. Simultaneously, the data value from AW_IN.D1 (type WORD) is forwarded to the data input Convert.IN.
3. After conversion, the result (USINT) is provided at data output Convert.OUT and transferred to data port AUS_OUT.D1.
4. The conversion block signals completion via its event CNF, which directly activates the event output AUS_OUT.E1.

This results in a synchronous, event-driven conversion from a WORD value to a USINT value.

Technical Features

- **Bit-reinterpretation**, value-preserving only if the source value fits the narrower destination width (otherwise the upper bits are silently dropped).
- **Composite Pattern**: The block is implemented as a composite function block (FB) that encapsulates the existing standard function F_WORD_TO_USINT.
- **Adapter Coupling**: The function block simplifies integration into existing systems that rely on the adapters AW and AUS by consolidating the conversion into a single block.
- **No Own State Logic**: All logic is delegated; the function block itself has no integrated event control (ECC) and behaves purely directionally.

State Overview

The function block does not have its own state machine. The sequence is entirely determined by the embedded function F_WORD_TO_USINT and the event connections. Therefore, the function block should be considered **stateless**.

Application Scenarios

- **Adapter Conversion**: When a 4diac application uses an adapter of type AW (with WORD data), but a subsequent component expects an adapter of type AUS (with USINT data).
- **Protocol Adaptation**: Simplifies the connection of components that use different data types via their adapter interfaces.
- **Minimal Conversion Overhead**: Ideal when no additional logic is required and only a simple type conversion (e.g., from a 16-bit value to an 8-bit value) needs to be performed.

Comparison with Similar Function Blocks

- **Direct Use of F_WORD_TO_USINT**: This standard function block operates at the data level but requires manual event and data connections. AW_TO_AUS encapsulates these connections and provides an adapter-based interface.
- **Other Adapter Converters (e.g., AW_TO_ABOOL)**: These differ in their target data type. The presented scheme (Socket -> Conversion Function Block -> Plug) can be implemented analogously for any data type.

Conclusion

AW_TO_AUSis a simple yet useful composite function block for convertingWORDadapter signals toUSINT` adapter signals. It utilizes a proven IEC 61131-3 standard function and offers a clean, adapter-based interface. The function block requires no configuration and integrates seamlessly

into event-driven processes. It is particularly suitable for applications where fast and reliable data type conversion without additional logic is desired.

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AUS_TO_AX

USINT Adapter Input – *AUS*

AX – BOOL Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AUS_TO_AX** is a composite FB for converting an **AUS** adapter (USINT data) into an **AX** adapter (BOOL data). It compares the incoming USINT value with zero and outputs the result as a Boolean signal. This enables the simple conversion of counter or sensor data into a binary status signal.

Interface Structure

The FB does not offer direct event or data connections, but only adapter interfaces.

Event Inputs

No direct event inputs. The event signal is provided via the **AUS_IN.E1** adapter.

Event Outputs

No direct event outputs. The event signal is output via the **AX_OUT.E1** adapter.

Data Inputs

No direct data inputs. The data signal (USINT) is provided via the adapter **AUS_IN.D1**.

Data Outputs

No direct data outputs. The data signal (BOOL) is output via the adapter **AX_OUT.D1**.

Adapters

Name	Direction	Type	Comment
AUS_IN	Socket	adapter::types::unidirectional::AUS	USINT input value and event
AX_OUT	Plug	adapter::types::unidirectional::AX	BOOL output value and event

Functionality

The function block internally uses an **F_NE** block (comparison for inequality) from the IEC 61131 library.

- An incoming event **AUS_IN.E1** triggers the **REQ** input of **F_NE**.
- **F_NE** compares the data value **AUS_IN.D1** (USINT) with the constant value **USINT#0**.
- The comparison result (BOOL: TRUE if not zero, otherwise FALSE) is forwarded to **AX_OUT.D1**.
- After processing is complete, **F_NE** generates a **CNF** event, which is passed to **AX_OUT.E1**.

Technical Features

- **Not-equal-to-zero comparison, not a bit pattern**: The result is `TRUE` for any value other than 0, not the least significant bit. The comment in the source block ("stores the bit pattern … truncates") describes different behaviour and is outdated; the `F_NE` network is authoritative.
- The function block (FB) is implemented as a **Composite FB**, meaning its logic is represented by an internal network of standard function blocks.
- It uses the **F_NE** comparison block, which is from the **iec61131::comparison** library.
- The package organization is **adapter::conversion::unidirectional**, indicating its use as an adapter converter.
- The function block (FB) does not have its own state machines; processing is exclusively event-driven via internal connections.

State Overview

As a composite FB, **AUS_TO_AX** does not have its own state machine.
All logic is performed by the integrated **F_NE**, which does not require stateful control.
The behavior is purely combinatorial with event-driven execution.

Application Scenarios

- Conversion of a counter value (USINT) into a Boolean signal indicating the state "value ≠ 0" (e.g., "fill level present" or "sensor active").
- Use in **agricultural technology** – the FB originates from HR Agrartechnik GmbH – for processing sensor data via adapter interfaces.
- Simplifies cabling in 4diac IDE projects when heterogeneous adapter types need to be coordinated.

Comparison with similar function blocks

- Direct comparison with a **NE** function block: **AUS_TO_AX** extends the basic comparison function with adapter conversion.
- While an **NE** function block typically expects two simple data inputs (e.g., ANY), this function block works exclusively with predefined adapters (AUS / AX) and hides its internal logic.
- It is therefore specifically optimized for systems with a uniform adapter concept (unidirectional interfaces).

Conclusion

AUS_TO_AX is a simple yet effective adapter converter that converts a USINT value into a Boolean signal by comparing it to zero.

Its encapsulation as a composite function block with adapter connections allows for seamless integration into modular 4diac projects. The function block (FB) does not offer its own states and, due to its low complexity, is reliable and requires little maintenance.

AX_TO_OFF

BOOL Adapter Input – *AX*

AUS – USINT Adapter Output

• – ○ • – ○ • – ○ •

Introduction

The **AX_TO_OFF** function block is a composite function block that converts a Boolean input adapter (type `AX`) into an integer output adapter (type `AUS`). It serves as a bridge between components that operate with different data types and enables seamless integration into control applications according to IEC 61499.

Interface Structure

Event Inputs

The function block does not have direct event inputs; however, the incoming adapter `AX_IN` provides the event `E1`. This triggers the conversion.

Event Outputs

There are no direct event outputs here either. The outgoing adapter `AUS_OUT` provides the event `E1`, which is triggered after successful conversion.

Data Inputs

Data is received via the adapter `AX_IN` as a Boolean value (`D1` of type `BOOL`).

Data Outputs

The converted value is output via the adapter `AUS_OUT` as an unsigned 8-bit integer (`D1` of type `USINT`).

Adapter

Direction	Name	Type	Description
Socket	AX_IN	adapter::types::unidirectional::AX	Boolean Input Adapter
Plug	AUS_OUT	adapter::types::unidirectional::AUS	USINT Output Adapter

Functionality

Internally, the function block uses the predefined conversion function block iec61131::conversion::F_BOOL_TO_USINT. The process is as follows:

1. An incoming event at the adapter AX_IN.E1 triggers the internal function block via its input REQ.
2. The Boolean value of AX_IN.D1 is forwarded to the input IN of the internal function block.
3. The internal function block converts the value of BOOL into a value of USINT (false ⟶ 0, true ⟶ 1) and places it at its output OUT.
4. The confirmation event CNF of the internal function block is forwarded to the adapter output AUS_OUT.E1.
5. The converted value from output OUT is transferred to the data output AUS_OUT.D1.

Technical Features

- **Bit-reinterpretation, value-preserving** (destination is same width or wider than the source bit-string).
- **Composite Function Block**: The function block encapsulates the conversion logic and provides a clean, reusable interface via adapters.
- **Plug/Socket Coupling**: The function block uses the adapter pattern (socket for input, plug for output), enabling flexible connectivity in an IEC 61499 application.
- **Dependency**: It imports the function block iec61131::conversion::F_BOOL_TO_USINT, which is part of the IEC 61131 conversion library.

State Overview

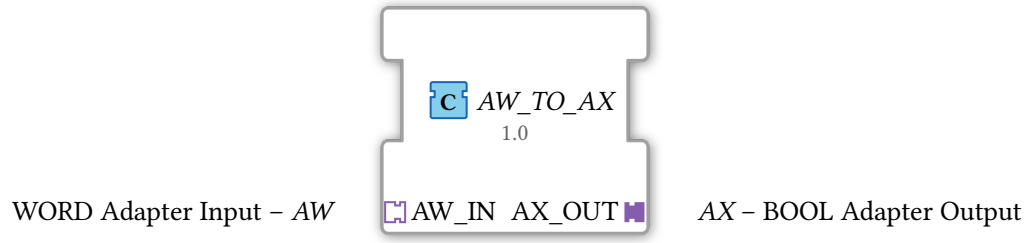
The function block does not have its own state machine. All functionality is implemented by the internal F_BOOL_TO_USINT function block, which operates in an event-driven manner and does not store internal states.

Application Scenarios

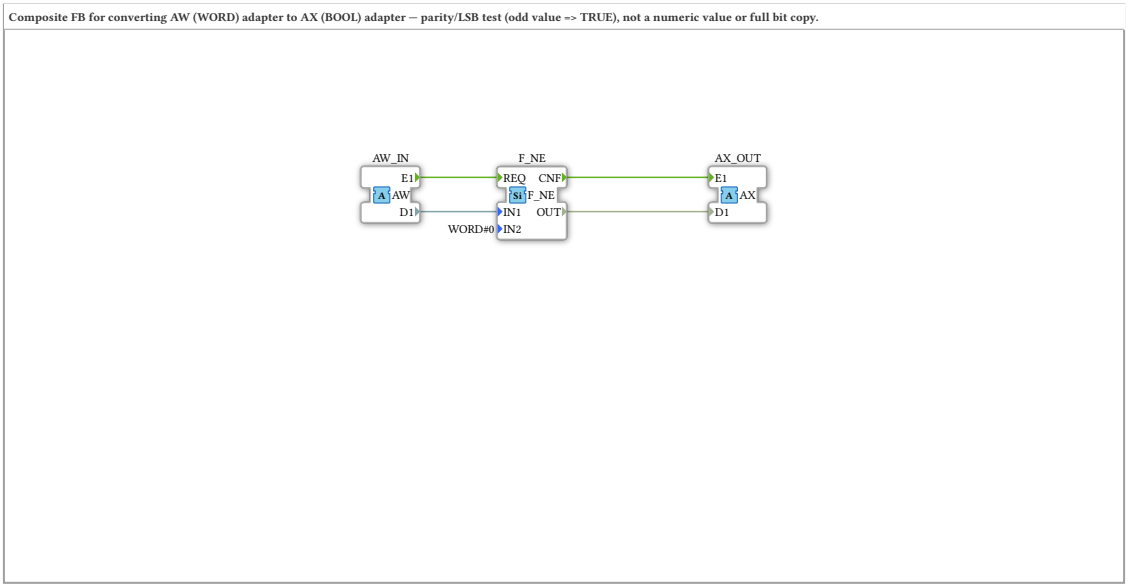
- **Signal Adaptation**: When a sensor or a Boolean adapter (e.g., switch, limit switch) needs to be connected to a component that expects an integer adapter.
- **Protocol Conversion**: In heterogeneous systems that use different data formats, this function block can serve as a simple converter.
- **Test and Simulation Environments**: To convert Boolean values into numerical values that can be more easily processed by analysis tools.

Comparison with Similar Function Blocks

Numerous conversion blocks exist in the IEC 61499 library, such as F_BOOL_TO_INT, F_BOOL_TO_WORD, and F_BOOL_TO_BYTE. The difference with AX_TO_AUS lies in the adapter interface: This block encapsulates the conversion not only at the data level but also at the event level in a compact adapter pair. Other blocks typically work with simple input/output data and require additional event wiring.



Conclusion



The **AX_TO_AUS** function block is a practical tool for converting Boolean adapter signals to the USINT format. By using adapters, it integrates seamlessly into the event-driven architecture according to IEC 61499 and significantly reduces wiring effort. It is particularly suitable for applications where a clean separation between the Boolean and numeric domains is desired.

Numeric Index (unidirectional)

Here you will find all exercises from the unidirectional workspace, listed in ascending order. …

AW_TO_AX

• – ○ • – ○ • – ○ •

Introduction

The composite function block **AW_TO_AX** converts an **AW adapter** (WORD) into an **AX adapter** (BOOL). It checks whether the 16-bit value received via the AW adapter is non-zero and outputs the result as a Boolean signal via the AX adapter.

Interface Structure

This function block does not have traditional event or data inputs/outputs, but only adapter interfaces.

Event Inputs

No separate event inputs. Events are received via the socket adapter.

Event Outputs

No separate event outputs. Events are sent via the plug adapter.

Data Inputs

No separate data inputs. Data is received via the socket adapter.

Data Outputs

No separate data outputs. Data is sent via the plug adapter.

Adapters

Name	Type	Direction	Comment
AW_IN	adapter::types::unidirectional::AW	Socket	WORD adapter input
AX_OUT	adapter::types::unidirectional::AX	Plug	BOOL adapter output

The socket **AW_IN** provides the event and data interface of a **WORD**-based adapter.

The plug **AX_OUT** provides the event and data interface of a **BOOL**-based adapter.

Functionality

When an event arrives at **AW_IN.E1**, the value of **AW_IN.D1** is compared to the constant value **WORD#0**. Internally, the function block **F_NE** (non-equal comparison from IEC 61131) is used for this comparison.

- If **AW_IN.D1 ≠ 0**, an event is sent to **AX_OUT.E1** and the data value **AX_OUT.D1** is set to **TRUE**.
- Otherwise, no event is generated at the output and the data value remains **FALSE** (i.e., it is not changed).

This behavior is event-driven and follows the IEC 61499 execution semantics: An event at the input triggers the comparison, the result of which is passed on to the output.

- If **AW_IN.D1 ≠ 0**, an event is sent to **AX_OUT.E1** and the data value **AX_OUT.D1** is set to **TRUE**.
-

Technical Features

- **Parity/LSB test** (odd value => TRUE), not a numeric value or full bit copy.
- The function block is implemented as a **composite function block**, meaning its functionality is represented by an internal network consisting of a single **F_NE** function block.
- It uses a **unidirectional adapter** (AW and AX) according to the adapter definition of the 4diac IDE.
- The comparison logic is taken from the IEC 61131 library (`iec61131::comparison::F_NE`).
- It is a pure signal conversion without any state management.

State Overview

The function block has **no internal state machine** (no ECC). The sequence control is derived directly from the internal network: An event at the input adapter triggers the comparison block, which in turn passes the result to the output adapter.

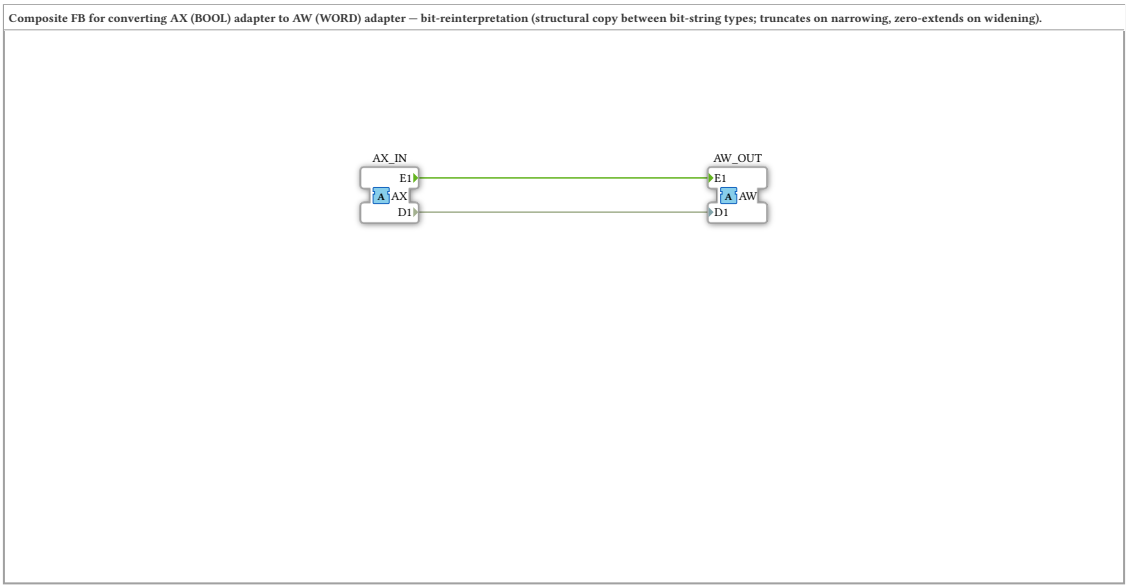
Application Scenarios

- **Signal Conditioning:** Conversion of a digital WORD value (e.g., from a sensor module) into a Boolean signal that indicates whether the value is non-zero.
- **Adapter Integration:** Use in systems that require adapter-based communication between different data types (e.g., linking a WORD-based bus component with BOOL-based control logic).
- **Threshold Check:** By changing the comparison value (in the internal block **F_NE**), the function block could also be adapted to other threshold values (e.g., “Value > 100”).

Comparison with Similar Blocks

- **WORD_TO_BOOL:** Simple, direct conversion of a WORD data type to BOOL (e.g., bit 0). In contrast, **AW_TO_AX** uses adapters and performs a comparison with zero – it reacts to the entire word.
- **Unequal Comparator (F_NE):** The **AW_TO_AX** encapsulates the **F_NE** block and adds the adapter interfaces, enabling its use in adapter-based architectures.

Conclusion



The **AW_TO_AX** is a compact yet useful composite block for converting Word adapters to Bool adapters. Its simple comparison principle makes it ideal for integration into event-driven automation systems based on adapter interfaces. The clear separation of input and output adapters facilitates modular design and reusability.

AX_TO_AW

No image available.

BOOL Adapter Input – *AX*

AW – WORD Adapter Output

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AX_TO_AW` is a composite function block (FB) for converting a unidirectional BOOL adapter (type `AX`) into a unidirectional WORD adapter (type `AW`). It acts as an interface converter, forwarding an incoming event and a BOOL data value directly to the output adapter, with the BOOL value being implicitly converted into a WORD.

Interface Structure

Event Inputs

The function block does not have separate event inputs. The event is provided via the socket adapter `AX_IN` (type `AX`) (internal event `E1`).

Event Outputs

The function block does not have separate event outputs. The event is output via the plug adapter `AW_OUT` (type `AW`) (internal event `E1`).

Data Inputs

The function block does not have separate data inputs. The input data (BOOL) is provided via the socket adapter `AX_IN` (data point `D1`, type `BOOL`).

Data Outputs

This function block does not have separate data outputs. The output data (WORD) is provided via the plug adapter `AW_OUT` (data point `D1`, type `WORD`).

Adapter

Direction	Label	Type	Comment
Socket	AX_IN	adapter::types::unidirectional::AX	BOOL adapter input (consisting of event E1 and data D1:BOOL)
Plug	AW_OUT	adapter::types::unidirectional::AW	WORD adapter output (consisting of event E1 and data D1:WORD)

Functionality

This component forwards the event (E1) received from socket AX_IN directly to plug AW_OUT (E1). Simultaneously, the incoming BOOL value (AX_IN.D1) is passed to the WORD output (AW_OUT.D1) without further processing. An implicit type conversion takes place from BOOL to WORD (typical mapping: FALSE ⟶ 0, TRUE ⟶ 1). No logic, delay, or state change occurs – the function block (FB) functions purely as a pass-through.

Technical Features

- **Bit-reinterpretation** (structural copy between bit-string types; truncates on narrowing, zero-extends on widening).
- **Composite FB:** The function block does not have its own state machine (ECC) but consists solely of wiring the included adapter interfaces.
- **Type Conversion:** The conversion from BOOL to WORD occurs automatically via the data connection between the adapters. No explicit conversion logic is implemented.
- **Performance:** Direct coupling eliminates the need for additional processing steps, ensuring minimal latency.
- **Reusability:** This function block can be used in projects that require connecting adapters of different types without needing separate conversion logic.

State Overview

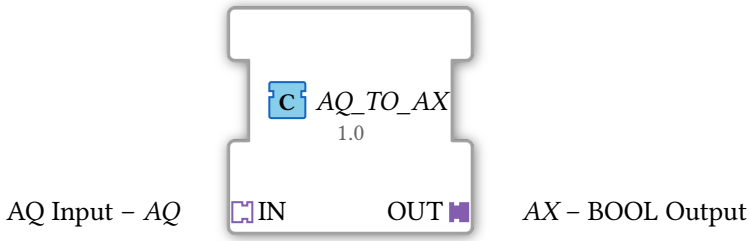
Since this is a composite function block without its own ECC, there are no explicit states. The function block behaves like a simple signal forwarder and has no behavioral model of its own.

Application Scenarios

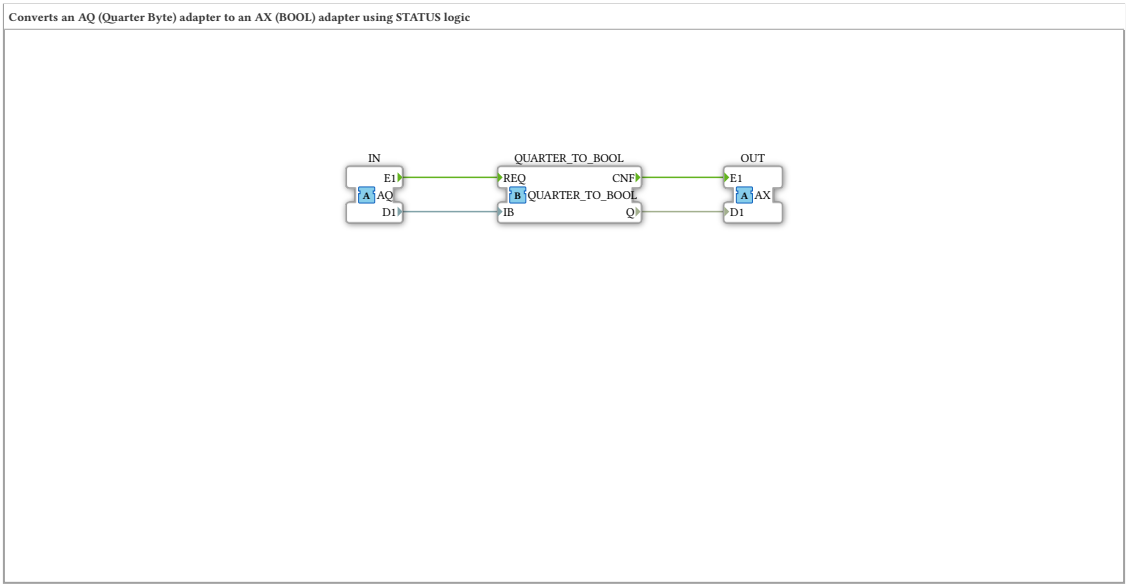
- **Connecting a BOOL-based sensor** to a control system that expects WORD interfaces (e.g., digital inputs as bitmasks).
- **Adapter layer** in libraries where components with different adapter types need to be combined without modifying the source function blocks.
- **Prototypical development** for the rapid integration of BOOL and WORD adapters prior to later optimization.

Comparison with Similar Blocks

- **AW_TO_AX (theoretical):** This would be the inverse conversion from WORD to BOOL – requiring a reduction of the value range (e.g., only bit 0 is evaluated).
- **TYPCONV Blocks:** IEC 61499 libraries typically offer explicit type converters (e.g., BOOL_TO_WORD), but these operate as standard function blocks with event and data inputs, not as adapter converters.
- **Direct Adapter Coupling:** Without AX_TO_AW, the adapter types would have to be identical, or a separate conversion would be required at the network layer.



Conclusion



The function block AX_TO_AW is a simple yet useful converter that enables coupling between BOOL and WORD adapters. Thanks to the direct pass-through of events and data with minimal overhead, it is ideally suited for interface adaptations in distributed automation systems. Its composite structure makes it transparent, easy to understand, and simple to integrate into existing projects.

Numeric Index (unidirectional)

Here you will find all exercises from the unidirectional workspace, listed in ascending order. …

AQ_TO_AX

• – ○ • – ○ • – ○ •

Introduction

The function block `AQ_TO_AX` converts an AQ adapter (Quarter Byte) to an AX adapter (BOOL) using STATUS logic. It enables the easy integration of AQ-based signals into systems that operate exclusively with AX interfaces. Internally, it uses the block `QUARTER_TO_BOOL` to perform the data conversion.

Interface Structure

Event Inputs

- No direct event inputs are available. Events are received via the AQ adapter (socket `IN`).

Event Outputs

- No direct event outputs are available. Events are sent via the AX adapter (plug `OUT`).

Data Inputs

- No direct data inputs are available. Data is received via the AQ adapter (socket `IN`).

Data Outputs

- No direct data outputs are available. Data is sent via the AX adapter (plug `OUT`).

Adapter

- **`IN` (Socket)**: Type `adapter::types::unidirectional::AQ` – AQ input (Quarter Byte)
- **`OUT` (Plug)**: Type `adapter::types::unidirectional::AX` – BOOL output (AX)

Functionality

The `AQ_TO_AX` module does not have its own event or data inputs/outputs, but performs the conversion exclusively via two adapter interfaces. Internally, an instance of the function block `QUARTER_TO_BOOL` is used:

1. **Event Forwarding**: The event `E1` of the incoming AQ adapter is connected to the `REQ` input of `QUARTER_TO_BOOL`. Its `CNF` event is output to the `E1` output of the AX adapter.
2. **Data Forwarding**: The data word `D1` of the AQ adapter (quarter byte) is forwarded to the `IB` input of `QUARTER_TO_BOOL`. The converted BOOL value from the output `Q` of `QUARTER_TO_BOOL` is passed to the `D1` output of the AX adapter.

The entire sequence control and data conversion thus takes place transparently within the function block.

Technical Features

- The function block functions purely as an adapter converter and has no states or application logic of its own; all functionality is provided by the embedded `QUARTER_TO_BOOL`.
- The use of adapters (socket/plug) allows for loose coupling in the 4diac IDE and facilitates the exchange of communication interfaces.
- The comment "using STATUS logic" indicates that the conversion may be based on a status query (e.g., valid/invalid data), which is implemented within the internal function block.

State Overview

This function block does not define its own states. The state logic is entirely contained within the internal function block `QUARTER_TO_BOOL`.

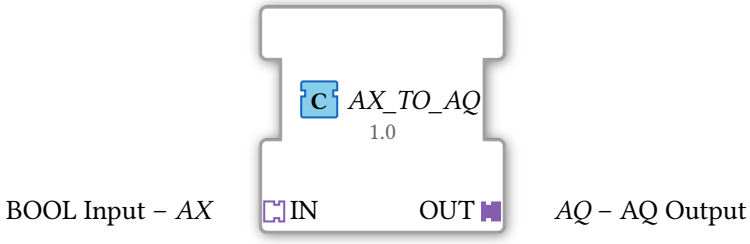
Application Scenarios

- **Interface Adaptation**: Integration of an AQ-based sensor or actuator into a system that only supports AX-compatible adapters.
- **Adapter Transformation**: Use in hierarchies where different adapter types need to be coordinated without changing the underlying data logic.
- **Prototypes and Migration**: Rapid switching between AQ and AX variants during the development or testing phase.

Comparison with Similar Function Blocks

- **`QUARTER_TO_BOOL`**: Direct conversion of a quarter-byte value to a BOOL value with its own event interface; `AQ_TO_AX` encapsulates this function block in an adapter context.
- **`BYTE_TO_BOOL` or `WORD_TO_BOOL`**: Similar converters for other bit widths, but not specifically designed for adapter coupling.
- **Direct coupling of AQ and AX**: A connection would not be possible without conversion, as the adapter types are incompatible.

Conclusion



AQ_TO_AX` is a lean yet essential adapter converter that bridges the gap between AQ and AX interfaces. It simplifies the integration of quarter-byte signals into BOOL-based controllers and contributes to the reusability of function blocks in different adapter environments.

]

AX_TO_AQ

• — ○ • — ○ • — ○ •

Introduction

The **AX_TO_AQ** function block converts a Boolean signal (AX adapter) into a quarter-byte signal (AQ adapter). The conversion is based on event-driven COMMAND logic, where an incoming event triggers the conversion and the result is acknowledged via an output event. The function block encapsulates the conversion logic in an internal sub-function block, thus enabling a clean separation between adapter types.

Interface Structure

Event Inputs

Event	Description
`IN.E1`	Starts the conversion of the incoming Boolean value. Interpreted as a command.

Event Outputs

Event	Description
`OUT.E1`	Confirms the completion of the conversion and signals the validity of the output quarter-byte value.

Data Inputs

Data	Type	Description
`IN.D1`	BOOL (via AX adapter)	Boolean input value to be converted into a quarter byte.

Data Outputs

Data	Type	Description
`OUT.D1`	Quarter Byte (via AQ adapter)	Output value – the converted quarter byte (4-bit representation).

Adapters

Adapter	Direction	Type	Description

IN	Socket	adapter::types::unidirectional::AX	Receives the Boolean signal. The AX adapter provides a unidirectional Boolean channel.
OUT	Plug	adapter::types::unidirectional::AQ	Provides the converted quarter-byte signal. The AQ adapter is a unidirectional quarter-byte channel.

Functionality

1. An event at IN.E1 triggers the internal processing.
2. The sub-function block BOOL_TO_QUARTER is activated via its event input REQ and converts the Boolean value at I into a quarter byte.
3. After the conversion is complete, BOOL_TO_QUARTER reports this via its event CNF, which is then passed on to OUT.E1.
4. Simultaneously, the converted value is transferred via the data connection from the output QB of the sub-block to OUT.D1.

The entire process is event-driven and operates without internal state storage – each command generates a complete conversion.

Technical Features

- **Internal Encapsulation**: The conversion logic is fully implemented by the embedded function block logiBUS::utils::quarter::BOOL_TO_QUARTER. This simplifies maintenance and replacement of the conversion implementation.
- **Unidirectionality**: Both the input and output adapters are unidirectional; Feedback or bidirectional use is not supported.
- **Event Synchronization**: The output event pulse OUT.E1 guarantees that the data at output OUT.D1 is valid before the calling block continues processing.
- **License and Origin**: The block is licensed under EPL-2.0 and is included in the package adapter::conversion::unidirectional (see CompilerInfo).

State Overview

The function block does not have an explicit state machine. It operates as pure combinational logic with event-driven triggering:

- **Idle State**: No event is present at IN.E1. Outputs remain unchanged.
- **Active**: An event at IN.E1 starts the conversion. Upon completion, OUT.E1 is triggered, and the new value is output to OUT.D1. The function block then returns to its idle state.

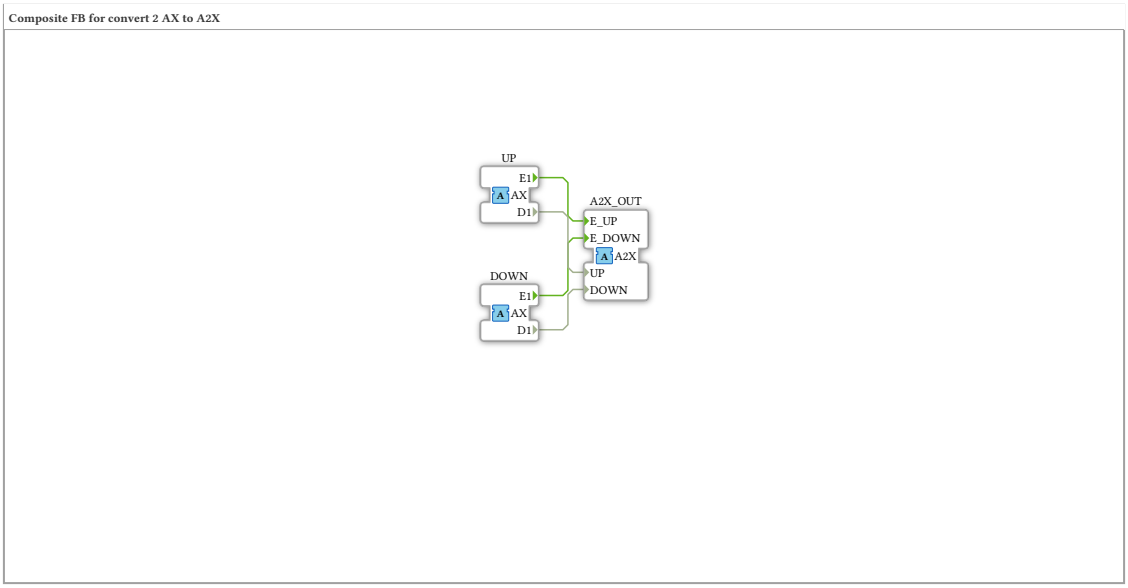
Application Scenarios

- **Bus Signal Translation**: In an industrial bus system, Boolean control signals (e.g., bit values from sensors) are converted into compact 4-bit data words to reduce bandwidth.
- **Bit-to-Quarter-Byte Converter in Automation Networks**: When a subsystem can only process quarter-byte values but receives Boolean inputs.
- **Adapter Bridge**: The function block acts as an intermediary between an AX-compatible transmitter and an AQ-compatible receiver in a unidirectional chain.

Comparison with Similar Function Blocks

Function Block	Task	Difference
BOOL_TO_BYTE	Converts BOOL to a byte (8-bit)	Works with 8-bit output instead of 4-bit. Requires other adapter types (e.g., AB).
BOOL_TO_WORD	Converts BOOL to a word (16-bit)	Provides a wider output, often for analog or digital word signals.

AX_TO_AQ	Converts BOOL (AX) to a quarter byte (AQ)	Specifically designed for the unidirectional AX↔AQ adapter combination, it generates only 4-bit values.

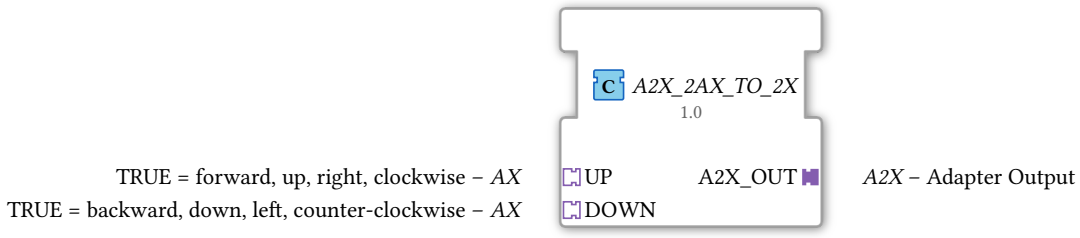


Conclusion

The **AX_TO_AQ** function block is a specialized and compact converter for converting Boolean adapter signals into the quarter-byte format. Its clear, event-driven structure and internal reuse of a standardized conversion block make it ideal for use in automation and bus systems where space-saving transmission of Boolean states is required. The simple interface and unidirectional nature facilitate integration into existing communication workflows.

Numerical Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace in ascending order.



A2X_2AX_TO_2X

• – ◦ • – ◦ • – ◦ •

Introduction

The A2X_2AX_TO_2X is a composite function block used to convert two AX signals into one A2X signal. This block allows the combination of two unidirectional AX adapter signals into a single A2X adapter output.

Interface Structure

Event Inputs

No direct event inputs available

Event Outputs

No direct event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Sockets (Inputs):

- **UP**: AX adapter for positive direction of movement (TRUE = forward, up, right, clockwise)
- **DOWN**: AX adapter for negative direction of movement (TRUE = backward, down, left, counterclockwise)

Plugs (Outputs):

- **A2X_OUT**: A2X adapter output for the combined signals

Functionality

The composite function block connects the two AX adapter inputs (UP and DOWN) directly to the A2X adapter output. Both event and data signals are forwarded:

- UP events and data are forwarded to E_UP and UP of the A2X_OUT adapter.
- DOWN events and data are forwarded to E_DOWN and DOWN of the A2X_OUT adapter.

Technical Features

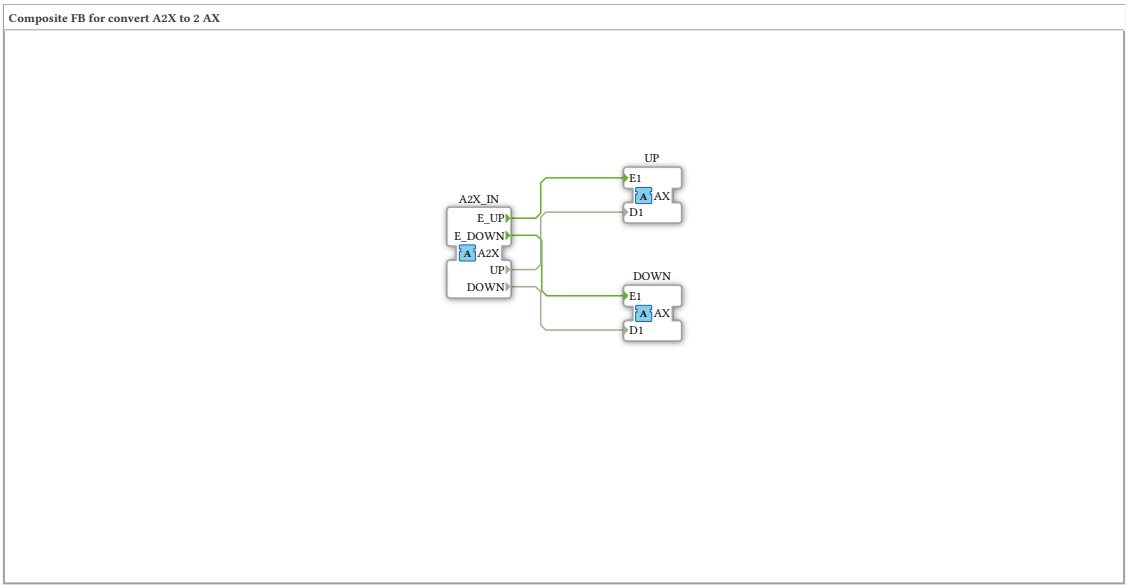
- Implemented as a composite function block without internal logic
- Direct signal pass-through without delay
- Uses unidirectional adapter types
- No state or internal processing

State Overview

The function block has no internal states, as it is a pure pass-through function.

Application Scenarios

- Combining two separate motion control signals
- Converting AX-based control systems to A2X interfaces
- Integration into larger control systems with A2X interface requirements
- Bidirectional motion sensing in automation systems

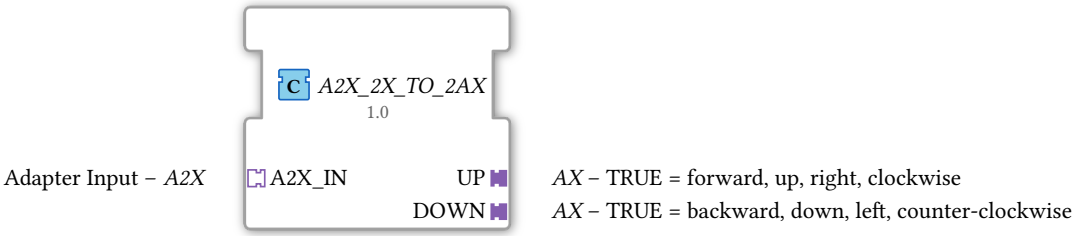


⚖️ Comparison with similar components

Compared to simple AX adapters, this component enables the combination of two opposing motion directions into a single A2X signal. It eliminates the need for manual wiring of two AX adapters to create one A2X adapter.

Conclusion

The A2X_2AX_TO_2X is a simple yet effective composite function block that simplifies the integration of AX-based control components into systems with A2X interfaces. Direct signal forwarding without additional processing ensures reliable and lossless signal transmission.



A2X_2X_TO_2AX

• – ○ • – ○ • – ○ •

Introduction

The A2X_2X_TO_2AX is a composite function block used to convert A2X signals into two separate AX signals. This block enables the conversion of bidirectional control signals into unidirectional motion commands.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- No direct event outputs available

Data Inputs

- No direct data inputs available

Data Outputs

- No direct data outputs available

Adapters

Input Adapters:

- `A2X_IN` (Socket) - Adapter input of type `adapter::types::unidirectional::A2X`

Output Adapters:

- `UP` (Plug) - Output for positive movement direction (TRUE = forward, up, right, clockwise)
- `DOWN` (Plug) - Output for negative movement direction (TRUE (backwards, down, left, counterclockwise)

Functionality

The composite function block forwards events and data directly from the A2X_IN adapter to the corresponding UP and DOWN output adapters:

- The E_UP event is forwarded to UP.E1
- The E_DOWN event is forwarded to DOWN.E1
- The UP data is forwarded to UP.D1
- The DOWN data is forwarded to DOWN.D1

Technical Features

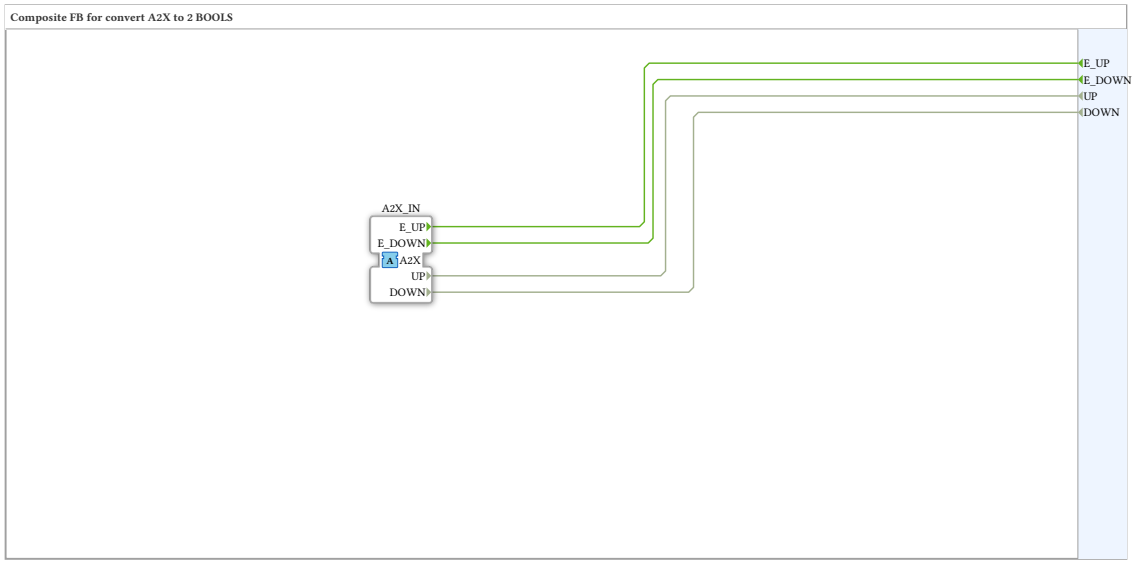
- Implemented as a composite function block without internal logic
- Direct signal forwarding without delay
- Uses unidirectional adapter types for clear signal flow

State Overview

The function block has no internal state and operates stateless. All input signals are immediately forwarded to the corresponding outputs.

Application Scenarios

- Conversion of bidirectional drive signals into separate forward/reverse controls
- Control of actuators with separate extension and retraction commands
- Integration into control systems with different signal formats
- Speed control with separate clockwise/counterclockwise controls

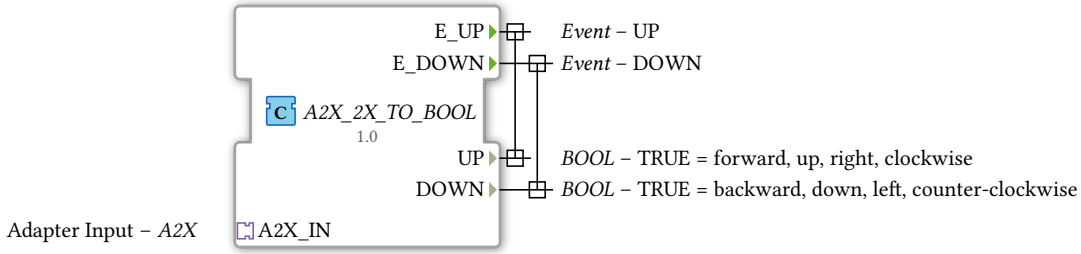


⚖️ Comparison with similar function blocks

Compared to simple converter function blocks, this composite function block offers a structured solution for splitting bidirectional signals into two independent unidirectional channels. The use of standardized adapter types ensures compatibility within the adapter framework.

Conclusion

The A2X_2X_TO_2AX function block represents an efficient and standards-compliant solution for signal conversion. Its simple, direct routing logic and the use of established adapter types make it ideal for integration into more complex control systems that require the separation of motion directions.



A2X_2X_TO_BOOL

• – ○ • – ○ • – ○ •

Introduction

The A2X_2X_TO_BOOL function block is a composite function block used to convert A2X signals into two separate BOOL signals. It enables the conversion of bidirectional control signals into simple logic outputs for various applications.

Interface Structure

Event Inputs

No direct event inputs available

Event Outputs

- **E_UP**: Activated when an upward/forward movement is detected
- **E_DOWN**: Activated when a downward/backward movement is detected

Data Inputs

No direct data inputs available

Data Outputs

- **UP**: BOOL - TRUE for forward, upward, right, or clockwise
- **DOWN**: BOOL - TRUE for backward, downward, left, or counterclockwise

Adapter

- **A2X_IN**: A2X adapter input for unidirectional communication

Functionality

The function block receives signals via the A2X adapter and forwards them directly to the corresponding outputs. The events and data values are passed directly from the adapter to the output interfaces without any additional processing or delay.

Technical Features

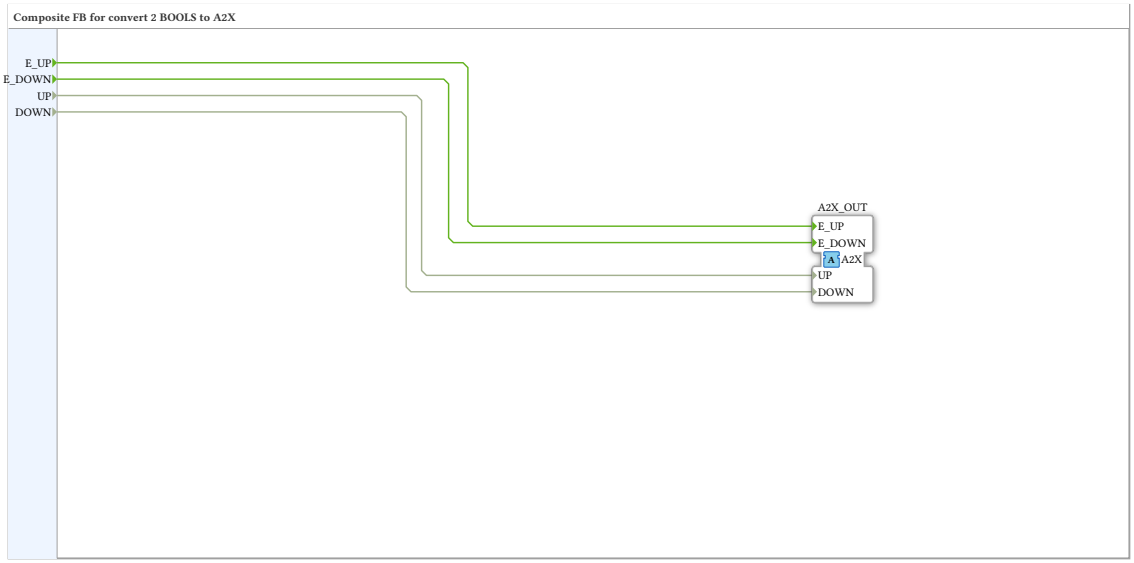
- Composite function block without internal logic
- Direct pass-through of adapter signals
- No state retention or storage
- Real-time signal forwarding

State Overview

The function block has no internal states. It behaves purely combinatorially and immediately forwards incoming signals to the outputs.

Application Scenarios

- Control of motion directions in actuators
- Conversion of complex control signals into simple direction commands
- Connection of A2X-compatible components to BOOL-based controllers
- Direction detection in drive systems

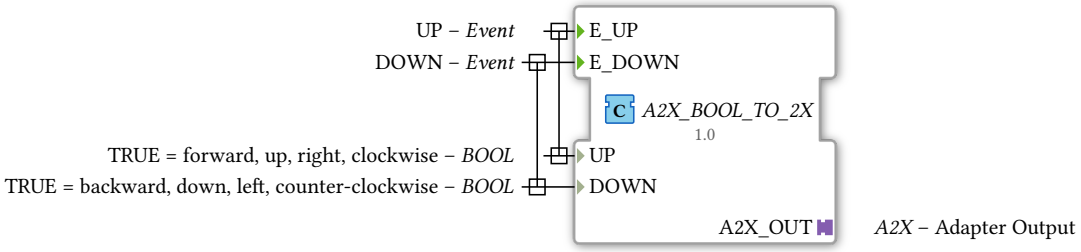


⚖️ Comparison with Similar Blocks

Compared to other conversion blocks, A2X_2X_TO_BOOL offers a specific solution for converting A2X signals into Boolean direction signals. Other function blocks could offer additional features such as filtering, delay, or more complex signal processing.

Conclusion

The A2X_2X_TO_BOOL function block provides a simple and efficient solution for converting A2X control signals into Boolean directional outputs. Its clear interface definition and direct signal routing make it particularly suitable for applications requiring unadulterated transmission of control information.



A2X_BOOL_TO_2X

• – ○ • – ○ • – ○ •

Introduction

The A2X_BOOL_TO_2X is a compound function block that converts two BOOL values into an A2X output format. This block serves as a bridge between simple Boolean control signals and the standardized A2X adapter interface.

Interface Structure

Event Inputs

- **E_UP**: Event input for up/forward movement
- **E_DOWN**: Event input for down/backward movement

Event Outputs

No direct event outputs available

Data Inputs

- **UP**: BOOL input for up/forward direction (TRUE = forward, up, right, clockwise)
- **DOWN**: BOOL input for down/backward direction (TRUE = backward, down, left, counterclockwise)

Data Outputs

No direct data outputs available

Adapters

- **A2X_OUT**: Unidirectional A2X output adapter for forwarding the converted signals

Functionality

The function block receives two independent Boolean input signals (UP and DOWN) along with their corresponding event inputs are passed directly to the A2X output adapter, with event and data connections processed in parallel.

Technical Features

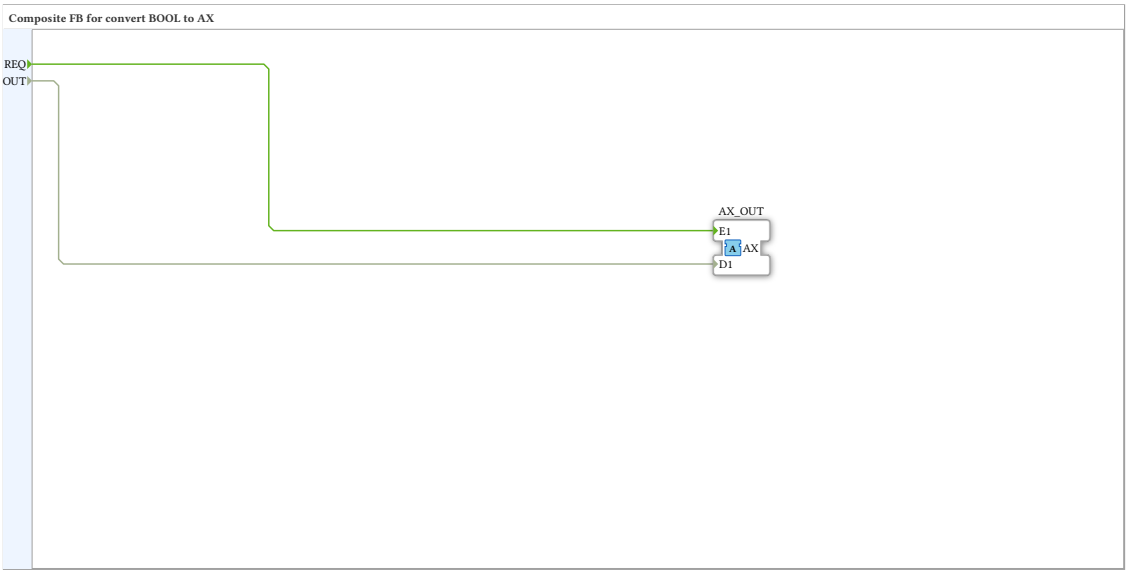
- Completely unidirectional signal processing
- Direct pass-through without additional logic processing
- Uses the standardized A2X adapter interface
- No internal states or delays

State Overview

The function block has no internal states and operates stateless. Every incoming event is immediately passed to the corresponding adapter output.

Application Scenarios

- Control of bidirectional actuators (e.g., motors, cylinders)
- Interface between simple switching logic and more complex control systems
- Conversion of push-button/switch signals into standardized motion signals
- Drive controls with forward/reverse functionality

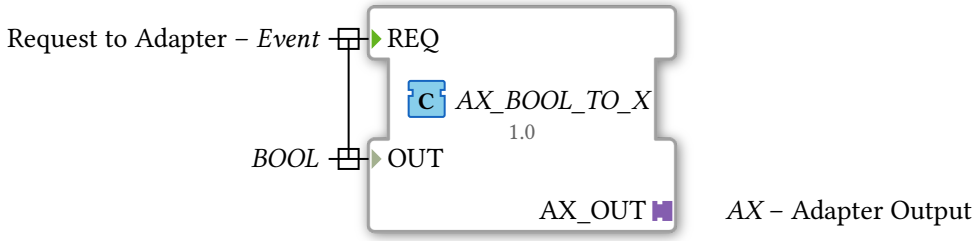


⚖️ Comparison with similar components

Compared to simple conversion components, A2X_BOOL_TO_2X offers the specific combination of two Boolean inputs with a standardized A2X interface. Other components might perform individual BOOL-to-A2X conversions, but this component combines both directions in a single component.

Conclusion

The A2X_BOOL_TO_2X is a specialized interface component that provides a simple and efficient interface between basic Boolean control signals and the standardized A2X protocol. Its clear structure and direct pass-through make it a reliable solution for bidirectional control applications.



AX_BOOL_TO_X

• — ○ • — ○ • — ○ •

Introduction

The AX_BOOL_TO_X function block is a composite function block used to convert a BOOL value into the AX adapter format. It enables the easy conversion of Boolean values into a standardized output format for further processing in automation systems.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

- No direct event outputs available

Data Inputs

- **OUT**: BOOL input value to be converted

Data Outputs

- No direct data outputs available

Adapters

- **AX_OUT**: Unidirectional AX adapter output for the converted data

Functionality

The function block receives a Boolean value at the OUT data input and converts it to the AX adapter format upon arrival of the REQ event. The conversion is automatic, and the converted value is output via the AX_OUT adapter. The block acts as a bridge between simple Boolean signals and the standardized AX communication format.

Technical Features

- Composite function block with internal networking
- Uses a unidirectional AX adapter for output
- Automatic forwarding of events and data to the adapter
- Simple and direct signal conversion without additional logic

State Overview

The function block has a simple state machine:

1. **Wait state**: Waits for a REQ event
2. **Process state**: Upon a REQ event, the BOOL value is converted and output via the adapter
3. Returns to wait state after conversion is complete

Application Scenarios

- Integration of simple switching states into more complex AX-based systems
- Interface adaptation between different automation components
- Protocol conversion in distributed control systems
- Integration of basic sensors into AX-compliant architectures

⚖️ Comparison with Similar Blocks

Compared to other conversion blocks, AX_BOOL_TO_X stands out due to its specific focus on the AX adapter format. While general conversion blocks often support multiple output formats, this block offers an optimized solution for the specific AX interface.

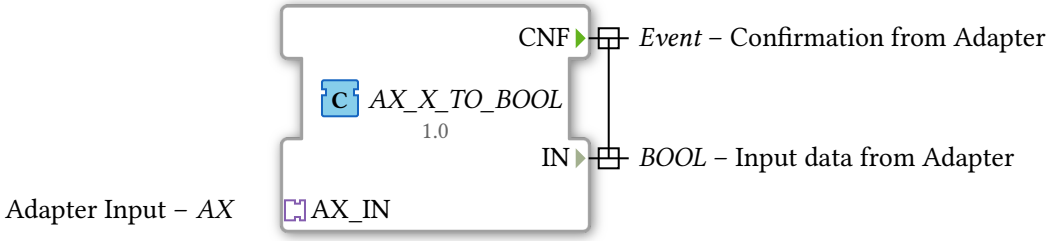
- Exercise_002a2_AX
- Exercise_004b_AX
- Exercise_004b_AX_ASR
- Exercise_004b_AX_ASR_X

Conclusion

AX_BOOL_TO_X is a specialized conversion block that provides a simple and efficient interface between Boolean signals and the AX adapter format. Its clear structure and direct functionality make it a reliable solution for integration tasks in automation systems.



AX_X_TO_BOOL

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_X_TO_BOOL function block is a composite function block designed for converting AX data to the BOOL data type. This block acts as an adapter converter and enables unidirectional data conversion between different data types in 4diac systems.

Interface Structure

Event Inputs

No direct event inputs are available.

Event Outputs

- **CNF** (Confirmation): Confirmation event output by the adapter.

Data Inputs

No direct data inputs are available.

Data Outputs

- **IN** (BOOL): Converted input data from the adapter.

Adapter

- **AX_IN**: Adapter input of type AX for unidirectional data transmission.

Functionality

The function block receives data via the AX_IN adapter and converts it to the BOOL data type. Upon successful conversion, the confirmation event CNF is triggered, and the converted data is made available at the IN output. The internal structure directly connects the adapter event output E1 to the CNF output and the adapter's data output D1 to the IN data output.

Technical Features

- Implemented as a composite function block
- Uses unidirectional adapter communication
- Direct passthrough without additional processing logic
- Simple and efficient data conversion

State Overview

The function block has a simple state:

- **Ready**: Waits for incoming data from the adapter
- Upon receiving data, conversion and output occur immediately

Application Scenarios

- Integration of AX-based components into BOOL-oriented controllers
- Adapter conversion in heterogeneous automation systems
- Interface adaptation between different device types
- Protocol conversion in distributed control systems

⚖️ Comparison with Similar Function Blocks

Compared to other conversion blocks, AX_X_TO_BOOL stands out due to its specific focus on AX-to-BOOL conversion. While universal converters often require more complex parameterization, this block offers an optimized solution for this specific use case.

AB_BYTE_TO_B

• – ◦ • – ◦ • – ◦ •

Introduction

The AB_BYTE_TO_B function block is a composite function block used to convert a BYTE data type to the AB adapter format. It enables unidirectional data transfer of byte values via a standardized adapter interface.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger adapter conversion

Event Outputs

No direct event outputs available

Data Inputs

- **OUT**: BYTE input value that is forwarded to the adapter

Data Outputs

No direct data outputs available

Adapter

- **AB_OUT**: Unidirectional AB adapter output for data output

Functionality

The function block receives a request for data conversion via the REQ event input. Simultaneously, the byte value at the OUT data input is processed. Upon arrival of the REQ event, the byte value is output via the AB_OUT adapter. Data transmission is unidirectional from the function block to the connected adapter.

Technical Features

- Implemented as a composite function block with an internal network structure
- Uses the unidirectional AB adapter interface
- Direct event and data connections between inputs and the adapter
- Positioning attributes for graphical representation in the development environment

State Overview

The function block has a simple state machine:

1. **Wait State**: No active processing
2. **Activate State**: Data is forwarded to the adapter upon a REQ event
3. **Return**: Automatic return to wait state after processing

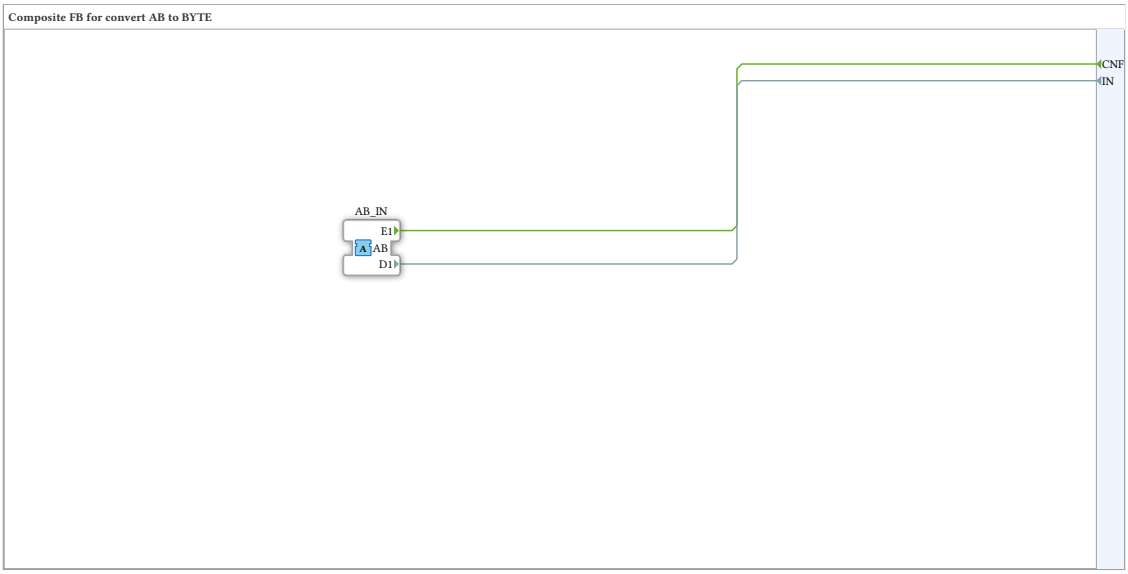
Application Scenarios

- Byte data conversion for adapter-based communication
- Integration into larger control systems with standardized adapter interfaces
- Data preparation for downstream processing components
- Protocol conversion for different data types

⚖️ Comparison with Similar Blocks

Compared to simple conversion blocks, AB_BYTE_TO_B offers the advantage of a standardized adapter interface, which allows for better reusability and integration. in more complex system architectures. Its unidirectional design makes it particularly suitable for output scenarios.

Conclusion



AB_BYTE_TO_B is a specialized conversion module that, thanks to its adapter-based architecture, enables flexible and standards-compliant integration into 4diac-based control systems. Its simple and robust operation makes it a reliable solution for byte-to-adapter conversions.

AB_B_TO_BYTE

• – ◦ • – ◦ • – ◦ •

Introduction

The AB_B_TO_BYTE function block is a composite function block used to convert AB data to the BYTE format. It acts as an adapter converter and enables the seamless integration of AB data sources into systems that expect BYTE data.

Interface Structure

Event Inputs

No direct event inputs are available – events are received via the adapter.

Event Outputs

- **CNF** (Confirmation): Confirmation event received by the adapter

Data Inputs

No direct data inputs are available – data is received via the adapter.

Data Outputs

- **IN** (BYTE): Input data converted by the adapter

Adapter

- **AB_IN**: Adapter input of type `adapter::types::unidirectional::AB` for receiving AB data

Functionality

The function block receives AB data via the adapter input AB_IN and converts it to the BYTE format. Upon receiving data via the adapter, the acknowledgment event CNF is automatically triggered, and the converted data is made available at the IN output.

Technical Features

- Implemented as a composite function block with an internal network structure
- Uses unidirectional adapter communication
- Automatic event forwarding from the adapter to the CNF output
- Direct data forwarding from the adapter to the IN output

State Overview

The function block operates without state and reacts immediately to incoming adapter events. Each E1 event from the adapter triggers the CNF event and outputs the adapter's current D1 data to IN.

Application Scenarios

- Integration of AB-based sensors or actuators into BYTE-oriented control systems
- Protocol conversion in industrial automation systems
- Adapter-based data conversion in distributed control systems

⚖️ Comparison with Similar Function Blocks

Compared to simple conversion blocks, AB_B_TO_BYTE offers the advantage of adapter integration, enabling a standardized and type-safe interface. Other conversion blocks typically use direct inputs/outputs instead of adapters.

Conclusion

AB_B_TO_BYTE provides an elegant solution for converting AB to BYTE data using adapter interfaces. The composite implementation ensures robust and reliable data conversion, which is particularly advantageous in complex automation systems with standardized communication interfaces.

ADI_DINT_TO_DI

Introduction

The ADI_DINT_TO_DI function block is a composite function block used to convert a DINT value to the ADI adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

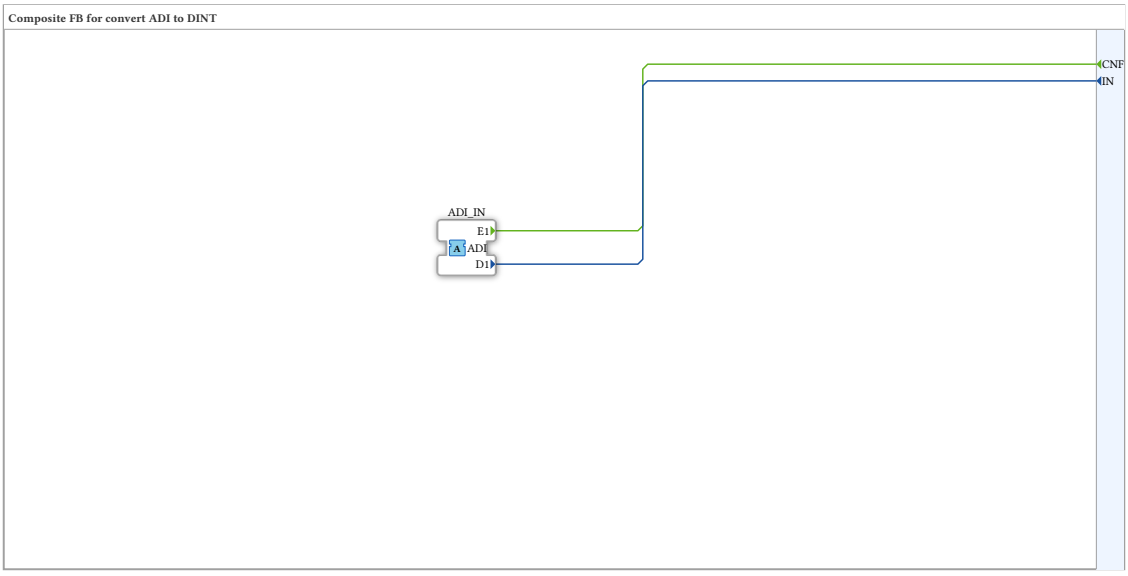
- No direct event outputs available

Data Inputs

- **OUT**: DINT input value to be converted

Data Outputs

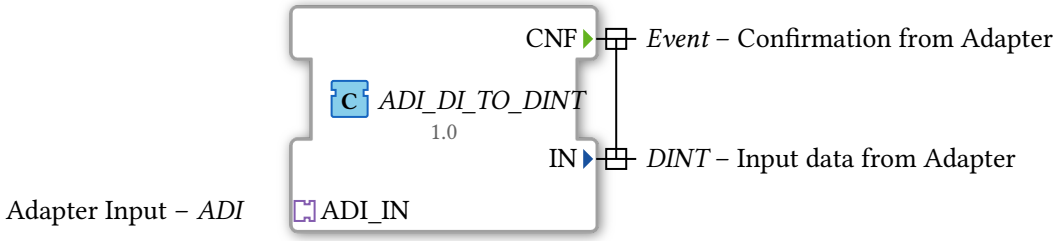
- No direct data outputs available



Adapter

- **ADI_OUT**: Plug of type `ADI`

Functionality



The function block receives a DINT value at the data input OUT and converts it to the ADI adapter format upon arrival of the REQ event.

ADI_DI_TO_DINT

Introduction

The ADI_DI_TO_DINT function block is a composite function block used to convert the ADI adapter format to a DINT value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

Data Outputs

- **IN**: DINT output value of the converted data

Adapter

- **ADI_IN**: Socket of type `ADI`

Functionality

The function block receives data via the ADI adapter socket and makes the contained DINT value available at the IN output as soon as an event arrives via the adapter (CNF).

AD_DWORD_TO_D

Introduction

The AD_DWORD_TO_D function block is a composite function block used to convert a DWORD value to the AD adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

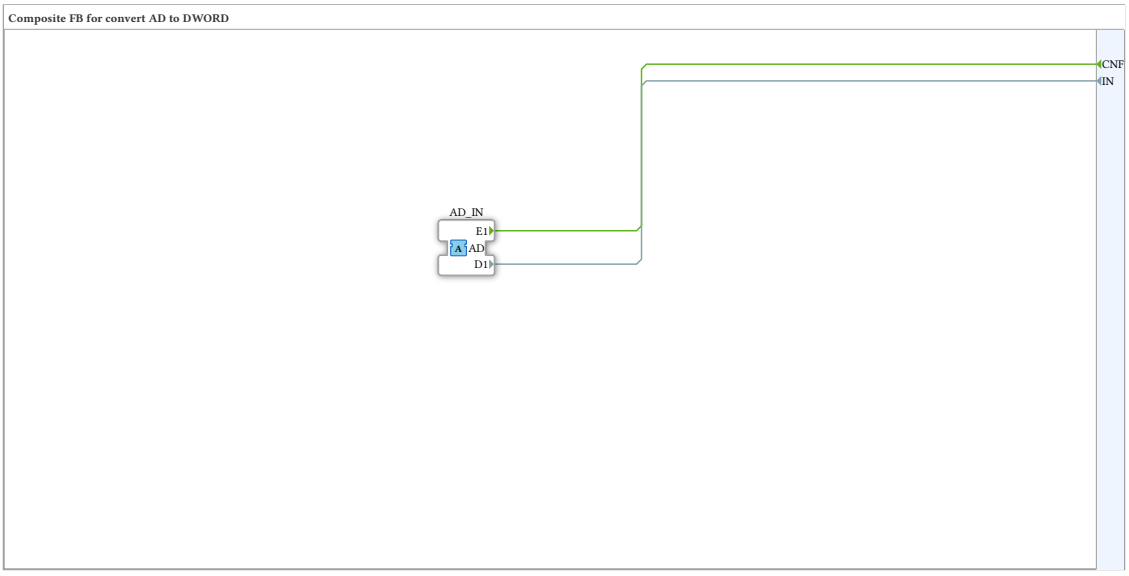
- No direct event outputs available

Data Inputs

- **OUT**: DWORD input value to be converted

Data Outputs

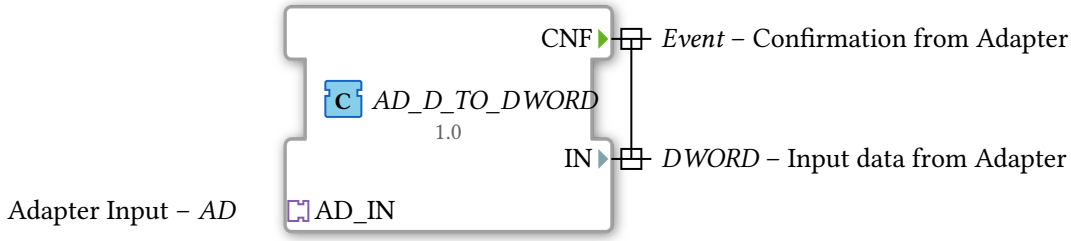
- No direct data outputs available



Adapter

- **AD_OUT**: Plug of type `AD`

Functionality



The function block receives a DWORD value at the OUT data input and converts it to the AD adapter format upon arrival of the REQ event.

AD_D_TO_DWORD

Introduction

The AD_D_TO_DWORD function block is a composite function block used to convert the AD adapter format to a DWORD value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

Data Outputs

- **IN**: DWORD output value of the converted data

Adapter

- **AD_IN**: Socket of type `AD`

Functionality

The function block receives data via the AD adapter socket and makes the contained DWORD value available at the IN output as soon as an event arrives via the adapter (CNF).

AE_EVENT_TO_E

• – ○ • – ○ • – ○ •

Introduction

The AE_EVENT_TO_E function block is a composite function block used to convert events into AE adapter signals. It enables the conversion of a simple event into an adapter-based output signal, which is particularly useful when integrating various communication interfaces.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger adapter conversion

Event Outputs

- No direct event outputs available

Data Inputs

- No data inputs available

Data Outputs

- No data outputs available

Adapter

- **AE_OUT**: Unidirectional AE adapter output for forwarding the converted events

Functionality

This function block acts as a simple converter that forwards incoming REQ events directly to the AE_OUT adapter. Each time a REQ event arrives, the corresponding E1 event is triggered at the AE adapter output. No data processing or transformation takes place, as the block only forwards events.

Technical Features

- Composite function block with a simple network structure
- Uses a unidirectional AE adapter interface
- Contains no data processing components
- Direct event forwarding without delay

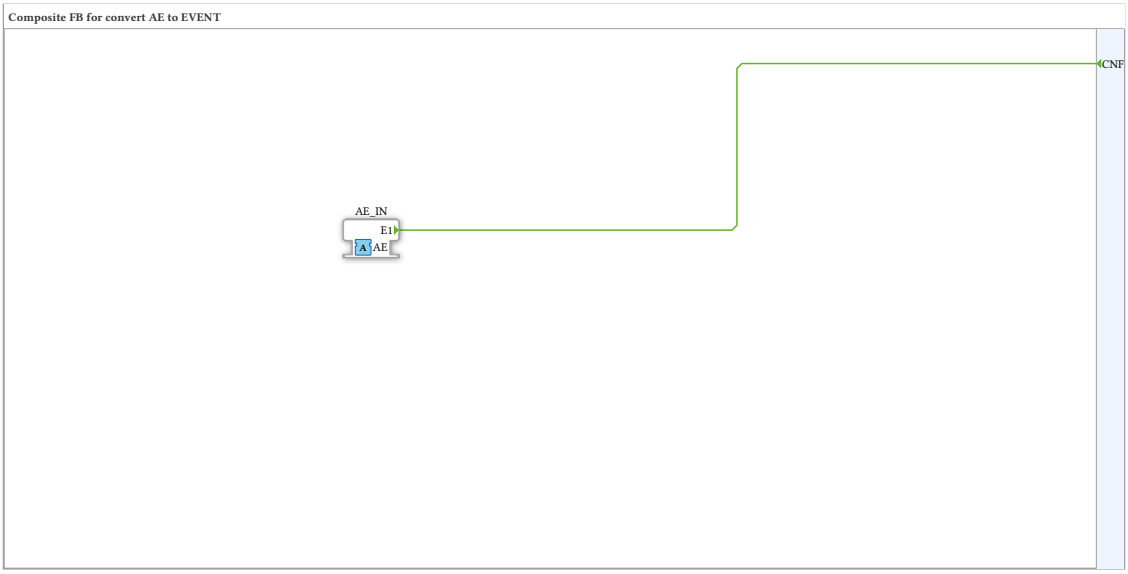
State Overview

The function block has a simple state:

- **Ready**: Waits for incoming REQ events
- Upon arrival of a REQ, AE_OUT.E1 is immediately triggered, and the block returns to the ready state

Application Scenarios

- Integration of event-based systems into adapter-based architectures
- Coupling of different communication protocols
- As a bridge between simple events and more complex adapter interfaces
- In systems requiring a standardized AE interface



⚖️ Comparison with Similar Blocks

Compared to other conversion blocks, AE_EVENT_TO_E is characterized by its simplicity. While other converters often perform data processing or protocol translation, this block is limited to pure event forwarding. It is specifically optimized for integration into adapter-based systems.

Conclusion

AE_EVENT_TO_E is a specialized function block for the simple conversion of events into AE adapter signals. Its strength lies in its minimalist implementation and reliable event forwarding, making it ideal for system integrations where no data processing is required.

AE_E_TO_EVENT

• – ○ • – ○ • – ○ •

Introduction

The AE_E_TO_EVENT function block is a composite function block used to convert adapter events into standard events. It enables the conversion of adapter signals into generally usable event outputs and serves as a bridge between adapter interfaces and standardized event-based communication structures.

Interface Structure

Event Inputs

No direct event inputs available

Event Outputs

- **CNF** - Acknowledge event from the adapter

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapter

- **AE_IN** - Adapter input of type `adapter::types::unidirectional::AE`

Functionality

The function block forwards the E1 event from the adapter input AE_IN directly to the CNF output. This is a simple pass-through functionality where adapter events are converted into standardized function block events.

Technical Features

- Unidirectional signal processing
- No data processing or conversion
- Direct event forwarding without delay
- Positioning of the CNF output at Y position 46

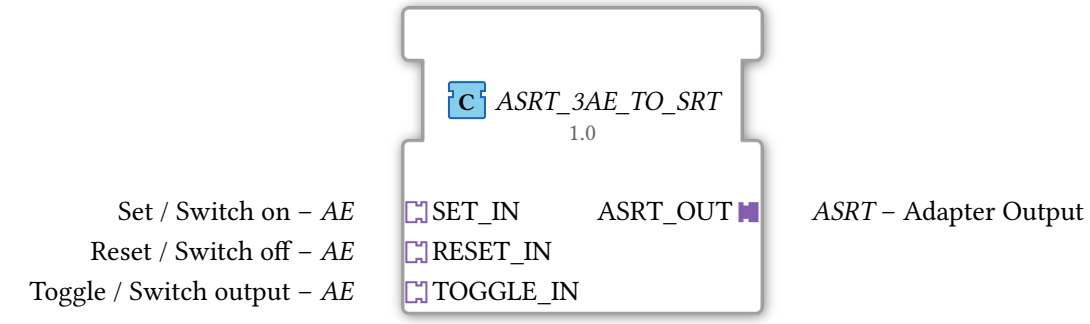
State Overview

The function block has a simple state:

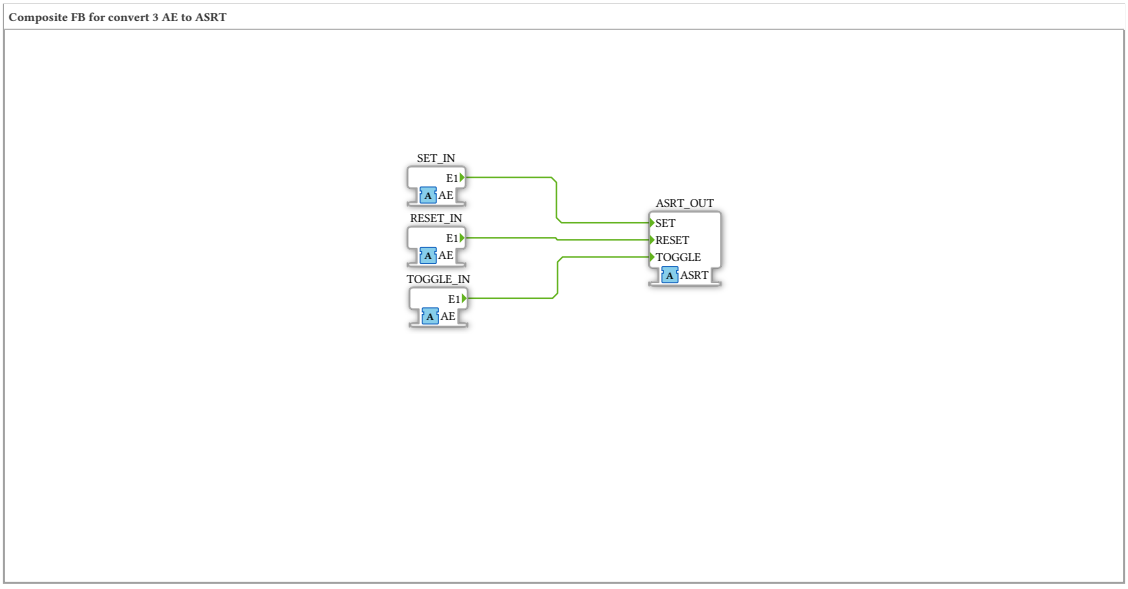
- **Ready**: Waiting for an E1 event from the adapter
- Upon arrival of E1, CNF is triggered immediately

Application Scenarios

- Integration of adapter interfaces into existing function block networks
- Coupling of different communication protocols
- Extension of systems with specific adapter requirements
- Protocol implementation in distributed automation systems



⚖️ Comparison with Similar Blocks



Compared to other conversion blocks, AE_E_TO_EVENT is characterized by its simplicity. While other converters often offer additional data processing or signal conditioning, this block is limited to pure event forwarding.

Conclusion

The AE_E_TO_EVENT function block represents a streamlined and efficient solution for adapter integration. Its simplicity makes it reliable and easy to understand, while simultaneously fulfilling the necessary bridging function between adapter interfaces and standardized event systems.

ASRT_3AE_TO_SRT

• – ○ • – ○ • – ○ •

Introduction

The function block **ASRT_3AE_TO_SRT** is a composite FB that merges three separate unidirectional AE adapters (pure event, no payload data) into one common ASRT adapter (a set/reset/toggle event triple). It is the `TOGGLE`-extended variant of ASR_2AE_TO_SR and the adapter-based counterpart of ASRT_3EVENTS_TO_SRT.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket	`SET_IN`	`adapter::types::unidirectional::AE`	Set / switch on.

Socket	RESET_IN	adapter::types::unidirectional::AE	Reset / switch off.
Socket	TOGGLE_IN	adapter::types::unidirectional::AE	Toggle / invert output.
Plug	ASRT_OUT	adapter::types::unidirectional::ASRT	Merged set/reset/toggle signal.

Functionality

The block is a pure FBNetwork of three event connections with no algorithms of its own: SET_IN.E1 is wired directly to ASRT_OUT.SET, RESET_IN.E1 to ASRT_OUT.RESET, and TOGGLE_IN.E1 to ASRT_OUT.TOGGLE. An event at the respective AE socket immediately triggers the matching event at the ASRT plug.

Technical Features

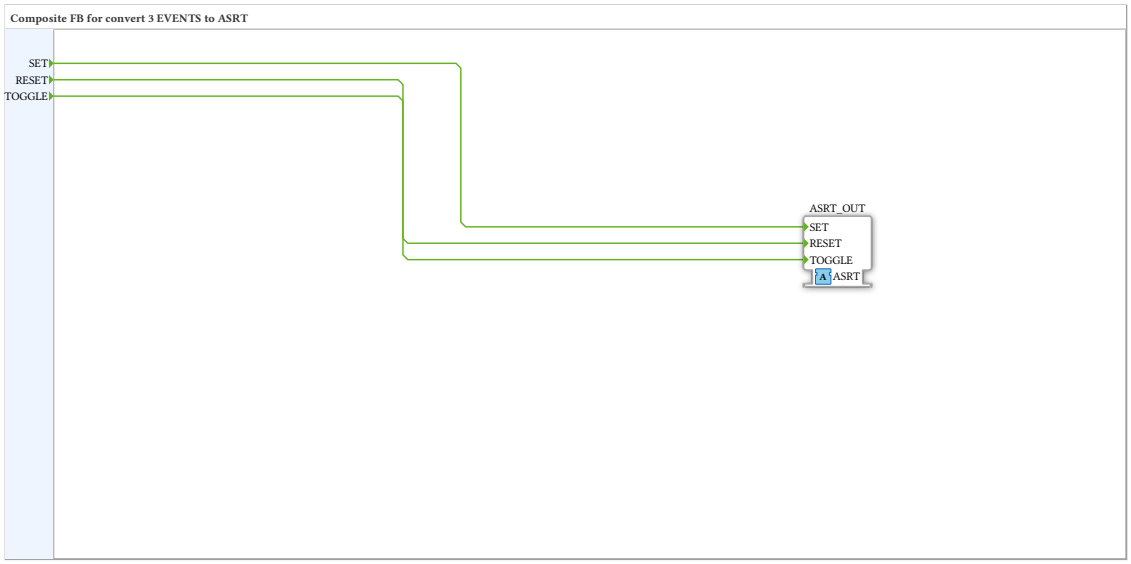
- **Pure wiring**: A composite FB with no ECC or algorithms, consisting solely of three direct event connections.
- **Adapter-based instead of event-based**: Unlike ASRT_3EVENTS_TO_SRT (classic event inputs), this block uses AE adapter sockets, letting it fit seamlessly into adapter-based networks.

State Overview

The function block has **no state machine**. Every event at SET_IN, RESET_IN, or TOGGLE_IN is forwarded immediately as the matching event type to ASRT_OUT.

Application Scenarios

- **Merging three AE signal sources** (e.g. from ASRT_MERGE_2 or directly from sensors) into a single ASRT adapter for downstream set/reset/toggle logic such as AX_T_FF_SR.
- **Adapterizing** existing AE-based networks to connect them to ASRT interfaces.

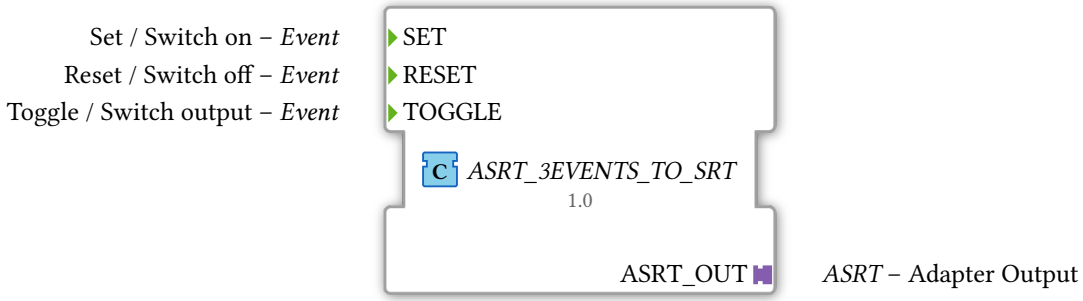


Comparison with Similar Components

- **ASRT_SRT_TO_3AE**: the reverse direction – splits an ASRT signal back into three AE adapters.
- **ASRT_3EVENTS_TO_SRT**: the same functionality with classic event inputs instead of AE adapter sockets.
- **ASR_2AE_TO_SR**: the TOGGLE-reduced variant for ASR.
- **ASRT_SR_AE_TO_SRT**: the same merge, but with SET/RESET already provided as a ready-made ASR adapter instead of two separate AE sockets.

Conclusion

ASRT_3AE_TO_SRT is a simple, pure-wiring solution for merging three AE adapters into one ASRT adapter, suitable for seamlessly integrating AE-based event sources into ASRT interfaces.



ASRT_3EVENTS_TO_SRT

• – ◦ • – ◦ • – ◦ •

Introduction

The ASRT_3EVENTS_TO_SRT function block is a composite function block that converts three separate events (Set/Reset/Toggle) into an ASRT signal. It serves as a bridge between event-based control signals and the ASRT adapter format, and is the TOGGLE-extended variant of ASR_2EVENTS_TO_SR.

Interface Structure

Event Inputs

- **SET**: Sets the output signal (power on)
- **RESET**: Resets the output signal (power off)
- **TOGGLE**: Inverts the output signal

Event Outputs

No direct event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapter

- **ASRT_OUT**: Unidirectional ASRT adapter output

Functionality

This function block forwards incoming SET, RESET, and TOGGLE events directly to the ASRT adapter. A SET event activates the corresponding SET signal on the ASRT adapter, a RESET event activates the RESET signal, and a TOGGLE event activates the TOGGLE signal.

Technical Features

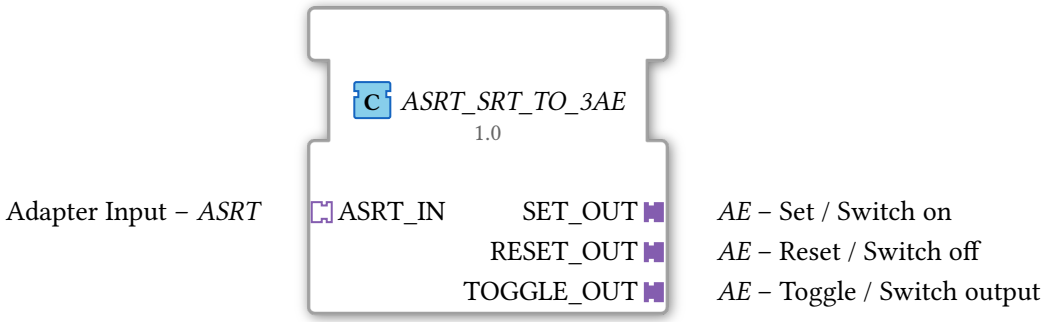
- Composite function block without internal logic processing
- Direct event pass-through to the adapter
- Uses unidirectional ASRT adapter technology

State Overview

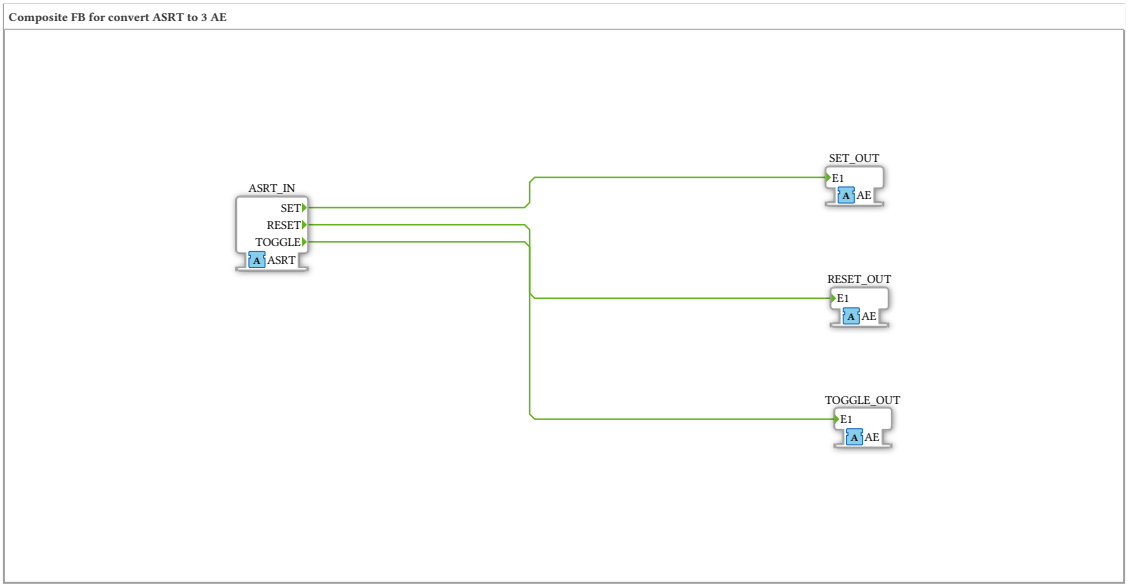
The function block has no internal state. It acts purely as a signal relay between the event inputs and the ASRT adapter.

Application Scenarios

- Integration of event-based control systems into ASRT-compatible environments
- Connection between different control levels
- Protocol implementation in automation systems



⚖️ Comparison with Similar Blocks



Compared to ASR_2EVENTS_TO_SR, ASRT_3EVENTS_TO_SRT additionally provides the TOGGLE event and therefore feeds an ASRT adapter instead of an ASR adapter.

Conclusion

ASRT_3EVENTS_TO_SRT is a specialized function block for converting three separate events (Set/Reset/Toggle) into the ASRT adapter format. Its simple and straightforward operation makes it a reliable solution for system integrations.

ASRT_SRT_TO_3AE

• – ○ • – ○ • – ○ •

Introduction

The function block **ASRT_SRT_TO_3AE** is a composite FB that splits a unidirectional ASRT adapter (a set/reset/toggle event triple) into three separate AE adapters (pure event, no payload data). It is the reverse of ASRT_3AE_TO_SRT and the adapter-based counterpart of ASRT_SRT_TO_3EVENTS.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter socket.

Event Outputs

None. Events are forwarded exclusively via the adapter plugs.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket	ASRT_IN	adapter::types::unidirectional::ASRT	Incoming set/reset/toggle signal.
Plug	SET_OUT	adapter::types::unidirectional::AE	Set / switch on.
Plug	RESET_OUT	adapter::types::unidirectional::AE	Reset / switch off.
Plug	TOGGLE_OUT	adapter::types::unidirectional::AE	Toggle / invert output.

Functionality

The block is a pure FBNetwork of three event connections with no algorithms of its own: ASRT_IN.SET is wired directly to SET_OUT.E1, ASRT_IN.RESET to RESET_OUT.E1, and ASRT_IN.TOGGLE to TOGGLE_OUT.E1. A SET, RESET, or TOGGLE event at the ASRT socket immediately triggers the matching event at the respective AE plug.

Technical Features

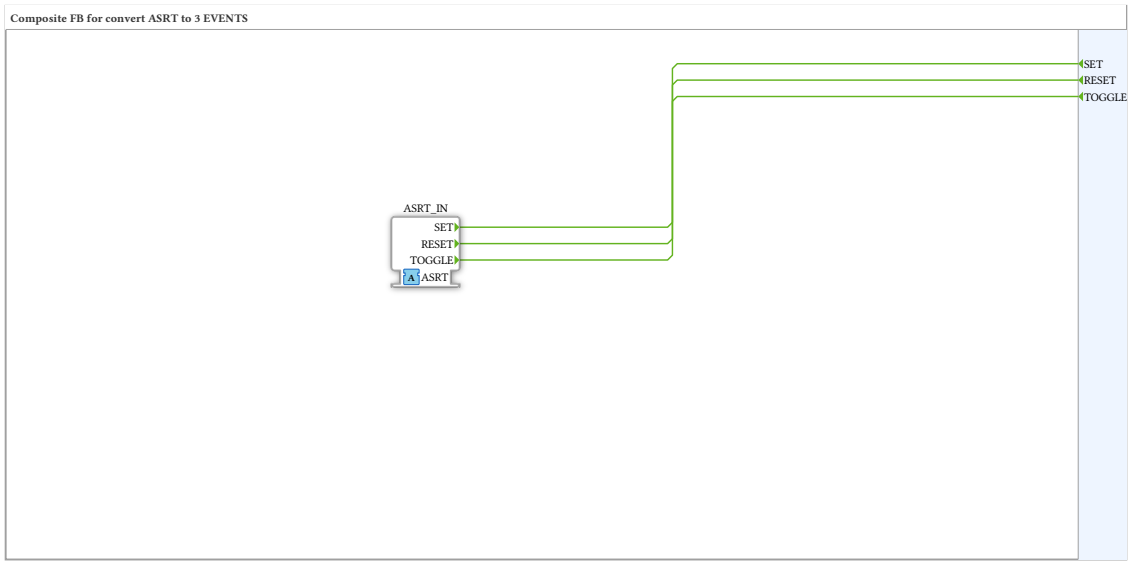
- **Pure wiring**: A composite FB with no ECC or algorithms, consisting solely of three direct event connections.
- **Adapter-based instead of event-based**: Unlike ASRT_SRT_TO_3EVENTS (classic event outputs), this block provides AE adapter plugs, letting it fit seamlessly into adapter-based networks.

State Overview

The function block has **no state machine**. Every SET, RESET, or TOGGLE event at ASRT_IN is forwarded immediately to the respective AE plug.

Application Scenarios

- **Fanning out an ASRT signal** (e.g. from AX_T_FF_SR) into three independently processable AE events.
- **Adapterizing** existing ASRT-based networks for further processing with plain AE adapters.

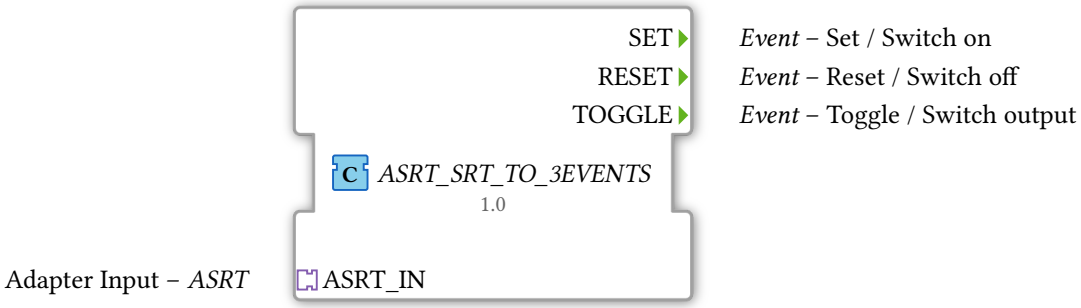


Comparison with Similar Components

- **ASRT_3AE_TO_SRT**: the reverse direction – merges three AE adapters into one ASRT signal.
- **ASRT_SRT_TO_3EVENTS**: the same functionality with classic event outputs instead of AE adapter plugs.
- **ASR_SR_TO_2AE**: the TOGGLE-reduced variant for ASR.
- **ASRT_SRT_TO_SR_AE**: the same split, but providing SET/RESET as a ready-made ASR adapter instead of two separate AE plugs.

Conclusion

ASRT_SRT_TO_3AE is a simple, pure-wiring solution for splitting an ASRT adapter into three AE adapters, suitable for seamlessly integrating ASRT signals into AE-based networks.



ASRT_SRT_TO_3EVENTS

• – ○ • – ○ • – ○ •

Introduction

The ASRT_SRT_TO_3EVENTS function block is a composite function block used to convert an ASRT signal into three separate events. It enables the conversion of a unidirectional adapter signal into independent SET, RESET, and TOGGLE events, and is the TOGGLE-extended variant of ASR_SR_TO_2EVENTS.

Interface Structure

Event Inputs

No direct event inputs available.

Event Outputs

- **SET**: Set / power on
- **RESET**: Reset / power off
- **TOGGLE**: Inverts the output signal

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

- **ASRT_IN**: Adapter input of type `adapter::types::unidirectional::ASRT`

Functionality

This function block forwards the SET, RESET, and TOGGLE signals of the ASRT adapter directly to the corresponding event outputs. The incoming adapter events are passed through transparently to the outputs of the function block.

Technical Features

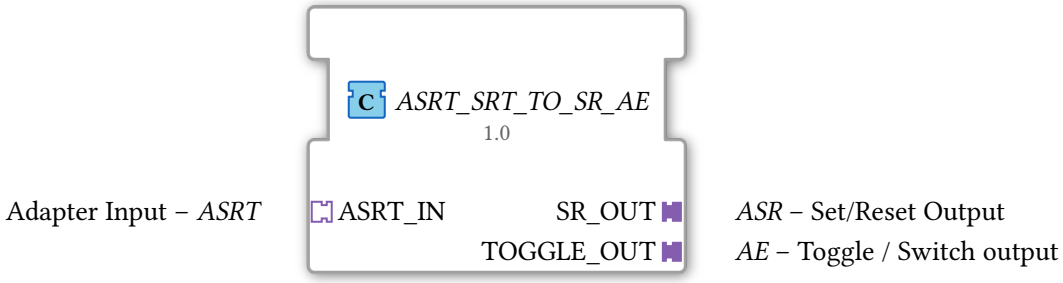
- Composite function block without internal logic processing
- Direct connection between adapter events and output events
- No data processing or state management

State Overview

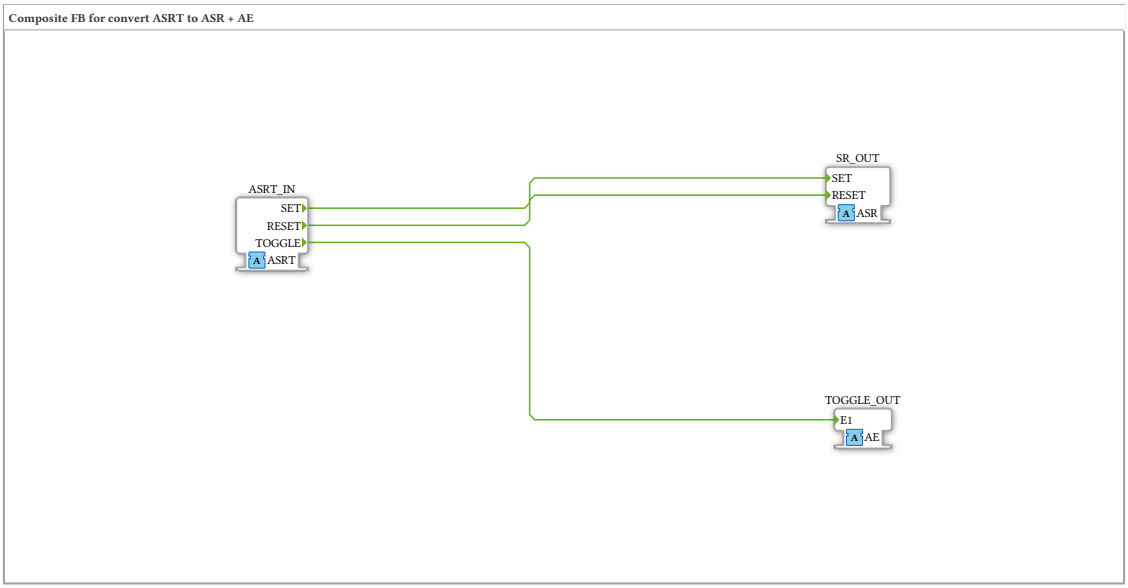
The function block has no internal state and operates statelessly. Every incoming adapter event is immediately forwarded to the corresponding output.

Application Scenarios

- Integration of ASRT adapters into event-based controls
- Conversion of unidirectional adapter signals into independent individual events
- Interface adaptation between different communication protocols



⚖️ Comparison with Similar Blocks



Compared to ASR_SR_TO_2EVENTS, this composite function block additionally handles the TOGGLE signal of an ASRT adapter instead of an ASR adapter.

Conclusion

The ASRT_SRT_TO_3EVENTS function block provides a simple and efficient solution for converting ASRT adapter signals into separate SET, RESET, and TOGGLE events. Its lean implementation without internal logic makes it a reliable and efficient component for interface adaptation.

ASRT_SRT_TO_SR_AE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_SRT_TO_SR_AE** is a composite FB that splits a unidirectional ASRT adapter (set/reset/toggle) into an ASR adapter (set/reset) and a separate AE adapter (toggle, pure event). It is the reverse of ASRT_SR_AE_TO_SRT and a mixed variant of ASRT_SRT_TO_3AE.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter socket.

Event Outputs

None. Events are forwarded exclusively via the adapter plugs.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket	`ASRT_IN`	`adapter::types::unidirectional::ASRT`	Incoming set/reset/toggle signal.
Plug	`SR_OUT`	`adapter::types::unidirectional::ASR`	Set/reset output.
Plug	`TOGGLE_OUT`	`adapter::types::unidirectional::AE`	Toggle / invert output.

Functionality

The block is a pure FBNetwork of three event connections with no algorithms of its own: `ASRT_IN.SET` is wired directly to `SR_OUT.SET`, `ASRT_IN.RESET` to `SR_OUT.RESET`, and `ASRT_IN.TOGGLE` to `TOGGLE_OUT.E1`. A SET, RESET, or TOGGLE event at the ASRT socket immediately triggers the matching event at `SR_OUT` or `TOGGLE_OUT`.

Technical Features

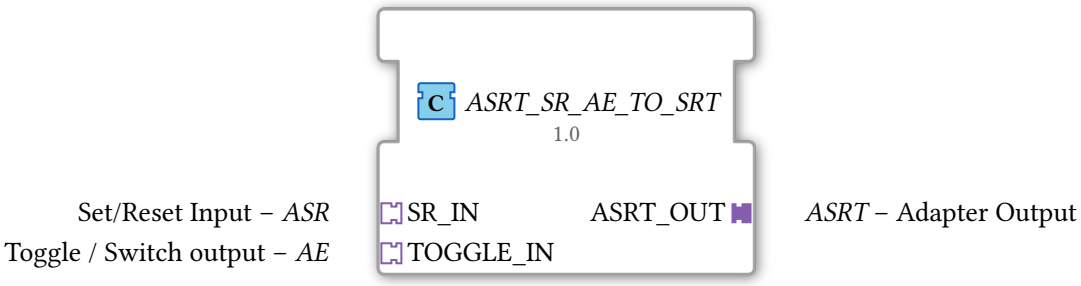
- **Pure wiring**: A composite FB with no ECC or algorithms, consisting solely of three direct event connections.
- **Mixed adapter outputs**: Provides SET/RESET already as a ready-made ASR adapter instead of two individual AE plugs — useful when downstream logic already expects an ASR input (e.g. `ASR_AX_SR`) and only TOGGLE needs to be handled separately.

State Overview

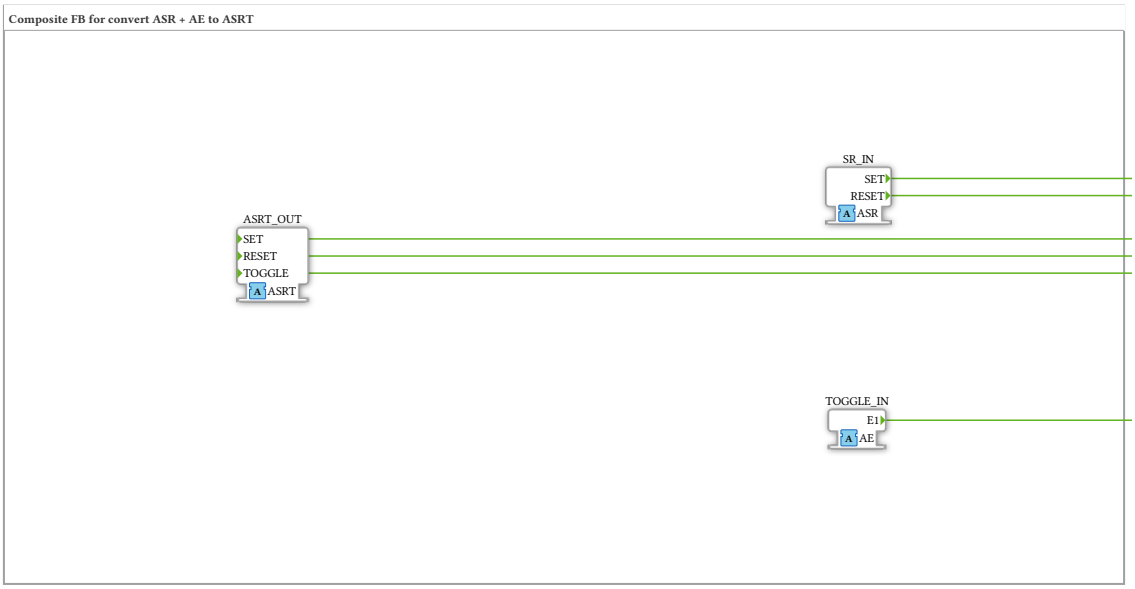
The function block has **no state machine**. Every `SET`, `RESET`, or `TOGGLE` event at `ASRT_IN` is forwarded immediately to `SR_OUT` or `TOGGLE_OUT`.

Application Scenarios

- **Connecting to existing ASR interfaces**: An ASRT signal needs to be forwarded to a block that only expects SET/RESET as an ASR adapter, while TOGGLE is tapped off separately (e.g. for diagnostics).
- **Simplifying downstream logic** that already processes set/reset bundled as an ASR adapter.



Comparison with Similar Components



- **ASRT_SR_AE_TO_SRT**: the reverse direction – merges ASR (SET/RESET) and AE (TOGGLE) into one ASRT signal.
- **ASRT_SRT_TO_3AE**: the same split, but with three individual AE plugs instead of a ready-made ASR adapter for SET/RESET.
- **ASR_SR_TO_2AE**: the `TOGGLE`-reduced variant for ASR.

Conclusion

`ASRT_SRT_TO_SR_AE` is a simple, pure-wiring solution that splits an ASRT signal into an ASR adapter (SET/RESET) and a separate toggle event.

ASRT_SR_AE_TO_SRT

• – ○ • – ○ • – ○ •

Introduction

The function block **ASRT_SR_AE_TO_SRT** is a composite FB that merges a unidirectional ASR adapter (set/reset) and a separate AE adapter (toggle, pure event) into one common ASRT adapter (set/reset/toggle). It is a mixed variant of ASRT_3AE_TO_SRT: instead of three individual AE sockets for SET, RESET, and TOGGLE, it accepts SET/RESET already as a ready-made ASR adapter and only adds TOGGLE separately.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket	SR_IN	adapter::types::unidirectional::ASR	Incoming set/reset signal.
Socket	TOGGLE_IN	adapter::types::unidirectional::AE	Toggle / invert output.
Plug	ASRT_OUT	adapter::types::unidirectional::ASRT	Merged set/reset/toggle signal.

Functionality

The block is a pure FBNetwork of three event connections with no algorithms of its own: SR_IN.SET is wired directly to ASRT_OUT.SET, SR_IN.RESET to ASRT_OUT.RESET, and TOGGLE_IN.E1 to ASRT_OUT.TOGGLE. A SET or RESET event at the ASR socket, or an event at the AE socket, immediately triggers the matching event at the ASRT plug.

Technical Features

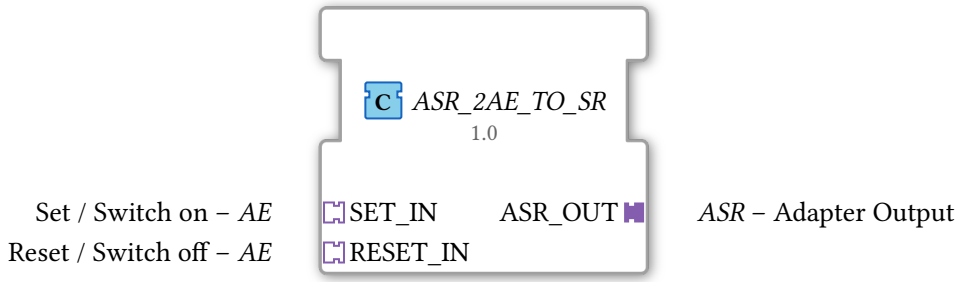
- **Pure wiring**: A composite FB with no ECC or algorithms, consisting solely of three direct event connections.
- **Mixed adapter inputs**: Combines an already-complete ASR adapter (SET/RESET) with a separate AE adapter (TOGGLE) — useful when SET/RESET already exist as an ASR signal (e.g. from ASR_2AE_TO_SR or an existing ASR network branch) and only TOGGLE needs to be added.

State Overview

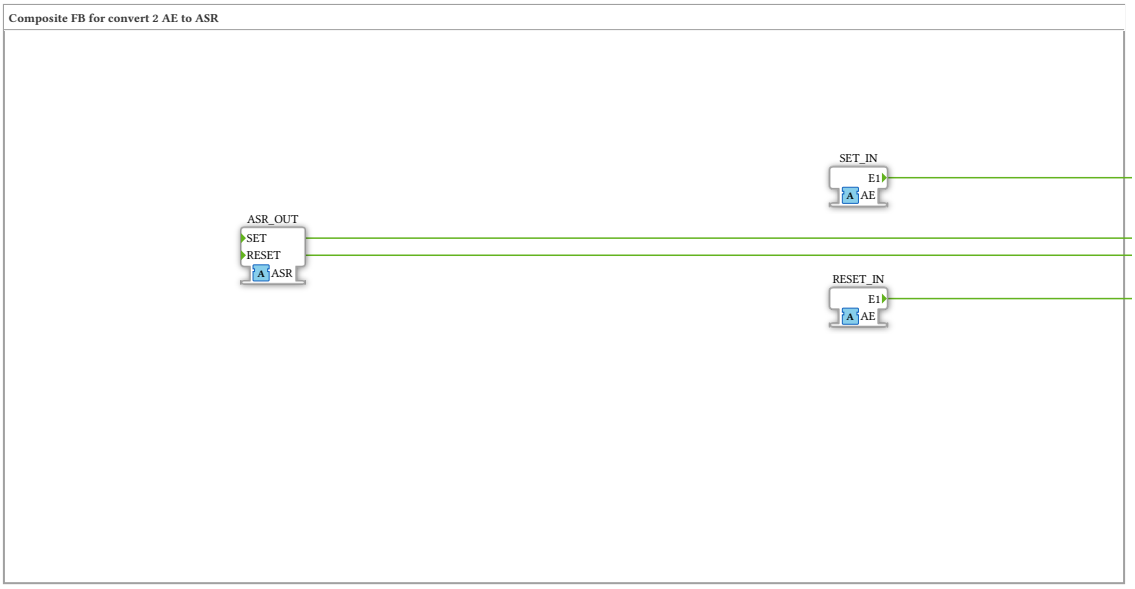
The function block has **no state machine**. Every event at SR_IN (SET/RESET) or TOGGLE_IN is forwarded immediately as the matching event type to ASRT_OUT.

Application Scenarios

- **Retrofitting TOGGLE**: An existing ASR network should be extended with a toggle function without rewiring SET/RESET.
- **Reusing existing ASR signal paths** in combination with a separate toggle source, e.g. a button via ASR_MERGE_2.



Comparison with Similar Components



- **ASRT_SRT_TO_SR_AE**: the reverse direction – splits an ASRT signal back into ASR (SET/RESET) and AE (TOGGLE).
- **ASRT_3AE_TO_SRT**: the same merge, but with three individual AE sockets instead of a ready-made ASR adapter for SET/RESET.
- **ASR_2AE_TO_SR**: the TOGGLE-reduced variant for ASR.

Conclusion

ASRT_SR_AE_TO_SRT is a simple, pure-wiring solution that extends an existing ASR adapter with a separate toggle event into a complete ASRT adapter.

ASR_2AE_TO_SR

• – ○ • – ○ • – ○ •

Introduction

The function block **ASR_2AE_TO_SR** is a composite FB that merges two separate unidirectional AE adapters (pure event, no payload data) into one common ASR adapter (a set/reset event pair). It is the adapter-based counterpart of ASR_2EVENTS_TO_SR, but uses AE adapter sockets instead of classic event inputs.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket	`SET_IN`	`adapter::types::unidirectional::AE`	Set / switch on.
Socket	`RESET_IN`	`adapter::types::unidirectional::AE`	Reset / switch off.
Plug	`ASR_OUT`	`adapter::types::unidirectional::ASR`	Merged set/reset signal.

Functionality

The block is a pure FBNetwork of two event connections with no algorithms of its own: `SET_IN.E1` is wired directly to `ASR_OUT.SET`, `RESET_IN.E1` directly to `ASR_OUT.RESET`. An event at the respective AE socket immediately triggers the matching SET or RESET event at the ASR plug.

Technical Features

- **Pure wiring**: A composite FB with no ECC or algorithms, consisting solely of two direct event connections.

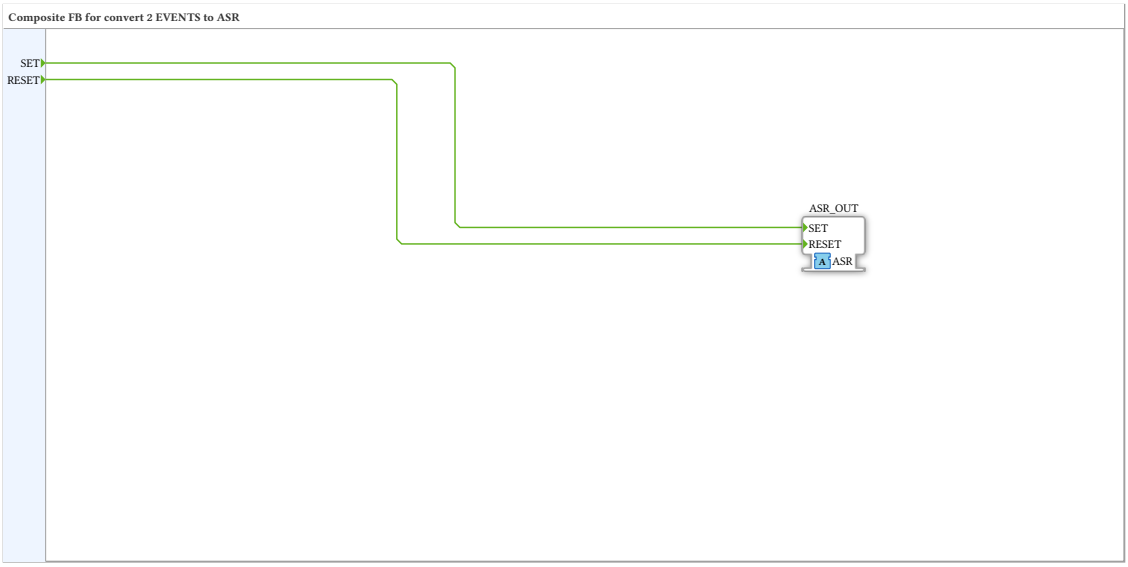
- **Adapter-based instead of event-based**: Unlike ASR_2EVENTS_TO_SR (classic event inputs SET/RESET), this block uses AE adapter sockets, letting it fit seamlessly into adapter-based networks.

State Overview

The function block has **no state machine**. Every event at SET_IN or RESET_IN is forwarded immediately as SET or RESET to ASR_OUT.

Application Scenarios

- **Merging two AE signal sources** (e.g. from ASR_MERGE_2 or directly from a sensor) into a single ASR adapter for downstream set/reset logic.
- **Adapterizing** existing AE-based networks to connect them to ASR interfaces (e.g. AX_SR).

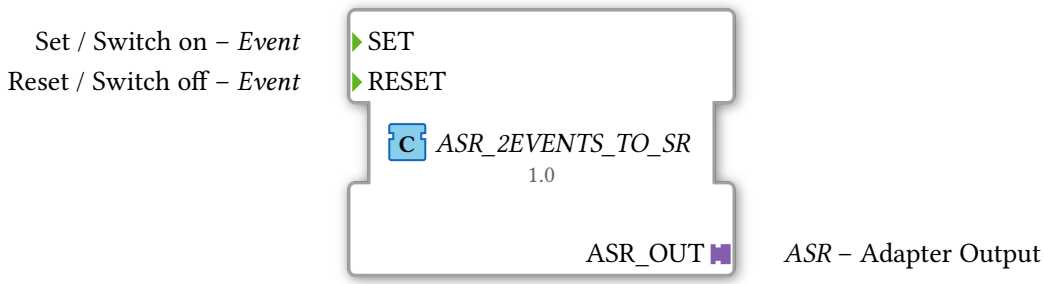


Comparison with Similar Components

- **ASR_SR_TO_2AE**: the reverse direction – splits an ASR signal back into two AE adapters.
- **ASR_2EVENTS_TO_SR**: the same functionality with classic event inputs instead of AE adapter sockets.
- **ASRT_3AE_TO_SRT**: the TOGGLE-extended variant for ASRT.

Conclusion

ASR_2AE_TO_SR is a simple, pure-wiring solution for merging two AE adapters into one ASR adapter, suitable for seamlessly integrating AE-based event sources into ASR interfaces.



ASR_2EVENTS_TO_SR

• – ◦ • – ◦ • – ◦ •

Introduction

The ASR_2EVENTS_TO_SR function block is a composite function block that converts two separate events into an ASR (Set-Reset) signal. It serves as a bridge between event-based control signals and the ASR adapter format.

Interface Structure

Event Inputs
- **SET**: Sets the output signal (power on)
- **RESET**: Resets the output signal (power off)

Event Outputs
No direct event outputs available

Data Inputs
No data inputs available

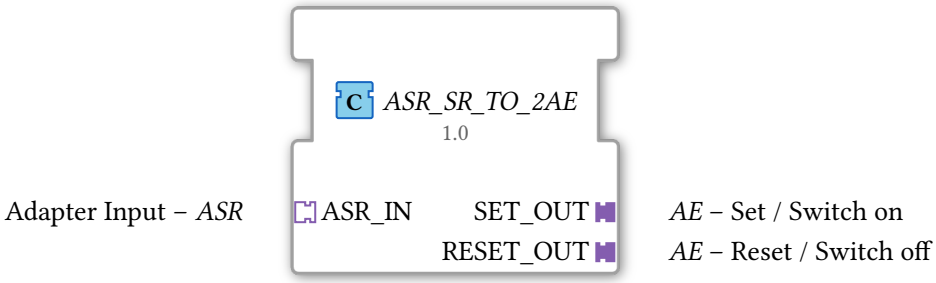
Data Outputs
No data outputs available

Adapter
- **ASR_OUT**: Unidirectional ASR adapter output

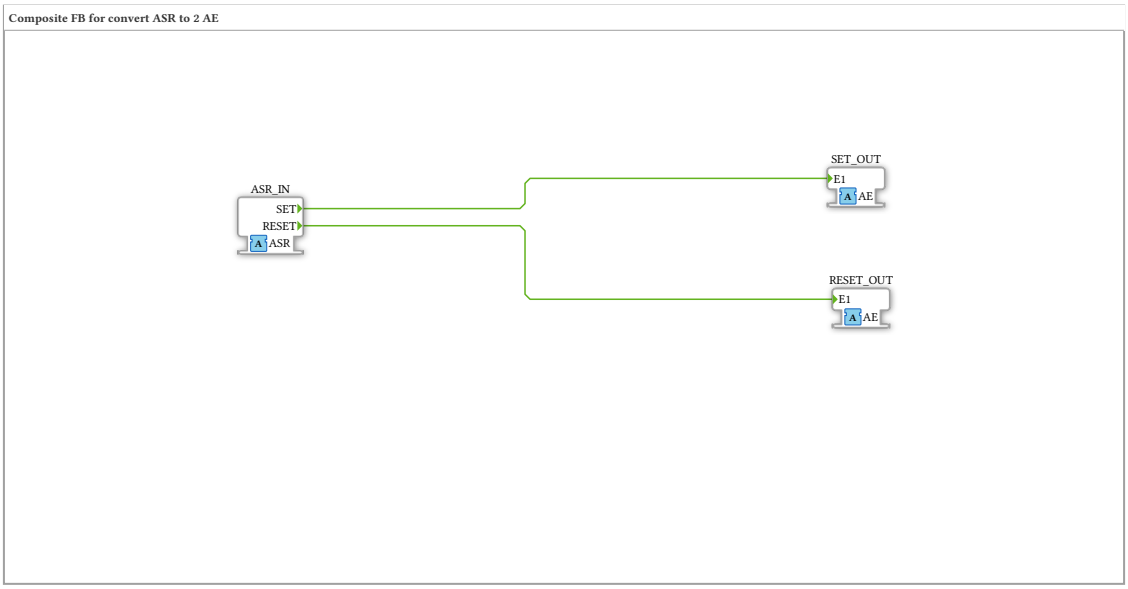
Functionality
This function block forwards incoming SET and RESET events directly to the ASR adapter. A SET event activates the corresponding SET signal on the ASR adapter, while a RESET event activates the RESET signal.

Technical Features
- Composite function block without internal logic processing
- Direct event pass-through to the adapter
- Uses unidirectional ASR adapter technology

State Overview
The function block has no internal state. It acts purely as a signal relay between the event inputs and the ASR adapter.



Application Scenarios
- Integration of event-based control systems into ASR-compatible environments
- Connection between different control levels
- Protocol implementation in automation systems



⚖️ Comparison with Similar Blocks
Compared to simple event function blocks, ASR_2EVENTS_TO_SR offers a specific interface to the ASR adapter, while other blocks may use direct data outputs.

🛠️ Related Exercises
- Exercise_171_AX

Conclusion
ASR_2EVENTS_TO_SR is a specialized function block for converting two separate events into the ASR adapter format. Its simple and straightforward operation makes it a reliable solution for system integrations.

ASR_SR_TO_2AE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_SR_TO_2AE** is a composite FB that splits a unidirectional ASR adapter (a set/reset event pair) into two separate AE adapters (pure event, no payload data). It is the reverse of ASR_2AE_TO_SR and the adapter-based counterpart of ASR_SR_TO_2EVENTS.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter socket.

Event Outputs

None. Events are forwarded exclusively via the adapter plugs.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket	`ASR_IN`	`adapter::types::unidirectional::ASR`	Incoming set/reset signal.
Plug	`SET_OUT`	`adapter::types::unidirectional::AE`	Set / switch on.

Plug	RESET_OUT	adapter::types::unidirectional::AE	Reset / switch off.

Functionality

The block is a pure FBNetwork of two event connections with no algorithms of its own: ASR_IN.SET is wired directly to SET_OUT.E1, ASR_IN.RESET directly to RESET_OUT.E1. A SET or RESET event at the ASR socket immediately triggers the matching event at the respective AE plug.

Technical Features

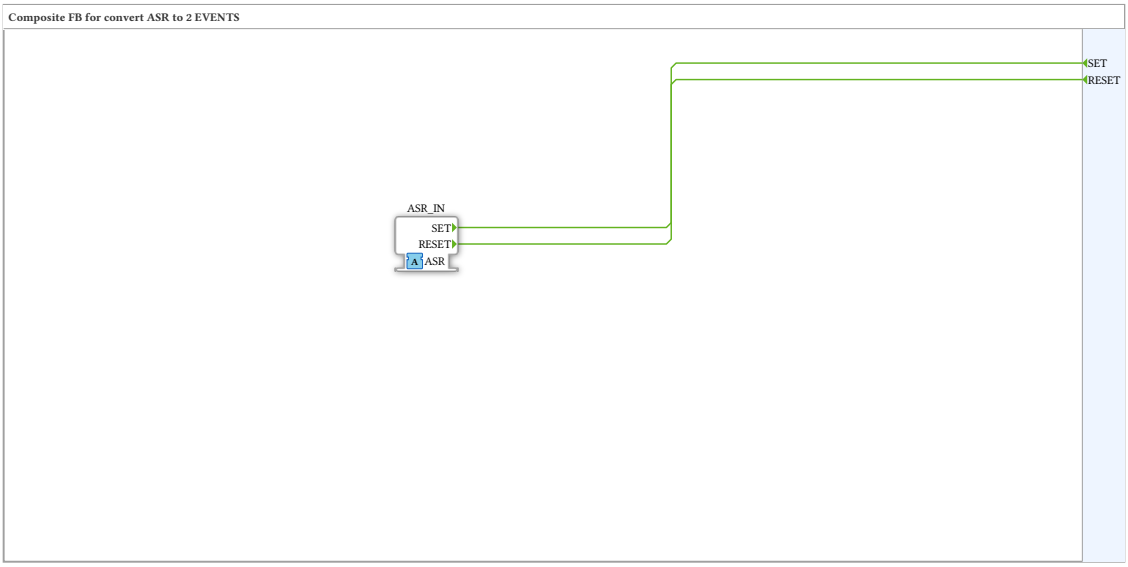
- **Pure wiring**: A composite FB with no ECC or algorithms, consisting solely of two direct event connections.
- **Adapter-based instead of event-based**: Unlike ASR_SR_TO_2EVENTS (classic event outputs), this block provides AE adapter plugs, letting it fit seamlessly into adapter-based networks.

State Overview

The function block has **no state machine**. Every SET or RESET event at ASR_IN is forwarded immediately to SET_OUT or RESET_OUT.

Application Scenarios

- **Fanning out an ASR signal** into two independently processable AE events, e.g. to route SET and RESET separately to different downstream blocks.
- **Adapterizing** existing ASR-based networks for further processing with plain AE adapters.

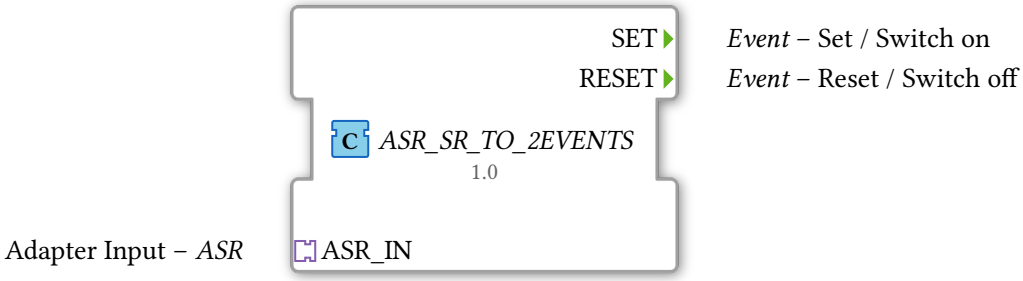


Comparison with Similar Components

- **ASR_2AE_TO_SR**: the reverse direction – merges two AE adapters into one ASR signal.
- **ASR_SR_TO_2EVENTS**: the same functionality with classic event outputs instead of AE adapter plugs.
- **ASRT_SRT_TO_3AE**: the TOGGLE-extended variant for ASRT.

Conclusion

ASR_SR_TO_2AE is a simple, pure-wiring solution for splitting an ASR adapter into two AE adapters, suitable for seamlessly integrating ASR signals into AE-based networks.



ASR_SR_TO_2EVENTS

• – ○ • – ○ • – ○ •

Introduction

The ASR_SR_TO_2EVENTS function block is a composite function block used to convert an ASR signal into two separate events. It enables the conversion of a bidirectional adapter signal into independent SET and RESET events.

Interface Structure

Event Inputs

No direct event inputs are available.

Event Outputs

- **SET**: Set / Turn On
- **RESET**: Reset / Turn Off

Data Inputs

No data inputs are available.

Data Outputs

No data outputs are available.

Adapter

- **ASR_IN**: Adapter input of type `adapter::types::unidirectional::ASR`

Functionality

The function block forwards the SET and RESET signals of the ASR adapter directly to the corresponding event outputs. The incoming adapter events are transparently passed through to the outputs of the function block.

Technical Features

- Composite function block without internal logic processing
- Direct connection between adapter events and output events
- No data processing or state management

State Overview

The function block has no internal state and operates stateless. Every incoming adapter event is immediately forwarded to the corresponding output.

Application Scenarios

- Integration of ASR adapters into event-based controllers
- Conversion of bidirectional signals into independent single events
- Interface adaptation between different communication protocols

⚖️ Comparison with similar components

Compared to simple adapter blocks, this composite function block offers specific conversion of ASR to event signals, while generic adapters enable more general interface adaptation.

Conclusion

The ASR_SR_TO_2EVENTS function block provides a simple and efficient solution for converting ASR adapter signals into separate SET and RESET events. Its streamlined implementation without internal logic makes it a reliable and high-performance component for interface adaptation.

AI_INT_TO_I

Introduction

The AI_INT_TO_I function block is a composite function block used to convert an INT value to the AI adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

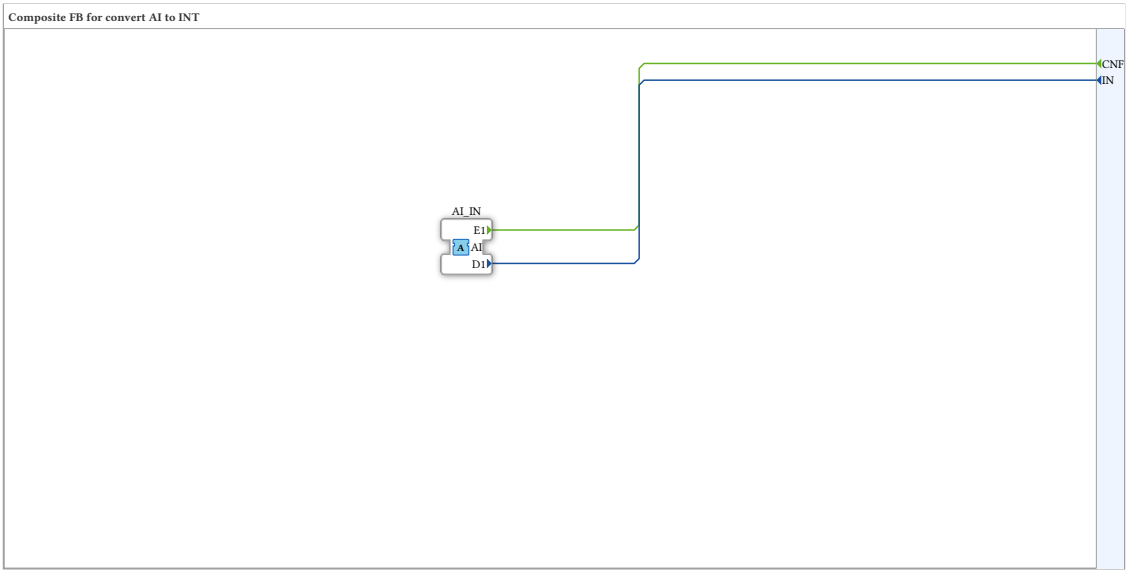
- No direct event outputs available

Data Inputs

- **OUT**: INT input value to be converted

Data Outputs

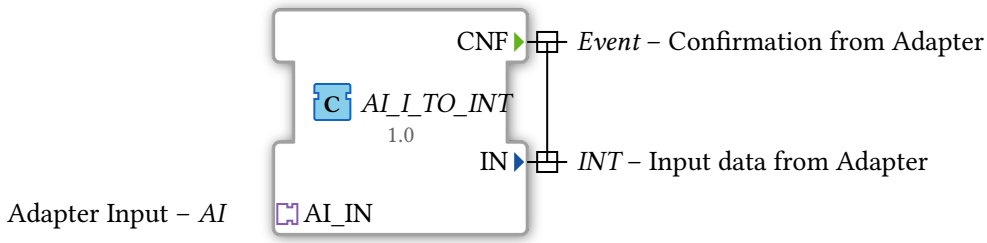
- No direct data outputs available



Adapter

- **AI_OUT**: Plug of type `AI`

Functionality



The function block receives an INT value at the data input OUT and converts it to the AI adapter format upon arrival of the REQ event.

AI_I_TO_INT

Introduction

The AI_I_TO_INT function block is a composite function block used to convert the AI adapter format to an INT value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

Data Outputs

- **IN**: INT output value of the converted data

Adapter

- **AI_IN**: Socket of type `AI`

Functionality

The function block receives data via the AI adapter socket and makes the contained INT value available at the IN output as soon as an event arrives via the adapter (CNF).

ALI_LINT_TO_LI

Introduction

The ALI_LINT_TO_LI function block is a composite function block used to convert a LINT value to the ALI adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

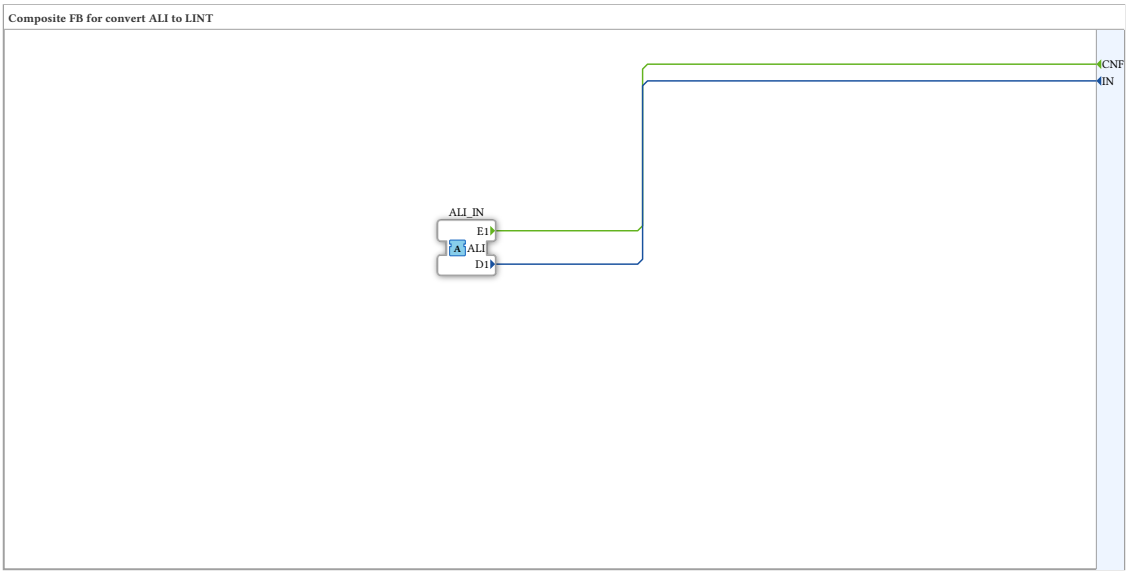
- No direct event outputs available

Data Inputs

- **OUT**: LINT input value to be converted

Data Outputs

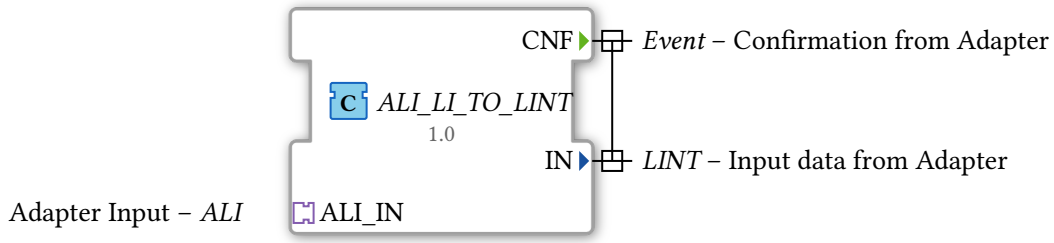
- No direct data outputs available



Adapter

- **ALI_OUT**: Plug of type `ALI`

Functionality



The function block receives a LINT value at the OUT data input and converts it to the ALI adapter format upon arrival of the REQ event.

ALI_LI_TO_LINT

Introduction

The ALI_LI_TO_LINT function block is a composite function block used to convert the ALI adapter format to a LINT value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

Data Outputs

- **IN**: LINT output value of the converted data

Adapter

- **ALI_IN**: Socket of type `ALI`

Functionality

The function block receives data via the ALI adapter socket and makes the contained LINT value available at the IN output as soon as an event arrives via the adapter (CNF).

AR_REAL_TO_R

Introduction

The AR_REAL_TO_R function block is a composite function block used to convert a REAL value to the AR adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

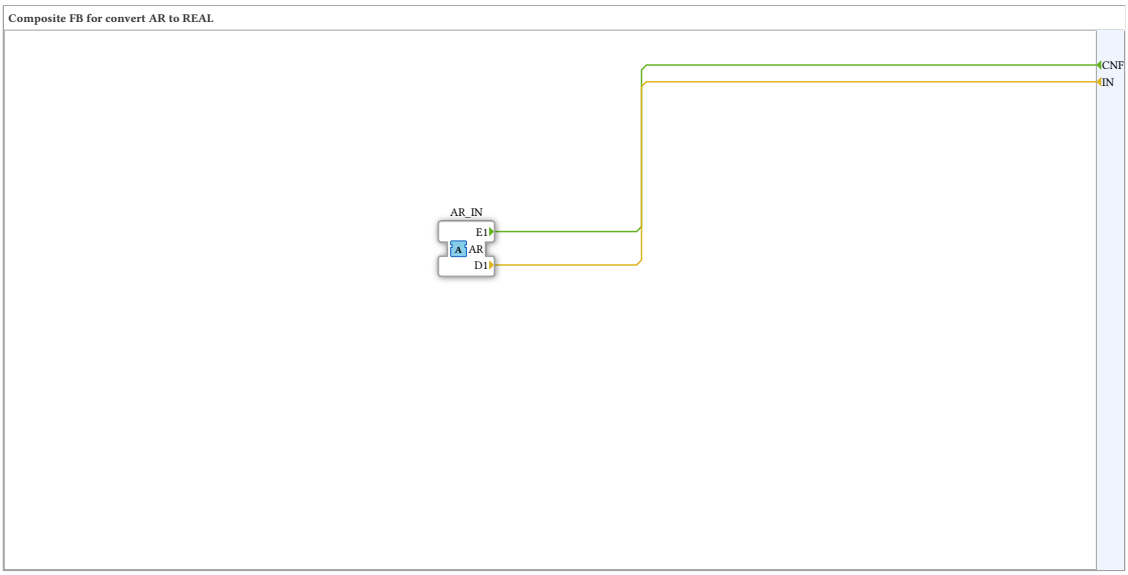
- No direct event outputs available

Data Inputs

- **OUT**: REAL input value to be converted

Data Outputs

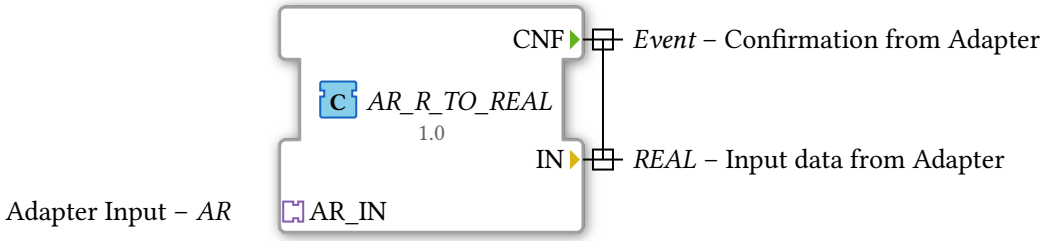
- No direct data outputs available



Adapter

- **AR_OUT**: Plug of type `AR`

Functionality



The function block receives a REAL value at the data input OUT and converts it to the AR adapter format upon arrival of the REQ event.

AR_R_TO_REAL

Introduction

The AR_R_TO_REAL function block is a composite function block used to convert the AR adapter format into a REAL value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

Data Outputs

- **IN**: REAL output value of the converted data

Adapter

- **AR_IN**: Socket of type `AR`

Functionality

The function block receives data via the AR adapter socket and makes the contained REAL value available at the IN output as soon as an event arrives via the adapter (CNF).

TIME

ATM_IN_MS_TO_ADI

Time value to convert – *ATM*

ADI – TIME value of IN expressed in MS as DINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_MS_TO_ADI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in milliseconds into a `DINT` value (32-bit signed integer), output via the ADI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `DINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ADI	Unidirectional `DINT` adapter as output interface, value of `IN` expressed in milliseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_MS_TO_DINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_MS_TO_DINT`.
3. `F_TIME_IN_MS_TO_DINT` converts the time value into a milliseconds figure of type `DINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_MS_TO_DINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_MS_TO_DINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in milliseconds and returns the result as `DINT` (32-bit signed integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

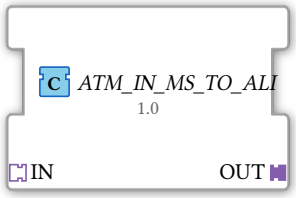
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (milliseconds) to `DINT` via `F_TIME_IN_MS_TO_DINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in milliseconds to an adapter socket of type `ADI`, for example for display on a panel or further use in a calculation.

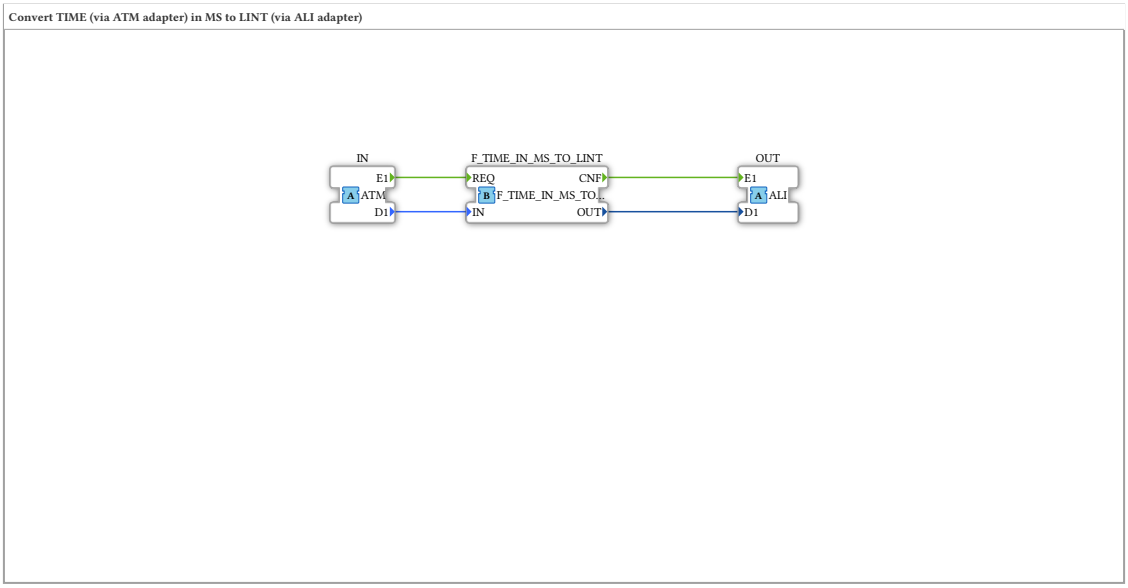
- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_MS_TO_ALI, ATM_IN_MS_TO_ALR, ATM_IN_MS_TO_AUDI, ATM_IN_MS_TO_AULI
- **Same target type, other units**: ATM_IN_NS_TO_ADI, ATM_IN_S_TO_ADI, ATM_IN_US_TO_ADI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_MS_TO_ADI`.

Conclusion



`ATM_IN_MS_TO_ADI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in milliseconds into a `DINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_MS_TO_ALI

Time value to convert – *ATM*

ALI – TIME value of IN expressed in MS as LINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_MS_TO_ALI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in milliseconds into a `LINT` value (64-bit signed integer), output via the ALI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `LINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ALI	Unidirectional `LINT` adapter as output interface, value of `IN` expressed in milliseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_MS_TO_LINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_MS_TO_LINT`.
3. `F_TIME_IN_MS_TO_LINT` converts the time value into a milliseconds figure of type `LINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_MS_TO_LINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_MS_TO_LINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in milliseconds and returns the result as `LINT` (64-bit signed integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

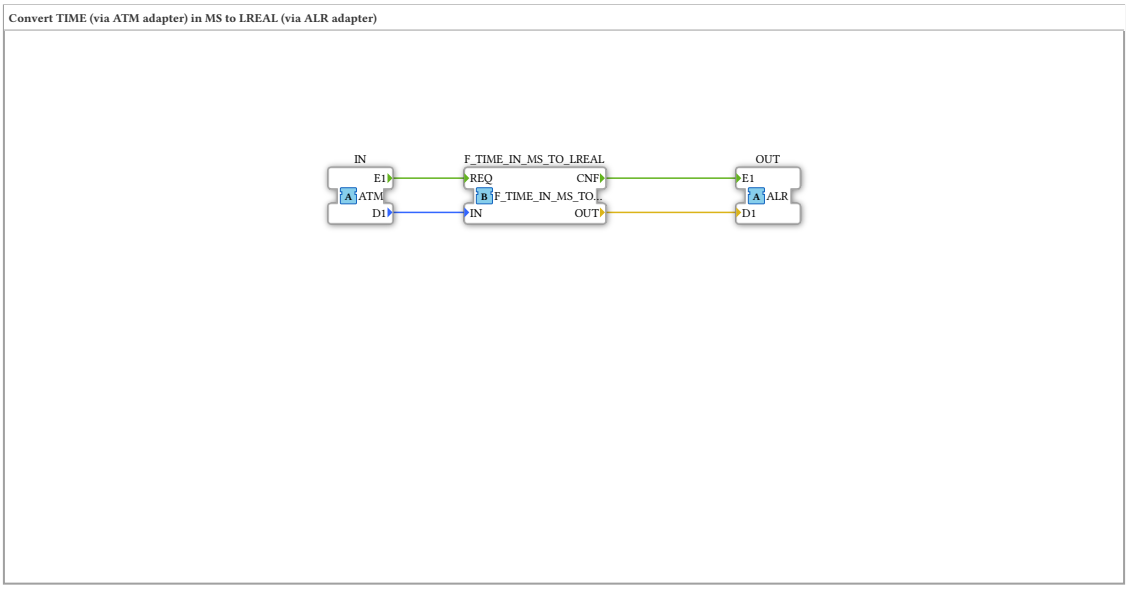
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (milliseconds) to `LINT` via `F_TIME_IN_MS_TO_LINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in milliseconds to an adapter socket of type `ALI`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_MS_TO_ADI, ATM_IN_MS_TO_ALR, ATM_IN_MS_TO_AUDI, ATM_IN_MS_TO_AULI
- **Same target type, other units**: ATM_IN_NS_TO_ALI, ATM_IN_S_TO_ALI, ATM_IN_US_TO_ALI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_MS_TO_ALI`.

Conclusion

`ATM_IN_MS_TO_ALI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in milliseconds into a `LINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_MS_TO_ALR

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_MS_TO_ALR** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in milliseconds into a `LREAL` value (64-bit floating-point number), output via the ALR adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `LREAL`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ALR	Unidirectional `LREAL` adapter as output interface, value of `IN` expressed in milliseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_MS_TO_LREAL`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_MS_TO_LREAL`.
3. `F_TIME_IN_MS_TO_LREAL` converts the time value into a milliseconds figure of type `LREAL` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_MS_TO_LREAL`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_MS_TO_LREAL` interprets the `TIME` value (internally held in nanoseconds) as a figure in milliseconds and returns the result as `LREAL` (64-bit floating-point number).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

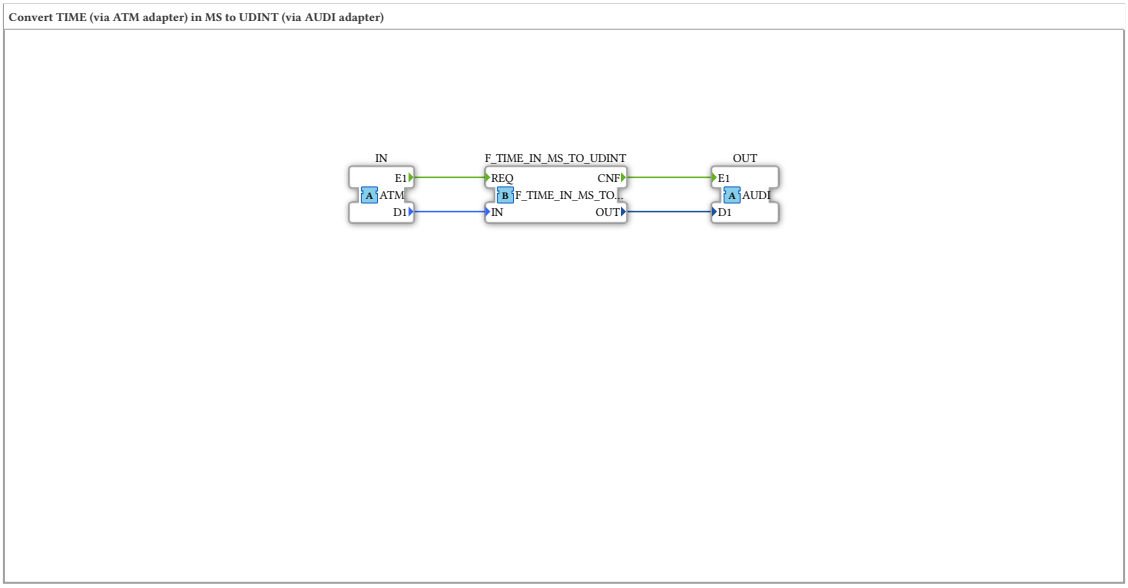
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (milliseconds) to `LREAL` via `F_TIME_IN_MS_TO_LREAL`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in milliseconds to an adapter socket of type `ALR`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_MS_TO_ADI, ATM_IN_MS_TO_ALI, ATM_IN_MS_TO_AUDI, ATM_IN_MS_TO_AULI
- **Same target type, other units**: ATM_IN_NS_TO_ALR, ATM_IN_S_TO_ALR, ATM_IN_US_TO_ALR
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_MS_TO_ALR`.

Conclusion

`ATM_IN_MS_TO_ALR` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in milliseconds into a `LREAL` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_MS_TO_AUDI

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_MS_TO_AUDI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in milliseconds into a `UDINT` value (32-bit unsigned integer), output via the AUDI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `UDINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::AUDI	Unidirectional `UDINT` adapter as output interface, value of `IN` expressed in milliseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_MS_TO_UDINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_MS_TO_UDINT`.
3. `F_TIME_IN_MS_TO_UDINT` converts the time value into a milliseconds figure of type `UDINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_MS_TO_UDINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_MS_TO_UDINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in milliseconds and returns the result as `UDINT` (32-bit unsigned integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

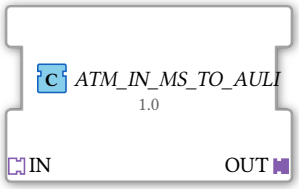
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (milliseconds) to `UDINT` via `F_TIME_IN_MS_TO_UDINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in milliseconds to an adapter socket of type `AUDI`, for example for display on a panel or further use in a calculation.

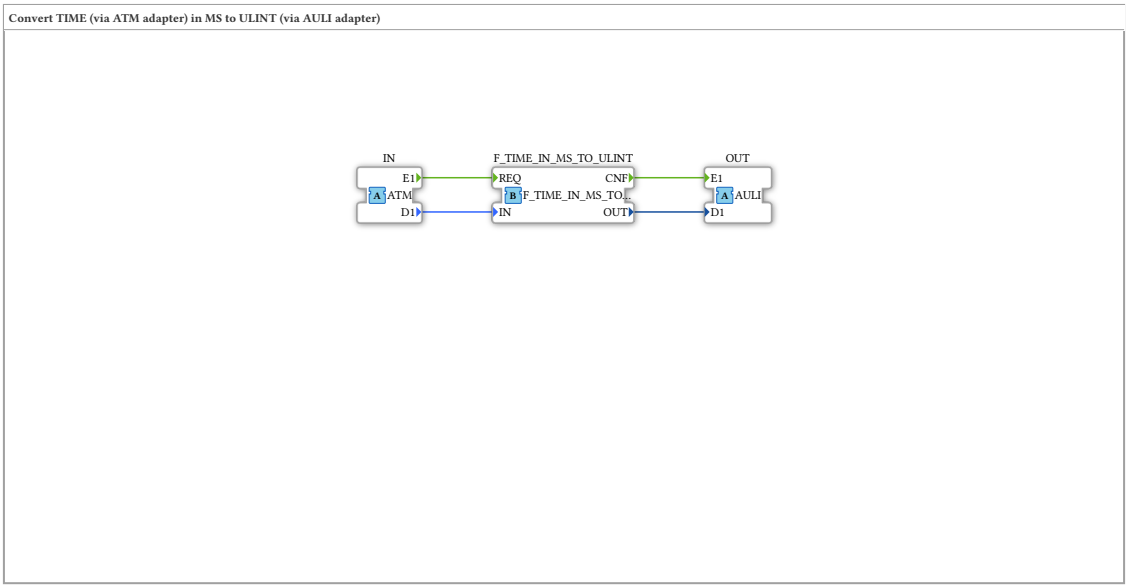
- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_MS_TO_ADI, ATM_IN_MS_TO_ALI, ATM_IN_MS_TO_ALR, ATM_IN_MS_TO_AULI
- **Same target type, other units**: ATM_IN_NS_TO_AUDI, ATM_IN_S_TO_AUDI, ATM_IN_US_TO_AUDI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_MS_TO_AUDI`.

Conclusion



`ATM_IN_MS_TO_AUDI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in milliseconds into a `UDINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_MS_TO_AULI

Time value to convert – *ATM*

AULI – TIME value of IN expressed in MS as ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ATM_IN_MS_TO_AULI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in milliseconds into a `ULINT` value (64-bit unsigned integer), output via the AULI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `ULINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::AULI	Unidirectional `ULINT` adapter as output interface, value of `IN` expressed in milliseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_MS_TO_ULINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_MS_TO_ULINT`.
3. `F_TIME_IN_MS_TO_ULINT` converts the time value into a milliseconds figure of type `ULINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_MS_TO_ULINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_MS_TO_ULINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in milliseconds and returns the result as `ULINT` (64-bit unsigned integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

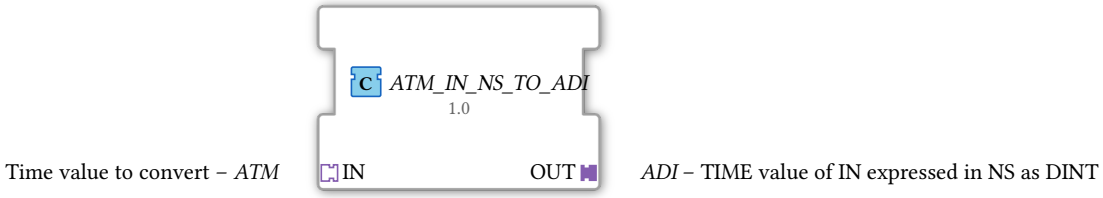
The function block does not have its own state machine. The process can be described as a simple step:

Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (milliseconds) to `ULINT` via `F_TIME_IN_MS_TO_ULINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

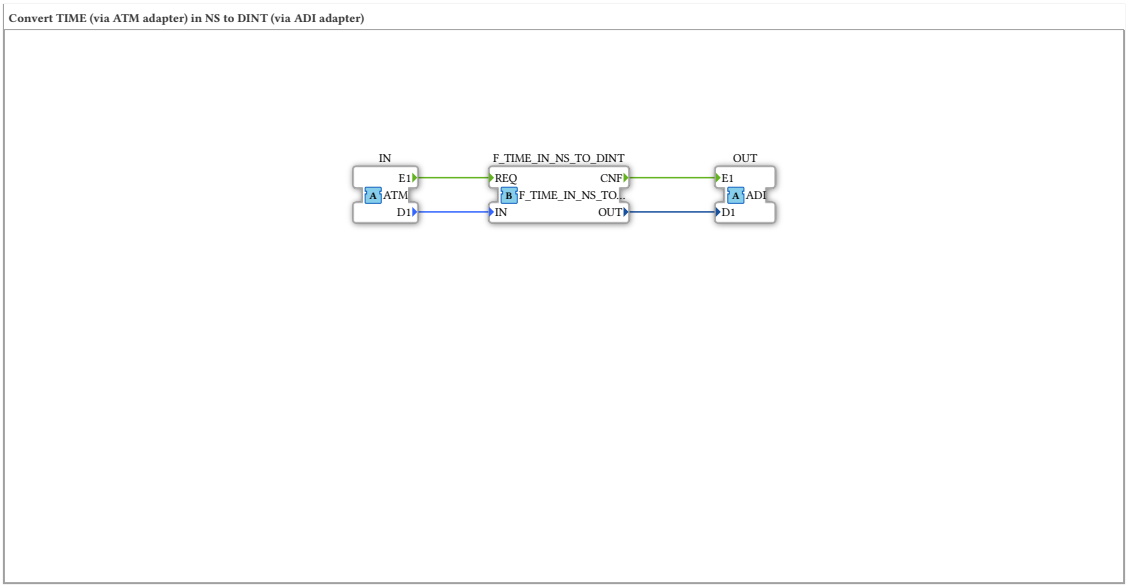
- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in milliseconds to an adapter socket of type `AULI`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.



Comparison with similar function blocks

- **Same unit, other target types**: ATM_IN_MS_TO_ADI, ATM_IN_MS_TO_ALI, ATM_IN_MS_TO_ALR, ATM_IN_MS_TO_AUDI
- **Same target type, other units**: ATM_IN_NS_TO_AULI, ATM_IN_S_TO_AULI, ATM_IN_US_TO_AULI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_MS_TO_AULI`.



Conclusion

`ATM_IN_MS_TO_AULI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in milliseconds into a `ULINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_NS_TO_ADI

Time value to convert – *ATM* — *ADI* – TIME value of IN expressed in NS as DINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_NS_TO_ADI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in nanoseconds into a `DINT` value (32-bit signed integer), output via the ADI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `DINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ADI	Unidirectional `DINT` adapter as output interface, value of `IN` expressed in nanoseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_NS_TO_DINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_NS_TO_DINT`.
3. `F_TIME_IN_NS_TO_DINT` converts the time value into a nanoseconds figure of type `DINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_NS_TO_DINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_NS_TO_DINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in nanoseconds and returns the result as `DINT` (32-bit signed integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

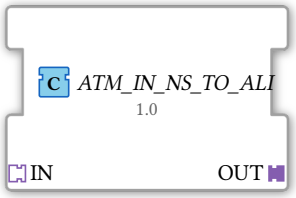
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (nanoseconds) to `DINT` via `F_TIME_IN_NS_TO_DINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in nanoseconds to an adapter socket of type `ADI`, for example for display on a panel or further use in a calculation.

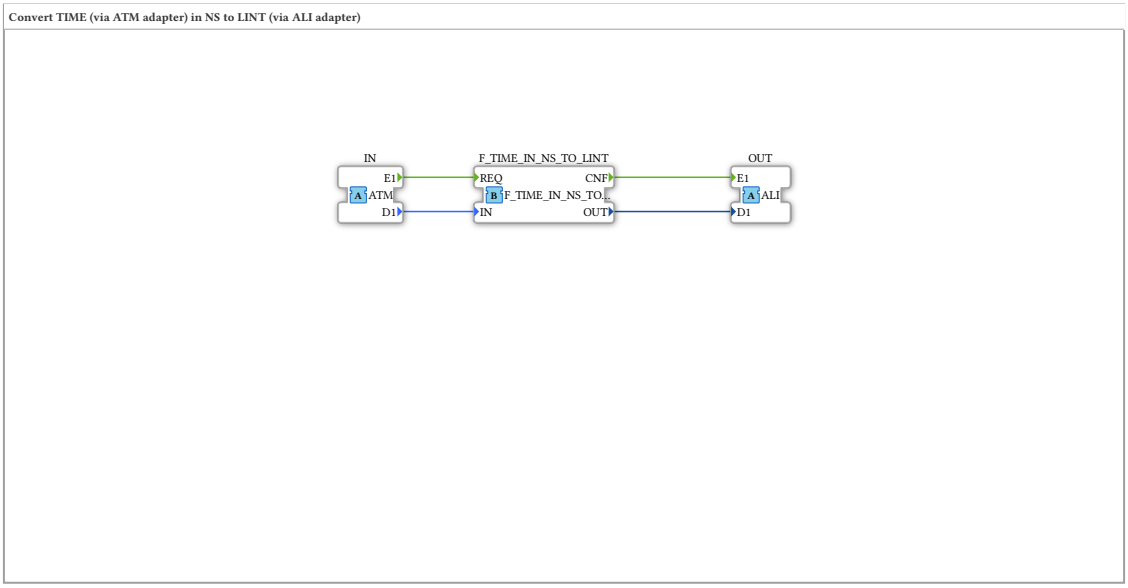
- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_NS_TO_ALI, ATM_IN_NS_TO_ALR, ATM_IN_NS_TO_AUDI, ATM_IN_NS_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_ADI, ATM_IN_S_TO_ADI, ATM_IN_US_TO_ADI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_NS_TO_ADI`.

Conclusion



`ATM_IN_NS_TO_ADI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in nanoseconds into a `DINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_NS_TO_ALI

Time value to convert – *ATM*

ALI – TIME value of IN expressed in NS as LINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_NS_TO_ALI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in nanoseconds into a `LINT` value (64-bit signed integer), output via the ALI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `LINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ALI	Unidirectional `LINT` adapter as output interface, value of `IN` expressed in nanoseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_NS_TO_LINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_NS_TO_LINT`.
3. `F_TIME_IN_NS_TO_LINT` converts the time value into a nanoseconds figure of type `LINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_NS_TO_LINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_NS_TO_LINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in nanoseconds and returns the result as `LINT` (64-bit signed integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

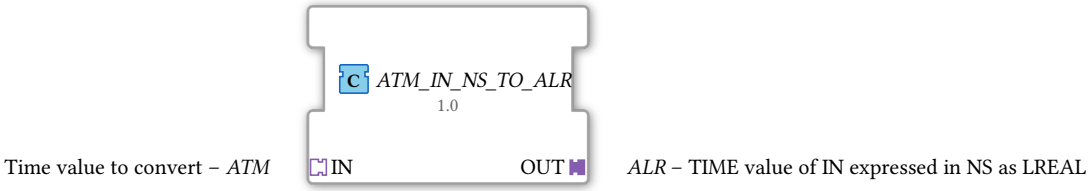
The function block does not have its own state machine. The process can be described as a simple step:

Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (nanoseconds) to `LINT` via `F_TIME_IN_NS_TO_LINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

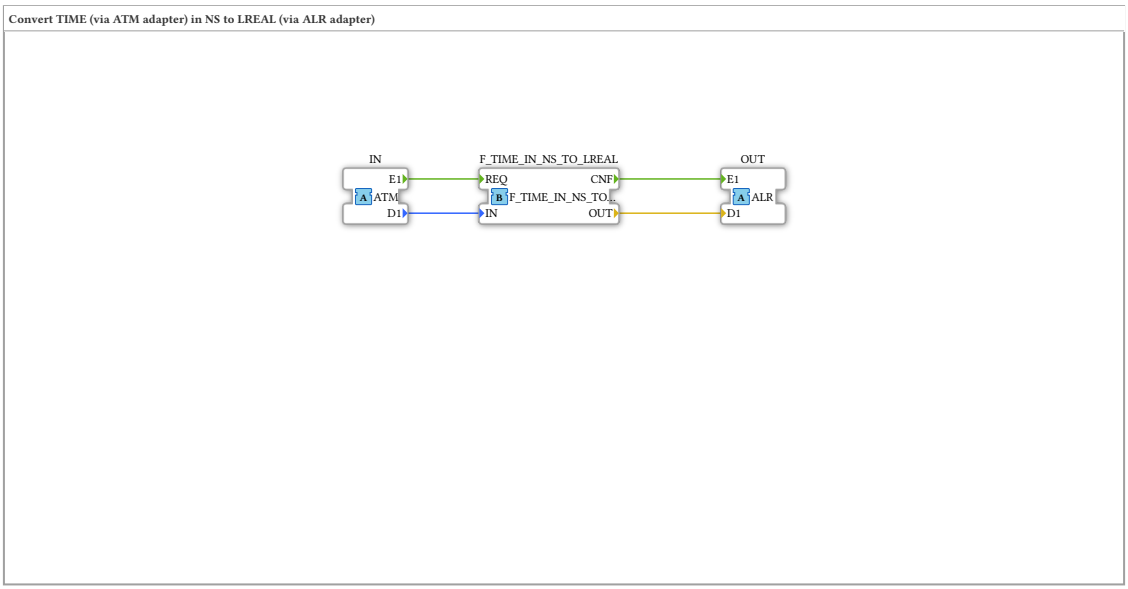
Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in nanoseconds to an adapter socket of type `ALI`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.



Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_NS_TO_ADI, ATM_IN_NS_TO_ALR, ATM_IN_NS_TO_AUDI, ATM_IN_NS_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_ALI, ATM_IN_S_TO_ALI, ATM_IN_US_TO_ALI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_NS_TO_ALI`.

Conclusion

`ATM_IN_NS_TO_ALI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in nanoseconds into a `LINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_NS_TO_ALR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ATM_IN_NS_TO_ALR** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in nanoseconds into a `LREAL` value (64-bit floating-point number), output via the ALR adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `LREAL`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ALR	Unidirectional `LREAL` adapter as output interface, value of `IN` expressed in nanoseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_NS_TO_LREAL`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_NS_TO_LREAL`.
3. `F_TIME_IN_NS_TO_LREAL` converts the time value into a nanoseconds figure of type `LREAL` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_NS_TO_LREAL`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_NS_TO_LREAL` interprets the `TIME` value (internally held in nanoseconds) as a figure in nanoseconds and returns the result as `LREAL` (64-bit floating-point number).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

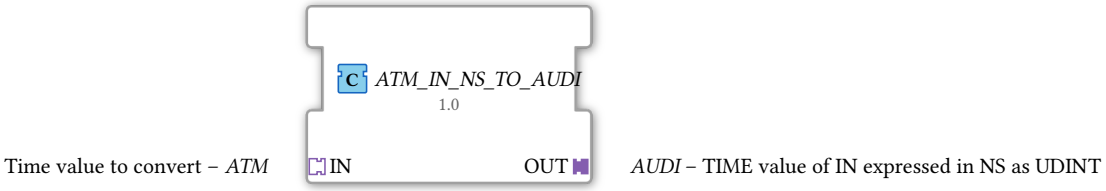
The function block does not have its own state machine. The process can be described as a simple step:

Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (nanoseconds) to `LREAL` via `F_TIME_IN_NS_TO_LREAL`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

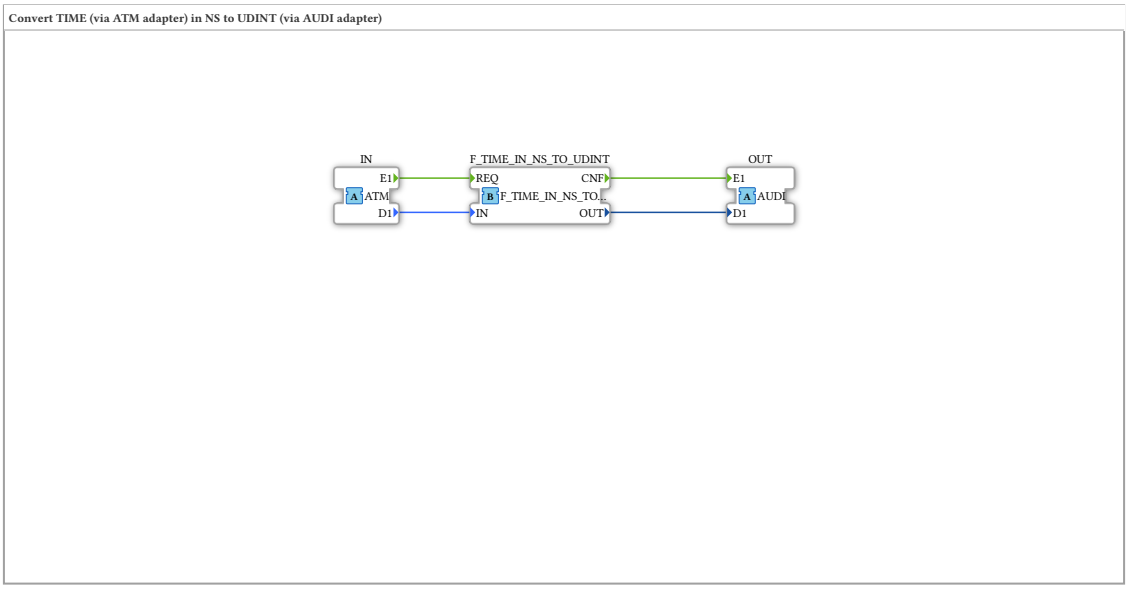
Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in nanoseconds to an adapter socket of type `ALR`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.



Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_NS_TO_ADI, ATM_IN_NS_TO_ALI, ATM_IN_NS_TO_AUDI, ATM_IN_NS_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_ALR, ATM_IN_S_TO_ALR, ATM_IN_US_TO_ALR
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_NS_TO_ALR`.

Conclusion

`ATM_IN_NS_TO_ALR` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in nanoseconds into a `LREAL` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_NS_TO_AUDI

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_NS_TO_AUDI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in nanoseconds into a `UDINT` value (32-bit unsigned integer), output via the AUDI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `UDINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::AUDI	Unidirectional `UDINT` adapter as output interface, value of `IN` expressed in nanoseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_NS_TO_UDINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_NS_TO_UDINT`.
3. `F_TIME_IN_NS_TO_UDINT` converts the time value into a nanoseconds figure of type `UDINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_NS_TO_UDINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_NS_TO_UDINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in nanoseconds and returns the result as `UDINT` (32-bit unsigned integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

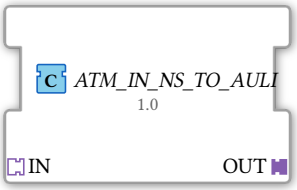
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (nanoseconds) to `UDINT` via `F_TIME_IN_NS_TO_UDINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in nanoseconds to an adapter socket of type `AUDI`, for example for display on a panel or further use in a calculation.

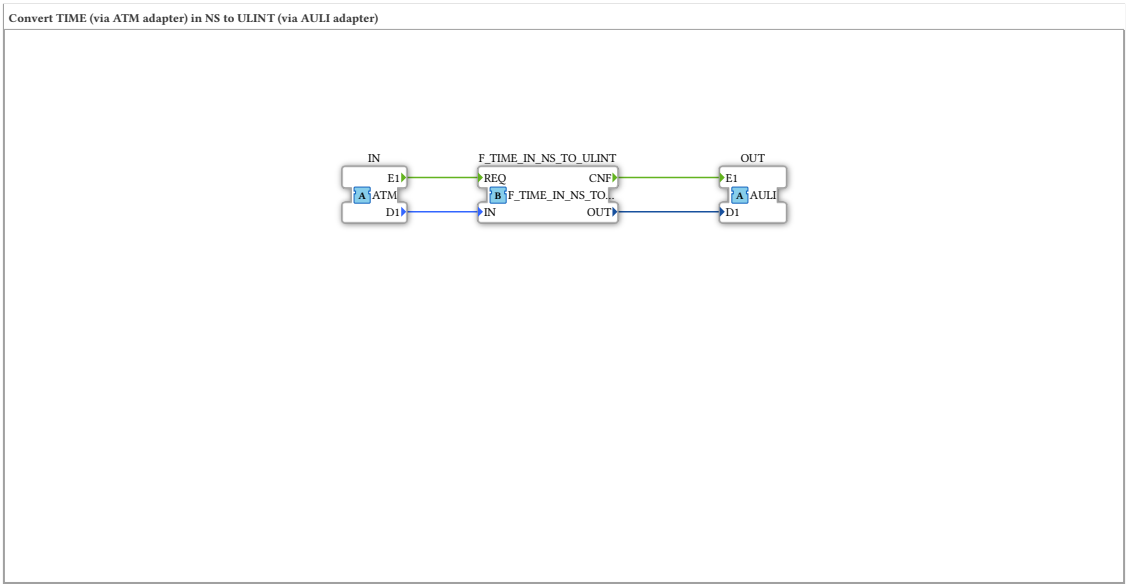
- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_NS_TO_ADI, ATM_IN_NS_TO_ALI, ATM_IN_NS_TO_ALR, ATM_IN_NS_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_AUDI, ATM_IN_S_TO_AUDI, ATM_IN_US_TO_AUDI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_NS_TO_AUDI`.

Conclusion



`ATM_IN_NS_TO_AUDI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in nanoseconds into a `UDINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_NS_TO_AULI

Time value to convert – *ATM*

AULI – TIME value of IN expressed in NS as ULINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_NS_TO_AULI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in nanoseconds into a `ULINT` value (64-bit unsigned integer), output via the AULI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `ULINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::AULI	Unidirectional `ULINT` adapter as output interface, value of `IN` expressed in nanoseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_NS_TO_ULINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_NS_TO_ULINT`.
3. `F_TIME_IN_NS_TO_ULINT` converts the time value into a nanoseconds figure of type `ULINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_NS_TO_ULINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_NS_TO_ULINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in nanoseconds and returns the result as `ULINT` (64-bit unsigned integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

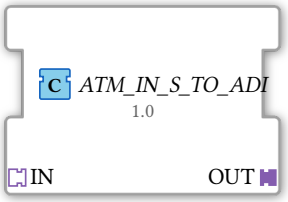
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (nanoseconds) to `ULINT` via `F_TIME_IN_NS_TO_ULINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in nanoseconds to an adapter socket of type `AULI`, for example for display on a panel or further use in a calculation.

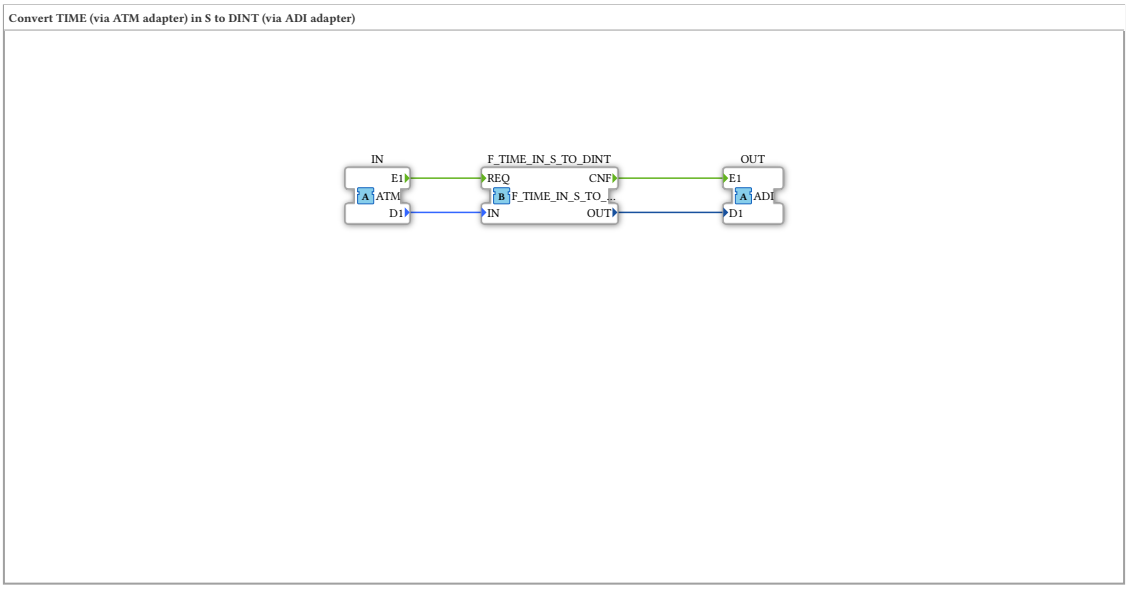
- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_NS_TO_ADI, ATM_IN_NS_TO_ALI, ATM_IN_NS_TO_ALR, ATM_IN_NS_TO_AUDI
- **Same target type, other units**: ATM_IN_MS_TO_AULI, ATM_IN_S_TO_AULI, ATM_IN_US_TO_AULI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_NS_TO_AULI`.

Conclusion



`ATM_IN_NS_TO_AULI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in nanoseconds into a `ULINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_S_TO_ADI

Time value to convert – *ATM*

ADI – TIME value of IN expressed in S as DINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_S_TO_ADI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in seconds into a `DINT` value (32-bit signed integer), output via the ADI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `DINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ADI	Unidirectional `DINT` adapter as output interface, value of `IN` expressed in seconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_S_TO_DINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_S_TO_DINT`.
3. `F_TIME_IN_S_TO_DINT` converts the time value into a seconds figure of type `DINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_S_TO_DINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_S_TO_DINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in seconds and returns the result as `DINT` (32-bit signed integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

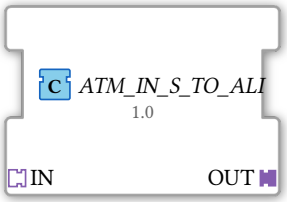
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (seconds) to `DINT` via `F_TIME_IN_S_TO_DINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in seconds to an adapter socket of type `ADI`, for example for display on a panel or further use in a calculation.

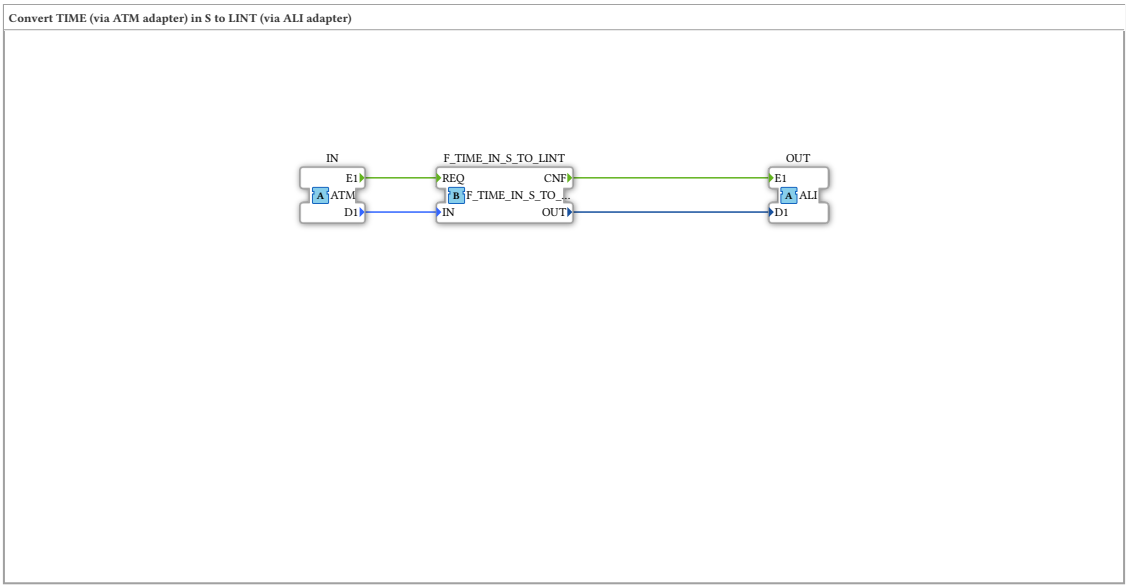
- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_S_TO_ALI, ATM_IN_S_TO_ALR, ATM_IN_S_TO_AUDI, ATM_IN_S_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_ADI, ATM_IN_NS_TO_ADI, ATM_IN_US_TO_ADI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_S_TO_ADI`.

Conclusion



`ATM_IN_S_TO_ADI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in seconds into a `DINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_S_TO_ALI

Time value to convert – *ATM*

ALI – TIME value of IN expressed in S as LINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_S_TO_ALI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in seconds into a `LINT` value (64-bit signed integer), output via the ALI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `LINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ALI	Unidirectional `LINT` adapter as output interface, value of `IN` expressed in seconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_S_TO_LINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_S_TO_LINT`.
3. `F_TIME_IN_S_TO_LINT` converts the time value into a seconds figure of type `LINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_S_TO_LINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_S_TO_LINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in seconds and returns the result as `LINT` (64-bit signed integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

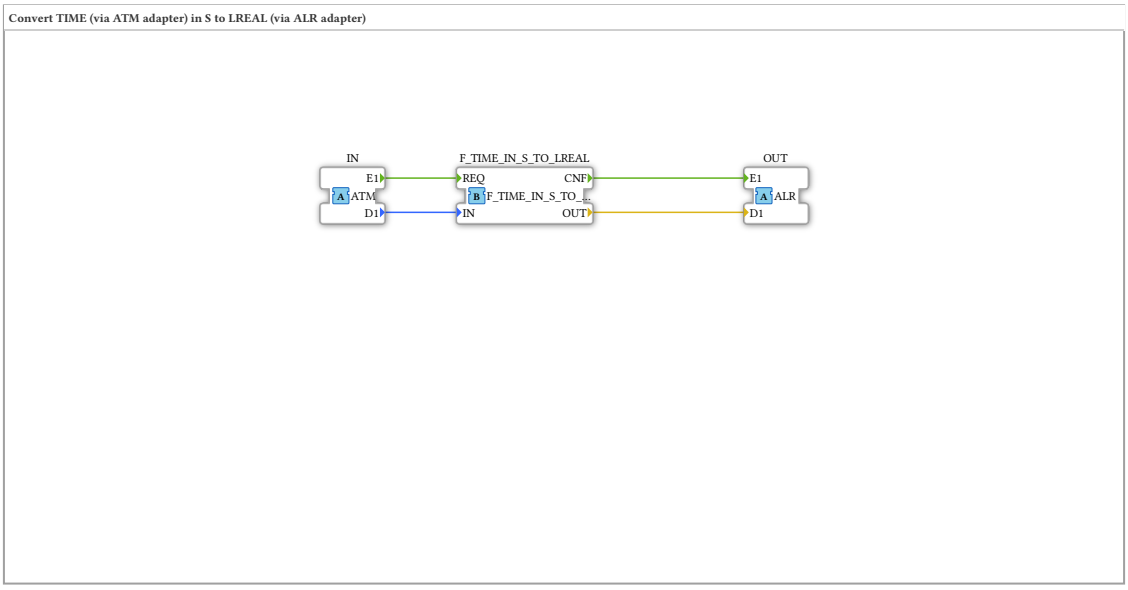
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (seconds) to `LINT` via `F_TIME_IN_S_TO_LINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in seconds to an adapter socket of type `ALI`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_S_TO_ADI, ATM_IN_S_TO_ALR, ATM_IN_S_TO_AUDI, ATM_IN_S_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_ALI, ATM_IN_NS_TO_ALI, ATM_IN_US_TO_ALI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_S_TO_ALI`.

Conclusion

`ATM_IN_S_TO_ALI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in seconds into a `LINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_S_TO_ALR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ATM_IN_S_TO_ALR** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in seconds into a `LREAL` value (64-bit floating-point number), output via the ALR adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `LREAL`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ALR	Unidirectional `LREAL` adapter as output interface, value of `IN` expressed in seconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_S_TO_LREAL`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_S_TO_LREAL`.
3. `F_TIME_IN_S_TO_LREAL` converts the time value into a seconds figure of type `LREAL` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_S_TO_LREAL`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_S_TO_LREAL` interprets the `TIME` value (internally held in nanoseconds) as a figure in seconds and returns the result as `LREAL` (64-bit floating-point number).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

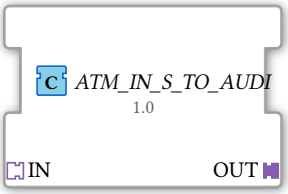
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (seconds) to `LREAL` via `F_TIME_IN_S_TO_LREAL`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in seconds to an adapter socket of type `ALR`, for example for display on a panel or further use in a calculation.

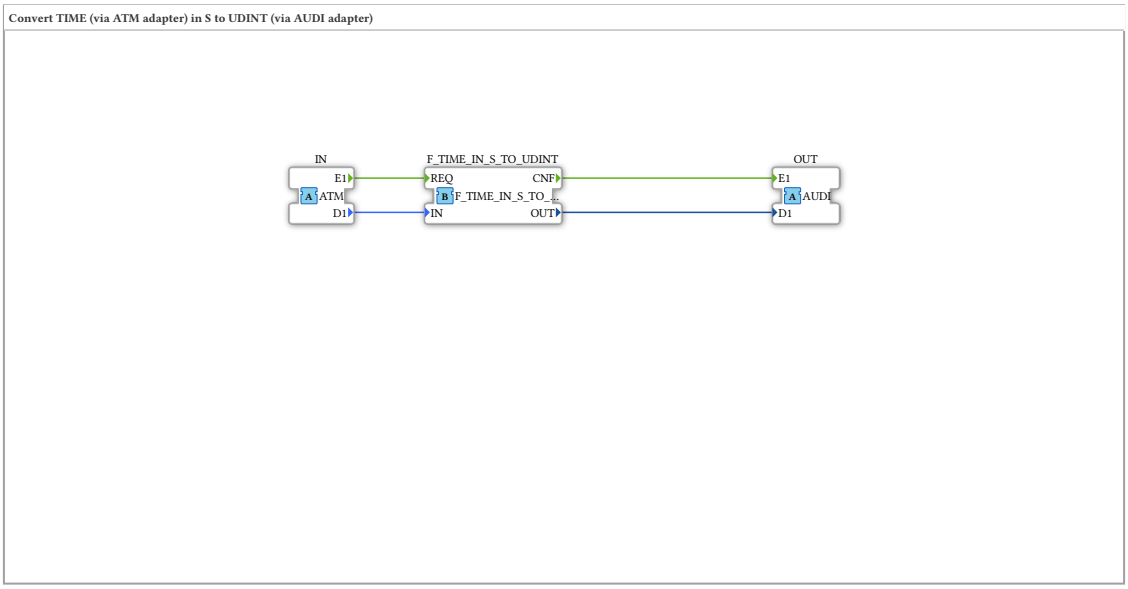
- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_S_TO_ADI, ATM_IN_S_TO_ALI, ATM_IN_S_TO_AUDI, ATM_IN_S_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_ALR, ATM_IN_NS_TO_ALR, ATM_IN_US_TO_ALR
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_S_TO_ALR`.

Conclusion



`ATM_IN_S_TO_ALR` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in seconds into a `LREAL` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_S_TO_AUDI

Time value to convert – *ATM*

AUDI – TIME value of IN expressed in S as UDINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_S_TO_AUDI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in seconds into a `UDINT` value (32-bit unsigned integer), output via the AUDI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `UDINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::AUDI	Unidirectional `UDINT` adapter as output interface, value of `IN` expressed in seconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_S_TO_UDINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_S_TO_UDINT`.
3. `F_TIME_IN_S_TO_UDINT` converts the time value into a seconds figure of type `UDINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_S_TO_UDINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_S_TO_UDINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in seconds and returns the result as `UDINT` (32-bit unsigned integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

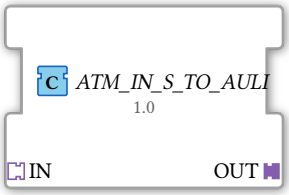
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (seconds) to `UDINT` via `F_TIME_IN_S_TO_UDINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in seconds to an adapter socket of type `AUDI`, for example for display on a panel or further use in a calculation.

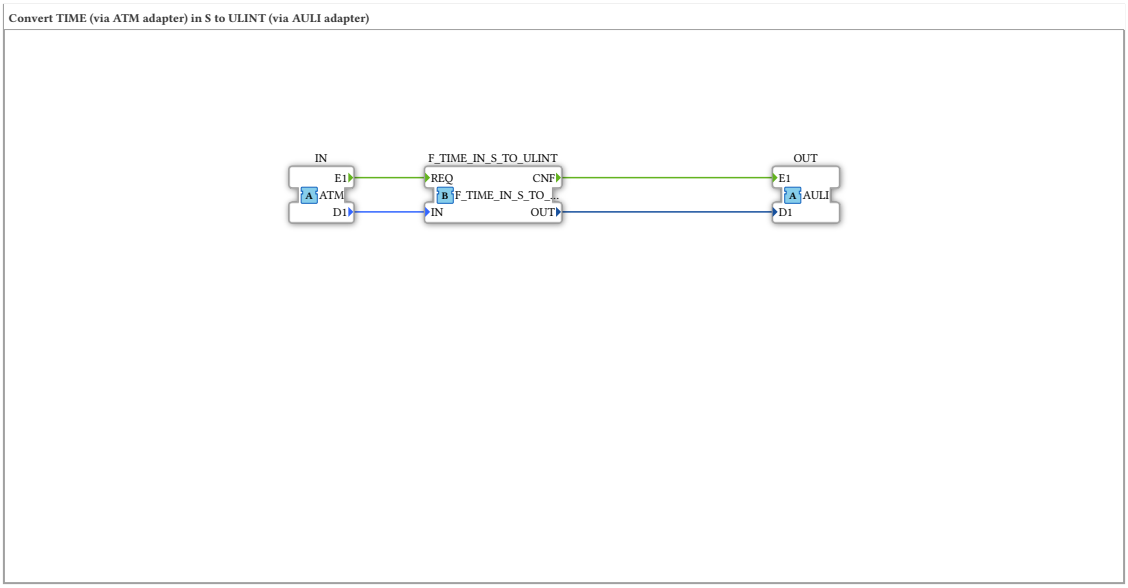
- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_S_TO_ADI, ATM_IN_S_TO_ALI, ATM_IN_S_TO_ALR, ATM_IN_S_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_AUDI, ATM_IN_NS_TO_AUDI, ATM_IN_US_TO_AUDI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_S_TO_AUDI`.

Conclusion



`ATM_IN_S_TO_AUDI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in seconds into a `UDINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_S_TO_AULI

Time value to convert – *ATM*

AULI – TIME value of IN expressed in S as ULINT

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ATM_IN_S_TO_AULI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in seconds into a `ULINT` value (64-bit unsigned integer), output via the AULI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `ULINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::AULI	Unidirectional `ULINT` adapter as output interface, value of `IN` expressed in seconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_S_TO_ULINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_S_TO_ULINT`.
3. `F_TIME_IN_S_TO_ULINT` converts the time value into a seconds figure of type `ULINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_S_TO_ULINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_S_TO_ULINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in seconds and returns the result as `ULINT` (64-bit unsigned integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (seconds) to `ULINT` via `F_TIME_IN_S_TO_ULINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

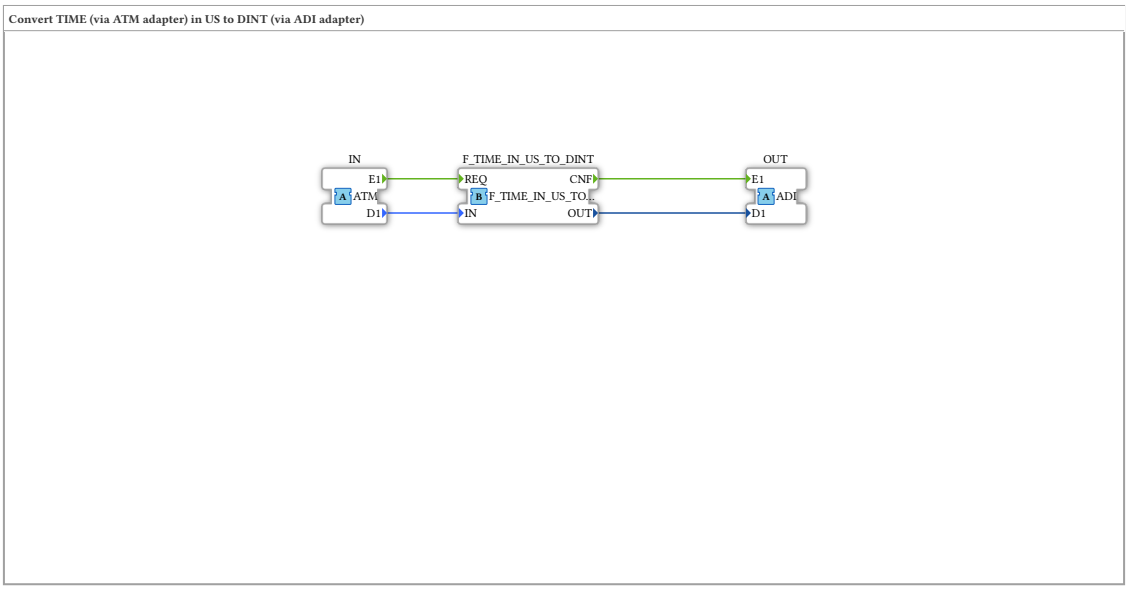
- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in seconds to an adapter socket of type `AULI`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks

- **Same unit, other target types**: ATM_IN_S_TO_ADI, ATM_IN_S_TO_ALI, ATM_IN_S_TO_ALR, ATM_IN_S_TO_AUDI
- **Same target type, other units**: ATM_IN_MS_TO_AULI, ATM_IN_NS_TO_AULI, ATM_IN_US_TO_AULI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_S_TO_AULI`.

Conclusion



`ATM_IN_S_TO_AULI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in seconds into a `ULINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_US_TO_ADI

Time value to convert – *ATM*

ADI – TIME value of IN expressed in US as DINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_US_TO_ADI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in microseconds into a `DINT` value (32-bit signed integer), output via the ADI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `DINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ADI	Unidirectional `DINT` adapter as output interface, value of `IN` expressed in microseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_US_TO_DINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_US_TO_DINT`.
3. `F_TIME_IN_US_TO_DINT` converts the time value into a microseconds figure of type `DINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_US_TO_DINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_US_TO_DINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in microseconds and returns the result as `DINT` (32-bit signed integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (microseconds) to `DINT` via `F_TIME_IN_US_TO_DINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

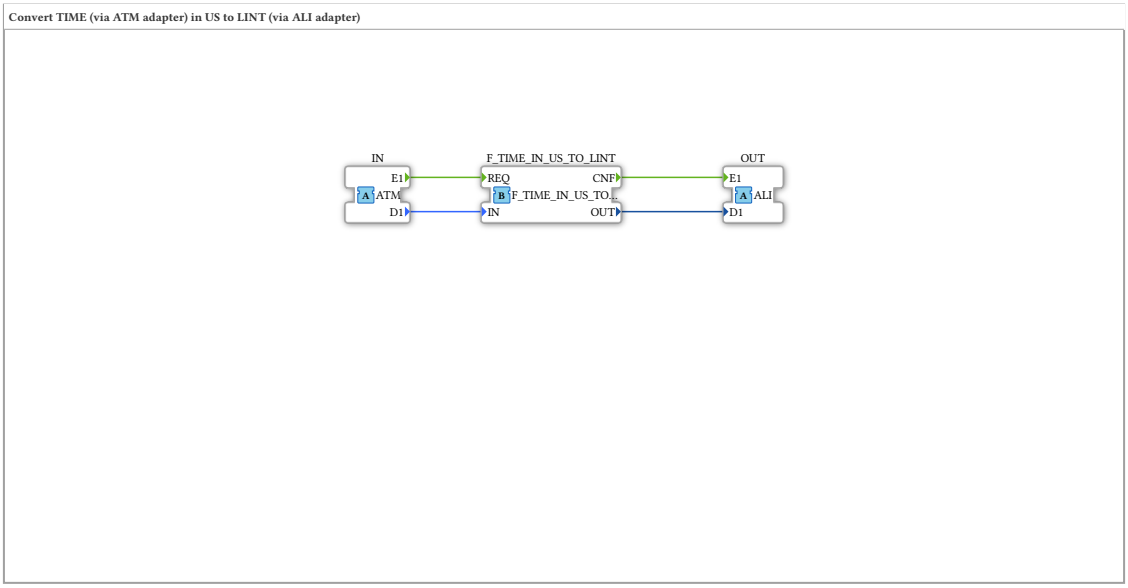
- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in microseconds to an adapter socket of type `ADI`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks

- **Same unit, other target types**: ATM_IN_US_TO_ALI, ATM_IN_US_TO_ALR, ATM_IN_US_TO_AUDI, ATM_IN_US_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_ADI, ATM_IN_NS_TO_ADI, ATM_IN_S_TO_ADI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_US_TO_ADI`.

Conclusion



`ATM_IN_US_TO_ADI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in microseconds into a `DINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_US_TO_ALI

Time value to convert – *ATM*

ALI – TIME value of IN expressed in US as LINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_US_TO_ALI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in microseconds into a `LINT` value (64-bit signed integer), output via the ALI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `LINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ALI	Unidirectional `LINT` adapter as output interface, value of `IN` expressed in microseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_US_TO_LINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_US_TO_LINT`.
3. `F_TIME_IN_US_TO_LINT` converts the time value into a microseconds figure of type `LINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_US_TO_LINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_US_TO_LINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in microseconds and returns the result as `LINT` (64-bit signed integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

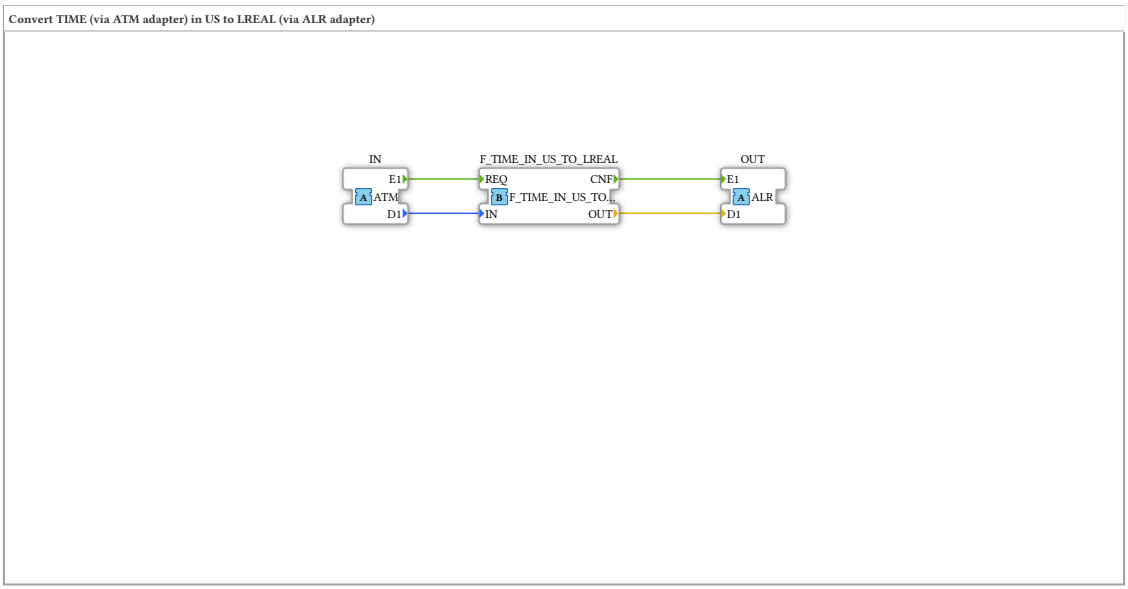
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (microseconds) to `LINT` via `F_TIME_IN_US_TO_LINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in microseconds to an adapter socket of type `ALI`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_US_TO_ADI, ATM_IN_US_TO_ALR, ATM_IN_US_TO_AUDI, ATM_IN_US_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_ALI, ATM_IN_NS_TO_ALI, ATM_IN_S_TO_ALI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_US_TO_ALI`.

Conclusion

`ATM_IN_US_TO_ALI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in microseconds into a `LINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_US_TO_ALR

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ATM_IN_US_TO_ALR** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in microseconds into a `LREAL` value (64-bit floating-point number), output via the ALR adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `LREAL`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::ALR	Unidirectional `LREAL` adapter as output interface, value of `IN` expressed in microseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_US_TO_LREAL`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_US_TO_LREAL`.
3. `F_TIME_IN_US_TO_LREAL` converts the time value into a microseconds figure of type `LREAL` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_US_TO_LREAL`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_US_TO_LREAL` interprets the `TIME` value (internally held in nanoseconds) as a figure in microseconds and returns the result as `LREAL` (64-bit floating-point number).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

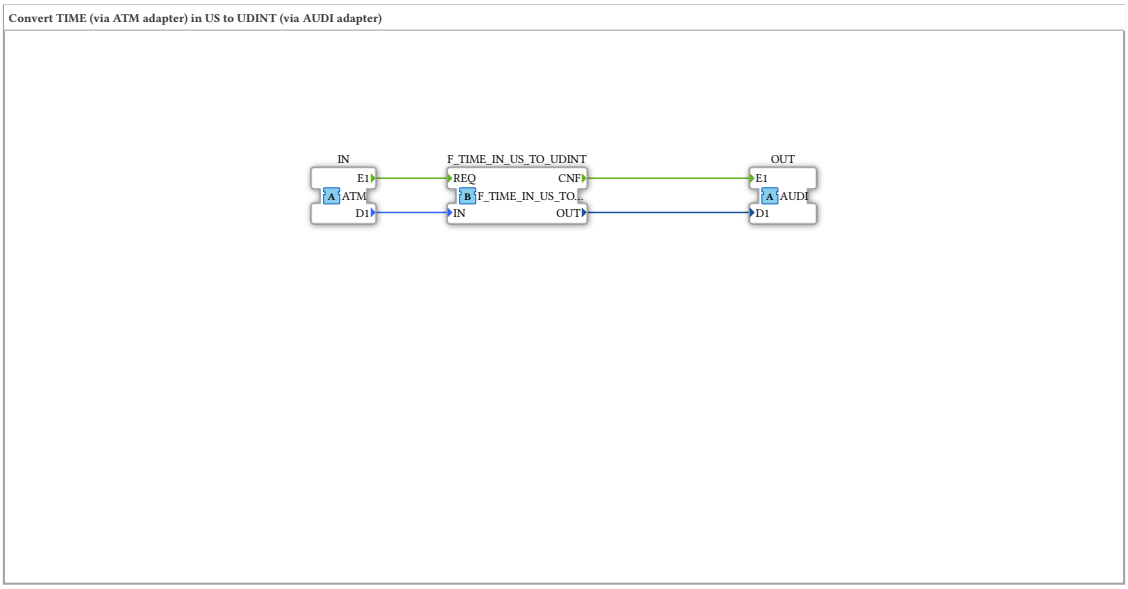
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (microseconds) to `LREAL` via `F_TIME_IN_US_TO_LREAL`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in microseconds to an adapter socket of type `ALR`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_US_TO_ADI, ATM_IN_US_TO_ALI, ATM_IN_US_TO_AUDI, ATM_IN_US_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_ALR, ATM_IN_NS_TO_ALR, ATM_IN_S_TO_ALR
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_US_TO_ALR`.

Conclusion

`ATM_IN_US_TO_ALR` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in microseconds into a `LREAL` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_US_TO_AUDI

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_US_TO_AUDI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in microseconds into a `UDINT` value (32-bit unsigned integer), output via the AUDI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `UDINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::AUDI	Unidirectional `UDINT` adapter as output interface, value of `IN` expressed in microseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_US_TO_UDINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_US_TO_UDINT`.
3. `F_TIME_IN_US_TO_UDINT` converts the time value into a microseconds figure of type `UDINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_US_TO_UDINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_US_TO_UDINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in microseconds and returns the result as `UDINT` (32-bit unsigned integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

The function block does not have its own state machine. The process can be described as a simple step:

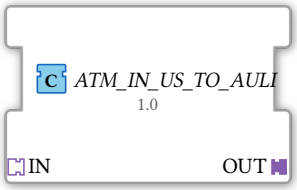
Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (microseconds) to `UDINT` via `F_TIME_IN_US_TO_UDINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in microseconds to an adapter socket of type `AUDI`, for example for display on a panel or further use in a calculation.

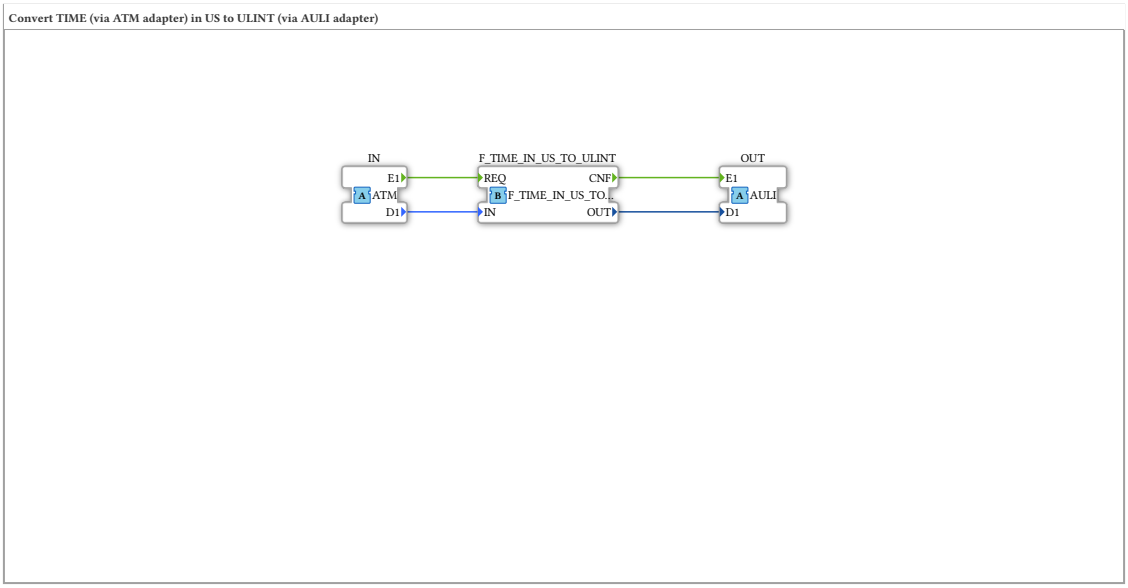
- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.

Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_US_TO_ADI, ATM_IN_US_TO_ALI, ATM_IN_US_TO_ALR, ATM_IN_US_TO_AULI
- **Same target type, other units**: ATM_IN_MS_TO_AUDI, ATM_IN_NS_TO_AUDI, ATM_IN_S_TO_AUDI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_US_TO_AUDI`.

Conclusion



`ATM_IN_US_TO_AUDI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in microseconds into a `UDINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_IN_US_TO_AULI

Time value to convert – *ATM*

AULI – TIME value of IN expressed in US as ULINT

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_IN_US_TO_AULI** is a composite block that converts a `TIME` value (carried via the ATM adapter) expressed in microseconds into a `ULINT` value (64-bit unsigned integer), output via the AULI adapter. It belongs to the `ATM_IN_<UNIT>_TO_<TARGET>` block family, which provides the same conversion for all four time units (MS, NS, S, US) and all five target integer/floating-point types.

Interface Structure

Event Inputs

- No directly visible event inputs. Event control is handled indirectly via the **IN** adapter (event E1).

Event Outputs

- No directly visible event outputs. Event signaling is handled indirectly via the **OUT** adapter (event E1).

Data Inputs

- No directly visible data inputs. The input value is provided via the **IN** adapter (data point D1 of type `TIME`).

Data Outputs

- No directly visible data outputs. The output value is provided via the **OUT** adapter (data point D1 of type `ULINT`).

Adapters

Adapter	Role	Type	Description
IN	Socket	adapter::types::unidirectional::ATM	Unidirectional `TIME` adapter as input interface.
OUT	Plug	adapter::types::unidirectional::AULI	Unidirectional `ULINT` adapter as output interface, value of `IN` expressed in microseconds.

Functionality

The function block internally contains a single function block, `F_TIME_IN_US_TO_ULINT`, from the IEC 61131-3 standard library. Sequence control is purely event-driven:

1. An event at the input adapter **IN.E1** triggers the input **REQ** of the internal conversion block.
2. The data value **IN.D1** (`TIME`) is passed to the input **IN** of `F_TIME_IN_US_TO_ULINT`.
3. `F_TIME_IN_US_TO_ULINT` converts the time value into a microseconds figure of type `ULINT` and signals this via its output **CNF**.
4. This event is forwarded to the output adapter **OUT.E1**.
5. Simultaneously, the converted value (output **OUT** of `F_TIME_IN_US_TO_ULINT`) is passed to the data point **OUT.D1**.

The entire process is synchronous and without intermediate storage – each successful conversion immediately triggers an output event.

Technical Features

- **Unit conversion per IEC 61131-3**: The internal block `F_TIME_IN_US_TO_ULINT` interprets the `TIME` value (internally held in nanoseconds) as a figure in microseconds and returns the result as `ULINT` (64-bit unsigned integer).
- **Unidirectional adapters**: Both the input and output adapters are unidirectional. Reverse communication is not supported.
- **Composite structure without its own logic**: The block consists solely of a data and an event connection to the internal conversion block; there is no ECC of its own.
- **Empty TypeHash**: As with all generated conversion composites in this package, `eclipse4diac::core::TypeHash` is empty (`''`).

State Overview

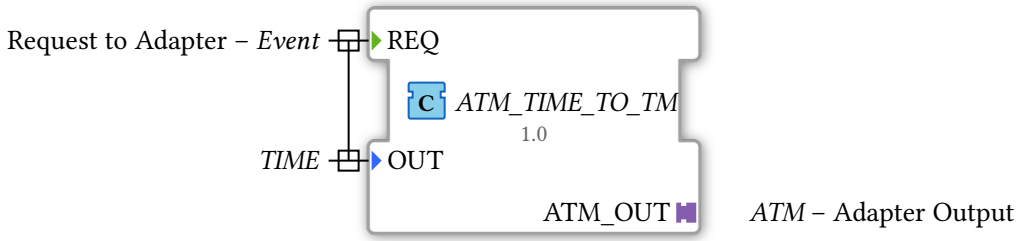
The function block does not have its own state machine. The process can be described as a simple step:

Step	Action
1	Wait for event at **IN.E1**
2	Convert the data value from `TIME` (microseconds) to `ULINT` via `F_TIME_IN_US_TO_ULINT`
3	Output the converted value to **OUT.D1** and event to **OUT.E1**
4	Return to step 1

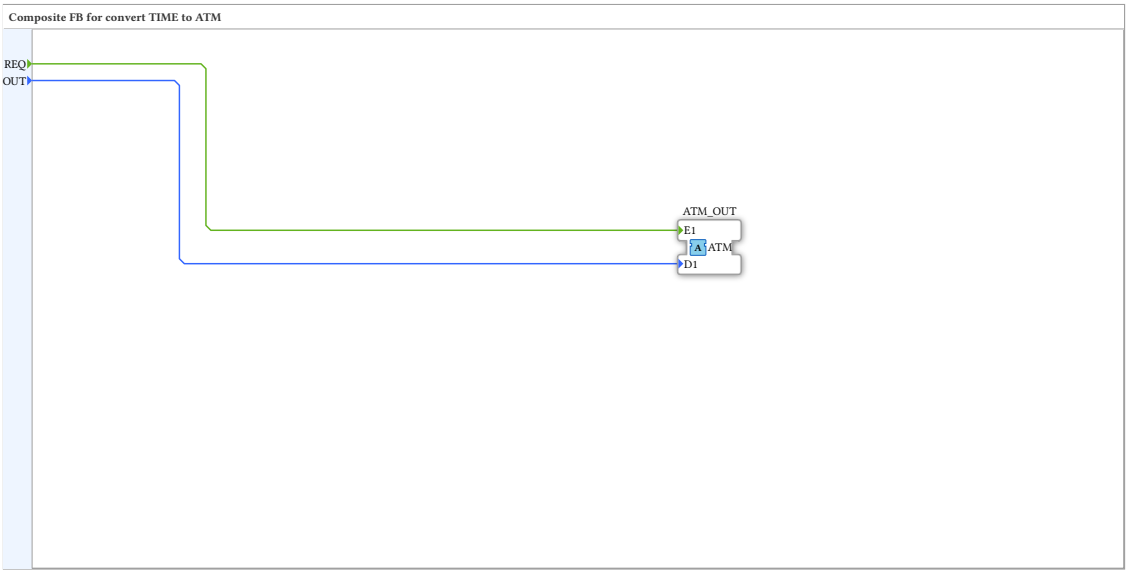
Application Scenarios

- **Displaying/processing durations**: A duration carried via an `ATM` adapter (e.g., a cycle time or delay) needs to be forwarded as a figure in microseconds to an adapter socket of type `AULI`, for example for display on a panel or further use in a calculation.

- **Interface adaptation**: In networks that consistently rely on adapter connections instead of classic data wiring, the block enables seamless conversion of a time adapter into a numeric adapter.



Comparison with similar function blocks



- **Same unit, other target types**: ATM_IN_US_TO_ADI, ATM_IN_US_TO_ALI, ATM_IN_US_TO_ALR, ATM_IN_US_TO_AUDI
- **Same target type, other units**: ATM_IN_MS_TO_AULI, ATM_IN_NS_TO_AULI, ATM_IN_S_TO_AULI
- **ATM_TIME_TO_TM / ATM_TM_TO_TIME**: pure adapter-to-variable passthrough without unit conversion, unlike the numeric conversion performed by `ATM_IN_US_TO_AULI`.

Conclusion

`ATM_IN_US_TO_AULI` provides a standards-compliant, fully adapter-based conversion of a `TIME` value in microseconds into a `ULINT` value, fitting seamlessly into networks that consistently rely on adapter connections instead of classic data wiring.

ATM_TIME_TO_TM

• – ○ • – ○ • – ○ •

Introduction

`ATM_TIME_TO_TM` is a composite function block that converts a plain `TIME` data value into the ATM adapter format. It follows exactly the same pattern as ADI_DINT_TO_DI (DINT→ADI) and AUI_UINT_TO_UI (UINT→AUI): a single data connection and a single event connection, passed straight through to the plug — no conversion logic of its own.

Interface Structure

Event Inputs

- **REQ**: request event that triggers the conversion; carries the value of `OUT` (`With Var="OUT"`).

Event Outputs

None of its own; the event flows exclusively through the ATM_OUT adapter plug.

Data Inputs

- **OUT** (TIME): the time value to convert.

Data Outputs

None of its own; the value is provided exclusively through the ATM_OUT adapter plug.

Adapters

- **ATM_OUT** (plug, type adapter::types::unidirectional::ATM): emits the value of OUT via its E1/D1 adapter event on REQ.

Functionality

When the REQ event arrives, it is forwarded directly to ATM_OUT.E1, while the current value of OUT is simultaneously placed onto ATM_OUT.D1. The ATM_OUT plug thus fires its adapter event carrying the supplied time value — no buffering, no change detection, freshly on every REQ.

Technical Details

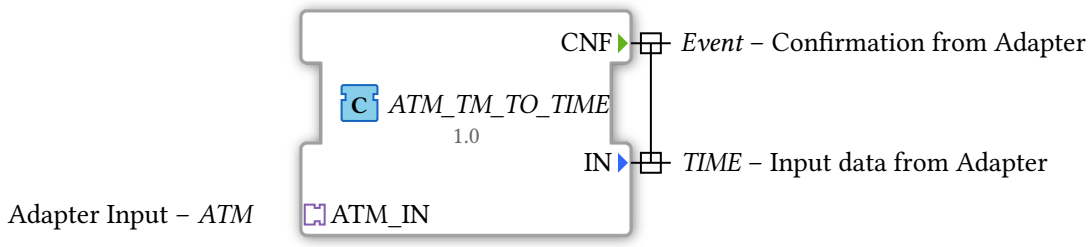
- **Pure wiring logic**, no ECC of its own, no ST algorithms — a composite FB that establishes exactly one data and one event connection.
- **No REAL_TO_TIME exists in the standard libraries.** This block does not convert a numeric value into TIME — it accepts an already-finished TIME value and merely forwards it as an adapter. The actual conversion (e.g. from REAL seconds) happens beforehand, typically via iec61131::arithmetic::F_MULTIME (T#1s * REAL#seconds) — see the Override_Timer SubApp (FBs::sys, Getreideannahme application code, not part of this library's documentation) for a concrete usage example.
- **No event is suppressed for an unchanged value** — unlike, say, AX_ATM_FB_TON's ET output, there is no E_D_FF/E_D_FF_ANY buffering here; every REQ produces a fresh adapter event.

State Overview

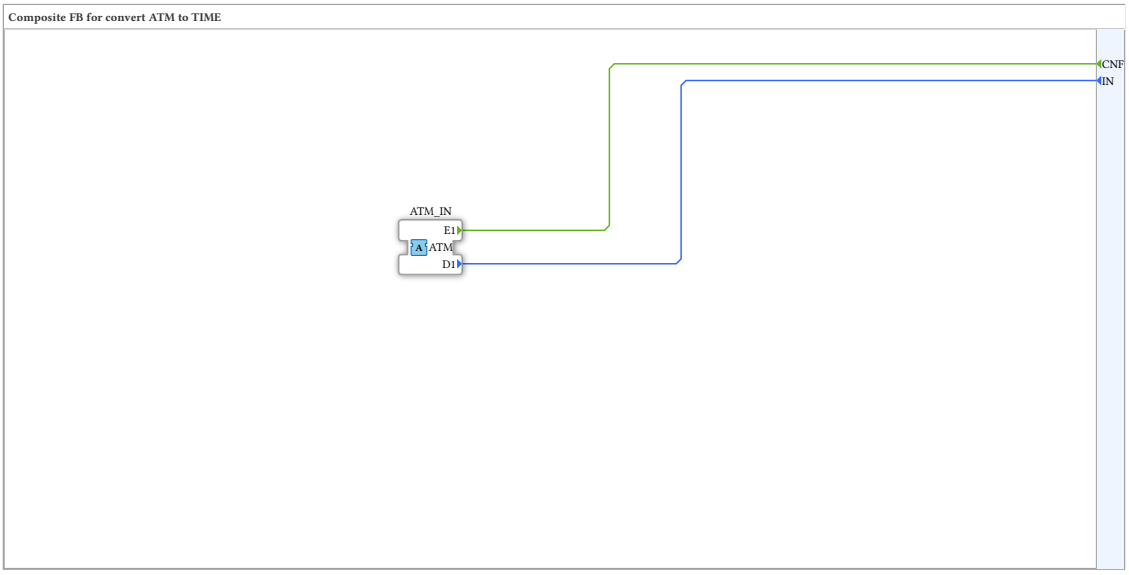
The block is stateless: every REQ event immediately outputs the current OUT value via ATM_OUT.

Application Scenarios

- **Feeding sockets that expect an ATM adapter instead of a plain TIME variable**, e.g. PT on AX_ATM_FB_TON/ AX_ATM_FB_TOF/ AX_ATM_FB_TP.
- The final step in a conversion chain from REAL seconds to an adapter-based time value (F_MULTIME → ATM_TIME_TO_TM), as used in the Override_Timer SubApp (FBs::sys).



⚖️ Comparison with Similar Blocks



- ATM_TM_TO_TIME: the reverse direction — accepts an ATM adapter socket and exposes the value as a plain TIME data variable.
- ADI_DINT_TO_DI / AUI_UINT_TO_UI / AR_REAL_TO_R: the same "data value → adapter plug" pattern for DINT, UINT, and REAL instead of TIME.

Conclusion

ATM_TIME_TO_TM is the simplest way to expose a TIME data value as an ATM adapter plug, bridging the gap between numeric time calculations (e.g. via F_MULTIME) and adapter-based time sockets such as PT on AX_ATM_FB_TON/TOF/TP.

ATM_TM_TO_TIME

• – ○ • – ○ • – ○ •

Introduction

`ATM_TM_TO_TIME` is the reverse of ATM_TIME_TO_TM: a composite function block that accepts an ATM adapter socket and exposes its value as a plain `TIME` data variable. It follows exactly the same pattern as AUI_UI_TO_UINT (AUI→UINT): a single data connection and a single event connection, read straight off the socket — no conversion logic of its own.

Interface Structure

Event Inputs

None of its own; the event arrives exclusively through the `ATM_IN` adapter socket.

Event Outputs

- **CNF**: confirmation event, fires when the `ATM_IN` adapter socket fires its event; carries the value of `IN` (`With Var="IN"`).

Data Inputs

None of its own; the value arrives exclusively through the `ATM_IN` adapter socket.

Data Outputs

- **IN** (TIME): the time value received from the adapter.

Adapters

- **ATM_IN** (socket, type `adapter::types::unidirectional::ATM`): receives the time value from the connected plug.

Functionality

As soon as the connected plug fires an event on `ATM_IN`, `ATM_IN.E1` is forwarded directly to `CNF`, while `ATM_IN.D1` is simultaneously placed onto the data output variable `IN`. The block thus makes the value of an incoming `ATM` adapter usable by downstream blocks that expect a plain `TIME` variable rather than an adapter socket (e.g. `OSCAT::Basic::POUs::conversion::TIME_TO_REAL`, whose `TM` input is a plain data variable).

Technical Details

- **Pure wiring logic**, no ECC of its own, no ST algorithms — a composite FB that establishes exactly one data and one event connection.
- **Necessary because plugs cannot feed a plain data variable directly.** An adapter plug (e.g. the `ET` output of AX_ATM_FB_TON) can only connect to a socket, never directly to a function's plain `InputVar`. `ATM_TM_TO_TIME` closes that gap.

- **No event is suppressed for an unchanged value** — the block itself buffers nothing; whether an event actually only arrives on a value change depends on the upstream plug (e.g. `AX_ATM_FB_TON.ET` already has its own `E_D_FF_ANY` change detection).

State Overview

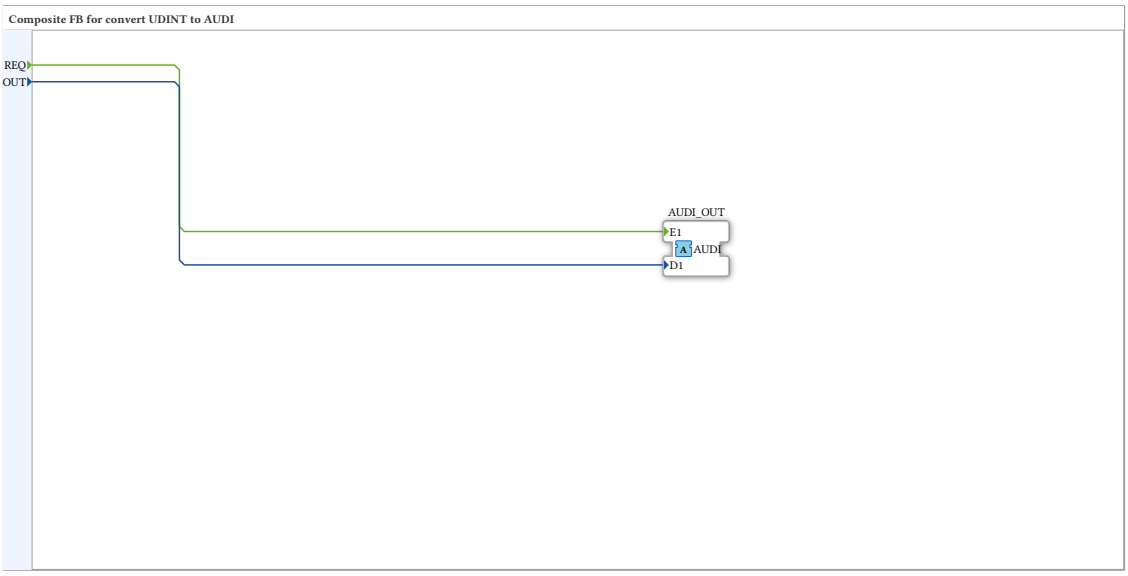
The block is stateless: every event on the `ATM_IN` socket immediately outputs the current value via `IN`/`CNF`.

Application Scenarios

- **Making an adapter plug readable for functions with plain data variables**, e.g. forwarding the `ET` output of AX_ATM_FB_TON/ AX_ATM_FB_TOF/ AX_ATM_FB_TP into `OSCAT::Basic::POUs::conversion::TIME_TO_REAL`.
- The first step in a conversion chain from an adapter-based time value back to REAL seconds (`ATM_TM_TO_TIME` → `TIME_TO_REAL` → `F_DIV`), as used in the `Override_Timer` SubApp (`FBs::sys`, Getreideannahme application code, not part of this library's documentation).

⚖️ Comparison with Similar Blocks

- **ATM_TIME_TO_TM**: the reverse direction — accepts a plain `TIME` data variable and exposes it as an `ATM` adapter plug.
- **AUI_UI_TO_UINT / ADI_DI_TO_DINT**: the same "adapter socket → data value" pattern for UINT and DINT instead of TIME.



Conclusion

`ATM_TM_TO_TIME` is the simplest way to make an `ATM` adapter plug's value usable as a plain `TIME` variable, bridging the gap between adapter-based time plugs (e.g. `ET` on `AX_ATM_FB_TON/TOF/TP`) and functions that only accept plain data variables.

AUDI_UDINT_TO_UDI

Introduction

The AUDI_UDINT_TO_UDI function block is a composite function block used to convert a UDINT value to the AUDI adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

- No direct event outputs available

Data Inputs

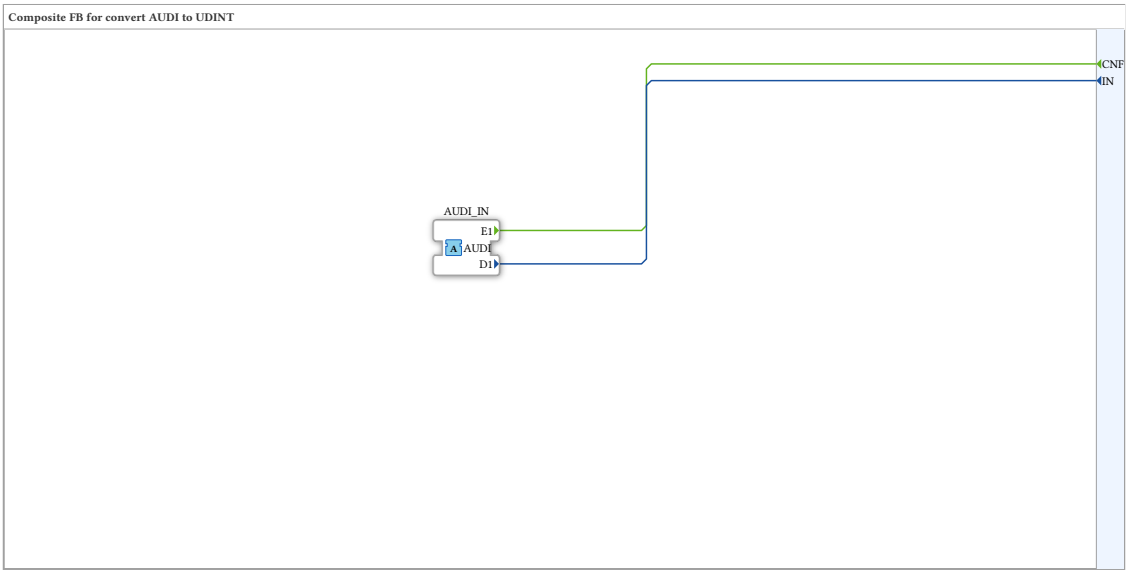
- **OUT**: UDINT input value to be converted

Data Outputs

- No direct data outputs available

Adapter

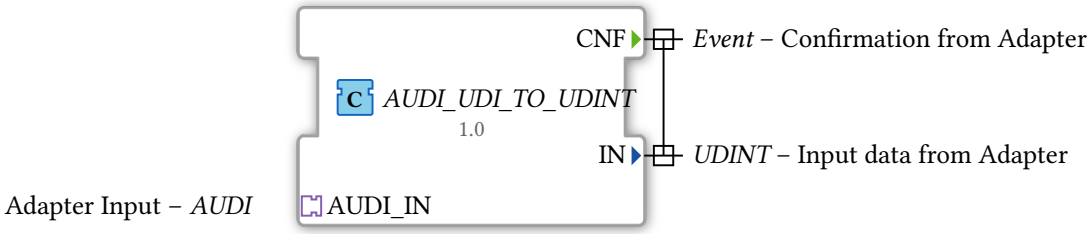
- **AUDI_OUT**: Plug of type `AUDI`



Functionality

The function block receives a UDINT value at the OUT data input and converts it to the AUDI adapter format upon arrival of the REQ event.

🛠️ Related Exercises



- Exercise_083_AX

AUDI_UDI_TO_UDINT

Introduction

The AUDI_UDI_TO_UDINT function block is a composite function block used to convert the AUDI adapter format to a UDINT value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

Data Outputs

- **IN**: UDINT output value of the converted data

Adapter

- **AUDI_IN**: Socket of type `AUDI`

Functionality

The function block receives data via the AUDI adapter socket and makes the contained UDINT value available at the IN output as soon as an event arrives via the adapter (CNF).

UDINT conversion

AUI_UINT_TO_UI

Introduction

The AUI_UINT_TO_UI function block is a composite function block used to convert a UINT value to the AUI adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

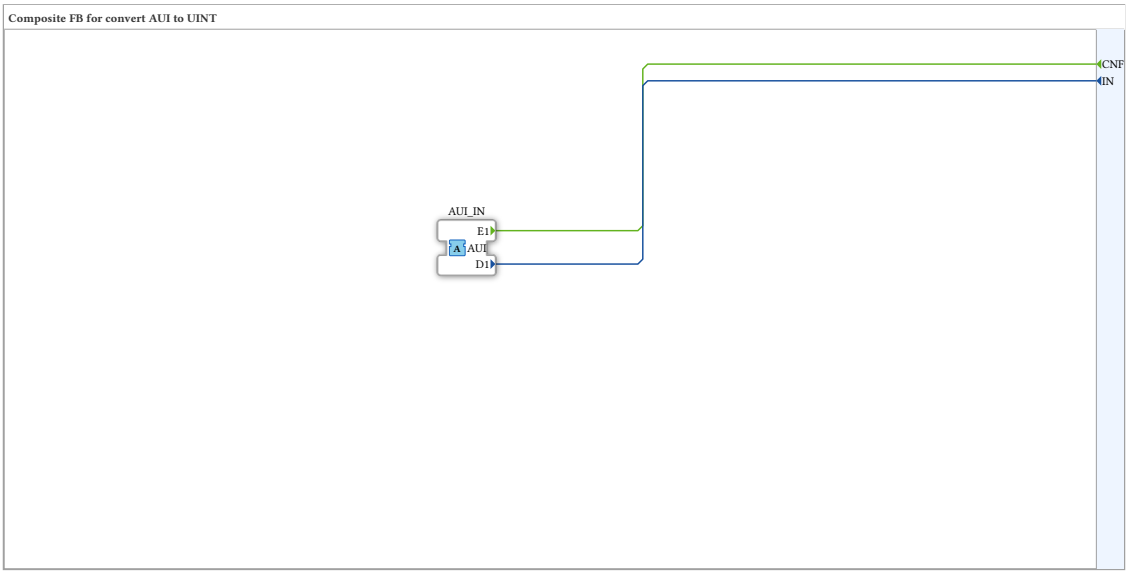
- No direct event outputs available

Data Inputs

- **OUT**: UINT input value to be converted

Data Outputs

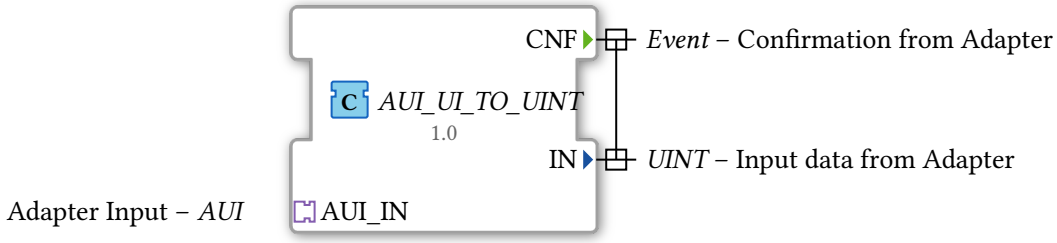
- No direct data outputs available



Adapter

- **AUI_OUT**: Plug of type `AUI`

Functionality



The function block receives a UINT value at the data input OUT and converts it to the AUI adapter format upon arrival of the REQ event.

AUI_UI_TO_UINT

Introduction

The AUI_UI_TO_UINT function block is a composite function block used to convert the AUI adapter format to a UINT value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

Data Outputs

- **IN**: UINT output value of the converted data

Adapter

- **AUI_IN**: Socket of type `AUI`

Functionality

The function block receives data via the AUI adapter socket and makes the contained UINT value available at the IN output as soon as an event arrives via the adapter (CNF).

AULI_ULINT_TO_ULI

Introduction

The AULI_ULINT_TO_ULI function block is a composite function block used to convert a ULINT value to the AULI adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

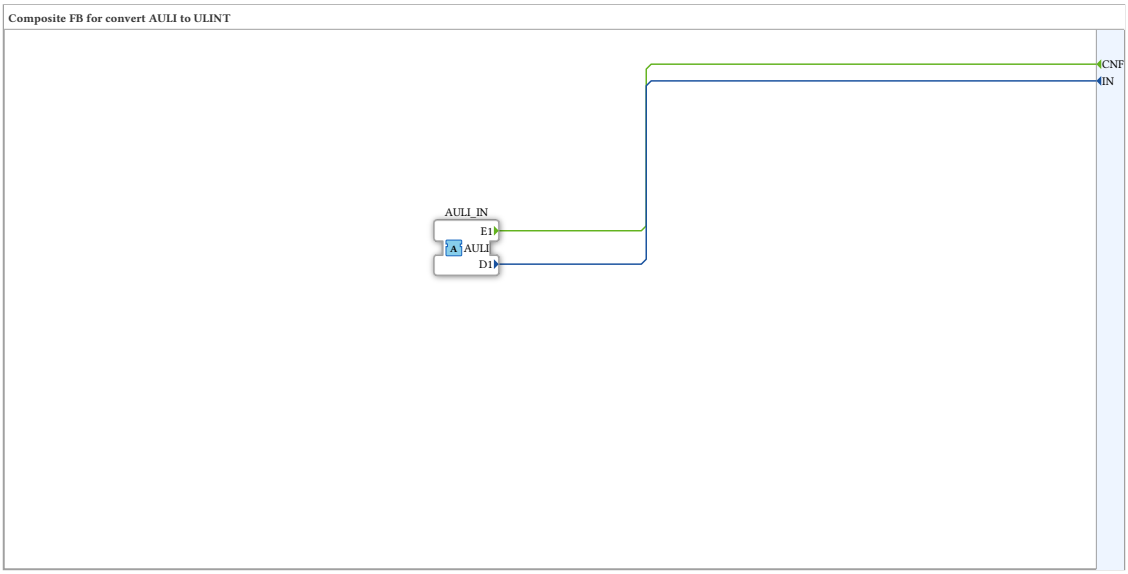
- No direct event outputs available

Data Inputs

- **OUT**: ULINT input value to be converted

Data Outputs

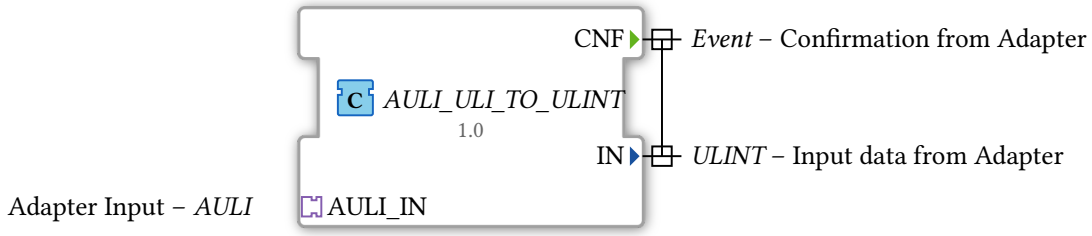
- No direct data outputs available



Adapter

- **AULI_OUT**: Plug of type `AULI`

Functionality



The function block receives a ULINT value at the OUT data input and converts it to the AULI adapter format upon arrival of the REQ event.

AULI_ULI_TO_ULINT

Introduction

The AULI_ULI_TO_ULINT function block is a composite function block used to convert the AULI adapter format to a ULINT value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

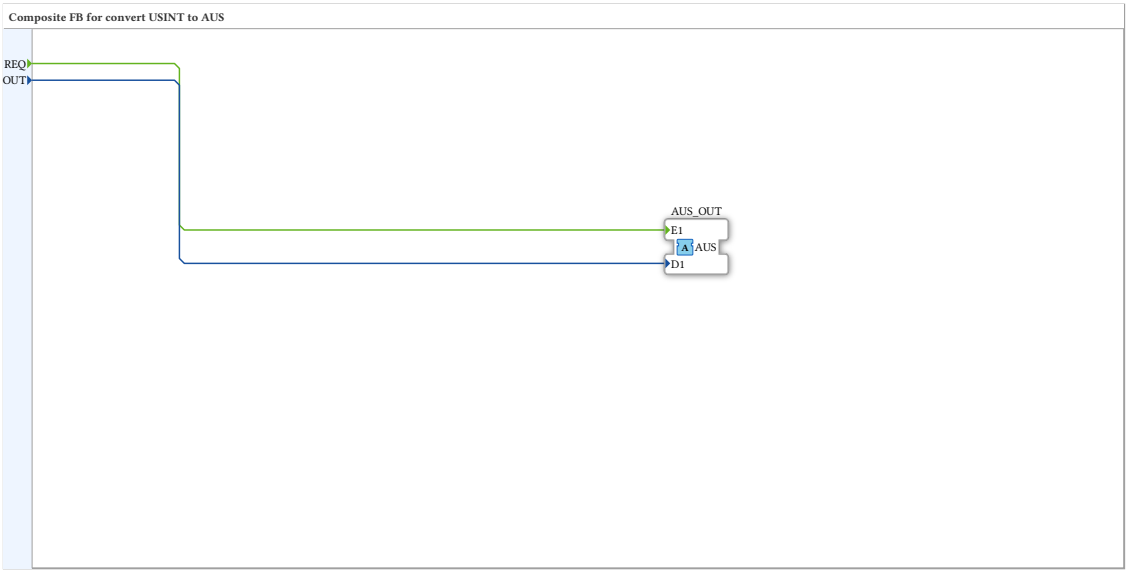
Data Outputs

- **IN**: ULINT output value of the converted data

Adapter

- **AULI_IN**: Socket of type `AULI`

Functionality



The function block receives data via the AULI adapter socket and makes the contained ULINT value available at the IN output as soon as an event arrives via the adapter (CNF).

ULINT Conversion

AUS_USINT_TO_US

Introduction

The AUS_USINT_TO_US function block is a composite function block used to convert a USINT value to the AUS adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

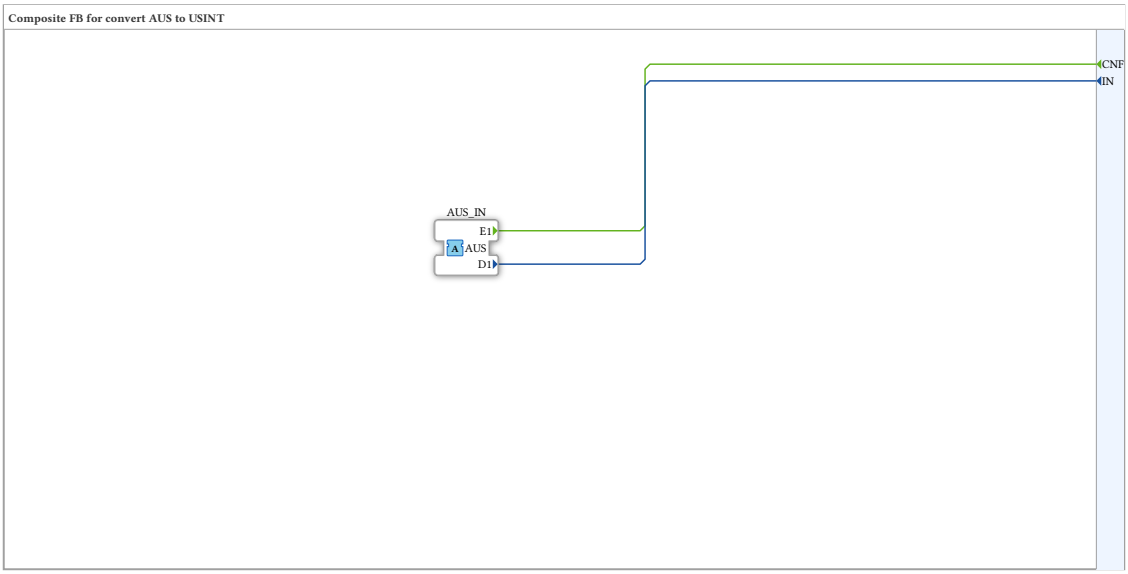
- No direct event outputs available

Data Inputs

- **OUT**: USINT input value to be converted

Data Outputs

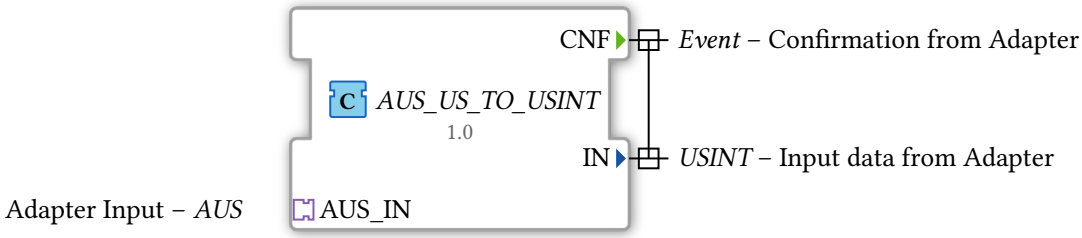
- No direct data outputs available



Adapter

- **AUS_OUT**: Plug of type `AUS`

Functionality



The function block receives a USINT value at the OUT data input and converts it to the AUS adapter format upon arrival of the REQ event.

AUS_US_TO_USINT

Introduction

The AUS_US_TO_USINT function block is a composite function block used to convert the AUS adapter format to a USINT value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

Data Outputs

- **IN**: USINT output value of the converted data

Adapter

- **AUS_IN**: Socket of type `AUS`

Functionality

The function block receives data via the AUS adapter socket and makes the contained USINT value available at the IN output as soon as an event arrives via the adapter (CNF).

USINT conversion

AW_WORD_TO_W

Introduction

The AW_WORD_TO_W function block is a composite function block used to convert a WORD value to the AW adapter format.

Interface Structure

Event Inputs

- **REQ**: Request event to trigger the conversion

Event Outputs

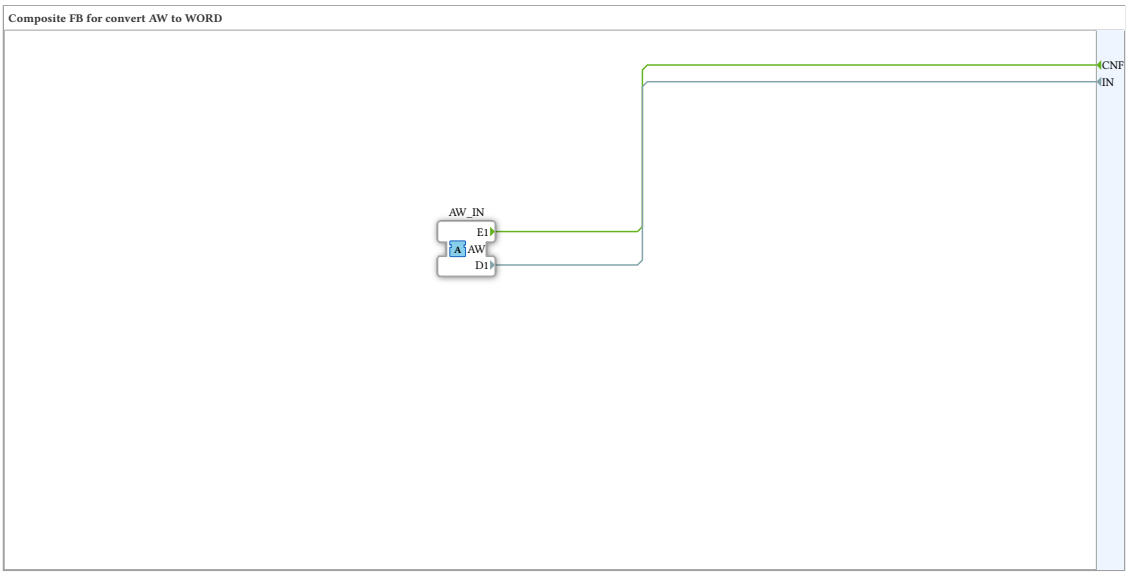
- No direct event outputs available

Data Inputs

- **OUT**: WORD input value to be converted

Data Outputs

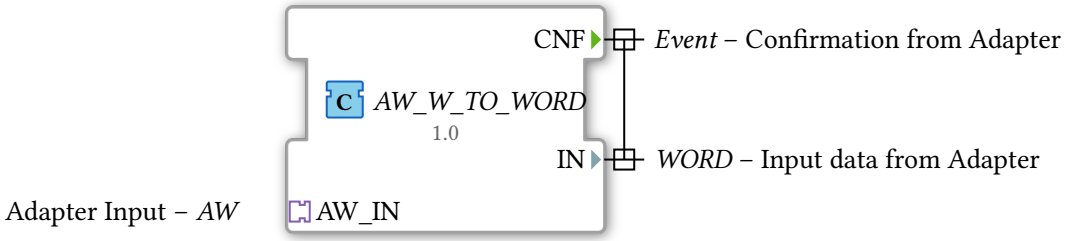
- No direct data outputs available



Adapter

- **AW_OUT**: Plug of type `AW`

Functionality



The function block receives a WORD value at the OUT data input and converts it to the AW adapter format upon arrival of the REQ event.

AW_W_TO_WORD

Introduction

The AW_W_TO_WORD function block is a composite function block used to convert the AW adapter format to a WORD value.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- **CNF**: Confirmation event after successful conversion

Data Inputs

- No direct data inputs available

Data Outputs

- **IN**: WORD output value of the converted data

Adapter

- **AW_IN**: Socket of type `AW`

Functionality

The function block receives data via the AW adapter socket and makes the contained WORD value available at the IN output as soon as an event arrives via the adapter (CNF).

TimeOut

ATimeTick

Plug (adapter output)

Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

The ATimeTick adapter provides a standardized interface for a time-out service, inspired by the ROOM modeling approach. It enables the coordination between a client and a server for starting, stopping, and confirming time-based operations. The adapter supports both plug and socket roles, facilitating communication between function blocks in an IEC 61499 system.

Interface Structure

The adapter exposes the following interface elements:

Event Inputs

- **CNF**: Execution confirmation event, triggered when the time-out service completes or acknowledges a request. It carries associated data (Q, ET, PT).
- **STARTO_IN**: Event to start the time-out operation (input).
- **STOPO_IN**: Event to stop the time-out operation (input).

Event Outputs

- **REQ**: Event output that issues a request to the counterpart, typically used to initiate or query the time-out service.

Data Inputs

- **Q** (BOOL): Indicates whether the time-out is currently active (TRUE when started).
- **PT** (TIME): Process time – the configured time-out duration.
- **ET** (TIME): Elapsed time – the time that has already advanced.

Data Outputs

The adapter has no data outputs. All data is passed as inputs, primarily associated with the CNF event.

Adapters

This is an adapter type itself, so it is intended to be used as a plug or socket in a connection. It defines a service interface with two service sequences: “Timeout” and “NormalOperation”.

Functionality

The ATimeTick adapter manages the lifecycle of a time-out operation. It receives start and stop commands (STARTO_IN, STOPO_IN) and provides a confirmation (CNF) after a time-out event. The REQ output serves as a request trigger to the paired service. The data inputs (Q, PT, ET) allow the status and timing parameters to be monitored.

The service definition shows two interaction patterns:

- **Timeout**: A start command (START with parameters TD) is propagated from the plug to the socket. Then, when a time-out occurs, the socket sends a TimeOut event back to the plug.
- **NormalOperation**: Start and stop (START/STOP) events are passed between plug and socket, without an explicit time-out event—likely for normal operation where the time-out is not triggered.

This implies that the adapter can be used in two modes: one where a time-out triggers an output, and another where it simply manages start/stop sequences.

Technical Features

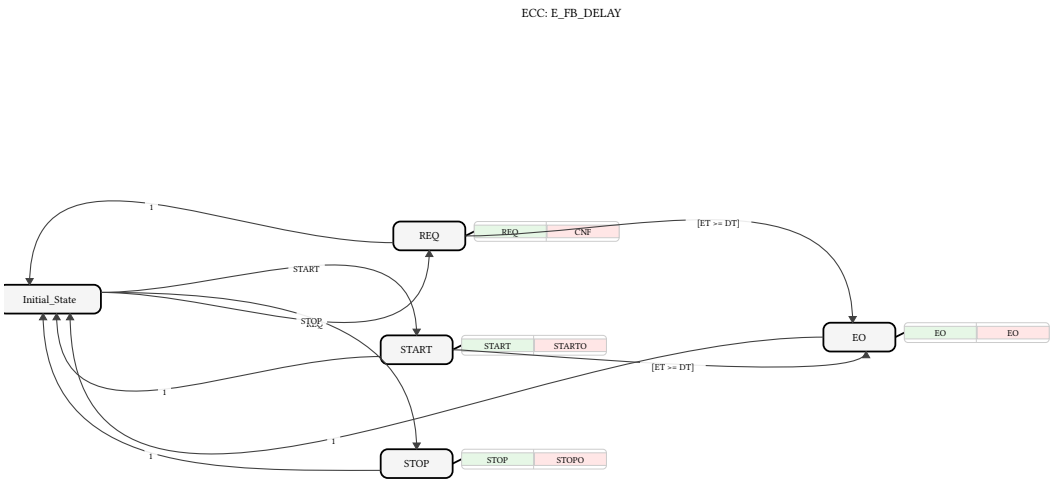
- **Service Type**: Supports both Plug and Socket roles, enabling bidirectional communication.
- **Event-Driven**: All operations are event-based, ensuring asynchronous coordination.
- **Data Association**: The CNF event is linked with Q, ET, and PT, allowing the confirmation to carry status and timing information.
- **Dynamic Timing**: The PT and ET parameters allow flexible configuration and monitoring of time intervals.
- **Standards Compliance**: Designed according to IEC 61499, with a version history and contributions from multiple organisations.

State Overview

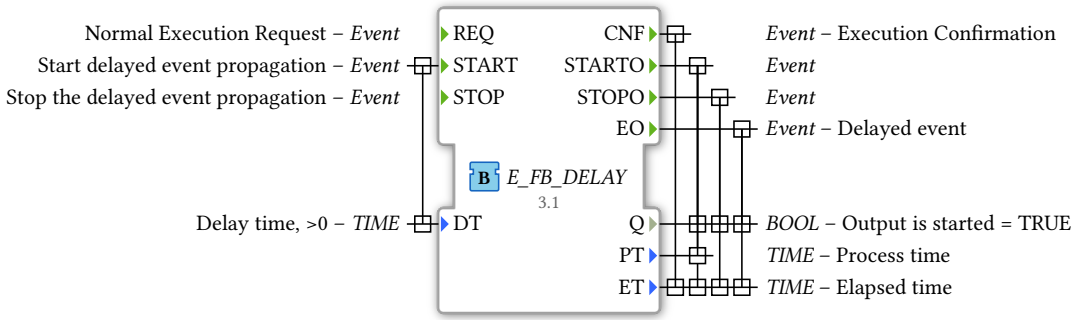
The adapter does not maintain an internal state machine within its definition; instead, it relies on the event sequences defined in the service. However, the Q data input provides a Boolean flag that can be interpreted as the active/inactive state of the time-out. The transitions are triggered by the events STARTO_IN (start), STOPO_IN (stop), and CNF (time-out occurrence).

Application Scenarios

- **Timeout Monitoring**: Use the adapter to enforce a time limit on a process. A function block can send STARTO_IN with a desired PT, and the service will respond with CNF after the time expires, allowing the block to react.
- **Process Synchronization**: In normal operation mode, the adapter can coordinate start/stop signals between two function blocks without triggering a time-out, useful for handshake protocols.
- **Error Detection**: By monitoring the ET value, it is possible to detect when a process takes longer than expected.



Comparison with Similar Blocks



Unlike standard timer function blocks (e.g., TON, TOF) which are self-contained, ATimeTick acts as an interface adapter that separates the timing logic from the requesting block. This promotes reusability and decoupling. Compared to generic adapter types, ATimeTick is specialised for time-out services, providing a clear contract for start/stop and confirmation events.

Conclusion

The ATimeTick adapter is a valuable component for implementing time-based coordination in IEC 61499 systems. Its clear event and data interface, along with its plug/socket capability, allows for flexible integration into distributed control applications. By following a ROOM-inspired design, it offers a structured approach to managing time-outs and normal operation sequences.

E_FB_DELAY

• – ○ • – ○ • – ○ •

Introduction

The **E_FB_DELAY** function block is a basic IEC 61499 FB designed to propagate an event after a predefined delay time. It provides a cyclic interface (similar to a `TON` timer) allowing external logic to start, stop, and poll the elapsed time while the delay is active. When the delay time is reached, an output event `EO` is emitted, indicating that the desired time has elapsed. The FB is particularly useful in scenarios where a timed response or a scheduled action is required, and it can be driven by an external cyclic trigger (e.g., an `E_CYCLE` block) to keep the elapsed time up-to-date.

Interface Structure

Event Inputs

- **REQ** (`Event`): Normal execution request. When the timer is armed (`Q = TRUE`), this event causes the FB to update the elapsed time (`ET`) by reading the system monotonic clock.
- **START** (`Event`): Starts the delayed event propagation. When this event is received, the FB records the current time, sets the output `Q` to `TRUE`, and resets `ET` to zero.

- **STOP** (Event): Stops the delayed event propagation. It cancels the active timer without generating an EO event; the output Q is cleared and ET is reset to zero.

Event Outputs

- **CNF** (Event): Execution confirmation. Emitted whenever the REQ algorithm completes (i.e., after an execution request).
- **STARTO** (Event): Confirmation that the timer has been started. Emitted after the START algorithm executes.
- **STOPO** (Event): Confirmation that the timer has been stopped. Emitted after the STOP algorithm executes.
- **EO** (Event): Delayed event. Emitted when the elapsed time (ET) reaches or exceeds the delay time (DT). This is the main output that signals the completion of the delay period.

Data Inputs

- **DT** (TIME): Delay time. Must be greater than zero. This is the duration the FB waits before generating the EO event.

Data Outputs

- **Q** (BOOL): Output indicating that the timer is currently armed (TRUE when the delay is in progress, FALSE otherwise).
- **PT** (TIME): Preset time (SOLL). Set to DT at START. It is provided as an output for informational purposes.
- **ET** (TIME): Elapsed time. Shows how much time has passed since the timer was started. This value is only updated when the REQ event is triggered while the timer is armed.
- **REST** (TIME): Remaining time = PT - ET. Set to PT at START, tracked on REQ, and reset to zero on STOP/EO.

Adapters

No adapters are defined for this FB.

Functionality

The E_FB_DELAY operates as a cyclic timer that can be started, polled, and stopped. The core logic is implemented as a basic FB with an ECC (Execution Control Chart) and four algorithms:

1. **START**:
   - Records the current monotonic time into the internal variable StartTime.
   - Sets Q = TRUE to indicate the timer is armed.
   - Resets ET = T#0s.
2. **REQ**:
   - If Q = TRUE (timer is armed), it reads the current monotonic time and calculates ET = NOW_MONOTONIC() - StartTime.
   - If Q = FALSE, it performs no operation.
   - This allows an external cyclic trigger (e.g., an E_CYCLE block) to refresh ET periodically.
3. **STOP**:
   - Clears Q = FALSE.
   - Resets ET = T#0s.
   - No EO event is generated.
4. **EO**:
   - Executed when the condition [ET >= DT] is true after a REQ or START event.
   - Clears Q = FALSE.
   - Resets ET = T#0s.
   - This prevents the condition from remaining true, so an EO event is fired only once per active delay period.

The ECC defines the state transitions that drive these algorithms. The block begins in Initial_State. From there:

- REQ → goes to REQ state, executes algorithm REQ, outputs CNF, then either transitions to EO (if ET >= DT) or back to Initial_State.

- START → goes to START state, executes algorithm START, outputs STARTO, then checks ET >= DT; if true, moves to EO, otherwise returns to Initial_State.
- STOP → goes to STOP state, executes algorithm STOP, outputs STOPO, and returns to Initial_State.
- From EO state (which executes EO and outputs the EO event), it always returns to Initial_State.

The block is intended to be driven cyclically: while a delay is active, the application should send REQ events (e.g., from a periodic cyclic function block) to update ET. When ET reaches DT, the FB will generate an EO event automatically. The START event can be used to (re)arm the timer, and STOP can cancel it prematurely.

Technical Features

- **Monotonic Clock Usage**: The FB uses NOW_MONOTONIC() to obtain a monotonic time source, ensuring that the elapsed time is not affected by system clock adjustments.
- **Single-Shot Delay**: The EO event is generated exactly once per START cycle. After EO is emitted, the timer is automatically disarmed and ET reset, so subsequent REQ events will not re-trigger EO.
- **Cyclic Polling Support**: The REQ event allows an external cyclic trigger to update ET continuously. This makes the block suitable for applications where the delay time must be monitored in real time.
- **Simple Interface**: The block exposes only the essential inputs and outputs, making it easy to integrate into larger IEC 61499 systems.
- **No Persistence**: The FB is stateless between activations (except for the StartTime internal variable), but after a START/STOP/EO sequence, all state variables are reset.

State Overview

The ECC contains five states:

1. **Initial_State**: The idle state where no timer is active. The block remains here until a START, STOP, or REQ event is received.
2. **REQ**: A transient state triggered by the REQ event. Executes the REQ algorithm and outputs CNF. After that, it either transitions to EO (if the delay time has elapsed) or returns to Initial_State.
3. **START**: A transient state triggered by the START event. Executes the START algorithm and outputs STARTO. Then it checks if the delay time has already been reached (unlikely since the timer was just started) and transitions to EO if so, otherwise returns to Initial_State.
4. **STOP**: A transient state triggered by the STOP event. Executes the STOP algorithm and outputs STOPO, then returns to Initial_State.
5. **EO**: A transient state that is entered when the condition [ET >= DT] is satisfied. Executes the EO algorithm, outputs the EO event, and then returns to Initial_State.

The transitions are summarized as follows:

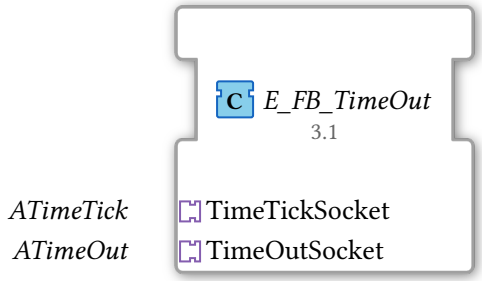
- Initial_State → REQ (on REQ)
- Initial_State → START (on START)
- Initial_State → STOP (on STOP)
- REQ → EO (if [ET >= DT])
- REQ → Initial_State (always, after executing REQ and CNF, if condition not met)
- START → EO (if [ET >= DT] – normally false immediately after start)
- START → Initial_State (always, after executing START and STARTO, if condition not met)
- STOP → Initial_State (always, after executing STOP and STOPO)
- EO → Initial_State (always, after executing EO)

Application Scenarios

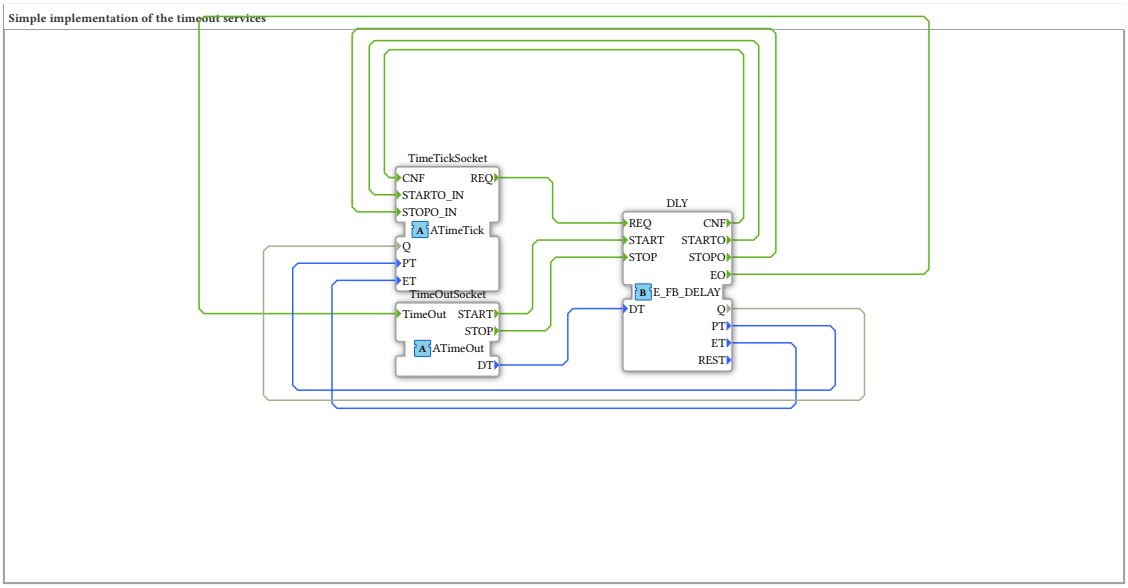
- **Timed Output Generation**: Trigger an action (e.g., a valve open/close, a light, a data acquisition) after a configurable delay.
- **Synchronization with Cyclic Tasks**: When integrated with a cyclic execution framework (e.g., an E_CYCLE block that sends REQ periodically), the FB provides an accurate timer that can be polled without blocking the system.
- **Timeout Monitoring**: Use START to arm a watchdog, poll ET via REQ to monitor progress, and receive EO if the timeout occurs. STOP can be used to cancel the watchdog when the expected action happens earlier.
- **Sequence Control**: In a sequential logic, the block can be used to enforce a minimum dwell time in a state before allowing a transition to the next step.

Comparison with Similar Blocks

Compared to the standard IEC 61499 **TON** (Timer On-Delay) function block, **E_FB_DELAY** offers a more explicit cyclic interface:



- It requires an external `REQ` event to update `ET`, while a `TON` block typically updates its elapsed time automatically within its own execution context.
- The `REQ` mechanism gives the developer control over when time evaluation occurs, which can be beneficial in deterministic or event-driven systems.
- The block provides separate output events for start/stop confirmation (`STARTO`, `STOPO`) and the actual delay completion (`EO`), whereas a `TON` block typically outputs a boolean `Q` and an elapsed time `ET` but no explicit event for "delay reached".
- The use of `NOW_MONOTONIC()` and the internal `StartTime` variable ensures high accuracy and independence from system time adjustments.



In essence, **E_FB_DELAY** is a more event-oriented timer that fits well into the IEC 61499 event-driven model, while a `TON` block is more oriented toward continuous monitoring.

Conclusion

The **E_FB_DELAY** function block provides a robust and flexible way to implement delayed event propagation in IEC 61499 applications. Its cyclic interface, combined with explicit start/stop controls and a single-shot delay output, makes it suitable for a wide range of timing requirements. The block is implemented as a basic FB with a clear ECC, making it easy to analyze, test, and maintain. Its use of a monotonic clock ensures reliable timing, and its design aligns with the event-driven philosophy of the 4diac IDE and the IEC 61499 standard.

E_FB_TimeOut

• – ○ • – ○ • – ○ •

Introduction

E_FB_TimeOut is a composite IEC 61499 function block that provides a simple timeout service. It wraps an internal timer instance and exposes its functionality through two adapter sockets:

- `TimeOutSocket` for starting, stopping, and receiving timeout events.
- `TimeTickSocket` for cyclic querying and monitoring of the timer state.

The block is designed to offer an `FB_TON`-like behavior with an event-driven cyclic interface. It is suitable for applications where a timeout must be armed, cancelled, and periodically observed.

Interface Structure

The function block has no direct event or data pins. All communication with the outside world is performed through adapter sockets.

Adapter Socket	Adapter Type	Purpose
`TimeOutSocket`	`iec61499::events::ATimeOut`	Standard timeout control and timeout notification.
`TimeTickSocket`	`adapter::events::TimeOut::ATimeTick`	Cyclic query and status observation of the timer.

Event Inputs

There are no direct event inputs on the FB. The following incoming events are provided through the adapter sockets:

Event	Adapter Socket	Description
`START`	`TimeOutSocket`	Starts the timeout evaluation.
`STOP`	`TimeOutSocket`	Stops or cancels the currently active timeout.
`REQ`	`TimeTickSocket`	Requests the current timer state; answered with `CNF`.

Event Outputs

There are no direct event outputs on the FB. The following outgoing events are provided through the adapter sockets:

Event	Adapter Socket	Description
`TimeOut`	`TimeOutSocket`	Emitted when the configured timeout duration has elapsed.
`CNF`	`TimeTickSocket`	Confirmation for a `REQ` query.
`STARTO_IN`	`TimeTickSocket`	Notifies that the internal timer has started.
`STOPO_IN`	`TimeTickSocket`	Notifies that the internal timer has stopped.

Data Inputs

There are no direct data inputs on the FB. The following incoming data is provided through the adapter sockets:

Data	Adapter Socket	Description
`DT`	`TimeOutSocket`	Timeout duration value forwarded to the internal timer.

Data Outputs

There are no direct data outputs on the FB. The following outgoing data is provided through the adapter sockets:

Data	Adapter Socket	Description
`ET`	`TimeTickSocket`	Elapsed time of the internal timer.
`Q`	`TimeTickSocket`	Timer state output of the internal timer.

PT	TimeTickSocket	Configured or current timer time value.

The data outputs are meaningful after an associated event such as CNF, STARTO_IN, STOPO_IN, or TimeOut has been issued.

Adapters

The FB uses two adapter sockets as its complete external interface:

- TimeOutSocket provides the standard timeout operations:
  - START and STOP as incoming events.
  - TimeOut as outgoing event.
  - DT as incoming data.
- TimeTickSocket provides a cyclic observation interface:
  - REQ as incoming query event.
  - CNF, STARTO_IN, and STOPO_IN as outgoing notification events.
  - ET, Q, and PT as outgoing data values.

Functionality

The behavior of E_FB_TimeOut is implemented by an internal instance of the event-based delay function block adapter::events::TimeOut::E_FB_DELAY.

The block works as follows:

1. When TimeOutSocket.START is received, the event is forwarded to the internal timer. The data value TimeOutSocket.DT is supplied as the delay/timeout duration.
2. The internal timer starts and counts the configured time.
3. If no STOP event arrives, the internal timer eventually generates an expiration event. This event is forwarded to TimeOutSocket.TimeOut.
4. When TimeOutSocket.STOP is received, it is forwarded to the internal timer and cancels the active timeout.
5. A cyclic query can be made through TimeTickSocket.REQ. The internal timer responds with CNF and provides the current values of Q, ET, and PT through TimeTickSocket.
6. Start and stop transitions of the internal timer are reported through TimeTickSocket.STARTO_IN and TimeTickSocket.STOPO_IN.

The internal wiring is summarized in the following table:

E_FB_TimeOut Interface	Internal E_FB_DELAY Connection
TimeOutSocket.START	DLY.START
TimeOutSocket.STOP	DLY.STOP
TimeOutSocket.DT	DLY.DT
DLY.EO	TimeOutSocket.TimeOut
TimeTickSocket.REQ	DLY.REQ
DLY.CNF	TimeTickSocket.CNF
DLY.STARTO	TimeTickSocket.STARTO_IN
DLY.STOPO	TimeTickSocket.STOPO_IN
DLY.ET	TimeTickSocket.ET
DLY.Q	TimeTickSocket.Q
DLY.PT	TimeTickSocket.PT

Technical Features

- Composite function block implementation.
- Contains a single internal function block instance: adapter::events::TimeOut::E_FB_DELAY.
- No plain event or data pins; the entire interface is adapter-based.

- Supports both event-driven timeout signaling and cyclic state polling.
- Uses standard IEC 61499 event and data connections for internal wiring.
- Provides `Q`, `ET`, and `PT` values for monitoring and diagnosis.
- Can be embedded in larger IEC 61499 applications where reusable timeout services are required.

State Overview

Although the block is a composite FB and does not define its own ECC state machine, the following observable states can be derived from the timer behavior:

State	Description
Idle	No timeout is active. The timer has not been started or has been stopped.
Running	A `START` event has been accepted and the timer is counting. `STARTO_IN` is emitted when this state is entered.
Expired	The configured timeout duration has elapsed. `TimeOut` is emitted and the timer state output `Q` reflects the timeout condition.
Stopped	A `STOP` event has cancelled the active timeout. `STOPO_IN` is emitted when this state is entered.

During all states, the current timer values can be queried through `TimeTickSocket.REQ` and `TimeTickSocket.CNF`.

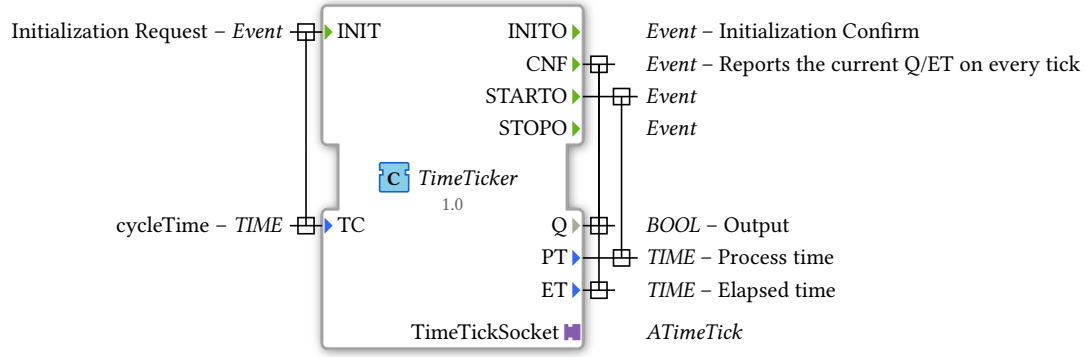
Application Scenarios

E_FB_TimeOut is suitable for the following use cases:

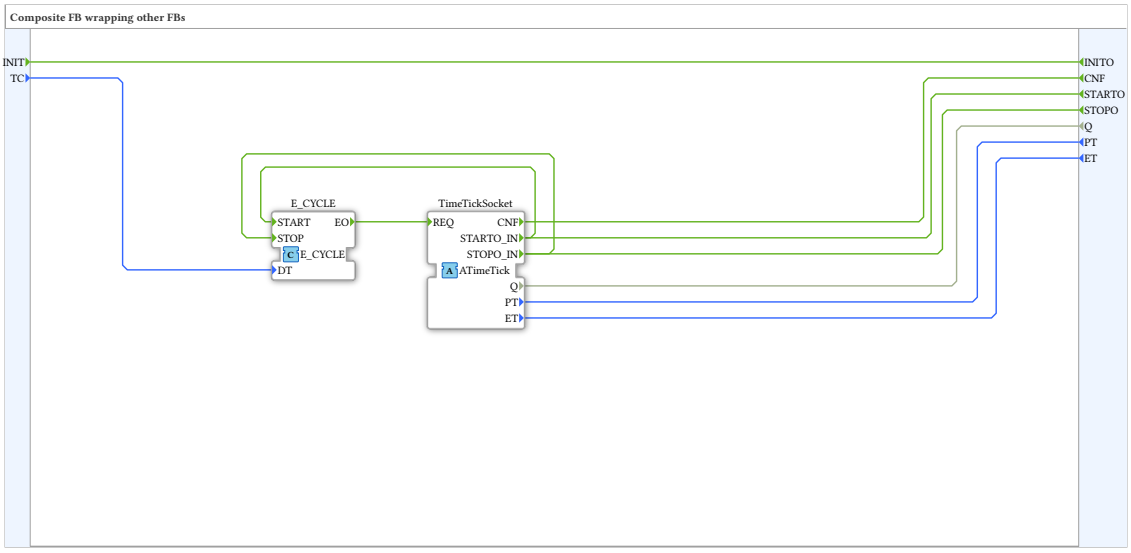
- Watchdog supervision of external operations.
- Timeout handling in communication protocols.
- Event-driven state machines requiring a start/stop timeout service.
- Cyclic control applications where the timeout state must be checked every PLC or IEC 61499 execution cycle.
- Reusable service blocks in distributed IEC 61499 systems.

The combination of `ATimeOut` and `ATimeTick` allows both a simple event-based usage and a more detailed cyclic monitoring of timing values.

Comparison with Similar Blocks



Block / Approach	Interface	Timeout Notification	Cyclic Query
`FB_TON`	Boolean input/output and data pins	`Q` changes, no timeout event	Usually not available
`E_DELAY`	Discrete event/data pins	Expiration event	Often not supported
`E_FB_TimeOut`	Adapter sockets `ATimeOut` and `ATimeTick`	`TimeOut` event	`REQ` / `CNF` with `Q`, `ET`, `PT`



Compared with a simple TON function block, E_FB_TimeOut provides an event-oriented timeout service and additionally exposes a cyclic query interface through `TimeTickSocket`.

Conclusion

E_FB_TimeOut is a compact, adapter-based timeout function block for IEC 61499 applications. It separates timeout control from cyclic status observation, which makes it flexible and reusable. Because it is a composite FB, its behavior is fully determined by the internal `E_FB_DELAY` instance and the adapter connections. This design provides a clean interface for event-driven timeout handling as well as periodic monitoring in automation and control systems.

TimeTicker

• – ○ • – ○ • – ○ •

Introduction

`TimeTicker` is a composite function block that encapsulates an `iec61499::events::E_CYCLE` function block and exposes an adapter-based interface for periodic tick generation. It provides a configurable cycle time, start/stop handling, and event-based reporting of output values such as process time and elapsed time.

The block is intended to be used as a reusable time-tick service inside IEC 61499 systems where adapter-based communication is preferred over direct event/data wiring.

Interface Structure

Event Inputs

Event	Type	With	Description
`INIT`	`EInit`	`TC`	Initialization request, carries the cycle time.

Event Outputs

Event	Type	With	Description
`INITO`	`EInit`	-	Initialization confirmation.
`CNF`	`Event`	`Q`, `ET`	Reports the current `Q` and `ET` on every tick.
`STARTO`	`Event`	`PT`	Indicates that the ticker has been started.
`STOPO`	`Event`	-	Indicates that the ticker has been stopped.

Data Inputs

Data	Type	Initial Value	Description
TC	TIME	T#200ms	Cycle time of the ticker.

Data Outputs

Data	Type	Description
Q	BOOL	Current output state supplied through the adapter.
PT	TIME	Process time, associated with the start event.
ET	TIME	Elapsed time, reported with each confirmation.

Adapters

Adapter	Type	Direction	Description
TimeTickSocket	adapter::events::TimeOut::ATimeTick	Plug	Adapter connection used for tick requests, confirmations, start/stop commands, and time data exchange.

Internally, the adapter is used with the following logical endpoints:

Adapter Endpoint	Role in the Internal Network
REQ	Receives the periodic event from E_CYCLE.EO.
CNF	Triggers the external CNF event output.
STARTO_IN	Starts the internal E_CYCLE and triggers STARTO.
STOPO_IN	Stops the internal E_CYCLE and triggers STOPO.
Q, PT, ET	Provide the data values connected to the outputs.

Functionality

The TimeTicker composite FB contains a single internal E_CYCLE block. The cycle time TC is connected to the DT input of E_CYCLE, so the period of the generated ticks is determined by TC.

When a start command arrives through the adapter (STARTO_IN), the composite FB:

- raises the STARTO event output together with PT,
- sends a start event to the internal E_CYCLE.

While the internal cycle block is running, it generates EO events periodically with the configured interval. Each EO event is forwarded to the adapter as REQ, producing a tick on the adapter interface.

When the adapter returns a confirmation CNF, the composite FB raises its own CNF event output and publishes the associated data values Q and ET.

A stop command arriving through the adapter (STOPO_IN) is forwarded to the stop input of the internal E_CYCLE and also triggers the STOPO output.

An INIT event is passed directly through to INITO, providing an immediate initialization confirmation.

Technical Features

- Composite FB implementation using an internal iec61499::events::E_CYCLE.
- Configurable cycle time through the TC data input, defaulting to 200 ms.
- Adapter-based tick interface using adapter::events::TimeOut::ATimeTick.
- Standard event/data association:
  - INIT is associated with TC.
  - CNF is associated with Q and ET.
  - STARTO is associated with PT.
- No internal algorithms or state-machines are required; the behavior is entirely defined by the function block network.

State Overview

The TimeTicker does not contain an explicit ECC state machine, but it can be described in terms of logical operational states:

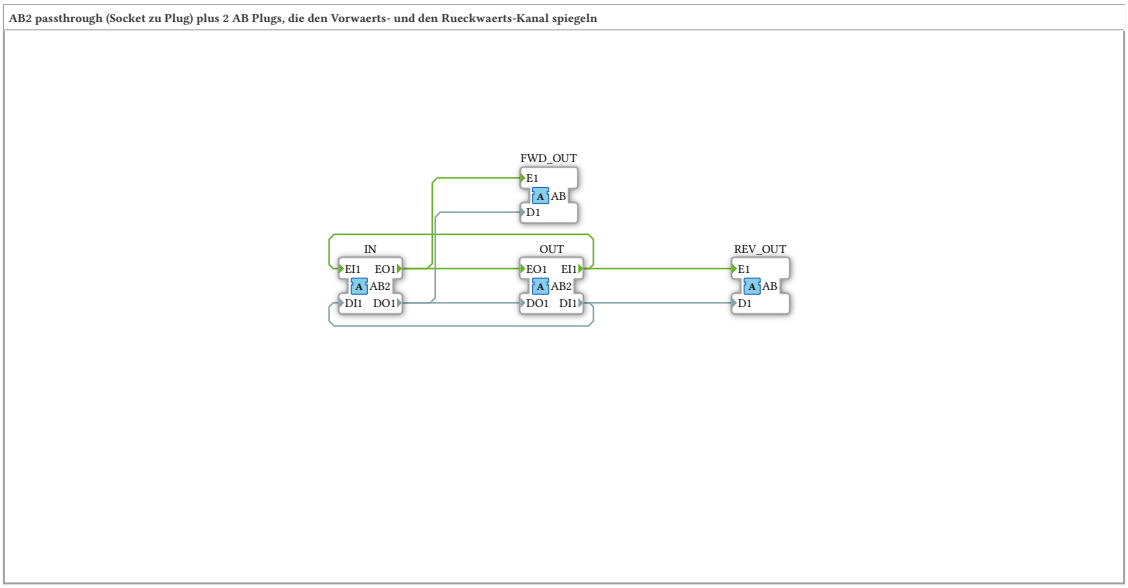
State	Description
Initialized	After INIT, the FB confirms initialization via INITO. No ticks are generated yet.
Stopped	The internal E_CYCLE is not running. No periodic REQ events are generated.
Running	After STARTO_IN, the internal E_CYCLE is started. Ticks are emitted periodically on the adapter.
Confirming	After each tick, the adapter returns CNF, causing the CNF output to fire with Q and ET.

Application Scenarios

- Periodic data polling in automation systems.
- Generation of cyclic time-tick events for adapter-based communication.
- Start/stop controlled time supervision with process time and elapsed time reporting.
- Integration into larger IEC 61499 applications that rely on adapters instead of direct wiring.
- Reusable timing component for service interfaces that require a periodic request/confirmation pattern.

Comparison with Similar Blocks

Block	Comparison
E_CYCLE	A low-level periodic event generator. TimeTicker wraps E_CYCLE and adds an adapter interface, start/stop events, and confirmation data.
TON / TOF	Classic timer blocks generate boolean timing outputs. TimeTicker generates periodic events and reports time values through an adapter.
Plain service FB	Many service FBs require manual event handling. TimeTicker encapsulates cycle control and adapter communication in one composite block.



Conclusion

The TimeTicker FB is a practical composite function block for producing periodic tick events in an adapter-based IEC 61499 environment. By combining an internal E_CYCLE with an ATimeTick adapter, it provides a clean and reusable interface for start/stop control, cyclic requests, confirmations, and time-related data exchange. Its configurable cycle time and straightforward internal network make it suitable for many event-driven automation and monitoring scenarios.

AB2_SPLIT_FWD_REV

• – ○ • – ○ • – ○ •

Introduction

`AB2_SPLIT_FWD_REV` is a composite function block that passes a bidirectional `AB2` adapter from socket `IN` unchanged through to plug `OUT` (passthrough) and additionally mirrors the forward and the backward channel onto two separate, unidirectional `AB` plugs. This allows both directions of an `AB2` connection to be tapped elsewhere without altering the connection itself.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

- **IN** (socket): Bidirectional adapter of type `adapter::types::bidirectional::AB2` (bidirectional input)
- **OUT** (plug): Bidirectional adapter of type `adapter::types::bidirectional::AB2` (bidirectional output, passthrough)
- **FWD_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AB`, mirrors the forward channel (`IN.EO1/DO1`)

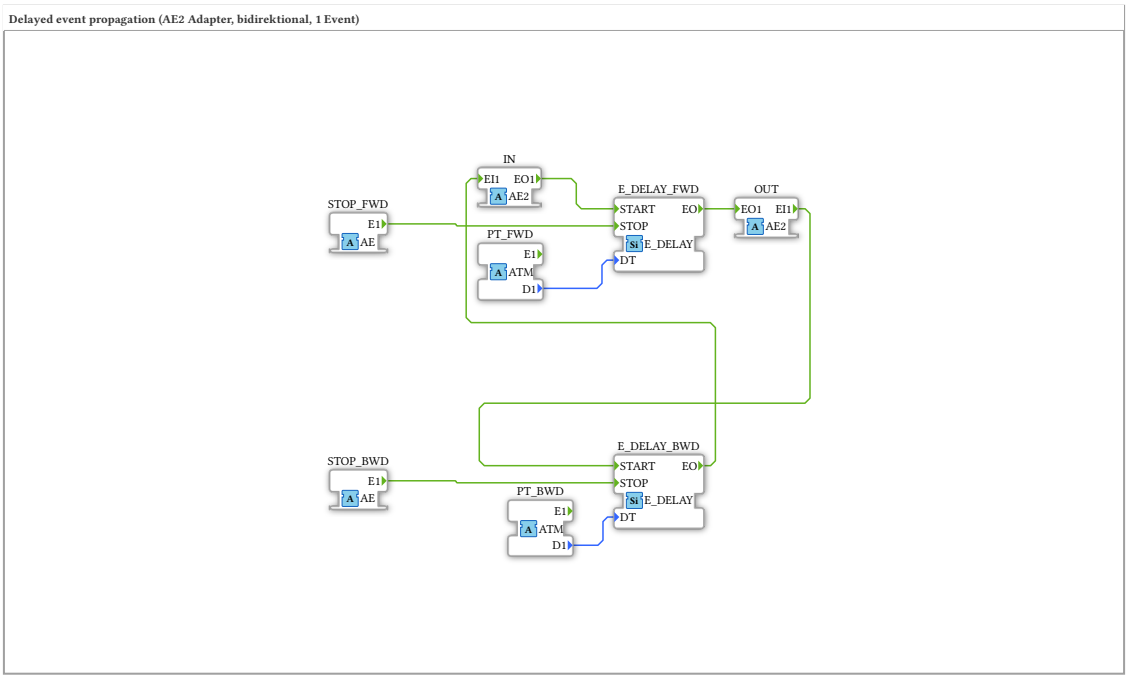
- **REV_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AB`, mirrors the backward channel (`OUT.EI1`/`DI1`)

How it works

1. **Forward (indication)**: `IN.EO1`/`IN.DO1` is forwarded unchanged to `OUT.EO1`/`OUT.DO1` and additionally mirrored to `FWD_OUT.E1`/`FWD_OUT.D1`.
2. **Backward (request)**: `OUT.EI1`/`OUT.DI1` is forwarded unchanged to `IN.EI1`/`IN.DI1` and additionally mirrored to `REV_OUT.E1`/`REV_OUT.D1`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Each passthrough event output feeds two targets (fan-out); the data runs in parallel with the events
- The two mirror plugs are unidirectional (`AB`) and therefore provide read access to the respective channel only

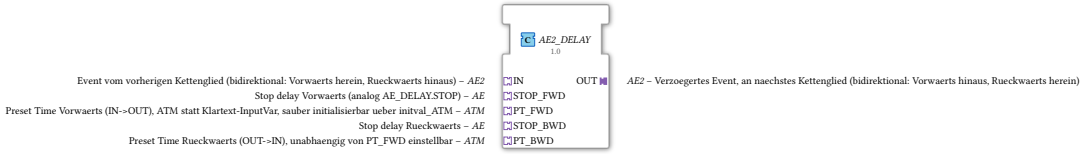


Application Scenarios

- Monitoring/diagnosing both directions of a bidirectional `AB2` connection
- Splitting an `AB2` connection into a separately evaluable forward and backward stream without interrupting the main connection

Summary

`AB2_SPLIT_FWD_REV` passes a bidirectional `AB2` connection through transparently and additionally provides the forward and backward channels as separate `AB` adapters.



AE2_DELAY

• — ○ • — ○ • — ○ •

Introduction

The `AE2_DELAY` function block delays events of a bidirectional `AE2` adapter. Because AE2 carries events in both directions (`EO1` forward, `EI1` backward), the block has two independent delay paths: one for the forward direction (`IN` ⟶ `OUT`) using the time `PT_FWD` and one for the backward direction (`OUT` ⟶ `IN`) using the time `PT_BWD`. Each direction can be aborted through its own `STOP` socket.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **IN** (socket): event from the previous chain element (forward in, backward out), type `adapter::types::bidirectional::AE2`
- **OUT** (plug): delayed event to the next chain element (forward out, backward in), type `adapter::types::bidirectional::AE2`
- **STOP_FWD** (socket): aborts the running forward delay, type `adapter::types::unidirectional::AE`
- **PT_FWD** (socket): preset time for the forward direction, type `adapter::types::unidirectional::ATM`
- **STOP_BWD** (socket): aborts the running backward delay, type `adapter::types::unidirectional::AE`
- **PT_BWD** (socket): preset time for the backward direction, adjustable independently of `PT_FWD`, type `adapter::types::unidirectional::ATM`

Functionality

The internal network consists of two instances of `E_DELAY`:

- **Forward** (`E_DELAY_FWD`): `IN.EO1` ⟶ `E_DELAY_FWD.START`, `STOP_FWD.E1` ⟶ `E_DELAY_FWD.STOP`, `PT_FWD.D1` ⟶ `E_DELAY_FWD.DT`. When the time has elapsed, `E_DELAY_FWD.EO` is output on `OUT.EO1`.
- **Backward** (`E_DELAY_BWD`): `OUT.EI1` ⟶ `E_DELAY_BWD.START`, `STOP_BWD.E1` ⟶ `E_DELAY_BWD.STOP`, `PT_BWD.D1` ⟶ `E_DELAY_BWD.DT`. When the time has elapsed, `E_DELAY_BWD.EO` is output on `IN.EI1`.

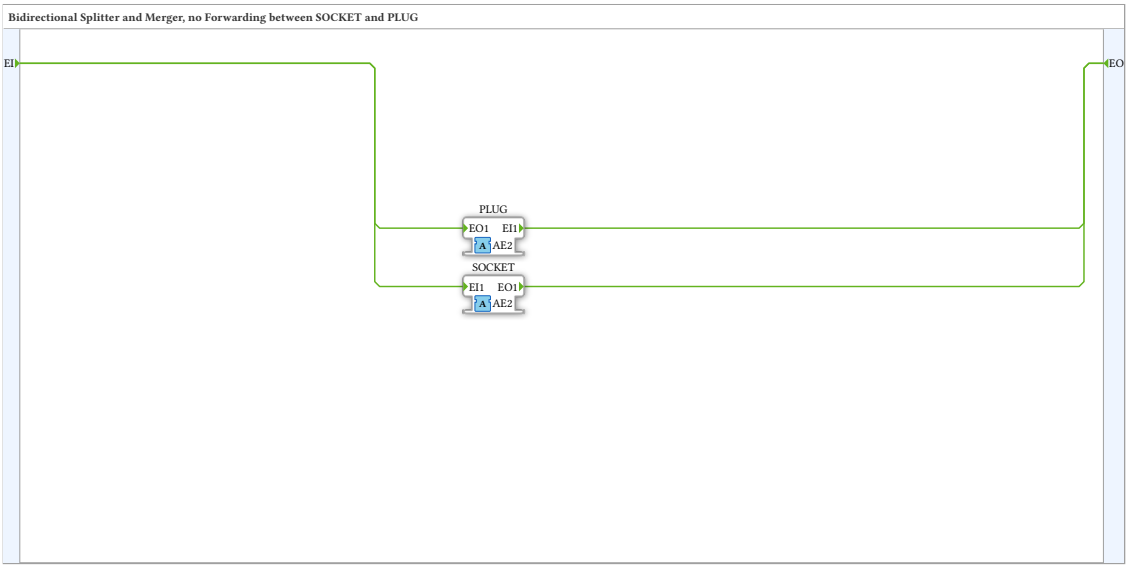
The data of the adapter is not processed; only the events `EO1`/`EI1` are passed on.

Technical Details

- Two independent delay paths (one `E_DELAY` instance per direction), each with its own time and its own `STOP`
- The times are supplied through `ATM` sockets instead of plain input variables and can therefore be initialised cleanly via `initval_ATM` (with `INIT`/`INITO`)
- The time sockets are named `PT` (preset time) rather than `DT`, because `DT` is a reserved keyword (`DATE_AND_TIME`) in IEC 61131-3
- The block itself is stateless; the state (running timer) resides in the two `E_DELAY` instances

Application Scenarios

- Time-shifted forwarding of events in an AE2 chain, e.g. staggered switch-on and switch-off with different times
- Decoupling of request and feedback in bidirectional event chains

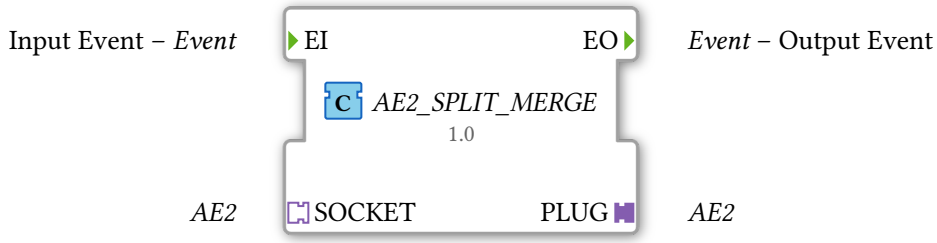


⚖️ Comparison with Similar Blocks

For chains with separately delayed set and reset branches there is `ASR2_DELAY`, whose variant with preset times is `ASR2_DELAY_SUB`. `AE2_DELAY`, in contrast, delays exactly one event per direction.

Conclusion

AE2_DELAY is a pure wiring block built from two E_DELAY instances. It delays events of an AE2 adapter in both directions, each with its own time adjustable through an ATM socket, and each direction can be stopped separately.



AE2_SPLIT_MERGE

• – ○ • – ○ • – ○ •

Introduction

The AE2_SPLIT_MERGE is a bidirectional splitter and merge function block that can process events in both directions. The block enables the distribution and merging of events via adapter interfaces, without direct routing between the SOCKET and PLUG.

Interface Structure

Event Inputs

- **EI**: Main event input for incoming events

Event Outputs

- **EO**: Main event output for outgoing events

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

- **PLUG**: Adapter interface of type “adapter::types::bidirectional::AE2”
- **SOCKET**: Adapter interface of type “adapter::types::bidirectional::AE2”

Functionality

The function block operates according to the following principles:

1. **Event Distribution**: Events at input EI are simultaneously forwarded to both adapter interfaces (PLUG and SOCKET).
2. **Event Merging**: Events from both adapter interfaces are combined. (PLUG.EI1 and SOCKET.EO1) are combined at output EO.
3. **Bidirectional Isolation**: There is no direct communication between the PLUG and SOCKET adapter interfaces.

Technical Features

- Pure event processing without data transfer
- Symmetrical handling of both adapter directions
- Isolated signal paths between the adapter interfaces
- Real-time event distribution

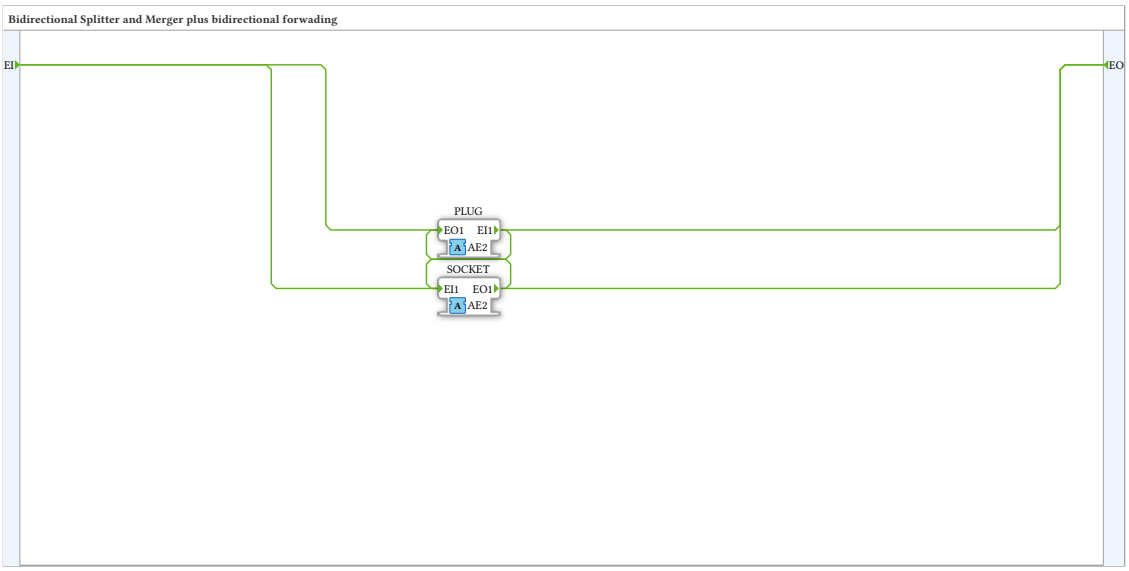
State Overview

The functional block has no internal state and operates stateless. All incoming events are processed and forwarded immediately.

Application Scenarios

- Distribution of control events to multiple subsystems
- Merging of status events from various sources
- Bidirectional communication in distributed control systems
- Event-based architectures with adapter patterns

⚖️ Comparison with similar building blocks

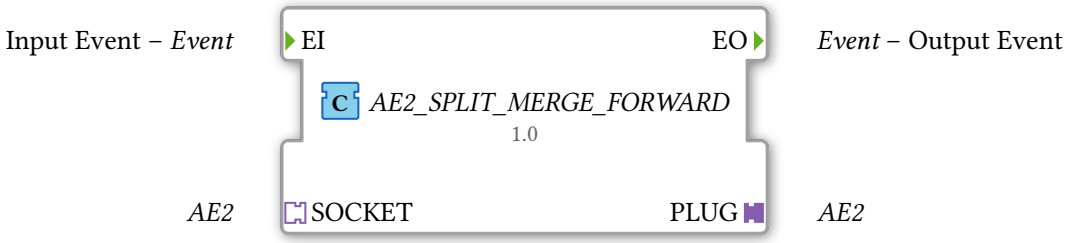


Compared to simple splitter or merger blocks, AE2_SPLIT_MERGE offers:

- Bidirectional functionality in a single block
- Adapter-based interfaces for standardized communication
- Isolated signal paths between different adapter directions

Conclusion

AE2_SPLIT_MERGE is a specialized function block for complex event distribution and merging scenarios in bidirectional communication architectures. Its adapter-based structure enables flexible and standardized integration into larger control systems.



AE2_SPLIT_MERGE_FORWARD

• – ◦ • – ◦ • – ◦ •

Introduction

The AE2_SPLIT_MERGE_FORWARD function block is a bidirectional splitter and merger with bidirectional forwarding. It serves as a universal distributor and collector for events in 4diac systems and enables the flexible distribution of events across various interfaces.

Interface Structure

Event Inputs

- **EI**: Input Event

Event Outputs

- **EO**: Output Event

Adapters

- **PLUG**: Bidirectional AE2 Adapter
- **SOCKET**: Bidirectional AE2 Adapter

Functionality

The function block operates according to the following principles:

1. **Event Distribution**: Every event received at the EI input is simultaneously forwarded to both adapters (PLUG and SOCKET).
2. **Event Merging**: Events received via either adapter (PLUG or SOCKET) are output at the EO output.
3. **Bidirectional Forwarding**: Events are forwarded bidirectionally between the two adapters, allowing PLUG and SOCKET events to be exchanged.

Technical Features

- Uses the bidirectional AE2 adapter type
- Enables parallel event distribution
- Provides full bidirectional communication between all interfaces
- No data connections – purely event-based

State Overview

The function block has no internal states and operates purely combinatorially. All event processing occurs immediately upon the arrival of an event.

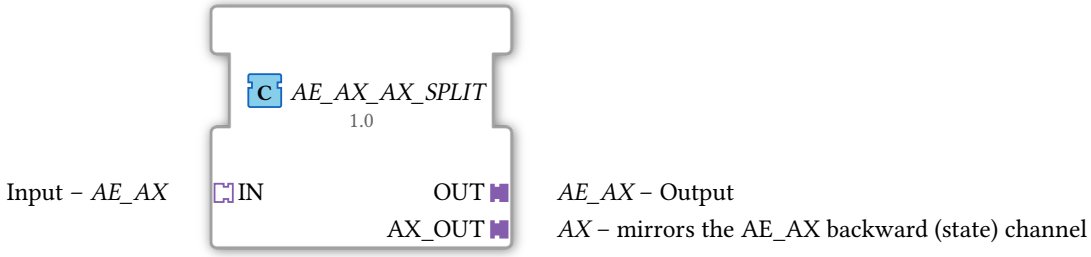
Application Scenarios

- Distributor for control events in complex automation networks
- Interface adapters between different system components
- Event routing in modular control architectures
- Bidirectional communication bridges between function blocks

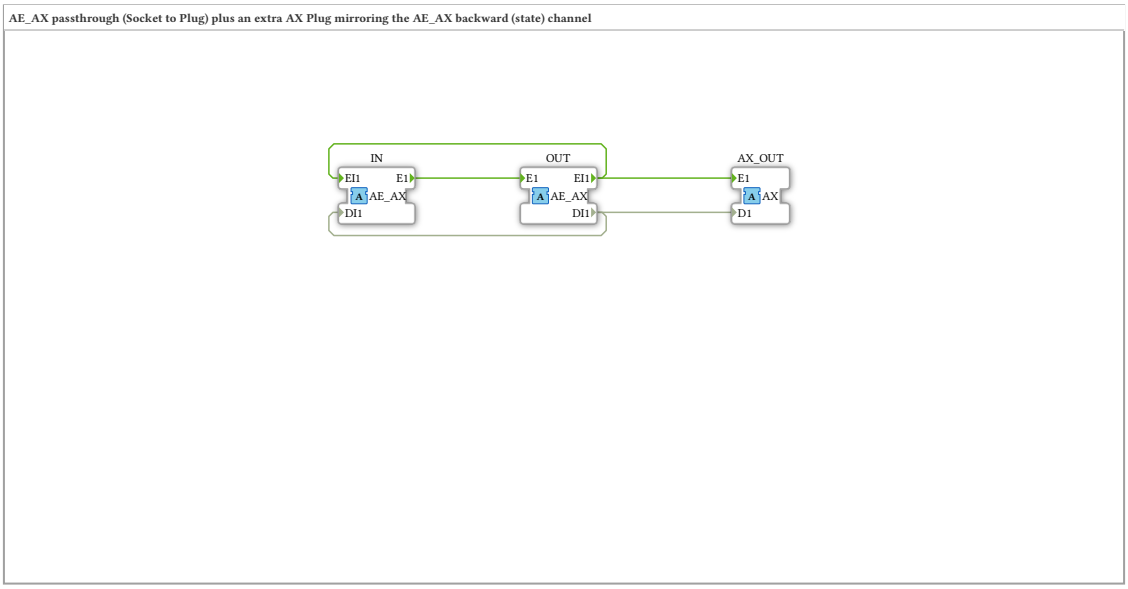
⚖️ Comparison with similar modules

Compared to simple splitter blocks, AE2_SPLIT_MERGE_FORWARD additionally offers:

- Bidirectional functionality
- Adapter-based interfaces
- Event merging
- Direct communication between adapters



Conclusion



The AE2_SPLIT_MERGE_FORWARD is a versatile function block for complex event distribution and collection tasks in 4diac systems. Its bidirectional nature and adapter interfaces make it particularly suitable for modular and expandable automation solutions.

AE_AX_AX_SPLIT

• – ○ • – ○ • – ○ •

Introduction

The AE_AX_AX_SPLIT is a composite function block that passes an incoming AE_AX event unchanged from its socket `IN` to the plug `OUT`, and additionally mirrors the state (event + bool) reported on the backward channel of `OUT` to the outside via a third, unidirectional `AX_OUT` plug. This allows the state of a downstream chain to be tapped in parallel at a second point without interrupting the actual AE_AX connection.

Interface Structure

Event Inputs

No direct event inputs available – events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

- **IN**: Bidirectional adapter socket of type `adapter::types::bidirectional::AE_AX` (input)
- **OUT**: Bidirectional adapter plug of type `adapter::types::bidirectional::AE_AX` (output)
- **AX_OUT**: Unidirectional adapter plug of type `adapter::types::unidirectional::AX`, mirrors the AE_AX backward channel (state)

Functionality

1. Every event arriving at `IN.E1` is forwarded unchanged to `OUT.E1` – the forward direction is passed through 1:1.
2. The backward-channel event `OUT.EI1` (together with its associated datum `OUT.DI1`) is relayed back to `IN.EI1`/`IN.DI1` and, at the same time, forwarded to `AX_OUT.E1`/`AX_OUT.D1`.
3. As a result, the state reported via `OUT` is visible at two points: at the original socket `IN` (as a pure passthrough would also provide) and additionally, in isolation, at the `AX_OUT` plug.

Technical Features

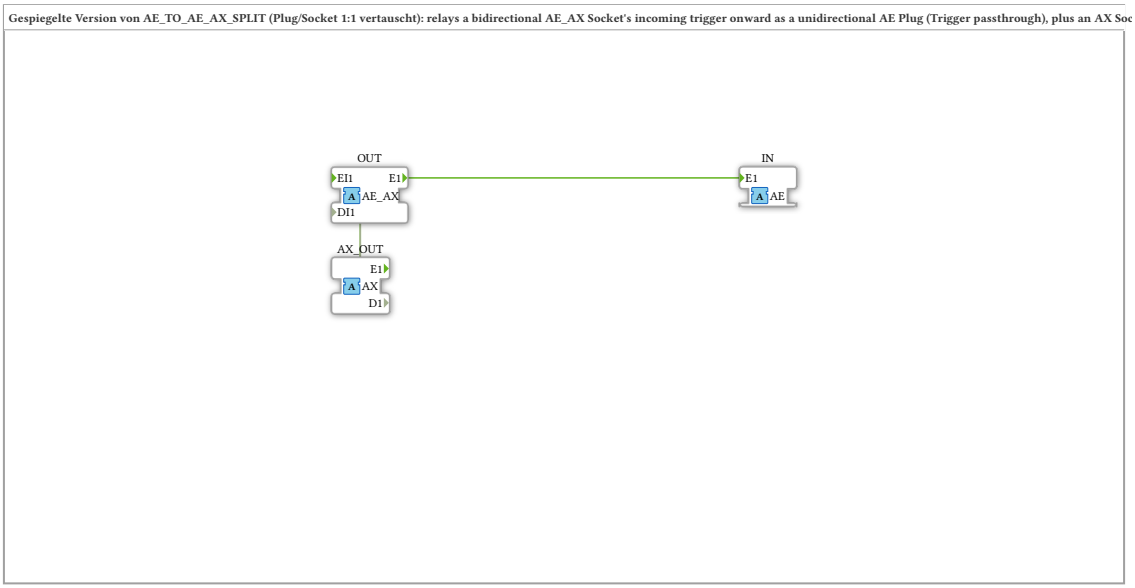
- Pure event/data connections (`FBNetwork`), no own logic or state management
- The forward direction (socket ⟶ plug) is a simple 1:1 passthrough
- The backward channel is duplicated rather than split: both destinations (`IN` and `AX_OUT`) receive the same information

State Overview

The function block has no internal state and operates statelessly. Every incoming event is immediately forwarded or mirrored.

Application Scenarios

- Additional, isolated tapping of the AE_AX backward channel (e.g. for a separate display or logging) without altering the actual connection between `IN` and `OUT`
- Building diagnostic/monitoring paths in AE_AX-based control networks

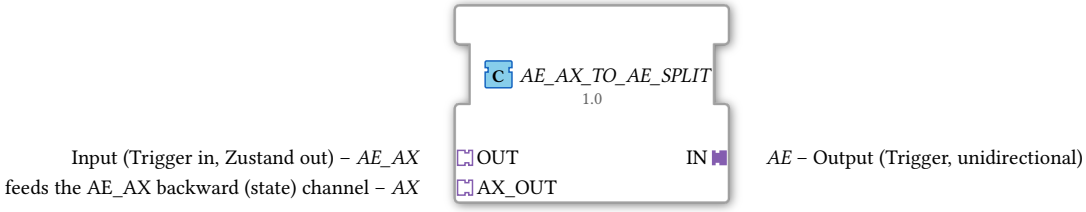


⚖️ Comparison with similar building blocks

Compared to AE2_SPLIT_MERGE, which distributes/merges the forward and backward directions between two separate, isolated adapters, AE_AX_AX_SPLIT is a pure passthrough between `IN` and `OUT` with an additional mirror output for the backward channel – the ASR_AX and ASRT_AX variants ASR_AX_AX_SPLIT and ASRT_AX_AX_SPLIT follow the same pattern with two and three forward events, respectively.

Conclusion

AE_AX_AX_SPLIT makes the AX backward channel of an AE_AX adapter pair additionally available at a second point in the network, without interrupting or altering the actual signal chain.



AE_AX_TO_AE_SPLIT

• – ○ • – ○ • – ○ •

Introduction

`AE_AX_TO_AE_SPLIT` is the mirrored version of `AE_TO_AE_AX_SPLIT` (plug and socket swapped 1:1). The block forwards the incoming trigger of a bidirectional `AE_AX` socket onward as a unidirectional `AE` plug (trigger pass-through), and an additional `AX` socket injects an externally supplied value into the backward (state) channel of the `AE_AX` socket.

Interface Structure

Event / Data Inputs and Outputs

No own event or data connections; all events and data travel through the adapters.

Adapters

Direction	Name	Adapter type	Comment
Plug (output)	`IN`	`adapter::types::unidirectional::AE`	Output (trigger, unidirectional).
Socket (input)	`OUT`	`adapter::types::bidirectional::AE_AX`	Input (trigger in, state out).
Socket (input)	`AX_OUT`	`adapter::types::unidirectional::AX`	Feeds the backward (state) channel of the `AE_AX`.

Functionality

The block is a composite FB without any internal function blocks; it consists only of adapter connections:

- **Event connections:** `OUT.E1` ⟶ `IN.E1` (the event arriving at the `AE_AX` socket is output unchanged at the `AE` plug); `AX_OUT.E1` ⟶ `OUT.EI1` (the event received at the `AX` socket is sent out as the backward-channel event via the `AE_AX` socket).
- **Data connection:** `AX_OUT.D1` ⟶ `OUT.DI1` (the value received at the `AX` socket is sent out as the backward-channel datum `DI1` of the `AE_AX` socket).

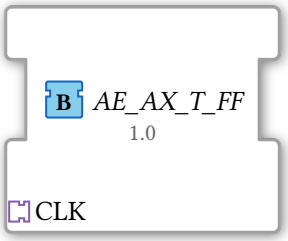
Technical Details

- Pure wiring, no logic and no delay.
- The names `IN`/`OUT` are inherited from the source `AE_TO_AE_AX_SPLIT` and are therefore swapped: `OUT` is a socket here, `IN` a plug.
- The trigger direction stays unidirectional (`AE`); the backward channel is fed entirely by the `AX` socket.

Application Scenarios

- Splitting a bidirectional `AE_AX` connection into a pure trigger path (`AE`) and a separately fed state path (`AX`).

Summary



`AE_AX_TO_AE_SPLIT` splits an `AE_AX` socket into a forwarded `AE` trigger and a backward channel fed via `AX`.

AE_AX_T_FF

Clock (in), Zustand (out) – *AE_AX*

ECC: AE_AX_T_FF

• – ○ • – ○ • – ○ •

Introduction

The AE_AX_T_FF is an event-driven toggle flip-flop with a single bidirectional `AE_AX` socket: the clock event arrives on the same adapter that also reports the new state back – unlike AX_T_FF, which uses a separate CLK event input and its own AX plug for the state.

Interface Structure

Event Inputs

No direct event inputs available – the clock event arrives via the adapter socket `CLK`

Event Outputs

No direct event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

- **CLK**: Bidirectional adapter socket of type `adapter::types::bidirectional::AE_AX` – clock (input), state (output) via the same adapter

Operation

The AE_AX_T_FF has two operating states:

- **START**: Initial state
- **SET**: State after toggling

Every event arriving at `CLK.E1` moves the function block from START to SET, firing the algorithm `TOGGLE`, which executes `CLK.DI1 := NOT CLK.DI1` and thereby reports the inverted state back over the same adapter via `CLK.EI1`. From the SET state the block unconditionally (condition `1`) returns immediately to START, so that every further `CLK.E1` event triggers the same TOGGLE transition again.

Technical Features

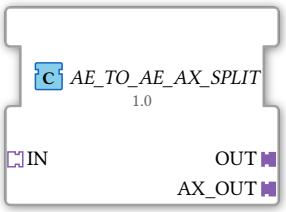
- Bidirectional communication over a single adapter socket instead of a separate event input plus AX plug
- The ECC state SET is only a pass-through state for firing the output event; the actual toggle semantics live in the algorithm assignment `CLK.DI1 := NOT CLK.DI1`
- A drop-in replacement for AX_T_FF in fully adapter-based (AE_AX) applications

State Overview

```
START (initial state)
    │
    └── CLK.E1 ─→ SET (CLK.DI1 := NOT CLK.DI1, reports state via CLK.EI1)
                      │
                      └── (unconditional) ─→ START
```

Application Scenarios

- Toggling a state (e.g. on/off) over a single bidirectional adapter connection, without wiring a separate state output
- Replacement for AX_T_FF in networks that consistently use AE_AX adapters

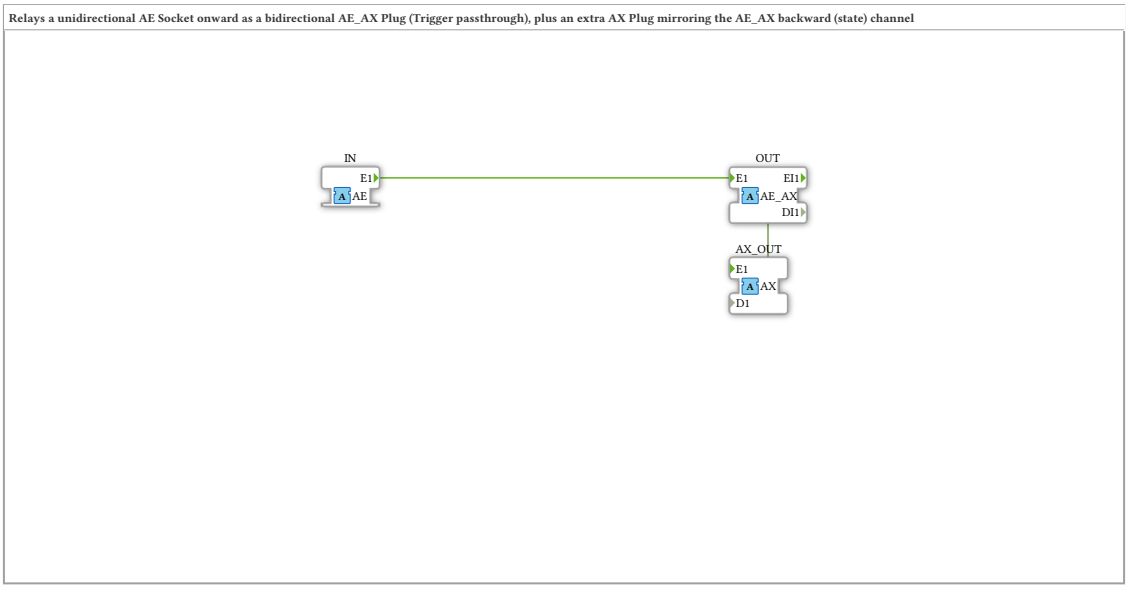


⚖️ Comparison with similar components

Compared to AX_T_FF, which uses a separate `CLK` event input and its own AX plug for the state, AE_AX_T_FF bundles both directions into a single AE_AX socket.

Conclusion

AE_AX_T_FF carries the proven toggle flip-flop pattern over into the bidirectional adapter world: clock input and state feedback share the same AE_AX socket, simplifying wiring in adapter-based networks.



AE_TO_AE_AX_SPLIT

Input (Trigger, unidirectional) – *AE*

AE_AX – Output (Trigger out, Zustand in)

AX – mirrors the AE_AX backward (state) channel

• – ○ • – ○ • – ○ •

Introduction

AE_TO_AE_AX_SPLIT is a composite function block that converts an incoming **unidirectional** AE event at its socket `IN` into a **bidirectional** AE_AX signal at plug `OUT`, and additionally mirrors the state (event + bool) reported on `OUT`'s backward channel out through a third, unidirectional `AX_OUT` plug. Unlike the pure passthrough `AE_AX_AX_SPLIT`, `IN` has no backward channel of its own here - so the backward state cannot be relayed back to `IN` and is exposed exclusively through `AX_OUT`.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

- **IN**: Unidirectional adapter socket of type `adapter::types::unidirectional::AE` (input, no backward channel)
- **OUT**: Bidirectional adapter plug of type `adapter::types::bidirectional::AE_AX` (output, with backward channel)
- **AX_OUT**: Unidirectional adapter plug of type `adapter::types::unidirectional::AX`, mirrors the AE_AX backward channel (state) to the outside

How it works

1. Every event arriving at `IN.E1` is forwarded to `OUT.E1` unchanged.
2. The backward-channel event `OUT.EI1` (with its associated data `OUT.DI1`), sent by the downstream counterpart via `OUT`, is forwarded exclusively to `AX_OUT.E1`/`AX_OUT.D1` - relaying it back to `IN` is technically impossible, since `IN` is a unidirectional AE adapter with no backward channel.
3. `AX_OUT` is therefore the only place where the state reported by `OUT` becomes visible.

Technical Details

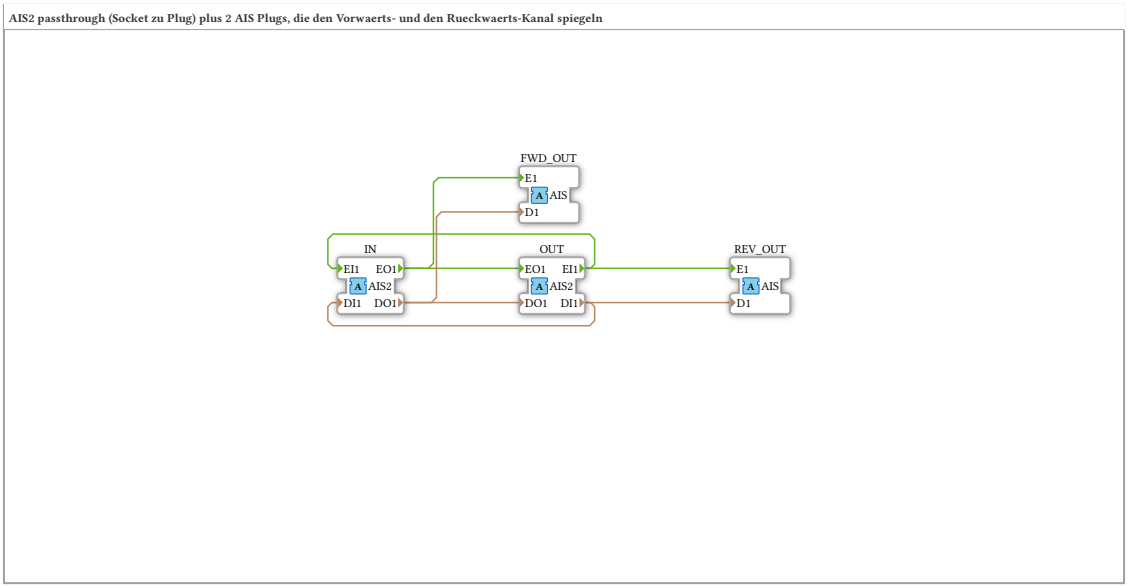
- Pure event/data connections (`FBNetwork`), no logic or state management of its own
- The forward direction (socket ⟶ plug) is a simple 1:1 passthrough
- Converts a unidirectional adapter (`IN`) into a bidirectional one (`OUT`) without needing a backward channel on the input itself
- The backward channel is not duplicated (as in AE_AX_AX_SPLIT), but exposed solely via `AX_OUT`

State Overview

The function block has no internal state and works statelessly. Every incoming event is forwarded/mirrored immediately.

Application Scenarios

- Connecting an existing, purely unidirectional AE signal source to a chain that expects a bidirectional AE_AX adapter
- Exposing the state of the downstream AE_AX counterpart via `AX_OUT`, even though the original source (`IN`) itself supports no backward channel

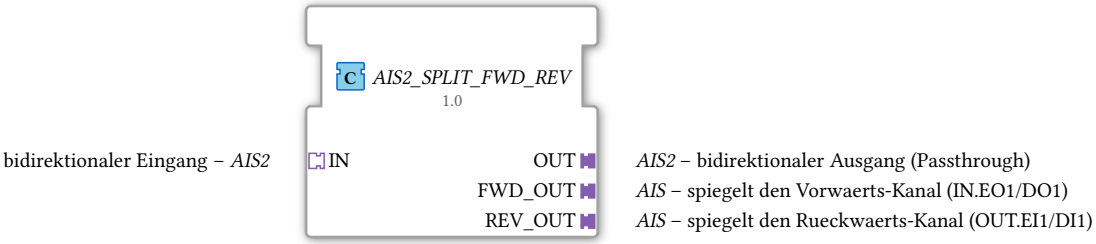


⚖️ Comparison with Similar Blocks

Unlike `AE_AX_AX_SPLIT`, which mediates between two already-bidirectional adapters and also mirrors the backward channel back to `IN`, AE_TO_AE_AX_SPLIT converts a unidirectional input into a bidirectional output - the backward channel can therefore only be observed via `AX_OUT`. The set/reset and set/reset/toggle variants `ASR_TO_ASR_AX_SPLIT` and `ASRT_TO_ASRT_AX_SPLIT` follow the same pattern with two or three forward events instead of a single one.

Summary

AE_TO_AE_AX_SPLIT allows a purely unidirectional AE signal source to connect to a bidirectional AE_AX chain and makes its backward channel available in isolation via `AX_OUT`, without requiring the original input itself to support a backward channel.



AIS2_SPLIT_FWD_REV

• – ○ • – ○ • – ○ •

Introduction

`AIS2_SPLIT_FWD_REV` is a composite function block that passes a bidirectional `AIS2` adapter from socket `IN` unchanged through to plug `OUT` (passthrough) and additionally mirrors the forward and the backward channel onto two separate, unidirectional `AIS` plugs. This allows both directions of an `AIS2` connection to be tapped elsewhere without altering the connection itself.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

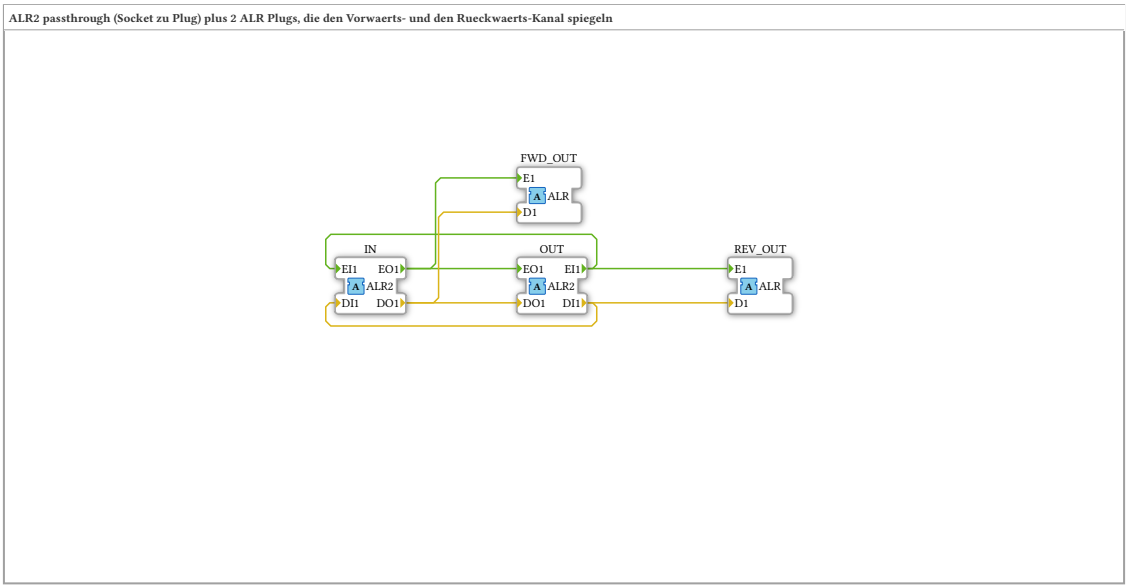
- **IN** (socket): Bidirectional adapter of type `adapter::types::bidirectional::AIS2` (bidirectional input)
- **OUT** (plug): Bidirectional adapter of type `adapter::types::bidirectional::AIS2` (bidirectional output, passthrough)
- **FWD_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AIS`, mirrors the forward channel (`IN.EO1`/`DO1`)
- **REV_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AIS`, mirrors the backward channel (`OUT.EI1`/`DI1`)

How it works

1. **Forward (indication)**: `IN.EO1`/`IN.DO1` is forwarded unchanged to `OUT.EO1`/`OUT.DO1` and additionally mirrored to `FWD_OUT.E1`/`FWD_OUT.D1`.
2. **Backward (request)**: `OUT.EI1`/`OUT.DI1` is forwarded unchanged to `IN.EI1`/`IN.DI1` and additionally mirrored to `REV_OUT.E1`/`REV_OUT.D1`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Each passthrough event output feeds two targets (fan-out); the data runs in parallel with the events
- The two mirror plugs are unidirectional (`AIS`) and therefore provide read access to the respective channel only

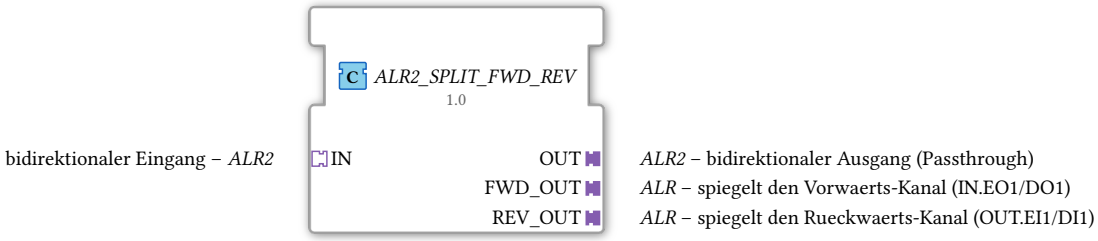


Application Scenarios

- Monitoring/diagnosing both directions of a bidirectional `AIS2` connection
- Splitting an `AIS2` connection into a separately evaluable forward and backward stream without interrupting the main connection

Summary

`AIS2_SPLIT_FWD_REV` passes a bidirectional `AIS2` connection through transparently and additionally provides the forward and backward channels as separate `AIS` adapters.



ALR2_SPLIT_FWD_REV

• – ○ • – ○ • – ○ •

Introduction

`ALR2_SPLIT_FWD_REV` is a composite function block that passes a bidirectional `ALR2` adapter from socket `IN` unchanged through to plug `OUT` (passthrough) and additionally mirrors the forward and the backward channel onto two separate, unidirectional `ALR` plugs. This allows both directions of an `ALR2` connection to be tapped elsewhere without altering the connection itself.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

- **IN** (socket): Bidirectional adapter of type `adapter::types::bidirectional::ALR2` (bidirectional input)
- **OUT** (plug): Bidirectional adapter of type `adapter::types::bidirectional::ALR2` (bidirectional output, passthrough)
- **FWD_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::ALR`, mirrors the forward channel (`IN.EO1/DO1`)

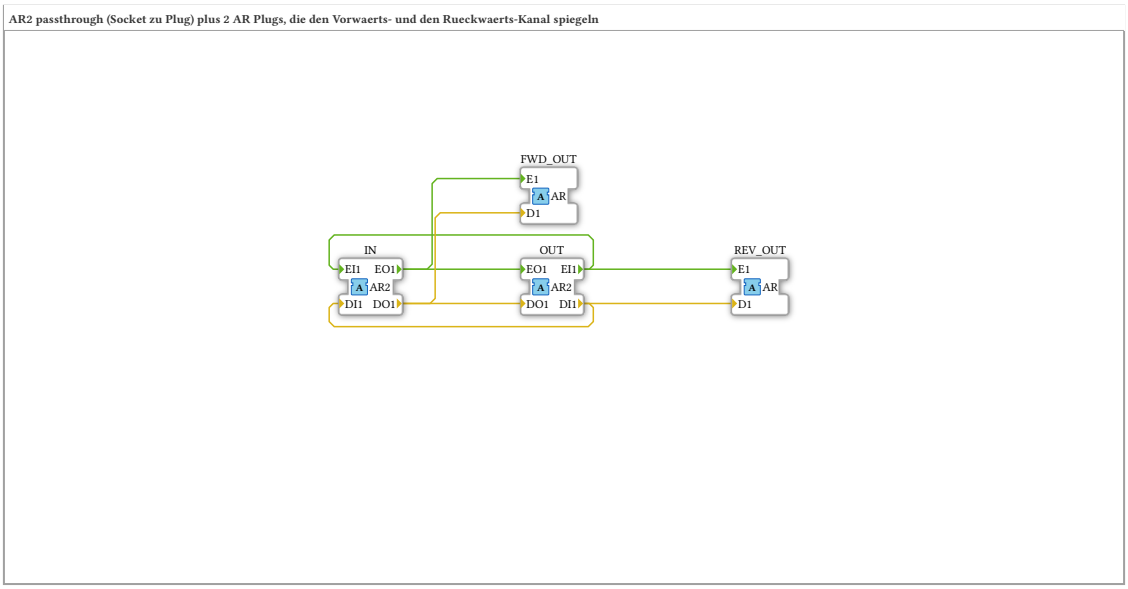
- **REV_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::ALR`, mirrors the backward channel (`OUT.EI1/DI1`)

How it works

1. **Forward (indication)**: `IN.EO1/IN.DO1` is forwarded unchanged to `OUT.EO1/OUT.DO1` and additionally mirrored to `FWD_OUT.E1/FWD_OUT.D1`.
2. **Backward (request)**: `OUT.EI1/OUT.DI1` is forwarded unchanged to `IN.EI1/IN.DI1` and additionally mirrored to `REV_OUT.E1/REV_OUT.D1`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Each passthrough event output feeds two targets (fan-out); the data runs in parallel with the events
- The two mirror plugs are unidirectional (`ALR`) and therefore provide read access to the respective channel only

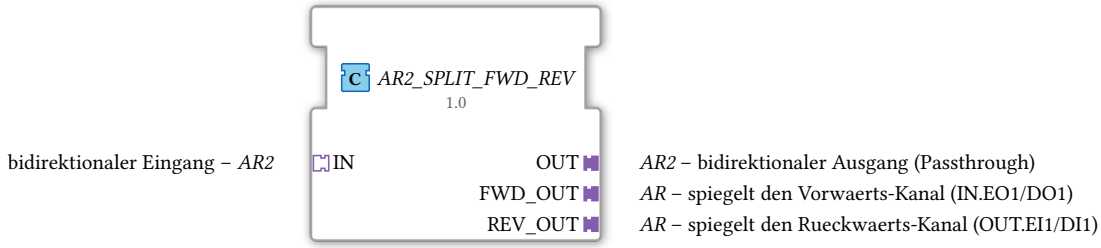


Application Scenarios

- Monitoring/diagnosing both directions of a bidirectional `ALR2` connection
- Splitting an `ALR2` connection into a separately evaluable forward and backward stream without interrupting the main connection

Summary

`ALR2_SPLIT_FWD_REV` passes a bidirectional `ALR2` connection through transparently and additionally provides the forward and backward channels as separate `ALR` adapters.



AR2_SPLIT_FWD_REV

• – ○ • – ○ • – ○ •

Introduction

The `AR2_SPLIT_FWD_REV` function block passes a bidirectional `AR2` adapter unchanged from `IN` (socket) to `OUT` (plug) and additionally mirrors both channels onto one unidirectional `AR` plug each: the forward channel (indication, `IN.EO1/DO1`) onto `FWD_OUT` and the backward channel (request, `OUT.EI1/DI1`) onto `REV_OUT`. This allows both directions of a bidirectional AR2 connection to be tapped separately as plain AR signals.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **IN** (socket): bidirectional input, type `adapter::types::bidirectional::AR2`
- **OUT** (plug): bidirectional output (passthrough), type `adapter::types::bidirectional::AR2`
- **FWD_OUT** (plug): mirrors the forward channel (`IN.EO1`/`DO1`), type `adapter::types::unidirectional::AR`
- **REV_OUT** (plug): mirrors the backward channel (`OUT.EI1`/`DI1`), type `adapter::types::unidirectional::AR`

Functionality

The block consists of wiring only:

- **Forward** (indication): `IN.EO1` ⟶ `OUT.EO1` and additionally `IN.EO1` ⟶ `FWD_OUT.E1`; `IN.DO1` ⟶ `OUT.DO1` and additionally `IN.DO1` ⟶ `FWD_OUT.D1`.
- **Backward** (request): `OUT.EI1` ⟶ `IN.EI1` and additionally `OUT.EI1` ⟶ `REV_OUT.E1`; `OUT.DI1` ⟶ `IN.DI1` and additionally `OUT.DI1` ⟶ `REV_OUT.D1`.

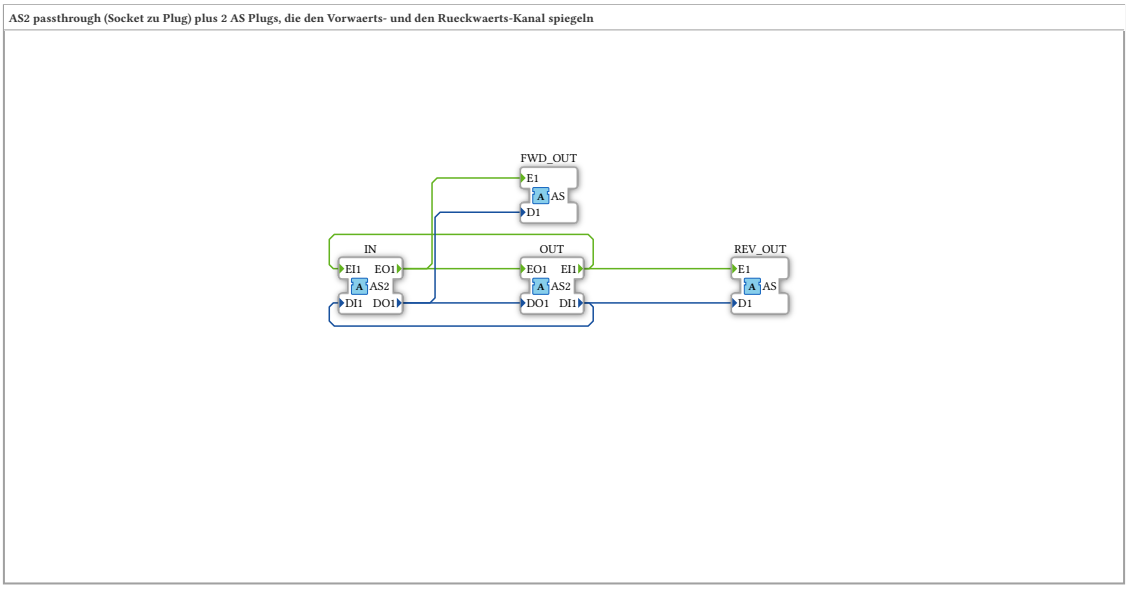
Both directions therefore pass through unchanged, and each one is additionally output as a plain unidirectional AR signal.

Technical Details

- Pure wiring without logic or state
- The passthrough `IN` ⟶ `OUT` is fully preserved; `FWD_OUT` and `REV_OUT` are pure observation taps
- Each source is fanned out to two destinations (event and data); the behaviour corresponds to a split onto both branches

Application Scenarios

- Monitoring the forward and the backward direction of a AR2 connection (e.g. for display, logging or diagnostics) without altering the connection itself
- Separate further processing of indication and request as plain AR signals

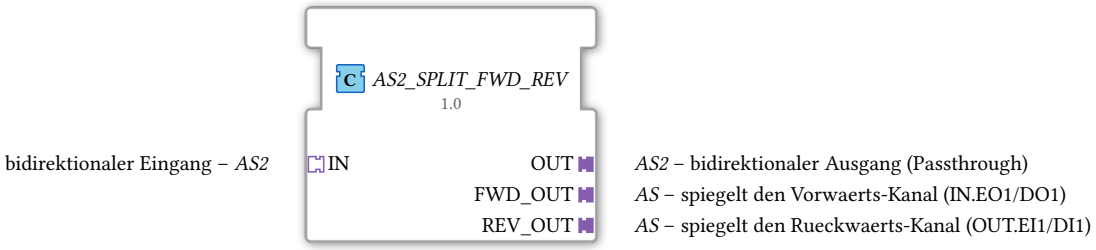


⚖️ Comparison with Similar Blocks

The same structure exists for further bidirectional adapters, e.g. `AR2_SPLIT_FWD_REV`, `AS2_SPLIT_FWD_REV`, `AX2_SPLIT_FWD_REV`, `AIS2_SPLIT_FWD_REV` and `ALR2_SPLIT_FWD_REV`; they differ only in the data type of the adapter.

Conclusion

AR2_SPLIT_FWD_REV is a stateless passthrough for AR2 that additionally mirrors the forward and backward channels onto two unidirectional AR plugs.



AS2_SPLIT_FWD_REV

• – ◦ • – ◦ • – ◦ •

Introduction

The AS2_SPLIT_FWD_REV function block passes a bidirectional AS2 adapter unchanged from IN (socket) to OUT (plug) and additionally mirrors both channels onto one unidirectional AS plug each: the forward channel (indication, IN.EO1/DO1) onto FWD_OUT and the backward channel (request, OUT.EI1/DI1) onto REV_OUT. This allows both directions of a bidirectional AS2 connection to be tapped separately as plain AS signals.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **IN** (socket): bidirectional input, type adapter::types::bidirectional::AS2

- **OUT** (plug): bidirectional output (passthrough), type `adapter::types::bidirectional::AS2`
- **FWD_OUT** (plug): mirrors the forward channel (`IN.EO1`/`DO1`), type `adapter::types::unidirectional::AS`
- **REV_OUT** (plug): mirrors the backward channel (`OUT.EI1`/`DI1`), type `adapter::types::unidirectional::AS`

Functionality

The block consists of wiring only:

- **Forward** (indication): `IN.EO1` ⟶ `OUT.EO1` and additionally `IN.EO1` ⟶ `FWD_OUT.E1`; `IN.DO1` ⟶ `OUT.DO1` and additionally `IN.DO1` ⟶ `FWD_OUT.D1`.
- **Backward** (request): `OUT.EI1` ⟶ `IN.EI1` and additionally `OUT.EI1` ⟶ `REV_OUT.E1`; `OUT.DI1` ⟶ `IN.DI1` and additionally `OUT.DI1` ⟶ `REV_OUT.D1`.

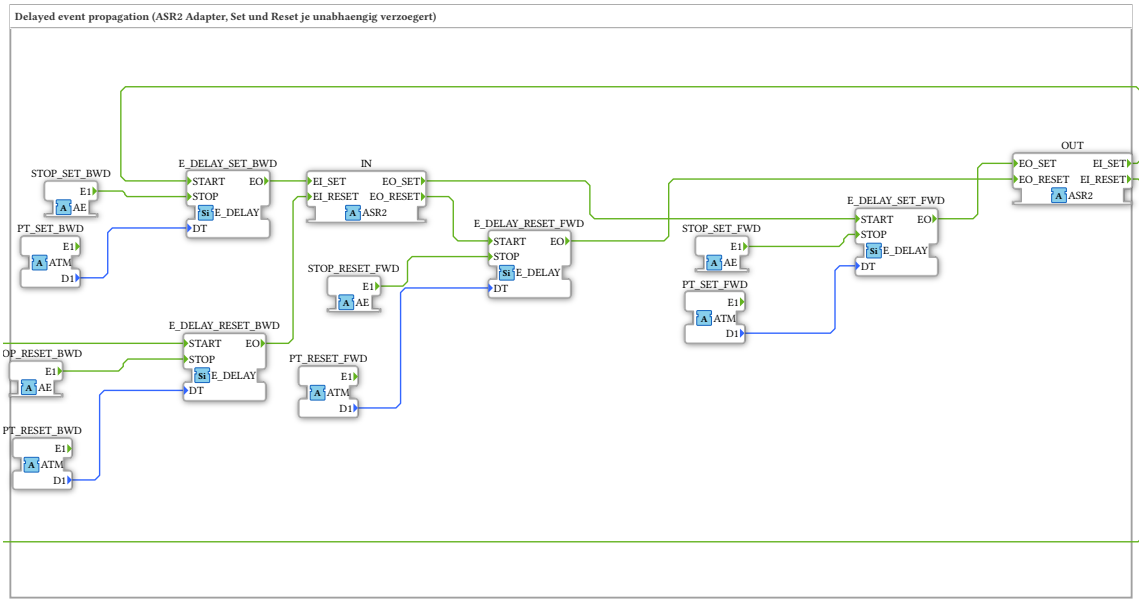
Both directions therefore pass through unchanged, and each one is additionally output as a plain unidirectional AS signal.

Technical Details

- Pure wiring without logic or state
- The passthrough `IN` ⟶ `OUT` is fully preserved; `FWD_OUT` and `REV_OUT` are pure observation taps
- Each source is fanned out to two destinations (event and data); the behaviour corresponds to a split onto both branches

Application Scenarios

- Monitoring the forward and the backward direction of a AS2 connection (e.g. for display, logging or diagnostics) without altering the connection itself
- Separate further processing of indication and request as plain AS signals

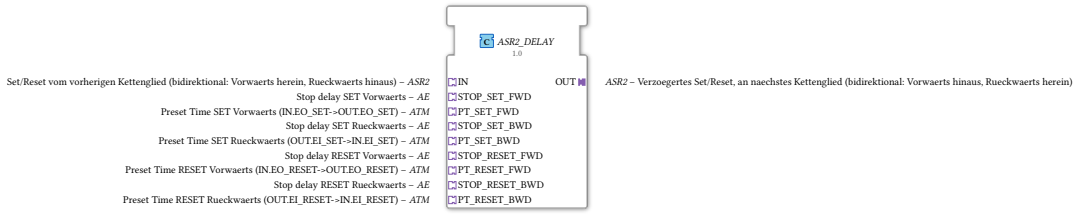


⚖️ Comparison with Similar Blocks

The same structure exists for further bidirectional adapters, e.g. `AR2_SPLIT_FWD_REV`, `AS2_SPLIT_FWD_REV`, `AX2_SPLIT_FWD_REV`, `AIS2_SPLIT_FWD_REV` and `ALR2_SPLIT_FWD_REV`; they differ only in the data type of the adapter.

Conclusion

`AS2_SPLIT_FWD_REV` is a stateless passthrough for AS2 that additionally mirrors the forward and backward channels onto two unidirectional AS plugs.



ASR2_DELAY

• – ○ • – ○ • – ○ •

Introduction

ASR2_DELAY is a composite function block that forwards the set/reset events of a bidirectional ASR2 adapter **with a delay** (e.g. for staggered switching on/off of several belts using AX_T_FF_SR_SEQ). Since ASR2 is truly bidirectional (EI_SET/EI_RESET/EO_SET/EO_RESET), **four independent** E_DELAY instances are used: set and reset, each in forward and backward direction, each with its own time and its own stop input.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs - the times are supplied via ATM sockets

Data Outputs

No data outputs

Adapters

- **IN** (socket): `adapter::types::bidirectional::ASR2` - set/reset from the previous chain element (forward in, backward out)
- **OUT** (plug): `adapter::types::bidirectional::ASR2` - delayed set/reset to the next chain element (forward out, backward in)
- **PT_SET_FWD** (socket, `adapter::types::unidirectional::ATM`): delay time SET forward (`IN.EO_SET` → `OUT.EO_SET`)
- **PT_SET_BWD** (socket, `ATM`): delay time SET backward (`OUT.EI_SET` → `IN.EI_SET`)
- **PT_RESET_FWD** (socket, `ATM`): delay time RESET forward (`IN.EO_RESET` → `OUT.EO_RESET`)
- **PT_RESET_BWD** (socket, `ATM`): delay time RESET backward (`OUT.EI_RESET` → `IN.EI_RESET`)
- **STOP_SET_FWD**, **STOP_SET_BWD**, **STOP_RESET_FWD**, **STOP_RESET_BWD** (sockets, `adapter::types::unidirectional::AE`): stop the respective delay

Function Blocks (FBs) Used

- **E_DELAY_SET_FWD**, **E_DELAY_SET_BWD**, **E_DELAY_RESET_FWD**, **E_DELAY_RESET_BWD**: each `iec61499::events::E_DELAY`

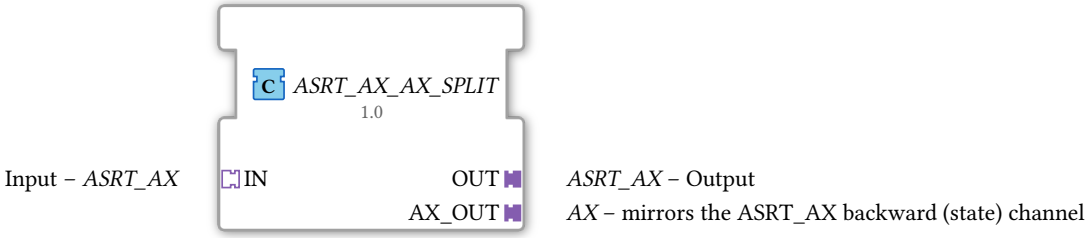
How it works

Path	START	STOP	Time (DT)	Output
SET forward	IN.EO_SET	STOP_SET_FWD.E1	PT_SET_FWD.D1	OUT.EO_SET
SET backward	OUT.EI_SET	STOP_SET_BWD.E1	PT_SET_BWD.D1	IN.EI_SET
RESET forward	IN.EO_RESET	STOP_RESET_FWD.E1	PT_RESET_FWD.D1	OUT.EO_RESET
RESET backward	OUT.EI_RESET	STOP_RESET_BWD.E1	PT_RESET_BWD.D1	IN.EI_RESET

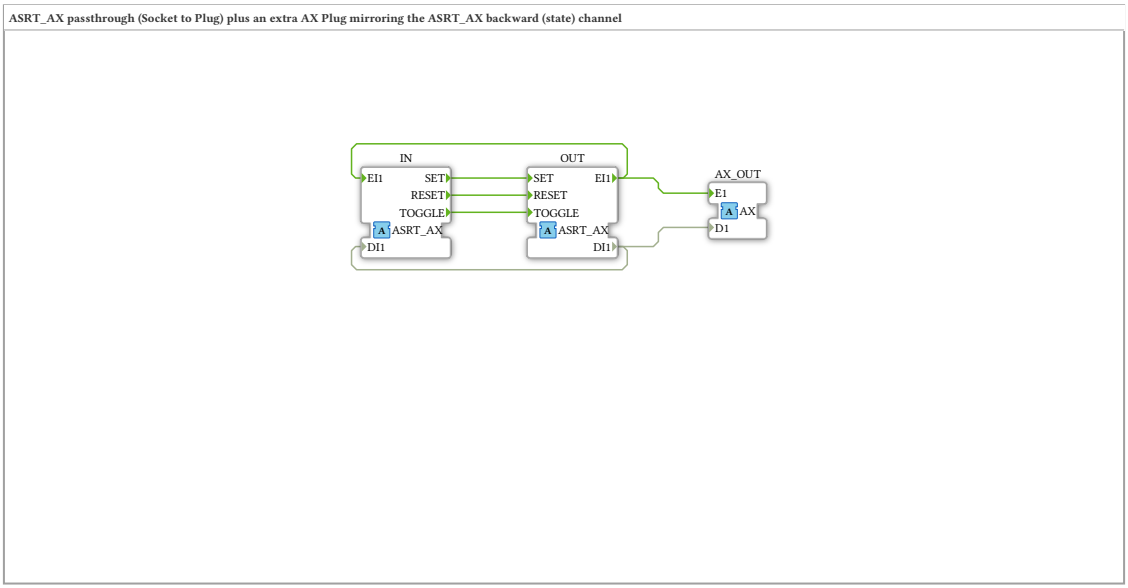
Each incoming event starts the associated E_DELAY instance; after the time has elapsed the event is fired at the output, unless the delay was stopped beforehand via the stop socket.

Technical Details

- The four times are provided via `ATM` sockets and can therefore be set independently of each other and initialized via `initval_ATM` with `INIT`/`INITO` (versions 1.1/1.2). The identifiers use the prefix `PT` instead of `DT` because `DT` is a reserved keyword.
- Since version 1.2 both directions are delayed (previously only forward).



Application Scenarios



- Staggered switching on/off of consecutive conveyor belts via an `AX_T_FF_SR_SEQ` chain

Summary

`ASR2_DELAY` delays set and reset of an `ASR2` chain element in both directions with four separately adjustable times and four stop inputs.

ASRT_AX_AX_SPLIT

• – ○ • – ○ • – ○ •

Introduction

The ASRT_AX_AX_SPLIT is a composite function block that passes three incoming ASRT_AX events (Set/Reset/Toggle) unchanged from its socket `IN` to the plug `OUT`, and additionally mirrors the state (event + bool) reported on the backward channel of `OUT` to the outside via a third, unidirectional `AX_OUT` plug. It is the Toggle-extended variant of ASR_AX_AX_SPLIT.

Interface Structure

Event Inputs

No direct event inputs available – events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

- **IN**: Bidirectional adapter socket of type `adapter::types::bidirectional::ASRT_AX` (input)
- **OUT**: Bidirectional adapter plug of type `adapter::types::bidirectional::ASRT_AX` (output)
- **AX_OUT**: Unidirectional adapter plug of type `adapter::types::unidirectional::AX`, mirrors the ASRT_AX backward channel (state)

Functionality

1. `IN.SET`, `IN.RESET`, and `IN.TOGGLE` are forwarded unchanged to `OUT.SET`, `OUT.RESET`, and `OUT.TOGGLE` respectively – the forward direction is passed through 1:1.
2. The backward-channel event `OUT.EI1` (together with its associated datum `OUT.DI1`) is relayed back to `IN.EI1`/`IN.DI1` and, at the same time, forwarded to `AX_OUT.E1`/`AX_OUT.D1`.
3. As a result, the state reported via `OUT` is visible at two points: at the original socket `IN` and additionally, in isolation, at the `AX_OUT` plug.

Technical Features

- Pure event/data connections (`FBNetwork`), no own logic or state management
- The forward direction (socket → plug) is a simple 1:1 passthrough for Set, Reset, and Toggle
- The backward channel is duplicated rather than split: both destinations (`IN` and `AX_OUT`) receive the same information

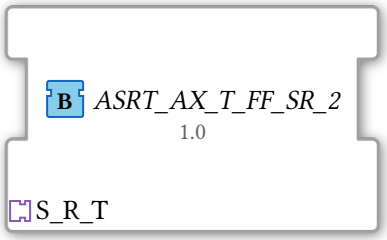
State Overview

The function block has no internal state and operates statelessly. Every incoming event is immediately forwarded or mirrored.

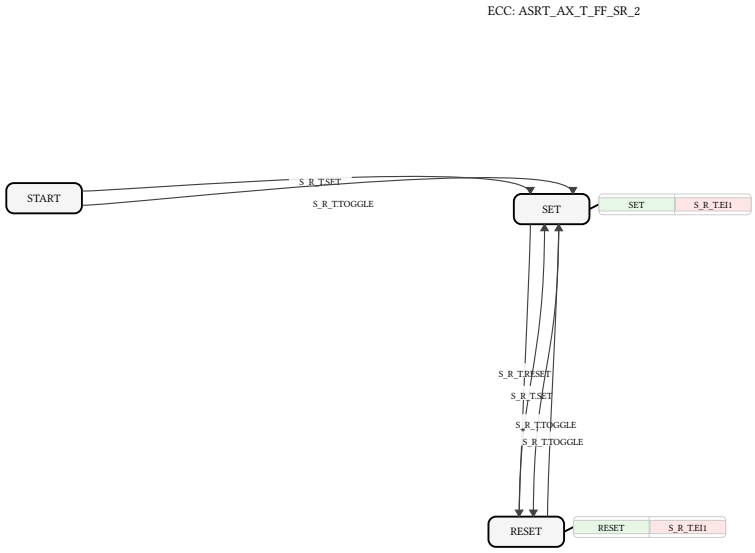
Application Scenarios

- Additional, isolated tapping of the ASRT_AX backward channel (e.g. for a separate display or logging) without altering the actual connection between `IN` and `OUT`
- Building diagnostic/monitoring paths in ASRT_AX-based control networks

⚖️ Comparison with similar building blocks



ASR_AX_AX_SPLIT follows the same pattern with only two forward events (no Toggle); AE_AX_AX_SPLIT reduces it to a single forward event.



Conclusion

ASRT_AX_AX_SPLIT makes the AX backward channel of an ASRT_AX adapter pair additionally available at a second point in the network, without interrupting or altering the actual signal chain.

ASRT_AX_T_FF_SR_2

Set/Reset/Toggle (in), Zustand (out) – *ASRT_AX*

• – ○ • – ○ • – ○ •

Introduction

The ASRT_AX_T_FF_SR_2 is an event-driven bistable flip-flop with toggle functionality and a single bidirectional `ASRT_AX` socket: Set/Reset/Toggle arrive on the same adapter that also reports the new state back. It is thus the bidirectional counterpart of ASRT_AX_T_FF_SR (unidirectional ASRT socket + separate AX plug) and the Toggle-extended variant of ASR_AX_SR_2.

Interface Structure

Event Inputs

No direct event inputs available – Set/Reset/Toggle arrive via the adapter socket `S_R_T`

Event Outputs

No direct event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

- **S_R_T**: Bidirectional adapter socket of type `adapter::types::bidirectional::ASRT_AX` – Set/Reset/Toggle (input), state (output) via the same adapter

Operation

The ASRT_AX_T_FF_SR_2 has three operating states:

- **START**: Initial state
- **SET**: State TRUE
- **RESET**: State FALSE

The state transitions are controlled by the adapter events arriving at socket `S_R_T`:

- `S_R_T.SET` transitions from any state to the SET state

- `S_R_T.RESET` transitions from any state to the RESET state
- `S_R_T.TOGGLE` toggles the current state (SET ⟶ RESET or RESET ⟶ SET, and from START to SET)

With each state change, the corresponding algorithm is executed, setting `S_R_T.DI1` (`TRUE` in the SET state, `FALSE` in the RESET state) and thereby reporting the state back over the same adapter via `S_R_T.EI1`.

Technical Features

- Bidirectional communication over a single adapter socket instead of a separate ASRT socket plus AX plug
- Identical ECC structure to ASRT_AX_T_FF_SR the only difference is the adapter direction (bidirectional instead of unidirectional plus separate plug)
- A drop-in replacement for ASRT_AX_T_FF_SR in fully adapter-based (ASRT_AX) applications

State Overview

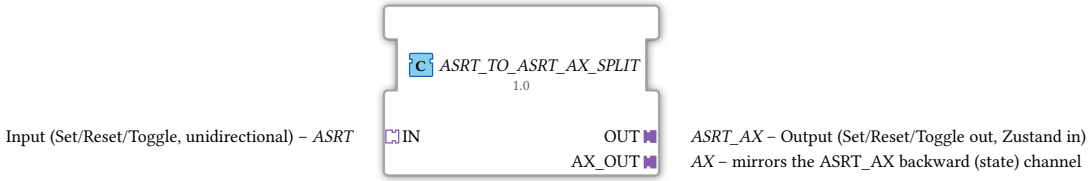
```
START (initial state)
     │
     ├── S_R_T.SET ────→ SET (S_R_T.DI1 = TRUE)
     │
     └── S_R_T.TOGGLE ─→ SET (S_R_T.DI1 = TRUE)

SET (S_R_T.DI1 = TRUE)
     │
     ├── S_R_T.RESET ──→ RESET (S_R_T.DI1 = FALSE)
     │
     └── S_R_T.TOGGLE ─→ RESET (S_R_T.DI1 = FALSE)

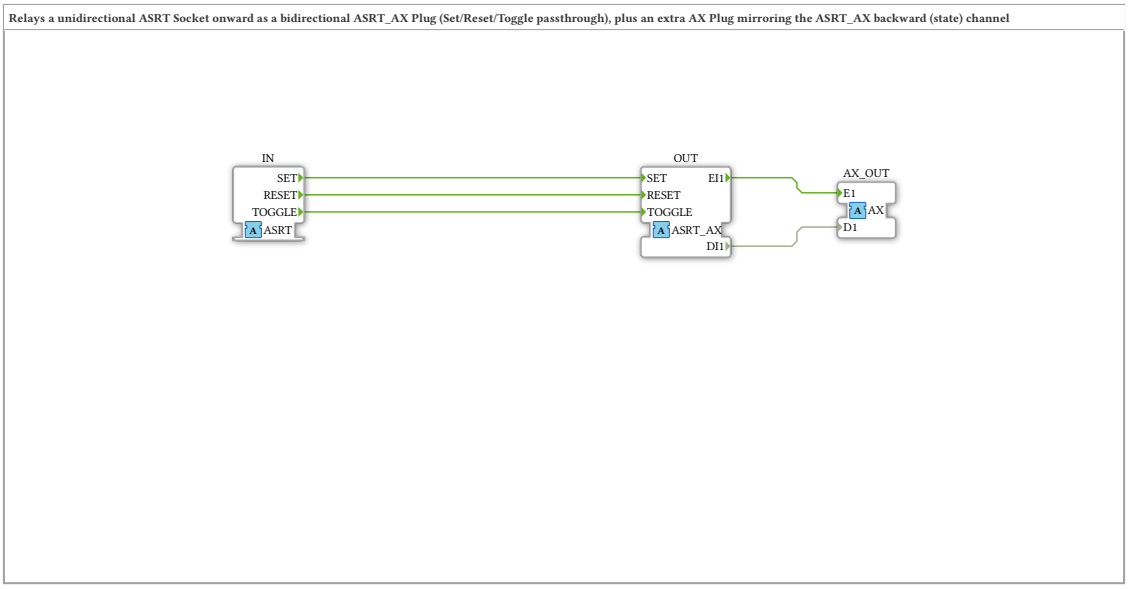
RESET (S_R_T.DI1 = FALSE)
     │
     ├── S_R_T.SET ────→ SET (S_R_T.DI1 = TRUE)
     │
     └── S_R_T.TOGGLE ─→ SET (S_R_T.DI1 = TRUE)
```

Application Scenarios

- State storage with Set/Reset/Toggle over a single bidirectional adapter connection, without wiring a separate state output
- Replacement for ASRT_AX_T_FF_SR in networks that consistently use ASRT_AX adapters



⚖️ Comparison with similar components



Compared to ASRT_AX_T_FF_SR, which uses a unidirectional ASRT socket and a separate AX plug for the state, ASRT_AX_T_FF_SR_2 bundles both directions into a single ASRT_AX socket. ASR_AX_SR_2 is the same family without the toggle input.

Conclusion

ASRT_AX_T_FF_SR_2 carries the proven Set/Reset/Toggle flip-flop pattern over into the bidirectional adapter world: control input and state feedback share the same ASRT_AX socket, simplifying wiring in adapter-based networks.

ASRT_TO_ASRT_AX_SPLIT

• – ○ • – ○ • – ○ •

Introduction

ASRT_TO_ASRT_AX_SPLIT is the set/reset/toggle variant of `ASR_TO_ASR_AX_SPLIT`: it converts an incoming **unidirectional** ASRT signal (set/reset/toggle, no backward channel) at its socket `IN` into a **bidirectional** ASRT_AX signal at plug `OUT`, and additionally mirrors the state reported on `OUT`'s backward channel out through a third, unidirectional `AX_OUT` plug.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

- **IN**: Unidirectional adapter socket of type `adapter::types::unidirectional::ASRT` (set/reset/toggle input, no backward channel)
- **OUT**: Bidirectional adapter plug of type `adapter::types::bidirectional::ASRT_AX` (set/reset/toggle output, with backward channel)
- **AX_OUT**: Unidirectional adapter plug of type `adapter::types::unidirectional::AX`, mirrors the ASRT_AX backward channel (state) to the outside

How it works

1. Every event arriving at `IN.SET` is forwarded to `OUT.SET` unchanged, likewise `IN.RESET` to `OUT.RESET` and `IN.TOGGLE` to `OUT.TOGGLE` - all three event paths run independently of each other.
2. The backward-channel event `OUT.EI1` (with its associated data `OUT.DI1`), sent by the downstream counterpart via `OUT`, is forwarded exclusively to `AX_OUT.E1`/`AX_OUT.D1` - relaying it back to `IN` is technically impossible, since `IN` is a unidirectional ASRT adapter with no backward channel.
3. `AX_OUT` is therefore the only place where the state reported by `OUT` becomes visible.

Technical Details

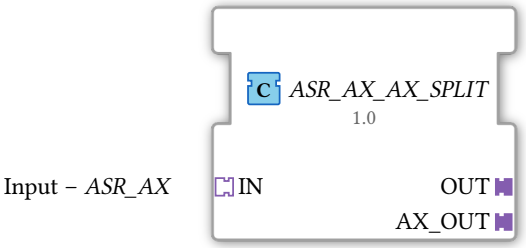
- Pure event/data connections (`FBNetwork`), no logic or state management of its own
- Three independent forward paths (SET, RESET, TOGGLE), each a simple 1:1 passthrough
- Converts a unidirectional adapter (`IN`) into a bidirectional one (`OUT`) without needing a backward channel on the input itself
- The backward channel is not duplicated, but exposed solely via `AX_OUT`

State Overview

The function block has no internal state and works statelessly. Every incoming event is forwarded/mirrored immediately.

Application Scenarios

- Connecting an existing, purely unidirectional ASRT signal source (e.g. a SoftKey with set/reset/toggle behavior) to a chain that expects a bidirectional ASRT_AX adapter
- Exposing the state of the downstream ASRT_AX counterpart via `AX_OUT`, even though the original source (`IN`) itself supports no backward channel

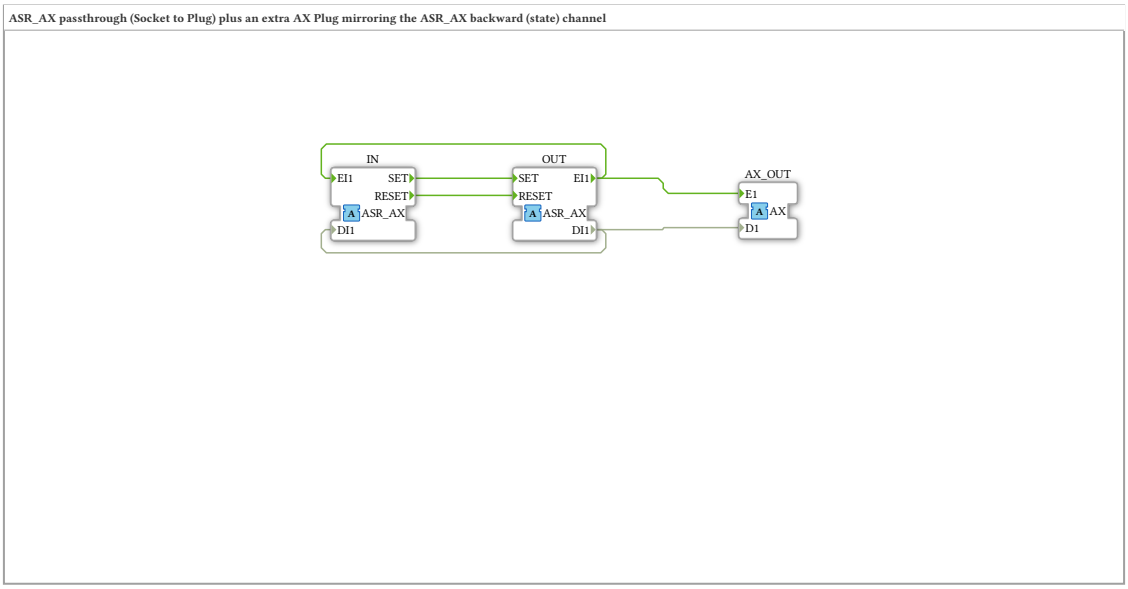


⚖️ Comparison with Similar Blocks

Structurally identical to `ASR_TO_ASR_AX_SPLIT`, just with one additional third forward event (TOGGLE). For the simpler set/reset variant without toggle, see `ASR_TO_ASR_AX_SPLIT` for the pure event variant without set/reset semantics, see `AE_TO_AE_AX_SPLIT`.

Summary

ASRT_TO_ASRT_AX_SPLIT allows a purely unidirectional ASRT signal source to connect to a bidirectional ASRT_AX chain and makes its backward channel available in isolation via `AX_OUT`, without requiring the original input itself to support a backward channel.



ASR_AX_AX_SPLIT

Input – *ASR_AX*

ASR_AX – Output

AX – mirrors the ASR_AX backward (state) channel

• – ○ • – ○ • – ○ •

Introduction

The ASR_AX_AX_SPLIT is a composite function block that passes two incoming ASR_AX events (Set/Reset) unchanged from its socket `IN` to the plug `OUT`, and additionally mirrors the state (event + bool) reported on the backward channel of `OUT` to the outside via a third, unidirectional `AX_OUT` plug. It is the Set/Reset-extended variant of AE_AX_AX_SPLIT.

Interface Structure

Event Inputs

No direct event inputs available – events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

- **IN**: Bidirectional adapter socket of type `adapter::types::bidirectional::ASR_AX` (input)
- **OUT**: Bidirectional adapter plug of type `adapter::types::bidirectional::ASR_AX` (output)
- **AX_OUT**: Unidirectional adapter plug of type `adapter::types::unidirectional::AX`, mirrors the ASR_AX backward channel (state)

Functionality

1. `IN.SET` and `IN.RESET` are forwarded unchanged to `OUT.SET` and `OUT.RESET` respectively – the forward direction is passed through 1:1.
2. The backward-channel event `OUT.EI1` (together with its associated datum `OUT.DI1`) is relayed back to `IN.EI1`/`IN.DI1` and, at the same time, forwarded to `AX_OUT.E1`/`AX_OUT.D1`.
3. As a result, the state reported via `OUT` is visible at two points: at the original socket `IN` and additionally, in isolation, at the `AX_OUT` plug.

Technical Features

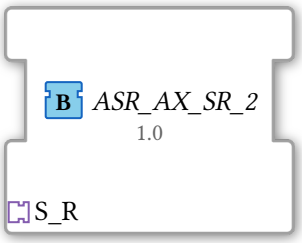
- Pure event/data connections (`FBNetwork`), no own logic or state management
- The forward direction (socket ⟶ plug) is a simple 1:1 passthrough for Set and Reset
- The backward channel is duplicated rather than split: both destinations (`IN` and `AX_OUT`) receive the same information

State Overview

The function block has no internal state and operates statelessly. Every incoming event is immediately forwarded or mirrored.

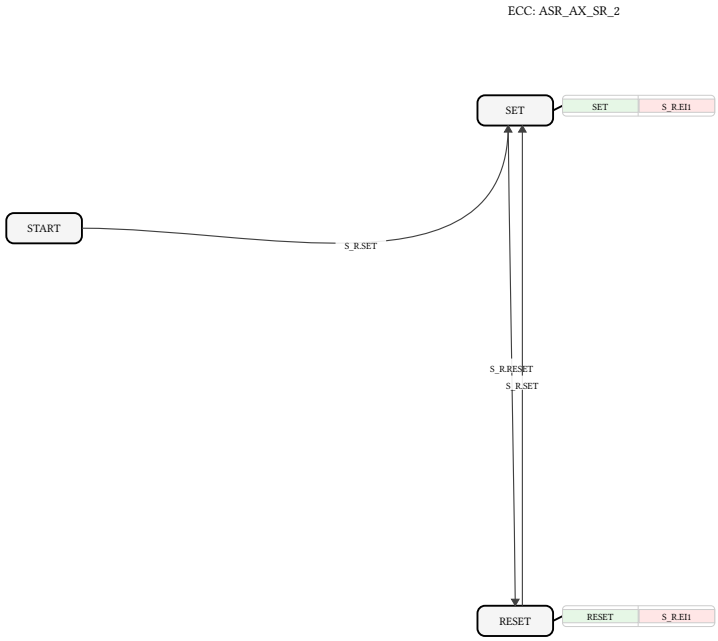
Application Scenarios

- Additional, isolated tapping of the ASR_AX backward channel (e.g. for a separate display or logging) without altering the actual connection between `IN` and `OUT`
- Building diagnostic/monitoring paths in ASR_AX-based control networks



⚖️ Comparison with similar building blocks

AE_AX_AX_SPLIT follows the same pattern with only one forward event; ASRT_AX_AX_SPLIT extends it with a third forward event (Toggle).



Conclusion

ASR_AX_AX_SPLIT makes the AX backward channel of an ASR_AX adapter pair additionally available at a second point in the network, without interrupting or altering the actual signal chain.

ASR_AX_SR_2

Set/Reset (in), Zustand (out) – *ASR_AX*

• – ○ • – ○ • – ○ •

Introduction

The ASR_AX_SR_2 is an event-driven bistable flip-flop (Set/Reset) with a single bidirectional `ASR_AX` socket: the Set and Reset events arrive on the same adapter that also reports the new state back – unlike ASR_AX_SR, which uses a unidirectional ASR socket and a separate AX plug for the state.

Interface Structure

Event Inputs

No direct event inputs available – Set/Reset arrive via the adapter socket `S_R`

Event Outputs

No direct event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

- **S_R**: Bidirectional adapter socket of type `adapter::types::bidirectional::ASR_AX` – Set/Reset (input), state (output) via the same adapter

Operation

The ASR_AX_SR_2 has three operating states:

- **START**: Initial state
- **SET**: State TRUE
- **RESET**: State FALSE

The state transitions are controlled by the adapter events arriving at socket `S_R`:

- `S_R.SET` transitions from START or RESET to the SET state
- `S_R.RESET` transitions from the SET state to the RESET state

With each state change, the corresponding algorithm is executed, setting `S_R.DI1` (`TRUE` in the SET state, `FALSE` in the RESET state) and thereby reporting the state back over the same adapter via `S_R.EI1`.

Technical Features

- Bidirectional communication over a single adapter socket instead of a separate ASR socket plus AX plug
- No toggle input – a pure Set/Reset flip-flop (unlike ASRT_AX_T_FF_SR_2)
- A drop-in replacement for ASR_AX_SR in fully adapter-based (ASR_AX) applications

State Overview

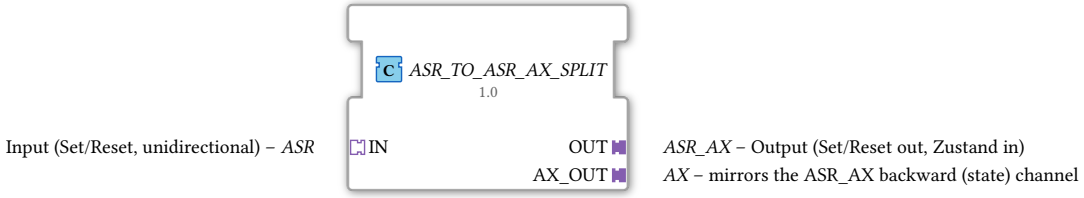
```
START (initial state)
    │
    └── S_R.SET ──→ SET (S_R.DI1 = TRUE)

SET (S_R.DI1 = TRUE)
    │
    └── S_R.RESET ─→ RESET (S_R.DI1 = FALSE)

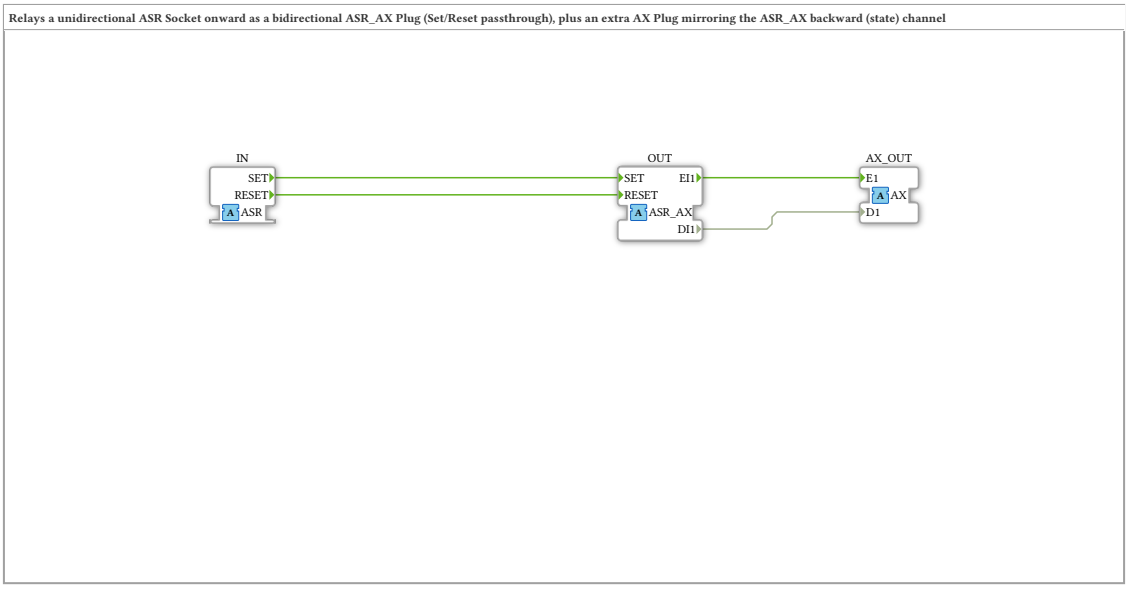
RESET (S_R.DI1 = FALSE)
    │
    └── S_R.SET ──→ SET (S_R.DI1 = TRUE)
```

Application Scenarios

- State storage (Set/Reset) over a single bidirectional adapter connection, without wiring a separate state output
- Replacement for ASR_AX_SR in networks that consistently use ASR_AX adapters



⚖️ Comparison with similar components



Compared to ASR_AX_SR, which uses a unidirectional ASR socket and a separate AX plug for the state, ASR_AX_SR_2 bundles both directions into a single ASR_AX socket. ASRT_AX_T_FF_SR_2 extends the same pattern with an additional toggle input.

Conclusion

ASR_AX_SR_2 carries the proven Set/Reset flip-flop pattern over into the bidirectional adapter world: Set/Reset input and state feedback share the same ASR_AX socket, simplifying wiring in adapter-based networks.

ASR_TO_ASR_AX_SPLIT

• – ○ • – ○ • – ○ •

Introduction

ASR_TO_ASR_AX_SPLIT is the set/reset variant of AE_TO_AE_AX_SPLIT: it converts an incoming **unidirectional** ASR signal (set/reset, no backward channel) at its socket `IN` into a **bidirectional** ASR_AX signal at plug `OUT`, and additionally mirrors the state reported on `OUT`'s backward channel out through a third, unidirectional `AX_OUT` plug.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

- **IN**: Unidirectional adapter socket of type `adapter::types::unidirectional::ASR` (set/reset input, no backward channel)
- **OUT**: Bidirectional adapter plug of type `adapter::types::bidirectional::ASR_AX` (set/reset output, with backward channel)
- **AX_OUT**: Unidirectional adapter plug of type `adapter::types::unidirectional::AX`, mirrors the ASR_AX backward channel (state) to the outside

How it works

1. Every event arriving at `IN.SET` is forwarded to `OUT.SET` unchanged, and likewise every `IN.RESET` to `OUT.RESET` - both event paths run independently of each other.
2. The backward-channel event `OUT.EI1` (with its associated data `OUT.DI1`), sent by the downstream counterpart via `OUT`, is forwarded exclusively to `AX_OUT.E1`/`AX_OUT.D1` - relaying it back to `IN` is technically impossible, since `IN` is a unidirectional ASR adapter with no backward channel.
3. `AX_OUT` is therefore the only place where the state reported by `OUT` becomes visible.

Technical Details

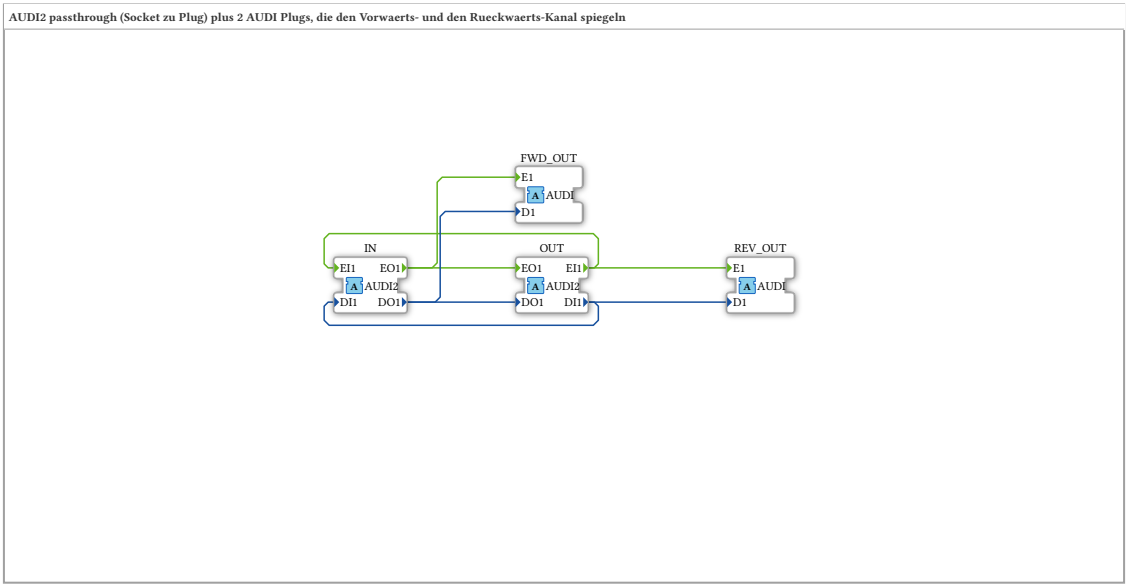
- Pure event/data connections (`FBNetwork`), no logic or state management of its own
- Two independent forward paths (SET, RESET), each a simple 1:1 passthrough
- Converts a unidirectional adapter (`IN`) into a bidirectional one (`OUT`) without needing a backward channel on the input itself
- The backward channel is not duplicated, but exposed solely via `AX_OUT`

State Overview

The function block has no internal state and works statelessly. Every incoming event is forwarded/mirrored immediately.

Application Scenarios

- Connecting an existing, purely unidirectional ASR signal source (e.g. a simple set/reset push button) to a chain that expects a bidirectional ASR_AX adapter
- Exposing the state of the downstream ASR_AX counterpart via `AX_OUT`, even though the original source (`IN`) itself supports no backward channel

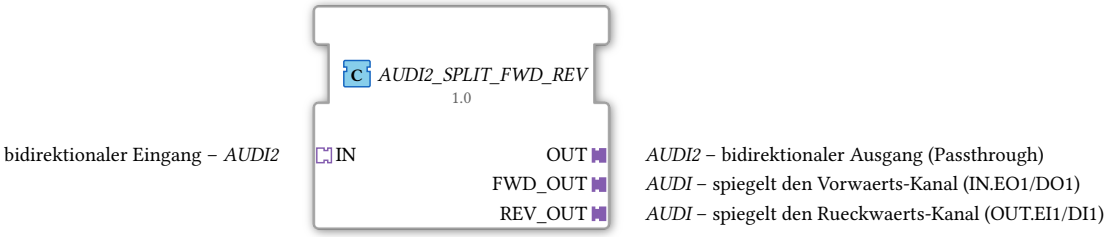


⚖️ Comparison with Similar Blocks

Structurally identical to `AE_TO_AE_AX_SPLIT`, just with two forward events (SET, RESET) instead of one. For the additional TOGGLE variant, see `ASRT_TO_ASRT_AX_SPLIT`.

Summary

ASR_TO_ASR_AX_SPLIT allows a purely unidirectional ASR signal source to connect to a bidirectional ASR_AX chain and makes its backward channel available in isolation via `AX_OUT`, without requiring the original input itself to support a backward channel.



AUDI2_SPLIT_FWD_REV

• — ○ • — ○ • — ○ •

Introduction

`AUDI2_SPLIT_FWD_REV` is a composite function block that passes a bidirectional `AUDI2` adapter from socket `IN` unchanged through to plug `OUT` (passthrough) and additionally mirrors the forward and the backward channel onto two separate, unidirectional `AUDI` plugs. This allows both directions of an `AUDI2` connection to be tapped elsewhere without altering the connection itself.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

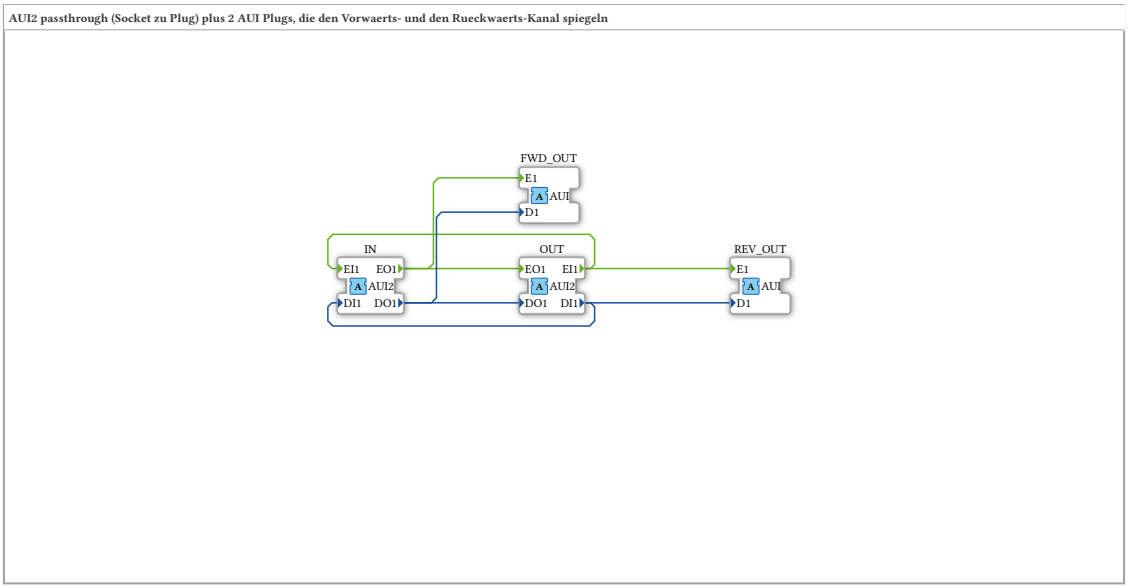
- **IN** (socket): Bidirectional adapter of type `adapter::types::bidirectional::AUDI2` (bidirectional input)
- **OUT** (plug): Bidirectional adapter of type `adapter::types::bidirectional::AUDI2` (bidirectional output, passthrough)
- **FWD_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AUDI`, mirrors the forward channel (`IN.EO1/DO1`)
- **REV_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AUDI`, mirrors the backward channel (`OUT.EI1/DI1`)

How it works

1. **Forward (indication)**: `IN.EO1/IN.DO1` is forwarded unchanged to `OUT.EO1/OUT.DO1` and additionally mirrored to `FWD_OUT.E1/FWD_OUT.D1`.
2. **Backward (request)**: `OUT.EI1/OUT.DI1` is forwarded unchanged to `IN.EI1/IN.DI1` and additionally mirrored to `REV_OUT.E1/REV_OUT.D1`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Each passthrough event output feeds two targets (fan-out); the data runs in parallel with the events
- The two mirror plugs are unidirectional (`AUDI`) and therefore provide read access to the respective channel only

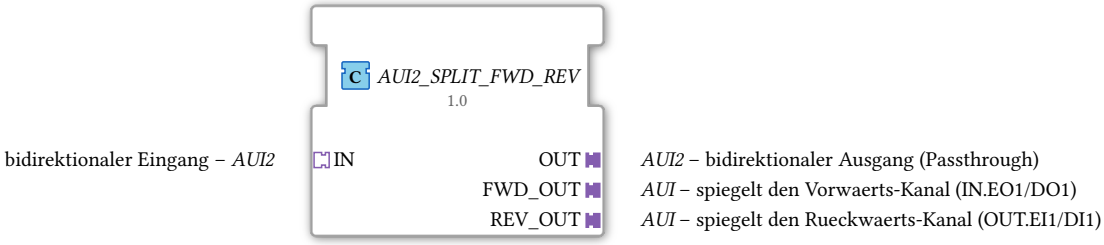


Application Scenarios

- Monitoring/diagnosing both directions of a bidirectional `AUDI2` connection
- Splitting an `AUDI2` connection into a separately evaluable forward and backward stream without interrupting the main connection

Summary

`AUDI2_SPLIT_FWD_REV` passes a bidirectional `AUDI2` connection through transparently and additionally provides the forward and backward channels as separate `AUDI` adapters.



AUI2_SPLIT_FWD_REV

• – ○ • – ○ • – ○ •

Introduction

`AUI2_SPLIT_FWD_REV` is a composite function block that passes a bidirectional `AUI2` adapter from socket `IN` unchanged through to plug `OUT` (passthrough) and additionally mirrors the forward and the backward channel onto two separate, unidirectional `AUI` plugs. This allows both directions of an `AUI2` connection to be tapped elsewhere without altering the connection itself.

Interface Structure

Event Inputs

No direct event inputs - events arrive via the adapter sockets/plugs

Event Outputs

No direct event outputs

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

- **IN** (socket): Bidirectional adapter of type `adapter::types::bidirectional::AUI2` (bidirectional input)
- **OUT** (plug): Bidirectional adapter of type `adapter::types::bidirectional::AUI2` (bidirectional output, passthrough)
- **FWD_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AUI`, mirrors the forward channel (`IN.EO1/DO1`)

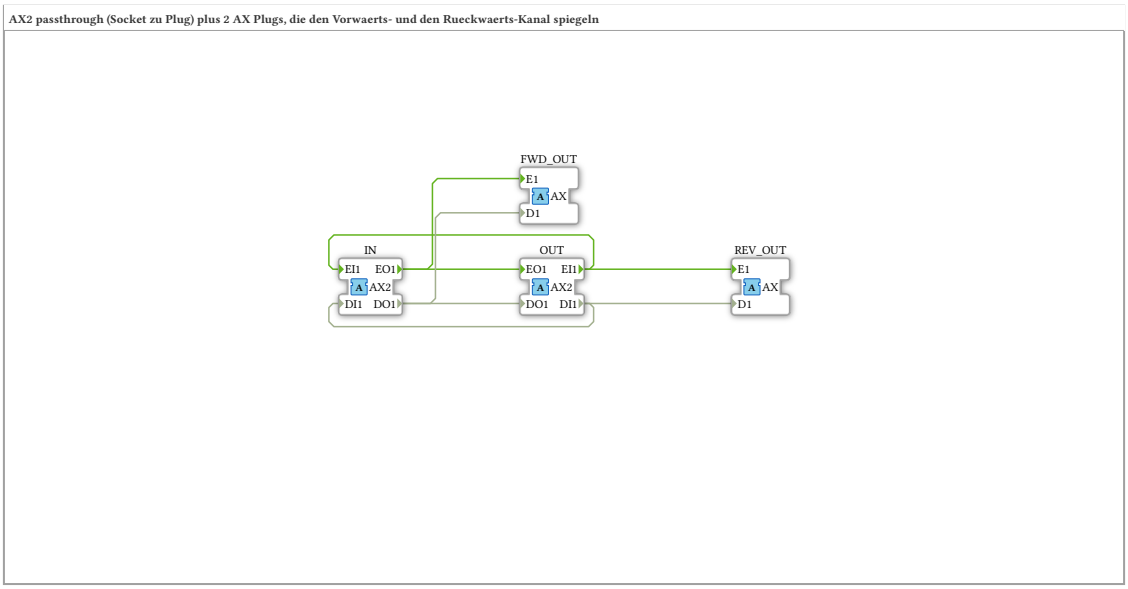
- **REV_OUT** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AUI`, mirrors the backward channel (`OUT.EI1/DI1`)

How it works

1. **Forward (indication)**: `IN.EO1/IN.DO1` is forwarded unchanged to `OUT.EO1/OUT.DO1` and additionally mirrored to `FWD_OUT.E1/FWD_OUT.D1`.
2. **Backward (request)**: `OUT.EI1/OUT.DI1` is forwarded unchanged to `IN.EI1/IN.DI1` and additionally mirrored to `REV_OUT.E1/REV_OUT.D1`.

Technical Details

- Pure event/data connections (`FBNetwork`), no logic of its own and no internal state
- Each passthrough event output feeds two targets (fan-out); the data runs in parallel with the events
- The two mirror plugs are unidirectional (`AUI`) and therefore provide read access to the respective channel only

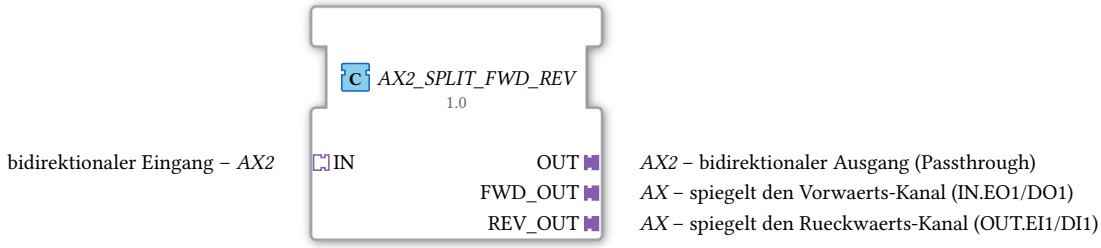


Application Scenarios

- Monitoring/diagnosing both directions of a bidirectional `AUI2` connection
- Splitting an `AUI2` connection into a separately evaluable forward and backward stream without interrupting the main connection

Summary

`AUI2_SPLIT_FWD_REV` passes a bidirectional `AUI2` connection through transparently and additionally provides the forward and backward channels as separate `AUI` adapters.



AX2_SPLIT_FWD_REV

• – ◦ • – ◦ • – ◦ •

Introduction

The `AX2_SPLIT_FWD_REV` function block passes a bidirectional `AX2` adapter unchanged from `IN` (socket) to `OUT` (plug) and additionally mirrors both channels onto one unidirectional `AX` plug each: the forward channel (indication, `IN.EO1/DO1`) onto `FWD_OUT` and the backward channel (request, `OUT.EI1/DI1`) onto `REV_OUT`. This allows both directions of a bidirectional AX2 connection to be tapped separately as plain AX signals.

Interface Structure

Event Inputs

The function block has no direct event inputs.

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **IN** (socket): bidirectional input, type `adapter::types::bidirectional::AX2`
- **OUT** (plug): bidirectional output (passthrough), type `adapter::types::bidirectional::AX2`
- **FWD_OUT** (plug): mirrors the forward channel (`IN.EO1`/`DO1`), type `adapter::types::unidirectional::AX`
- **REV_OUT** (plug): mirrors the backward channel (`OUT.EI1`/`DI1`), type `adapter::types::unidirectional::AX`

Functionality

The block consists of wiring only:

- **Forward** (indication): `IN.EO1` ⟶ `OUT.EO1` and additionally `IN.EO1` ⟶ `FWD_OUT.E1`; `IN.DO1` ⟶ `OUT.DO1` and additionally `IN.DO1` ⟶ `FWD_OUT.D1`.
- **Backward** (request): `OUT.EI1` ⟶ `IN.EI1` and additionally `OUT.EI1` ⟶ `REV_OUT.E1`; `OUT.DI1` ⟶ `IN.DI1` and additionally `OUT.DI1` ⟶ `REV_OUT.D1`.

Both directions therefore pass through unchanged, and each one is additionally output as a plain unidirectional AX signal.

Technical Details

- Pure wiring without logic or state
- The passthrough `IN` ⟶ `OUT` is fully preserved; `FWD_OUT` and `REV_OUT` are pure observation taps
- Each source is fanned out to two destinations (event and data); the behaviour corresponds to a split onto both branches

Application Scenarios

- Monitoring the forward and the backward direction of a AX2 connection (e.g. for display, logging or diagnostics) without altering the connection itself
- Separate further processing of indication and request as plain AX signals

⚖️ Comparison with Similar Blocks

The same structure exists for further bidirectional adapters, e.g. `AR2_SPLIT_FWD_REV`, `AS2_SPLIT_FWD_REV`, `AX2_SPLIT_FWD_REV`, `AIS2_SPLIT_FWD_REV` and `ALR2_SPLIT_FWD_REV`; they differ only in the data type of the adapter.

Conclusion

`AX2_SPLIT_FWD_REV` is a stateless passthrough for AX2 that additionally mirrors the forward and backward channels onto two unidirectional AX plugs.

A2X_LAST_2

ECC: A2X_LAST_2

Introduction

The A2X_LAST_2 function block merges two A2X adapter signals (**IN1**, **IN2**) into one shared output (**OUT**). Unlike the single-channel AX_LAST_2, A2X carries two independent channels (**UP** and **DOWN**), which are therefore also merged independently by last-writer-wins: whichever socket last wrote on UP wins for UP; whichever last wrote on DOWN wins for DOWN - regardless of what happens on the other channel.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: A2X adapter (unidirectional) - first signal source (UP + DOWN)
- **IN2**: A2X adapter (unidirectional) - second signal source (UP + DOWN)

Output adapter (Plug):

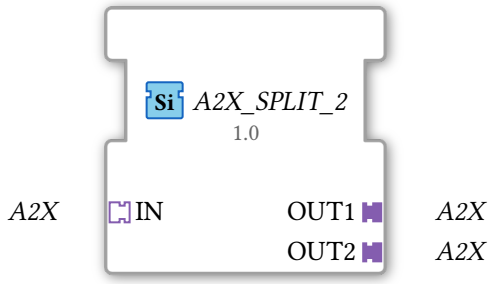
- **OUT**: A2X adapter (unidirectional) - merged signal (UP + DOWN)

How it works

The block is implemented as a Basic FB with a 5-state ECC (START, PASS1_UP, PASS2_UP, PASS1_DOWN, PASS2_DOWN) that serves both channels through the same ECC - since only one event is processed per FB invocation, UP and DOWN processing never collide. When an event arrives at IN1.UP or IN2.UP, that UP value is copied to OUT.UP and OUT.E_UP is fired. Symmetrically, an event at IN1.DOWN/IN2.DOWN copies the DOWN value to OUT.DOWN and fires OUT.E_DOWN. The two channels therefore have independent “winners” - IN1 might currently dominate the UP channel while IN2 dominates the DOWN channel.

Technical Details

- Two independent last-writer-wins merges (UP and DOWN) in one block
- Extends the generic single-channel LAST_2 pattern to the 2-channel A2X adapter type
- One shared ECC for both channels, since only one event is processed per invocation - no state conflict possible
- No signal delay: the value is passed through in the same cycle the triggering event arrives



Application Scenarios

- Merging two equally-valid A2X signal sources (e.g. two operator stations for an up/down control) into one downstream adapter path
- Arbitrating between two independent up/down sources where UP and DOWN may come from different origins

⚖️ Comparison with Similar Blocks

A2X_LAST_2 is the two-channel variant of the generic AX_LAST_2 pattern, applied to the A2X adapter type with its two independent UP/DOWN channels. For mixed operation between a data adapter and a pure event adapter, use AX_AE_MERGE instead.

A2X_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `A2X_SPLIT_2` splits an incoming A2X adapter signal into two identical output adapters. It is implemented as a generic function block (`GEN_A2X_SPLIT`) and allows an A2X signal to be forwarded to two independent target function blocks without signal loss or modification.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::A2X`	`IN`	Socket	Input adapter that receives the A2X signal to be distributed.
`adapter::types::unidirectional::A2X`	`OUT1`	Plug	First output adapter that provides an identical copy of the input signal.
`adapter::types::unidirectional::A2X`	`OUT2`	Plug	Second output adapter that provides an identical copy of the input signal.

Functionality

The function block forwards the A2X adapter signal present at socket `IN` directly to the two plugs `OUT1` and `OUT2` without any transformation or delay. Every event transmitted via the A2X adapter appears simultaneously and unchanged at both outputs. The function block has no internal logic, no state, and no latency.

Technical Features

- **Generic Function Block**: The function block is declared as the generic type `GEN_A2X_SPLIT` and utilizes the Eclipse 4diac Generic Class concept. This allows for flexible reuse in different projects.
- **Pure Adapter Forwarding**: No event or data inputs/outputs are used; all communication takes place exclusively via the A2X adapter interfaces.
- **Unidirectional**: The A2X adapter is unidirectional, therefore data and events only flow from the socket to the plugs (input → output).

State Overview

The module has no internal state machine and is completely **stateless**. Every input value is immediately passed to both outputs without storage.

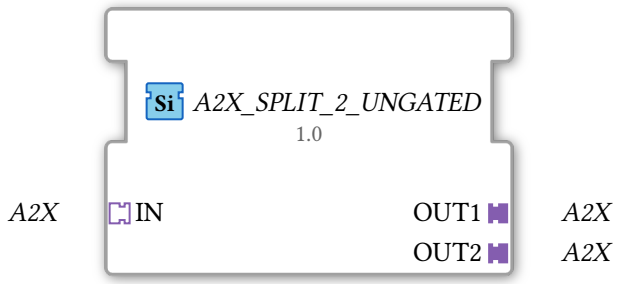
Application Scenarios

- **Signal Multiplication**: An A2X signal provided by a sensor or controller is to be distributed to two different devices (e.g., actuators, displays, superimposed logic) simultaneously.
- **Redundancy or Monitoring**: A signal is to be routed to a diagnostic or monitoring module in parallel with a primary destination.
- **Testing and Simulation**: An A2X signal is to be connected to both the actual hardware and a simulator during testing.

Comparison with Similar Modules

- **A2X_SPLIT_3**: Analog module with three outputs instead of two. Both modules function identically, differing only in the number of output plugs.
- **A2X_MERGE**: Combines two A2X signals into one – opposite functionality.
- **Generic Splitters (e.g., for other adapter types)**: Same operating principle, but adapted to the adapter type.

Conclusion



The `A2X_SPLIT_2` is a simple yet useful module for signal distribution in 4diac applications. Its generic nature allows for flexible use without additional configuration. It is particularly suitable for scenarios where an A2X signal needs to be passed on to multiple receivers without compromising signal integrity.

A2X_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **A2X_SPLIT_3** is used to split an incoming A2X adapter data stream into three identical outputs. It is implemented as a generic function block (FB) and is suitable for applications where a signal is required multiple times.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::A2X`	**IN**	Socket (Input)	Source adapter whose data stream is split.
`adapter::types::unidirectional::A2X`	**OUT1**	Plug (Output)	First identical output.
`adapter::types::unidirectional::A2X`	**OUT2**	Plug (Output)	Second identical output.
`adapter::types::unidirectional::A2X`	**OUT3**	Plug (Output)	Third identical output.

The adapters are all of type **A2X** (unidirectional) and transmit data in one direction. The device is passive, meaning it does not require event control for data transmission.

Functionality

The function block receives the A2X data stream arriving via socket **IN** and forwards it unchanged to the three plugs **OUT1**, **OUT2**, and **OUT3**. No processing, filtering, or buffering takes place – the data stream is distributed 1:1 to all outputs.

Since this is a generic function block, the specific data type of the A2X adapter can be defined at runtime by typing (e.g., via the attribute `GenericClassName`).

Technical Features

- **Generic Design**: The function block is declared as a generic FB (`GenericClassName = 'GEN_A2X_SPLIT'`), allowing the A2X adapter to be parameterized with different specific data structures depending on the application.

- **No State Automation**: The function block does not have an ECC (Execution Control Chart) or event interfaces. It operates purely in a data flow-oriented manner.
- **Runtime Type Adaptation**: A unique type identifier for the generic instance can be stored via the attribute `TypeHash` (currently empty; must be set project-specifically).

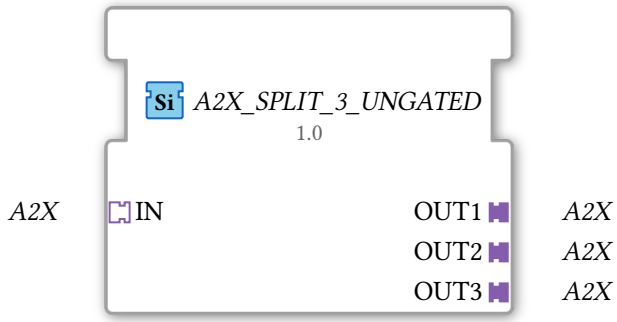
State Overview

The function block has no internal states, as it contains no sequential logic or state machine. Data transmission occurs continuously without delay.

Application Scenarios

- **Signal Distribution**: An A2X signal from a sensor or controller must be forwarded in parallel to several downstream function blocks (e.g., displays, loggers, actuators).
- **Redundancy / Monitoring**: A data stream should be sent to both the actual processing unit and a diagnostic or monitoring system.
- **Prototypical Setups**: During the development phase, a single generic splitter can be flexibly used for various adapter types.

Comparison with Similar Function Blocks



- **A2X_SPLIT_2**: Splits an A2X stream across two outputs. This function block extends this to three outputs.
- **Manual Duplication**: Without a splitter, the architect would have to reference the source adapter multiple times in the configuration, which reduces readability and maintainability.
- **Generic Splitters**: Other splitting function blocks (e.g., for data or event adapters) follow the same principle but are specialized for different adapter types.

Conclusion

The **A2X_SPLIT_3** is a simple yet useful generic function block for duplicating an A2X data stream across three paths. Its generic nature allows it to adapt flexibly to different data structures and facilitates modular interconnection in IEC 61499-based automation systems.

A2X_SPLIT_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `A2X_SPLIT_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Conclusion

The **A2X_SPLIT_3_UNGATED** is a simple yet useful generic function block for duplicating an A2X data stream across three paths. Its generic nature allows it to adapt flexibly to different data structures and facilitates modular interconnection in IEC 61499-based automation systems.

A2X_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **A2X_SPLIT_4** is used to split an incoming A2X adapter signal into four identical A2X outputs. It is designed as a generic block, enabling flexible use in a wide variety of automation environments where an A2X signal is required multiple times.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Direction	Identifier	Type	Description
Socket (Input)	IN	`adapter::types::unidirectional::A2X`	One incoming A2X signal (unidirectional)
Plug (Output 1)	OUT1	`adapter::types::unidirectional::A2X`	First outgoing A2X channel
Plug (Output 2)	OUT2	`adapter::types::unidirectional::A2X`	Second outgoing A2X channel
Plug (Output 3)	OUT3	`adapter::types::unidirectional::A2X`	Third outgoing A2X channel
Plug (Output 4)	OUT4	`adapter::types::unidirectional::A2X`	Fourth Outgoing A2X Channel

Functionality

This function block operates as a pure signal distributor. The A2X adapter interface connected to socket **IN** is internally routed to the four output plugs **OUT1** to **OUT4** without any further processing or delay. Each output delivers exactly the same signal as the input. Since these are unidirectional adapters, there is no feedback from the outputs to the input.

Technical Features

- **Generic Function Block** – The function block is instantiated as `GEN_A2X_SPLIT` and can be adapted to different A2X variants using type parameters.
- **No Event or Data Processing** – The entire functionality is limited to forwarding the adapter signal. There are no events or data inputs/outputs.
- **Licensing** – This function block is licensed under the Eclipse Public License 2.0 (EPL-2.0).

State Overview

This function block has no state machines (ECCs) and no internal behavior that is time- or state-dependent. The output signals follow the input signal immediately.

Application Scenarios

- **Distribution of an A2X signal** to multiple downstream function blocks that rely on the same A2X information.
- **Star topologies** in communication between components of a distributed control system.
- **Test and simulation environments** where an A2X signal needs to be recorded or analyzed in parallel.

Comparison with Similar Function Blocks

- **A2X_SPLIT_2** / **A2X_SPLIT_3** / **A2X_SPLIT_N** – These function blocks offer the same functionality with a different number of outputs.

A2X_SPLIT_N Unlike a **multiplexer** or **demultiplexer**, no selection takes place here – the signal is always duplicated to all outputs.

Conclusion

The **A2X_SPLIT_4** is a simple yet useful component for duplicating a unidirectional A2X adapter signal. Its generic design and clear interface make it easy to integrate into existing 4diac IDE projects and contribute to the modularization of control applications.

A2X_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **A2X_SPLIT_5** is used to split an incoming A2X adapter into five identical A2X outputs. It is provided as a generic block that can be configured via attributes.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Direction	Name	Type	Description
Socket	IN	A2X (unidirectional)	Input adapter (split)
Plug	OUT1	A2X (unidirectional)	First output adapter
Plug	OUT2	A2X (unidirectional)	Second output adapter
Plug	OUT3	A2X (unidirectional)	Third output adapter
Plug	OUT4	A2X (unidirectional)	Fourth output adapter
Plug	OUT5	A2X (unidirectional)	Fifth output adapter

Functionality

The module forwards the A2X adapter input at socket `IN` unchanged and in parallel to all five plugs (`OUT1` to `OUT5`). There is no delay or buffering – any change at the input is immediately propagated to all outputs. Thus, the module behaves like a simple splitter for A2X interfaces.

Technical Features

- **Generic Module:** The actual instance can be configured via the attributes `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash`, allowing adaptation to various A2X variants.
- **No Event or Data Ports:** All communication takes place exclusively via adapters. This simplifies integration with other A2X-based components.
- **Scalability:** The module can serve as the basis for splitters with a different number of outputs (e.g., `A2X_SPLIT_2`, `A2X_SPLIT_10`).

State Overview

The module has no internal states or state machines. It operates purely combinatorially as a passive forwarder.

Application Scenarios

- **Distributing a Bus Signal:** When an A2X adapter (e.g., for a fieldbus) needs to be transmitted to multiple downstream modules without interfering with each other.
- **Test and Simulation Setups:** An incoming A2X data stream can be routed in parallel to various analysis or monitoring components.
- **Expanding Control Systems:** A sensor or actuator adapter can be split across multiple function blocks that implement different logic.

Comparison with Similar Function Blocks

- **A2X_SPLIT_2 / A2X_SPLIT_N:** These variants differ only in the number of outputs. `A2X_SPLIT_5` offers a fixed 5-way split.
- **A2X_MERGE:** While the splitter distributes one input to multiple outputs, the merge function block combines multiple A2X inputs into a single output.
- **Data splitters (e.g., SPLIT_INT):** These operate at the data level (e.g., integers) and not at the adapter level. The function block described here operates at the adapter level, which enables structural decoupling.

Conclusion

The `A2X_SPLIT_5` is a simple yet useful adapter splitter for A2X interfaces. Due to its generic nature and pure adapter communication, it integrates seamlessly into IEC 61499-based control systems. It is particularly suitable for applications where an A2X signal needs to be distributed across multiple paths without requiring additional logic or states.

A2X_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `A2X_SPLIT_6` is used to distribute an incoming A2X adapter to six identical A2X outputs. It is implemented as a generic function block (GFB) and enables the forwarding of adapter data without delay or state change. Typical applications include the parallel power supply of multiple devices or signal cascading in industrial control systems.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Direction	Name	Type	Description
Input (Socket)	`IN`	`adapter::types::unidirectional::A2X`	Receives the incoming A2X adapter signal
Output (Plug) 1	`OUT1`	`adapter::types::unidirectional::A2X`	First outgoing A2X adapter
Output (Plug) 2	`OUT2`	`adapter::types::unidirectional::A2X`	Second outgoing A2X adapter
Output (Plug) 3	`OUT3`	`adapter::types::unidirectional::A2X`	Third outgoing A2X adapter
Output (Plug) 4	`OUT4`	`adapter::types::unidirectional::A2X`	Fourth outgoing A2X adapter
Output (Plug) 5	`OUT5`	`adapter::types::unidirectional::A2X`	Fifth outgoing A2X adapter
Output (Plug) 6	`OUT6`	`adapter::types::unidirectional::A2X`	Sixth outgoing A2X adapter

Functionality

The module functions as a simple distributor (splitter). As soon as socket `IN` is connected to an A2X adapter, the complete adapter signal—consisting of all data and event channels contained within this

adapter—is passed on to all six plugs (`OUT1` … `OUT6`). This transmission occurs without buffering or internal logic; any change at the input is reflected instantly at all outputs.

Technical Features

- **Unidirectionality** – The adapter `A2X` is designed to be unidirectional; data flow reversal is not supported.
- **Generic Design** – The function block (FB) is stored as a generic type (`GenericClassName = 'GEN_A2X_SPLIT'`), allowing it to be used in various contexts.
- **No States or Events** – There are no internal state machines or event-driven processes; The function block (FB) is purely combinational.
- **Complete Decoupling** – The use of adapters decouples the connected blocks, increasing reusability.

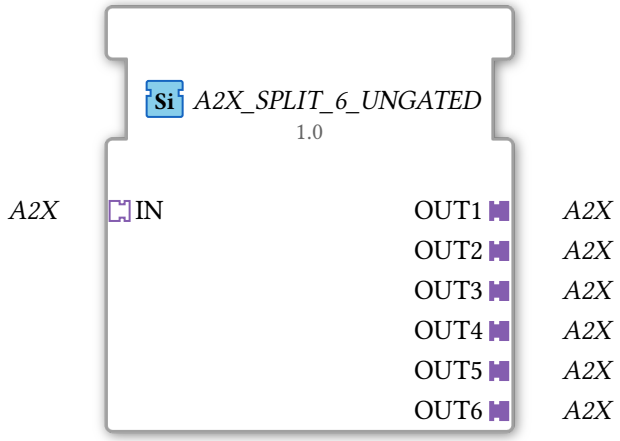
State Overview

The function block does not have its own state machine. It is always passive and only active via the adapter data present at its input. Therefore, there are no defined states such as INIT, RUN, or IDLE.

Application Scenarios

- **Signal Distribution in Automation** – A sensor delivers measured values via an A2X adapter, which must be forwarded in parallel to multiple controllers or evaluation units.
- **Cascading of Adapter Signals** – In complex hierarchies, an A2X signal can be distributed across multiple subordinate modules.
- **Test and Simulation Environments** – For simultaneously connecting multiple test benches or visualization components to a single data source.

Comparison with Similar Function Blocks



- **A2X_SPLIT_2 / A2X_SPLIT_4 / A2X_SPLIT_N** – These function blocks offer the same functionality, but with two, four, or a configurable number of outputs. `A2X_SPLIT_6` provides a fixed 6-way distribution.
- **A2X_MERGE** – Unlike the splitter, this function block combines multiple A2X inputs into a single output.
- **Standard Data Splitters** (e.g., for simple data types) – Adapter-based splitters like this one operate at a higher level of abstraction and encapsulate complex signal bundles.

Conclusion

The `A2X_SPLIT_6` is a simple yet useful function block for multiplying A2X adapter signals. Its generic structure and pure distribution function make it particularly suitable for scenarios where a signal needs to be sent to multiple receivers without any processing logic. The absence of events and states makes it easy to understand and resource-efficient to use.

A2X_SPLIT_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of `A2X_SPLIT_6`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `A2X_SPLIT_6_UNGATED` is used to distribute an incoming A2X adapter to six identical A2X outputs. It is implemented as a generic function block (GFB) and enables the forwarding of adapter data without delay or state change. Typical applications include the parallel power supply of multiple devices or signal cascading in industrial control systems.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

Adapter

Direction	Name	Type	Description
Input (Socket)	`IN`	`adapter::types::unidirectional::A2X`	Receives the incoming A2X adapter signal
Output (Plug) 1	`OUT1`	`adapter::types::unidirectional::A2X`	First outgoing A2X adapter
Output (Plug) 2	`OUT2`	`adapter::types::unidirectional::A2X`	Second outgoing A2X adapter
Output (Plug) 3	`OUT3`	`adapter::types::unidirectional::A2X`	Third outgoing A2X adapter
Output (Plug) 4	`OUT4`	`adapter::types::unidirectional::A2X`	Fourth outgoing A2X adapter
Output (Plug) 5	`OUT5`	`adapter::types::unidirectional::A2X`	Fifth outgoing A2X adapter
Output (Plug) 6	`OUT6`	`adapter::types::unidirectional::A2X`	Sixth outgoing A2X adapter

Functionality

The module functions as a simple distributor (splitter). As soon as socket `IN` is connected to an A2X adapter, the complete adapter signal—consisting of all data and event channels contained within this adapter—is passed on to all six plugs (`OUT1` … `OUT6`). This transmission occurs without buffering or internal logic; any change at the input is reflected instantly at all outputs.

Technical Features

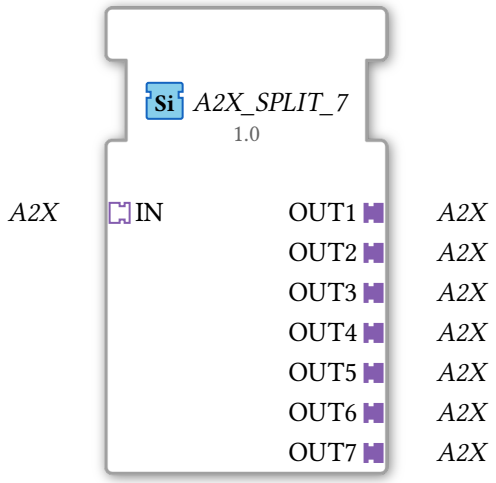
- **Unidirectionality** – The adapter `A2X` is designed to be unidirectional; data flow reversal is not supported.
- **Generic Design** – The function block (FB) is stored as a generic type (`GenericClassName = 'GEN_A2X_SPLIT'`), allowing it to be used in various contexts.
- **No States or Events** – There are no internal state machines or event-driven processes; The function block (FB) is purely combinational.
- **Complete Decoupling** – The use of adapters decouples the connected blocks, increasing reusability.

State Overview

The function block does not have its own state machine. It is always passive and only active via the adapter data present at its input. Therefore, there are no defined states such as INIT, RUN, or IDLE.

Application Scenarios

- **Signal Distribution in Automation** – A sensor delivers measured values via an A2X adapter, which must be forwarded in parallel to multiple controllers or evaluation units.
- **Cascading of Adapter Signals** – In complex hierarchies, an A2X signal can be distributed across multiple subordinate modules.
- **Test and Simulation Environments** – For simultaneously connecting multiple test benches or visualization components to a single data source.



Comparison with Similar Function Blocks

- **A2X_SPLIT_2 / A2X_SPLIT_4 / A2X_SPLIT_N** – These function blocks offer the same functionality, but with two, four, or a configurable number of outputs. `A2X_SPLIT_6_UNGATED` provides a fixed 6-way distribution.
- **A2X_MERGE** – Unlike the splitter, this function block combines multiple A2X inputs into a single output.
- **Standard Data Splitters** (e.g., for simple data types) – Adapter-based splitters like this one operate at a higher level of abstraction and encapsulate complex signal bundles.

Conclusion

The `A2X_SPLIT_6_UNGATED` is a simple yet useful function block for multiplying A2X adapter signals. Its generic structure and pure distribution function make it particularly suitable for scenarios where a signal needs to be sent to multiple receivers without any processing logic. The absence of events and states makes it easy to understand and resource-efficient to use.

A2X_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **A2X_SPLIT_7** is used to distribute an incoming A2X adapter signal to seven identical outputs. It is provided as a generic FB and enables efficient signal multiplication within 4diac IDE projects.

Interface Structure

Event Inputs
- None

Event Outputs
- None

Data Inputs
- None

Data Outputs
- None

Adapter

Type	Name	Description
A2X (Socket)	**IN**	Input adapter for the A2X signal to be distributed
A2X (Plug)	**OUT1** ... **OUT7**	Seven output adapters, each providing an identical copy of the input signal

Functionality
The function block forwards the A2X signal present at the **IN** adapter unchanged to all seven output adapters (**OUT1** to **OUT7**). No data manipulation takes place – the signals are simply passively duplicated. The function block is purely adapter-based and requires neither event nor data inputs.

Technical Features
- **Generic Function Block**: The function block is declared as a generic type (`GEN_A2X_SPLIT`) and can be reused in various contexts.
- **Unidirectional Adapters**: All A2X adapters used are of type `unidirectional`, meaning data flows in only one direction (from the socket to the plug).
- **No Event Control**: Signal transmission is purely data flow-driven without additional events or states.
- **Easily Extensible**: Any number of outputs (e.g., 2, 4, 10) can be implemented by modifying the XML definition.

State Overview
The function block (FB) does not have its own state machine (ECC). The output signals are always an exact representation of the input signal. There are no internal states or time delays.

Application Scenarios
- **Distributing a sensor or control signal** to multiple parallel function blocks or subsystems.
- **Providing identical adapter data** for redundant processing paths (e.g., backups).
- **Simulation or test setups** where a signal is needed multiple times without instantiating the source multiple times.

Comparison with similar function blocks
- **A2X_SPLIT_2, A2X_SPLIT_3, ...**: These function blocks distribute the input signal to two, three, or more outputs. This function block is specifically designed for seven outputs and can be considered a specialization of a generic split function block.
- **Manual multiplication via connection**: Theoretically, an A2X signal could also be distributed by connecting an output multiple times – however, the split function block provides a clean, structured, and reusable solution.

Conclusion
The **A2X_SPLIT_7** is a simple yet useful function block for signal multiplication in A2X-based adapter systems. Its generic nature and clear interface make it ideally suited for modular automation solutions using the 4diac IDE.

A2X_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The A2X_SPLIT_8 function block serves as a generic building block to distribute an incoming A2X adapter (socket) to eight identical A2X adapter outputs (plugs). It is used in industrial automation when a signal is required multiple times.

Interface Structure

Event Inputs

Not present.

Event Outputs

Not present.

Data Inputs

Not present.

Data Outputs

Not present.

Adapters

The FB has the following adapter interfaces:
Socket (Input):

- `IN` (Type: `adapter::types::unidirectional::A2X`)

Plugs (Outputs):

- `OUT1` to `OUT8` (each type: `adapter::types::unidirectional::A2X`)

Functionality

The FB forwards the data received via socket `IN` unchanged to all eight plugs `OUT1` to `OUT8`. No processing or conversion of the data takes place. The FB functions purely as a distributor (splitter) for A2X adapters.

Technical Features

- The function block is implemented as a generic FB (GenericClassName: `GEN_A2X_SPLIT`), enabling flexible reuse in various contexts.
- There are no events or data points; all communication takes place via the A2X adapters.
- The FB is compliant with the IEC 61499-2 standard.
- The outputs are independent of each other and can be individually connected to other FBs.

State Overview

Since the FB has neither event inputs nor an execution state, there is no state machine. The FB operates continuously without an internal state.

Application Scenarios

- Distribution of a sensor signal (e.g., temperature, pressure) to multiple consumers or controllers.
- Parallel connection of a control signal to multiple actuators.
- Provision of a reference value for multiple control loops.

Comparison with Similar Function Blocks

- **A2X_SPLIT_2**, **A2X_SPLIT_4**: Function blocks with fewer outputs that can be used as needed.
- **A2X_MERGE**: Combines multiple A2X inputs into one output – the opposite function.
- **A2X_SELECT**: Selects one of several A2X inputs, while the splitter operates all outputs simultaneously.

Conclusion

The A2X_SPLIT_8 is a simple yet useful function block for multiplying A2X signals in automation projects. Its generic design and clear separation of inputs and outputs provide a clean and reusable solution.

A2X_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The **A2X_SPLIT_9** is a generic function block that splits one incoming A2X adapter (socket) into nine separate A2X output adapters (plugs). It enables the star topology distribution of an A2X signal to up to nine independent receivers without requiring any dedicated logic or state machines.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapters

Type	Name	Direction	Description
Socket	IN	Input	Incoming A2X adapter, whose signals are distributed to the nine outputs.
Plug	OUT1 ... OUT9	Output	Nine identical A2X output adapters that forward the input data.

Functionality

This function block has no internal logic or state machines. It functions purely as a “wiring aid” in the 4diac IDE: The A2X adapter connected to socket **IN** is passed unchanged and in parallel to all nine plugs **OUT1** to **OUT9**. Thus, all connected receivers receive identical signals to the input.

Technical Features

- **Generic Function Block**: The function block is declared as generic (attribute `GenericClassName = 'GEN_A2X_SPLIT'`). It can be parameterized for various specific A2X adapter types in the IDE.

- **No Runtime Logic**: The function block contains no ECC (Execution Control Chart) and no algorithms – all functionality is implemented through the internal connection of the adapters.
- **Unidirectional Adapters**: The adapters used, `adapter::types::unidirectional::A2X`, only allow data flow in one direction (from the socket to the plugs).

State Overview

A state overview is not required, as the function block has no internal state. Data flow is continuous and uncontrolled by events.

Application Scenarios

- **Signal Distribution in Automation**: Distributing an analog or binary A2X signal to multiple actuators or higher-level controllers.
- **Test and Simulation Setups**: Feeding a reference signal into multiple parallel test paths.
- **Topology Implementation**: Star-shaped cabling in the graphical configuration to utilize a central data point multiple times.

Comparison with Similar Function Blocks

- **A2X_SPLIT_N**: A configurable splitter with a variable number of outputs, e.g., 2, 4, or 8. The **A2X_SPLIT_9** is fixed to nine outputs.
- **A2X_MERGE**: The reverse function block that combines multiple inputs into one output (e.g., for bus topologies).
- **Event-Based Splitters**: Function blocks like `SPLIT` or `E_SPLIT` operate with event signals and require control logic – the **A2X_SPLIT_9** does not require events.

Conclusion

The **A2X_SPLIT_9** is a simple yet effective function block for distributing an A2X signal to nine identical outputs. Its generic nature and lack of internal logic make it lightweight and ideal for pure wiring scenarios in the 4diac IDE. It is particularly well-suited for applications where a signal is needed multiple times without requiring additional programming.

ASRT_AX_T_FF_SR

Set/Reset/Toggle – *ASRT*

AX – value of flip flop

• – ○ • – ○ • – ○ •

Introduction

The ASRT_AX_T_FF_SR is an event-driven bistable function block with toggle functionality – the direct counterpart of AX_T_FF_SR, where the three event inputs S/R/CLK are combined into a single unidirectional **ASRT socket** (Set/Reset/Toggle) instead of being routed as three separate event inputs.

Interface Structure

Event Inputs

- No direct event inputs available – Set/Reset/Toggle arrive bundled via the adapter socket `S_R_T`

Event Outputs

- No direct event outputs available

Data Inputs

- No data inputs available

Data Outputs

- No direct data outputs available

Adapters

- **S_R_T**: Unidirectional adapter socket of type `adapter::types::unidirectional::ASRT` (Set/Reset/Toggle)
- **Q**: Unidirectional adapter plug of type `adapter::types::unidirectional::AX` that provides the flip-flop value

Operation

The ASRT_AX_T_FF_SR has three operating states:

- **START**: Initial state
- **SET**: Output Q is TRUE
- **RESET**: Output Q is FALSE

The state transitions are controlled by the adapter events arriving at socket `S_R_T`:

- `S_R_T.SET` transitions from any state to the SET state
- `S_R_T.RESET` transitions from any state to the RESET state
- `S_R_T.TOGGLE` toggles the current state (SET ⟶ RESET or RESET ⟶ SET, and from START to SET)

With each state change, the corresponding algorithm is executed, setting the adapter value `Q.D1` accordingly (`TRUE` in the SET state, `FALSE` in the RESET state).

Technical Features

- Combines SR flip-flop and T flip-flop functionality like AX_T_FF_SR, but with a bundled adapter interface instead of three separate event inputs
- Uses the unidirectional ASRT adapter interface for Set/Reset/Toggle and the AX adapter interface for data output
- Initial state is START, from which a transition to SET can occur directly or via TOGGLE

State Overview

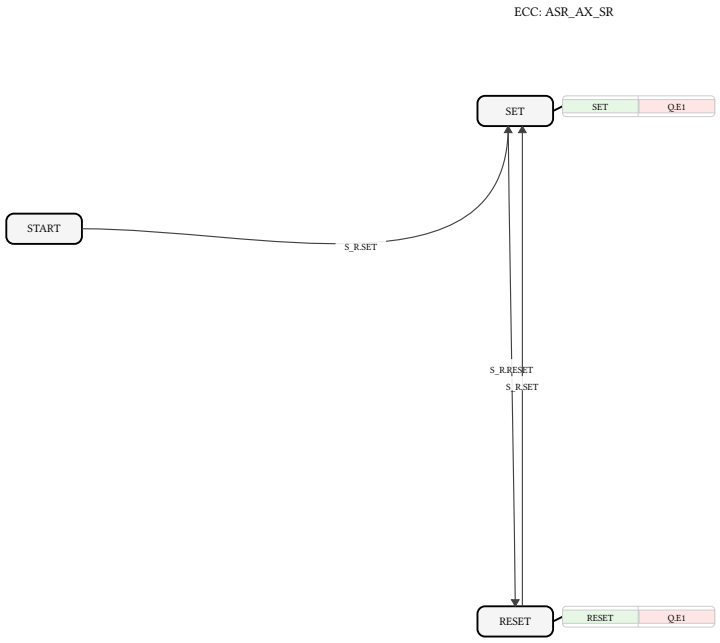
```
START (initial state)
     │
     ├── S_R_T.SET ─────→ SET (Q.D1 = TRUE)
     │
     └── S_R_T.TOGGLE ─→ SET (Q.D1 = TRUE)

SET (Q.D1 = TRUE)
     │
     ├── S_R_T.RESET ──→ RESET (Q.D1 = FALSE)
     │
     └── S_R_T.TOGGLE ─→ RESET (Q.D1 = FALSE)

RESET (Q.D1 = FALSE)
     │
     ├── S_R_T.SET ─────→ SET (Q.D1 = TRUE)
     │
     └── S_R_T.TOGGLE ─→ SET (Q.D1 = TRUE)
```

Application Scenarios

- State storage in control applications where Set/Reset/Toggle are already bundled via an ASRT adapter (e.g. from ASRT_CLIENT_0 or ASRT_3EVENTS_TO_SRT)
- Clock and frequency division
- State machines with memory function in fully adapter-based applications



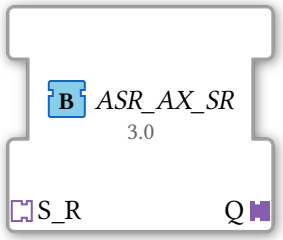
⚖️ Comparison with similar components

Compared to AX_T_FF_SR, the ASRT_AX_T_FF_SR offers the same functionality, but with a single ASRT adapter socket instead of three separate event inputs (S/R/CLK) – allowing it to be connected directly to an ASRT-providing block without wiring the events individually.

Conclusion

The ASRT_AX_T_FF_SR is the adapter-based variant of the proven SR/T flip-flop pattern from AX_T_FF_SR. By bundling Set/Reset/Toggle into a single ASRT socket, it is particularly suited to fully adapter-based control architectures.

ASR_AX_SR



• – ○ • – ○ • – ○ •

Introduction

The ASR_AX_SR is an event-driven bistable function block (flip-flop) that operates according to the set-reset principle. It is used to store a binary state and is controlled via adapter interfaces.

Set/Reset – *ASR*

AX – value of flip flop

Interface Structure

Event Inputs

No direct event inputs are available – control is exclusively via adapters.

Event Outputs

No direct event outputs are available – output is exclusively via adapters.

Data Inputs

No direct data inputs are available.

Data Outputs

No direct data outputs are available.

Adapters

- **S_R (Socket)**: Set/Reset control adapter of type `adapter::types::unidirectional::ASR`
- **Q (Plug)**: Output adapter of type `adapter::types::unidirectional::AX` for the flip-flop state

Functionality

The ASR_AX_SR operates as a set/reset flip-flop with three states:

- **START**: Initial state
- **SET**: Set state (Q = TRUE)
- **RESET**: Reset state (Q = FALSE)

Upon a SET event via the S_R adapter, the block switches to the SET state and sets the output Q to TRUE. Upon a RESET event, it switches to the RESET state and sets Q to FALSE.

Technical Features

- **No Prioritization (Dominance)**: Since setting and resetting are triggered by separate events (`S_R.SET`, `S_R.RESET`), there is no simultaneous dominance as in IEC 61131-3. The state is determined by the last event received ("Last Event Wins").
- **Use of Adapters**: Uses unidirectional adapters for input and output (`ASR` for set/reset, `AX` for output).
- **Implementation**: Implemented as a Basic Function Block with an explicit state machine (ECC).
- **Interface**: No direct inputs/outputs; communication is exclusively adapter-based.

State Transitions

START ⟶ SET: bei S_R.SET Ereignis SET ⟶ RESET: bei S_R.RESET Ereignis RESET ⟶ SET: bei S_R.SET Ereignis

Algorithms

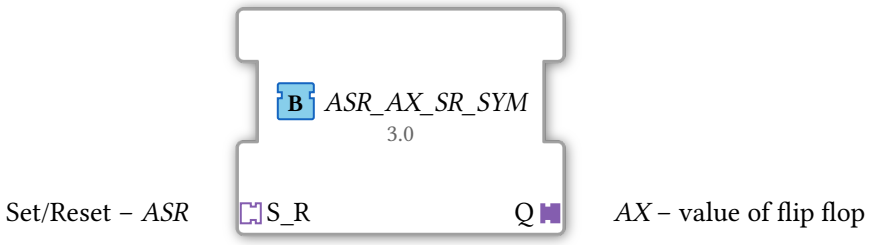
- **SET**: Sets the output value Q.D1 to TRUE
- **RESET**: Sets the output value Q.D1 to FALSE

Application Scenarios

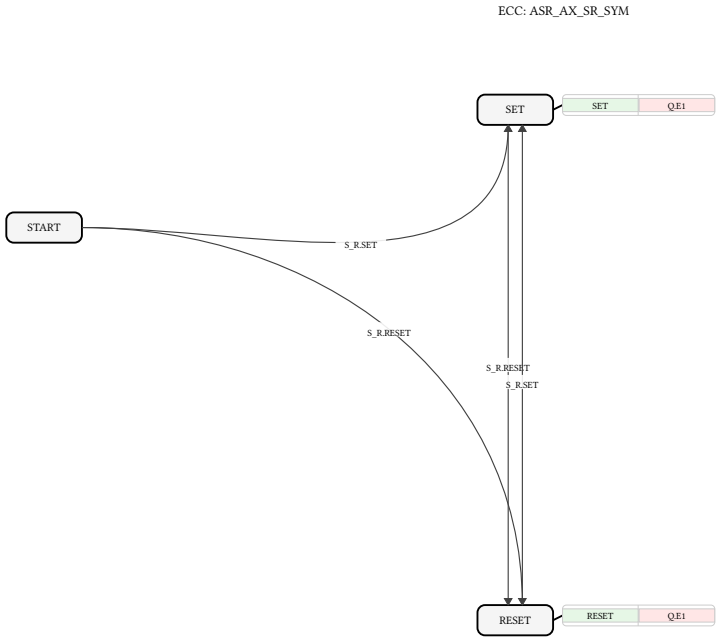
- Storage of switching states in control applications
- State storage in sequential control systems
- Flip-flop functionality in distributed automation systems

⚖️ Comparison with similar components

- **SR (IEC 61131-3)**: The classic SR component has a defined set dominance for simultaneous signals. In contrast, the `ASR_AX_SR` behaves in a time-dependent manner (last event counts).
- **E_SR**: Functionally similar (event-driven), but with direct event pins instead of adapters.
- **Conventional Flip-Flops**: Compared to flip-flops with direct inputs/outputs, the adapter design facilitates integration into modular system architectures.



🛠️ Related Exercises



- Exercise_171_AX

Conclusion

The ASR_AX_SR offers a clean, adapter-based implementation of a bistable memory element, ideally suited for use in modular IEC 61499 systems. The exclusive use of adapters allows for high flexibility in system integration.

ASR_AX_SR_SYM

• – ○ • – ○ • – ○ •

Introduction

The function block **ASR_AX_SR_SYM** implements an event-driven, bistable flip-flop (SR flip-flop) with symmetric start behavior. It is implemented as a Basic FB according to IEC 61499-1 (Annex A) and operates exclusively via adapter interfaces – without direct event or data inputs. The block is suitable for applications where the initial state is determined by the first arriving event and neither input has priority.

Interface Structure

Event Inputs

The FB has no direct event inputs. All events are received via the **socket adapter `S_R`** (type `adapter::types::unidirectional::ASR`). This adapter provides the following event inputs:

- `S_R.SET` – Set event
- `S_R.RESET` – Reset event

Event Outputs

The FB has no direct event outputs. Outgoing events are sent via the **plug adapter `Q`** (type `adapter::types::unidirectional::AX`). This adapter provides the following event output:

- `Q.E1` – Output event, triggered by a state change

Data Inputs

No direct data inputs.

Data Outputs

The output value is provided via the plug adapter `Q`:

- `Q.D1` (BOOL) – current state of the flip-flop (`TRUE` = set, `FALSE` = reset)

Adapter

Name	Type	Direction	Description
`S_R`	`adapter::types::unidirectional::ASR`	Socket	Set/Reset Events (Input)

Q	adapter::types::unidirectional::AX	Plug	State Output (Event + Data)

Functionality

After initialization, the module starts in the **START** state. In this state, it waits for the first arriving event at S_R.SET or S_R.RESET. Depending on which event arrives first, it switches to the **SET** or **RESET** state:

- **SET State**:

The data output Q.D1 is set to TRUE, and the event Q.E1 is triggered.
Upon a subsequent S_R.RESET event, the module transitions to the RESET state.
... - **RESET State**:
The data output Q.D1 is set to FALSE, triggering the event Q.E1.
Upon a subsequent event, S_R.SET, the transition to the SET state occurs.
After the first transition, the function block remains in one of the two stable states until the complementary event occurs. There is no precedence between SET and RESET – the first event at startup determines the initial state.

Technical Features

- **Symmetrical Startup Behavior**: Unlike typical SR flip-flops, neither input has priority. The initial state is determined by the first event.
- **Pure Adapter Interface**: Both events and data are exchanged via IEC 61499 adapters, not via direct input/output ports. This simplifies reuse in complex, adapter-based systems.
- **No explicit event I/O**: The function block (FB) does not have its own event inputs/outputs and instead uses the integrated event ports of the adapters.
- **Compact ST implementation**: The two algorithms SET and RESET simply set the data output and trigger the output event.

State Overview

(Note: A graphical state diagram can be extracted from the ECC XML, but is not embedded here as an image.)

State	Description	Action	Output
START	Initial wait state	–	No output
SET	Stored state “set”	Q.D1 := TRUE	Triggering Q.E1
RESET	Saved state “reset”	Q.D1 := FALSE	Triggering Q.E1

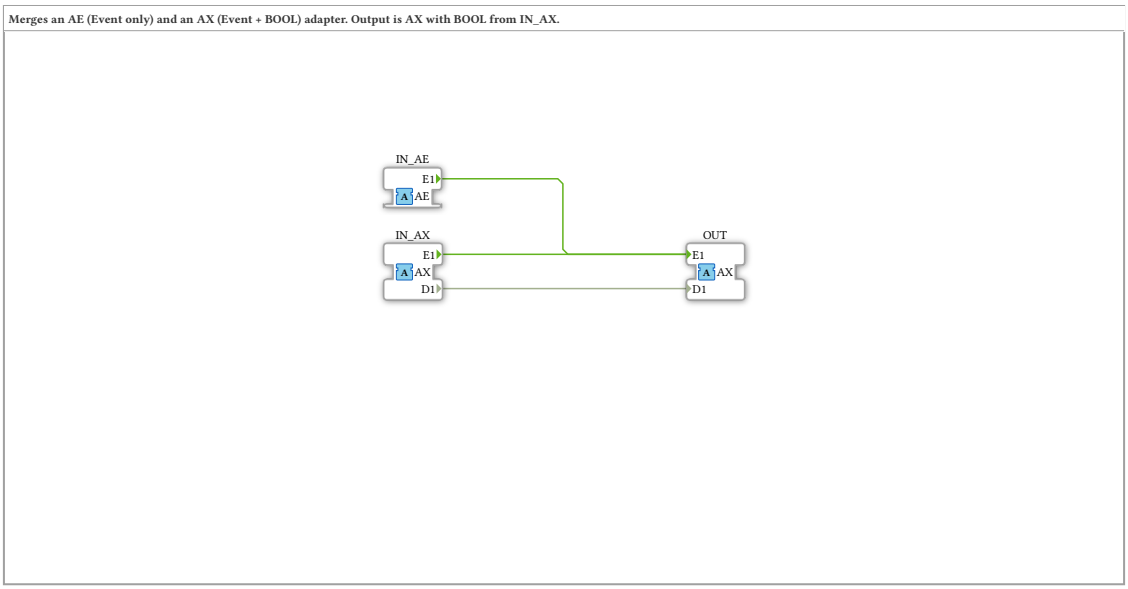
Transitions:

- START ⟶ SET: when S_R.SET arrives
- START ⟶ RESET: when S_R.RESET arrives
- SET ⟶ RESET: when S_R.RESET arrives (after the first set)
- RESET ⟶ SET: when S_R.SET arrives (after the first reset)

Application Scenarios

- **Binary State Memory**: Storing an on/off state controlled by two separate events (e.g., “Start” and “Stop”).
- **Controlling Actuators with Set and Reset Inputs**: Used in controllers where an output needs to be set and reset symmetrically without prioritization.
- **First-Event Initialization**: Systems where the start state is not predefined but determined by the first command (set or reset).

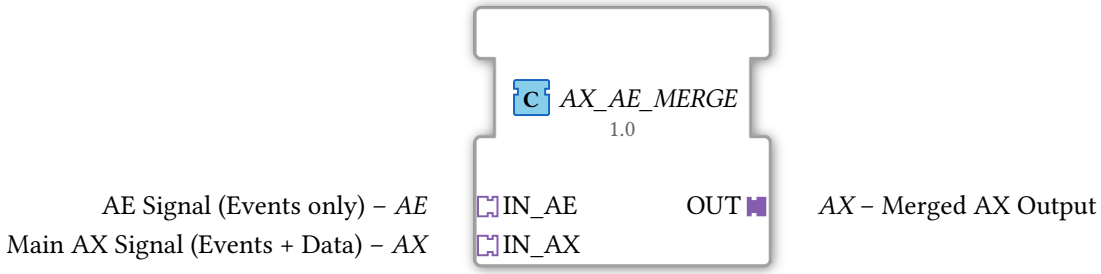
Comparison with Similar Function Blocks



- **Standard SR Flip-Flop (e.g., SR classic)**: Often, one input is dominant (e.g., reset takes precedence). The ASR_AX_SR_SYM treats both inputs equally – at startup, the first event determines the state.
- **RS Flip-Flop with Prioritized Set**: Other implementations prioritize the set input.

This function block is characterized by its symmetrical handling of both events and its exclusive adapter interface, making it flexible for use in adapter-based libraries.

Conclusion



The ASR_AX_SR_SYM function block offers a reliable, event-driven SR flip-flop with symmetric start behavior. Its adapter interfaces allow for seamless integration into IEC 61499 systems, making it particularly suitable for applications requiring equal set/reset control without precedence. Its simple state logic and small number of algorithms make it efficient and easy to understand.

AX_AE_MERGE

Introduction

The AX_AE_MERGE function block allows you to merge a pure event signal (**AE**) with a combined event-data signal (**AX**). The result is an AX signal flow where the data bit from the AX branch is preserved but can be triggered by either source. This is particularly useful when a cyclic event (e.g., from a AE_CYCLE) needs to force a status check or action in an AX-based data stream without modifying the data itself.

Interface Structure

Adapter

- **IN_AX** (Socket): Primary input (event E1 + data D1).
- **IN_AE** (Socket): Additional event input (only event E1).
- **OUT** (Plug): Merged output (event from both inputs, data only from IN_AX).

Functionality

When an event arrives at IN_AX, it is passed to the output along with the current value of D1. When an event arrives at IN_AE, an event is also triggered at the output, with the *last known* value of IN_AX.D1 present at the output.

⚖️ Comparison with similar building blocks

In many exercises (e.g., with the blinker in Uebung_007a3_AX), a AX_OR_2 was incorrectly used to feed a AE event (from AE_CYCLE) into a AX data stream.

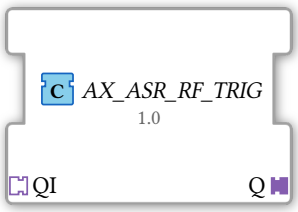
- **AX_OR_2**: Expects two fully functional AX adapters. Connecting an AE adapter is technically incorrect, as the data value for one of the inputs remains undefined.
- **AX_AE_MERGE**: Is designed precisely for this mixed operation. It ensures that the event is passed through while the data source (`IN_AX`) remains uniquely defined.

AX_OR_2: Expects two fully functional AX adapters. Connecting an AE adapter is technically incorrect, as the data value for one of the inputs remains undefined.

Technical Features

✓ **Event Merge**: Internally uses a `E_MERGE`.
✓ **Data Preservation**: No data is modified, only additional triggering occurs.
✓ **Clean Typing**: Prevents the direct connection of dissimilar adapter types.

Application Scenarios



- **Blinker Logic**: A `AE_CYCLE` regularly triggers the transmission of the current state of a `AX_SR` flip-flop.
- **Status Refresh**: A timer regularly triggers the transmission of the current AX state.
- **Multiple Triggering**: An AX signal flow should also be triggered by external AE events (e.g., button clicks).

AX_ASR_RF_TRIG

value to check for a rising or falling edge – *AX*

ASR – Set/Reset Output

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_ASR_RF_TRIG** is used for bidirectional edge detection (rising and falling) of a Boolean input signal. It is designed as an adapter-based envelope of the IEC 61499 standard function block `E_RF_TRIG`. The signal to be monitored is read via two unidirectional adapters, and the result is provided as a set/reset output.

Interface Structure

The function block has **no direct** event or data inputs/outputs. All communication takes place via two adapters.

Event Inputs

- **none**

Event Outputs

- **none**

Data Inputs

- **none**

Data Outputs

- **none**

Adapters

Adapter	Type	Direction	Description
QI	`adapter::types::unidirectional::AX`	Socket	Input adapter – provides the Boolean value to be monitored (via channel `D1`) as well as an event (`E1`) for processing.
Q	`adapter::types::unidirectional::ASR`	Plug	Output adapter – signals the detected edge state via the events `SET` (rising edge) and `RESET` (falling edge).

Functionality

1. An event received at socket **QI** (via `QI.E1`) simultaneously transmits the Boolean value `QI.D1` to the internal `E_RF_TRIG` module.
2. The integrated `E_RF_TRIG` detects a **rising edge** (transition from FALSE to TRUE) and a **falling edge** (transition from TRUE to FALSE).
3. On a rising edge, the internal function block (FB) generates the event `ER`, which is output via the **Q** plug as `Q.SET`.
4. On a falling edge, the internal FB generates the event `EF`, which is output as `Q.RESET`.

Thus, the input signal is converted into a set/reset signal without the user having to deal with the internal event processing.

Technical Features

- **Pure Adapter Interface:** The FB has no direct inputs/outputs in the FB type interface, which enables loose coupling and reusability in different adapter networks.
- **Use of the standard function block `E_RF_TRIG`:** Edge detection is based on the proven IEC 61499 implementation, which reliably detects both rising and falling edges.
- **No state storage outside the internal function block:** All logic is implemented by the embedded `E_RF_TRIG`; the external function block serves solely as encapsulation and adapter adaptation.

State Overview

The function block does **not have its own explicit state machine**. The internal `E_RF_TRIG` operates according to the following implicit state logic:

last value	current value	triggered event
FALSE	TRUE	rising edge (SET)
TRUE	FALSE	Falling Edge (RESET)
else	–	no event

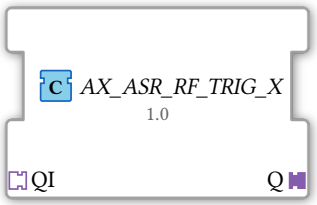
State storage occurs exclusively within the internal function block.

Application Scenarios

- **Button Press Detection:** Monitoring of a button signal; `SET` when pressed, `RESET` when released.
- **Signal Edge Evaluation in Controllers:** Detection of limit exceedances or pulse beginnings/ends.
- **Adapter-Based Sensor Integration:** Integration of sensors with Boolean outputs into an adapter network, e.g., via the AX/ASR adapter family.

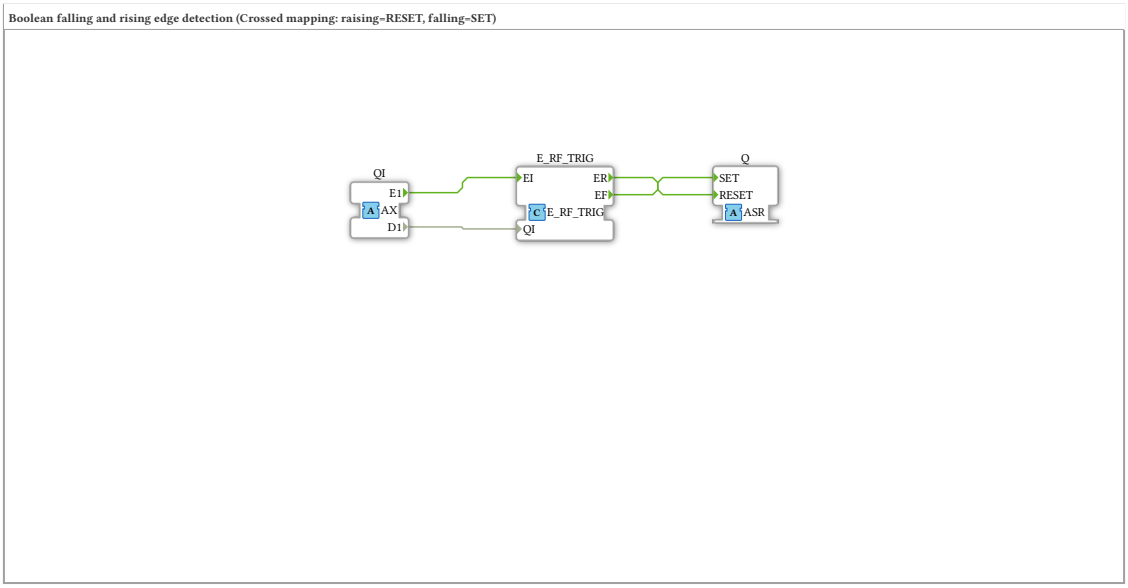
Comparison with Similar Function Blocks

Function Block	Edge Detection	Output Signal	Interface
`E_RF_TRIG`	Ascending + Falling	Separate Event Outputs	Direct Events
`E_TRIG`	Ascending only	One Event	Direct Events
`E_F_TRIG`	Falling only	One Event	Direct Events
AX_ASR_RF_TRIG	Ascending + Falling	Set/Reset Events via Adapter	Pure Adapters



Unlike pure event blocks, this function block offers an adapter interface, enabling simpler connections in hierarchical or typed adapter networks.

Conclusion



The `AX_ASR_RF_TRIG` is a compact, adapter-based edge detector for Boolean signals. It simplifies the use of the standard `E_RF_TRIG` module in adapter-based architectures and directly converts the detected edges into a set/reset signal. Its loose coupling makes it particularly suitable for modular, reusable control applications.

AX_ASR_RF_TRIG_X

value to check for a rising or falling edge – *AX*

ASR – Set/Reset Output

• – ◦ • – ◦ • – ◦ •

The function block **AX_ASR_RF_TRIG_X** detects the rising and falling edges of a Boolean signal. It maps the detected edges to a set/reset output signal using crossed mapping: The rising edge triggers a reset operation, and the falling edge triggers a set operation. The block is implemented as a pure adapter

block and internally uses the standard function block E_RF_TRIG. The function block has no direct event or data inputs/outputs at the interface level. All communication takes place via two specified adapters.

None (Event control is handled via the **QI** adapter)
None (Event output is handled via the **Q** adapter)
None (Data input is handled via the **QI** adapter)
None (Data output is handled via the **Q** adapter)

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

Adapter	Type	Direction	Description
QI	adapter::types::unidirectional::AX	Socket	Receives the Boolean signal to be checked for edges. Contains the event E1 (trigger) and the data word D1 (value).
Q	adapter::types::unidirectional::ASR	Plug	Outputs the set/reset signals. The corresponding actions are signaled via the events SET (falling edge) and RESET (rising edge).

Functionality

An instance of the standard function block E_RF_TRIG is used in the block's FB network. The connections are configured as follows:

- The event input QI.E1 triggers edge detection and is connected to E_RF_TRIG.EI.
- The data value QI.D1 is forwarded to E_RF_TRIG.QI.
- The output event E_RF_TRIG.EF (falling edge) is assigned to the adapter output Q.SET.
- The output event E_RF_TRIG.ER (rising edge) is assigned to the adapter output Q.RESET.

This configuration results in the desired "crossed mapping":

- **Rising edge** at the input value → **RESET** pulse at the output.
- **Falling edge** at the input value → **SET** pulse at the output.
- The function block is implemented entirely as an adapter function block, i.e., It does not have its own event/data interfaces, but communicates exclusively via the defined adapters **QI** and **Q**.
- The inverse assignment of edges (Rising → Reset, Falling → Set) is a special feature compared to the standard use of E_RF_TRIG.
- The implementation follows the IEC 61499-1 specification and uses the adapter::events::unidirectional library.

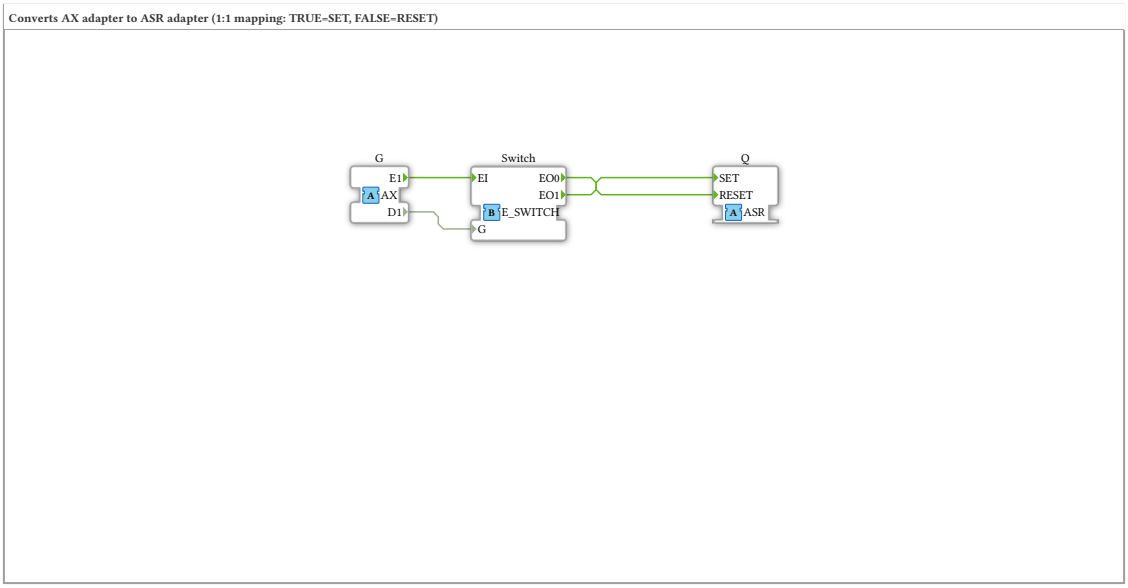
The function block does not have its own state machine. Internal edge detection is performed by the integrated function block E_RF_TRIG, whose state logic (waiting for edge) is responsible for the functionality.

- **Reverse Set/Reset Logic**: In controllers where an active HIGH state is to be reset by a rising edge and set by a falling edge.
- **Simplification of Adapter Chains**: By encapsulating the inverse logic in a separate function block, the network structure becomes clearer.
- **E_RF_TRIG** (IEC 61499 Standard): Provides a rising edge on ER and a falling edge on EF. AX_ASR_RF_TRIG_X inverts this assignment.

- **`E_RS_TRIG`**: Detects only rising edges. This function block detects both edges and assigns them to different outputs.
- **`AX_ASR_TRIG_X`**: Possible alternative variants with different mapping logic differ in their edge-output assignment.

The function block `AX_ASR_RF_TRIG_X` offers specialized edge detection with inverted output assignment. By using adapters, it integrates seamlessly into ad-hoc 61499 communication and enables clear, reusable encapsulation of this logic. It is particularly suitable for scenarios where the standard mapping of `E_RF_TRIG` does not meet the desired behavior.

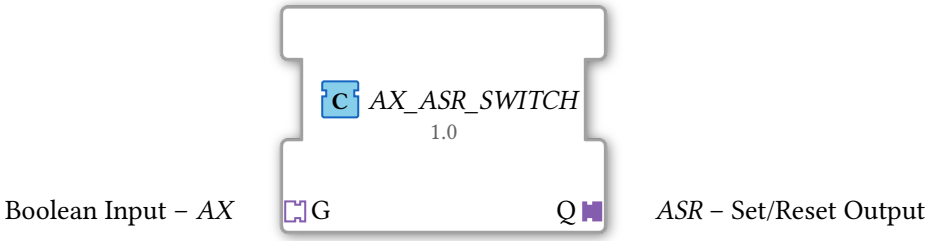
Technical Features



State Overview

Application Scenarios

Comparison with Similar Function Blocks



Conclusion

AX_ASR_SWITCH / AX_ASR_SWITCH_X

Introduction

These function blocks serve as a bridge between the data-oriented AX world and the event-oriented ASR world (Set/Reset). They convert a Boolean signal (encapsulated in an AX adapter) into dedicated `SET` and `RESET` events. Since the direction of the events (which sets the state, which clears it) is hard-coded in the adapter, two variants are available.

Variants

AX_ASR_SWITCH (1:1)

- Input `G = TRUE` (1) ➜ Output `SET`

- Input `G = FALSE` (0) ➜ Output `RESET`

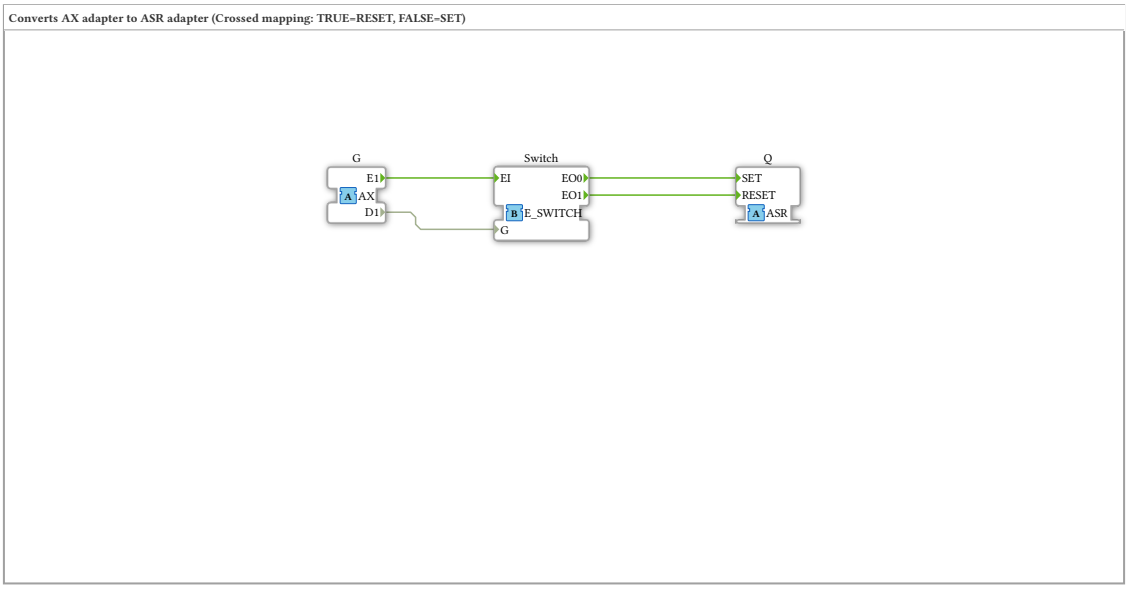
AX_ASR_SWITCH_X (Crossed)

- Input `G = TRUE` (1) ➜ Output `RESET`
- Input `G = FALSE` (0) ➜ Output `SET`

Interface Structure

Adapter

- **G** (Socket): Input adapter type `AX`.
- **Q** (Plug): Output adapter type `ASR`.

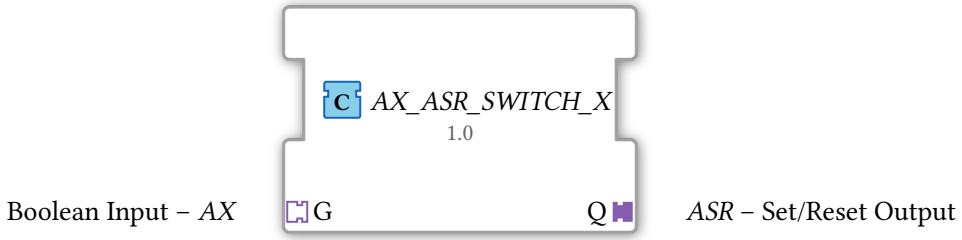


Functionality

The modules internally use a `E_SWITCH`. Each time an event (`E1`) arrives at the input adapter `G`, the current data value (`D1`) is checked, and the corresponding event (`SET` or `RESET`) is triggered at the output adapter `Q`.

Application Scenarios

- Controlling bistable components (flip-flops) with a `ASR` input directly from a `AX` signal flow.
- Simplifying logic circuits where events need to be generated based on a static signal state.



AX_ASR_SWITCH_X

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_ASR_SWITCH_X** is a composite function block responsible for converting between two different adapter types. It converts signals from an **AX** adapter (Boolean Event) into signals from an **ASR** adapter (Asynchronous Set/Reset). The special feature of this function block is the **"Crossed Mapping"** indicated by the suffix "X" and the comment. Unlike a standard mapping, this function block inverts the logic: A `TRUE` signal at the input results in a `RESET` event at the output, while a `FALSE` signal triggers a `SET` event.

Interface Structure

The function block interacts primarily via adapter interfaces.

Event Inputs

This function block does not have direct event inputs in the interface list, as these are encapsulated within the adapter `G`.

Event Outputs

This function block does not have direct event outputs in the interface list, as these are encapsulated within the adapter `Q`.

Data Inputs

This function block does not have direct data inputs in the interface list, as these are encapsulated within the adapter `G`.

Data Outputs

This function block does not have direct data outputs.

Adapter

Name	Type	Component	Comment
G	`adapter::types::unidirectional::AX`	Socket (Input)	Boolean input adapter (contains event `E1` and data `D1`).
Q	`adapter::types::unidirectional::ASR`	Plug (Output)	Set/Reset output adapter (contains events `SET` and `RESET`).

Functionality

The **AX_ASR_SWITCH_X** internally uses a standard `E_SWITCH` block (`iec61499::events::E_SWITCH`) to execute the logic. The circuit is configured as follows:

1. An event at input adapter **G** (event `E1`) triggers processing.
2. The data value from input adapter **G** (data `D1`) is evaluated.
3. **Logic Inversion (Crossed Mapping):**

- If **G.D1** = **TRUE**: The internal switch forwards the event to its output `EO1`. This output is connected to **Q.RESET**.
- If **G.D1** = **FALSE**: The internal switch forwards the event to its output `EO0`. This output is connected to **Q.SET**.
- In summary:
- Input `TRUE` → Output `RESET`
- Input `FALSE` → Output `SET`

Technical Features

- **Adapter Conversion:** Bridge between the simple Boolean event world (AX) and the set/reset control logic (ASR).
- **Inverted Logic:** This block is specifically designed for applications where an active signal (`TRUE`) should trigger a reset or deactivation (`RESET`), and an inactive signal (`FALSE`) should trigger an activation (`SET`) – or vice versa, depending on the interpretation of the connected systems.

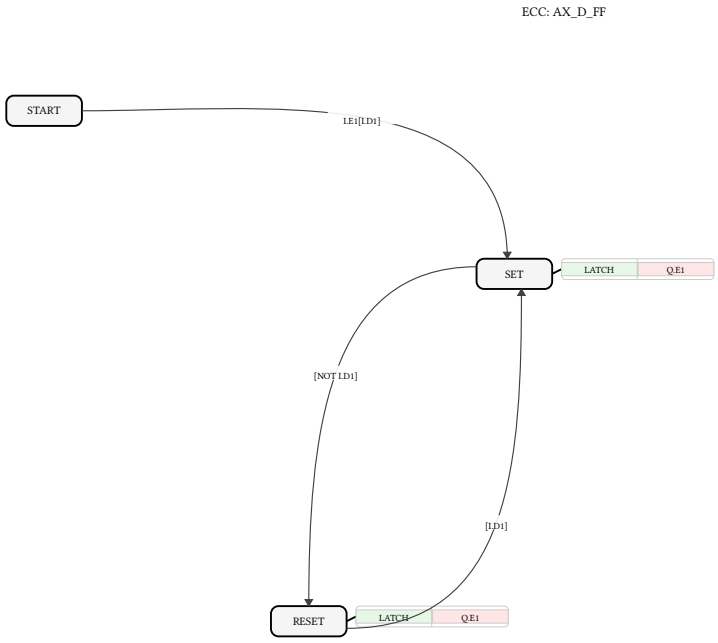
State Overview

Since this is a Composite Function Block without its own state machine (ECC), its behavior is defined solely by signal passthrough.

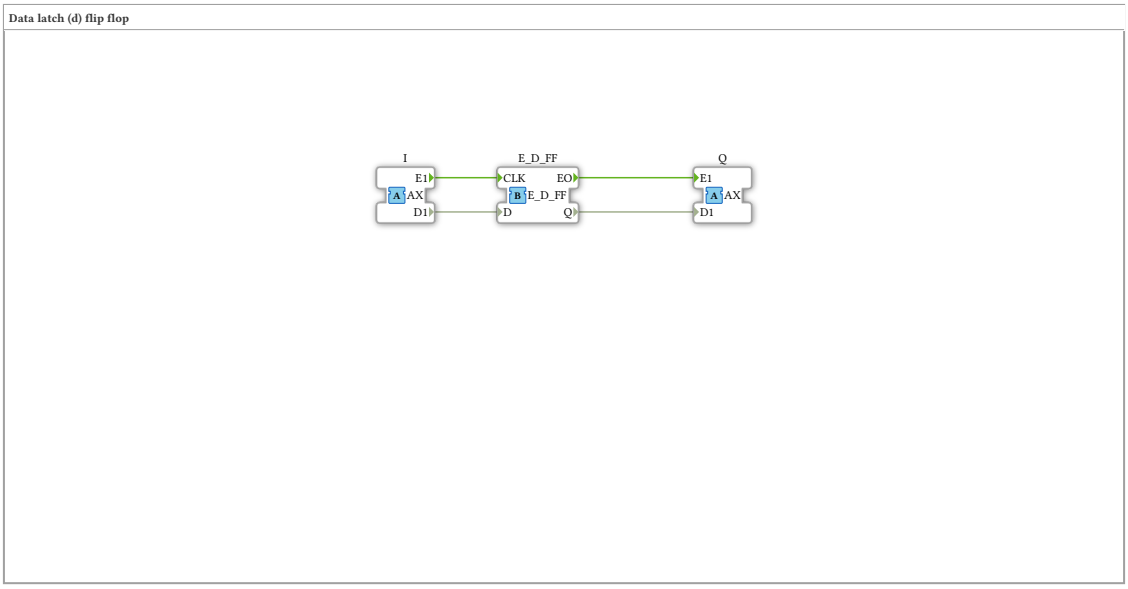
Input G (D1) on Event G (E1)	Triggered Event at Q	Logical Meaning
TRUE	**RESET**	Reset / Stop
FALSE	**SET**	Set / Start

Application Scenarios

- **Fail-Safe Logic:** In systems where an active signal (High/True) represents the "normal state" or "idle state" (Reset), and the absence of the signal (Low/False) should trigger an action (Set) (wire break safety).
- **Logic Inversion:** Adapting sensors that output "Active High" to actuators or control modules that expect "Active Low" (or reset on high).
- **Specific Protocol Adaptation:** When a subsystem communicates via an AX adapter, but the receiving subsystem requires an ASR adapter with inverted polarity.



⚖️ Comparison with Similar Modules

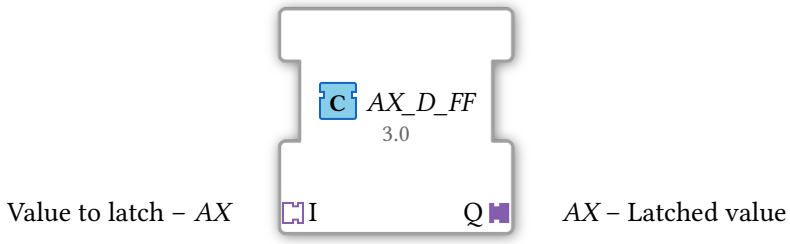


- **AX_ASR_SWITCH (hypothetical/standard):** A standard converter would typically map `TRUE` to `SET` and `FALSE` to `RESET`. The `_X` module described here is the exact opposite.
- **AX_ASR_SWITCH (hypothetical/standard):** * **E_SWITCH:** The underlying IEC 61499 standard function block, which handles the actual switching of events based on a Boolean value, but without the encapsulation in an adapter.

Conclusion

The **AX_ASR_SWITCH_X** is a specialized adapter converter that performs a logical inversion ("crossed mapping") between an AX input and an ASR output. It is essential for system integrations where the signal polarity between source and sink needs to be reversed without placing additional discrete logic devices in the main network.

AX_D_FF



• – ○ • – ○ • – ○ •

Introduction

The AX_D_FF is a data latch flip-flop that serves as a basic building block in digital circuitry. It is a D-type flip-flop that stores the applied data value and outputs it upon certain events.

Interface Structure

Event Inputs

- No direct event inputs available

Event Outputs

- No direct event outputs available

Data Inputs

- No direct data inputs available

Data Outputs

- No direct data outputs available

Adapters

- **I** (Socket): Input adapter of type `adapter::types::unidirectional::AX` - Receives the value to be stored
- **Q** (Plug): Output adapter of type `adapter::types::unidirectional::AX` - Outputs the stored value

Functionality

The AX_D_FF operates as a D-latch flip-flop with three states:

- **START**: Initial state
- **SET**: Stores the input value and outputs it
- **RESET**: Sets the output Back

The LATCH algorithm copies the input value `I.D1` to the output `Q.D1`. The state transitions are controlled by the value of `I.D1`.

Technical Features

- Uses unidirectional adapters for inputs and outputs
- Implemented as a Basic Function Block according to IEC 61499
- Features simple latch functionality without clocking

State Overview

1. **START → SET**: Upon arrival of `I.E1` with `I.D1 = TRUE`
2. **SET → RESET**: When `I.D1 = FALSE`
3. **RESET → SET**: When `I.D1 = TRUE`

Application Scenarios

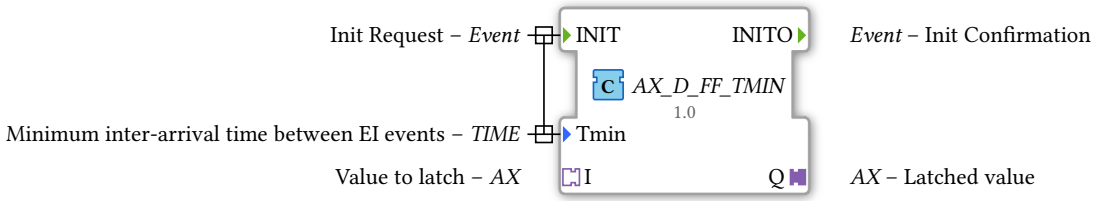
- Data storage in control systems
- State storage in sequential processes
- Signal delay and buffering
- As a basic building block for more complex flip-flop circuits

⚖️ Comparison with similar components

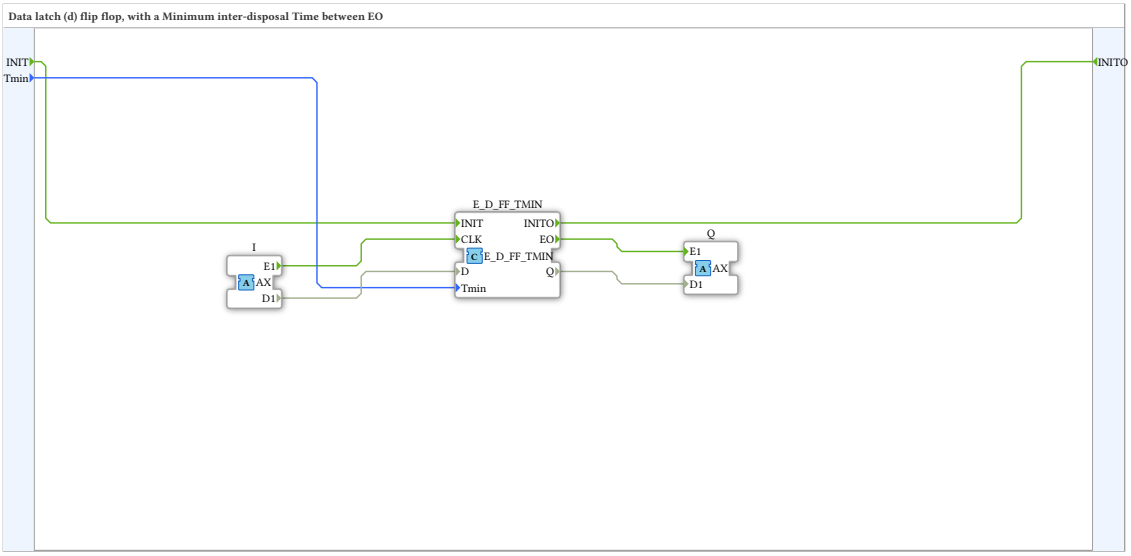
Compared to clocked D flip-flops, the AX_D_FF is asynchronous and saves the value immediately upon a change in the input conditions. It is a level-triggered element rather than an edge-triggered one.
Compare with E_D_FF

🛠️ Related Exercises

- Exercise_170_AX



Conclusion



The AX_D_FF offers a simple and effective solution for basic data storage tasks in 4diac control systems. Its clear state logic and the use of standardized adapters make it a reliable component for various use cases.

AX_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_D_FF_TMIN** implements a data-latch D flip-flop that additionally enforces a minimum time between successive event outputs (e.g., EO). It serves as a modular wrapper around the IEC 61499 standard function block `E_D_FF_TMIN` and uses a unidirectional adapter (`adapter::types::unidirectional::AX`) for event-driven data transfer. This function block is particularly suitable for applications requiring reliable data transfer with an adjustable minimum interval between output pulses.

Interface Structure

Event Inputs

Event	Type	Description
`INIT`	EInit	Initialization request; sets the minimum delay time (parameter `Tmin`).

Event Outputs

Event	Type	Description
`INITO`	EInit	Confirmation of successful initialization.

Data Inputs

Name	Type	Description
`Tmin`	TIME	Minimum inter-disposal time between two consecutive events at output `EO`. The value is only adopted upon a `INIT` event.

Data Outputs

This function block has no direct data outputs; the latching data value is provided via the adapter `Q`.

Adapters

Role	Name	Type	Description
Socket	`I`	adapter::types::unidirectional::AX	Input adapter; Provides the data word to be latched (`D1`) and the clock event (`E1`).

Plug	Q	adapter::types::unidirectional::AX	Output adapter; provides the latching data word (D1) and the output event (E1).

The adapters AX are unidirectional: They transmit exactly one event and one associated data value.

Functionality

The function block encapsulates the internal function block E_D_FF_TMIN, which operates as follows:

1. **Initialization**: When a INIT event is received, the current time Tmin is stored as the minimum lock time for the output E0. The function block acknowledges this with INITO.
2. **Clocking (D Flip-Flop)**:

- An event at socket I.E1 is forwarded as a clock signal (CLK) to the internal flip-flop.
- Simultaneously, the data value I.D1 is adopted as the new input value D.
- On each rising edge of the clock (here: each E1 event), the current data value D is acquired and made available at output Q.
- After acquisition, an output event E0 is generated at plug Q.E1 – but only after the minimum lock time since the last E0 has elapsed. This ensures that output pulses do not follow each other faster than specified by Tmin.

1. **Output**: The latching data value appears at plug Q.D1, and the corresponding event at plug Q.E1.

Technical Features

- **Minimum Interval Time**: The function block enforces an adjustable minimum time (Tmin) between two output events. If the clock signal frequency exceeds this time, individual clock events are suppressed so that the output does not exceed a maximum permissible event sequence.
- **Adapter Interface**: By using the unidirectional adapter AX, loose coupling between transmitter and receiver is achieved. The adapter transports both the event and the data value in a single logical unit.
- **Initialization Dependency**: The minimum time Tmin is set only once at INIT and remains constant until the next INIT. Changes during operation are not permitted.

State Overview

The function block does not have an explicit state machine. The internal logic of the embedded E_D_FF_TMIN can assume the following states:

- **Idle**: Waiting for a INIT or a clock event.
- **Initialized**: Tmin has been acquired; the function block is ready for operation.
- **Lockout Time Active**: After an output event, the delay defined by Tmin is applied; incoming clock events are ignored.
- **Ready**: After the lockout time has expired, the next clock event can trigger a new output event.

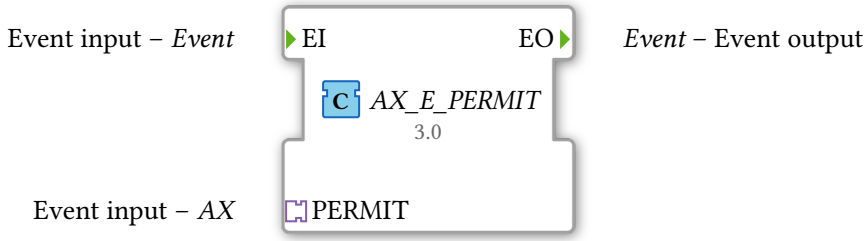
Application Scenarios

- **Buffered Sensor Values**: A sensor delivers data at an irregular rate. The AX_D_FF_TMIN acquires the last valid value and passes it on to a subsequent controller with a maximum permissible output frequency.
- **Signal Debouncing**: Mechanical pushbuttons or switches generate bounce pulses. The minimal delay suppresses excessively rapid state changes.
- **Data Forwarding with Bandwidth Limiting**: In communication networks, this component can be used to limit the output rate of a data channel without requiring adaptation of the sender.

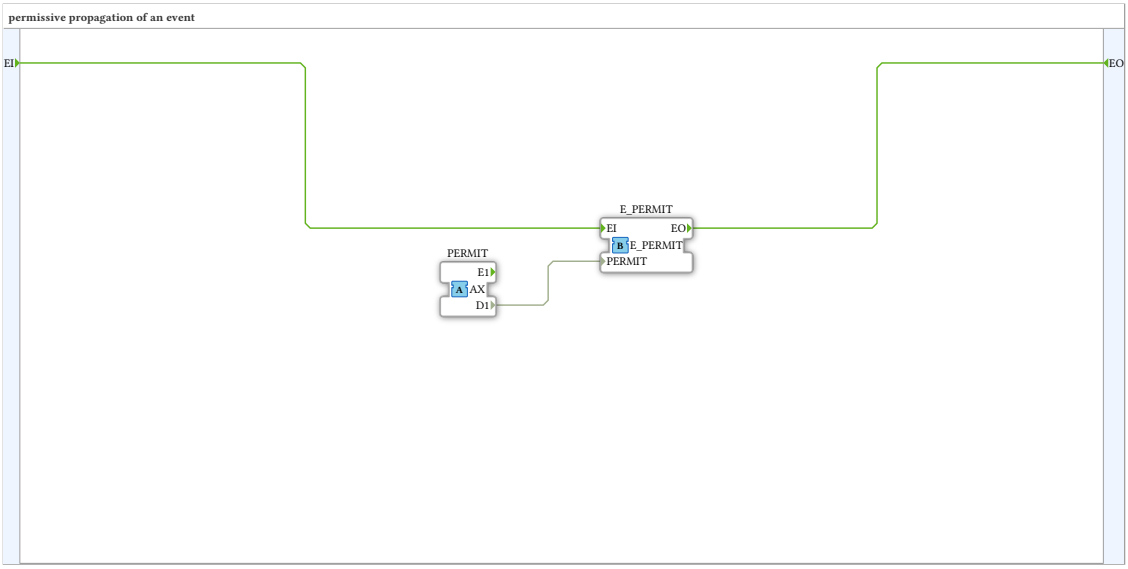
Comparison with Similar Components

Component	Difference
E_D_FF (Standard D Flip-Flop)	No time limit on output pulses; events are forwarded immediately.
AX_D_FF_TMIN (present)	Inserts the minimum interval Tmin between output events, implemented via the built-in E_D_FF_TMIN.
E_CTD / E_CTU (counter)	Count events; do not offer data transfer or latching functionality.

The AX_D_FF_TMIN combines the latching data transfer of a flip-flop with the time-based filtering of a monostable multivibrator, but is implemented as a pure event-to-data adapter.



Conclusion



The **AX_D_FF_TMIN** is a specialized function block for applications that require clocked data transfer with a guaranteed minimum time between output events. The encapsulation of the standard function block `E_D_FF_TMIN` and the adapter interface facilitate integration into modular 4diac projects. The function block offers a clean separation of initialization and dynamic operation and is particularly suitable for time-critical, event-driven systems.

AX_E_PERMIT

• – ○ • – ○ • – ○ •

Introduction

The **AX_E_PERMIT** function block implements conditional event propagation (permissive propagation). An incoming event is only forwarded to the output if a permit signal provided via an adapter has the value `TRUE`. The function block acts as a gate that can interrupt or enable the processing chain depending on external conditions.

Interface Structure

Event Inputs

Name	Type	Comment
EI	Event	Event Input

Event Outputs

Name	Type	Comment
EO	Event	Event Output

Data Inputs

This function block has no data inputs of its own. The enable signal is provided via an adapter.

Data Outputs

This function block has no data outputs.

Adapter

Role	Name	Type	Comment
Socket	PERMIT	`adapter::types::unidirectional::AX`	Provides the enable signal (D1)

The adapter is unidirectional and provides a Boolean value (`D1`) that controls the behavior of the event gate.

Functionality

The function block internally contains a standard function block `E_PERMIT` from the IEC 61499 library. The incoming event `EI` is directly forwarded to the internal input `E_PERMIT`. Its output `EO` is only active if the corresponding enable input (`PERMIT` of the internal block) assumes the value `TRUE`. This enable signal is fed from the adapter `PERMIT` via the connection `PERMIT.D1`.

Therefore:

- **Permit = TRUE:** The event `EI` is passed on to `EO` without delay.
- **Permit = FALSE:** The event is suppressed; `EO` remains inactive.

Technical Features

- **Adapter-Based Interface:** The enable signal is not provided as a classic data input, but via an adapter (`AX`, unidirectional). This enables modular coupling and reuse of the enable logic.
- **No Data Forwarding:** The function block itself does not output any data. It serves solely to control the event flow.
- **Unidirectional Adapter:** The adapter provides only one data value (D1) to the function block; feedback is not provided.
- **Use of a Standard Block:** Internally, the proven `E_PERMIT` block is used, which implements the actual enable logic.

State Overview

The block itself has no visible states. Its internal behavior is determined by the `E_PERMIT` block, which essentially represents a passive wait loop:

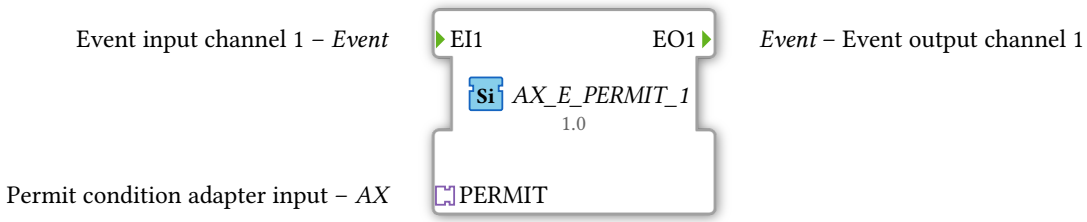
- **Waiting for Event:** The block waits for an event at input `EI`.
- **Permit Check:** Upon arrival of an event, the state of the enable signal is evaluated.
- **Forwarding:** The event is only output to `EO` if `PERMIT = TRUE` is present.

There is no explicit state machine; the block operates purely combinatorially at the event level.

Application Scenarios

- **Safety Interlock:** An event (e.g., machine start) is only forwarded if an external safety circuit provides a release signal.
- **Conditional Processing:** In a production control system, data from sensors can only be sent to the higher-level controller when the operating mode is activated.
- **Test and Simulation Environments:** An event can be selectively enabled or disabled via a manual release signal to test specific scenarios.
- **Resource Conservation:** In a complex automation system, unnecessary events can be suppressed by disabling the permit to reduce bus load.

Comparison with Similar Blocks



Block	Special Feature
E_PERMIT	Standard block with direct Boolean input. No adapter required.
AX_E_PERMIT	Same logic, but the enable signal is provided via a unidirectional adapter, which facilitates coupling across subsystems.
E_SR (Set-Reset)	Event-based state storage; not directly suitable as a gate.
E_MUX	Event switch that toggles between two outputs depending on a data input – not a pure blocking function.

The advantage of `AX_E_PERMIT` lies in the clean separation of the enable logic by an adapter, which promotes the reuse of control modules.

Conclusion

The `AX_E_PERMIT` function block represents a flexible and modular solution for conditional event forwarding. By using an adapter for the enable signal, the interface is clearly defined and can be used across hierarchical boundaries. The block is particularly suitable for safety-critical or configurable control applications where event processing depends on external conditions.

AX_E_PERMIT_1

• – ◦ • – ◦ • – ◦ •

Introduction

AX_E_PERMIT_1 is a compact event gating function block that propagates a single event channel only when a permit condition is satisfied. Instead of using a direct Boolean data input, the permit condition is provided through a unidirectional adapter socket named `PERMIT`. This makes the block suitable for modular automation solutions in which permission logic is separated from the event consumer.

The block follows the IEC 61499-1 model and is declared as a generic function block type. It has one event input, one event output, and no dedicated data inputs or data outputs. All condition information is received through the adapter interface.

Interface Structure

Event Inputs

Name	Type	Comment
`EI1`	Event	Event input channel 1

Event Outputs

Name	Type	Comment
`EO1`	Event	Event output channel 1

Data Inputs

There are no data inputs.

Data Outputs

There are no data outputs.

Adapters

Direction	Name	Type	Comment
Socket	PERMIT	adapter::types::unidirectional::AX	Permit condition adapter input

The block contains a single adapter socket. The connected adapter supplies the permit or enable condition used to decide whether an incoming event is forwarded.

Functionality

AX_E_PERMIT_1 acts as a permissive event gate.

When an event arrives at EI1, the block evaluates the condition received through the PERMIT adapter socket. If the condition is active, the event is immediately propagated to EO1. If the condition is not active, the event is suppressed and no output event is generated.

The adapter is unidirectional, meaning that the condition data flows from the connected adapter into the socket. The block itself does not send data or events back through the adapter. This keeps the permission source decoupled from the event handling logic.

Because the block has no data inputs, the adapter connection replaces the conventional PERMIT Boolean input that would otherwise be needed. This allows a permission signal to come from a reusable adapter-based logic component without adding explicit data wires to the function block network.

Technical Features

- Single-channel event permit gating.
- Adapter-based condition input using adapter::types::unidirectional::AX.
- No direct data inputs or data outputs.
- Suitable for generic use through the declared generic class name GEN_AX_E_PERMIT.
- Compact interface with only one event input, one event output, and one adapter socket.
- Compatible with IEC 61499-1 Annex A type identification.
- The logic structure makes the block easy to reuse in different permission and interlock scenarios.

State Overview

The function block type does not define an explicit state machine. From the IEC 61499 point of view, the block behaves as a stateless event gate.

Conceptually, the following behavior can be expected:

Condition	Behavior
Event arrives at EI1 and permit is active	EO1 is triggered
Event arrives at EI1 and permit is inactive	The event is ignored
No event arrives at EI1	No output event is generated

Since no internal state is stored between events, the block returns to its idle condition after each event processing step.

Application Scenarios

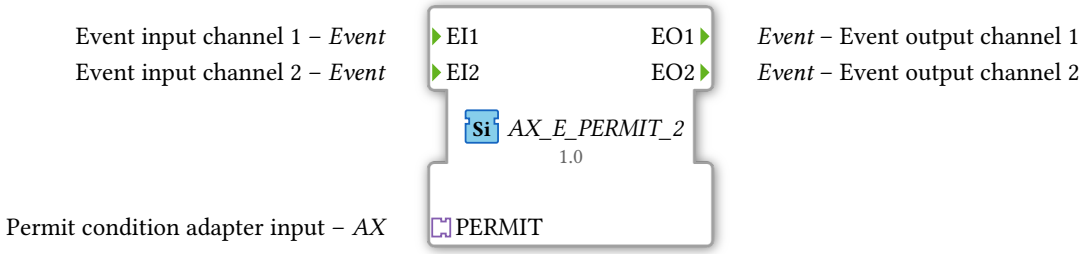
AX_E_PERMIT_1 is useful wherever an event must be allowed or blocked by an external condition. Typical scenarios include:

- Machine start commands that are only allowed when a safety permission is present.
- Event propagation controlled by an operating mode selector.
- Interlock logic where a process event must be suppressed until a precondition is fulfilled.
- Modular automation architectures where permission signals are provided by reusable adapter blocks.
- Communication between independent control modules that share a common enable condition through an adapter network.

The adapter-based design is particularly helpful when the same permission source must be connected to multiple event consumers without creating complex data wiring.

Comparison with Similar Blocks

Block or Approach	Characteristics	Difference



`E_PERMIT` with Boolean input	Uses a direct `PERMIT` data input	Simpler wiring, but permission source must be connected through an explicit Boolean data connection
`E_SWITCH`	Routes an event to one of several outputs based on a selector input	Performs selection, not simple pass/block behavior
`E_SPLIT`	Forwards one event to multiple outputs	Does not apply a permission condition
Generic adapter-based gate	Uses an adapter socket for the enable condition	More modular and reusable, but requires a compatible adapter connection

Compared with a direct Boolean implementation, AX_E_PERMIT_1 trades a small amount of wiring simplicity for a much cleaner and more modular interface. The adapter connection allows the permission logic to be encapsulated, reused, and independently maintained.

Conclusion

AX_E_PERMIT_1 is a focused and reusable event gating block. Its adapter-based permit interface makes it well suited for modular automation systems where conditions are managed through adapter connections rather than plain data signals. With one event input, one event output, and one adapter socket, it provides a simple way to implement permissive event propagation while keeping the overall function block structure clear and maintainable.

AX_E_PERMIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_E_PERMIT_2 is a generic function block designed to propagate events from two independent input channels to corresponding output channels, but only when a permit condition is satisfied. The permit condition is provided externally via a unidirectional adapter of type `AX`. This block is useful for gating event flows based on dynamic or configurable criteria without hardcoding the logic inside the FB itself.

Interface Structure

The block has no data inputs or outputs; it operates purely on event signals and an adapter-based condition input.

Event Inputs

Event	Description
`EI1`	Event input channel 1
`EI2`	Event input channel 2

Event Outputs

Event	Description

`EO1`	Event output channel 1
`EO2`	Event output channel 2

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter	Type	Description
`PERMIT`	`adapter::types::unidirectional::AX`	Unidirectional adapter providing the permit condition for both event channels.

Functionality

The AX_E_PERMIT_2 acts as a dual-channel event gate. When an event occurs on `EI1` or `EI2`, the block checks the current condition presented by the `PERMIT` adapter. If the condition evaluates to *permit* (i.e., the adapter indicates that events are allowed), the corresponding event is emitted on `EO1` or `EO2`, respectively. If the condition is not satisfied, the event is suppressed and no output is triggered.

The block is generic; the actual permit logic is implemented by the connected adapter instance. This allows the same FB to be reused in different contexts with different permit rules (e.g., based on sensor values, system state, or user-defined logic).

Technical Features

- **Generic Design**: The FB is parameterized via the adapter type, enabling reusability across various permit scenarios.
- **Two Independent Channels**: EI1/EO1 and EI2/EO2 operate independently, each gated by the same adapter condition. This is useful for coordinating multiple event streams under a single permit criterion.
- **No Internal State**: The FB is stateless; it does not store information between event occurrences. It simply passes events through when permitted.
- **Unidirectional Adapter**: The `PERMIT` adapter is unidirectional, meaning the FB reads a value from the adapter without sending data back to the providing block.
- **Event Semantics**: All inputs and outputs are pure event signals, making this block suitable for event-driven control logic.

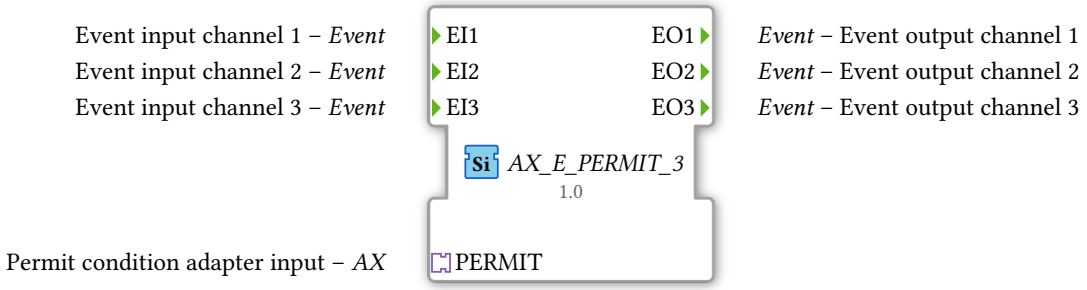
State Overview

The FB maintains no internal state. Its behavior is deterministic and based solely on the current event input and the instantaneous value of the permit adapter. The block can be considered a combinatorial gate in the event domain.

Application Scenarios

- **Safety Interlocking**: Allow event propagation only when a safety condition (e.g., machine guard closed) is met.
- **Mode-Dependent Operation**: Enable event flows only in certain operating modes of a system (e.g., automatic vs. manual).
- **Load Shedding**: Permit events only when system load is below a threshold.
- **Conditional Logging or Monitoring**: Forward events to a monitoring subsystem only when a specific state is active.

Comparison with Similar Blocks



- **Direct Event Propagation (e.g., E_REND)**: Without a permit mechanism, events are always forwarded. AX_E_PERMIT_2 adds a gating condition.
- **Two Separate SINGLE-CHANNEL Permit Blocks**: Using two individual permit blocks would require duplicating the condition logic and potentially cause inconsistent states. AX_E_PERMIT_2 uses a single adapter for both channels, simplifying the design.

- **Event Combination Blocks (e.g., E_MERGE)**: These combine events but do not provide conditional filtering; AX_E_PERMIT_2 filters each channel independently.

Conclusion

The AX_E_PERMIT_2 is a flexible, generic function block that efficiently manages event propagation under a shared permit condition. Its dual-channel structure, combined with an external adapter, makes it a valuable component for building event-driven control systems that require conditional gating. The stateless design ensures predictable behavior and easy integration into larger IEC 61499 orchestration.

AX_E_PERMIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The **AX_E_PERMIT_3** is a generic function block (FB) designed for permissive propagation of three independent event channels. It acts as a gate that forwards each incoming event to its corresponding output only when a global enable condition is satisfied. The enable condition is provided via an adapter interface, making the block highly reusable in various control scenarios where event flow must be conditionally allowed.

This FB is part of the unidirectional event adapter family, specifically tailored for applications that require a single permission signal to control multiple event streams. It is defined as a generic FB, meaning its behavior can be instantiated and customized through type attributes.

Interface Structure

The interface consists of three event input channels, three matching event output channels, and one adapter socket for the permission signal. There are no data inputs or outputs.

Event Inputs

Name	Data Type	Description
EI1	Event	Event input channel 1 – triggers propagation to EO1 if permitted.
EI2	Event	Event input channel 2 – triggers propagation to EO2 if permitted.
EI3	Event	Event input channel 3 – triggers propagation to EO3 if permitted.

Event Outputs

Name	Data Type	Description
EO1	Event	Event output channel 1 – emits an event when EI1 occurs and permission is granted.
EO2	Event	Event output channel 2 – emits an event when EI2 occurs and permission is granted.
EO3	Event	Event output channel 3 – emits an event when EI3 occurs and permission is granted.

Data Inputs

None.

Data Outputs

None.

Adapters

Type	Role	Name	Description
adapter::types::unidirectional::AX	Socket	PERMIT	Provides a unidirectional permission signal. The adapter must be connected to a compatible plug that supplies an enable/disable condition. The exact semantics (e.g., boolean value) depend on the specific adapter implementation.

Functionality

The FB implements a simple gating mechanism for three independent event streams. When an event arrives on any of the input channels (EI1, EI2, or EI3), the FB checks the current state of the **PERMIT** adapter. If the permission condition is **true** (or "allowed"), the corresponding output event (EO1, EO2, or EO3 respectively) is emitted. If the permission condition is **false**, the event is discarded and no output event occurs.

The propagation is **not mutually exclusive**: each channel operates independently, and the permission check is identical for all three channels at any given moment. This means that a single permission signal can simultaneously enable or disable all three event paths.

Since the FB has no data inputs or outputs, the permission condition is entirely derived from the adapter. The adapter is expected to provide a boolean-like signal, but the exact representation is defined by the underlying adapter type (in this case, `unidirectional::AX`).

The block is **stateless** in the sense that it does not maintain any internal memory; the decision to forward an event is made at the moment the event occurs based solely on the current adapter value.

Technical Features

- **Generic Implementation**: The FB is marked with the attribute `eclipse4diac::core::GenericClassName = 'GEN_AX_E_PERMIT'`, indicating that it serves as a generic template. This allows the system to instantiate a specialized version of the block for specific adapter definitions via type generation mechanisms.
- **Three-Channel Design**: Supports exactly three event input/output pairs, making it suitable for applications with three parallel event streams.
- **Unidirectional Adapter**: Uses a socket adapter of type `unidirectional::AX`, which is a unidirectional connection. This ensures a clear data flow direction for the permission signal.
- **No Data Interface**: Simplifies usage by eliminating data handling; only event flow control is performed.
- **Direct Event Mapping**: Each input event is mapped one-to-one to its output event with identical naming conventions (EI1→EO1, EI2→EO2, EI3→EO3), simplifying wiring and readability.

State Overview

The FB does not implement an explicit state machine. It operates **combinatorially** with respect to events: each event is processed independently and immediately. There is no history or internal state that could affect subsequent events. The block can be considered as a pure function: given an event on an input and a current permission value, it either emits an output event or does nothing.

In practice, the only "state" is the value of the adapter signal, which is external to the FB.

Application Scenarios

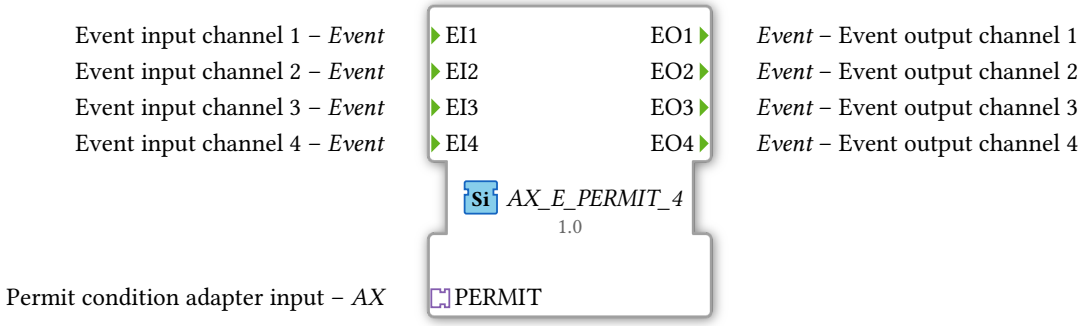
- **Safety Interlocks**: Use a single safety relay or enable signal to block or allow multiple control commands (e.g., start/stop/emergency) simultaneously.
- **Mode Selection**: In machinery, a mode selector can enable or disable a set of event-driven actions (e.g., automatic, manual, maintenance modes).
- **Conditional Data Flow**: When three independent event sources must only be forwarded when a master condition holds (e.g., a supervisory system grants permission).

- **Event Gating in Distributed Systems**: In IEC 61499 based applications, this FB can be used to gate events between function blocks without complex logic, relying on an adapter to provide the permission.
- **Test and Simulation**: The block can be used to simulate an enable/disable switch for a group of event paths in a model.

Comparison with Similar Blocks

Given the generic nature of the FB, several similar blocks exist, often differing in the number of channels or the type of permission signal:

- **AX_E_PERMIT_1** / **AX_E_PERMIT_2** (if they exist): Single- or two-channel versions, where the same permission is applied to fewer event streams. The three-channel version provides a balance between simplicity and parallelism.
- **AX_E_GATE** (generic): May implement a more complex gating logic, possibly with per-channel enable signals instead of a single global permission.
- **AX_E_SELECT** (if available): Might route events to different outputs based on a condition, rather than simply allowing or blocking them.
- **Adapter-Based vs. Data-Based Gating**: Compared to a block with a boolean data input (e.g., `E_PERMIT`), using an adapter decouples the permission source from the FB itself, enabling reuse in different contexts without changing the FB's interface. This makes the adapter-based approach more flexible and modular.



The key differentiator of **AX_E_PERMIT_3** is its **explicit adapter interface** and its **fixed number of three independent channels**, which suits mid-complexity event management tasks.

Conclusion

The **AX_E_PERMIT_3** function block provides a clean, deterministic solution for conditionally propagating three independent event streams under a single permission signal. Its design, leveraging a unidirectional adapter, promotes modularity and reusability in IEC 61499 applications. The simple event-to-event mapping and lack of data handling make it easy to integrate into existing control logic, while its generic nature allows for adaptation to specific adapter definitions when needed.

By offering a straightforward gating mechanism, this block contributes to safer and more controlled event-driven execution in automated systems.

AX_E_PERMIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

AX_E_PERMIT_4 is a generic function block designed for conditional propagation of four independent event channels. It acts as a permissive gate: each incoming event at one of its four event inputs is forwarded to the corresponding event output only if the attached permit condition via the unidirectional adapter socket `PERMIT` allows it. This block is particularly useful in safety-oriented or mode-dependent control applications where event flow must be gated by an external authorization signal.

Interface Structure

Event Inputs

Event	Type	Description

EI1	Event	Event input channel 1
EI2	Event	Event input channel 2
EI3	Event	Event input channel 3
EI4	Event	Event input channel 4

Event Outputs

Event	Type	Description
EO1	Event	Event output channel 1
EO2	Event	Event output channel 2
EO3	Event	Event output channel 3
EO4	Event	Event output channel 4

Data Inputs

This function block has no data inputs.

Data Outputs

This function block has no data outputs.

Adapters

Socket	Type	Description
PERMIT	adapter::types::unidirectional::AX	Unidirectional permit condition input

Functionality

AX_E_PERMIT_4 implements a permissive event propagation scheme. Each pair of input/output events (EI1/EO1, EI2/EO2, EI3/EO3, EI4/EO4) forms an independent channel. When an event is received on one of the event inputs, the block checks the current value of the `PERMIT` adapter. If the permit condition evaluates to true (permission granted), the corresponding event is released on the associated output. If the permit condition is false, the event is suppressed and no output is generated.

The block is generic, meaning it can be instantiated in a project with a concrete adapter type that matches the `adapter::types::unidirectional::AX` interface. The unidirectional nature of the adapter means that the permit signal flows only from the connected partner into this block, without requiring any return data.

Technical Features

- **Generic instantiation**: Declared with `eclipse4diac::core::GenericClassName` equal to `'GEN_AX_E_PERMIT'`, enabling type replacement at instantiation time.
- **Four independent channels**: Allows simultaneous handling of up to four separate event streams with identical gating behavior.
- **Unidirectional adapter**: The permit signal is supplied through a unidirectional adapter socket, simplifying the connection to a permit source (e.g., a safety interlock or operator authorization block).
- **No data processing**: The block does not modify or buffer any data; it purely gates event occurrence.
- **Package compliance**: Aligned with the IEC 61499-1 Annex A standard and located in the `adapter::events::unidirectional` compiler package.

State Overview

The function block does not maintain an explicit internal state machine. Its behavior is combinatorial with respect to events:

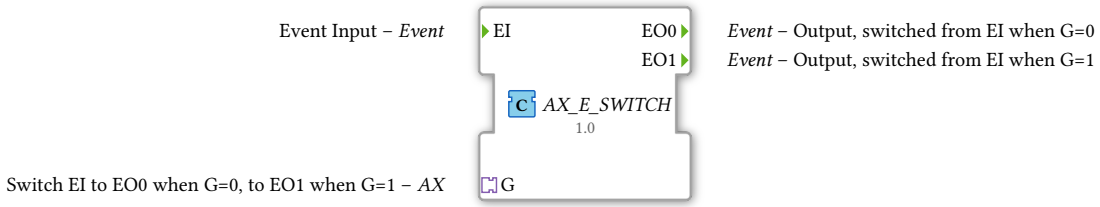
- **Permit Granted**: An input event immediately triggers the corresponding output event.
- **Permit Denied**: An input event is discarded; no output event is emitted.

The only dynamic condition is derived from the external permit signal carried by the adapter. Consequently, the block is stateless between event occurrences and responds identically to each event based on the current permit value.

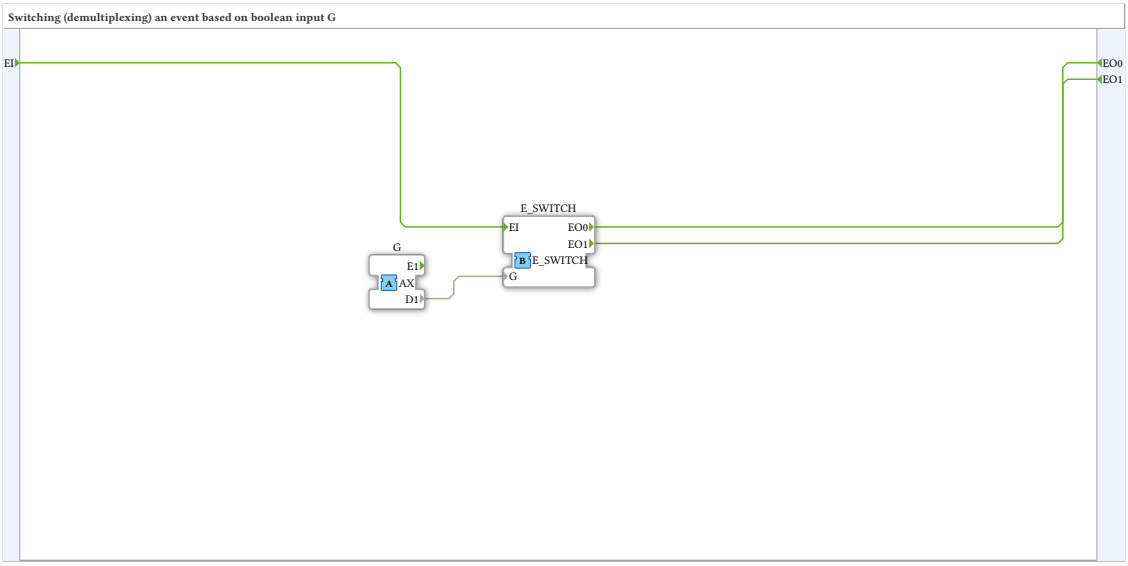
Application Scenarios

- **Safety interlocks**: Suppressing start commands or motion signals when a safety condition is not satisfied.
- **Mode-based operation**: Allowing or blocking commands depending on the current operational mode (e.g., manual vs. automatic).
- **Conditional alarming**: Forwarding alarm events only when a monitoring system is armed.
- **Line gating in production cells**: Passing control events to downstream equipment only when the upstream permit is active.

Comparison with Similar Blocks



Feature	AX_E_PERMIT_4	AX_E_PERMIT (single channel)	Standard event propagation (no permit)
Number of event channels	4	1	1 or more (direct wiring)
Permit gating	Yes (via unidirectional adapter)	Yes (via unidirectional adapter)	No
Generic type support	Yes	Yes	Not applicable
Data interface	None	None	Usually none
Typical use	Multi-channel safety or mode gating	Simple single-channel gate	Unconditional event forwarding



The main advantage of AX_E_PERMIT_4 over a single-channel variant is its compactness when four independent event streams must be gated by the same permit condition. Compared to direct event wiring, it adds a controlled suppression layer, which is essential in safety-related architectures.

Conclusion

AX_E_PERMIT_4 provides a straightforward and reusable solution for conditional event propagation across four independent channels. Its generic design and dependence on a unidirectional permit adapter make it a flexible building block in IEC 61499-based control applications that require event gating under external authorization. The block is easy to integrate, requires no data handling, and contributes to cleaner and more maintainable safety and mode-management logic.

AX_E_SWITCH

• – ○ • – ○ • – ○ •

Introduction

The **AX_E_SWITCH** function block implements event-driven demultiplexing (switching) based on a Boolean signal. It receives an event at input **EI** and forwards it to either output **EO0** or **EO1**, depending on the value of adapter **G**. This allows event flows to be split based on states or decisions

---

Interface Structure

Event Inputs

Name	Type	Description
EI	Event	Event input that is switched

Event Outputs

Name	Type	Description
EO0	Event	Activated when **G** = 0
EO1	Event	Activated when **G** = 1

Data Inputs

This function block has no separate data inputs. The switching information is provided via the **G** adapter.

Data Outputs

No data outputs are available.

Adapter

Name	Type	Description
G	`adapter::types::unidirectional::AX`	Boolean interface; provides the value for switching (0 ⟶ EO0, 1 ⟶ EO1)

Functionality

The **AX_E_SWITCH** is implemented internally as an encapsulation of the standard function block **E_SWITCH**. An incoming event at **EI** is forwarded to the internal function block. The adapter **G** provides the Boolean value (via the data connection `G.D1` ⟶ `E_SWITCH.G`).

- If **G = 0**, the event is output to **EO0**.
- If **G = 1**, the event is output to **EO1**.

The function block operates deterministically and without internal state management; the switching occurs in a single execution step.

–

Technical Features

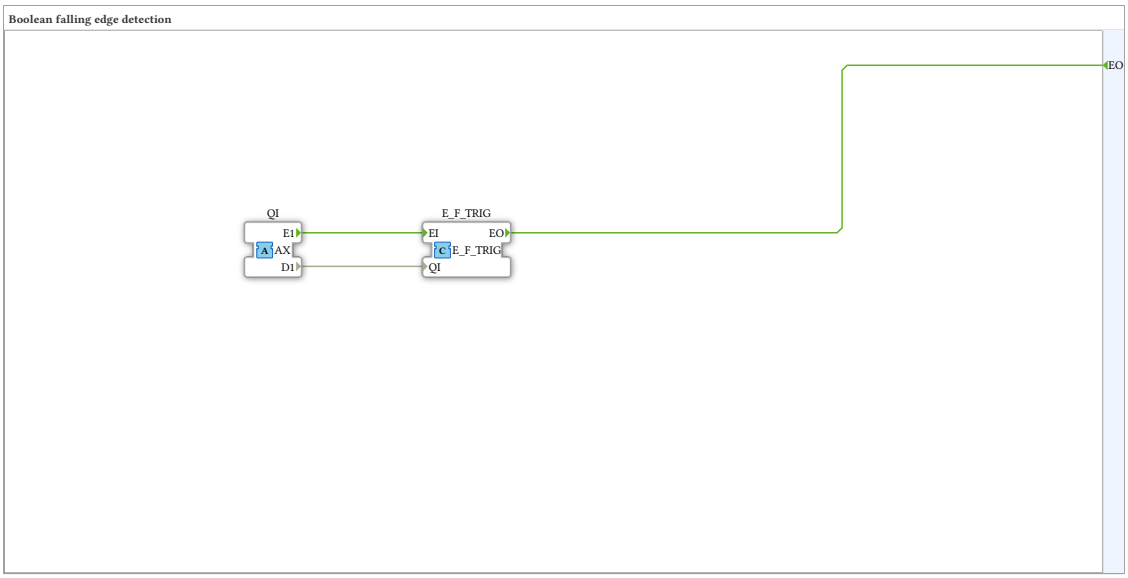
- **Adapter Interface:** The Boolean switching value is not provided as a classic data input, but via an adapter. This enables loose coupling and reuse of standardized interfaces (type `unidirectional::AX`).
- **Reusability:** Internally, the IEC 61499 standard function block `E_SWITCH` is used, ensuring compatibility and easy traceability.
- **No Side Effects:** The function block is purely component-based and does not modify any global data or states.

State Overview

The **AX_E_SWITCH** does not have its own explicit state machine. Its behavior is purely event-driven and does not differ from a simple switch. Therefore, a state overview is not required.

Application Scenarios

- **Event Switch in Control Logic:** Splitting an event stream into two paths, e.g., depending on a sensor value or operating mode.
- **Quality Control:** Forwarding an event to different processing blocks depending on the test result (pass/fail).
- **Operating Mode Switching:** Controlling processes that react differently in normal or fault mode.



Comparison with Similar Function Blocks

- **Standard function block `E_SWITCH`:** Has a direct Boolean data input instead of an adapter. The **AX_E_SWITCH** encapsulates this input and offers an adapter-based interface, which is preferred in modular architectures.
- **`E_DEMUX` (comparable function):** Some libraries also offer demultiplexers, but usually with multiple outputs or without adapter connectivity. The **AX_E_SWITCH** focuses on the special case of dual outputs with an adapter.

Conclusion

The **AX_E_SWITCH** is a simple yet useful function block for event-based switching. Its adapter interface allows it to be seamlessly integrated into component-oriented control projects and enables a clean separation of event logic and decision data. It is particularly suitable for modular and reusable automation solutions.

AX_F_TRIG

• – ○ • – ○ • – ○ •

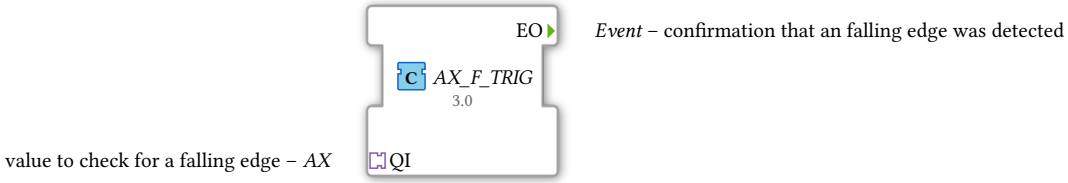
The function block **AX_F_TRIG** (Boolean falling edge detection) is used to detect a falling edge (change from TRUE to FALSE) based on an adapter interface. It is specifically designed for use with the unidirectional adapter type `AX`. The block checks the Boolean value received via the adapter and triggers an output event if this value is `FALSE`. In the context of event chains where the adapter's event signals a value change, this corresponds to the detection of a falling edge.

The block has an adapter interface (socket) for input and an event output.

This block does not have direct event inputs. Event control is handled via the adapter.

- **EO** (Event Output): This event is triggered when a falling edge (or a logical FALSE state) is detected at the adapter.

This function block has no direct data inputs. The data is obtained via the adapter.



This function block has no direct data outputs.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

- **QI** (Type: `adapter::types::unidirectional::AX`): The input socket. The function block receives both the trigger event and the Boolean value to be checked via this adapter.
- *Comment:* Value to be checked for a falling edge.

Functionality

The **AX_F_TRIG** is implemented as a composite function block (FB). Its internal logic is based on processing the signals from the `QI` adapter:

1. The `QI` adapter provides an event (`E1`) and a Boolean data value (`D1`).
2. These signals are passed to a D flip-flop (`E_D_FF`). The event acts as the clock (CLK), and the data as the input (D).
3. The flip-flop stores the value and triggers an acknowledgment event.
4. A downstream `E_SWITCH` component evaluates the output state (`Q`) of the flip-flop.
5. If the value `FALSE` (logic 0) is present, `E_SWITCH` passes the event to output **EO**.
6. If the value `TRUE` (logic 1) is present, no event is generated at output **EO**.

In summary: If the adapter sends an event and the transmitted data value is `FALSE`, the function block `EO` fires.

- **Adapter Integration:** The function block encapsulates the logic for splitting the `AX` adapter into individual events and data for logical processing.
- **Composite Network:** The implementation is achieved purely through the interconnection of standard IEC 61499 components (`E_D_FF`, `E_SWITCH`) and contains no custom algorithms in ST or C++.

Since it is a Composite Function Block, the **AX_F_TRIG** does not have its own ECC (Execution Control Chart). Its state is implicitly determined by the state of the internal components (especially the D flip-flop `E_D_FF`).

- **Signal Processing:** Used in systems that utilize `AX` adapters to communicate binary state changes.
- **Event Filtering:** Blocks events as long as the associated data signal is `TRUE` and allows them to pass if it is `FALSE`.
- **E_F_TRIG:** The standard function block for falling edge detection in IEC 61499. It uses separate event (`EI`) and data inputs (`QI`) instead of an adapter.
- **AX_R_TRIG:** The direct counterpart to this function block. It detects a rising edge (change to `TRUE`) using the same adapter type.
- **E_SWITCH:** A generic switch that routes events based on a Boolean value. **AX_F_TRIG** is essentially a specialization of this for adapters.

The **AX_F_TRIG** is a specialized utility block for structured event processing in 4diac. It significantly simplifies working with `AX` adapters by abstracting the logic for detecting the “low” state (falling edge) and directly providing it as the event `EO`, without requiring the user to manually split and examine the adapter signal.

AX_LAST_2

ECC: AX_LAST_2

Introduction

The AX_LAST_2 function block merges two same-type Boolean (BOOL)adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: Boolean (BOOL)adapter (unidirectional) - first signal source
- **IN2**: Boolean (BOOL)adapter (unidirectional) - second signal source

Output adapter (Plug):

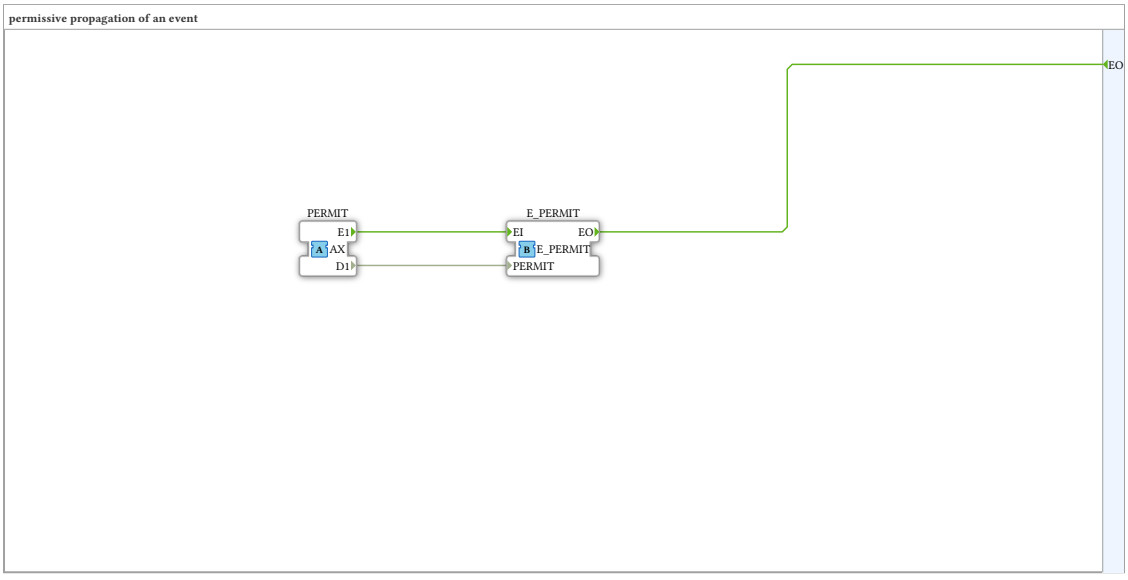
- **OUT**: Boolean (BOOL)adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

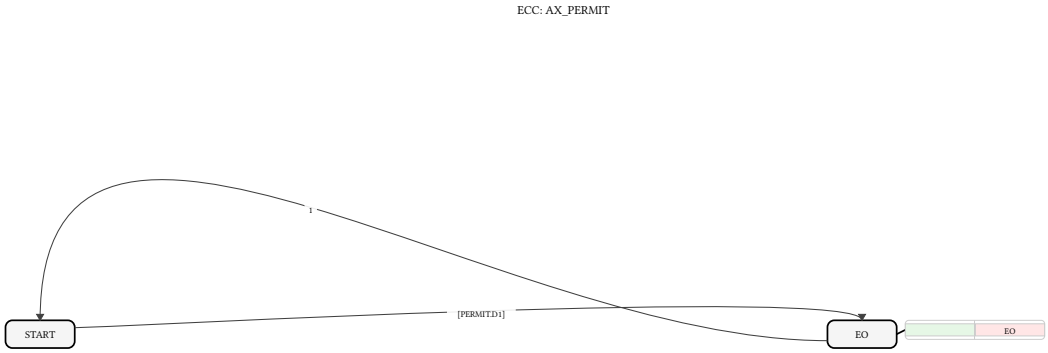
Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



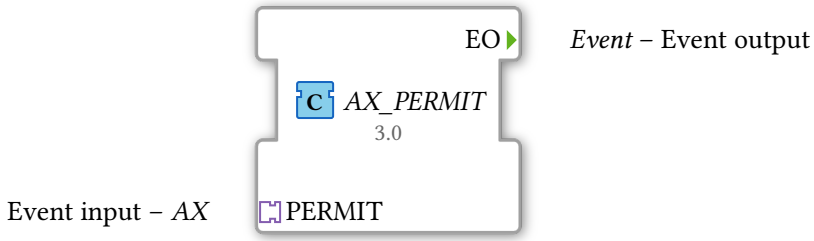
Application Scenarios

- Merging two equally-valid Boolean (BOOL)signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same Boolean (BOOL)value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct



⚖️ Comparison with Similar Blocks

AX_LAST_2 is the inverse of `AX_SPLIT_2`: AX_SPLIT_2 distributes 1 input to 2 outputs, AX_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.



AX_PERMIT (Unidirectional Adapter Permit)

Introduction

The AX_PERMIT function block is an adapter-based variant of the E_PERMIT block, implemented as a **Basic Function Block**. It enables the conditional propagation of an event based on the Boolean data value of an incoming AX adapter. The block receives a combined event and Boolean signal via a AX adapter (referred to as PERMIT). The incoming event is only forwarded to the output (EO) if the Boolean data value of the PERMIT adapter (PERMIT.D1) is TRUE. The data value PERMIT.D1 is **not** passed on to the output (EO), but is only used as a condition.

Interface Structure

Adapter (Socket)

- **PERMIT**: Input adapter of type AX (event E1 + data D1). This adapter controls the function block.

Event Outputs

- **EO**: Pure event output (type Event). This event is triggered when the condition is met.

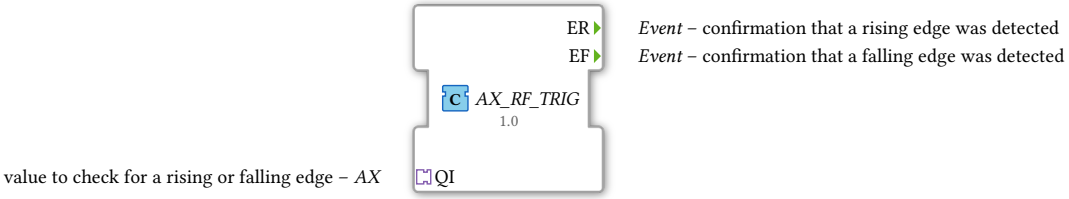
Functionality

1. **Event Receipt**: When an event (PERMIT.E1) arrives at the PERMIT socket, the corresponding Boolean data value (PERMIT.D1) is checked as a condition.
2. **Conditional Forwarding**: The event output EO is triggered only if PERMIT.D1 = TRUE is true. Otherwise, the event is blocked.
3. **Data Pass-Through**: The Boolean data value (PERMIT.D1) is used by the function block, but **not** passed on via the event output EO.

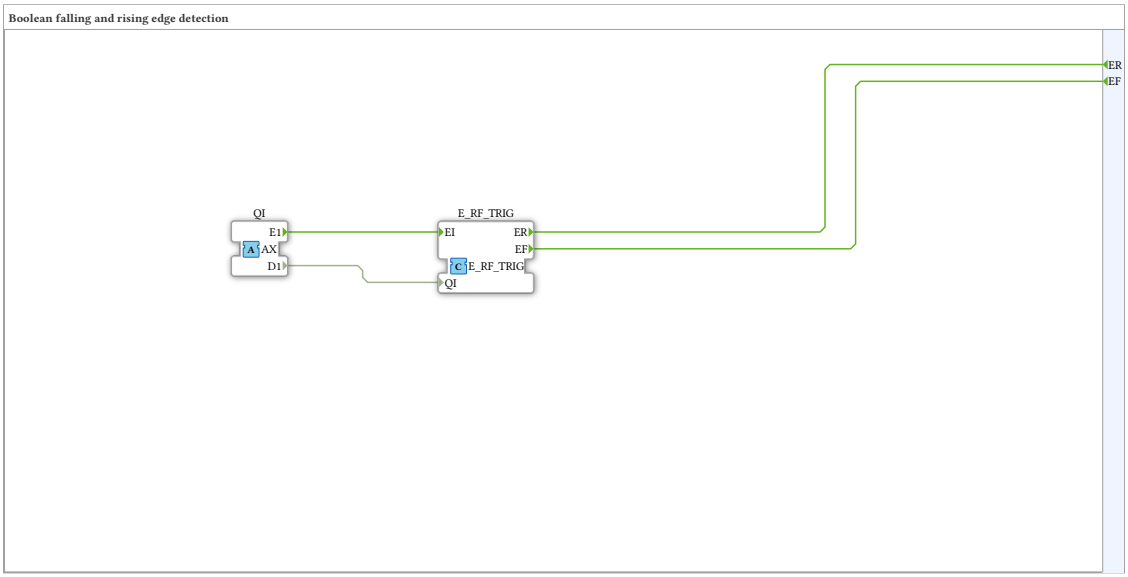
Technical Features

✓ **Basic Function Block**: Direct implementation of the logic.
✓ **Adapter-Based**: Uses the AX adapter as an input.

✓ **Permissive Logic**: Passes on events conditionally.
✓ **No Data Pass-Through at the Output**: The output `EO` is a pure event output and contains no data (`With Var` is undefined).



Application Scenarios



- **Enable Circuit**: A subsequent function block should only be triggered if an enable condition (`PERMIT.D1 = TRUE`) is active.
- **Conditional Event Control**: Control of the event flow based on an external Boolean status received via an AX adapter.

AX_RF_TRIG

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_RF_TRIG** is used to detect rising and falling edges of a Boolean signal. It receives the signal value via an adapter and outputs corresponding events when an edge changes. The block encapsulates the standard logic of IEC 61499 edge detection (E_RF_TRIG) and provides it via a uniform adapter interface.

Interface Structure

Event Inputs

The block does not have direct event inputs. Edge detection is triggered by the connected adapter (see Adapter).

Event Outputs

Name	Comment

ER	Confirmation that a rising edge (0⟶1) has been detected.
EF	Confirmation that a falling edge (1⟶0) has been detected.

Data Inputs

No direct data inputs. The Boolean value to be monitored is provided via the adapter.

Data Outputs

No data outputs.

Adapter

Name	Type	Comment
QI	adapter::types::unidirectional::AX	Receives the Boolean value whose edges are to be monitored. The adapter provides both an event (E1) and the data value (D1).

Functionality

The function block internally uses the IEC 61499 standard function block **E_RF_TRIG**. The adapter **QI** queries the current Boolean data value for each incoming event. If the value changes, the internal function block generates an event:

- **ER** on a transition from *false* to *true* (rising edge).
- **EF** on a transition from *true* to *false* (falling edge).

No output events are sent without an edge change.

Technical Features

- The function block is implemented as a pure adapter wrapper. It does not have its own state machine but delegates all logic to the standardized **E_RF_TRIG**.
- The use of an adapter type (here **AX**) enables loose coupling between the signal source and edge detection. The adapter can be reused in different contexts.
- Only event outputs are provided; the current signal value is not passed on as a data output.

State Overview

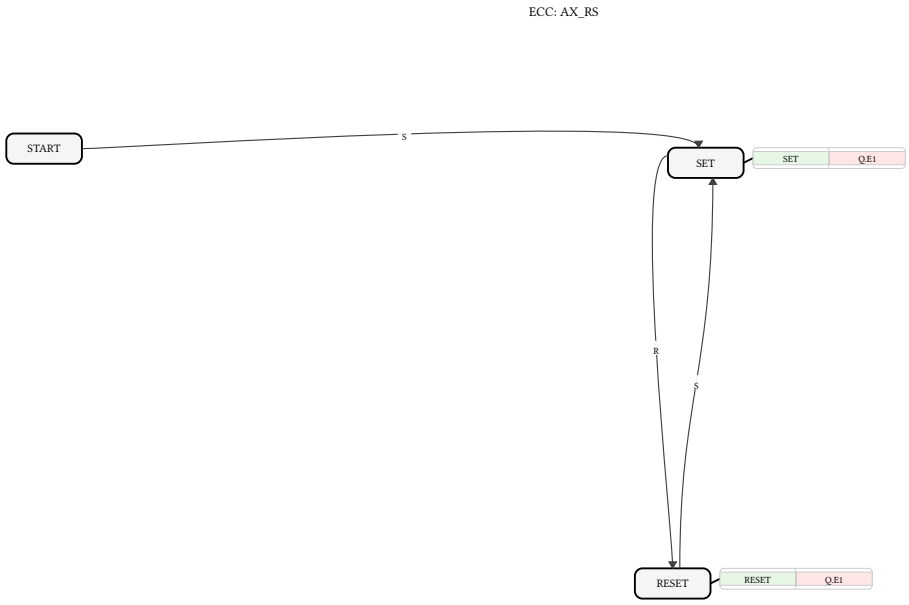
This function block does not have an explicitly defined state machine. Its behavior corresponds to that of the internal **E_RF_TRIG**, which stores an implicit state (last value). Essentially, two phases can be distinguished:

1. **Waiting for rising edge:** the last value was *false* if *true*, ER is triggered.
2. **Waiting for falling edge:** the last value was *true* if *false*, EF is triggered.

Application Scenarios

- Monitoring of binary sensor signals (e.g., limit switches, light barriers) in automation technology.
- Triggering actions upon signal changes (e.g., starting/stopping a machine).
- Event-driven processing of Boolean states in industrial control systems.

Comparison with Similar Function Blocks

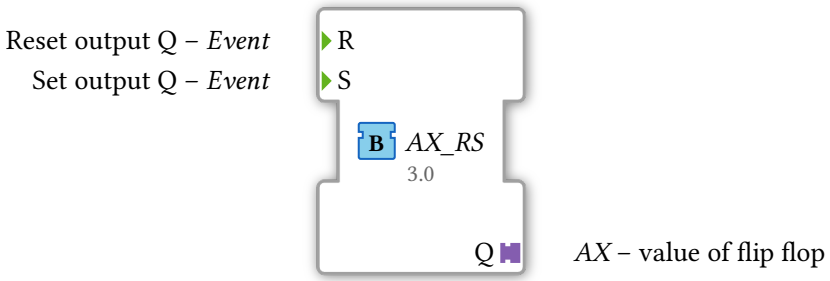


- **E_RF_TRIG:** The standard function block of IEC 61499. **AX_RF_TRIG** encapsulates this and provides an adapter interface, so the signal source does not need to be directly bound to the function block.
- **R_TRIG / F_TRIG:** Detect only one edge direction. **AX_RF_TRIG** detects both directions and outputs corresponding events.
- **Adapter-Based Alternatives:** Other adapter types with similar semantics can also be used for edge detection, provided they supply the Boolean value and an event.

Conclusion

The **AX_RF_TRIG** function block represents a practical, adapter-based solution for detecting both edges of a Boolean signal. By using the standard function block **E_RF_TRIG**, the function is robust and stan-

dards-compliant. The adapter interface facilitates integration into modular systems where signal sources and processing logic need to be decoupled.



AX_RS

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_RS function block is an event-driven bistable element (flip-flop) based on the RS principle. It is a Basic Function Block that implements a set-reset mechanism and communicates via adapter interfaces.

Interface Structure

Event Inputs

- **R**: Reset event - resets output Q
- **S**: Set event - sets output Q

Event Outputs

No direct event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

- **Q**: Adapter of type `adapter::types::unidirectional::AX` - represents the value of the flip-flop

Functionality

The AX_RS function block operates as an RS flip-flop with the following properties:

- Upon the occurrence of an S event (Set), output Q is set to TRUE
- Upon the occurrence of an R event (Reset), output Q is set to FALSE
- The state is retained until a The opposite event occurs

Technical Features and Comparison with Standards

As with all event-driven bistable elements in IEC 61499 (see also Note 8 in Table A.1 of DIN EN 61499-1), there is no inherent “dominance” of one input, as is known from IEC 61131-3.

- **Comparison to IEC 61131-3**: See RS (Bistable, priority reset). While in the classic PLC world, if S and R1 are TRUE simultaneously, the reset takes precedence, in IEC 61499 each event is processed sequentially. The final state depends on which event was processed last in the execution chain (ECC).
- **Functional Identity**: `AX_RS` is functionally identical to AX_SR. The different naming conventions are solely for consistency with traditional programming and improved readability in the schematic.
- **Adapter Communication**: The component outputs its status exclusively via the adapter `Q` (type `AX`). A change to `Q` triggers the event `Q.E1`.

State Overview

The function block has three states in the ECC:

1. **START**: Initial state
2. **SET**: State after a set operation (Q.D1 = TRUE)
3. **RESET**: State after a reset operation (Q.D1 = FALSE)

State Transitions:

- START ⟶ SET: on S event
- SET ⟶ RESET: on R event
- RESET ⟶ SET: on S event

Application Scenarios

- Storage of binary states with adapter output
- Implementation of interlock circuits in distributed systems
- State storage in sequential processes
- Signal processing in event-driven systems

Related Blocks

- **AX_SR**: Functionally identical, inputs reversed in the symbol.
- **E_RS**: The standard equivalent with direct data/event outputs instead of adapters.

⚖️ Comparison with Similar Building Blocks

Compared to other flip-flop implementations:

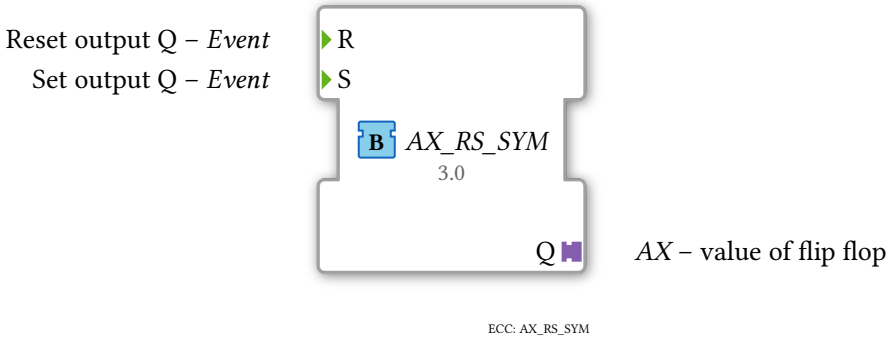
- Uses adapter-based communication instead of direct data outputs
- Event-driven state changes
- Simple RS logic without additional clock or enable signals

Comparison with E_RS

🛠️ Related Exercises

- Exercise_006b_AX
- Exercise_020a_AX
- Exercise_020b_AX
- Exercise_020d_AX

Conclusion



The AX_RS function block provides a simple and efficient implementation of an RS flip-flop for 4diac-based Control systems. Using adapters, it enables flexible integration into various system architectures and is particularly suitable for applications requiring reliable state storage with event-driven updates.

AX_RS_SYM

ECC: AX_RS_SYM

• – ○ • – ○ • – ○ •

Introduction

The **AX_RS_SYM** is an event-driven, bistable function block (RS flip-flop) with symmetrical start-up behavior. It has two event inputs, `R` (Reset) and `S` (Set), each of which sets the state of the output `Q`. The output is provided as a unidirectional adapter, through which both a data value (D1) and an event (E1) can be transmitted.

Interface Structure

Event Inputs

Name	Type	Comment
R	Event	Sets output Q.D1 to FALSE and fires Q.E1
S	Event	Sets output Q.D1 to TRUE and fires Q.E1

Event Outputs

The function block (FB) does not have its own event outputs. The event is output via the adapter Q using Q.E1.

Data Inputs

None.

Data Outputs

The FB has no separate data outputs. The current state is provided via the adapter Q as Q.D1 (of type BOOL).

Adapters

Name	Type	Comment
Q	adapter::types::unidirectional::AX	Provides the flip-flop value (D1) and an acknowledgment event (E1)

Functionality

The function block implements a classic RS flip-flop:

- Upon arrival of the event S, the output value Q.D1 is set to TRUE, and then the event Q.E1 is triggered.
- Upon arrival of the event R, the output value Q.D1 is set to FALSE, and Q.E1 is also triggered.

The special feature is the **symmetrical start-up behavior**: Immediately after initialization, the function block is in the state START. If the first event received is S, it transitions to state SET; if R is received, it transitions to state RESET. This ensures a defined state from the start – there is no undefined or random initial value.

Technical Features

- **Symmetrical Start Behavior**: Both inputs, R and S, are treated equally. The function block has no preferred initial state; the first incoming pulse determines the state.
- **Adapter-Based Output**: The output is implemented as a unidirectional adapter. This allows for flexible reuse of the value and the event in more complex structures.
- **No undefined state**: The state machine with three states (START, SET, RESET) prevents the function block from remaining in an unknown or metastable state after startup.

State Overview

The internal state machine consists of the following states and transitions:

State	Meaning	Action on entry
START	Initial state after power-on	No action (waits for first event)
SET	Output Q.D1 is TRUE	Executes algorithm SET: Q.D1 := TRUE and fires Q.E1
RESET	Output Q.D1 is FALSE	Executes algorithm RESET: Q.D1 := FALSE and fires Q.E1

` **Transitions:**

- START ⟶ SET on condition S
- START ⟶ RESET on condition R
- SET ⟶ RESET on condition R
- RESET ⟶ SET on condition S

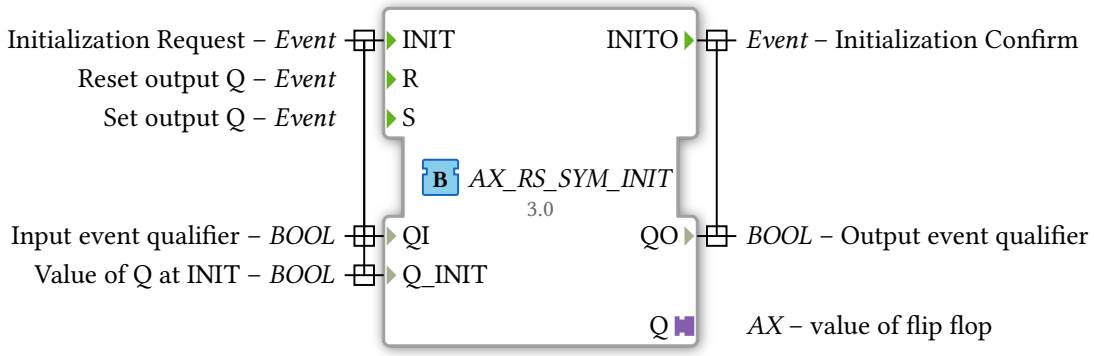
Application Scenarios

- **Simple Switch/Button**: One button press sets a marker bit, a second button press It resets.
- **Interlocks** (e.g., in safety controllers): A set pulse activates an action, a reset pulse deactivates it.
- **State control in sequence sequences**: As a memory block for events that are evaluated later.
- **Start-up behavior**: Particularly suitable when the system should start in a defined state after power-up, but one not yet specified by pre-logic.

Comparison with similar blocks

- **AX_RS**: A frequently used RS flip-flop with asynchronous set/reset. Unlike `AX_RS_SYM`, most implementations define a preferred state (e.g., the "R" signal resets the output at startup). `AX_RS_SYM` handles both events symmetrically, which makes the start-up behavior predictable.
- **AX_SR (Set-dominant)** or **AX_RS (Reset-dominant)**: These function blocks have a dominant input order when S and R arrive simultaneously. However, the symmetry here only applies to the startup behavior; during operation, the order is determined by the event processing of the runtime environment in the case of simultaneous events – the function block itself cannot handle simultaneity.
- **SR flip-flops in IEC 61131-3**: (e.g., `SR` or `RS`) usually operate with static signals. `AX_RS_SYM` is purely event-driven and therefore optimized for event-oriented controllers (e.g., 4diac IDE with FORTE).

Conclusion



The **AX_RS_SYM** is a simple yet flexible event-driven RS flip-flop. Its unique feature lies in its symmetrical startup behavior, which allows for a defined initial state without a fixed preset. The adapter interface facilitates integration into larger systems. This component is the ideal choice for applications where neither setting nor resetting is preferred after startup.

]

AX_RS_SYM_INIT

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_RS_SYM_INIT** implements an event-driven, bistable flip-flop (RS flip-flop) with symmetrical startup behavior and an explicit initialization mechanism. It extends a simple RS flip-flop by adding the ability to assume a predefined state at startup (INIT) and to control both initialization and deinitialization via the INIT event input. The actual state of the flip-flop is provided via an adapter, while the data outputs QO and the adapter output Q.D1 are synchronized.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request (with QI, Q_INIT)
R	Event	Reset Signal (resets Q)
S	Event	Set Signal (sets Q)

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement (with QO)

Data Inputs

Name	Type	Comment
QI	BOOL	Event Qualifier – Controls Execution
Q_INIT	BOOL	Desired Value of Q at Initialization

Data Outputs

Name	Type	Comment
QO	BOOL	Event Qualifier – passes QI to INITO or on S/R

Adapter

Name	Type	Comment
Q	adapter::types::unidirectional::AX	Adapter for the value of the flip-flop (D1)

Functionality

The function block cycles through various states, controlled by the INIT, S, and R events.

- In the **START** state, it waits for an INIT event.
- When INIT is received with `QI = TRUE`, it switches to the **INIT** state. The action `initialize` sets `QO := QI`.
- Depending on the value of `Q_INIT`:
- If `Q_INIT = TRUE` ⟶ transition to the **SET** state.
- If `Q_INIT = FALSE` ⟶ transition to the **RESET** state.
- After the action, `INITO` is triggered.
- If INIT is received with `QI = FALSE` (regardless of whether it's from **SET** or **RESET**), it transitions to the **DeInit** state. The action `deInitialize` sets `QO := FALSE`. Then, `INITO` is triggered, and the function block (FB) returns to **START**.
- In the **SET** and **RESET** states, the FB behaves like a conventional RS flip-flop:
- On **S** event, the action `SET` is executed: `QO := QI`; if `QI = TRUE`, `Q.D1 := TRUE` is also set (adapter output).
- On **R** event, the action `RESET` is executed: `QO := QI`; if `QI = TRUE`, `Q.D1 := FALSE` is set.
- The event at `Q.E1` is sent after each action.

The `QI` variable acts as a qualifier: Only if `QI = TRUE` is present are the operations on the adapter (setting/resetting `Q.D1`) actually performed. Otherwise, only `QO` is passed on.

Technical Features

- **Symmetrical Startup Behavior**: Initialization takes the value of `Q_INIT` into account, allowing the flip-flop to start in either the SET or RESET state. The behavior is symmetrical because both possibilities are explicitly implemented.
- **Adapter Coupling**: The flip-flop's state is not directly output as a data output, but is provided via a **unidirectional adapter** (`Q`) with output `D1`. This enables loose coupling with other function blocks.
- **Deinitialization**: INIT with `QI = FALSE` resets the function block and returns it to the START state. All internal variables are set to their defined values (`QO = FALSE`).
- **Event Qualifiers**: `QI` and `QO` control event propagation and provide an additional conditional level.

State Overview

State	Description
START	Wait for INIT event
INIT	Initialization: Sets QO and selects target state
DEINIT	Deinitialization: Sets QO = FALSE
SET	Active set state (Q.D1 = TRUE)
RESET	Active reset state (Q.D1 = FALSE)

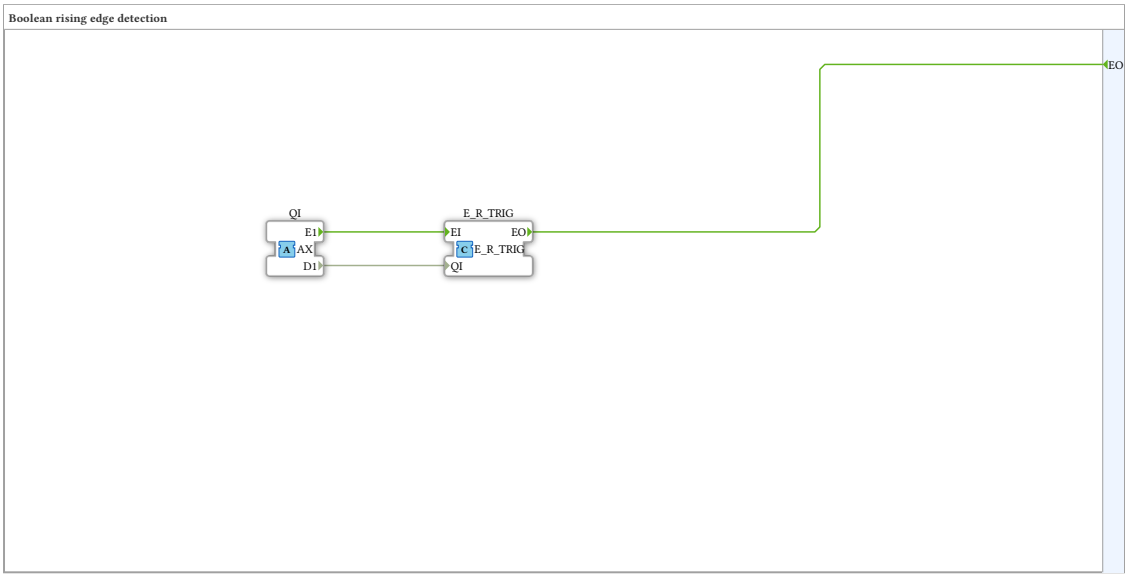
Important Transitions:

- START ⟶ Initialize on INIT with QI = TRUE
- Initialize ⟶ SET on Q_INIT = TRUE
- Initialize ⟶ RESET on Q_INIT = FALSE
- SET ⟶ RESET on R
- RESET ⟶ SET on S

- SET/RESET ⟶ DeInit on INIT with QI = FALSE
- DeInit ⟶ START (automatic after completion)

Application Scenarios

- **Startup Control**: A flip-flop that should assume a defined initial state after a start or reset (e.g., a machine starts in the "Ready" state).
- **Safe Initialization**: In safety-critical systems where the start state must be explicitly specified.
- **Modular Design**: Used as a fundamental storage element in an adapter-based architecture where the state is passed to other components via the adapter.

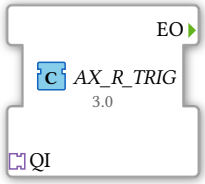


Comparison with Similar Function Blocks

- **Standard RS (e.g., RS Flip-Flop)**: Simple RS flip-flop without INIT and without an adapter. `AX_RS_SYM_INIT` extends this with initialization logic and an adapter interface.
- **Bistable Flip-Flops with Reset**: Many function blocks only offer asynchronous reset. This function block integrates the reset into the event-driven behavior and allows for symmetrical target setting.
- **SR Latch with INIT**: Similar function blocks exist, but usually without the qualifier `QI` and the deinitialization option.

Conclusion

The function block `AX_RS_SYM_INIT` combines classic RS flip-flop behavior with flexible initialization logic that allows both setting and resetting at startup. The use of an adapter for the state value and the inclusion of qualifiers (`QI`, `QO`) make it a robust and versatile building block for event-driven automation applications that require a defined and resettable initial state.



AX_R_TRIG

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AX_R_TRIG** (Boolean rising edge detection) is used to detect a rising edge based on a Boolean signal provided via an adapter. It is specifically designed for use with unidirectional adapters of type `AX` and only forwards an event if the transmitted data value is `TRUE`.

Event – confirmation that an rising edge was detected

value to check for a rising edge – *AX*

Interface Structure

The function block primarily uses an adapter interface for communicating input data and events.

Event Inputs

This function block does not have direct event inputs. Events are received via the adapter `QI`.

Event Outputs

- **EO**: (Event Output) Confirmation that a rising edge (or a high signal) has been detected.

Data Inputs

This function block has no direct data inputs. Data is received via the adapter `QI`.

Data Outputs

This function block has no direct data outputs.

Adapters

- **QI** (Socket): Of type `adapter::types::unidirectional::AX`. This adapter provides the value to be checked (Boolean) and the corresponding event.
- Typically expects an event (e.g., `E1`) and a Boolean value (e.g., `D1`).

Functionality

The component is implemented as a Composite Function Block (CFB) and is based on the internal circuitry of a D flip-flop (`E_D_FF`) and an event switch (`E_SWITCH`).

1. As soon as an event is received via the **QI** adapter, it is routed to the clock input of the internal `E_D_FF`.
2. Simultaneously, the Boolean data value is loaded from the adapter into the flip-flop.
3. The flip-flop passes the stored value to a `E_SWITCH`.
4. If the value of `TRUE` is high, the `E_SWITCH` switches on and triggers the output event **EO**.
5. If the value `FALSE` (Low), the event is blocked and **EO** is not triggered.

Technically, the function block acts as a gate that only allows the adapter event to pass if the adapter data is `TRUE`. In an event-driven system that only sends when values change, this corresponds to the logic of edge detection (0 -> 1).

Technical Features

- **Internal Structure:** Uses standard IEC 61499 function blocks (`E_D_FF`, `E_SWITCH`).
- **Adapter-based:** Unlike classic trigger blocks, which have separate `CLK` and `QI` inputs, this block encapsulates the signals in a `AX` adapter.

State Overview

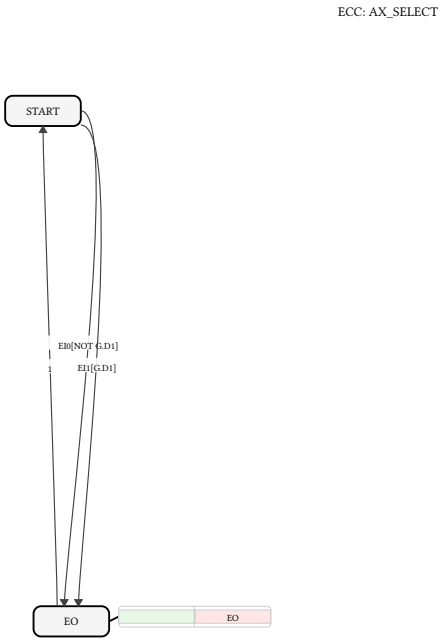
Since this is a Composite Function Block, it does not have its own state machine (ECC). Its behavior is determined solely by the data flow and the interconnection of its internal sub-blocks.

Application Scenarios

- **Signal Filtering:** Forwarding of events only when a specific state is active.
- **Adapter Logic:** Use in systems that rely heavily on adapter connections to minimize wiring complexity.
- **Start Trigger:** Triggers processes as soon as a Boolean flag within an adapter structure changes to `TRUE`.

⚖️ Comparison with similar function blocks

- **E_R_TRIG:** The standard function block for event-based rising edge detection with separate event and data inputs. `AX_R_TRIG` is the equivalent for adapter connections.
- **R_TRIG:** The classic PLC function block (IEC 61131-3) that is polled cyclically. `AX_R_TRIG`, on the other hand, operates purely event-driven.



Conclusion

The **AX_R_TRIG** is a specialized component for the 4diac environment that seamlessly integrates the logic of rising edge detection or a high-pass filter into designs using `AX` adapters. It simplifies the network by eliminating the need to explicitly split adapter signals for testing.

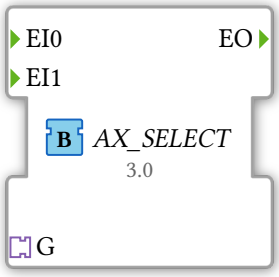
AX_SELECT



• – ○ • – ○ • – ○ •

Introduction

The AX_SELECT function block, based on a Boolean input, switches one of two AX adapter inputs to the output.

Input event, selected when G=0 – *Event*
Input event, selected when G=1 – *Event*

Event – Output Event

Select EI0 when G=0, EI1 when G=1 – *AX*

Interface Structure

Event Inputs

- **EI0**: Input event, selected when G = 0.
- **EI1**: Input event, selected when G = 1.

Event Outputs

- **EO**: Output event.

Adapters

Sockets (Inputs):

- **G** (adapter::types::unidirectional::AX): Selection signal. EI0 is selected when G = 0, EI1 when G = 1.

Functionality

If G = 0, the event EI0 is output as EO.
If G = 1, the event EI1 is output as EO.

Technical Features

- Uses unidirectional adapters.

State Overview

Combinatorial.

Application Scenarios

Selection of signals.

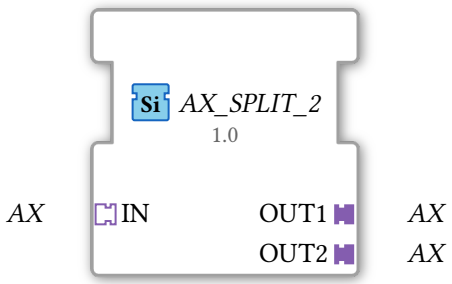
⚖️ Comparison with Similar Function Blocks

- **E_SELECT**: Standard event select without adapters.

🛠️ Related Exercises

- Exercise_095_AX

Conclusion



Adapter-based select function block.

AX_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SPLIT_2 function block serves as a generic building block for distributing an AX signal to two separate outputs. The block enables the splitting of an incoming AX signal to two independent output channels.

Interface Structure

Event Inputs

No direct event inputs available

Event Outputs

No direct event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN**: AX adapter (unidirectional) - Receives the incoming AX signal

Output Adapters:

- **OUT1**: AX adapter (unidirectional) - First output channel for the distributed signal
- **OUT2**: AX adapter (unidirectional) - Second output channel for the distributed signal

Functionality

The AX_SPLIT_2 function block receives an AX signal via the IN adapter and simultaneously distributes this signal to both output adapters OUT1 and OUT2. OUT2. This is a 1:2 distribution, where the incoming signal is passed on to both outputs without modification.

Technical Features

- Generic implementation for AX signals
- Unidirectional signal transmission
- No signal delay between input and output
- Simultaneous activation of both outputs

State Overview

The function block operates statelessly – with every incoming signal via the IN adapter, both output adapters are immediately activated.

Application Scenarios

- Signal distribution in control systems
- Parallel supply of multiple components with the same signal
- Branching of AX communication paths
- Redundant signal routing

⚖️ Comparison with Similar Function Blocks

Compared to other distribution blocks, AX_SPLIT_2 offers a specific 1:2 split for AX signals. Other splitter blocks may support different numbers of outputs or other signal types.

Comparison with E_SPLIT

AX_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SPLIT_3 is a generic function block that splits one AX adapter input into three separate AX adapter outputs. This block allows the distribution of an incoming AX signal to three different receivers within a 4diac system.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

Input Adapters:

- **IN** - AX adapter (socket) - Receives the incoming AX signal

Output Adapters:

- **OUT1** - AX adapter (plug) - First output channel
- **OUT2** - AX adapter (plug) - Second output channel
- **OUT3** - AX adapter (plug) - Third output channel

Functionality

The functional block acts as a signal distributor for unidirectional AX adapters. Every incoming signal at the IN adapter is forwarded in parallel to all three output adapters (OUT1, OUT2, OUT3). The distribution is synchronous, so all outputs are activated simultaneously.

Technical Features

- Uses unidirectional AX adapters for communication
- Implemented as a generic function block (GEN_AX_SPLIT)
- No event or data inputs - operates exclusively via adapters
- Plug-and-socket architecture according to IEC 61499 standard

State Overview

The function block has a simple state: In the operating state, it forwards incoming signals unchanged to all three outputs. There are no internal state transitions or delays.

Application Scenarios

- Distribution of control signals to multiple actuators
- Parallel control of multiple devices with the same signal
- Signal branching in complex control architectures

- Redundant signal distribution for safety applications

⚖️ Comparison with similar function blocks

Compared to other distribution function blocks, AX_SPLIT_3 stands out due to its specific focus on AX adapters. While general distribution function blocks can support various adapter types, this function block is specifically optimized for AX adapters.

Comparison with E_SPLIT

AX_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SPLIT_4 function block is a generic function block that splits one AX adapter input into four separate AX adapter outputs. The block acts as a distributor for unidirectional AX adapters and enables the transmission of data and events to multiple receivers.

Interface Structure

Event Inputs

No direct event inputs available (event processing is handled via adapters)

Event Outputs

No direct event outputs available (event processing is handled via adapters)

Data Inputs

No direct data inputs available (data processing is handled via adapters)

Data Outputs

No direct data outputs available (data processing is handled via adapters)

Adapters

Input Adapter:

- `IN` - AX Adapter (Socket) - Receives unidirectional AX data and events

Output Adapter:

- `OUT1` - AX Adapter (Plug) - First output channel
- `OUT2` - AX Adapter (Plug) - Second Output Channel
- `OUT3` - AX Adapter (Plug) - Third Output Channel
- `OUT4` - AX Adapter (Plug) - Fourth Output Channel

Functionality

The AX_SPLIT_4 block receives data and events via the input adapter `IN` and distributes them in parallel to all four output adapters (`OUT1` to `OUT4`). All incoming information is forwarded to all outputs simultaneously, thus achieving a 1:4 distribution.

Technical Features

- Generic implementation for maximum reusability
- Uses unidirectional AX adapters for data transmission
- No buffering or delay in data transmission

- Parallel distribution without output prioritization

State Overview

The function block operates statelessly – incoming data and events are immediately forwarded to all outputs without storing any internal state.

Application Scenarios

- Distribution of control commands to multiple actuators
- Broadcasting of sensor data to various processing units
- Distribution of control information in distributed systems
- Redundant data distribution for safety applications

⚖️ Comparison with Similar Function Blocks

Compared to simple split function blocks, AX_SPLIT_4 offers a specific 1:4 split for AX adapters. Other split variants may support different numbers of outputs or other adapter types.

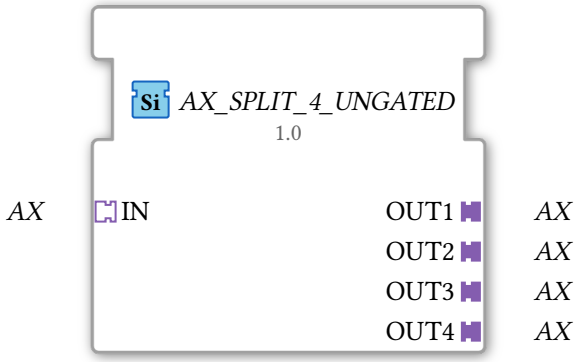
Comparison with E_SPLIT

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AX_SPLIT_4 function block offers a simple and efficient solution for distributing AX adapter data to four parallel outputs. Its generic nature and the use of standardized adapters make it versatile for use in various automation applications.



AX_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_SPLIT_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SPLIT_4_UNGATED function block is a generic function block that splits one AX adapter input into four separate AX adapter outputs. The block acts as a distributor for unidirectional AX adapters and enables the transmission of data and events to multiple receivers.

Interface Structure

Event Inputs

No direct event inputs available (event processing is handled via adapters)

Event Outputs

No direct event outputs available (event processing is handled via adapters)

Data Inputs

No direct data inputs available (data processing is handled via adapters)

Data Outputs

No direct data outputs available (data processing is handled via adapters)

Adapters

Input Adapter:

- `IN` - AX Adapter (Socket) - Receives unidirectional AX data and events

Output Adapter:

- `OUT1` - AX Adapter (Plug) - First output channel
- `OUT2` - AX Adapter (Plug) - Second Output Channel
- `OUT3` - AX Adapter (Plug) - Third Output Channel
- `OUT4` - AX Adapter (Plug) - Fourth Output Channel

Functionality

The AX_SPLIT_4_UNGATED block receives data and events via the input adapter `IN` and distributes them in parallel to all four output adapters (`OUT1` to `OUT4`). All incoming information is forwarded to all outputs simultaneously, thus achieving a 1:4 distribution.

Technical Features

- Generic implementation for maximum reusability
- Uses unidirectional AX adapters for data transmission
- No buffering or delay in data transmission
- Parallel distribution without output prioritization

State Overview

The function block operates statelessly – incoming data and events are immediately forwarded to all outputs without storing any internal state.

Application Scenarios

- Distribution of control commands to multiple actuators
- Broadcasting of sensor data to various processing units
- Distribution of control information in distributed systems
- Redundant data distribution for safety applications

⚖️ Comparison with Similar Function Blocks

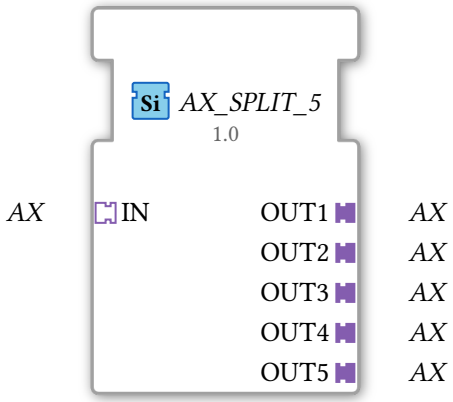
Compared to simple split function blocks, AX_SPLIT_4_UNGATED offers a specific 1:4 split for AX adapters. Other split variants may support different numbers of outputs or other adapter types.

Comparison with E_SPLIT

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The AX_SPLIT_4_UNGATED function block offers a simple and efficient solution for distributing AX adapter data to four parallel outputs. Its generic nature and the use of standardized adapters make it versatile for use in various automation applications.

AX_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SPLIT_5 function block is a generic function block used to split an AX adapter into five separate AX outputs. The block enables the distribution of an input signal to multiple output channels and is particularly useful in control applications where signals need to be distributed to different components.

Interface Structure

Event Inputs

No direct event inputs available (event processing is handled via adapters)

Event Outputs

No direct event outputs available (event processing is handled via adapters)

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- **IN** - AX unidirectional adapter (socket)

Output Adapters:

- **OUT1** - AX unidirectional adapter (plug)
- **OUT2** - AX unidirectional adapter (plug)
- **OUT3** - AX unidirectional adapter (plug)
- **OUT4** - AX unidirectional adapter (plug)
- **OUT5** - AX Unidirectional Adapter (Plug)

Functionality

The AX_SPLIT_5 function block receives signals via the input adapter IN and simultaneously distributes them to all five output adapters (OUT1 to OUT5). Every event received at the IN adapter is forwarded to all outputs in parallel, thus achieving a 1:5 distribution.

Technical Features

- Generic function block with the class ‘GEN_AX_SPLIT’
- Uses unidirectional AX adapters for communication
- No data processing or transformation
- Pure event distribution without delay

State Overview

The block has a simple state: In its idle state, it waits for incoming events at the IN adapter. Upon receiving an event, all five output adapters are immediately activated.

Application Scenarios

- Distribution of control signals to multiple actuators
- Distribution of sensor values to different processing units
- Parallel activation of multiple subsystems
- Signal distribution in decentralized control architectures

⚖️ Comparison with similar components

Compared to simple split components, the AX_SPLIT_5 offers a fixed number of five outputs. Other split variants can offer different numbers of outputs or configurable distribution logics. The focus here is on the simple, fixed 1:5 distribution.

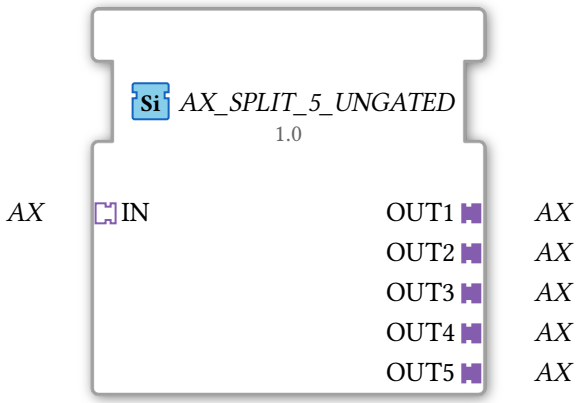
Comparison with E_SPLIT

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AX_SPLIT_5 is a specialized distribution component whose simple and deterministic operation makes it ideal for applications where a signal needs to be distributed to exactly five receivers. The use of standardized AX adapters ensures compatibility within existing control systems.



AX_SPLIT_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_SPLIT_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

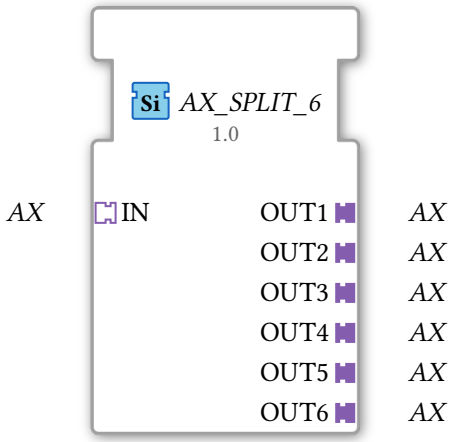
Conclusion



The AX_SPLIT_5_UNGATED is a specialized distribution component whose simple and deterministic operation makes it ideal for applications where a signal needs to be distributed to exactly five receivers. The use of standardized AX adapters ensures compatibility within existing control systems.

AX_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SPLIT_6 function block is a generic component used to split a single AX adapter into six separate AX outputs. This component enables the distribution of signals and data streams from a central source to multiple devices.

Interface Structure

Event Inputs

No direct event inputs available

Event Outputs

No direct event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapter:

- **IN** (Socket): Receives incoming AX signals from the source system

Output Adapter:

- **OUT1** (Plug): First output channel
- **OUT2** (Plug): Second output channel
- **OUT3** (Plug): Third output channel
- **OUT4** (Plug): Fourth output channel
- **OUT5** (Plug): Fifth output channel
- **OUT6** (Plug): Sixth output channel Output Channel

All adapters use the type: `adapter::types::unidirectional::AX`

Functionality

The AX_SPLIT_6 module functions as a signal distributor. It receives signals via the input adapter IN and forwards them in parallel to all six output adapters (OUT1 to OUT6). Since these are unidirectional AX adapters, signal transmission only occurs in one direction – from the input to the outputs.

Technical Features

- Generic function block with the class 'GEN_AX_SPLIT'
- Uses unidirectional AX adapters for communication
- No data processing or modification, only signal distribution
- Parallel output to all six outputs

State Overview

The block has a simple state:

- **Ready**: Receives signals from IN and distributes them to OUT1-OUT6

Application Scenarios

- Distribution of control signals to multiple actuators
- Splitting of sensor values to different processing units
- Signal distribution in redundant systems
- Multi-casting of control commands

⚖️ Comparison with Similar Blocks

Compared to other splitter blocks, AX_SPLIT_6 offers a fixed number of six outputs, which is advantageous for specific applications. Other splitters can offer more or fewer outputs, but may be more complex to configure.

Comparison with E_SPLIT

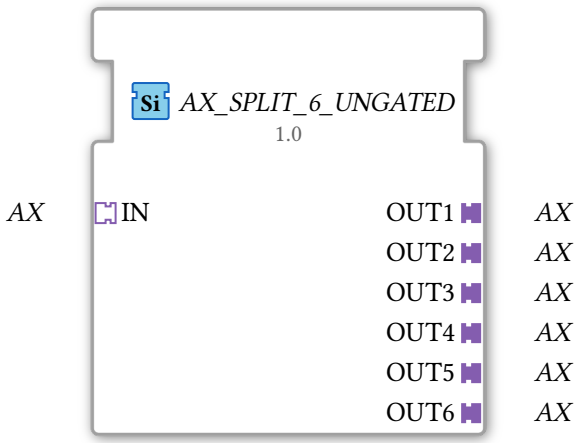
- `AX_SPLIT_6_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AX_SPLIT_6 is a specialized distribution module ideally suited for applications where a signal needs to be distributed to exactly six receivers. Its simple structure and the use of standardized AX adapters make it a reliable solution for signal distribution tasks in automation systems.



AX_SPLIT_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_SPLIT_6`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

⚖️ Comparison with Similar Blocks
Compared to other splitter blocks, AX_SPLIT_6_UNGATED offers a fixed number of six outputs, which is advantageous for specific applications. Other splitters can offer more or fewer outputs, but may be more complex to configure.

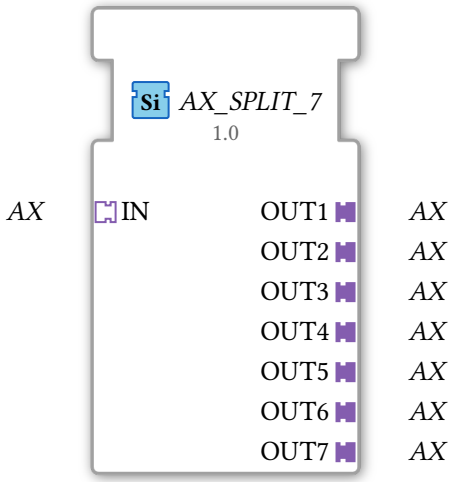
Comparison with E_SPLIT

- **`AX_SPLIT_6`**: The gated variant – updates the output only on an actual value change.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



AX_SPLIT_6_UNGATED is a specialized distribution module ideally suited for applications where a signal needs to be distributed to exactly six receivers. Its simple structure and the use of standardized AX adapters make it a reliable solution for signal distribution tasks in automation systems.

AX_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SPLIT_7 function block is a generic component that splits a single AX adapter input into seven separate AX adapter outputs. The component acts as a distributor for unidirectional AX adapters and allows a single input signal to be distributed to multiple receivers.

Interface Structure

Event Inputs

No direct event inputs available (adapter-based communication)

Event Outputs

No direct event outputs available (adapter-based communication)

Data Inputs

No direct data inputs available (adapter-based communication)

Data Outputs

No direct data outputs available (adapter-based communication)

Adapters

Input Adapter:

- **IN** (Socket): Unidirectional AX adapter input

Output Adapter:

- **OUT1** (Plug): Unidirectional AX adapter output 1
- **OUT2** (Plug): Unidirectional AX adapter output 2
- **OUT3** (Plug): Unidirectional AX Adapter Output 3
- **OUT4** (Plug): Unidirectional AX Adapter Output 4
- **OUT5** (Plug): Unidirectional AX Adapter Output 5
- **OUT6** (Plug): Unidirectional AX Adapter Output 6

- **OUT7** (Plug): Unidirectional AX Adapter Output 7

Functionality

The AX_SPLIT_7 function block receives data via the input adapter IN and simultaneously distributes it to all seven output adapters (OUT1 to OUT7). Each signal received at the IN adapter is forwarded in parallel to all seven outputs, thus achieving a 1:7 distribution.

Technical Features

- Generic implementation for maximum reusability
- Uses unidirectional AX adapters for communication
- No internal delays in signal distribution
- Parallel output to all seven outputs

State Overview

The function block has a simple state: In the active state, it immediately forwards incoming signals to all outputs. There are no complex state transitions or internal processing logic.

Application Scenarios

- Distribution of control signals to multiple actuators
- Splitting of sensor data to different processing units
- Signal distribution in branched control architectures
- Redundant signal forwarding to multiple receivers

⚖️ Comparison with Similar Components

Compared to simpler splitter components, AX_SPLIT_7 offers a fixed number of seven outputs, which is optimized for specific use cases with exactly seven receivers. Compared to variable splitters, this component has the advantage of fixed interfaces.

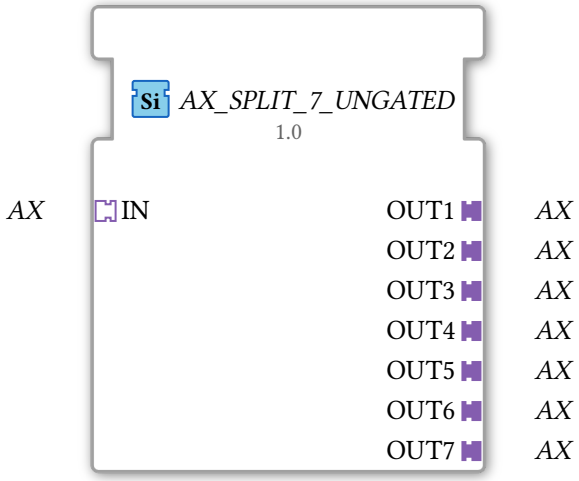
Comparison with E_SPLIT

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AX_SPLIT_7 function block provides an efficient solution for distributing unidirectional AX signals to seven receivers. Its generic nature and simple operation make it a robust and reliable component for distributed control systems.



AX_SPLIT_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AX_SPLIT_7`. AX_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SPLIT_8 function block is a generic function block that splits a single AX adapter into eight separate AX outputs. It is used to distribute adapter signals in complex control architectures.

Interface Structure

Event Inputs

No direct event inputs available

Event Outputs

No direct event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapter:

- **IN** (Socket): AX adapter input type `adapter::types::unidirectional::AX`

Output Adapter:

- **OUT1** (Plug): AX adapter output 1 type `adapter::types::unidirectional::AX`
- **OUT2** (Plug): AX adapter output 2 type `adapter::types::unidirectional::AX`
- **OUT3** (Plug): AX adapter output 3 of type `adapter::types::unidirectional::AX`
- **OUT4** (Plug): AX adapter output 4 of type `adapter::types::unidirectional::AX`
- **OUT5** (Plug): AX adapter output 5 of type `adapter::types::unidirectional::AX`
- **OUT6** (Plug): AX adapter output 6 of type `adapter::types::unidirectional::AX`
- **OUT7** (Plug): AX adapter output 7 of type `adapter::types::unidirectional::AX`
- **OUT8** (Plug): AX adapter output 8 of type `adapter::types::unidirectional::AX`

Functionality

The AX_SPLIT_8 function block distributes incoming Adapter signals from the input adapter IN are simultaneously sent to all eight output adapters (OUT1 to OUT8). As a unidirectional adapter block, it forwards all incoming events and data in parallel to all connected outputs.

Technical Features

- Generic function block with the generic class 'GEN_AX_SPLIT'
- Uses unidirectional AX adapters
- No internal signal processing or filtering
- Parallel signal distribution without delay

State Overview

The block has no internal state and operates stateless. All incoming signals are immediately forwarded to all outputs.

Application Scenarios

- Distribution of control signals to multiple actuators
- Distribution of sensor information to different processing units
- Signal distribution in redundant system architectures
- Cascading of adapter-based control systems

⚖️ Comparison with Similar Blocks

Compared to other split blocks, AX_SPLIT_8 offers a fixed number of eight outputs and operates exclusively at the adapter level. Other split components can have a variable number of outputs or operate at the data or event level.

Comparison with E_SPLIT

- **`AX_SPLIT_8_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AX_SPLIT_8 function block provides a simple and efficient solution for distributing adapter signals in 4diac systems. Its fixed output of eight ports makes it particularly suitable for standardized distribution tasks in industrial control applications.

AX_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SPLIT_9 function block is a generic component that splits a single AX adapter into nine separate AX outputs. The block acts as a distributor for unidirectional adapter connections and allows a single input signal to be distributed across multiple output channels.

Interface Structure

Event Inputs

No direct event inputs available

Event Outputs

No direct event outputs available

Data Inputs

No direct data inputs available

Data Outputs

No direct data outputs available

Adapters

Input Adapters:

- `IN` - Unidirectional AX adapter (socket)

Output Adapters:

- `OUT1` to `OUT9` - Nine unidirectional AX adapters (plugs)

Functionality

The AX_SPLIT_9 block functions as an adapter splitter, which receives incoming signals and data from the input adapter. The input signal is distributed in parallel to all nine output adapters (`IN` to `OUT9`). Each output receives an identical copy of the input signal.

Technical Features

- Generic implementation for maximum reusability
- Unidirectional adapter architecture
- Parallel signal distribution without delay
- No data processing or modification

State Overview

The function block has a simple state: When the input adapter is activated, all nine output adapters are activated simultaneously.

Application Scenarios

- Distribution of control signals to multiple actuators
- Distribution of sensor values to different processing units

- Signal distribution in complex control systems
- Redundant signal routing

⚖️ Comparison with Similar Blocks

Compared to simpler splitter blocks, AX_SPLIT_9 offers a higher number of outputs (9 instead of the typical 2-4). Compared to serial distributors, it allows simultaneous activation of all outputs without sequential delay.

Comparison with E_SPLIT

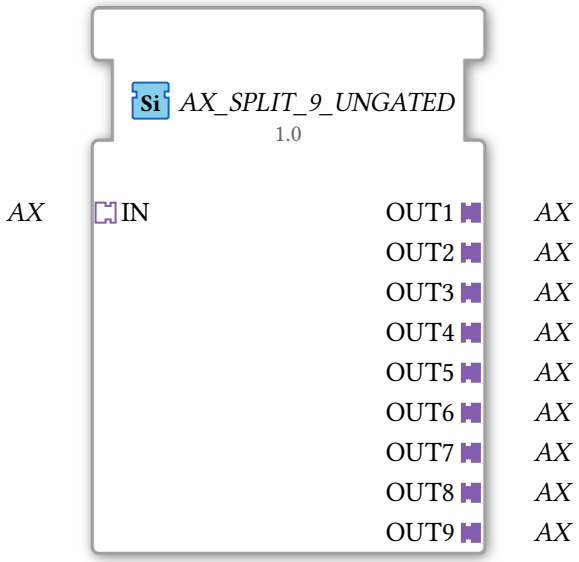
- **AX_SPLIT_9_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AX_SPLIT_9 function block represents an efficient solution for the parallel distribution of unidirectional adapter signals. Its generic nature and the high number of outputs make it particularly suitable for complex control applications where a signal needs to be distributed to multiple receivers.



AX_SPLIT_9_UNGATED

> **i UNGATED variant:** This block is the ungated version of AX_SPLIT_9. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. The AX_SPLIT_9_UNGATED function block represents an efficient solution for the parallel distribution of unidirectional adapter signals. Its generic nature and the high number of outputs make it particularly suitable for complex control applications where a signal needs to be distributed to multiple receivers.

AX_SR

• – ◦ • – ◦ • – ◦ •

Introduction

The AX_SR function block is an event-driven bistable element (flip-flop) that functions as a set-reset memory. It allows setting and resetting a logical state and makes this state available via an adapter interface.

Interface Structure

Event Inputs

- **S**: Sets output Q to TRUE
- **R**: Sets output Q to FALSE

Event Outputs

- No direct event outputs available

Data Inputs

- No data inputs available

Data Outputs

- No direct data outputs available

Adapters

- **Q**: Unidirectional adapter of type “adapter::types::unidirectional::AX”, which provides the current state of the flip-flop

Functionality

The AX_SR function block operates as a set-reset flip-flop with the following properties:

- On an S event, the internal state is set to SET and output Q to TRUE
- On an R event, the internal state is set to RESET and output Q to FALSE
- The state Remains in state until a contrary event occurs.
- State changes are communicated via adapter Q.

Technical Features and Comparison with Standards

As with all event-driven bistable elements in IEC 61499 (see also Note 8 in Table A.1 of DIN EN 61499-1), there is no inherent “dominance” of one input, as is known from IEC 61131-3.

- **Comparison to IEC 61131-3**: See SR (Bistable, set with priority). While in the classic PLC world, if S1 and R are TRUE simultaneously, the set takes precedence, in IEC 61499, each event is processed sequentially. The final state depends on which event was processed last in the execution chain (ECC).
- **Functional Identity**: `AX_SR` is functionally identical to AX_RS. The different naming and pin arrangement are solely for the convenience of developers familiar with IEC 61131-3.
- **Adapter Communication**: The device makes its status available via the adapter `Q`.

State Overview

1. **START**: Initial state
2. **SET**: State after S-event, output Q.D1 = TRUE
3. **RESET**: State after R-event, output Q.D1 = FALSE

State Transitions:

- START ⟶ SET: On S-event
- SET ⟶ RESET: On R-event
- RESET ⟶ SET: On S-event

Application Scenarios

- Storage of switching states in distributed control applications
- State management via adapter interfaces
- Signal processing with memory function
- Monitoring of operating states

Related Function Blocks

- **AX_RS**: Functionally identical, inputs reversed in the symbol.
- **E_SR**: The standard equivalent with direct data/event outputs instead of adapters.

⚖️ Comparison with Similar Building Blocks

Compared to other memory elements, AX_SR offers:

- Clear separation of set and reset functionality
- Adapter-based interface for flexible integration
- Event-driven state changes
- Simple and robust state management

Comparison with E_SR

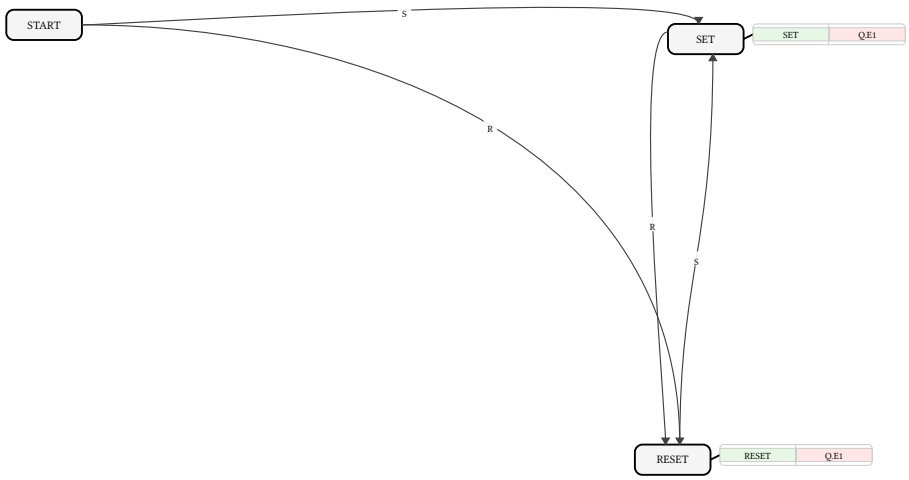
- Exercise_171_AX



Conclusion

The AX_SR function block provides a reliable and easy-to-use solution for bistable memory functions in distributed automation systems. Through the use of adapters, it enables flexible integration into various system architectures and offers a clear, event-driven interface for Set-reset operations.

AX_SR_SYM

ECC: AX_SR_SYM

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_SR_SYM** is an event-driven, bistable flip-flop with symmetrical turn-on behavior. It implements a set/reset memory, which is accessed via the events `S` (Set) and `R` (Reset). Unlike similar function blocks, the start state is not predefined; the block reacts to the first arriving event – regardless of whether it is `S` or `R`.

Interface Structure

Event Inputs

Name	Type	Description

S	Event	Sets output Q to TRUE.
R	Event	Sets output Q to FALSE.

Event Outputs

None (the output value is provided via an adapter).

Data Inputs

None.

Adapter

Name	Type	Description
Q	`adapter::types::unidirectional::AX`	Provides the current binary state. The adapter provides an event (`E1`) and a data value (`D1`). After each state change, `Q.E1` is triggered, and the new value is output to `Q.D1`.

Functionality

The function block is based on a simple state machine with three states:

- **START**: Initial state after startup. No output value is output.
- **SET**: The output is set to TRUE. Upon entering this state, `Q.E1` is triggered, and `Q.D1` is set to `TRUE`.
- **RESET**: The output is set to FALSE. Upon entering this state, `Q.E1` is triggered, and `Q.D1` is set to `FALSE`.

Transitions occur exclusively through the events `S` and `R`. From the START state, both `S` and `R` lead to SET (symmetrical behavior). From SET, only `R` leads to RESET, and from RESET, only `S` leads back to SET.

Technical Features

- **Symmetrical Start-up Behavior**: The function block starts in the START state without a defined output value. Only the first arriving event (S or R) determines the initial state. This differs from function blocks that initialize to FALSE or TRUE by default.
- **Adapter Interface**: The state is not directly transmitted as a data output, but via a unidirectional adapter (`AX`). Changes are signaled by an event (`Q.E1`), allowing the receiving function block to react asynchronously.

State Overview

State	Description
START	Waiting for first event; no output value defined.
SET	Output value TRUE; set by event `S`.
RESET	Output value FALSE; reset by event `R`.

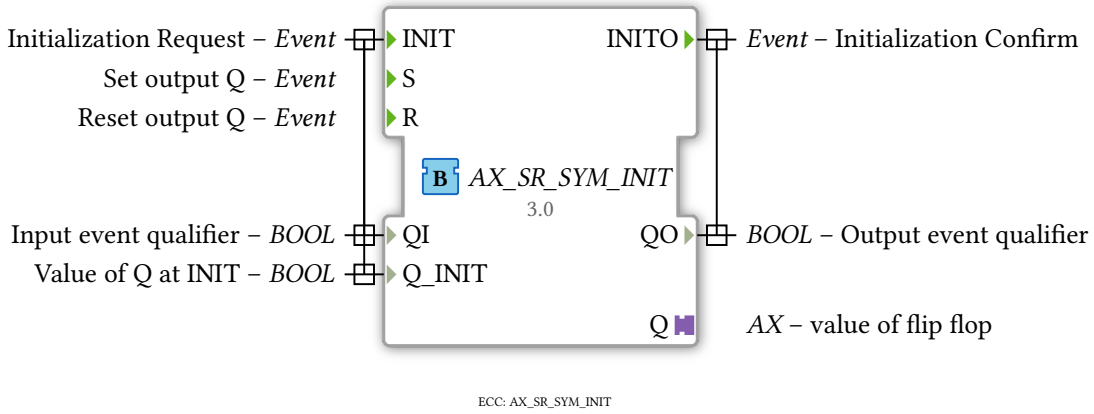
Transitions:

- START ⟶ SET on event `S`
- START ⟶ RESET on event `R`
- SET ⟶ RESET on event `R`
- RESET ⟶ SET on event `S`

Application Scenarios

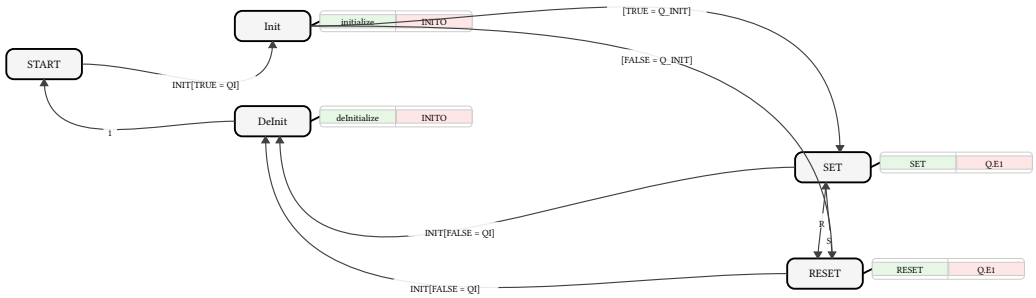
- **Storing a binary state** in control logic where the initial value is defined by an event.
- **Event-driven switches** in conjunction with adapter-based communication patterns.
- **Replacing an SR flip-flop** when symmetrical turn-on behavior is required.

Comparison with Similar Function Blocks



- **SR Flip-Flop** (e.g., `AX_SR`): Often has a defined initial value (e.g., FALSE) and behaves asymmetrically when both inputs are active simultaneously. In contrast, the `AX_SR_SYM` only sets its initial value upon the first event.

- **RS Flip-Flop**: Fundamentally similar logic, but with reversed priority (reset dominates). The `AX_SR_SYM` has no priority – the last received input determines the state.
- **Adapter-Based Function Blocks**: Advantage of event-driven state transfer via adapters; many standard function blocks use direct data outputs instead.



Conclusion

The `AX_SR_SYM` is ideally suited for applications requiring bistable memory behavior with an undefined initial value. The symmetrical response to `S` and `R` in the startup state, as well as the output via an adapter, makes it a flexible component in event-driven automation systems.

AX_SR_SYM_INIT

ECC: AX_SR_SYM_INIT

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_SR_SYM_INIT** implements an event-driven, bistable flip-flop (set-reset) with symmetrical start-up behavior and special initialization logic. It extends the classic SR flip-flop with a qualified initialization and deinitialization sequence, where the output state is specified via the input `Q_INIT`, and the entire logic is only active if the qualifier `QI` has the value `TRUE`.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initialization request; linked to QI and Q_INIT
S	Event	Sets output Q (via adapter)
R	Event	Resets output Q

Event Outputs

Event	Type	Description
INITO	EInit	Initialization confirmation; linked to QO

Data Inputs

Variable	Type	Description
QI	BOOL	Input qualifier – controls whether actions are executed
Q_INIT	BOOL	Desired value of the output Q after initialization

Data Outputs

Variable	Type	Description
QO	BOOL	Output qualifier – reflects the value of QI at the time of the triggering event

Adapters

Adapter	Type	Description
Q	adapter::types::unidirectional::AX	Flip-flop value – set/reset via the interface

Functionality

The function block has four main states: START, Init, DeInit, SET, and RESET.

- **START** – Wait state after system startup.
- **Init** – Activated when INIT and QI = TRUE are both present. In this state, the algorithm initialize is executed, which sets QO := QI. The state then branches depending on Q_INIT:
- If Q_INIT = TRUE is present, the system switches to the SET state (the flip-flop is set).
- If Q_INIT = FALSE is present, the system switches to the RESET state (the flip-flop is reset).
- **DeInit** – Activated when INIT and QI = FALSE occur (from states SET or RESET). The algorithm deInitialize sets QO := FALSE. Afterwards, the state reverts to START.
- **SET** – Reached by the event S (from RESET or after initialization with Q_INIT=TRUE). The algorithm SET sets QO := QI and writes the value TRUE to the adapter output Q.D1 **only if QI = TRUE**. A subsequent S has no effect as long as the state SET is active.
- **RESET** – This is reached by the event R (from SET or after initialization with Q_INIT=FALSE). The algorithm RESET sets QO := QI and writes the value FALSE to Q.D1 **only if QI = TRUE**. A subsequent R has no effect.

The transitions between SET and RESET are triggered only by the events S and R, respectively. The INIT transitions can result from either stable state in DeInit if QI = FALSE is present. …

Technical Features

- **Qualifier-Dependent Actions**: The actual change to the flip-flop output (Q.D1) only occurs if QI = TRUE is present. Otherwise, only the output qualifiers (QO) are updated; the adapter remains unchanged.

- **Symmetrical Startup**: The device can be initialized with either a "set" or a "reset" state, depending on the value of `Q_INIT`.
- **Deinitialization**: If `QI = FALSE` is present during initialization, the device is set to the `DeInit` state, which clears the output qualifier and then returns to the startup state.
- **Guard Conditions**: The state transitions use conditions like `INIT[TRUE = QI]` or `[FALSE = Q_INIT]` to precisely control the logic.

State Overview

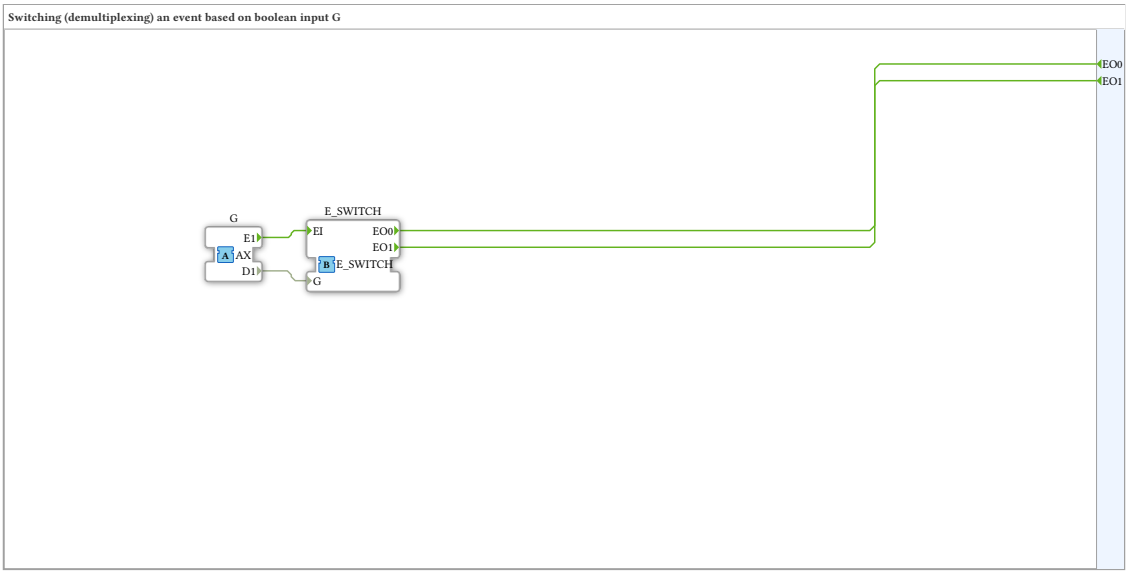
- **START** → Idle state after startup.
- **Init** → Initialization run (only with `QI=TRUE`).
- **DeInit** → Deinitialization run (only with `QI=FALSE`).
- **SET** → Stable state in which `Q.D1 = TRUE` is set (if previously set).
- **RESET** → Stable state in which `Q.D1 = FALSE` is reset (if previously reset).

Transitions:

- `START` → `Init` : if `INIT` & `QI=TRUE`
- `Init` → `SET` : if `Q_INIT=TRUE`
- `Init` → `RESET` : if `Q_INIT=FALSE`
- `SET` → `RESET` : if `R`
- `RESET` → `SET`: if `S`
- `SET` → `DeInit`: if `INIT` & `QI=FALSE`
- `RESET` → `DeInit`: if `INIT` & `QI=FALSE`
- `DeInit` → `START`: automatically after completion of the DeInit algorithm

Application Scenarios

- **Control of actuators with defined start behavior**: A motor or valve should perform a certain action after being switched on. Assume a specific state (e.g., closed = `Q=FALSE`), depending on an initialization specification.
- **Qualified State Changes**: In systems where an enable signal (`QI`) allows the actual value change, while the qualifier output (`QO`) signals validity.
- **Resettable Initialization Routine**: A component can be set or reset by an INIT call, but can later be put into a defined idle state by another INIT call with `QI=FALSE`.

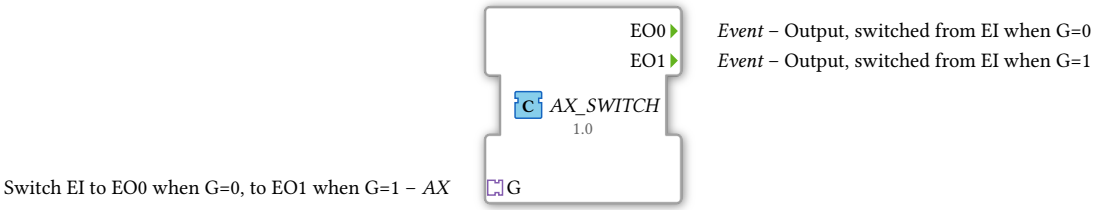


Comparison with Similar Function Blocks

- **Standard SR Flip-Flop (e.g., `SR` or `AX_SR`)**: Simple set/reset without initialization or qualifier. `AX_SR_SYM_INIT` additionally offers a qualified initialization and deinitialization process.
- **Function Blocks with INIT Interface (e.g., `E_SR` with `INIT`)**: These often lack pronounced deinitialization or a qualifier. The function block presented here differs in its symmetrical behavior – both setting and resetting can be specified in the INIT step.
- **Function Blocks with Adapter (`unidirectional::AX`)**)**: These are used to transmit the state externally via a standardized adapter interface. The `AX_SR_SYM_INIT` encapsulates this logic in a function block.

Conclusion

The `AX_SR_SYM_INIT` is a versatile function block for applications that require qualified startup and initialization behavior. By combining event control, qualifier logic, and an adapter interface, it is particularly suitable for modular automation solutions according to IEC 61499, where a defined system startup and clean deinitialization are required.



AX_SWITCH

• – ○ • – ○ • – ○ •

Introduction

The AX_SWITCH function block serves as a switching module (demultiplexer) for events based on a Boolean input value. It forwards incoming events to one of two possible outputs, depending on the state of the control signal.

Interface Structure

Event Inputs

- No direct event inputs - event input is handled via adapters

Event Outputs

- **EO0**: Output event that is activated when an event occurs at G=0
- **EO1**: Output event that is activated when an event occurs at G=1

Data Inputs

- No direct data inputs - data is provided via adapters

Data Outputs

- No data outputs available

Adapters

- **G**: Adapter of type `adapter::types::unidirectional::AX`
- Switches incoming events from EI to EO0 when G=0
- Switches incoming events from EI to EO1 when G=1

Functionality

The AX_SWITCH block receives events and control data via adapter G. Based on the Boolean value of the The control signal G forwards each incoming event either to output EO0 (when G=0) or to output

EO1 (when G=1). Internally, the block uses an E_SWITCH function block to implement the switching function.

Technical Features

- Implemented as a wrapper around the standard E_SWITCH function block
- Uses unidirectional adapters for event and data communication
- No direct interfaces; all communication occurs via adapters

State Overview

The block has no internal states in the traditional sense. It operates purely event-driven and immediately forwards each incoming event to the corresponding output based on the current value of G.

Application Scenarios

- Control of alternative process paths
- Switching between operating modes
- Distribution functions in event-based controllers
- Demultiplexing of event streams

⚖️ Comparison with Similar Function Blocks

Compared to the standard E_SWITCH block, AX_SWITCH offers an adapter-based interface, enabling better integration into adapter-based architectures. While E_SWITCH has direct inputs and outputs, AX_SWITCH communicates exclusively via adapters.

Comparison with E_SWITCH

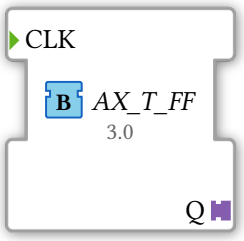
- Uebung_020f2_AX
- Uebung_020i_AX

Conclusion

AX_SWITCH is a specialized switching device for event-based systems thanks to its adapter-based architecture It enables flexible integration into more complex control systems. The clear separation of event and data flow via adapters ensures a clear system structure.

AX_T_FF



• – ○ • – ○ • – ○ •

Introduction

The AX_T_FF (Toggle Flip-Flop) is a fundamental memory component in 4diac that functions as a toggle flip-flop. With each clock event, the output value toggles between its two possible states. The component implements a simple switching behavior where the output value is toggled on each clock pulse.

Clock for triggering a output toggle – *Event*

AX – value of flip flop

Interface Structure

Event Inputs

- **CLK**: Clock input that triggers an output toggle

Event Outputs

- No direct event outputs available

Data Inputs

- No data inputs available

Data Outputs

- No direct data outputs available

Adapters

- **Q**: Unidirectional adapter of type AX that provides the current flip-flop value

Functionality

The AX_T_FF operates as a simple toggle flip-flop. Upon each incoming CLK event, the TOGGLE algorithm is executed, which inverts the current value of adapter Q.D1. The device starts in the START state and transitions to the SET state upon each CLK event, where the toggle is performed.

Technical Features

- Uses a unidirectional adapter for output
- Implemented as a Basic Function Block (BFB)
- Features a simple two-state machine
- The TOGGLE algorithm performs a logical negation of the output value

State Overview

The block has two states:

1. **START**: Initial state, waits for a CLK event
2. **SET**: Active state in which the TOGGLE algorithm is executed

State Transitions:

- START ⟶ SET: On a CLK event
- SET ⟶ START: Always (Condition "1" = true)

Application Scenarios

- Frequency division of clock signals
- Generation of square waves with half the input frequency
- Counter and divider circuits
- State control with alternating behavior

⚖️ Comparison with Similar Blocks

Compared to other flip-flop types such as RS or D flip-flops, the A toggle flip-flop is a specialized functionality for simple switching operations. It has a simpler structure than more general-purpose flip-flop types and requires no additional data inputs.

Comparison with E_T_FF

AX_T_FF_INIT

ECC: AX_T_FF_INIT

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_T_FF_INIT** implements a triggered toggle flip-flop with an initialization function. It can be set to a defined start state via an INIT event and subsequently toggles between the SET and RESET states with each CLK event. The current state is provided via an adapter output. This block is particularly suitable for applications where an output signal needs to be switched at each clock cycle, with the initial state defined by initialization.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization request; triggers the initialization of the flip-flop. The corresponding data inputs QI and Q_INIT are evaluated.
CLK	Event	Clock input; the internal state toggles between SET and RESET with each event.

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization confirmation; output after successful initialization or deinitialization.

Data Inputs

Name	Type	Comment
QI	BOOL	Input qualifier; controls whether actions are actually executed (TRUE = active).
Q_INIT	BOOL	Value assigned to the flip-flop during initialization (TRUE = SET, FALSE = RESET).

Data Outputs

Name	Type	Comment
QO	BOOL	Output qualifier; reflects the value of QI if an action has been performed, otherwise FALSE.

Adapters

Name	Type	Comment
Q	Adapter `adapter::types::unidirectional::AX`	Adapter output that passes the current flip-flop state (TRUE or FALSE) to connected function blocks.

Functionality

The function block has the following internal states: START, Init, DeInit, SET, and RESET.

1. **Initialization (INIT Event)**

- On an INIT event with **QI** = **TRUE**, the system transitions from the start state to the **Init** state.
- In the Init state, the algorithm *initialize* is executed: `QO := QI`.
- Subsequently, the output qualifier QO is set to TRUE, and the **INITO** event is output.
- Depending on the value of **Q_INIT**, the transition occurs:

If Q_INIT = TRUE ⟶ transition to the **SET** state
If Q_INIT = FALSE ⟶ transition to the **RESET** state

1. **Toggle Operation (CLK Event)**

- Starting from **SET** or **RESET**, the state changes with each **CLK** event:
- From SET ⟶ RESET (and vice versa)

- Upon exiting the states, the corresponding algorithms are executed:
- **SET**: `QO := QI;` If QI = TRUE, **Q.D1** = **TRUE** is assigned to the adapter output.
- **RESET**: `QO := QI;` If QI = TRUE, **Q.D1** = **FALSE** is assigned to the adapter output.
- In both cases, the event **Q.E1** is output (via the adapter).

1. **Deinitialization (INIT event with QI = FALSE)**

- If an INIT event with **QI** = **FALSE** occurs during operation (in SET or RESET), the function block switches to the **DeInit** state.
- The *deInitialize* algorithm sets `QO := FALSE`.
- **INITO** is output, and the function block returns to the start state.

The function block remains in the start state until an INIT event with QI = TRUE occurs. Toggle operation is not possible without initialization.

Technical Features

- **Adapter-based output signal**: The current flip-flop state is not provided as a simple data output, but via an **adapter** (`adapter::types::unidirectional::AX`). This enables flexible and typed communication with other function blocks that use the same adapter.
- **State-Dependent Execution**: The actions (setting/resetting the adapter output) are only executed if the qualifier **QI** = TRUE. If QI = FALSE, the adapter output is not changed, but the state still changes.
- **Initialization with Start Value**: The initial state after initialization can be specifically defined via the input **Q_INIT** (TRUE = set, FALSE = reset).

State Overview

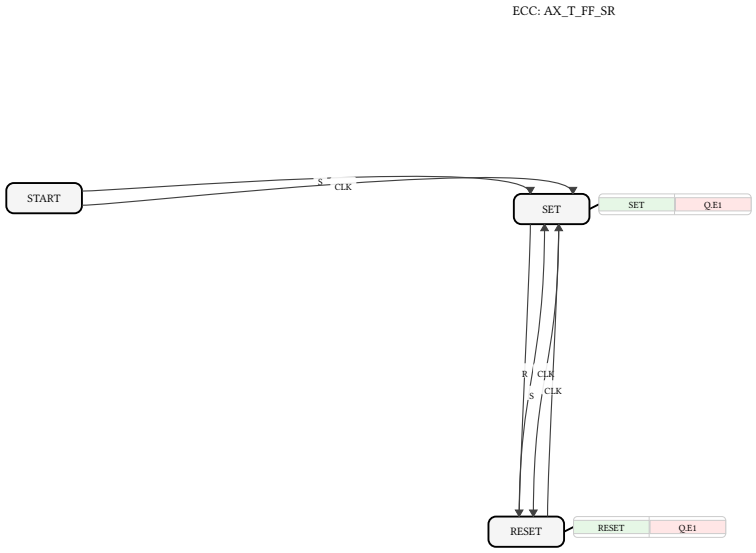
State	Meaning
START	Waiting for first INIT event.
Init	Initialization is in progress; QO is set to QI, then transition to SET or RESET depending on Q_INIT.
DeInit	Deinitialization is in progress; QO is set to FALSE, return to START.
SET	Flip-flop is in the set state; Adapter output Q.D1 = TRUE (when QI=TRUE).
RESET	Flip-flop is in the reset state; adapter output Q.D1 = FALSE (when QI=TRUE).

The state transitions are controlled by the INIT event (with a corresponding condition on QI) and CLK.

Application Scenarios

- **Controlling outputs with toggle function**: A digital output should switch between on and off with each clock cycle, e.g., for blink signals or pulse trains.
- **Initializable state machines**: In automation systems where a process must assume a defined start state (set or reset) after a reset.
- **Adapter-based communication**: Devices using the same adapter can directly read the flip-flop state without relying on separate data outputs.

Comparison with similar devices

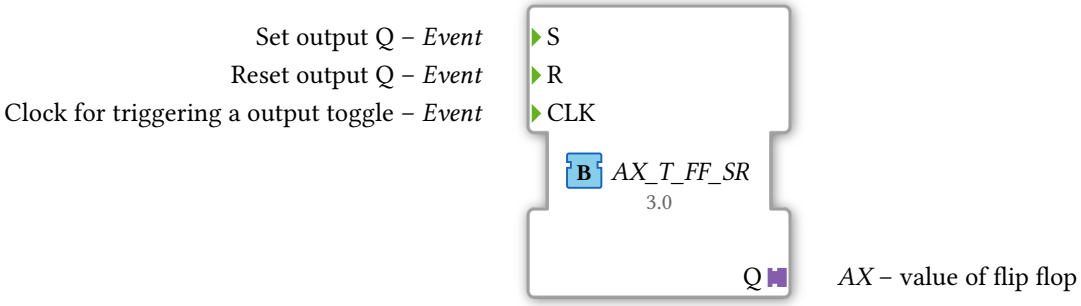


Criterion	AX_T_FF_INIT	Simple Toggle Flip-Flop (without INIT)	SR Flip-Flop
Initialization	Yes, via INIT with Q_INIT	No, state undefined after startup	No (set/reset via separate inputs)
State Change	Clocked by CLK	Clocked by CLK	Asynchronous via S and R
Output	Via adapter (typed)	Often as a BOOL data output	BOOL data output
Qualifier QI	Controls whether an action is executed	Not present	Not present

Compared to a simple toggle flip-flop, the **AX_T_FF_INIT** offers the possibility of defined initialization and uses an adapter for the output, which simplifies configuration in complex systems.

Conclusion

The function block **AX_T_FF_INIT** is a versatile building block for clocked toggle operations with initialization logic. Its combination of INIT and CLK events, the QI qualifier, and the adapter output allows for precise control of the state behavior. It is particularly suitable for industrial automation applications where a defined start value and clocked switching are required.



AX_T_FF_SR

• – ○ • – ○ • – ○ •

Introduction

The AX_T_FF_SR is an event-driven bistable function block with toggle functionality. It is a flip-flop element that can operate as both a set-reset flip-flop and a toggle flip-flop. The component combines the properties of an SR flip-flop with additional toggle functionality via a clock input.

Interface Structure

Event Inputs

- **S**: Sets output Q to TRUE
- **R**: Sets output Q to FALSE (Reset)
- **CLK**: Clock signal for toggling the output

Event Outputs

- No direct event outputs available

Data Inputs

- No data inputs available

Data Outputs

- No direct data outputs available

Adapters

- **Q**: Unidirectional AX-type adapter that provides the flip-flop value

Operation

The AX_T_FF_SR has three operating states:

- **START**: Initial state
- **SET**: Output Q is TRUE
- **RESET**: Output Q is FALSE

The state transitions are controlled by the event inputs:

- The S event transitions from any state to the SET state.

The R event transitions from any state to the RESET state.
The CLK event toggles the current state (SET → RESET or RESET → SET).
With each state change, the corresponding algorithm is executed, setting the adapter value Q.D1 accordingly.

Technical Features

- Combines SR flip-flop and T flip-flop functionality
- Uses the adapter interface for data output
- Unidirectional communication via the Q adapter
- Initial state is START, from which a transition to SET can occur directly or via CLK

State Overview

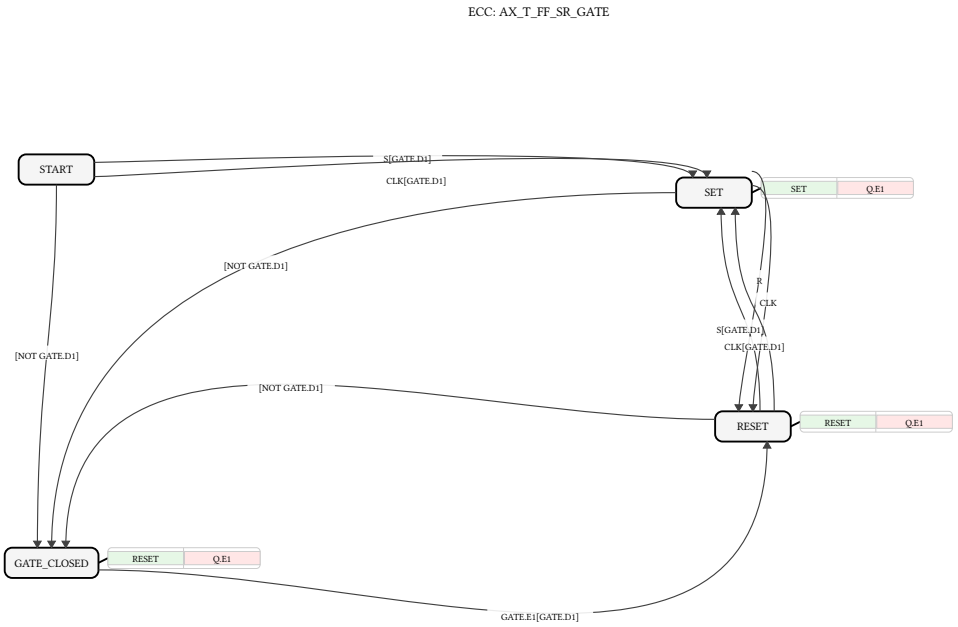
START (Initialzustand) │ ├── S ──→ SET (Q.D1 = TRUE) │ └── CLK ──→ SET (Q.D1 = TRUE)
SET (Q.D1 = TRUE) │ ├── R ──→ RESET (Q.D1 = FALSE) │ └── CLK ──→ RESET (Q.D1 = FALSE)
RESET (Q.D1 = FALSE) │ ├── S ──→ SET (Q.D1 = TRUE) │ └── CLK ──→ SET (Q.D1 = TRUE)

Application Scenarios

- State storage in control applications
- Clock and frequency division
- Event counting
- State machines with memory function
- Switching networks with feedback

⚖️ Comparison with similar components

Compared to a simple E_SR flip-flop, the AX_T_FF_SR offers additional toggle functionality through its CLK input. While a pure SR flip-flop only has set and reset inputs, this component also allows clock-controlled switching of the output state.
Comparison with E_T_FF_SR

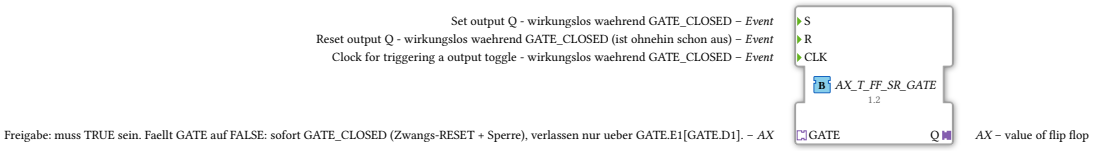


🛠️ Related exercises

- Uebung_004a7_AX
- Uebung_006a2_AX
- Uebung_006a3_AX
- Uebung_006a4_AX
- Uebung_006a_AX

Conclusion

The AX_T_FF_SR is a versatile bistable memory device that combines the advantages of SR and T flip-flops. Thanks to its adapter-based interface, it enables flexible integration into larger control systems and is particularly suitable for applications that require both direct state setting and clock-controlled switching.



AX_T_FF_SR_GATE

• – ○ • – ○ • – ○ •

Introduction

`AX_T_FF_SR_GATE` corresponds to `AX_T_FF_SR`, but additionally has an enable socket `GATE` (`AX`) and a state of its own, `GATE_CLOSED`, without chaining (no `CHAIN_IN`/`CHAIN_OUT`). It is suited for cases where only the gate lock is needed but no chain delay; for the chained variant see `AX_T_FF_SR_SEQ_GATE`.

Interface Structure

Event Inputs

- **S**: Sets the output `Q` - no effect during `GATE_CLOSED`
- **R**: Resets the output `Q` - no effect during `GATE_CLOSED` (it is off there anyway)
- **CLK**: Clock for toggling the output - no effect during `GATE_CLOSED`

Event Outputs

No direct event outputs - the event is output via `Q.E1`.

Data Inputs / Data Outputs

None.

Adapters

- **Q** (plug, `adapter::types::unidirectional::AX`): Value of the flip-flop

- **GATE** (socket, `adapter::types::unidirectional::AX`): Enable, must be `TRUE`. If `GATE` falls to `FALSE`, the block immediately enters `GATE_CLOSED` (forced reset and lock); this state is left only via `GATE.E1[GATE.D1]`

How it works

States and actions:

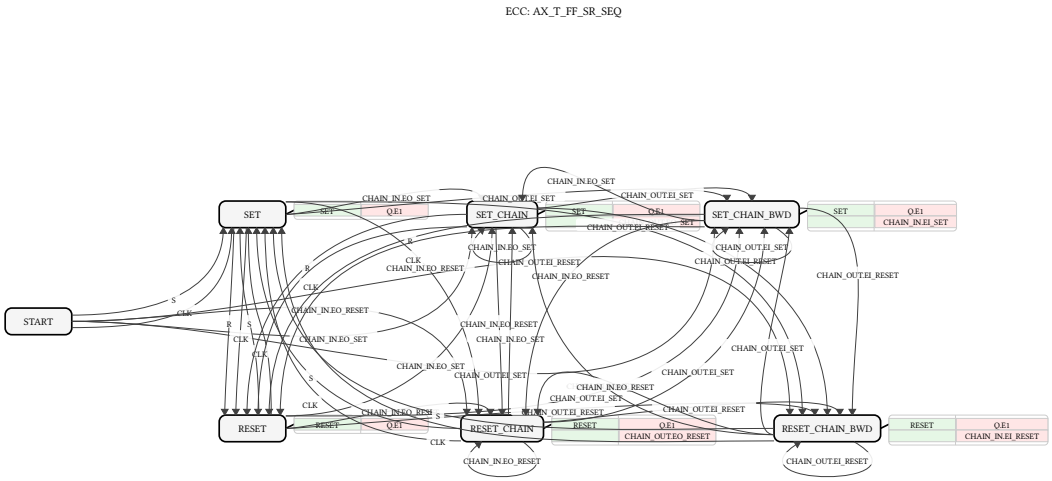
- **START**: Initial state
- **SET**: Algorithm `SET` (`Q.D1 := TRUE`), output `Q.E1`
- **RESET**: Algorithm `RESET` (`Q.D1 := FALSE`), output `Q.E1`
- **GATE_CLOSED**: locked (`GATE.D1 = FALSE`), `Q` forced to `FALSE` (algorithm `RESET`, output `Q.E1`); `S`/`R`/`CLK` have no effect here

Transitions (in declaration order):

From	To	Condition
START	GATE_CLOSED	`[NOT GATE.D1]`
START	SET	`S[GATE.D1]`
START	SET	`CLK[GATE.D1]`
SET	GATE_CLOSED	`[NOT GATE.D1]`
SET	RESET	`R`
SET	RESET	`CLK`
RESET	GATE_CLOSED	`[NOT GATE.D1]`
RESET	SET	`S[GATE.D1]`
RESET	SET	`CLK[GATE.D1]`
GATE_CLOSED	RESET	`GATE.E1[GATE.D1]`

Technical Details

- **Lock first**: `[NOT GATE.D1]` comes first in the declaration order of every state. Since `S`/`CLK` without a guard are always `TRUE`, according to IEC 61499-1 Table 1 rule c) the gate lock would otherwise never take effect (bugfix v1.2). If the gate is open, the guard is `FALSE` and is skipped
- **Boot window**: The event-less transition `START` → `GATE_CLOSED` is evaluated immediately on entering `START` and covers the state before a `GATE.E1` has ever fired (v1.1)
- From `GATE_CLOSED` the block returns only to `RESET`, so `Q` stays `FALSE` until `S` or `CLK` takes effect
- Copy of `AX_T_FF_SR` with `GATE` socket and state `GATE_CLOSED`, same pattern as `AX_T_FF_SR_SEQ_GATE`



Application Scenarios

- Toggle/set-reset output that must be forcibly locked by an enable (e.g. safety or operating enable)

Summary

`AX_T_FF_SR_GATE` is a toggle/SR flip-flop with enable: if `GATE` is `FALSE`, `Q` is reset and all inputs remain without effect until the enable returns.

AX_T_FF_SR_SEQ

• — ○ • — ○ • — ○ •

Introduction

`AX_T_FF_SR_SEQ` is an event-driven bistable flip-flop with toggle function (a copy of `AX_T_FF_SR`) that is additionally **truly bidirectionally chainable** via the adapter `ASR2` (`CHAIN_IN`/`CHAIN_OUT`). This allows several belts to be switched on and off in a staggered manner (e.g. together with `ASR2_DELAY`). The local events `S`/`R`/`CLK` behave exactly like in `AX_T_FF_SR` and **never** trigger `CHAIN_IN`/`CHAIN_OUT`.

Interface Structure

Event Inputs

- **S**: Sets output `Q` (local, never affects `CHAIN_IN`/`CHAIN_OUT`)
- **R**: Resets output `Q` (local, never affects `CHAIN_IN`/`CHAIN_OUT`)
- **CLK**: Clock for toggling the output (local, never affects `CHAIN_IN`/`CHAIN_OUT`)

Event Outputs

No direct event outputs - events run via the adapter plugs

Data Inputs

No data inputs

Data Outputs

No data outputs - the state is output via the adapter `Q`

Adapters

- **Q** (plug): Unidirectional adapter of type `adapter::types::unidirectional::AX` - value of the flip-flop
- **CHAIN_IN** (socket): Bidirectional adapter of type `adapter::types::bidirectional::ASR2` - forward: receive set/reset from the previous chain element (`EO_SET`/`EO_RESET`); backward: pass set/reset on to the previous chain element (`EI_SET`/`EI_RESET`)
- **CHAIN_OUT** (plug): Bidirectional adapter of type `adapter::types::bidirectional::ASR2` - forward: pass set/reset on to the next chain element (`EO_SET`/`EO_RESET`); backward: receive set/reset from the next chain element (`EI_SET`/`EI_RESET`)

How it works

The block has seven states (`START`, `SET`, `RESET`, `SET_CHAIN`, `RESET_CHAIN`, `SET_CHAIN_BWD`, `RESET_CHAIN_BWD`). On entering a set state the output `Q` is set to `TRUE` by the algorithm `SET`, in a reset state to `FALSE` by `RESET`, and output via `Q.E1`.

There are **four strictly separate, non-branching chain paths**:

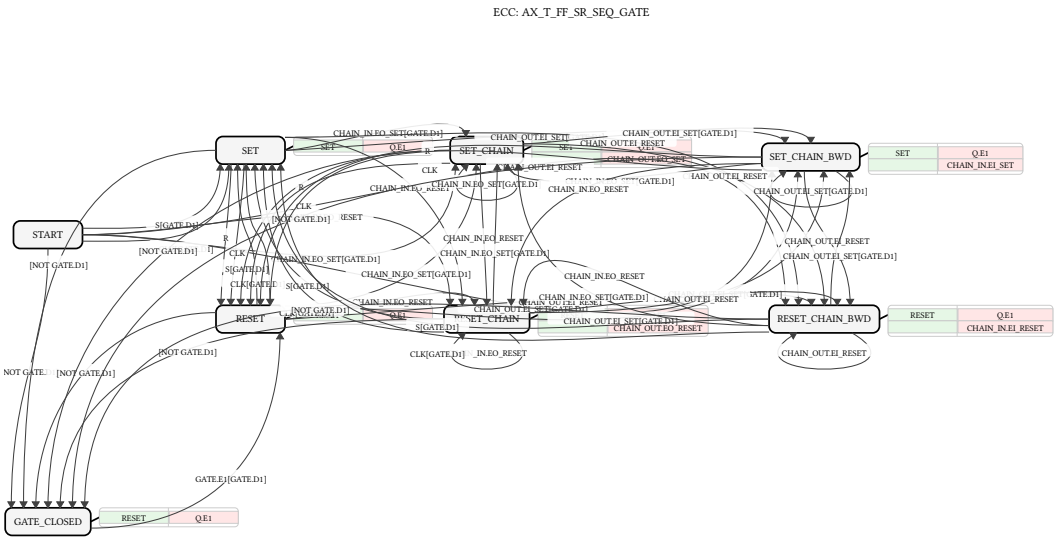
1. `CHAIN_IN.EO_SET` ⟶ local `SET` + `CHAIN_OUT.EO_SET` (forward set)
2. `CHAIN_IN.EO_RESET` ⟶ local `RESET` + `CHAIN_OUT.EO_RESET` (forward reset)
3. `CHAIN_OUT.EI_SET` ⟶ local `SET` + `CHAIN_IN.EI_SET` (backward set)
4. `CHAIN_OUT.EI_RESET` ⟶ local `RESET` + `CHAIN_IN.EI_RESET` (backward reset)

A set arriving via path 1 never additionally triggers path 3 or 4 and vice versa - each state fires exactly one chain action. Locally:

- `S` or `CLK` in `START` or `RESET`/`RESET_CHAIN`/`RESET_CHAIN_BWD` ⟶ `SET`
- `R` or `CLK` in `SET`/`SET_CHAIN`/`SET_CHAIN_BWD` ⟶ `RESET`
- The four chain events are possible from every state and lead to the respective chain state.

Technical Details

- Local `S`/`R`/`CLK` only changes `Q`; the chain is not triggered.
- With the backward paths (version 1.1) the same physical chain elements can be switched in a staggered manner both forward (e.g. set, downstream first) and backward (e.g. reset, upstream first), without a forward event also propagating backward or vice versa.
- An `R` in state `START` has no effect, since no transition with `R` exists from there.



Application Scenarios

- Staggered switching on/off of several conveyor belts (e.g. hedgehog belt, elevator, cross belt) with delay via `ASR2_DELAY`

Summary

`AX_T_FF_SR_SEQ` extends the set/reset/toggle flip-flop by four separate chain paths (forward/backward, set/reset) for cascaded, staggered switching operations.

AX_T_FF_SR_SEQ_GATE

• — ○ • — ○ • — ○ •

Introduction

The `AX_T_FF_SR_SEQ_GATE` is a toggle/set/reset flip-flop with bidirectional chain forwarding, like `AX_T_FF_SR_SEQ`, and additionally has an enable socket `GATE` (type `AX`) and a dedicated state `GATE_CLOSED`. While `GATE` is TRUE the block works normally. If `GATE` falls to FALSE, a RESET is forced immediately and the block is locked; the only way out of `GATE_CLOSED` is `GATE.E1[GATE.D1]`, i.e. reopening the gate.

Interface Structure

Event Inputs

- **S**: sets the output `Q` (local, never acts on `CHAIN_IN`/`CHAIN_OUT`); has no effect during `GATE_CLOSED`
- **R**: resets the output `Q` (local); has no effect during `GATE_CLOSED`
- **CLK**: clock for toggling the output (local); has no effect during `GATE_CLOSED`

Event Outputs

The function block has no direct event outputs.

Data Inputs

The function block has no direct data inputs.

Data Outputs

The function block has no direct data outputs.

Adapters

- **Q** (plug, `adapter::types::unidirectional::AX`): value of the flip-flop
- **CHAIN_OUT** (plug, `adapter::types::bidirectional::ASR2`): forward Set/Reset to the next chain element (`EO_SET`/`EO_RESET`), backward Set/Reset received from the next chain element (`EI_SET`/`EI_RESET`); not during `GATE_CLOSED`
- **CHAIN_IN** (socket, `adapter::types::bidirectional::ASR2`): forward Set/Reset received from the previous chain element (`EO_SET`/`EO_RESET`), backward Set/Reset passed on to the previous chain element (`EI_SET`/`EI_RESET`); not during `GATE_CLOSED`
- **GATE** (socket, `adapter::types::unidirectional::AX`): enable, must be TRUE. If `GATE` falls to FALSE, `GATE_CLOSED` follows immediately (forced RESET and lock); the state is left only via `GATE.E1[GATE.D1]`

Functionality

The ECC has the states `START`, `SET`, `RESET`, `SET_CHAIN`, `RESET_CHAIN`, `SET_CHAIN_BWD`, `RESET_CHAIN_BWD` and `GATE_CLOSED`. There are four strictly separate chain paths (forward set, forward reset, backward set, backward reset) without event duplication:

- **Local**: `S[GATE.D1]` or `CLK[GATE.D1]` leads to `SET` (algorithm `SET`: `Q.D1 := TRUE`, output `Q.E1`); `R` or `CLK` from a set state leads to `RESET` (`Q.D1 := FALSE`). These local events never act on the chain.
- **Forward**: `CHAIN_IN.EO_SET[GATE.D1]` leads to `SET_CHAIN` (sets `Q` and outputs `CHAIN_OUT.EO_SET`), `CHAIN_IN.EO_RESET` leads to `RESET_CHAIN` (resets `Q` and outputs `CHAIN_OUT.EO_RESET`).
- **Backward**: `CHAIN_OUT.EI_SET[GATE.D1]` leads to `SET_CHAIN_BWD` (sets `Q` and outputs `CHAIN_IN.EI_SET`), `CHAIN_OUT.EI_RESET` leads to `RESET_CHAIN_BWD` (resets `Q` and outputs `CHAIN_IN.EI_RESET`).
- **Gate**: every state except `GATE_CLOSED` has `[NOT GATE.D1]` to `GATE_CLOSED` as its first transition. There the algorithm `RESET` is executed with output `Q.E1`; `S`, `R`, `CLK`, `CHAIN_IN` and `CHAIN_OUT` have no effect because no transition is defined. The only way back to `RESET` is `GATE.E1[GATE.D1]`.

Technical Details

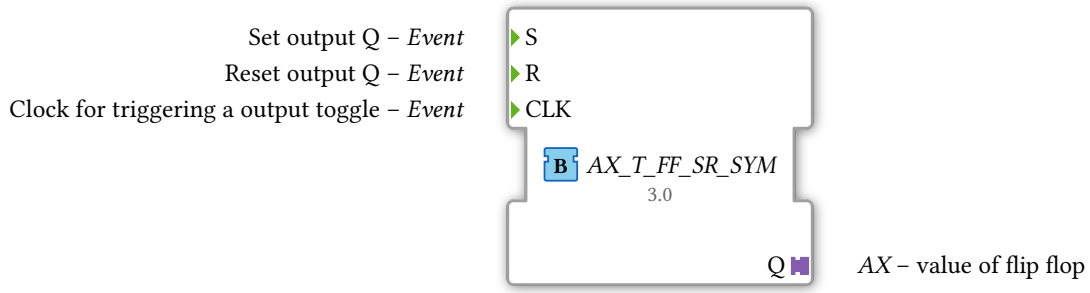
- The gate check `[NOT GATE.D1]` is eventless and comes first in the transition order of every state so that it is evaluated before the unguarded event transitions (e.g. `R`, `CLK`, `CHAIN_IN.EO_RESET`)
- The lock is level-based rather than a mere edge pulse on `R`: while the gate is closed, the block cannot be switched on again
- Set requests (`S`, `CLK` for setting, `CHAIN_IN.EO_SET`, `CHAIN_OUT.EI_SET`) are accepted only when `GATE.D1 = TRUE`; reset paths may always pass
- Nothing is forwarded to `CHAIN_IN`/`CHAIN_OUT` during `GATE_CLOSED`

State Overview

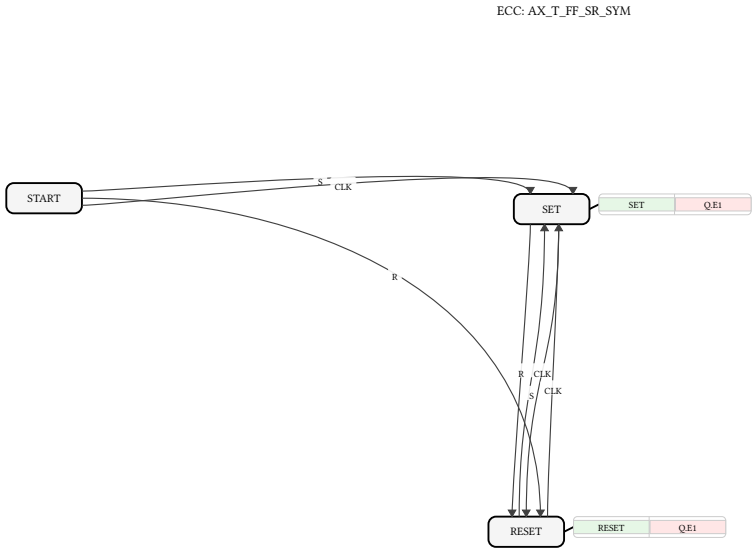
State	Meaning
START	initial state; with `GATE.D1 = FALSE` it goes to `GATE_CLOSED` immediately
SET	`Q` = TRUE through local `S/CLK`
RESET	`Q` = FALSE through local `R/CLK`
SET_CHAIN	`Q` = TRUE, set came forward and is passed on to `CHAIN_OUT.EO_SET`
RESET_CHAIN	`Q` = FALSE, reset came forward and is passed on to `CHAIN_OUT.EO_RESET`
SET_CHAIN_BWD	`Q` = TRUE, set came backward and is passed on to `CHAIN_IN.EI_SET`
RESET_CHAIN_BWD	`Q` = FALSE, reset came backward and is passed on to `CHAIN_IN.EI_RESET`
GATE_CLOSED	locked, `Q` = FALSE; exit only via `GATE.E1[GATE.D1]` to `RESET`

Application Scenarios

- Switchable outputs with a higher-level, level-based safety shutdown (e.g. PTO monitoring) that may only be switched on again after the enable has been granted again
- Sequenced chains of several flip-flops in which one element is to be locked depending on an enable



⚖️ Comparison with Similar Blocks



Compared with `AX_T_FF_SR_SEQ` (same four chain paths without an enable), `AX_T_FF_SR_SEQ_GATE` additionally offers the socket `GATE` and the state `GATE_CLOSED`. The lock is truly level-based here and thus solves a problem that a pure edge pulse on `R` does not: immediate re-enabling despite a shutdown that is still present.

Conclusion

The `AX_T_FF_SR_SEQ_GATE` extends the sequenceable AX flip-flop with a level-based enable: if `GATE` falls, the block is reset and locked immediately, and only a renewed `GATE.E1[GATE.D1]` releases it again.

AX_T_FF_SR_SYM

• – ○ • – ○ • – ○ •

Introduction

The AX_T_FF_SR_SYM function block is an event-driven bistable toggle switch with an additional toggle function and symmetrical start behavior. It combines the characteristics of an SR flip-flop (set and reset) with those of a T flip-flop (toggling on every clock signal). The behavior after power-on is symmetrical, meaning the block is initially in a neutral start state and only transitions to a defined state upon an event.

Interface Structure

Event Inputs

- **S** – Set: Sets output Q to TRUE.
- **R** – Reset: Sets output Q to FALSE.
- **CLK** – Clock: Toggles the output Q (TRUE ⟶ FALSE or FALSE ⟶ TRUE).

Event Outputs

No direct event outputs. The state is output via adapter Q. The adapter triggers event Q.E1 upon a state change.

Data Inputs

None.

Data Outputs

No direct data outputs. The current value is provided via adapter Q (Q.D1).

Adapters

- **Q**: Adapter of type `adapter::types::unidirectional::AX` (unidirectional). Provides the current state of the flip-flop as a Boolean value (TRUE/FALSE). The adapter triggers event Q.E1 after each state change.

Functionality

The function block (FB) has three event inputs and a state machine with three states: `START`, `SET`, and `RESET`.

- **START** is the initial state after power-on. In this state, no algorithm is active, and the output value is undefined.
- Upon receiving `S` or `CLK`, the FB transitions to state `SET`.
- Upon receiving `R`, it transitions to state `RESET`.
- In the **SET** state, the algorithm `SET` is executed: `Q.D1 := TRUE`. Then, the event `Q.E1` is triggered.
- At `R` or `CLK`, the function block transitions to the state `RESET`.
- In the **RESET** state, the algorithm `RESET` is executed: `Q.D1 := FALSE`. Then, `Q.E1` is triggered.
- At `S` or `CLK`, the function block (FB) switches back to state `SET`.

The toggle function is implemented by the `CLK` transitions: regardless of the current state, `CLK` leads to the other state.

Technical Features

- **Symmetrical Start Behavior**: After power-on, the FB is in the neutral `START` state. Only the first event determines the initial state. This allows for a defined system initialization.
- **Adapter-Based Output**: Instead of a direct data output, the state is provided via an adapter (`AX`). This enables flexible coupling with other function blocks and easy event propagation.
- **Combination of SR and T flip-flops**: This component combines set, reset, and toggle functions in a single compact unit.

State Overview

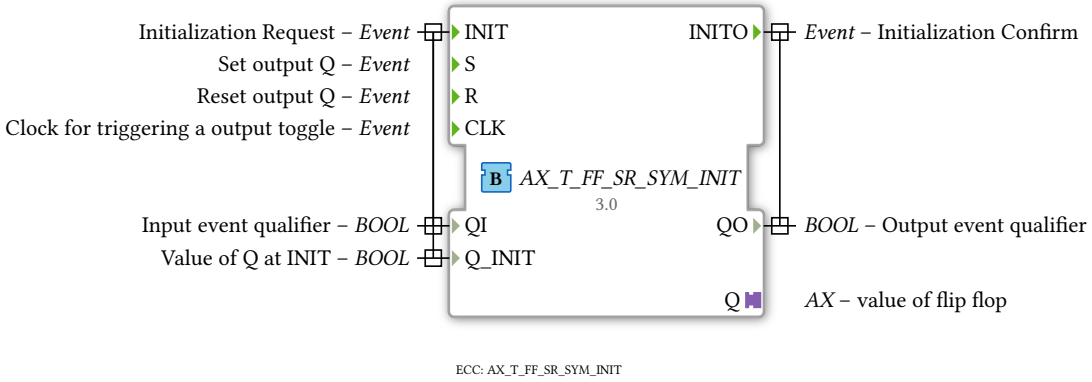
State	Description	Output Q.D1	Event by Algorithm
START	Initial state, no defined value	undefined	-
SET	Output is set to TRUE	TRUE	Q.E1
RESET	Output is set to FALSE	FALSE	Q.E1

Transitions (Event ⟶ Target State):

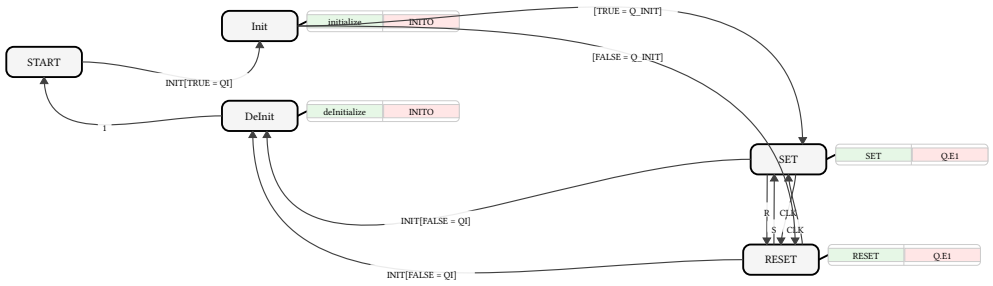
- START ⟶ SET: `S`, `CLK`
- START ⟶ RESET: `R`
- SET ⟶ RESET: `R`, `CLK`
- RESET ⟶ SET: `S`, `CLK`

Application Scenarios

- **Control of Binary Outputs**: An output can be set, reset, or toggled (e.g., manual operation with Set/Reset and automatic toggling via a clock signal).
- **Toggle Switching**: A process that changes its state with each clock signal but can also be explicitly set or reset.
- **Defined Start Sequences**: The symmetrical start behavior ensures that the component does not output any value after being powered on until a command arrives.



Comparison with Similar Components



- **E_SR (Pure SR Flip-Flop)**: Has only Set and Reset inputs, no toggle function. After startup, the output is typically FALSE.
- **E_T (Toggle Flip-Flop)**: Only a toggle input, no Set/Reset.
- **AX_T_FF_SR_SYM**: Combines all three functions and additionally offers a neutral start state, allowing for flexible initialization.

Conclusion

The AX_T_FF_SR_SYM is a versatile function block for binary state logic. The combination of Set, Reset, and Toggle, as well as the symmetrical start behavior, makes it particularly suitable for applications requiring both manual control and automatic switching. The adapter interface facilitates integration into modular systems such as IEC 61499.

AX_T_FF_SR_SYM_INIT

• – ○ • – ○ • – ○ •

Introduction

The function block **AX_T_FF_SR_SYM_INIT** implements an event-driven bistable flip-flop with **Set**, **Reset**, and **Toggle** functionality. It features **symmetrical start-up behavior**, where the output state after the INIT event can be defined via the parameter `Q_INIT`. The block is designed according to IEC 61499-1 Annex A and is suitable for applications requiring a resettable, set, or toggleable binary state with an initializable preset.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Initialization Request
S	Event	Set output Q (dependent on QI)
R	Event	Reset output Q (dependent on QI)
CLK	Event	Clock to toggle Q

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization Confirmation

Data Inputs

Variable	Type	Comment
QI	BOOL	Event Qualifier (Enable Actions)
Q_INIT	BOOL	Value of Q on the INIT event

Data Outputs

Variable	Type	Comment
QO	BOOL	Output Event Qualifier

Adapters

Adapter	Type	Comment
Q	adapter::types::unidirectional::AX	Value of the flip-flop (D1)

Functionality

The component has a finite state machine with five states: **START**, **INIT**, **DEINIT**, **SET**, and **RESET**.

- **START** is the initial state after power-on.
- An **INIT** event initiates the initialization:
- When `QI = TRUE` occurs, the system switches to the **Init** state. The algorithms `initialize` set `QO := QI`.
- Subsequently, based on `Q_INIT`, a decision is made whether to transition to the **SET** state (`Q_INIT = TRUE`) or the **RESET** state (`Q_INIT = FALSE`).
- During operation, **S**, **R**, or **CLK** can be processed:
- With **S** (Set), the adapter output `Q.D1` is set to `TRUE` in the algorithm `QI = TRUE`. `QO` receives the value of `QI`.
- With **R** (Reset), `Q.D1` is set to `FALSE`, also only if `QI` is active.
- With **CLK** (Toggle), the state is toggled: If the FB is in the **SET** state, a CLK event leads to the **RESET** state; if it is in **RESET**, it leads to **SET**. Does the toggle function operate independently of `QI`? *Note:* The transitions `SET–CLK→RESET` and `RESET–CLK→SET` are defined without further conditions; however, in the algorithms, `Q.D1` is only changed at `QI = TRUE`. If `QI = FALSE`, the adapter value remains unchanged, but the state transition still occurs. The internal state (SET/RESET) is always toggled, but the actual output to `Q.D1` only occurs if `QI` is true.
- A subsequent **INIT** event with `QI = FALSE` leads to the **DeInit** state, in which `QO := FALSE` is set. Afterward, the function block returns to the **START** state.

The output `QO` is set to the current value of `QI` with each executed algorithm. It serves as an event qualifier for the INITO output.

Technical Features

- **Symmetrical Start-up Behavior**: The initial value of the output is set via `Q_INIT`, allowing for both set and reset start states.
- **Event Qualifier QI**: The actual change to the adapter `Q.D1` (i.e., the flip-flop output) is only executed if `QI = TRUE`. With `QI = FALSE`, the events S, R, and CLK are processed (state change), but the adapter value remains unchanged.
- **Toggle Functionality**: The CLK event allows the output to be switched between 0 and 1, enabling simple square wave generation or state transitions in many applications.

- **INIT Handling**: The INIT event can be used for both initialization (`QI = TRUE`) and deinitialization (`QI = FALSE`).

State Overview

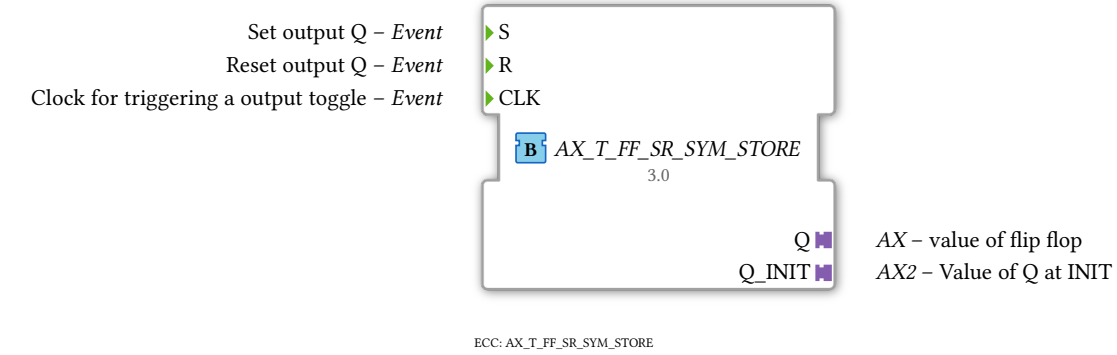
State	Action	Output/Event	Description
START	–	–	Waits for first INIT event.
Init	`initialize`	INITO	Sets `QO := QI`; Then switch to SET or RESET depending on `Q_INIT`.
DeInit	`deInitialize`	INITO	Sets `QO := FALSE`; then returns to START.
SET	`SET`	Q.E1	Sets `Q.D1 := TRUE` (if QI = TRUE) and `QO := QI`.
RESET	`RESET`	Q.E1	Sets `Q.D1 := FALSE` (if QI = TRUE) and `QO := QI`.
DeInit	`RESET`	Q.E1	Sets `Q.D1 := FALSE` (if QI = TRUE) and `QO := QI`.
DeInit	`Q_INIT = FALSE`	INITO	Sets `QO := FALSE` (if QI = TRUE) and `QO := QI`.
Set	`SET`	Q.E1	Sets `Q.D1 := FALSE` (if QI = TRUE) and `QO := QI`.
Set	`Q_INIT = FALSE`	Q.E1	**Transitions** (excerpt):

- START ⟶ Init: `INIT[QI = TRUE]`
- Init ⟶ SET: `Q_INIT = TRUE`
- Init ⟶ RESET: `Q_INIT = FALSE`
- SET ⟶ RESET: `R` or `CLK`
- RESET ⟶ SET: `S` or `CLK`
- SET ⟶ DeInit: `INIT[QI = FALSE]`
- RESET ⟶ DeInit: `INIT[QI = FALSE]`
- DeInit ⟶ START: (always, condition = 1)

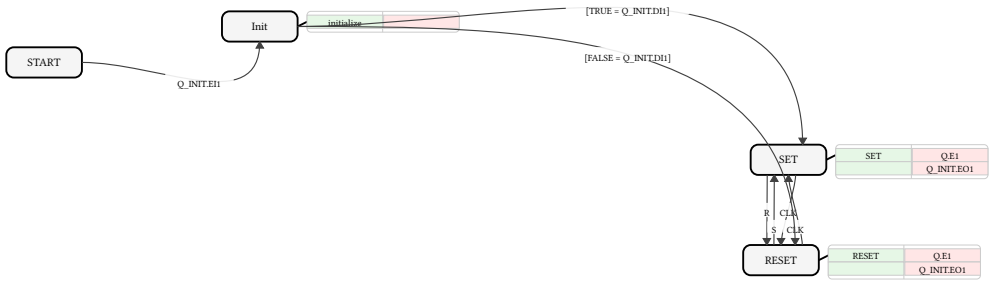
Application Scenarios

- **Machine Control**: Defined start state after power-up (e.g., Valve Closed = `Q_INIT = FALSE`).
- **State Change with Toggle**: Switches a light or drive with each CLK pulse.
- **Safe Initialization**: The action can be made conditional via `QI` (e.g., enabling by a higher-level controller).
- **Fault Reset**: A RESET event resets the output, while setting is possible via S.

Comparison with Similar Function Blocks



Function Block	Special Feature
`E_SR` (Standard IEC 61499)	Pure set/reset flip-flop without toggle and without INIT symmetry.
`E_RS`	Like E_SR, but Reset takes precedence.
`E_Toggle`	Toggle function only, no Set/Reset, no Initialization.
`AX_T_FF_SR_SYM_INIT`	Combines Set, Reset, **Toggle**, **Symmetric INIT Preset**, and Event Qualifier `QI`.



The function block described here thus offers greater flexibility for applications requiring multiple operating modes and a defined initial state.

Conclusion

The **AX_T_FF_SR_SYM_INIT** is a versatile and robust function block for binary state control in IEC 61499 systems. Its combination of Set, Reset, and Toggle functions, coupled with a freely configurable start state via `Q_INIT` and the qualifier `QI`, enables a compact and reliable implementation of many automation requirements. Thanks to its well-designed INIT handling, it is particularly suitable for applications requiring defined and reproducible start-up behavior.

AX_T_FF_SR_SYM_STORE

• – ○ • – ○ • – ○ •

Introduction

The function block `AX_T_FF_SR_SYM_STORE` implements an event-driven, bistable flip-flop with set (S), reset (R), and toggle (CLK) functions. Its special feature is its symmetrical startup behavior: The initial state at system startup can be defined and saved via a special adapter (`Q_INIT`).

Interface Structure

Event Inputs

Name	Type	Comment
S	Event	Sets the output `Q` to TRUE
R	Event	Sets output `Q` to FALSE
CLK	Event	Toggles output `Q` (TRUE ↔ FALSE)

Event Outputs

No direct event outputs are available. Output data is provided exclusively via the adapter interfaces.

Data Inputs

No direct data inputs. Initial value and state are read and output via adapters.

Data Outputs

No direct data outputs. The current state is made available via the adapters.

Adapters

Name	Type	Comment
Q	adapter::types::unidirectional::AX	Returns the current state of the flip-flop (single-wire Boolean value)
Q_INIT	adapter::types::bidirectional::AX2	Bidirectional interface for the initial value of `Q` at INIT (includes three inputs/outputs: e.g., DI1/DO1, EI1/EO1)

Functionality

The function block operates as an SR flip-flop (set-reset) with an additional toggle function. The process is divided into initialization and operation:

1. **Initialization (START → Init)**

After system startup, the function block is in the START state. As soon as the event `EI1` arrives at the adapter `Q_INIT`, it switches to the Init state. There, the initial value provided via `Q_INIT.DI1` is read.

- If the initial value is FALSE, the system subsequently enters the RESET state.
- If the initial value is TRUE, the system enters the SET state.

In both cases, the corresponding outputs `Q.D1` and `Q_INIT.DO1` are set to their initial values.

1. **Operation (SET ↔ RESET)**

Starting from SET or RESET, each event at inputs S, R, or CLK toggles the state:

- **S** → switches to SET (sets Q = TRUE)
- **R** → switches to RESET (sets Q = FALSE)
- **CLK** → toggles the state (from SET to RESET or vice versa)

With each state change, the output data is updated via the adapters, and the events `Q.E1` and `Q_INIT.EO1` are output.

Technical Features

- **Adapter-Based Input/Output**

Instead of classic data inputs/outputs, the module uses adapter interfaces. This enables flexible coupling with other modules or system components that also support the adapter protocol.

- **Symmetrical Startup Behavior**

The bidirectional adapter `Q_INIT` allows the initial state to be set externally and read after initialization. This ensures deterministic restart behavior – particularly important for safety-critical or stateful applications.

- **Toggle Function (CLK)**

In addition to the classic set and reset events, the clock input CLK allows for easy switching of the output without requiring a separate set/reset signal.

- **No Data Inputs/Outputs**

This functional reduction simplifies the interface and avoids confusion with the adapters.

State Overview

State	Description	Output on Event
START	Initial Wait State	Waits for initialization event via Q_INIT.EI1
Init	Initialization	Reads Q_INIT.DI1, sets Q and Q_INIT.DO1 accordingly

SET	Output Q = TRUE	Processes S, R, CLK (see Transitions)
RESET	Output Q = FALSE	Processes S, R, CLK (see Transitions)

State Transitions (Simplified)

- START ⟶ Init (Event Q_INIT.EI1)
- Init ⟶ SET (if Q_INIT.DI1 = TRUE)
- Init ⟶ RESET (if Q_INIT.DI1 = FALSE)
- SET ⟶ RESET (on Event R or CLK)
- RESET ⟶ SET (on Event S or CLK)

Application Scenarios

- **Machine State Storage**

In production plants, this function block can store the current operating mode (e.g., “On” or “Off”) and restore it upon restart.

- **Initialization of Control Sequences**

Scenarios requiring a defined start value (e.g., valve position at the beginning of a batch) benefit from the symmetrical INIT behavior.

- **Event-Driven Toggle Functions**

For example, toggling an indicator light with each key press, without requiring separate on and off commands.

Comparison with Similar Function Blocks

- **Standard E_SR (E_R-SET)**

Simple set-reset flip-flop without toggle functionality and without symmetric start initialization. The initial state is usually undefined or must be set externally.

- **E_RS**

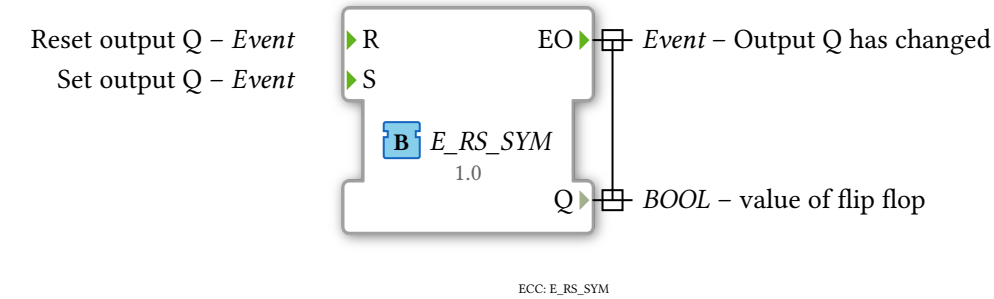
Offers reset prioritization, but also no toggle or INIT functionality.

- **Toggle Function Blocks (e.g., E_Toggle)**

Pure toggle function blocks usually only have a clock input and no bidirectional adapter for initialization. The AX_T_FF_SR_SYM_STORE combines all three functions in one function block.

- **Adapter-Based Function Blocks**

A few function blocks in the 4diac library use adapters for state output. This design allows for a clean separation of event and data paths and facilitates reuse in complex systems.



Conclusion

The `AX_T_FF_SR_SYM_STORE` is a powerful and flexible function block for stateful control tasks. Its combination of Set, Reset, and Toggle functions, coupled with symmetrical startup behavior via adapters, makes it ideal for applications requiring defined restart behavior. Through the use of adapters, it integrates seamlessly into modular and distributed automation systems.

E_RS_SYM

ECC: E_RS_SYM

• – ○ • – ○ • – ○ •

Introduction

The function block **E_RS_SYM** is an event-driven, bistable flip-flop with symmetrical start behavior. It implements set-reset functionality, where the output Q is defined by both a set and a reset event. Unlike a classic RS flip-flop, this component has an explicit start state that reacts to both events equally.

Interface Structure

Event Inputs

Name	Type	Description
R	Event	Reset of output Q
S	Event	Set of output Q

Event Outputs

Name	Type	Description	With Data
EO	Event	Output Q has changed	Yes (with Q)

Data Inputs

No data inputs available.

Data Outputs

Name	Type	Description
Q	BOOL	Flip-flop value (TRUE/FALSE)

Adapters

No adapters available.

Functionality

After being switched on, the module is in the **START** state. From this state, an event at S triggers the **SET** state, and an event at R triggers the **RESET** state. In each case, the output Q is set to TRUE (SET) or FALSE (RESET), and the event EO is output.

- In the **SET** state, an event at R returns the module to the **RESET** state.
- In the **RESET** state, an event at S returns the module to the **SET** state.
- The output Q is only updated upon a state change (i.e., transition to SET or RESET).

The symmetrical start behavior means that both a Set and a Reset event are accepted immediately after initialization – there is no default setting for Q.

Technical Features

- **Symmetrical Start Behavior:** No output value is set in the START state. The device responds equally to the first arriving event (S or R). This distinguishes it from typical RS flip-flops, which usually deliver a defined (often FALSE) initial value after startup.
- **Event-Driven Output:** The event EO is triggered precisely when the value of Q changes. Thus, a signal change is explicitly transmitted.
- **No Data Inputs:** This function block operates purely event-driven without additional data parameters.

State Overview

The function block has three states:

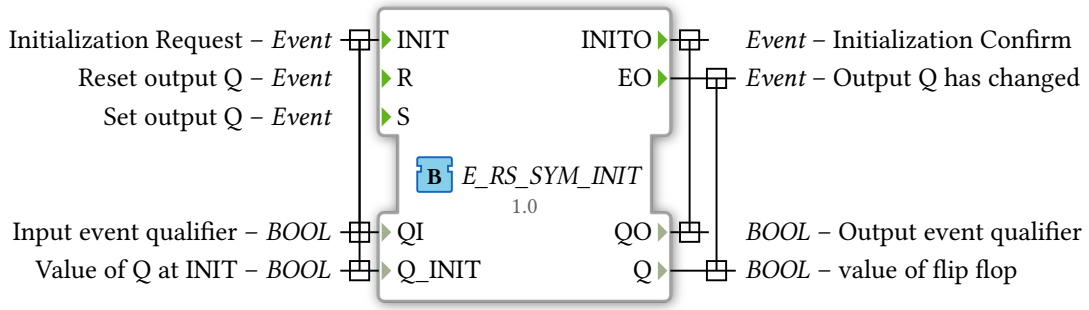
State	Description
START	Initial state after power-on; waits for the first S or R event.
SET	Q = TRUE; can be switched to the RESET state by R.
RESET	Q = FALSE; can be switched to the SET state by S.

Transitions:

- START ⟶ SET on event S
- START ⟶ RESET on event R
- SET ⟶ RESET on event R
- RESET ⟶ SET on event S

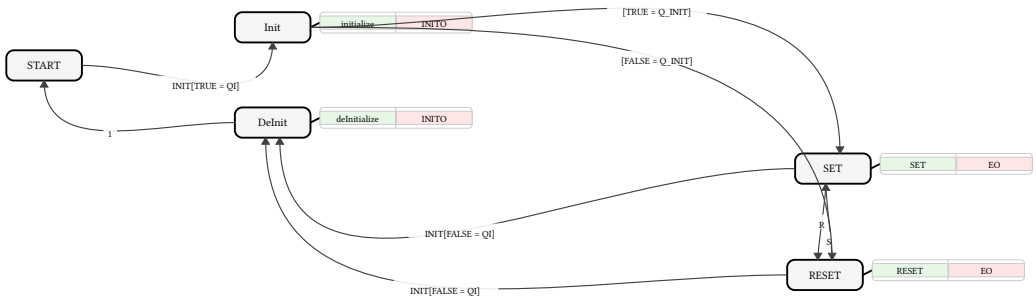
Application Scenarios

- **Initialization of memory bits** in controllers where the initial value should not be predefined.
- **Symmetrical switching logic** that allows both setting and resetting a marker at the beginning.
- **Alternative to classic RS holders** when a defined startup behavior must be avoided (e.g., in safety-critical applications where an undefined initial state is tolerated).



Comparison with Similar Function Blocks

Function Block	Property
E_RS	Classic RS flip-flop with typically asymmetric start behavior (Q initial FALSE).
E_RS_SYM	Like E_RS, but with symmetric start behavior – no preset value, start state accepts both events equally.
SR flip-flop	Similar function, but often with priority for Set or Reset; E_RS_SYM is priority-neutral.



Conclusion

The **E_RS_SYM** is suitable for all applications that require simple, yet start-symmetric memory behavior. Due to the clean separation of event change (EO) and data output (Q), it can be easily integrated into event-driven control architectures according to IEC 61499. Its clear state machine makes it reliable and easy to understand.

E_RS_SYM_INIT

ECC: E_RS_SYM_INIT

• – ○ • – ○ • – ○ •

Introduction

The function block **E_RS_SYM_INIT** is an event-driven, bistable toggle switch (flip-flop) with symmetrical startup behavior and explicit initialization. It implements the familiar RS flip-flop logic, where the output **Q** can be set to either TRUE or FALSE during initialization (event **INIT**) – depending on the value of the parameter **Q_INIT**. This enables defined behavior after a system startup or reinitialization.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Initialization Request; Takes the values of **QI** and **Q_INIT**

R	Event	Resets output **Q**
S	Event	Sets output **Q**

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization confirmation; passes the value of **QO**
EO	Event	Indicates that output **Q** has changed

Data Inputs

Variable	Type	Comment
QI	BOOL	Event Qualifier: Set/reset operations are only executed if *QI=TRUE*. During initialization, *QI* sets the value of **QO**.
Q_INIT	BOOL	Sets the initial value of **Q**, which is inherited during initialization.

Data Outputs

Variable	Type	Comment
QO	BOOL	Output Qualifier: Indicates whether an operation was valid (inheritance of **QI**).
Q	BOOL	The actual flip-flop output.

Adapters

No adapters available.

Functionality

The **E_RS_SYM_INIT** operates as a state machine with five states: **START**, **Init**, **DeInit**, **SET**, and **RESET**.

- **Start Behavior**: After an initial **INIT** event with **QI=TRUE**, the block transitions to the **Init** state. Depending on the value of **Q_INIT**, it transitions either to **SET** (**Q** = TRUE) or to **RESET** (**Q** = FALSE). The output qualifier **QO** takes the value of **QI** (i.e., TRUE) and is output via **INITO**.
- **Setting and Resetting**:
- In the **SET** state, an **R** event leads to the **RESET** state; the action sets **Q** to FALSE (if **QI=TRUE**).
- In the **RESET** state, an **S** event leads to the **SET** state; The action sets **Q** to TRUE (if **QI=TRUE**).
- On every state change, **QO** is set to the current value of **QI**, and the **EO** event is output.
- **Deinitialization**: As soon as an **INIT** event occurs while **QI=FALSE** (e.g., deinitialization), the block transitions from **SET** or **RESET** to the **DeInit** state. There, **QO** is set to FALSE, and the block returns to the **START** state via **INITO**. The flip-flop is not reset – **Q** retains its previous value.
- **Qualifier QI**: The actual change to **Q** only occurs if **QI=TRUE**. If **QI=FALSE**, the set and reset signals are ignored, but **QO** still passes the value of **QI**. This enables conditional behavior, e.g.,... B. for valid/invalid releases.

Technical Features

- **Symmetrical Start Behavior**: The initial state of **Q** is explicitly defined via the parameter **Q_INIT**. This distinguishes the function block from a standard RS flip-flop, whose start state is undefined.
- **INIT as an Event with Parameters**: The INIT event input carries the values **QI** and **Q_INIT** simultaneously, clearly separating initialization and deinitialization.
- **QC (Event Qualifier) Passed Through**: For every valid operation (Set, Reset, or INIT), **QO** is set to the value of **QI**, allowing the calling application to verify the operation's validity.
- **Five-State Machine**: The separation of start, initialization, and deinitialization states enables robust behavior, particularly in automation systems with cyclic restarts.

State Overview

State	Description	Action on Entry	Exit Event
START	Initial sleep state after system startup or deinitialization	none	–
INIT	Initialization requested (**INIT** with **QI=TRUE**)	sets **QO** = **QI**	INITO
DeInit	Deinitialization requested (**INIT** with **QI=FALSE**)	sets **QO** = FALSE	INITO
SET	Flip-flop is set (**Q** = **TRUE**)	Set **Q** to TRUE (only if **QI=TRUE**)	EO
RESET	Flip-flop is reset (**Q** = **FALSE**)	Set **Q** to FALSE (only if **QI=TRUE**)	EO

Transitions:

- START ⟶ Init: INIT ∧ (QI = TRUE)
- Init ⟶ SET: Q_INIT = TRUE
- Init ⟶ RESET: Q_INIT = FALSE
- SET ⟶ RESET: R
- RESET ⟶ SET: S
- SET ⟶ DeInit: INIT ∧ (QI = FALSE)
- RESET ⟶ DeInit: INIT ∧ (QI = FALSE)
- DeInit ⟶ START: 1 (always)

Application Scenarios

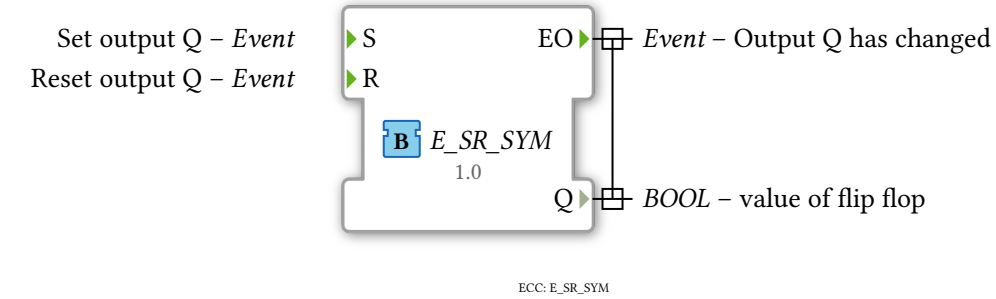
- **Controllers with Defined Power-On Behavior**: If a specific start value is required for a flag or output after a restart of the automation system (e.g., TRUE for “system running” or FALSE for “shut down”), **Q_INIT** can be set accordingly.
- SET ⟶ DeInit: INIT ∧ (QI = FALSE)
- SET ⟶ START: 1 (always)

** Application Scenarios**

** Controllers with Defined Power-On Behavior**: If a specific start value is required for a flag or output after a restart of the automation system (e.g., TRUE for “system running” or FALSE for “shut down”), **Q_INIT** can be set accordingly.

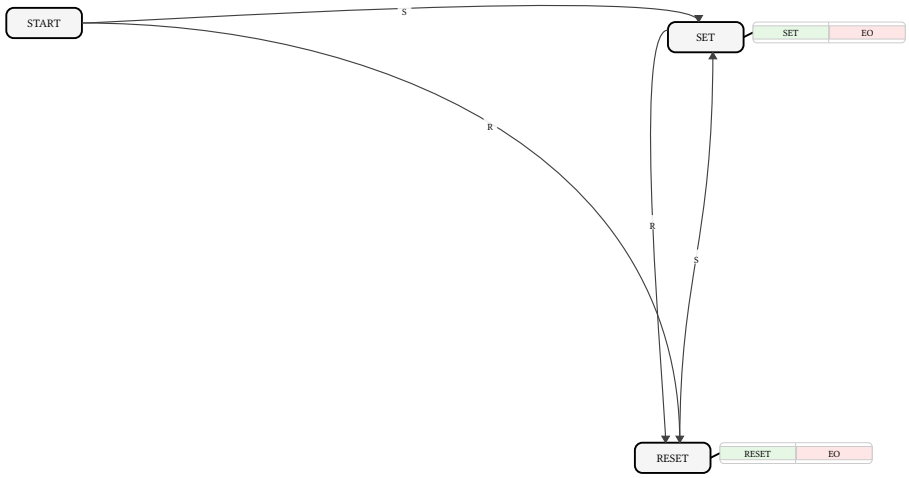
** * **Safe Resets in Case of Faults**: By deinitializing (INIT with QI=FALSE), the function block can be reset to a defined “initial state” without clearing the current value of **Q**. This is useful, for example, to implement a “restart after a fault.”

- **Qualified Set and Reset Operations**: A higher-level condition (e.g., “Enable active operation”) can be controlled via **QI**. Only when **QI** = TRUE do setting and resetting actually affect **Q**.
- **Initialization of State Machines**: This function block is ideally suited as a basic building block for custom state machines that are intended to assume a specific initial state upon INIT.



Comparison with Similar Function Blocks

Function Block	Difference to E_RS_SYM_INIT	
E_RS (Standard RS Flip-Flop)	No explicit start behavior; **Q** is not defined during INIT. **Q_INIT** is missing.	
E_SR (Set-Dominant Flip-Flop)	Set dominates over Reset; no initializable start state.	
E_RS_SYM	Symmetric RS logic without an INIT function; no start behavior.	
E_RS_SYM	**E_RS_SYM_INIT** (this one)	Combines symmetrical RS logic with selectable initial value and deinitialization.



Conclusion

E_RS_SYM_INIT is a powerful and flexible IEC 61499-1 function block for event-driven bistable toggle switches. Due to its explicit initialization with **Q_INIT** and the option for deinitialization while retaining the output value, it is particularly suitable for safety-related and automation applications where defined startup behavior and a clear separation of initialization and operation are required. The inclusion of a **QI** qualifier also enables efficient integration into complex sequence control systems.

E_SR_SYM

ECC: E_SR_SYM

• – ○ • – ○ • – ○ •

Introduction

The E_SR_SYM function block is an event-driven bistable element with symmetric start behavior. It implements a flip-flop that responds to set and reset events and whose initial state is not predetermined but is determined by the first arriving event.

Interface Structure

Event Inputs

- **S** (Event): Sets the output (Q) to `TRUE`.
- **R** (Event): Sets the output (Q) to `FALSE`.

Event Outputs

- **EO** (Event): Triggered when the value of (Q) changes (after an S or R event). The output data memory (Q) is assigned to this event (`With Var="Q"`).

Data Inputs

None.

Data Outputs

- **Q** (BOOL): Current logical state of the flip-flop (`TRUE` or `FALSE`).

Adapters

None.

Functionality

The function block operates in a state-based manner and has three states:

- **START** – Initial state after powering on or resetting the controller.
- **SET** – State after a Set event.
- **RESET** – State after a reset event.

If an event arrives at **S** while the device is in the START state, it switches to the SET state, sets (Q := \text{TRUE}), and sends the **EO** event. If, instead, an event arrives at **R**, it switches to RESET, sets (Q := \text{FALSE}), and also sends **EO**.

If the device is already in one of the active states (SET or RESET), it can be switched by the other event. This results in symmetrical behavior: Neither S nor R has a priority – the last received pulse determines the output.

If the device is already in one of the active states (SET or RESET), it can be switched by the other event.

Technical Features

- **Symmetrical Start Behavior:** Unlike classic SR flip-flops, which deliver a fixed initial value (usually `FALSE`) after startup, E_SR_SYM waits in the START state for the first event. Until then, the output (Q) remains in an undefined or unset state. This allows for flexible initialization by the environment.
- **Three-State Machine:** The ECC uses the states START, SET, and RESET, as well as two algorithms (SET, RESET) in structured text.
- **Compact Interface:** Only two event inputs, one event output, and one data output – making it easy to integrate into larger control systems.

State Overview

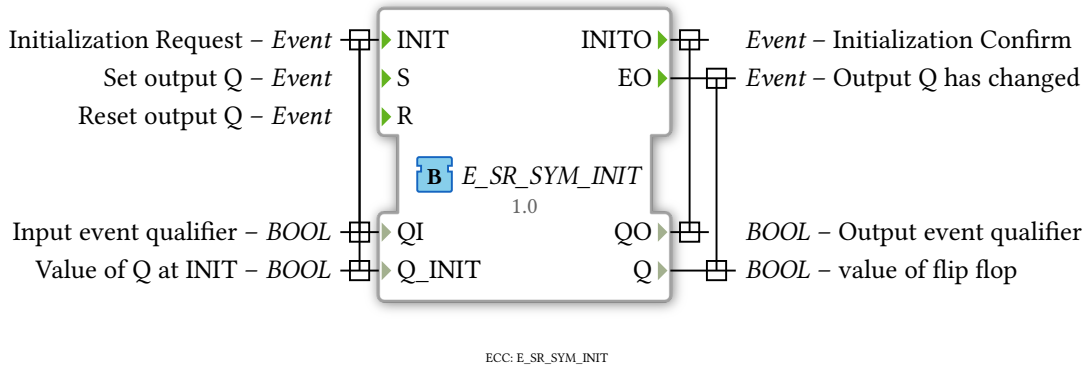
| State | Meaning | Action on Entry | Trigger for Transitions | | |———|————|———————|——————————| | **START** | Initial state | None (Waiting for first event) | S → SET, R → RESET | | **SET** | Output (Q) is `TRUE` | Execute algorithm SET ((Q := \text{TRUE})), send EO | R → RESET | | **RESET** | Output (Q) is `FALSE` | Execute algorithm RESET ((Q := \text{FALSE})), send EO | S → SET |

Transitions:

- START → SET at **S**
- START → RESET at **R**
- SET → RESET at **R**
- RESET → SET at **S**

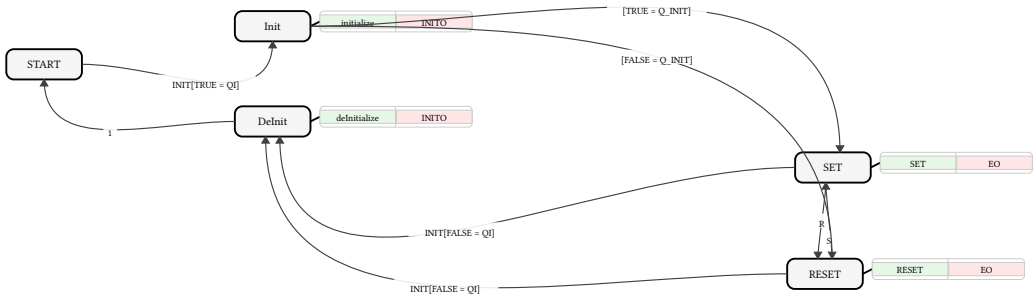
Application Scenarios

- **Event-driven enable signals:** A binary enable signal is set by a set pulse and reset by a reset pulse.
- **Initially indeterminate systems:** Startup behavior where the first valid command (set or reset) determines the subsequent sequence.
- **Simple two-point control:** Switching actuators (e.g., valve open/close) using external command transmitters.
- **Toggle replacement:** Combination with downstream logic blocks also enables toggle functions.



Comparison with Similar Function Blocks

The standard function block **E_SR** (or E_RS) typically has a predefined initial state (usually `FALSE`) and immediately resets to the RESET state after startup. In contrast, the initial state of E_SR_SYM is neutral (START), allowing for symmetrical handling of both events. Unlike dominant variants (E_SR with set dominance or E_RS with reset dominance), there is no priority here – the last event to arrive determines the output.



Conclusion

The function block **E_SR_SYM** offers a flexible, event-driven bistable memory cell with symmetrical startup behavior. Its simple state machine and clear interface make it particularly suitable for control tasks where the initial state is not predefined but rather determined by the first impulse from the environment. This distinguishes it from classic SR modules and expands the toolbox for event-based automation solutions.

E_SR_SYM_INIT

ECC: E_SR_SYM_INIT

• – ○ • – ○ • – ○ •

Introduction

The function block `E_SR_SYM_INIT` implements an event-driven, bistable flip-flop with symmetric startup behavior and an INIT interface. It extends a simple SR flip-flop by adding the ability to set the output `Q` to a predefined value (`Q_INIT`) and perform deinitialization during the INIT event. The input qualification `QI` controls whether the operations (S, R, INIT) actually affect `Q`.

Interface Structure

Event Inputs

Event	Type	Comment
`INIT`	EInit	Initialization request; evaluated with `QI` and `Q_INIT`

S	Event	Set output Q to TRUE (only effective if QI = TRUE)
R	Event	Set output Q to FALSE (only effective if QI = TRUE)

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization/Deinitialization Confirmation
EO	Event	Triggered when Q has changed (by S or R)

Data Inputs

Variable	Type	Comment
QI	BOOL	Input Qualifier; controls whether the operations (S, R, INIT) affect Q
Q_INIT	BOOL	Value that Q should assume upon successful initialization (INIT with QI = TRUE)

Data Outputs

Variable	Type	Comment
QO	BOOL	Output qualifier; returns the value of QI during the last action (FALSE upon deinitialization)
Q	BOOL	Value of the flip-flop (bistable output)

Adapter

None.

Functionality

The function block has five states: START, Init, DeInit, SET, and RESET.

- **START**: Idle state after initialization.
- **INIT**: Achieved by INIT with QI = TRUE. The algorithm initialize sets QO := QI. The system then switches to state SET (if Q_INIT = TRUE) or RESET (if Q_INIT = FALSE), depending on Q_INIT. During this process, Q is set to the value of Q_INIT (via the algorithms SET and RESET, respectively), and EO is triggered.

Q ...8qz is then set to the value of Q_INIT (via the algorithms SET and RESET, respectively). - **DeInit**: This is achieved by INIT with QI = FALSE from the states SET or RESET. The algorithm deInitialize sets QO := FALSE. The function block then automatically returns to the state START.

- **SET** and **RESET**: Normal operating states of the flip-flop. On a S event, the algorithm SET is executed: QO := QI, and if QI = TRUE, Q := TRUE is set; EO is triggered. On a R event, the algorithm Q := FALSE is executed analogously. A INIT event with QI = FALSE returns to DeInit. The output INIT with QI = TRUE would only be possible from the state START.

The qualification QI acts as an enable signal: Only if QI = TRUE is active do S, R, and the initialization affect the output Q. The output QO reflects the last valid value of QI (except after DeInit, in which case it is QO = FALSE).

The qualification QI acts as an enable signal: S, R, and the initialization only affect the output Q. The output QO reflects the last valid value of QI (except after DeInit, in which case it is QO = FALSE).

Technical Features

- **Symmetrical Start-up**: After initialization, the value of Q is determined solely by Q_INIT – regardless of the previous state. This enables deterministic behavior after startup.
- **Qualified Operations**: All actions (S, R, INIT) are only executed if QI = TRUE is active. This allows the function block to be switched on and off, for example, via a higher-level controller.

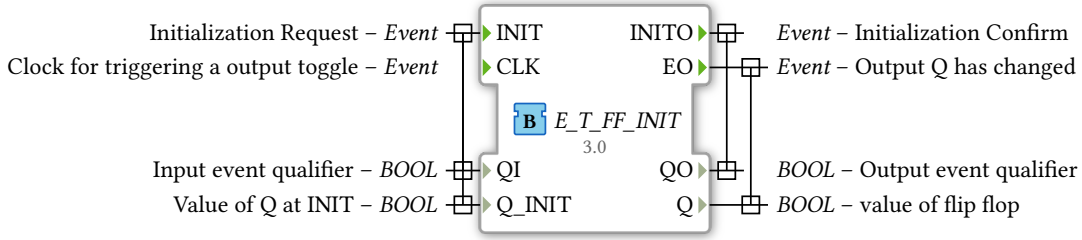
- **Deinitialization**: A `INIT` followed by `QI = FALSE` puts the function block into a defined deinitialization state (`DeInit`), which prevents any further actions until a subsequent `INIT` followed by `QI = TRUE` occurs.
- **No QO Storage**: `QO` is reset with each transition; no separate storage occurs.

State Overview

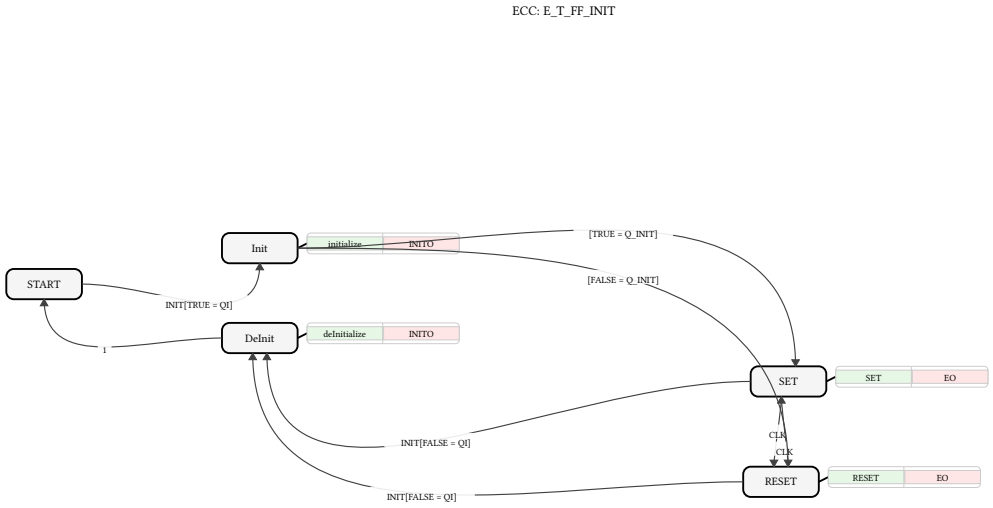
Application Scenarios

- **Controllers that require a defined output state after power-up** (e.g., machines: valve closed or open).
- **Systems with safety-critical initialization**, where the output may only be set after authorization by a qualifier (`QI`).
- **Block chains**, where deinitialization (e.g., during a system reset) should return the function block to a default state without the actual set/reset signals still being active.

Comparison with Similar Function Blocks



- **E_SR** (Standard SR Flip-Flop): Has no initialization behavior; it starts undefined or with the last value. `E_SR_SYM_INIT` extends this with defined initialization and deinitialization.
- **E_RS**: Swaps set/reset priority, but without an initialization mechanism.
- **E_SR_SYM**: Symmetric SR flip-flop without an INIT interface; `E_SR_SYM_INIT` adds the INIT startup logic.



The advantage of `E_SR_SYM_INIT` lies in the combination of qualified initialization with an explicit deinitialization path.

Conclusion

The function block `E_SR_SYM_INIT` offers a robust, qualified flip-flop with a defined startup state. Its symmetric startup logic and deinitialization capability make it ideal for applications requiring reproducible behavior after system startup or reset. The separation of events and qualification allows for flexible integration into higher-level control structures.

E_T_FF_INIT

• – ○ • – ○ • – ○ •

The function block **E_T_FF_INIT** implements a **toggle flip-flop** with integrated initialization logic. It combines the classic behavior of a T flip-flop (switching the output *Q* on each *CLK* event) with targeted output setting during initialization. This block is particularly suitable for applications where a defined initial state is required after startup before normal toggle operation begins.

Event	Type	With Variables	Description
INIT	EInit	QI, Q_INIT	Initialization request; sets *Q* to *Q_INIT*.
CLK	Event	–	Clock signal; triggers the toggling of *Q* on each rising edge (if *QI* = TRUE).
Event	Type	With Variables	Description
–––––	–––––	–––––	–––––––––––––––––––
INITO	EInit	QO	Initialization confirmation; signals the end of initialization.
EO	Event	Q	Output event; is output after each state change of *Q*.
Variable	Type	Description	
–––––	–––	–––––––––––––––––––––	
QI	BOOL	Enable signal for the normal toggle function.	
Q_INIT	BOOL	Desired value of *Q* after initialization (if TRUE, *Q* is set).	
Variable	Type	Description	
–––––	–––	–––––––––––––––––––––	
QO	BOOL	Output qualifier; set to *QI* on INIT, to FALSE on de-initialization.	

Q	BOOL	Toggle output; toggles with each *CLK* (only if *QI* = TRUE).

Event Inputs

Interface Structure

Introduction

Adapters

No adapters available.

Functionality

The module operates as a **state-controlled machine (ECC)** with five states: `START`, `Init`, `DeInit`, `SET`, and `RESET`.

1. **Initialization (state *Init*)**:

- Triggered by the **INIT** event, provided *QI* = TRUE.
- The algorithm `initialize` sets *QO* to the value of *QI* (here TRUE).
- The transition from *Init* depends on the value of *Q_INIT*:
- *Q_INIT* = TRUE ⟶ transition to the **SET** state (*Q* becomes TRUE).
- *Q_INIT* = FALSE ⟶ Transition to the **RESET** state (*Q* remains FALSE).
- After the transition, the **INITO** event is output.

1. **De-Initialization (State *DeInit*)**:

- Triggered by an **INIT** event with *QI* = FALSE (from the *SET* or *RESET* states).
- The algorithm `deInitialize` sets *QO* to FALSE.
- Subsequently, the transition back to the **START** start state occurs, and the **INITO** event is output.

1. **Normal Toggle Operation**:

- In the **SET** (*Q* = TRUE) and **RESET** (*Q* = FALSE) states.
- Each **CLK** event toggles between the two states.
- The algorithms `SET` and `RESET` set *QO* to the current value of *QI* and, if *QI* = TRUE, the output *Q* to the corresponding state (TRUE or FALSE).
- After each toggle, the event **EO** is output.

Important: The toggle function is only active if *QI* = TRUE. If *QI* = FALSE, *Q* remains unchanged (the IF condition in the algorithms prevents the change).

- **Combined Init/Toggle Logic**: This function block allows the output *Q* to be set to a defined value during initialization (*Q_INIT*). This distinguishes it from a simple T flip-flop, which usually starts in the RESET state.
- **Enable via QI**: The variable *QI* acts as a global enable. Switching occurs only when *QI* = TRUE at *CLK*. When *QI* = FALSE, INIT events can still be processed, but toggle operation is disabled.
- **Output Qualifier QO**: *QO* reflects the enable state – it is set to TRUE upon successful initialization and to FALSE upon de-initialization. This allows for easy monitoring of the block status.

State	Description	Incoming Transition(s)	Outgoing Action (Algorithm)	Outgoing Event
START	Idle state after initialization (or after de-initialization).	*DeInit* ⟶ START	–	–

Init	Initialization phase, sets *QO* and determines *Q*.	START → Init (when INIT & QI = TRUE)	`initialize`	INITO
DeInit	De-initialization phase, sets *QO* to FALSE.	SET/RESET → DeInit (when INIT & QI = FALSE)	`deInitialize`	INITO
SET	Normal toggle state: *Q* = TRUE.	Init → SET (when Q_INIT = TRUE) RESET → SET (when CLK)	`SET`	EO
RESET	Normal toggle state: *Q* = FALSE.	Init → RESET (when Q_INIT = FALSE) SET → RESET (when CLK)	`RESET`	EO

Transition conditions (simplified):

- `START → Init : INIT & (QI = TRUE)`
- `Init → SET : (Q_INIT = TRUE)`
- `Init → RESET : (Q_INIT = FALSE)`
- `SET ↔ RESET : CLK`
- `SET / RESET → DeInit : INIT & (QI = FALSE)`
- `DeInit → START`: always (condition = 1)

1. **Initializing a Machine with a Defined Start State**

A conveyor belt should always be in the "ready" position (*Q* = TRUE) after being switched on. This is achieved with *Q_INIT* = TRUE and *QI* = TRUE. A clock can then switch the belt between the two states via *CLK*.

1. **Safety-Controlled Toggle**

A safety signal *QI* enables the block. Toggle operations may only be performed when this signal is active. A failure of the enable signal (*QI* = FALSE) leads to de-initialization – the output *Q* remains unchanged and *QO* becomes FALSE.

1. **State Sequence with Initialization Block**

In a sequence control, *E_T_FF_INIT* is used as a flip-flop for a step. Initialization allows the step to be set to either active or inactive immediately after starting, without a separate set or reset pulse.

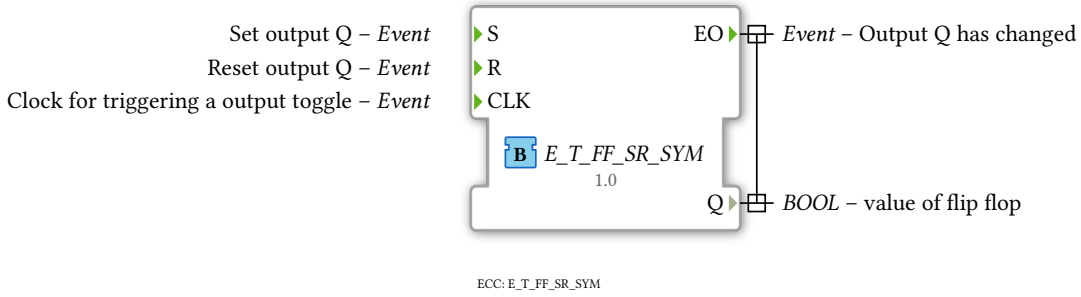
``## Comparison with Similar Components

Component	Special Feature
E_T_FF	Pure T flip-flop without initialization logic. Always starts in the RESET state.
E_FF	S-R or D flip-flop – allows setting and resetting via separate events.
E_SR	Memory component (set-reset) without toggle functionality.
E_T_FF_INIT	Combines toggle functionality with a freely selectable initial state and enable via *QI*.

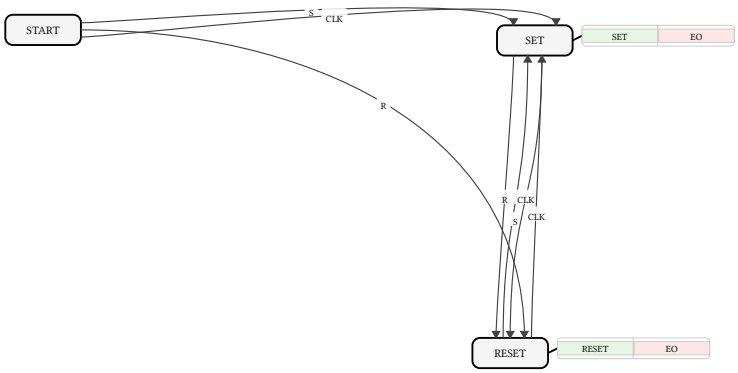
Unlike *E_T_FF*, *E_T_FF_INIT* can set the output to TRUE during initialization and provides explicit enable for toggle operation via *QI*.

The function block **E_T_FF_INIT** is an extended variant of a T-flip-flop, specifically designed for controllers that require a defined initial state after startup. The combination of initialization (via *Q_INIT*), enable (via *QI*), and switching logic (via *CLK*) makes it highly versatile. It is suitable for safety-critical processes where operation is only permitted with active enable, as well as for applications requiring a reproducible startup state. The clearly structured state machine ensures deterministic and predictable behavior.

Technical Features



State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

E_T_FF_SR_SYM

• – ○ • – ○ • – ○ •

Introduction

The function block **E_T_FF_SR_SYM** is an event-driven, bistable toggle switch with an integrated toggle function. It combines the properties of an SR flip-flop (set-reset) and a toggle flip-flop (toggles on clock). Its unique feature is its symmetrical startup behavior: In the initial state, both set and clock events result in the set state, while a reset event directly results in the reset state. This enables defined and predictable behavior immediately after commissioning.

Interface Structure

Event Inputs

Name	Type	Comment

S	Event	Set output Q (to TRUE)
R	Event	Reset output Q (to FALSE)
CLK	Event	Clock to toggle output Q

Event Outputs

Name	Type	With Variable	Comment
EO	Event	Q	Output Q has changed

Data Inputs

None.

Data Outputs

Name	Type	Comment
Q	BOOL	Flip-flop value (TRUE = set, FALSE = reset)

Adapters

None.

Functionality

The component operates as a finite automaton with three states: **START**, **SET**, and **RESET**.

- In the **START** state (initial state), a **S** event or a **CLK** event causes the component to transition to the **SET** state. A **R** event causes it to transition to the **RESET** state.
- In the **SET** state, an **R** event causes the component to transition to the **RESET** state, as does a **CLK** event. An **S** event would maintain the state (not explicitly modeled, but the output only changes upon transition).
- In the **RESET** state, an **S** event or a **CLK** event causes the component to transition to the **SET** state. An **R** event would maintain the state.

The corresponding algorithm is executed with each state change:

- **SET**: `Q := TRUE;`
- **RESET**: `Q := FALSE;`

The **EO** event is then output, which accompanies the new value of **Q**.

The **toggle** behavior is implemented by ensuring that a CLK event always toggles the current state – regardless of whether SET or RESET is active.

Technical Features

- No data inputs: Control is achieved exclusively via events. This reduces the number of required connections and simplifies timing analysis.
- Symmetrical start behavior: The initial state START is not equivalent to a defined output value. Instead, a defined subsequent state is immediately assumed with each of the three possible start events (S, R, CLK). This prevents undefined states after the start.
- All algorithms are implemented in ST (Structured Text) and consist of simple assignments.
- Output Q is only updated upon a state change – the EO event indicates precisely this change.

State Overview

State	Description
START	Initial state after activation of the function block
SET	Output Q = TRUE
RESET	Output Q = FALSE

Transitions (Event → Target State):

Initial State	Event	Target State
START	S	SET
START	R	RESET
START	CLK	SET
SET	R	RESET
SET	CLK	RESET
RESET	S	SET
RESET	CLK	SET

Note: S events remaining in the SET state or R events remaining in the RESET state are not explicitly mapped – the state is retained, and no EO output is generated.

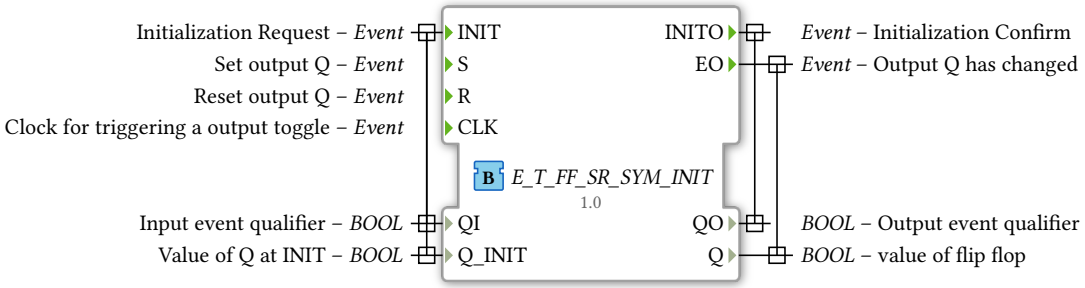
Application Scenarios

- **Clock Switching Operations**: This function block is suitable for applications where a binary signal needs to be switched by a clock signal, but separate setting or resetting must also be possible (e.g., manual priority control).
- **Symmetrical Start Initialization**: In safety-critical systems, responding equally to S or CLK in the start state prevents the presence of an undefined value.
- **Pulse Width Modulation or Toggle Locking**: As a simple toggle function block with set/reset priority.

Comparison with Similar Function Blocks

Function Block	Difference
E_FF_SR	Pure SR flip-flop without toggle. No clock function.
E_FF_Toggle	Pure toggle flip-flop, no set/reset.
E_T_FF_SR	Similar, but without symmetric start behavior. Here, CLK in the START state may lead to undefined behavior.
E_T_FF_SR_SYM	Combines SR and toggle with defined start behavior for all input signals.

Conclusion



The **E_T_FF_SR_SYM** is a versatile event-driven flip-flop component that combines both set/reset and toggle functions. Its symmetric start behavior makes it particularly suitable for applications where a defined state must be reached immediately after activation – regardless of which event occurs first. Thanks to its purely event-driven control, it can be easily integrated into time-critical control processes.

E_T_FF_SR_SYM_INIT

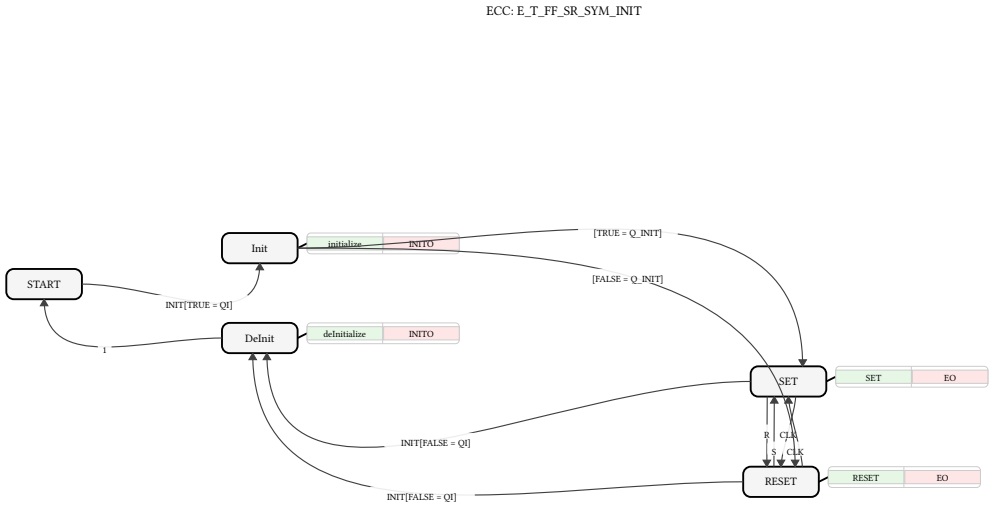

Image of the function block: (not available)

• — ○ • — ○ • — ○ •

Introduction

The function block `E_T_FF_SR_SYM_INIT` implements an event-driven, bistable flip-flop with set, reset, and toggle functionality. It features symmetrical startup behavior: Upon the initialization event (`INIT`), the output `Q` is set to the value specified at the input `Q_INIT`, provided the qualifier `QI` is active. The block combines the properties of an SR flip-flop and a toggle flip-flop in a single unit.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request
S	Event	Sets output Q (set)
R	Event	Resets output Q
CLK	Event	Clock for toggling Q

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement
EO	Event	Signals a change in Q

Data Inputs

Name	Type	Comment
QI	BOOL	Event qualifier (controls execution)

Q_INIT	BOOL	Value that Q should assume at INIT

Data Outputs

Name	Type	Comment
QO	BOOL	Output qualifier (mirror of QI)
Q	BOOL	Flip-flop value

Adapters

None.

Functionality

The function block traverses a finite state machine with five states: `START`, `Init`, `DeInit`, `SET`, and `RESET`.

- **Initialization (`INIT`)**

If a signal is present at the event input `INIT`, the function block distinguishes between the following states depending on the state of the qualifier `QI`:

- If `QI = TRUE`, the function block transitions to state `Init`. There, the output qualifier `QO` is set to the value of `QI` (i.e., `TRUE`), and the output `INITO` is triggered. Subsequently, the automaton—again depending on `Q_INIT`—enters state `SET` (if `Q_INIT = TRUE`) or state `RESET` (if `Q_INIT = FALSE`). Thus, `Q` receives the desired starting value.

If `QI = FALSE`, the function block transitions to state `DeInit`. There, `QO` is set to `FALSE`, and `INITO` is triggered. The machine then returns to its initial state.

- **Setting (`S`)**

When an event occurs at `S`, the algorithm `SET` is executed:
QOreceives the value ofQI. If QI = TRUEis present,Qis set toTRUE. The output EOis triggered to signal a change inQ`.

- **Reset (`R`)**

When an event occurs at `R`, the algorithm `RESET` is executed:
QOreceives the value ofQI. If QI = TRUEis present,Qis set toFALSE. In this case, EO` is also triggered.
QI = TRUEis set toQ. EO is also triggered in this case. - **Toggle (CLK`)**
An event at `CLK` always causes a state change:
If the automaton is in state `SET`, it switches to `RESET` and vice versa. The respective algorithm (`SET` or `RESET`) is executed with the current evaluation from `QI`. The output `Q` is therefore toggled at every clock cycle, provided `QI = TRUE` is in state.

Technical Features

- **Symmetrical Start-up Behavior**: The initial value of `Q` is determined by the configurable input `Q_INIT` and is not set to a fixed default. This allows the system to start reproducibly in a defined state.
- **Event Qualifier `QI`**: All actions (`SET`, `RESET`) are only executed if `QI = TRUE` is present. For `QI = FALSE`, the output qualifier `QO` is simply set to `FALSE`; the value of `Q` remains unchanged. This enables conditional control by upstream function blocks.
- **Deinitialization**: If a `INIT` event with `QI = FALSE` is received during runtime, the function block is deinitialized and enters its idle state (`START`). In this state, it does not respond to any further events until it is reinitialized.

State Overview

State	Description	Action on Occurrence
START	Waiting for initialization	–
Init	Initializing QO	`QO := QI`; Triggering `INITO`
DeInit	Deinitializing (if QI=false)	`QO := FALSE`; Triggering `INITO`

SET	Q is set (TRUE)	Q := TRUE (only if QI=true); Triggering EO
RESET	Q is reset (FALSE)	Q := FALSE (only if QI=true); Trigger EO

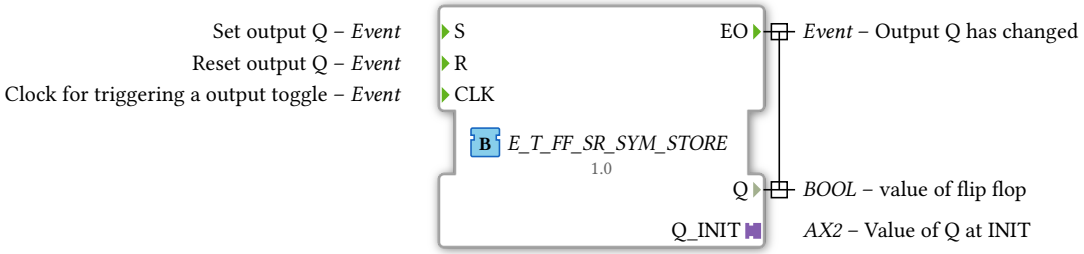
Q is reset (FALSE) | Q := FALSE (only if QI=true);
Q is reset (EO) ...80qz) | Q is reset (Q := FALSE) |
Q is reset (q Transitions:

- START ⟶ Init: at INIT and QI = TRUE
- START ⟶ DeInit: at INIT and QI = FALSE
- Init ⟶ SET: when Q_INIT = TRUE
- Init ⟶ RESET: when Q_INIT = FALSE
- SET ⇄ RESET : via S, R or CLK (each taking QI into account)
- SET ⟶ DeInit : if INIT is reused with QI = FALSE
- RESET ⟶ DeInit : if INIT is reused with QI = FALSE
- DeInit ⟶ START : always (transition with condition 1)

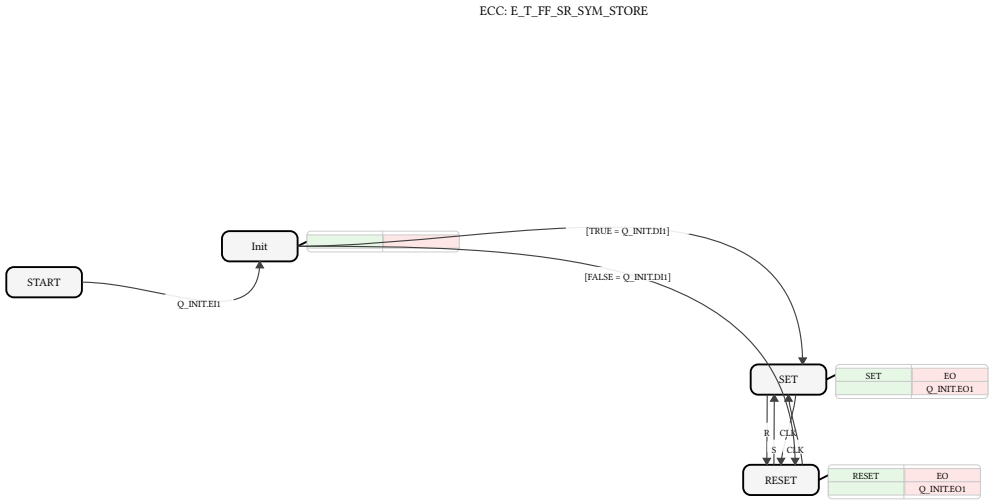
Application Scenarios

- **Control with defined start state**: In safety controllers or systems that require a specific initial state after a restart, Q_INIT can be set accordingly.
- **Toggle function for command switches**: A single push button (connected to CLK)) switches an output with each press – e.g., for lighting controls.
- **Conditional Set/Reset Logic**: The qualifier QI allows actions to be made dependent on higher-level conditions without losing the flip-flop's state.

Comparison with Similar Components



- **Standard SR Flip-Flop (E_SR)**: Offers only set and reset functionality, no toggle function, and no adjustable initial value.
- **Toggle Flip-Flop (E_TOGGLE)**: Only toggles on each clock cycle; no separate set/reset functionality and no defined initial value.
- **SR Flip-Flop with Initialization (E_SR_INIT)**: Similar, but without a toggle function.



This function block combines all three functions (Set, Reset, Toggle) with flexible initialization behavior – a comprehensive solution for many event-driven control tasks.

Conclusion

E_T_FF_SR_SYM_INITis a versatile function block for IEC 61499-based event-driven automation. By combining Set, Reset, and Toggle functions with configurable initialization, it covers a wide range of requirements. Using the qualifierQI` increases flexibility and enables secure integration into complex sequence control systems.

E_T_FF_SR_SYM_STORE

• – ○ • – ○ • – ○ •

Introduction

The function block `E_T_FF_SR_SYM_STORE` implements an event-driven bistable flip-flop with the functions **Set** (S), **Reset** (R), and **Toggle** (CLK). Its special feature is the **symmetrical start-up behavior**: The initial state of the output Q is set via an adapter (`Q_INIT`) during startup or after a `INIT` event. This ensures that the function block behaves deterministically and repeatably at every start time – an important property for safety-critical or predictable automation systems.

Interface Structure

Event Inputs

Name	Type	Comment
`S`	Event	Set output Q to TRUE
`R`	Event	Reset output Q to FALSE
`CLK`	Event	Toggle – switches Q (TRUE ⟶ FALSE or FALSE ⟶ TRUE)

Event Outputs

Name	Type	With Data	Comment
`EO`	Event	Q	Indicates that the value of Q has changed

Data Inputs

None (all inputs are via events).

Data Outputs

Name	Type	Comment
`Q`	BOOL	Current value of the flip-flop (TRUE or FALSE)

Adapter

Name	Type	Comment
Q_INIT	adapter::types::bidirectional::AX2	Sets the initial value of Q on the INIT event. The adapter provides an event-driven, bidirectional channel: Q_INIT.EI1 triggers the initialization, and Q_INIT.DI1 returns the desired initial value (TRUE or FALSE). Additionally, the function block returns the set value via Q_INIT.DO1.

Functionality

The internal process is controlled by the finite state machine (ECC):

1. **START State:** After power is supplied or a system reset is performed, the function block is in state START.
2. **Initialization (State Init):** As soon as the event Q_INIT.EI1 occurs, state Init is reached. The following is then determined based on the Boolean value of Q_INIT.DI1:

- TRUE ⟶ Transition to state SET
- FALSE ⟶ Transition to state RESET

1. **Operating states SET and RESET:**

- **SET:** Sets Q := TRUE and Q_INIT.DO1 := TRUE. Sends output event EO and adapter output event Q_INIT.EO1.
- **RESET:** Sets Q := FALSE and Q_INIT.DO1 := FALSE. Also sends EO and Q_INIT.EO1.

1. **Toggling between SET and RESET:**

- Event S (when in RESET state) ⟶ toggles to SET.
- Event R (when in SET state) ⟶ toggles to RESET.
- Event CLK (always) ⟶ toggles between the two states.

The output EO is activated with every state change of Q.

Technical Features

- **Symmetrical Start-Up:** Unlike simple SR flip-flops with a fixed start value (e.g., FALSE), the start value can be configured via the adapter. This increases flexibility and reproducibility.
- **Toggle Function:** The CLK input allows changing the state without knowing the current value – useful for counters, flashers, or state machines.
- **Bidirectional Adapter Interface:** The device reports its set value back to the adapter (Q_INIT.DO1), so the initializer can confirm the final state.
- **Prioritization:** If S, R, or CLK arrive simultaneously, only the first processed event is considered (based on the event order in the 4diac IDE). In this specific design, CLK is applied as a toggle to the current state, while S and R set the state independently of the toggle. The state transitions show that CLK transitions from each state to the other.

State Overview

The state machine (ECC) comprises four states:

State	Description	Outgoing Transitions
START	Initial sleep state after power-on	⟶ Init at Q_INIT.EI1
Init	Initialization state – determines the start value	⟶ SET at TRUE = Q_INIT.DI1 ⟶ RESET at FALSE = Q_INIT.DI1
SET	Q = TRUE	⟶ RESET at R or CLK
RESET	Q = FALSE	⟶ SET at S or CLK

After exiting Init, the state SET or RESET is reached; the states START and Init are not traversed during normal operation.

Application Scenarios

- **Machine Control with Defined Start State:** A system should always start in a specific operating mode after a reset. Using `Q_INIT`, for example, a PLC configuration can be used to specify whether a valve position is open or closed at startup.
- **Toggling as a Flashing Function:** The `CLK` input can be triggered periodically (e.g., by a timer block) to implement a flashing signal.
- **Redundant Feedback:** The adapter output `Q_INIT.DO1` returns the set value – ideal for safety functions that require feedback on the switching state.

Comparison with Similar Blocks

Block	Properties	Difference to `E_T_FF_SR_SYM_STORE`
`E_SR_FF` (Standard SR Flip-Flop)	Set, reset; usually no toggle, no configurable start value	Missing toggle function; start value often fixed at FALSE
`E_RS_FF`	Set prioritized	Different prioritization; no toggle
`E_D_FF` (D Flip-Flop)	Receives a data input with clock	No set/reset without data; no symmetric start
`E_CTU` (Counter)	Counts events	No bistable behavior, but counter value

The `E_T_FF_SR_SYM_STORE`Combines SR functionality, toggle switching, and an initialized start value in a single component – a rare combination in the IEC 61499 world.

Conclusion

The **E_T_FF_SR_SYM_STORE** is a powerful event-driven flip-flop component for the 4diac IDE. It offers full SR functionality, a toggle option, and symmetrical start-up behavior configurable via an adapter. This makes it particularly suitable for applications requiring deterministic initialization and flexible switching mechanisms. The bidirectional adapter interface increases the integration depth in complex control architectures.

AX_BLINK

• – ○ • – ○ • – ○ •

Introduction

The AX_BLINK is a function block that outputs a flashing signal via an AX adapter.

Interface Structure

Event Inputs

- **START**: Starts the periodic generation of events; carries `TIMELOW` and `TIMEHIGH`.
- **STOP**: Stops the generation of events.

Data Inputs

- **TIMELOW** (TIME): Time for OUT to be FALSE.
- **TIMEHIGH** (TIME): Time for OUT to be TRUE.

Adapters

Plugs (Outputs):

- **OUT** (adapter::types::unidirectional::AX): Output value, starts with FALSE and switches between TRUE and FALSE for the given high and low times.

Functionality

After `START`, the function block alternately switches the output OUT off (FALSE) for the time `TIMELOW` and on (TRUE) for the time `TIMEHIGH`, until `STOP` arrives.

Technical Features

- Uses unidirectional adapters.

State Overview

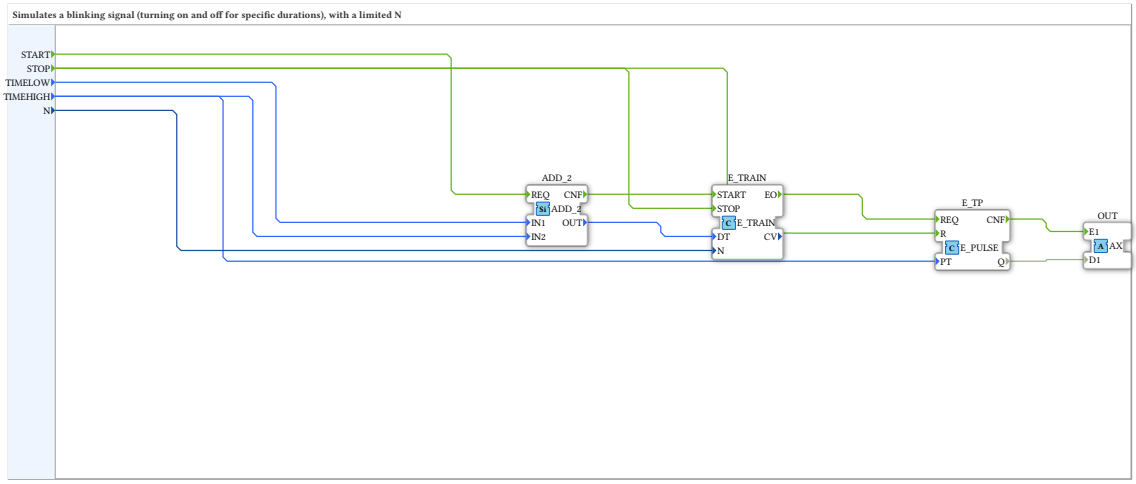
State-based (flashing).

Application Scenarios

Flashing displays.

⚖️ Comparison with Similar Function Blocks

- **E_BLINK**: Standard flashing function block.

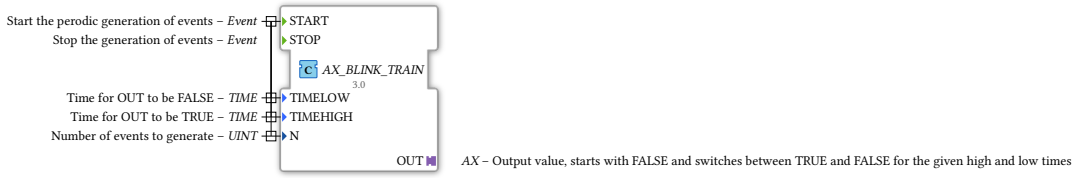


🛠️ Related Exercises

- Exercise_020f3_AX

Conclusion

Adapter-based blink module.



AX_BLINK_TRAIN

• — ○ • — ○ • — ○ •

Introduction

The AX_BLINK_TRAIN is a function block that outputs a flashing signal with a limited number N of events (defined on and off times) via an AX adapter.

Interface Structure

Event Inputs

- **START** (Event): Starts the periodic generation of events (with TIMELOW, TIMEHIGH, N).
- **STOP** (Event): Stops the generation.

Data Inputs

- **TIMELOW** (TIME): Time for OUT to be FALSE.
- **TIMEHIGH** (TIME): Time for OUT to be TRUE.
- **N** (UINT): Number of events to generate.

Adapters

Plugs (Outputs):

- **OUT** (adapter::types::unidirectional::AX): Output value, starts with FALSE and switches between TRUE and FALSE for the given high and low times.

Functionality

After `START`, the function block outputs a flashing signal at the adapter OUT: the output starts with FALSE and is TRUE for TIMEHIGH and FALSE for TIMELOW in each cycle. N events are generated; `STOP` ends the generation.

Technical Features

- Uses unidirectional adapters.

State Overview

State-based.

Application Scenarios

Railway crossings, warning signals.

⚖️ Comparison with similar modules

- No direct standard equivalent.

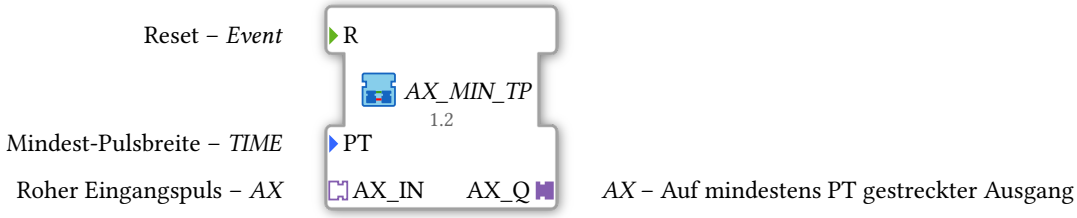
AX_MIN_TP



• – ○ • – ○ • – ○ •

Introduction

`AX_MIN_TP` is a minimum pulse width block: `AX_Q` follows `AX_IN`, but is **at least `PT` long**. Shorter pulses are stretched to `PT`, longer pulses are passed through unchanged. It is the counterpart of `AX_TP`, which always outputs exactly `PT`, and of `AX_TLIM`, which caps at a maximum of `PT`. Use case: the hopper floor lead-in in automatic mode needs a minimum time.

Safety note (Martin Schuder): The block itself has **no hard abort**. A limit switch that is to interrupt the pulse immediately at any time must be combined externally via `AX_AND(AX_Q, NOT limit switch)` **after** this block.

Function Blocks (FBs) Used

Sub-blocks: AX_MIN_TP

- **Type**: SubAppType
- **Internal FBs used**:
  - **AX_SPLIT_2_In**: `adapter::events::unidirectional::AX_SPLIT_2` - `AX_IN` is needed for `AX_TP_MinZeit.IN` **and** directly for `AX_OR_Halten`
  - **AX_TP_MinZeit**: `adapter::events::unidirectional::timers::AX_TP` - non-retriggerable: after the rising edge of `AX_IN` it always runs exactly `PT`, regardless of whether `AX_IN` drops again earlier
  - **AX_OR_Halten**: `adapter::booleanOperators::AX_OR_2` - `AX_IN OR AX_TP_MinZeit.Q`: holds the output as long as either the raw pulse is still present (longer pulses) or the minimum time is still running (shorter pulses)

Interface Structure

Event Inputs

- **R**: Reset (passed through to `AX_TP_MinZeit.R`)

Event Outputs

None - events travel via the adapters.

Data Inputs

- **PT** (`TIME`): Minimum pulse width

Data Outputs

None.

Adapters

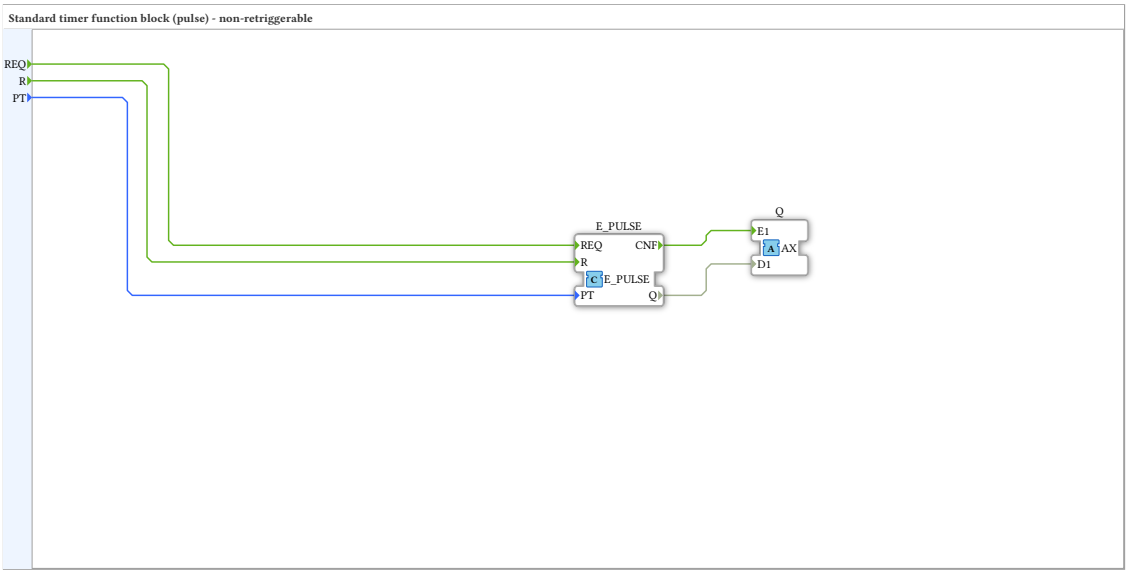
- **AX_IN** (socket, `adapter::types::unidirectional::AX`): Raw input pulse
- **AX_Q** (plug, `adapter::types::unidirectional::AX`): Output stretched to at least `PT`

Program Flow and Connections

- `AX_IN` ⟶ `AX_SPLIT_2_In.IN`
- `AX_SPLIT_2_In.OUT1` ⟶ `AX_TP_MinZeit.IN`
- `AX_SPLIT_2_In.OUT2` ⟶ `AX_OR_Halten.IN2`
- `AX_TP_MinZeit.Q` ⟶ `AX_OR_Halten.IN1`
- `AX_OR_Halten.OUT` ⟶ `AX_Q`
- `PT` ⟶ `AX_TP_MinZeit.PT`; `R` ⟶ `AX_TP_MinZeit.R`

Technical Details

- No latch and no `AX_TON` needed: `AX_TP` is non-retriggerable, hence `AX_Q = AX_IN OR AX_TP_MinZeit.Q`
- Shorter pulses are stretched (`AX_TP.Q` holds until `PT`), longer ones remain unchanged (`AX_IN` keeps `Q` high even after `AX_TP.Q` has expired)
- Version 1.2 (2026-09-29): simplification compared to v1.1 (`ACTIVE`/`AX_TON`/`AX_R_TRIG` latch construction, discarded); new event input `R`

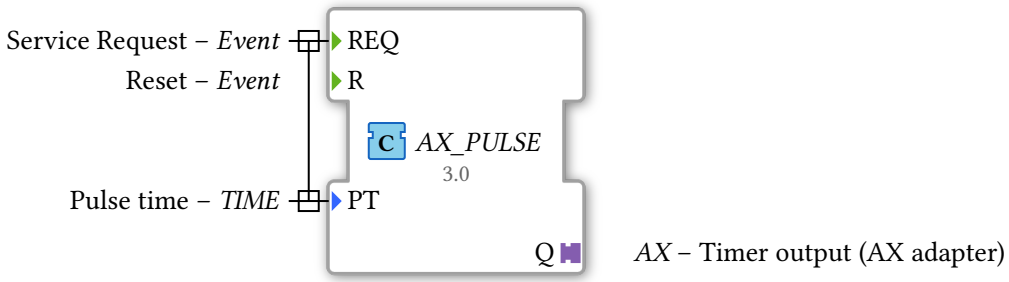


Application Scenarios

- Minimum run time for a drive (e.g. hopper floor lead-in in automatic mode)
- Stretching pulses that are too short

Summary

AX_MIN_TP outputs an AX pulse of at least PT length by ORing the input with a non-retriggerable AX_TP.



AX_PULSE

• – ◦ • – ◦ • – ◦ •

Introduction

Important Note: This function block requires only one event and no cyclic calls. It has no output ET and does not display the elapsed time. The AX_PULSE is a function block that outputs a pulse via an AX adapter.

Interface Structure

Event Inputs

- **REQ** (Event): Service request (with PT); triggers the pulse.
- **R** (Event): Reset.

Data Inputs

- **PT** (TIME): Pulse time.

Adapters

Plugs (Outputs):

- **Q** (adapter::types::unidirectional::AX): Timer output (AX adapter), delivers the pulse.

Functionality

On REQ, Q is activated for the duration PT (non-retriggerable); R resets the pulse. Internally an E_PULSE is used, whose CNF/Q are routed to the adapter Q.

Technical Features

- Uses unidirectional adapters.

State Overview

Pulse.

Application Scenarios

Signaling

Adapter-Based Pulse Component

AX_PULSE_RETRIG

• – ○ • – ○ • – ○ •

Introduction

The **AX_PULSE_RETRIG** function block is a retriggerable pulse shaper with an AX adapter interface. It generates a pulse with a predefined duration (PT) at its output. A restart command within the pulse duration resets the timer and extends the pulse. This block is typically used to generate precisely timed, extendable output signals in automation systems.

Interface Structure

Event Inputs

Name	Type	Description
REQ	EVENT	Service request to start or restart the timer (connected to PT)
R	EVENT	Reset Timer (End Pulse Immediately)

Event Outputs

This function block does not have direct event outputs. Output signals are provided via the Q adapter.

Data Inputs

Name	Type	Description
PT	TIME	Pulse Duration (Pulse Time)

Data Outputs

This function block does not have direct data outputs. Output data is provided via the Q adapter.

Adapter

Name	Type	Description
Q	`adapter::types::unidirectional::AX`	Adapter interface that outputs the pulse status (event and data)

Functionality

- The function block internally encapsulates the standard function block `E_PULSE_RETRIG` (according to IEC 61499).
- A **REQ** event starts the timer: Output Q (via adapter) becomes active and the pulse begins.
- If another **REQ** event occurs during the pulse duration, the timer is reset and the pulse duration starts again (retrigger function).
- An **R** event immediately interrupts the pulse – output Q becomes inactive.
- Adapter Q transmits the current pulse state as an event (via `Q.E1`) and as a data value (via `Q.D1`).

Technical Features

- Uses the standardized `E_PULSE_RETRIG` function block as an internal implementation.
- Output is exclusively via an AX adapter, which provides both an event signal (upon state change) and the binary pulse state (type BOOL).
- A subsequent trigger restarts the timing – ideal for pushbuttons with a delay or pulse-width modulated signals.
- The pulse duration PT can be changed during propagation, but this change only takes effect upon the next REQ.

State Overview

This function block maps the states of the internal `E_PULSE_RETRIG`:

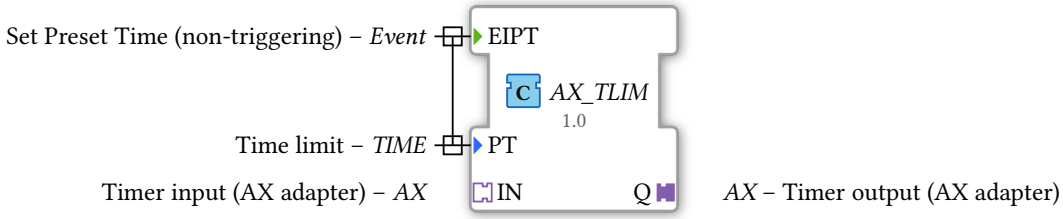
State	Description
IDLE	No pulse active; output Q = FALSE
PULSE	Pulse running; output Q = TRUE; timer running. A REQ event returns to PULSE with a new timer start.

- Transition IDLE → PULSE via REQ.
- Transition PULSE → IDLE by expiration of the PT time or by Reset R.

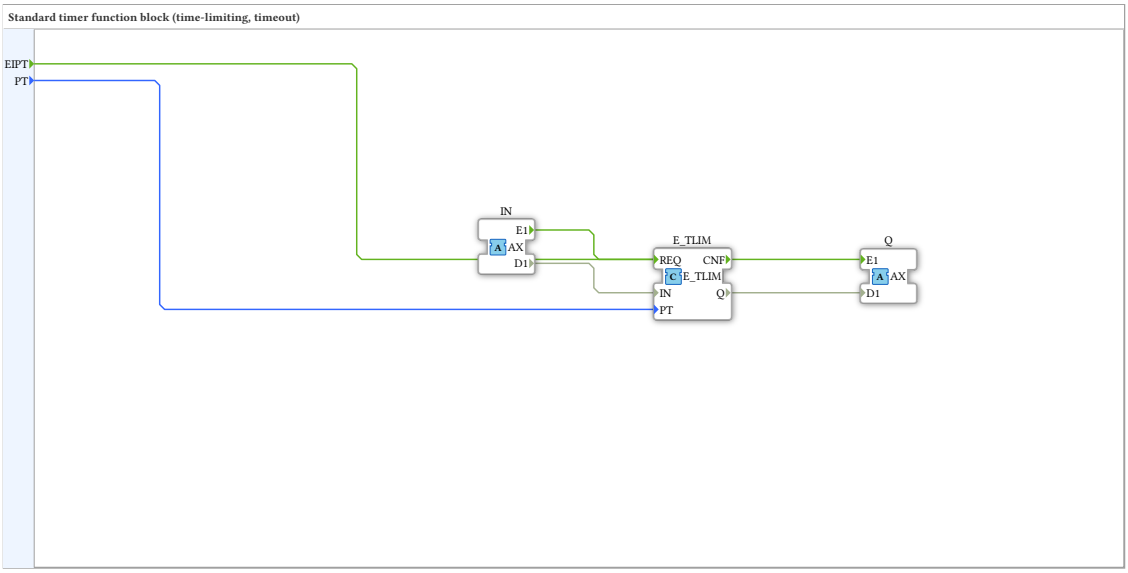
Application Scenarios

- **Extendable Switch-On Pulses**: If a sensor triggers multiple times within the pulse duration, the output should remain permanently active (e.g., for level monitoring).
- **Clock Generator with Retriggerable Pulse Width**: Control of valves or lamps that are switched on again for a fixed time upon repeated request.
- **Safety Functions**: Monitoring of machines where a renewed start command resets the downtime.

Comparison with Similar Function Blocks



Function Block	Property
E_PULSE	Simple pulse without retrigger – one-time timer start, no restart upon subsequent request.
AX_PULSE_RETRIG	Retriggerable version with AX adapter (event + data).
TON / TOF	Delay blocks (turn-on delay / turn-off delay) – no pulse shaper.



The AX_PULSE_RETRIG thus offers the flexibility of a retriggerable pulse with a standardized adapter interface for easy integration into larger function block networks.

Conclusion

The **AX_PULSE_RETRIG** is a compact, high-performance function block for generating retriggerable pulses. Thanks to the AX adapter interface, it can be seamlessly integrated with other function blocks and is particularly suitable for applications where an output signal needs to be extended for repeated requests. The use of the established `E_PULSE_RETRIG` function block ensures standards-compliant and reliable timing behavior.

AX_TLIM

• – ◦ • – ◦ • – ◦ •

Introduction

The **AX_TLIM** function block is a time-limiting timer according to IEC 61499-2. It monitors a Boolean input signal provided via a unidirectional **AX adapter**. As long as the signal is active (TRUE), the output remains active – but only for a predefined time. If the activation duration exceeds the limit, the output is reset (timeout). A separate event input allows the time limit to be preset without triggering a new execution.

Interface Structure

Event Inputs

Name	Type	Description
EIPT	Event	Resets the time limit PT (does not trigger execution)

Event Outputs

This function block does not have direct event outputs. Instead, the output event and value are provided via the **adapter Q** (see the Adapters section).

Data Inputs

Name	Type	Description
PT	TIME	Time limit (Preset Time) for the timer

Data Outputs

Direct data outputs are not available. The current timer status is output via the **adapter Q**.

Adapter

Name	Type	Direction	Description
IN	AX	Socket	Input adapter: receives (via event E1 and date D1) the Boolean value to be monitored
Q	AX	Plug	Output adapter: sends (via event E1 and date D1) the timer state (TRUE = active, FALSE = inactive or timeout)

Note: The adapter type AX is a unidirectional standard adapter consisting of an event (E1) and a Boolean date (D1).

Functionality

1. **Initial State** – The output variable Q.D1 is FALSE; the timer is not running.

Note: The adapter type AX is a standard unidirectional adapter consisting of an event (E1) and a Boolean date (D1).

1. **Activation** – As soon as the input adapter IN delivers an event (E1) with the date TRUE, Q.D1 is immediately set to TRUE, and an internal timer is started.
2. **Time Monitoring** – The timer counts the time that IN.D1 remains on TRUE. The timer uses the value last set via EIPT, PT.

- *Case A:* If IN.D1 becomes FALSE before PT expires, then Q.D1 is immediately set to FALSE.
- *Case B:* If IN.D1 remains on TRUE longer than PT, then after PT expires, Q.D1 is set to FALSE (timeout).

Case B: If IN.D1 remains on TRUE for longer than PT expires, then Q.D1 is set to FALSE (timeout). 4. **Event Output** – Every change to Q.D1 is signaled via the output adapter Q.E1.

1. **Default** – The event EIPT resets the time limit PT without affecting the current timer execution. Only the next activation of the timer (by IN.E1 with TRUE) uses the new value.

Technical Features

- The function block is implemented as a **composite FB** internally, it uses the standard FB `E_TLIM` (from `iec61499::events::timers`). The underlying logic is identical, but the interface is provided via unidirectional **AX adapters**.
- The use of an adapter socket (`IN`) and an adapter plug (`Q`) enables a clean separation of event and data communication and simplifies integration with other function blocks using compatible adapters.
- The timer is triggered **on an edge**: Only a rising edge on `IN.D1` starts a new timer cycle. A subsequent event on `IN.E1` with `TRUE` during a running timer does not reset the timer (unless the value briefly goes to `FALSE` and then back to `TRUE`).

State Overview

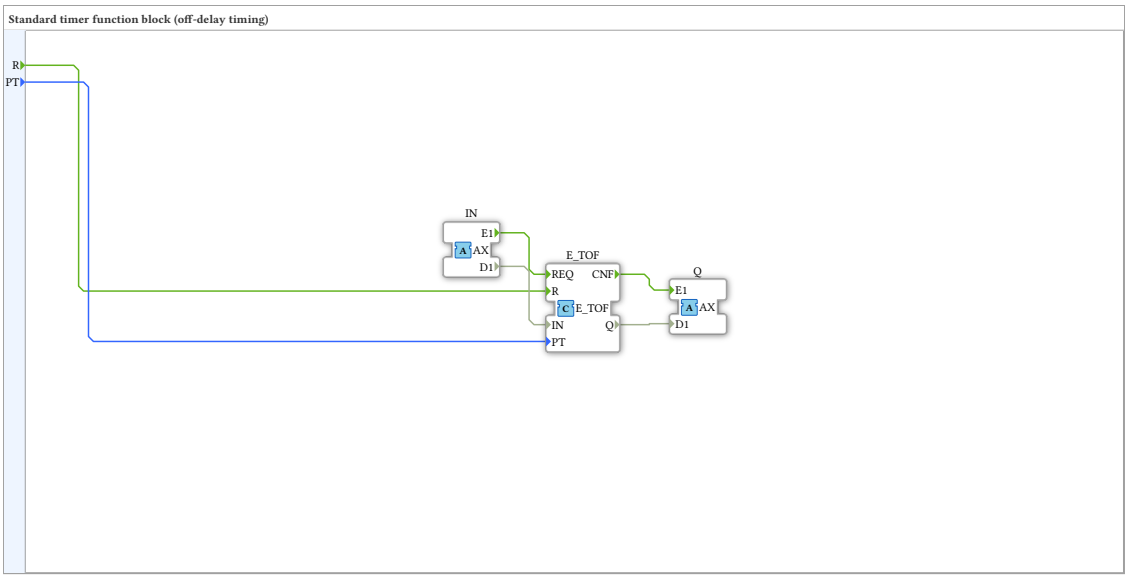
The function block cycles through the following logical states (not explicitly represented as a state machine in the XML):

State	Condition `IN.D1`	Output `Q.D1`	Timer running	Description
Inactive	`FALSE`	`FALSE`	no	Waiting for activation
Active	`TRUE`	`TRUE`	yes	Timer counting, output active
Timeout	`TRUE`	`FALSE`	no	Timeout, timer expired, output inactive
Return	`FALSE`	`FALSE`	no	Input reverts before timeout, output immediately inactive

A switch from **Active** to **Timeout** occurs when the remaining timer time reaches zero. A switch from **Active** to **Revert** occurs when `IN.D1` changes to `FALSE` before the timer expires.

Application Scenarios

- **Actuator Monitoring** – e.g., checking whether a valve remains open longer than permitted.
- **Safety Functions** – Switching off a signal after a maximum activation time.
- **Time-Based Plausibility Check** – Detection of a stuck sensor that continuously reports `TRUE`.
- **Control of blinking or pulse sequences** – the timer can be used as a simple monostable multivibrator with a timeout.

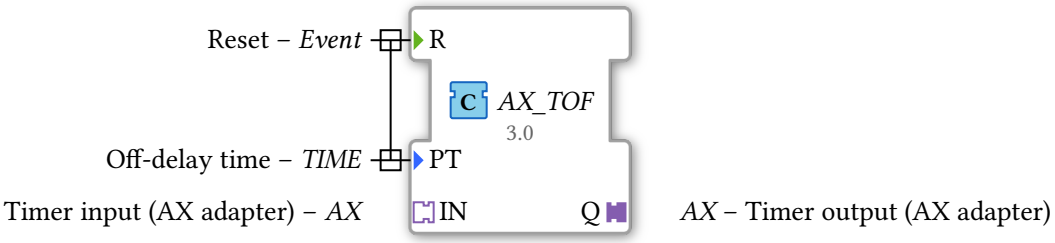


Comparison with similar function blocks

Function block	Description	Difference to AX_TLIM
`E_TLIM`	Standard timer (IEC 61499-2), direct event and data interfaces	AX_TLIM encapsulates `E_TLIM` and provides an adapter-based interface (`AX`) that is easier to integrate into certain architectures.
`E_DELAY`	Delay function block (response delay, fallback delay)	`E_DELAY`Delays signal changes, while AX_TLIM enforces a maximum activation duration.
`E_SR`	Set-Reset Flip-Flop	AX_TLIM does not reset the output as long as the input is active (except via timeout). `E_SR` responds to separate set/reset events.

Conclusion

The **AX_TLIM** function block offers a compact, adapter-based solution for time-limited monitoring of Boolean signals. By encapsulating the standard `E_TLIM` and using unidirectional AX adapters, it can be flexibly integrated into IEC 61499 systems, especially when communication paths need to be encapsulated via adapters. Its operation is intuitive: As long as the input is active, the output remains active – for a maximum of the configurable time `PT`. This makes the component ideal for safety and monitoring tasks in automation technology.



AX_TOF

• – ○ • – ○ • – ○ •

Introduction

Important note: This function block requires only one event and no cyclic calls. It has no output ET and does not display the elapsed time. The AX_TOF function block is a standard timer function block for off-delay timing. It implements a time delay when a signal is switched off and is controlled via adapter interfaces.

Interface Structure

Event Inputs

- **R**: Reset event to reset the timer

Event Outputs

No direct event outputs available

Data Inputs

- **PT**: TIME - Process time for the delay

Data Outputs

No direct data outputs available

Adapters

- **IN** (Socket): Input adapter of type `adapter::types::unidirectional::AX`
- Event: E1
- Data: D1
- **Q** (Plug): Output adapter of type `adapter::types::unidirectional::AX`
- Event: E1
- Data: D1

Functionality

The AX_TOF block implements an off-delay. When an incoming signal is received via the IN adapter, the output is activated immediately. When the input signal is switched off, the timer starts and keeps the output active for the set time PT before it is deactivated. ...

Technical Features

- Internally uses the E_TOF standard timer block
- Unidirectional adapter interfaces for input and output
- Reset functionality for immediate timer reset
- Time base in TIME data type

State Overview

1. **Idle State**: No active signal
2. **Enabled**: Input signal present, output active
3. **Delay**: Input signal switched off, timer running, output remains active
4. **Expired**: Timer expired, output disabled

Application Scenarios

- Control of switch-off delays in industrial processes
- Safety functions with overrun times
- Delayed shutdown of motors or actuators
- Process control with defined shutdown sequences

⚖️ Comparison with Similar Blocks

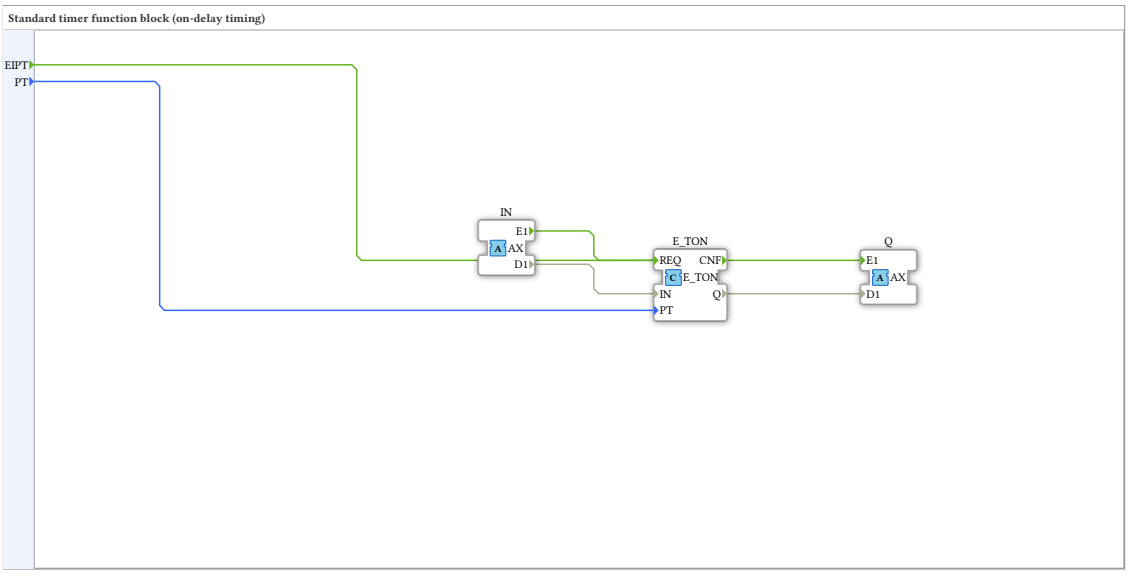
Compared to other timer blocks, AX_TOF offers:

- Specialized in switch-off delays
- Adapter-based interface for modular design
- Integrated reset functionality
- Standardized TIME Data Types

Comparison with E_TOF

🛠️ Related Exercises

- Exercise_020e_AX



Conclusion

The AX_TOF function block offers a reliable and standardized solution for turn-off delays in 4diac-based control systems. Through the use of adapter interfaces, it enables flexible integration into more complex function block networks.

AX_TON

• – ◦ • – ◦ • – ◦ •

Introduction

Important note: This function block requires only one event and no cyclic calls. It has no output ET and does not display the elapsed time. AX_TON is a standardized timer function block that implements on-delay timing. After activation, the block waits a defined time before setting the output signal.

Interface Structure

Event Inputs

- **EIPT** (Event): Set Preset Time (non-triggering); carries PT

Event Outputs

- No direct event outputs available

Data Inputs

- **PT** (TIME): Process time - defines the delay duration

Data Outputs

- No direct data outputs available

Adapters

- **IN** (Input Adapter): Receives input events and data
- **Q** (Output Adapter): Sends output events and data

Functionality

The AX_TON block functions as a power-on delay timer. When an input event is received via the IN adapter, the internal timer starts. After the set process time (PT) has elapsed, an output event with the

status TRUE is sent via the Q adapter. If the input is deactivated during the time monitoring period, the timer is reset.

Technical Features

- Implemented based on the E_TON standard timer block
- Uses unidirectional adapters for inputs and outputs
- Supports TIME data type for precise timing control
- Compatible with IEC 61499-2 standard

State Overview

1. **Idle State**: No active timer, output FALSE
2. **Activation State**: Timer runs after input signal
3. **Delay State**: Timer counts down, output remains FALSE
4. **Trigger State**: After time elapses, output becomes TRUE

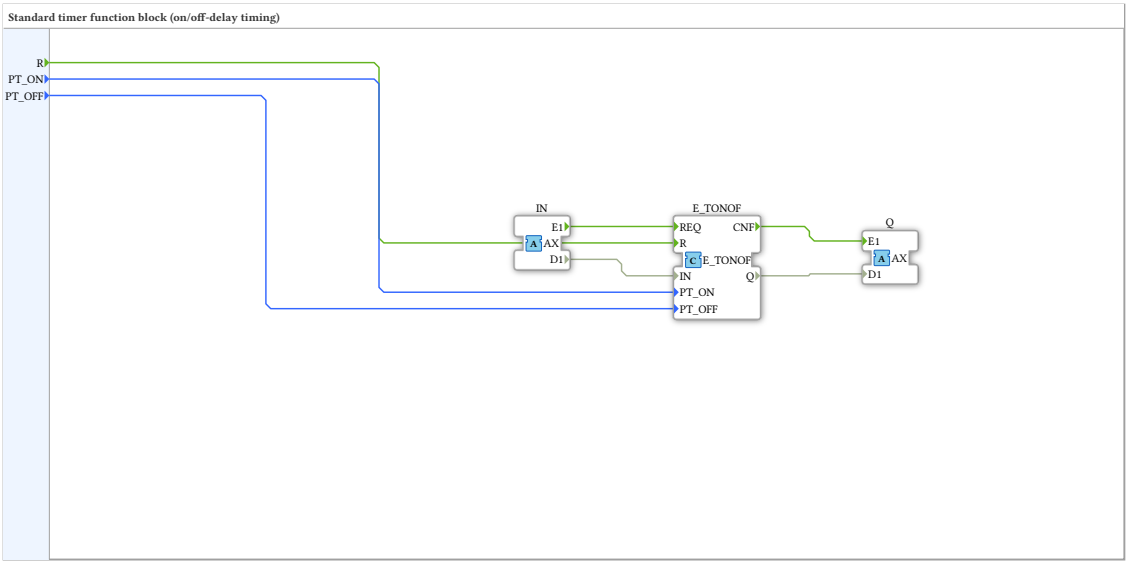
Application Scenarios

- Control of time-delayed process starts
- Monitoring of minimum runtimes
- Delayed activation of machine components
- Safety-relevant time monitoring

⚖️ Comparison with Similar Blocks

Compared to other timer blocks, AX_TON offers a standardized interface via adapters, which facilitates reusability and modular integration into larger control systems.

Comparison with E_TON

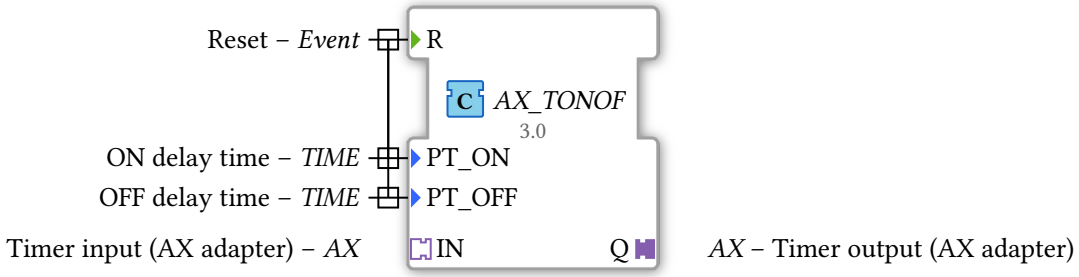


🛠️ Related Exercises

- Exercise_020c_AX
- Exercise_160b2_AX

Conclusion

AX_TON is a robust and reliable timer module for power-on delays, which, thanks to its standardized adapter-based interface, enables flexible integration into various automation systems.



AX_TONOF

• – ○ • – ○ • – ○ •

Introduction

Important note: This function block requires only one event and no cyclic calls. It has no output ET and does not display the elapsed time. AX_TONOF is a standardized timer function block that implements both on and off delays. This function block combines the functionalities of an on-delay and an off-delay timer in a compact solution.

Interface Structure

Event Inputs

- **R**: Reset event to reset the timer

Event Outputs

No direct event outputs available

Data Inputs

- **PT_ON**: TIME - Process time for the power-on delay
- **PT_OFF**: TIME - Process time for the power-off delay

Data Outputs

No direct data outputs available

Adapters

- **IN**: Input adapter (socket) for control signals
- **Q**: Output adapter (plug) for status outputs

Functionality

The AX_TONOF function block processes input signals via the IN adapter and applies the configured delay times depending on the signal state. When an input signal is active, the PT_ON delay is taken into account; when the signal is inactive, the PT_OFF delay is used. The result is output via the Q-adapter.
...))))) ``) ``) ``)) is taken into account. The `PT_ON` delay is taken into account when an

Technical Features

- Supports bidirectional time delays (on and off delay)
- Integrated reset functionality
- Uses adapters for inputs and outputs instead of direct interfaces
- Based on the E_TONOF core function block

State Overview

The function block can assume the following states:

- **Idle State**: No active time measurement
- **On Delay**: Time measurement for PT_ON active
- **Off Delay**: Time measurement for PT_OFF active
- **Reset State**: All active time measurements are canceled

Application Scenarios

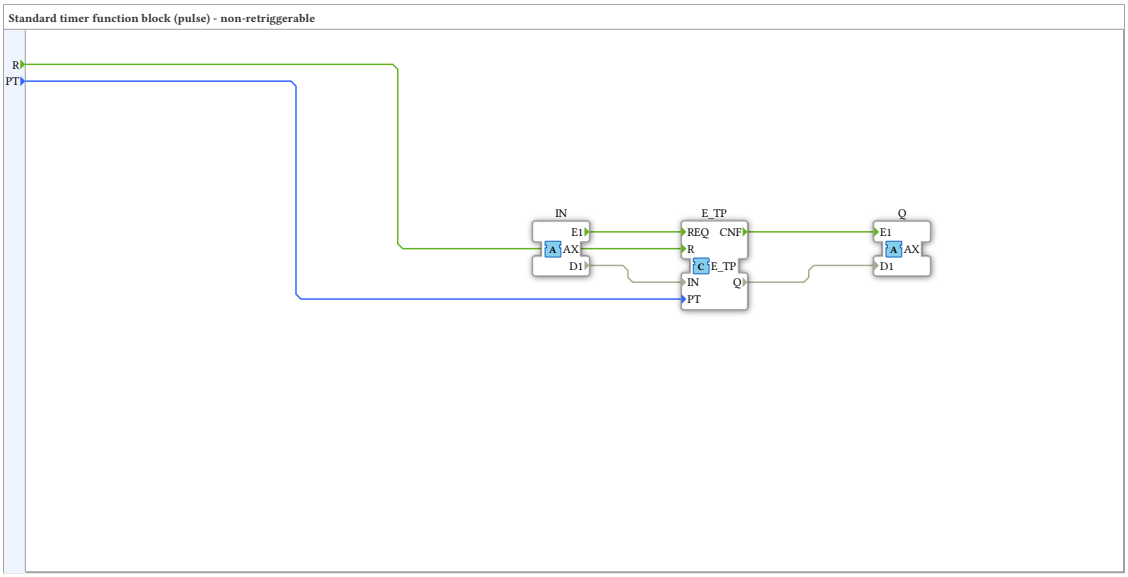
- Motor controls with start and stop delays
- Lighting control with on/off delays
- Process controls with staggered switching operations

- Safety-related applications with delayed responses

⚖️ Comparison with Similar Function Blocks

Compared to simple timer function blocks like TON or TOF, AX_TONOF offers the combined functionality of both timer types in a single block. The use of adapters instead of direct inputs/outputs allows for more flexible integration into complex control structures.

Comparison with E_TONOF

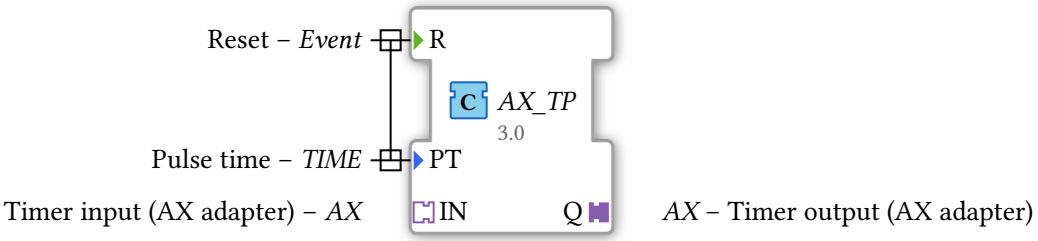


🛠️ Related Exercises

- Exercise_020g_AX

Conclusion

The AX_TONOF is a versatile timer module that, thanks to its combined on/off delay functionality and adapter-based interface design, is particularly well-suited for modular control architectures. The integrated reset function increases flexibility in practical applications.



AX_TP

• – ○ • – ○ • – ○ •

Introduction

Important Note: This function block requires only one event and no cyclic calls. It has no output ET and does not display the elapsed time. The AX_TP is a standardized timer function block of type "Pulse" used in 4diac IDE applications. This function block generates a timed pulse output based on a configurable time interval.

Interface Structure

Event Inputs

- **R**: Reset Event - Resets the timer

Event Outputs
- No direct event outputs available

Data Inputs
- **PT**: TIME - Pulse Time (Pulse Duration)

Data Outputs
- No direct data outputs available

Adapters
- **IN**: Input Adapter (Socket) - Receives input events and data
- **Q**: Output Adapter (Plug) - Sends output events and data

Functionality
The AX_TP function block operates as a pulse timer. When an event is received via the IN adapter, a timed pulse is generated, the duration of which is defined by the PT input. The reset input (R) allows the timer to be reset prematurely. The internal E_TP function block handles the actual timer functionality.

Technical Features
- Uses the standardized E_TP timer block as its core component
- Implemented via adapter interfaces for modular connection
- Supports the TIME data type for pulse time configuration
- Provides separate reset functionality

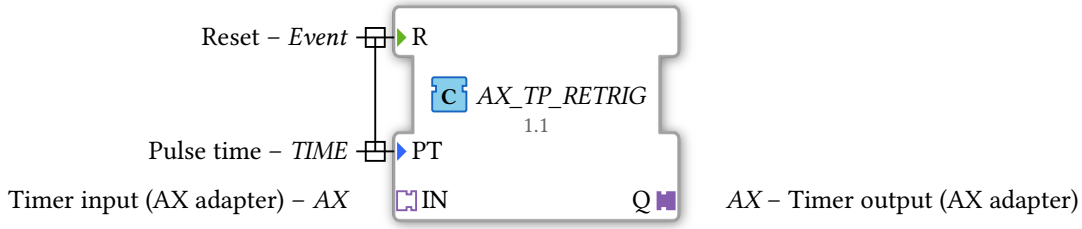
State Overview
The function block has the following operating states:

- **Inactive**: No active timer
- **Active**: Timer is running with configured pulse time
- **Reset**: Timer has been reset

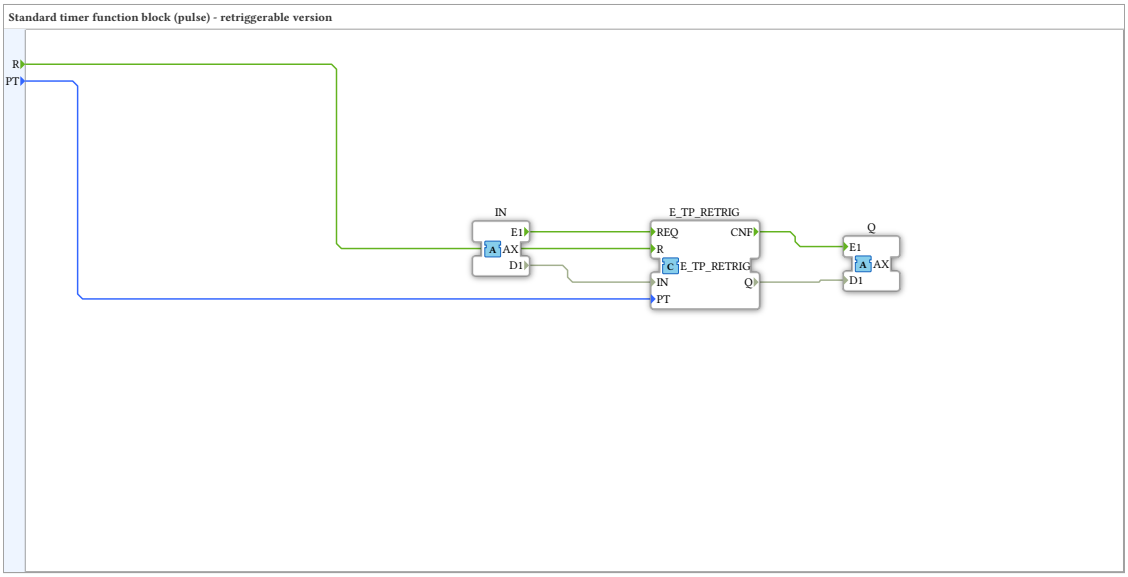
Application Scenarios
- Time-controlled sequences
- Pulse generation for actuators
- Delay circuits
- Process control with defined time intervals

⚖️ Comparison with Similar Blocks
Compared to other timer blocks, AX_TP offers:

- Adapter-based interface for improved modularity
- Explicit reset functionality
- Standardized pulse timer implementation



Comparison with E_TP



🛠️ Related Exercises
- Exercise_020f_AX
- Exercise_020j2_AX_sub
- Exercise_020j_AX
- Exercise_177_AX
- Exercise_178_AX

Conclusion
The AX_TP is a robust and standards-compliant timer function block, ideally suited for time-controlled applications in distributed automation systems. Its adapter-based architecture enables flexible integration into more complex control structures.

AX_TP_RETRIG

• – ○ • – ○ • – ○ •

Introduction

The **AX_TP_RETRIG** function block is a standardized timer function block (pulse) in a retriggerable configuration. It generates a pulse of duration **PT** on the adapter output **Q** as soon as the input signal **IN** receives a rising edge (event REQ). The pulse is restarted (retriggered) with each new REQ event. A reset via the event input **R** advances the pulse duration **PT** and resets the timer. The function block is designed for use in IEC 61499-based automation systems and utilizes the AX adapter interface for efficient, unidirectional signal transmission.

Interface Structure

Event Inputs

Event	Description
R	Reset – Sets the pulse time **PT** and immediately terminates a running pulse.

Event Outputs

No dedicated event outputs – output is provided via the **Q** adapter (event **E1**).

Data Inputs

Name	Type	Description
PT	TIME	Pulse duration (pulse time).

Data Outputs

No dedicated data outputs – pulse status is output via the **Q** adapter (data value **D1**).

Adapters

Name	Type	Direction	Description
IN	`adapter::types::unidirectional::AX`	Socket	Input – Receives the start signal (event **E1**) and the logical value (**D1**). A rising edge on **E1** triggers the pulse.
Q	`adapter::types::unidirectional::AX`	Plug	Output – Outputs the pulse: As long as the pulse is active, **D1** = `TRUE`, otherwise it is FALSE. The event **E1** is sent with every state change.

Functionality

1. **Initial State** – **Q.D1** is `FALSE`, no pulse is active.
2. **Start** – Upon an event **IN.E1** (a rising edge interpreted as REQ), the function block initiates a pulse of duration **PT**. **Q.D1** is immediately set to `TRUE`, and the event **Q.E1** is sent.
3. **Retrigger** – While the pulse is still active, another **IN.E1** resets the timer, and the pulse restarts for the full duration **PT**. **Q.D1** remains `TRUE` for the entire duration of the pulse.
4. **Pulse End** – After **PT** has elapsed (without a new trigger), **Q.D1** is reset to `FALSE`, and **Q.E1** is sent again.
5. **Reset** – The **R** event immediately terminates a running pulse and sets **Q.D1** to `FALSE`. Simultaneously, **PT** is prepended with the current value at input **PT** (this can be used for a new pulse duration).

Technical Features

- **Retriggerability** – Unlike simple timer blocks, a running pulse is not interrupted by a new start pulse, but rather extended (timer restart).
- **Adapter Interface** – Instead of individual event/data ports, the AX adapter interface is used, which enables a standardized, unidirectional connection. This simplifies integration in adapter-based architectures.
- **License** – The block is released under the **Eclipse Public License 2.0** (see copyright information).
- **Implementation** – Internally, the IEC 61499 standard function block **E_TP_RETRIG** is used, which is integrated via the network.

State Overview

The function block goes through the following states (based on the internal timer function block):

State	Description
IDLE	No pulse active; **Q.D1** = `FALSE`.
RUNNING	Pulse active; **Q.D1** = `TRUE`. The timer runs for the duration **PT**. Upon retriggering, the timer is reset (remains in the RUNNING state).
TIMEOUT	Pulse terminated; transition back to IDLE.

Note: The reset (event **R**) always immediately returns to the IDLE state.

Application Scenarios

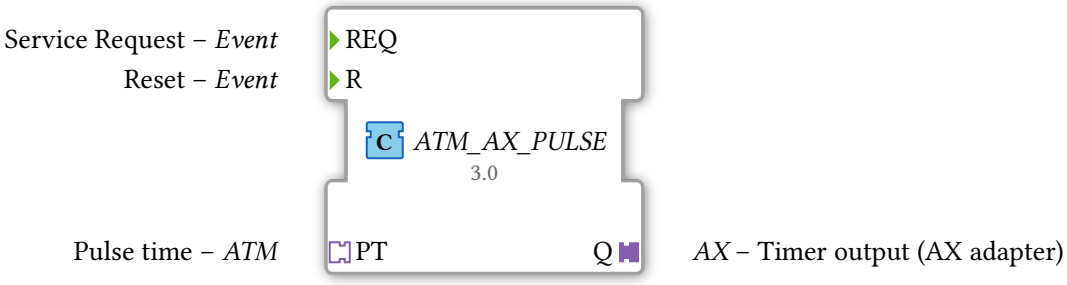
- **Control of output signals with fixed pulse duration** – e.g., controlling a relay that is switched for a defined time.
- **Clock generator with retriggering** – If a new start signal arrives during a pulse, the pulse duration should be extended (e.g., for a manual push button that is pressed for a longer time).
- **Safety interlocks** – An alarm or action should remain active for a minimum duration, even if the triggering state disappears briefly.
- **Time-controlled enables** – e.g., a machine movement that is executed for the duration **PT** after a start signal, but restarts upon a new start pulse.

Comparison with similar function blocks

Function block	Property

AX_TP_RETRIG	Retriggerable pulse timer with AX adapter.
E_TP (Standard IEC 61499)	Simple pulse timer, non-retriggerable – restarting during the pulse is ignored.
E_TP_RETRIG	Retriggerable version without adapter (pure event/data interface).
E_DELAY (Delay)	Delays a signal by a fixed time, but does not generate a pulse of fixed duration.

The **AX_TP_RETRIG** combines retrigger functionality with a compact adapter interface and is therefore particularly suitable for modular, adapter-based systems.



Conclusion

The **AX_TP_RETRIG** is a flexible and standardized timer function block for IEC 61499 applications. Its retrigger capability makes it ideal for situations where a pulse needs to be extended during repeated start commands. The use of the AX adapter interface simplifies integration with other adapter-based components and promotes a clean, modular system architecture. Thanks to the clear separation of event and data flows and adherence to the standard, the module is suitable for reliable use in industrial control systems.

Numeric Index (timers)

Here you will find all exercises from the `timers` workspace, listed in ascending order. …

ATM_AX_PULSE

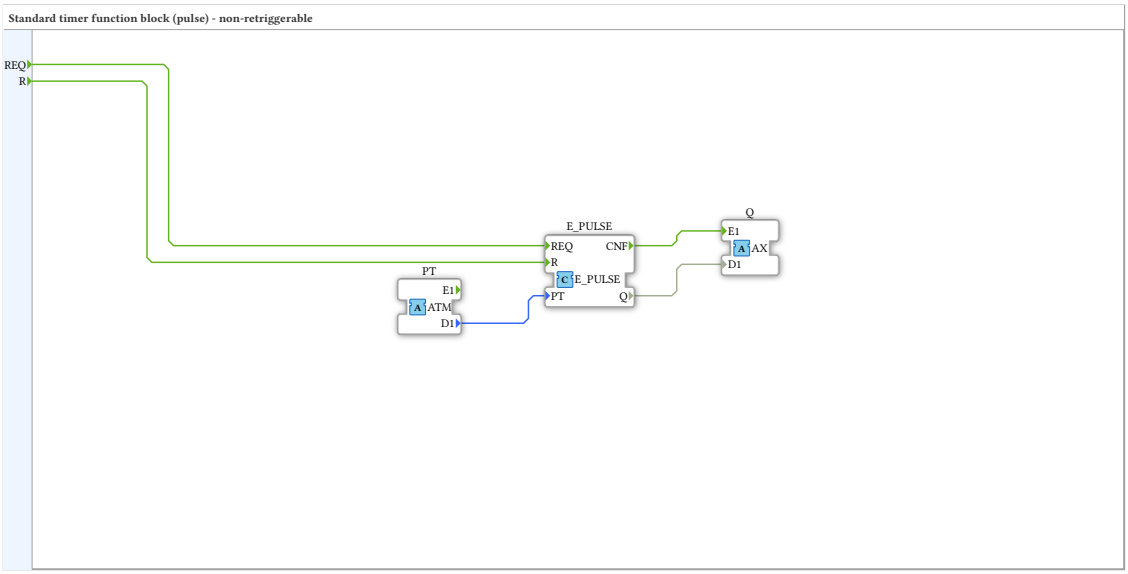


Image not available

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ATM_AX_PULSE** is a standardized timer module for generating a non-retriggerable pulse. It is configured and read via the adapter interfaces **PT** (ATM) and **Q** (AX). The module complies with the IEC 61499-2 standard and is part of the library **adapter::events::unidirectional::timers**.

Interface Structure

Event Inputs

Name	Type	Description
REQ	Event	Service request – starts the pulse.
R	Event	Reset – terminates the pulse prematurely.

Event Outputs

No direct event outputs. Output is provided via the **Q** adapter (see below).

Data Inputs

No direct data inputs. The pulse duration is provided via the **PT** adapter.

Data Outputs

No direct data outputs. The pulse status is queried via the **Q** adapter.

Adapters

Adapter	Direction	Type	Description
PT	Socket	`adapter::types::unidirectional::ATM`	Returns the pulse duration as a time value.
Q	Plug	`adapter::types::unidirectional::AX`	Outputs the pulse status: **D1** = current value (TRUE during the pulse); **E1** = event at the end or change of the pulse.

Functionality

This function block implements the behavior of a non-retriggerable pulse generator (E_PULSE). Upon arrival of the **REQ** event, a pulse is initiated, the duration of which is determined by the value applied to the **PT** adapter. During the pulse, the output **Q.D1** = *TRUE*. After the pulse duration has elapsed, **Q.D1** becomes *FALSE* and the **Q.E1** event is triggered. A subsequent **REQ** during an ongoing pulse is ignored (non-retriggerable). The pulse can be prematurely terminated at any time via the **R** reset input; **Q.E1** is also triggered in this case.

Technical Features

- **Adapter-based communication:** Instead of direct data/event ports, typed adapters (ATM for time, AX for output) are used. This simplifies reuse in modular systems.
- **Non-retriggerable:** A second start pulse during an ongoing pulse has no effect.
- **Validated versions:** The function block has been revised several times (versions 1.0 to 3.0, most recently in 2025) and includes a reset function.
- **Licensed under EPL 2.0** (Eclipse Public License 2.0).

State overview

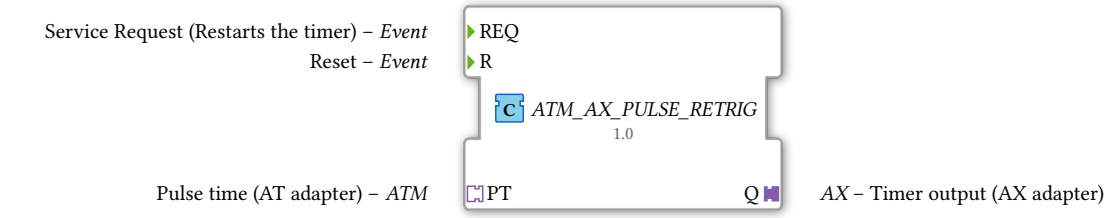
1. **Idle** – No pulse active. **Q.D1** = FALSE.
2. **PulseActive** – Pulse running. **Q.D1** = TRUE. Entered by **REQ** and exited either by timeout or **R**.

- At time elapse: Transition to Idle, triggering **Q.E1**.
- At **R**: Transition to Idle, triggering **Q.E1**.

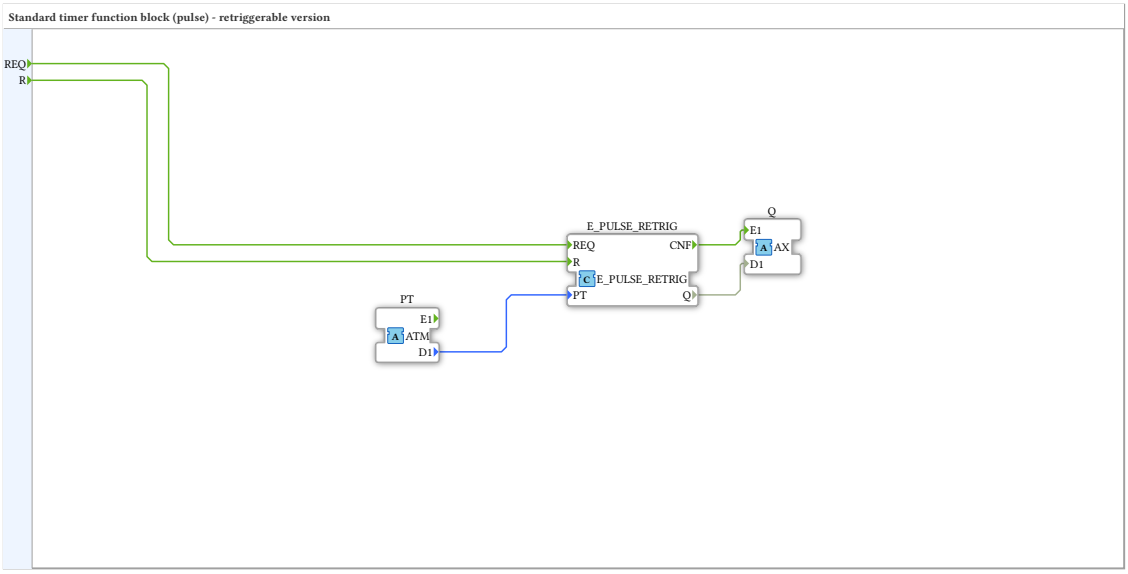
1. During **PulseActive**, **REQ** is ignored.

Application Scenarios

- Control of actuators (e.g., valves, lamps) with a defined on-time.
- Timers in production machines that require one-time pulses.
- Signal conditioning in sensor-actuator networks (AX/ATM-compatible peripherals).



Comparison with Similar Function Blocks



- **E_PULSE (iec61499::events::timers):** Standard implementation without an adapter interface. ATM_AX_PULSE encapsulates this function block and adds the adapter connection.
- **ATM_AX_PULSE_R (retriggerable):** Retriggerable variant; a subsequent **REQ** extends the pulse. The present block is not retriggerable.
- **E_DELAY, E_CYCLE:** Different timing behavior (delay, periodic) – not comparable.

Conclusion

The **ATM_AX_PULSE** is a robust, non-retriggerable pulse block that, thanks to its adapter interface, can be particularly well integrated into modular automation solutions using the AX/ATM protocol. It offers clear, reliable functionality for generating time-defined pulses and meets the requirements of IEC 61499-2.

ATM_AX_PULSE_RETRIG

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_AX_PULSE_RETRIG** generates a pulse of defined duration at its output. It is designed as a retriggerable version, meaning that a new start command during a running pulse resets the pulse duration. Control and parameter transfer are handled exclusively via two standardized adapter interfaces (ATM / AX), so the block does not require direct data inputs/outputs.

Interface Structure

Event Inputs

Name	Type	Comment

REQ	Event	Start command – triggers a new pulse and restarts the timer
R	Event	Reset – immediately terminates a running pulse

Event Outputs
None.

Data Inputs
None. The pulse duration is provided via the **PT** adapter (Socket).

Data Outputs
None. The pulse status (active/inactive) is output via the **Q** adapter (Plug).

Adapters

Role	Name	Type	Direction	Description	
Input	PT	ATM	Socket	Provides the desired pulse duration (D1 → PT)	
Output	Q	AX	Plug	Displays the pulse state (D1 = HIGH during the pulse)	

Functionality
When the function block is triggered by a **REQ** event, it starts a timer with the duration specified by the **PT** adapter (data value D1). The **Q** output (D1) is immediately set to **HIGH** and remains active for exactly this duration. If another **REQ** event arrives during an ongoing pulse, the timer is reset and the pulse duration starts again (retriggerable). A **Reset** event (**R**) terminates the pulse prematurely and sets **Q** to **LOW**.

The function block implements the internal logic using the standardized IEC 61499 function block **E_PULSE_RETRIG**, which handles all timing functions. The adapters (PT → D1 to internal timer, internal output Q → Q.D1) are connected via a hidden network.

Technical Features
- **Retriggerable Behavior**: Each new **REQ** during an active pulse extends the pulse duration to the full value of PT.
- **Adapter-Based Interface**: The module has no direct event outputs or data ports; all communication takes place via the standardized **ATM** (parameter) and **AX** (output) adapters.
- **Reusability**: Due to the strict separation of control and parameterization, the module is particularly suitable for modular and reusable applications.

State Overview
The module has two states:

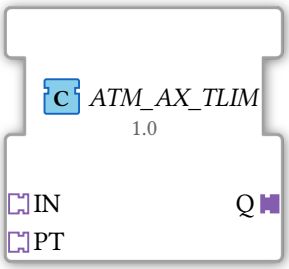
- **Inactive** (Q.D1 = FALSE): No pulse is active, timer is not running.
- **Active** (Q.D1 = TRUE): Pulse is running; upon entry by a REQ, the timer is started with PT. Each subsequent REQ resets the timer. An R event immediately returns the device to the inactive state.

Application Scenarios
- **Clock Generator for Signal Lights**: A continuous start signal (e.g., push button or sensor) generates a defined light pulse. The retrigger function keeps the light on continuously with a constant signal.
- **Pulse Extension in Controllers**: Short input pulses are extended to a minimum or defined duration.
- **Control of Actuators with Minimum On-Time**: Valves, motors, or relays requiring a specific on-time can be reliably controlled.

Comparison with Similar Components

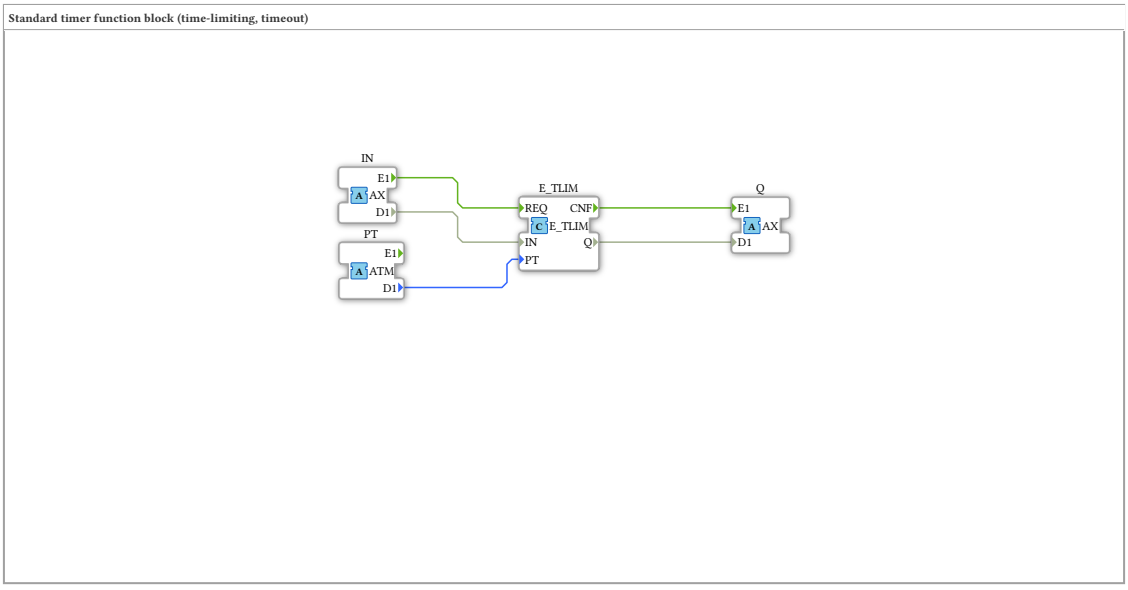
Component	Retriggerable	Interface	Application Area
ATM_AX_PULSE_RETRIG	Yes	Adapter (ATM/AX)	Modular Controllers with Adapter Concept

ATM_AX_PULSE	No	Adapter (ATM/AX)	Single pulses, no retriggering
Standard E_PULSE_RETRIG	Yes	Direct inputs/outputs	More flexible, but without adapter encapsulation



This module stands out due to its exclusive use of adapter interfaces, which simplifies integration into existing adapter-based libraries.

Conclusion



ATM_AX_PULSE_RETRIG is a compact, retriggerable pulse module characterized by its clean encapsulation using an ATM/AX adapter. It is ideally suited for use in distributed control systems based on the IEC 61499 adapter concept. Its ease of use (two events, two adapters) and proven timer behavior make it a reliable component for time-controlled outputs.

ATM_AX_TLIM

Timer input (AX adapter) – *AX*
Time limit (AT adapter) – *ATM*

AX – Timer output (AX adapter)

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_AX_TLIM** is a standardized time monitoring module (timer) with a special adapter interface. It implements time limiting (timeout) for Boolean input signals. The module communicates via adapters instead of individual event and data ports, enabling flexible and encapsulated integration into industrial control systems.

Interface Structure

Event Inputs

Name	Type	Comment
EIPT	Event	Set Preset Time (non-triggering)

Event Outputs

The module does not have separate event outputs. Event forwarding occurs exclusively via the adapter output **Q**, which triggers an event on its `E1` port after a change in the output signal.

Data Inputs

There are no direct data inputs. The required data (input signal IN and time limit PT) is provided via the corresponding adapter ports.

Data Outputs

Similarly, there are no direct data outputs. The result (Boolean value Q) is output via the adapter output **Q** (port `D1`).

Adapters

Name	Type	Direction	Comment
IN	AX	Input	Boolean Input (Adapter)
PT	ATM	Input	Time Limit (Adapter)
Q	AX	Output	Boolean Output (Adapter)

Functionality

The function block internally uses the standard function block **E_TLIM** and wraps it in an adapter. The logic is as follows:

1. **Activation**: An event at the adapter input **IN** (port `E1`) triggers processing. Simultaneously, the Boolean value from **IN.D1** is taken.
2. **Time Measurement**: When the input signal `IN` becomes **TRUE**, the function block sets the output `Q` to **TRUE** and starts a timer with a duration of **PT** (from adapter **PT**, port `D1`).
3. **Timeout**: If `IN` remains active longer than `PT`, `Q` is reset to **FALSE** (timeout).
4. **Premature Termination**: If `IN` becomes **FALSE** before the time expires, the function block `Q` is immediately reset (also to **FALSE**).
5. **Setting the Time Limit**: The event input **EIPT** allows you to specify the value of **PT** without triggering a new event. This is used to configure the time limit before the actual use.
6. **Premature Termination**: The output adapter **Q** outputs an event on its `E1` port as soon as `Q` changes (rising or falling edge).

Technical Features

- **Adapter-Based Communication**: Instead of individual event and data ports, AX/ATM adapters are used. These enable modular and reusable coupling with other components.
- **Internal Standard Component**: The implementation uses the established **E_TLIM** (IEC 61499), ensuring reliable and tested timing logic.
- **Non-Triggering Time Setting**: The **EIPT** input only changes the time limit without starting or resetting the timer. This is useful for dynamically adjusting parameters.
- **Typical Time Measurement**: Suitable for monitoring applications where a signal must not be active for a specific duration.

State Overview

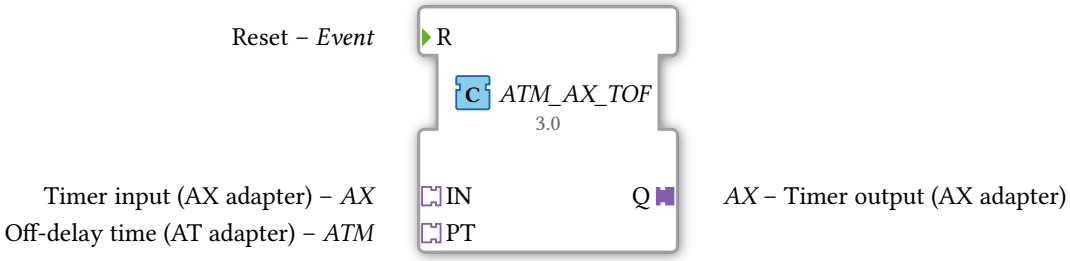
The function block (FB) implicitly cycles through the following states:

State	Description
Idle	IN = FALSE, Q = FALSE, Timer is not running.
Timing	IN = TRUE, Q = TRUE, Timer is running.
Timeout	IN = TRUE, Timer expires, Q = FALSE (remains until IN = FALSE).

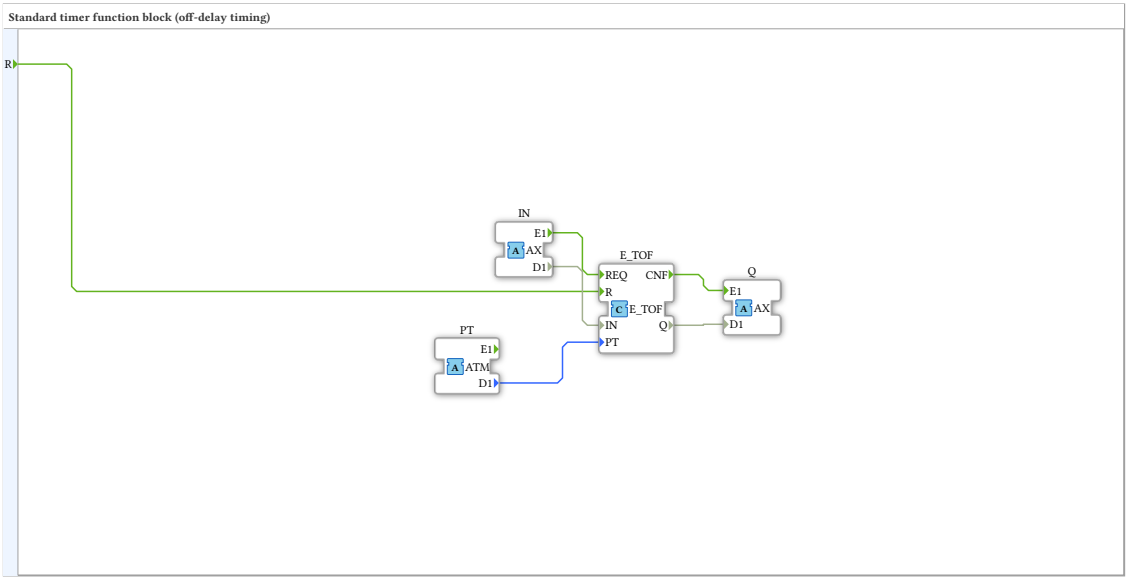
A switch back to **Idle** occurs as soon as IN becomes FALSE. The **Timeout** state is only reached when the timeout has occurred.

Application Scenarios

- **Monitoring of signals** in automation technology (e.g., maximum on-time of an actuator).
- **Safety functions** where an output must be deactivated if a signal persists for too long.
- **Timed resets** in communication protocols (watchdog functionality).
- **Simple time limiting** in complex control systems based on adapter interfaces.



Comparison with similar function blocks



- **E_TLIM (Standard)**: Offers the same core logic, but with classic input/output ports. **ATM_AX_TLIM** encapsulates this logic in an adapter interface and is therefore better suited for modular and reusable components.
- **E_TON / E_TOF**: These function blocks implement turn-on and turn-off delays, respectively. In contrast, **ATM_AX_TLIM** monitors the maximum duration of an active signal and responds with a timeout.
- **E_CYCLE**: A cyclic timer that periodically generates signals has a different objective than simple monitoring.

Conclusion

The **ATM_AX_TLIM** function block offers a compact, adapter-based solution for time monitoring tasks. It combines the proven functionality of the standard timer **E_TLIM** with the flexibility of adapter interfaces and allows dynamic specification of the time limit via **EIPT**. This makes it particularly suitable for modern, modular automation projects based on IEC 61499 that require a clear separation of interfaces and logic.

ATM_AX_TOF

• – ○ • – ○ • – ○ •

Introduction

The function block `ATM_AX_TOF` implements off-delay timing with a modular adapter interface based on the types `AX` and `ATM`. It is typically used to keep an output active for a defined period after an input signal is lost. The block is classified as a standard timer function block according to IEC 61499-2 and is implemented internally with the function block `E_TOF`.

Interface Structure

Event Inputs

Name	Type	Comment
R	Event	Resets the timer

Event Outputs

No direct event outputs are available. The output is provided via the `Q` adapter.

Data Inputs

No direct data inputs are available. Data is provided via the `IN` and `PT` adapters.

Data Outputs

No direct data outputs are available. The output is provided via the `Q` adapter.

Adapters

Name	Direction	Type	Description
IN	Socket	AX	Input adapter: Provides the Boolean trigger signal (D1: BOOL) and an event (E1) to trigger the timer function
PT	Socket	ATM	Time adapter: Provides the delay time (D1: TIME)
Q	Plug	AX	Output adapter: Provides the Boolean output signal (D1: BOOL) and an acknowledgment event (E1)

Functionality

The `ATM_AX_TOF` operates on the principle of an **off-delay**:

1. **Normal operation:** As long as the input `IN.D1` (BOOL) has the value `TRUE`, the output `Q.D1` is immediately `TRUE` (without delay).
2. **Shutdown Delay:** When `IN.D1` changes from `TRUE` to `FALSE`, `Q.D1` remains at `TRUE` for the time specified in `PT.D1` (TIME). After this time has elapsed, `Q.D1` changes to `FALSE`.
3. **Reset:** An event at input `R` immediately resets the internal timer. `Q.D1` immediately becomes `FALSE`, regardless of the current state of `IN.D1` or the remaining time.

The trigger is the event `IN.E1` – a new value at `IN.D1` is only applied after an event. An event on `Q.E1` confirms every state change of `Q.D1`.

Technical Features

- **Adapter-Based Interface:** The use of the universal adapters `AX` and `ATM` enables flexible connection to addressing or other modules without fixed wiring.
- **Internal Implementation:** The function block uses the standard FB `E_TOF` from the IEC 61499 library, ensuring robust and tested timer logic.
- **Reset Function:** The reset input `R` allows for immediate cancellation of the delay, e.g., for controlling safety functions.
- **Compatibility:** Developed for the 4diac IDE and based on the Eclipse Public License 2.0.

State Overview

The function block goes through the following operating states:

State	Conditions	Q.D1	Description
Idle	IN.D1 = FALSE, timer is not running	FALSE	Idle state after expiration or reset
Active	IN.D1 = TRUE	TRUE	Input active, output immediately TRUE
Timing	IN.D1 changes from TRUE to FALSE, timer active	TRUE	Delay phase: Output remains TRUE for the duration of the delay phase

Resetting	Event R during Timing or Active	FALSE	Timer is stopped immediately, output goes to FALSE

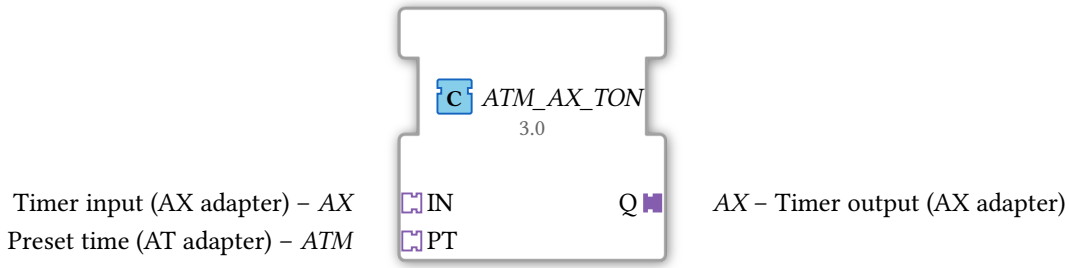
Application Scenarios

- **Fan Run-On:** After a motor is switched off, the fan continues to run for an adjustable time to dissipate residual heat.
- **Signal Debouncing:** Short interruptions in a sensor signal are bridged by the delay.
- **Lighting Control:** Lights remain on for a defined run-on time after leaving a room.
- **Safety Shutdowns:** Reset via R enables immediate shutdown in emergencies.

Comparison with Similar Function Blocks

Property	ATM_AX_TOF	E_TOF (Standard)
Interface	Adapter (AX/ATM)	Direct Events/Data
Reset Function	Yes (Event R)	Yes (Event R)
Triggering	Event-driven via adapter event	Event-driven via REQ
Flexibility	Increased through adapter coupling	Simpler, but more rigid
Application Area	Modular automation systems	Basic function in IEC 61499 editors

Conclusion



The `ATM_AX_TOF` offers a reliable and flexible turn-off delay for modular automation projects. Thanks to the adapter interface, it can be easily integrated into various system landscapes and extends the functionality of the standard timer `E_TOF` by adding a reset option and loose coupling via AX/AT adapters. It is ideal for applications requiring a delayed shutdown with optional immediate reset.

ATM_AX_TON

• – ○ • – ○ • – ○ •

Introduction

The **ATM_AX_TON** is a function block for on-delay. It implements standard timer functionality according to IEC 61499-2, which is controlled via an adapter interface (AX/AT). The block allows a timer to be started via an input adapter and the output state and confirmation of completion to be provided via an output adapter.

Interface Structure

Event Inputs

Name	Type	Comment
EIPT	Event	Sets the lead time (non-triggering)

Event Outputs

The function block does not have its own event outputs. Acknowledgments and state changes are communicated via the **Q** adapter (E1).

Data Inputs

The function block (FB) has no explicit data inputs. All input data is provided via the adapter interfaces.

Data Outputs

The FB has no explicit data outputs. Output data is provided via the **Q** adapter (D1).

Adapters

Direction	Name	Type	Comment
Socket	IN	adapter::types::unidirectional::AX	Timer input (AX adapter) – provides the Boolean input signal and the start pulse
Socket	PT	adapter::types::unidirectional::ATM	Lead time (AT adapter) – provides the delay time
Plug	Q	adapter::types::unidirectional::AX	Timer output (AX adapter) – outputs the timer status and confirmation

Functionality

The **ATM_AX_TON** encapsulates a standard on-delay timer (E_TON) from the IEC 61499 library. Detailed functionality:

1. **Starting the timer:**

The input adapter **IN** provides the start pulse (REQ) via its event **E1** and the Boolean value **IN** via its data signal **D1**. When **IN.D1** becomes TRUE, the timer starts.

1. **Delay time:**

The desired delay time is provided via the adapter **PT** (via **PT.D1**). Once the timer is running, the output **Q.D1** is set to TRUE after this delay time has elapsed.

1. **Output Signal and Acknowledgement:**

The output adapter **Q** outputs the current timer state via **Q.D1** (TRUE when the delay time has elapsed, FALSE when the input goes to FALSE). The event **Q.E1** is sent after each state change (CNF of the internal E_TON).

1. **Setting the Lead Time Without Triggering:**

According to the specification, the event input **EIPT** is used to set the lead time **PT** without starting the timer. However, in this FBNetwork, this input is not connected internally – it is available for external use if an application requires a time preset.

1. **Fallback:**

If **IN** goes to FALSE, the timer is immediately reset and **Q.D1** becomes FALSE (without delay).

Technical Features

- **Adapter-Based Interface:** The function block uses only adapters (AX and ATM) for communication, not traditional input/output grooves. This enables flexible encapsulation and reuse in complex systems.
- **Unidirectional Adapters:** The adapters used are unidirectional (AX for Boolean values and ATM for time values). The function block expects the adapters to be correctly integrated into the higher-level hierarchy.
- **Unconnected Event Input EIPT:** The **EIPT** input is defined but not connected to the internal E_TON. This could indicate a planned extension or external use by the user. In the current version, it has no direct function within the function block network.
- **Authors and Version:** The function block was originally developed by Franz Höpfinger (HR Agrartechnik GmbH) and later revised by Patrick Aigner (version 3.0, April 2025). It is available under the Eclipse Public License 2.0.

State Overview

The FB itself does not manage its own state machine – the state logic resides in the integrated **E_TON**. Nevertheless, its behavior can be described as follows:

Input IN State	Behavior	Output Q.D1
FALSE → TRUE (rising edge)	Timer starts; after the timer expires, Q becomes TRUE	FALSE (until the timer expires) → TRUE
TRUE (while the timer is running)	Timer continues running	FALSE
TRUE → FALSE (falling edge)	Timer is immediately reset	TRUE → FALSE
TRUE (after the timer expires)	Output remains TRUE as long as IN is TRUE	TRUE
FALSE (any)	Output remains FALSE	FALSE

Application Scenarios

- **Machine Control:** Delaying the activation of drives or valves to prevent multiple components from starting simultaneously.
- **Signal Conditioning:** Debouncing switching signals by only considering a short pulse as valid after a defined time.

- **Process Automation:** Initiating subsequent steps only after a waiting period (e.g., in conveyor belts or dosing systems).
- **Adapter Integration:** Use in systems already based on the AX/AT adapter protocol without additional data lines.

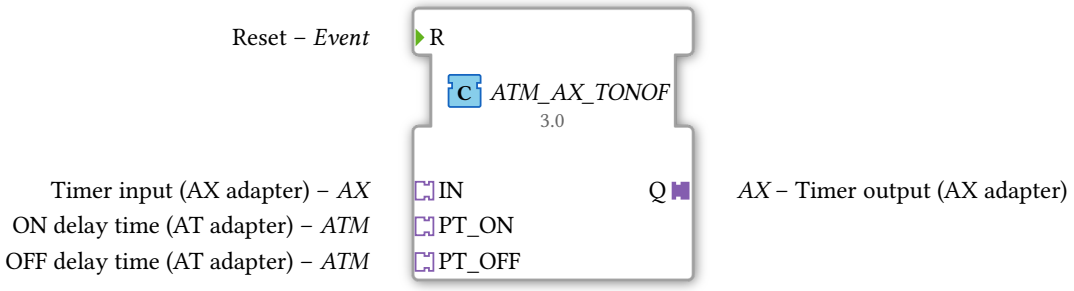
Comparison with Similar Function Blocks

Function Block	Type	Special Feature
E_TON (IEC 61499)	Standard On-Delay	Classic input/output interface; direct event and data ports
ATM_AX_TON	Adapter-based	Encapsulates E_TON and provides an AX/AT adapter; additional EIPT input (not connected)
E_TOF	Off-Delay	Delay on power-off (opposite behavior)
E_CTU	Up-counter	Counts events, not a timer

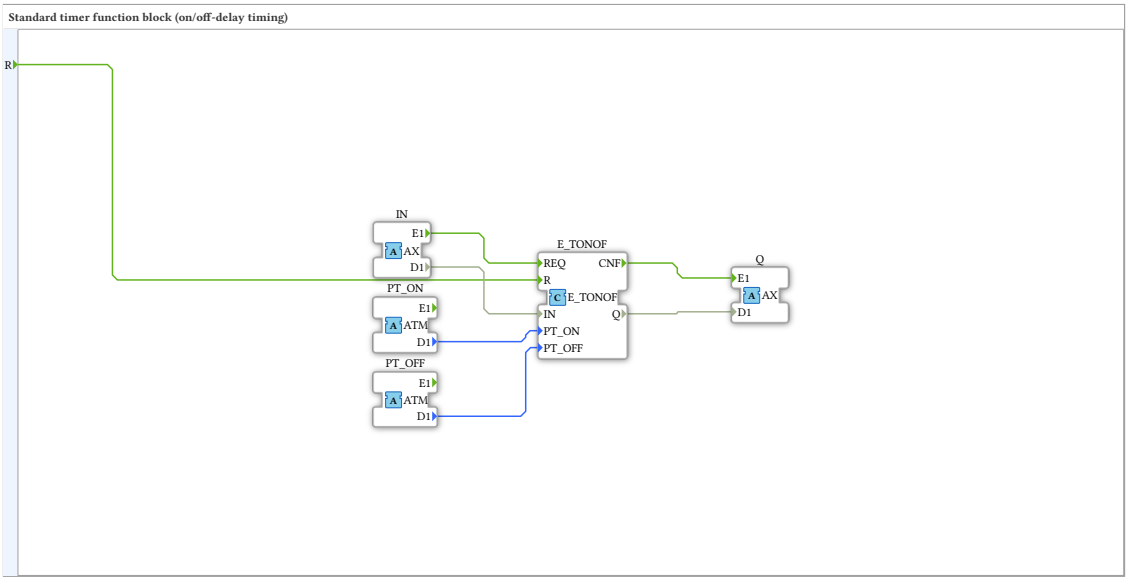
The **ATM_AX_TON** differs in its pure adapter interface and the lack of direct data coupling. It is particularly suitable for modular, hierarchically structured controllers.

Conclusion

The **ATM_AX_TON** is a ready-made on-delay timer with a modern, adapter-based interface. It simplifies the integration of time delays into larger systems that already use the AX/AT concept. The unconnected **EIPT** input offers potential for future expansions or customer-specific adaptations. Overall, the module is robust, well-documented, and available under an open-source license.



The **ATM_AX_TON** is a ready-to-use on-delay timer with a modern, adapter-based interface. It simplifies the integration of time delays into larger systems that already use the AX/AT concept. The unconnected **EIPT** input offers potential for future expansions or customer-specific adaptations. Overall, the module is robust, well-documented, and available under an open-source license.



The **ATM_AX_TON** is a ready-to-use, adapter-based interface. —

ATM_AX_TONOF

• – ○ • – ○ • – ○ •

Introduction

The function block **ATM_AX_TONOF** implements a combined on/off delay timer. It is designed as a standard timer module according to IEC 61499 and uses only adapter interfaces for communication. This allows it to be flexibly integrated into various communication structures. The module processes a Boolean input signal and outputs the delayed signal – both the on delay (ON-Delay) and the off delay (OFF-Delay) are configured via separate adapters.

Interface Structure

Event Inputs

Name	Type	Description
R	Event	Resets the timer. Both running delays are aborted, and output Q is immediately set to FALSE.

Event Outputs

The function block does not have any independent event outputs. The output event is provided via the output adapter **Q** (see Adapters).

Data Inputs

The function block does not have any direct data inputs. All necessary data (Boolean input and delay times) is read via the adapter interfaces.

Data Outputs

There are also no dedicated connections for data outputs. The current output state (BOOL) is output via the output adapter **Q**.

Adapters

Name	Direction	Type	Description
IN	Socket	AX (unidirectional)	Input adapter that triggers execution via its event E1 and provides the Boolean input value via its data D1.
PT_ON	Socket	ATM (unidirectional)	Adapter for the power-on delay time (TIME). The value is provided via D1.

PT_OFF	Socket	ATM (unidirectional)	Adapter for the power-off delay time (TIME). The value is provided via D1.
Q	Plug	AX (unidirectional)	Output adapter. Event E1 signals the update of the output value; data D1 contains the Boolean state of Q (TRUE or FALSE).

Functionality

The function block operates according to the following sequence:

- When the input signal **IN** changes from FALSE to TRUE, the timer starts the power-on delay with the time **PT_ON**. After this time has elapsed, the output **Q** is set to TRUE.
- When **IN** changes from TRUE to FALSE, the timer starts the power-off delay with the time **PT_OFF**. After this time has elapsed, **Q** is set to FALSE.
- An event at the reset input **R** immediately stops both running timers and sets **Q** to FALSE, regardless of the current state of **IN**.

The internal implementation uses the standardized function block **E_TONOF** from the IEC 61499 library. This ensures defined, robust timing behavior.

Technical Features

- **Adapter-based interface**: All inputs and outputs are handled via adapters (AX, ATM) instead of discrete event and data ports. This facilitates integration into modular systems and allows for a clean separation of communication and logic.
- **Standard compliance**: The function block is classified as a standard timer according to IEC 61499 and can be used in any 4diac IDE project.
- **Reset function**: The separate reset input enables immediate resetting without dependence on the current timer state.
- **Reusable adapter types**: The AX and ATM adapters are used multiple times in the application, so no additional type definitions are required.

State Overview

The internal timer **E_TONOF** cycles through the following states:

1. **IDLE**: No delay active. Output Q = state of IN (if updated after a previous delay).
2. **START_ON**: After the rising edge of IN – the timer for PT_ON runs.
3. **START_OFF**: After the falling edge of IN – the timer for PT_OFF runs.
4. **RESET**: Triggered by the event R, this interrupts any active timer and returns to the IDLE state with Q = FALSE.

Application Scenarios

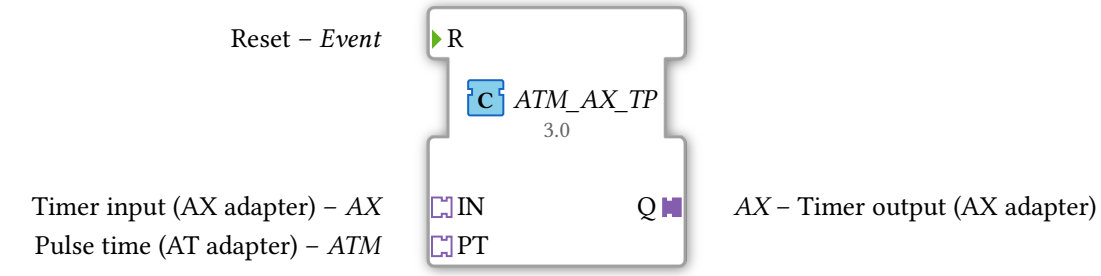
- **Delayed Switching On and Off of Actuators**: For example, to prevent bouncing or to stagger switching operations.
- **Motor Protection**: Switch-on delay prevents frequent switching on/off cycles; switch-off delay enables a defined overrun.
- **Door Control**: ON delay for time-delayed closing after release, OFF delay for automatic opening after a waiting period.
- **HMI Filtering**: Suppression of short, unwanted signal changes through adjustable dead times.

Comparison with similar function blocks

- **E_TON (TON)**: Implements only an on delay; the output is set to TRUE after the delay and remains TRUE as long as IN=TRUE.
- **E_TOF (TOF)**: Implements only an off delay; the output is set to TRUE immediately when IN=TRUE and falls back to FALSE after the delay when IN=FALSE.
- **E_TONOF**: Combines both delays in one function block. The **ATM_AX_TONOF** extends this concept with an adapter interface, thus simplifying integration with other adapter-based components. It offers the same functionality but with increased flexibility in system integration.

E_TONOF: Combines both delays in one function block.

Conclusion



The **ATM_AX_TONOF** is a powerful timer function block for delayed on/off switching operations. Its adapter-based interface allows it to be seamlessly integrated into modular automation solutions while remaining fully compliant with the IEC 61499 standard. Combining ON delay and OFF delay in a single block reduces wiring effort and simplifies application development. Thanks to its separate reset input and robust internal implementation, it is suitable for a wide range of industrial applications.

ATM_AX_TP

• – ○ • – ○ • – ○ •

Introduction

The **ATM_AX_TP** is a special timer function block that generates a time-limited pulse from an input signal. It implements the functionality of a **non-retriggerable pulse shaper**. The block is controlled via an AX adapter and outputs the result via another AX adapter; the pulse duration is specified via a separate ATM adapter. The adapter interfaces make it particularly easy to integrate into modular automation systems.

Interface Structure

Event Inputs

Name	Type	Comment
R	Event	Resets the timer

Event Outputs

No dedicated event outputs – the pulse output is provided via the **Q** adapter (see Adapter section).

Data Inputs

No direct data inputs. The input values (IN and PT) are provided via the corresponding adapter sockets.

Data Outputs

No direct data outputs. The output value (Q) is provided via the **Q** adapter.

Adapters

Name	Type	Direction	Description
Q	AX	Plug	Output: Provides the pulse signal
IN	AX	Socket	Input: Receives the triggering signal
PT	ATM	Socket	Input: Provides the pulse duration (pulse time)

Note: The adapters are of type *adapter::types::unidirectional::AX* (or *ATM*) and transmit an event along with a data value.

Functionality

The **ATM_AX_TP** operates based on the standardized IEC 61499 function block **E_TP**, which is instantiated within the network.

- **Triggering:** A rising edge at input **IN** (event IN.E1 and data value IN.D1 = TRUE) starts the timing.
- **Pulse Generation:** The output **Q** is immediately set to TRUE and remains active for the duration **PT**. After this time has elapsed, Q returns to FALSE.
- **Non-Retriggerable:** During an ongoing pulse, a subsequent rising edge from IN is ignored – the pulse continues at its original length.
- **Reset:** An event at input **R** immediately ends the current pulse (Q = FALSE) and resets the timer. A new pulse can then be started.

Internal wiring:
IN.E1 ⟶ E_TP.REQ `IN.D1 → E_TP.IN` PT.D1 ⟶ E_TP.PT `E_TP.CNF → Q.E1` (Event output at pulse end) E_TP.Q ⟶ Q.D1 `(Output data value) R → E_TP.R`

Technical Features

- **Adapter-based connection:** Unlike a direct E_TP, ATM_AX_TP operates exclusively via adapters (AX and ATM). This allows for loose coupling in distributed systems and simplifies the exchange of signal types.
- **Compatibility:** This function block is optimized for use with the Eclipse 4diac framework (recognizable by the package attribute `adapter::events::unidirectional::timers`).
- **Versioning:** Multiple versions document the evolution (reset function, package changes).
- **License:** Eclipse Public License 2.0 – the source code may be used, modified, and distributed.

State Overview

This function block does not have any explicit state machines at the top level – the state logic is implemented entirely by the internal **E_TP**. This state cycles through the following states:

- **IDLE** – waiting for the rising edge of IN
- **ACTIVE** – pulse is running (Q = TRUE, timer is running)
- **RESET** – returned to IDLE by event R (pulse terminates prematurely)

After the timer expires, E_TP automatically switches from ACTIVE to IDLE.

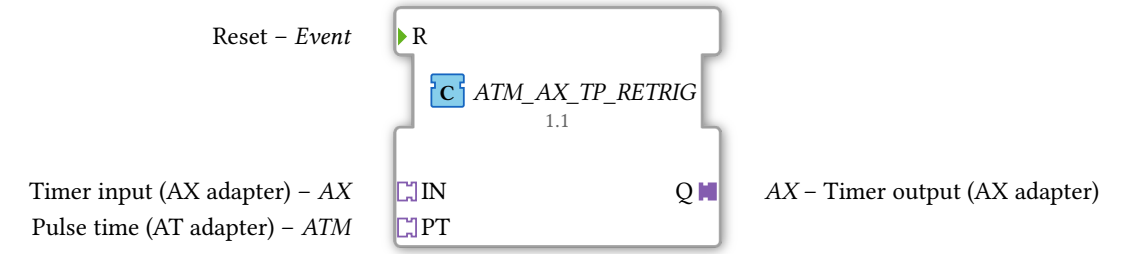
Application Scenarios

- **Control of momentary actuators:** Valves, lights, signal transmitters that should only be switched on for a specific duration.
- **Debouncing / Pulse shaping:** An incoming signal (e.g., push button) is converted into a precisely defined pulse.

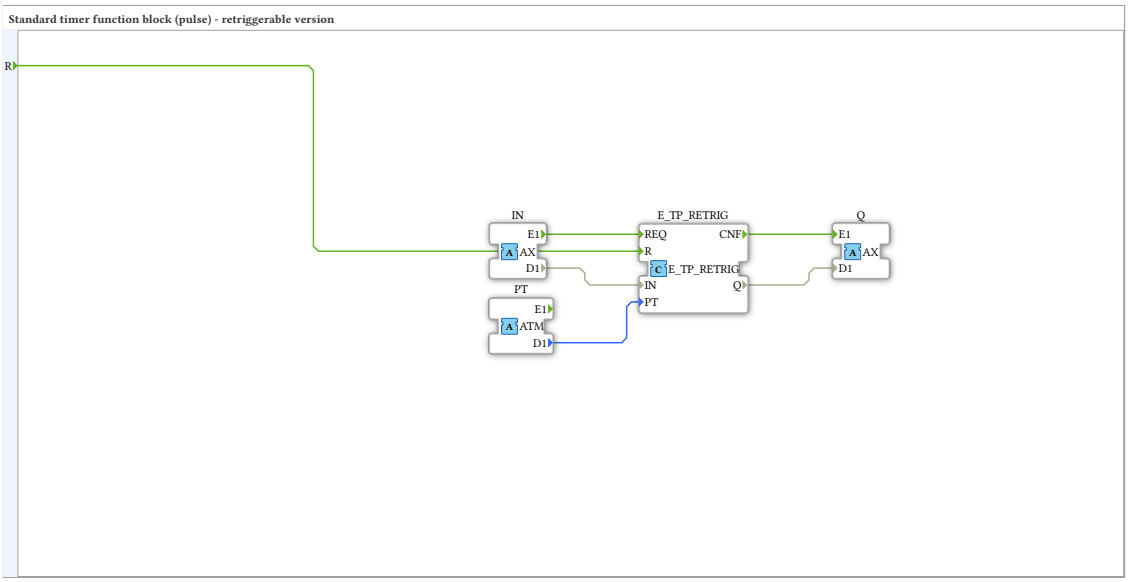
- **Modular automation:** Thanks to the adapter interfaces, the function block is suitable for use in distributed systems where signals are exchanged between different components.

Comparison with similar function blocks

Function block	Properties	Difference from ATM_AX_TP
E_TP (Standard)	Direct event/data connections, no adapter.	ATM_AX_TP encapsulates E_TP and provides adapters.
E_R_TRIG	Edge detection without pulse extension.	Generates only a very short pulse, no time control.
E_CYCLE	Cyclic timer, repeats pulses.	Single pulse.



Conclusion



The **ATM_AX_TP** is a useful function block for generating a non-retriggerable pulse with adjustable duration. Its special feature lies in the adapter-based interface, which enables flexible and loose coupling in IEC 61499 systems. The embedded standard timer E_TP ensures robust and proven functionality. A practical function block for all applications where a defined time window needs to be triggered by an external signal.

ATM_AX_TP_RETRIG

• – ○ • – ○ • – ○ •

Introduction

The `ATM_AX_TP_RETRIG` is a retriggerable pulse timer function block. It generates a pulse of defined duration at the output when the input switches to TRUE. During the pulse's execution, additional triggers can restart the timer (retrigger function). A reset input immediately terminates the pulse. The block uses standardized adapters for input and output, enabling flexible integration into modular control systems.

Interface Structure

Event Inputs

- **R** (Event) – Reset: Resets the timer and terminates the current pulse.

Event Outputs

- **Q.E1** (Event) – Output Event: Triggered via adapter Q when the pulse state changes (start or end).

Data Inputs

- **IN.D1** (BOOL) – Trigger Input: On a rising edge and a TRUE value, the timer starts.
- **PT.D1** (TIME) – Pulse Duration: Specifies the time for which output Q is set to TRUE after a trigger.

Data Outputs

- **Q.D1** (BOOL) – Pulse Output: Displays TRUE during the pulse duration, otherwise FALSE.

Adapters

- **IN** (Socket, Type AX) – Input Adapter: Couples the trigger event (E1) and the Boolean trigger value (D1).
- **PT** (Socket, Type ATM) – Time Adapter: Returns the pulse duration as a TIME value (D1).
- **Q** (Plug, Type AX) – Output Adapter: Provides the pulse state (D1) and an event on state change (E1).

Functionality

The function block internally uses the standard function block `E_TP_RETRIG`. An event at the input **IN** (rising edge of IN.E1) starts the timer, provided **IN.D1** = TRUE. The output **Q.D1** is set to TRUE for the time specified in **PT.D1**. During this time, a subsequent trigger (repeated IN.E1 with IN.D1 = TRUE) triggers a retrigger: The timer is reset, and the pulse starts again. An event at the reset input **R** immediately ends the pulse, and **Q.D1** becomes FALSE. After the pulse duration has elapsed without a further trigger, **Q.D1** automatically returns to FALSE.

Technical Features

- **Retriggerable**: Multiple triggers during a running pulse restart the timer without extending the pulse duration.
- **Adapter-based interface**: The IN, PT, and Q adapters ensure a clean separation of event and data communication.
- **Internal standard module**: The actual timer logic is executed by the IEC 61499-compliant `E_TP_RETRIG` module.
- **Unidirectional adapters**: Both the AX and ATM adapters are unidirectional, clearly defining the data flow direction.

State overview

The module has two main states:

State	Q.D1	Description
IDLE	FALSE	Idle state, no pulse active.
TIMING	TRUE	Pulse running, timer counts down the duration PT.

Transitions:

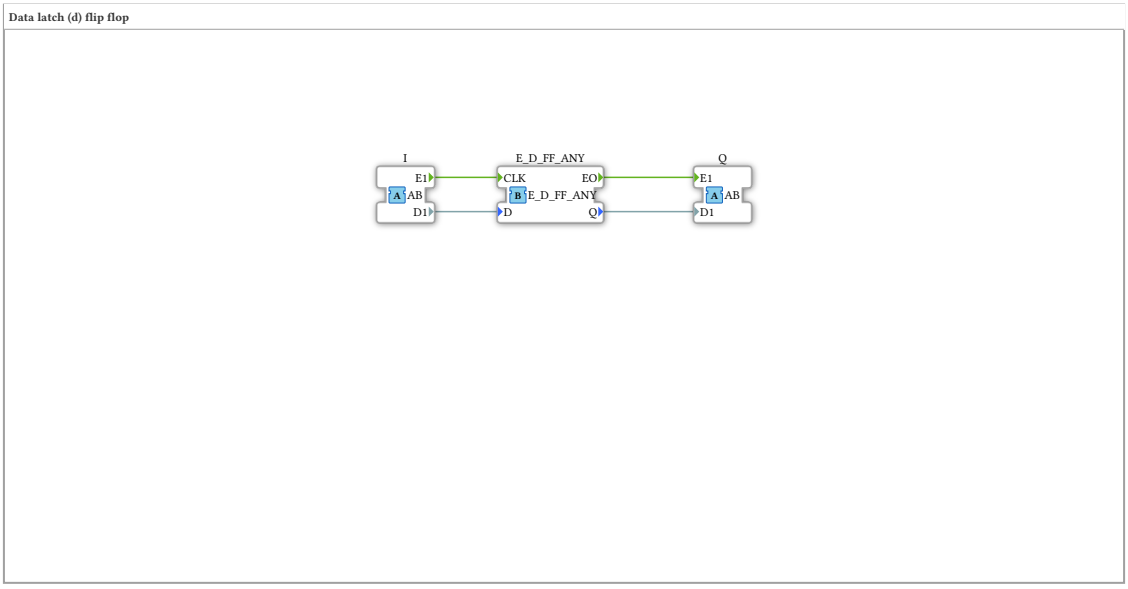
- IDLE ⟶ TIMING: Trigger (IN.E1 with IN.D1 = TRUE)
- TIMING ⟶ TIMING (Retrigger): A subsequent trigger restarts the timer.
- TIMING ⟶ IDLE: Timer expires or Reset (R)
- IDLE ⟶ IDLE: Reset has no effect

Application Scenarios

- **Pulse Control for Actuators**: Control of valves, lamps, or motors that are activated for a defined time upon receiving a start signal.
- **Safety Applications**: Retriggerable pulses allow for a renewed request during an ongoing action, e.g., for button retriggering.
- **Modular Automation Systems**: Use in combination with other adapter-based components for standardized communication via AX/ATM interfaces.

Comparison with Similar Function Blocks

- *E_TP (non-retriggerable)*: Ignores a subsequent trigger during the running pulse; once started, the pulse always runs its full course.
- *E_TP_RETRIG (Standard)*: Same timer logic, but without an adapter interface – connected directly via event and data inputs.
- *TON / TOF*: Other timer types; TON delays power-on, TOF delays power-off – neither generates pulses.



Conclusion

The `ATM_AX_TP_RETRIG` combines the proven retriggerable pulse function with an adapter-based interface. By using standardized AX and ATM adapters, it is particularly well-suited for modular and reusable control solutions. The retrigger feature offers flexibility in applications where a pulse needs to be restarted upon request.

AB_D_FF

No image available.

Value to latch – *AB*

AB – Latched value

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_D_FF** implements an asynchronous data latch (D flip-flop) based on an adapter concept according to IEC 61499. It receives a data value via the input adapter **I** as soon as an event occurs and outputs this value via the output adapter **Q**. The internal state of the flip-flop is represented by a standardized `E_D_FF_ANY` function block.

Interface Structure

Event Inputs

- **I.E1** (via adapter `I`): Initiates the data value acquisition.

Event Outputs

- **Q.E1** (via adapter `Q`): Signals the output of the latched data value.

Data Inputs

- **I.D1** (via adapter `I`): The data value to be latched (any type, depending on the adapter type used, `adapter::types::unidirectional::AB`).

Data Outputs

- **Q.D1** (via adapter `Q`): The latched and output data value.

Adapters

- **I** (Socket): Input adapter of type `adapter::types::unidirectional::AB` – receives the value to be latched and the control event.
- **Q** (Plug): Output adapter of the same type – outputs the stored value and the associated event.

Functionality

The function block operates in an event-driven manner:

1. As soon as an event arrives at the input adapter **I.E1**, the current value at the data input **I.D1** is transferred to the internal D flip-flop (`E_D_FF_ANY`).
2. Subsequently, the stored value is output at **Q.D1**, and an event is simultaneously generated at the output **Q.E1**.

Thus, the component behaves like a classic edge-triggered D latch, where the transfer and output occur synchronously with the input event.

Technical Features

- **Adapter Interface**: The component uses only adapters (`adapter::types::unidirectional::AB`) for input and output, which allows for flexible typing and loose coupling with other components.
- **Internal Implementation**: The latching core is implemented using the standardized function block `E_D_FF_ANY` from the IEC 61499 library `iec61499::events`. This stores the data value and generates the output event.
- **Event and data paths** are strictly separated: The event triggers the data transfer; data flows independently.

State Overview

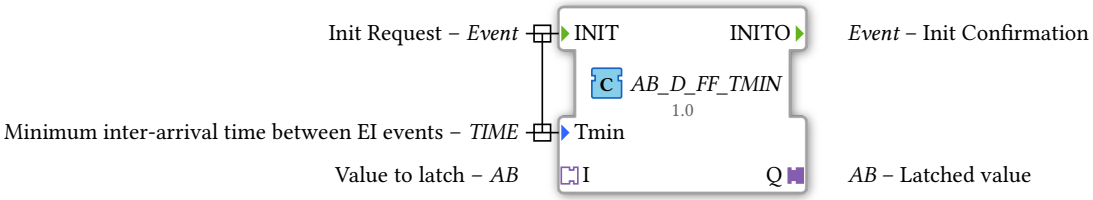
The function block does not have an explicit internal state machine but relies on the implicit state of the embedded `E_D_FF_ANY`:

- **Idle**: Waiting for an event on `I.E1`.
- **Latching**: After receiving the event, the data value is transferred and output.
- The internally stored value is retained until the next event.

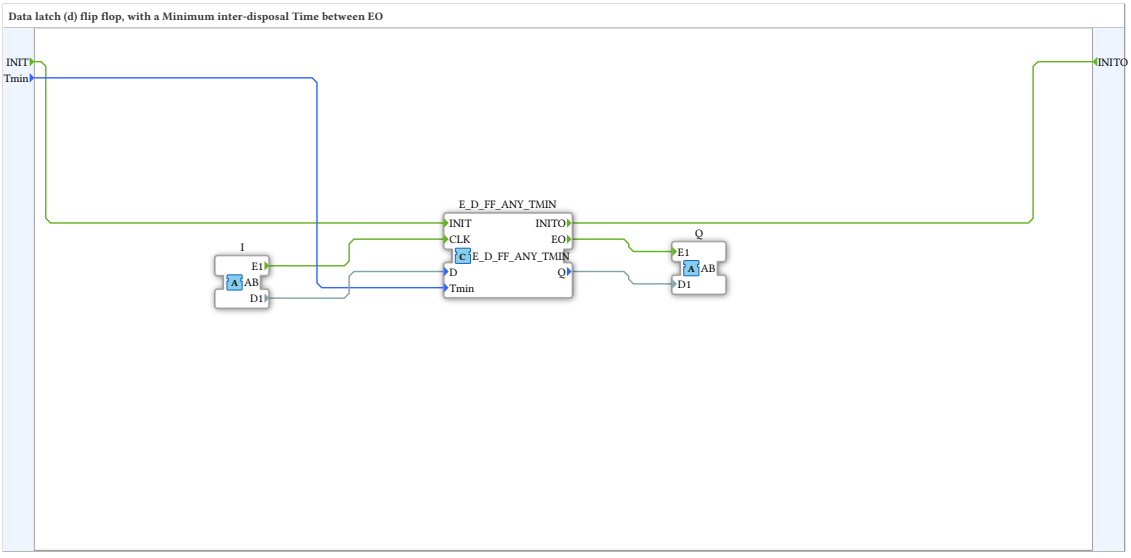
Application Scenarios

- **Data Synchronization**: Reliable transfer of measured values or control data at defined times (e.g., clock pulse).
- **Buffering**: Intermediate storage of values in sequence control systems between different function blocks.
- **Register Creation**: Construction of shift registers or memory cells in modular automation systems.

Comparison with Similar Function Blocks



Function Block	Description
AB_SR_FF	Set-Reset Flip-Flop, stores two states (Set/Reset) without a data value.
AB_T_FF	Toggle Flip-Flop, changes the output state with each event.
E_D_FF	Standard D Flip-Flop without an adapter interface, direct event and data pins.



The **AB_D_FF** offers type-safe and reusable encapsulation through its adapter interface, whereas comparable devices often rely on fixed data types.

Conclusion

The **AB_D_FF** is a compact and flexible D-latch device that leverages the advantages of the IEC 61499 architecture. Its adapter interface allows it to be used in a wide variety of contexts without being restricted to a specific data type. Together with the internal standard flip-flop, it ensures reliable and event-driven data storage.

AB_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The **AB_D_FF_TMIN** is an adapter-based function block (FB) according to IEC 61499 that implements the functionality of a data latch (D flip-flop) with a minimum time condition between successive output events. It serves to transfer a digital data value from an adapter socket (input) to an adapter plug (output), ensuring that the output events (EO) do not occur faster than permitted by a configured time parameter `Tmin`. The block abstracts the pure D flip-flop logic by using an internal flip-flop block and encapsulates data and events in adapter interfaces.

Interface Structure

Event Inputs

Name	Type	Comment

INIT	EInit	Initialization Request (sets the minimum time)

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement

Data Inputs

Name	Type	Comment
Tmin	TIME	Minimum time between two output events (EO)

Data Outputs

No direct data outputs; Data output is handled via the adapter plug Q.

Adapter

Direction	Name	Type	Comment
Socket	I	adapter::types::unidirectional::AB	Input adapter: returns event E1 and data value D1 (the value to be latched)
Plug	Q	adapter::types::unidirectional::AB	Output adapter: outputs the latched data value D1 and the event E1

Note: The adapter unidirectional::AB defines an event E1 and a data value D1 (typically a Boolean or any generic type). The exact type definition of the adapter is outside this function block.

Functionality

The function block works internally with the function block E_D_FF_ANY_TMIN (type iec61499::events::E_D_FF_ANY_TMIN), which implements the core logic of the D flip-flop with a minimal hold time between output events. The functionality is structured as follows:

1. **Initialization:**

An event at INIT passes the parameter Tmin (minimum time) to the inner function block. The function block acknowledges this with INITO.

1. **Data Acquisition and Transmission:**

- An event E1 occurs at socket I, which carries the data value D1 (the signal to be latched).
- This event is forwarded as CLK to the inner flip-flop, which simultaneously receives the data value D1 from I.D1.
- The inner flip-flop stores the value D1 and outputs it at its output Q.
- The latched value is passed out via plug Q.D1, and at the same time, the output event EO of the inner flip-flop is triggered.
- This EO is forwarded to Q.E1, so that the receiving adapter is informed of the update.

` 3. **Time Control:**
The internal function block E_D_FF_ANY_TMIN ensures that after an output event EO, no further output events can be generated for the duration of Tmin – regardless of how quickly input events arrive. If the time between two E1 inputs exceeds the Tmin threshold, the value is immediately adopted; otherwise, it is blocked until the minimum time has elapsed.

Technical Features

- **Adapter-Based Interface:**

Instead of individual event/data ports, the function block uses adapters that transport events and data as an encapsulated unit. This increases reusability and reduces the number of external connections.

- **Minimum Output Time (Tmin):**

The setting `Tmin` prevents output events from being triggered too quickly, which is useful in time-critical control systems (e.g., for debouncing or maintaining processing cycles).

- **Internal Use of a Specialized Function Block:**

The function block delegates the actual flip-flop logic to the system-internal function block `E_D_FF_ANY_TMIN`, which is responsible for correct timing. This keeps the external function block lean and error-free.

- **Typed Adapter:**

The adapter type `adapter::types::unidirectional::AB` is defined as unidirectional: data and events flow only in one direction (from the socket to the plug). This makes the function block strictly upward compatible.

State Overview

The function block does not have an explicit visible state machine; The state is determined by the internal flip-flop and the timing:

- **State 0 (initial / not latched):** After INIT or a reset (not explicitly implemented), the state is undefined. The value `Q.D1` is only set after the first valid `E1` event at the socket.
- **State 1 (latched and active):** The internal flip-flop has a data value stored. After an output event, a lock state is maintained for the duration `Tmin`, during which incoming `E1` events are ignored or delayed. After the minimum time has elapsed, the function block is ready for the next takeover.
- **State 1 (latched and active):** (No SFC or ECC is defined in the XML; the state logic is entirely contained within the internal function block.)

Application Scenarios

- **Signal Debouncing:**

If a sensor or button generates multiple rapid pulses (bounce), the function block (FB) can prevent multiple values from being passed on in quick succession by setting `Tmin` to, for example, 20 ms.

- **Cyclic Data Passing with Minimum Interval:**

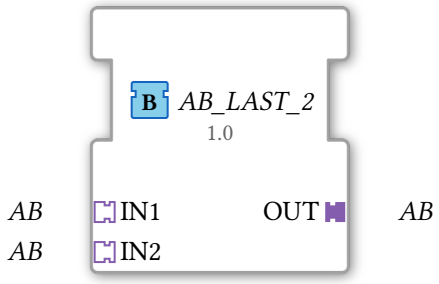
In a distributed control system, a measured value should only be sent to a higher-level component at certain minimum intervals. The FB acts as a buffer that limits the update rate.

- **Reliable Transfer in Time-Critical Systems:**

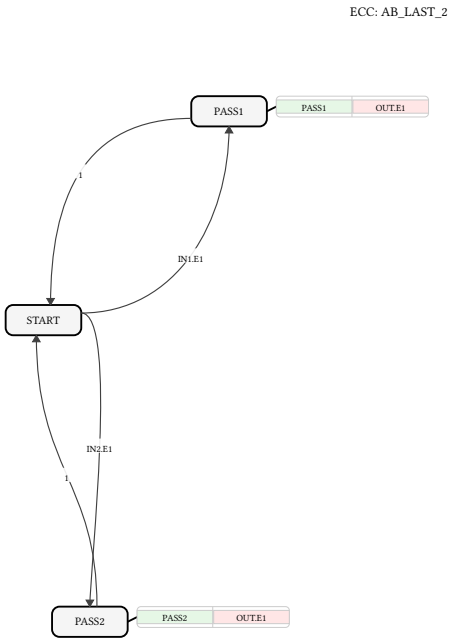
When transferring a value from a fast to a slower clock range, the FB can be set to a suitable `Tmin`.Prevent data loss or noise.

Comparison with similar components

Component	Properties
AB_D_FF	Pure D flip-flop without a minimum output time – events are passed on immediately.
E_D_FF_ANY	Standard event data flip-flop without a time limit, but with discrete ports (no adapters).
AB_D_FF_TMIN	Combines adapter encapsulation with a configurable minimum time between output events.
R_TRIG / F_TRIG	Detects rising/falling edges – no functionality for latching a data value.



The **AB_D_FF_TMIN** stands out due to the integration of timing control into adapter-based D flip-flop logic and is therefore particularly suitable for applications requiring both data latching and temporal decoupling.



Conclusion

The **AB_D_FF_TMIN** is a compact, adapter-based function block that extends the basic functionality of a D flip-flop by adding the ability to maintain a minimal waiting time between output events. The encapsulated adapter interface and the internal use of a specialized flip-flop component ensure high

reusability and a clear separation of logic and timing control. This component is particularly well-suited for industrial control applications where signal processing with temporal constraints is required.

AB_LAST_2

Introduction

The AB_LAST_2 function block merges two same-type BYTE adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: BYTE adapter (unidirectional) - first signal source
- **IN2**: BYTE adapter (unidirectional) - second signal source

Output adapter (Plug):

- **OUT**: BYTE adapter (unidirectional) - merged signal

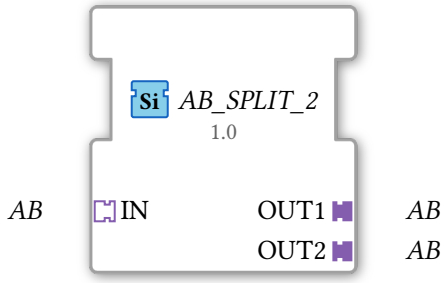
How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event

is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid BYTE signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same BYTE value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AB_LAST_2 is the inverse of `AB_SPLIT_2`: AB_SPLIT_2 distributes 1 input to 2 outputs, AB_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

AB_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_SPLIT_2** splits a unidirectional adapter of type `AB` into two separate adapter outputs. It is implemented as a generic function block (Generic FB) and allows the simultaneous forwarding of the incoming adapter to two independent target addresses. This simplifies the topology in control applications when a signal is needed multiple times without affecting the original data flow.

Interface Structure

Event Inputs

No event inputs are available.

Event Outputs

No event outputs are available. Adapter communication occurs without events via the data exchange mechanism of the adapter type.

Data Inputs

No data inputs are available. Data flows exclusively through the adapter input `IN`.

Data Outputs

No data outputs are available. Outputs are provided via the adapter outputs `OUT1` and `OUT2`.

Adapter

Role	Name	Type	Direction
Socket	IN	`adapter::types::unidirectional::AB`	Input

Plug	OUT1	`adapter::types::unidirectional::AB`	Output
Plug	OUT2	`adapter::types::unidirectional::AB`	Output

Functionality

The function block forwards the adapter connected via socket `IN` unchanged to both plugs `OUT1` and `OUT2`. Any change to the data or state of the incoming adapter is propagated simultaneously to both outputs. The distribution occurs without delay or buffering – it is a pure distribution logic.

Technical Features

- **Generic Function Block:** The function block is declared as a generic type (`GEN_AB_SPLIT`), so it can work with different subtypes of the adapter `AB`, provided they have the same unidirectional semantics.
- **Unidirectionality:** The adapter is designed exclusively in one direction – data flows from the socket to the plugs. Backward communication is not supported.
- **License:** This function block is licensed under the Eclipse Public License 2.0 (EPL-2.0), which permits free use, modification, and distribution in your own projects.
- **No State Machines:** The function block has no internal states or event-driven processes, as adapter routing is entirely data-driven.

State Overview

The function block does not have a state machine. The output adapters always reflect the current state of the input adapter.

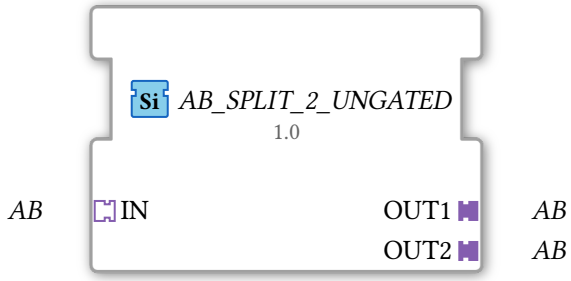
Application Scenarios

- **Signal Distribution in Modular Systems:** Separation of a sensor signal from a fieldbus component for parallel processing in two independent control logics.
- **Redundancy Setup:** An incoming signal can be sent to different controllers or monitoring units via two separate paths.
- **Prototypes and Test Setups:** Easy duplication of an adapter stream for simulation and debugging purposes without modifying the actual application.

Comparison with Similar Function Blocks

Compared to dedicated **SPLIT FBs** with event/data ports, `AB_SPLIT_2` operates purely on an adapter basis. While classic split function blocks often require triggered data copies, distribution here occurs continuously and without explicit activation. Adapter multiplexers or bus couplers offer similar functionality, but with more complex configurations. This function block is specifically designed for the unidirectional `AB` adapter.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AB_SPLIT_2` is a simple yet effective generic function block for splitting a unidirectional adapter into two outputs. It increases the flexibility of adapter cabling in industrial control systems according to IEC 61499 and is freely available thanks to the EPL 2.0 license. For applications requiring a 1:2 distribution of adapter data, it offers a clean and maintainable solution.

AB_SPLIT_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AB_SPLIT_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_SPLIT_2_UNGATED** splits a unidirectional adapter of type `AB` into two separate adapter outputs. It is implemented as a generic function block (Generic FB) and allows the simultaneous forwarding of the incoming adapter to two independent target addresses. This simplifies the topology in control applications when a signal is needed multiple times without affecting the original data flow.

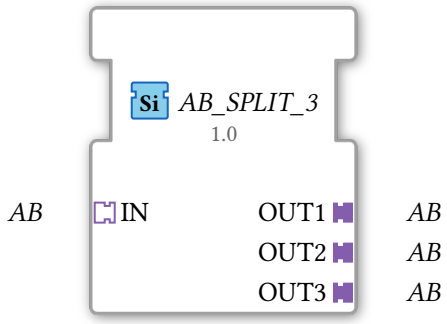
- **Prototypes and Test Setups:** Easy duplication of an adapter stream for simulation and debugging purposes without modifying the actual application.

Comparison with Similar Function Blocks

Compared to dedicated **SPLIT FBs** with event/data ports, `AB_SPLIT_2_UNGATED` operates purely on an adapter basis. While classic split function blocks often require triggered data copies, distribution here occurs continuously and without explicit activation. Adapter multiplexers or bus couplers offer similar functionality, but with more complex configurations. This function block is specifically designed for the unidirectional `AB` adapter.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AB_SPLIT_2_UNGATED` is a simple yet effective generic function block for splitting a unidirectional adapter into two outputs. It increases the flexibility of adapter cabling in industrial control systems according to IEC 61499 and is freely available thanks to the EPL 2.0 license. For applications requiring a 1:2 distribution of adapter data, it offers a clean and maintainable solution.

AB_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_SPLIT_3** is used to split an incoming unidirectional data/signal adapter (type `AB`) into three identical output adapters. It is implemented as a generic function block and represents a simple 1-to-3 distribution without additional logic or delay.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AB`	`IN`	Socket (Input)	Receives a unidirectional AB-type adapter.
`adapter::types::unidirectional::AB`	`OUT1`	Plug (Output)	First output of the incoming signal.
`adapter::types::unidirectional::AB`	`OUT2`	Plug (Output)	Second output of the incoming signal.
`adapter::types::unidirectional::AB`	`OUT3`	Plug (Output)	Third output of the incoming signal.

Functionality

The module forwards the unidirectional adapter connected to socket `IN` **without manipulation** to the three plugs `OUT1`, `OUT2`, and `OUT3` in parallel. No buffering, processing, or timing control takes place. The module functions purely as a **splitter** (distributor) for adapter-based signals.

Since the adapter `AB` is unidirectional, data transmission occurs exclusively in one direction (from the socket to the plugs). The three outputs are independent of each other and always provide the current state of the input.

Technical Features

- **Generic Block**: The function block is marked as generic by the attribute `eclipse4diac::core::GenericClassName('GEN_AB_SPLIT')`. This means the actual adapter type can be specified at runtime or during instantiation, as long as it has the basic structure of a unidirectional AB adapter.
- **Unidirectionality**: Both the input and output adapters are of type `unidirectional::AB`. Reverse communication is not supported.
- **No State Maintenance**: The block has no internal state machine or memory. The routing is passive and continuous.
- **Copyright**: The block was released by HR Agrartechnik GmbH under the Eclipse Public License 2.0.

State Overview

The function block has **no explicit state machine**. The behavior is purely data-flow oriented: As soon as the input adapter provides data, it is immediately propagated to all outputs. No state monitoring or control is required.

Application Scenarios

- **Signal Distribution in Automation Technology**: Splitting a sensor signal (e.g., temperature, pressure) to multiple processing units.
- **Parallelization of Control Sequences**: Providing the same adapter stream to different function blocks that operate independently.
- **Prototyping and Testing**: Using a simulated adapter to supply multiple system components simultaneously.

Comparison with Similar Function Blocks

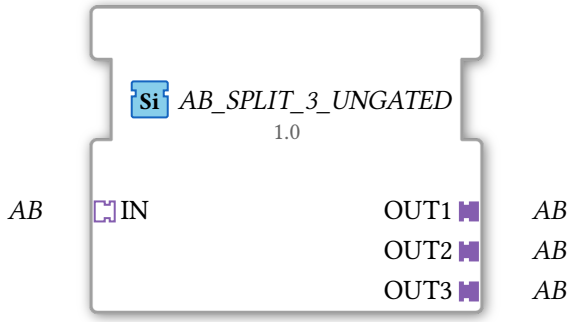
Function Block	Behavior	Special Feature
`SPLIT_2`	1-to-2 Distribution	Analog function block with two outputs.
`AB_SPLIT_3`	1-to-3 Distribution	This block.
`AB_JOIN`	Combining Multiple Adapters	Counterpart to the splitter.

While `SPLIT_2` offers only two outputs, `AB_SPLIT_3` covers the need for triple distribution. No additional logic functions such as filtering or delay are implemented.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The **AB_SPLIT_3** is a simple yet useful generic splitter block for unidirectional adapters. It enables clean structuring of automation applications by splitting an incoming signal path into three parallel paths. Thanks to its generic nature, it can be used with any AB adapter type and integrates seamlessly into the IEC 61499-2 compliant 4diac development environment.

adapter::types::unidirectional::AB	OUT3	Plug (Output)	Third output of the incoming signal.

Functionality

The module forwards the unidirectional adapter connected to socket `IN` **without manipulation** to the three plugs `OUT1`, `OUT2`, and `OUT3` in parallel. No buffering, processing, or timing control takes place. The module functions purely as a **splitter** (distributor) for adapter-based signals.

Since the adapter `AB` is unidirectional, data transmission occurs exclusively in one direction (from the socket to the plugs). The three outputs are independent of each other and always provide the current state of the input.

Technical Features

- **Generic Block**: The function block is marked as generic by the attribute `eclipse4diac::core::GenericClassName ('GEN_AB_SPLIT')`. This means the actual adapter type can be specified at runtime or during instantiation, as long as it has the basic structure of a unidirectional AB adapter.
- **Unidirectionality**: Both the input and output adapters are of type `unidirectional::AB`. Reverse communication is not supported.
- **No State Maintenance**: The block has no internal state machine or memory. The routing is passive and continuous.
- **Copyright**: The block was released by HR Agrartechnik GmbH under the Eclipse Public License 2.0.

State Overview

The function block has **no explicit state machine**. The behavior is purely data-flow oriented: As soon as the input adapter provides data, it is immediately propagated to all outputs. No state monitoring or control is required.

Application Scenarios

- **Signal Distribution in Automation Technology**: Splitting a sensor signal (e.g., temperature, pressure) to multiple processing units.
- **Parallelization of Control Sequences**: Providing the same adapter stream to different function blocks that operate independently.
- **Prototyping and Testing**: Using a simulated adapter to supply multiple system components simultaneously.

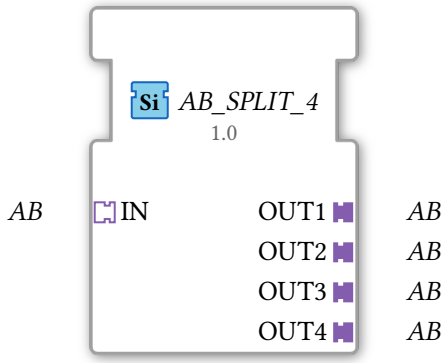
Comparison with Similar Function Blocks

Function Block	Behavior	Special Feature
SPLIT_2	1-to-2 Distribution	Analog function block with two outputs.
AB_SPLIT_3_UNGATED	1-to-3 Distribution	This block.
AB_JOIN	Combining Multiple Adapters	Counterpart to the splitter.

While `SPLIT_2` offers only two outputs, `AB_SPLIT_3_UNGATED` covers the need for triple distribution. No additional logic functions such as filtering or delay are implemented.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.



Conclusion

The **AB_SPLIT_3_UNGATED** is a simple yet useful generic splitter block for unidirectional adapters. It enables clean structuring of automation applications by splitting an incoming signal path into three parallel paths. Thanks to its generic nature, it can be used with any AB adapter type and integrates seamlessly into the IEC 61499-2 compliant 4diac development environment.

AB_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_SPLIT_4** is used to distribute a single incoming unidirectional adapter connection of type `AB` to four parallel outgoing adapter connections of the same type. It is designed as a generic block and enables the distribution of a data or signal flow across multiple downstream components.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AB`	Incoming unidirectional adapter connection
Plug	`OUT1`	`adapter::types::unidirectional::AB`	First outgoing adapter connection
Plug	`OUT2`	`adapter::types::unidirectional::AB`	Second outgoing adapter connection
Plug	`OUT3`	`adapter::types::unidirectional::AB`	Third outgoing adapter connection
Plug	`OUT4`	`adapter::types::unidirectional::AB`	Fourth Outgoing Adapter Connection

Functionality

This component functions as a passive splitter at the adapter level. As soon as an adapter connection of type `AB` is established at socket `IN`, the component forwards the data or signals arriving via this connection unchanged to all four plugs `OUT1` to `OUT4`. The distribution occurs without data modification or buffering. The component has no events or data points of its own; all communication takes place exclusively via the adapter interfaces.

Technical Features

- **Generic Design:** The function block is implemented as a generic FB (`GenericClassName = 'GEN_AB_SPLIT'`) and can therefore be used for various specific implementations of the adapter type `AB`.
- **Unidirectionality:** The adapters are declared as unidirectional. This means that data flow occurs only in one direction (from the socket to the plugs). No return channels are provided.
- **No Active Logic:** The function block contains no algorithm or state machine. It functions purely passively as a wiring aid at the architecture level.
- **Simplicity:** The function block reduces the complexity of system wiring by modeling a physical or logical division of an adapter signal.

State Overview

The function block does not have an internal state machine (ECC – Execution Control Chart). It behaves statically and forwards the data present at `IN` to all outputs throughout its entire runtime. There are no interrupt or initialization states.

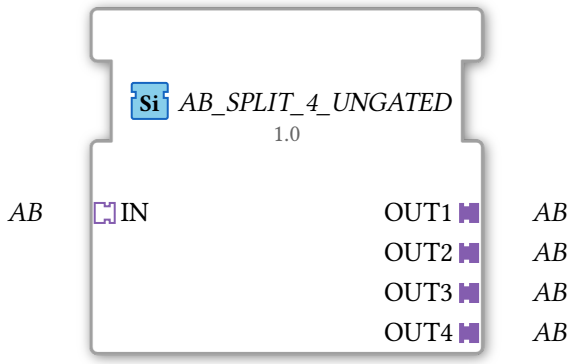
Application Scenarios

- **Distributing Sensor Values:** A sensor delivers data via a `AB` adapter, which must be forwarded in parallel to several control modules or display units.
- **Test and Diagnostic Environments:** A data stream is sent to a processing unit and simultaneously to a logging or monitoring component.
- **Modular Systems:** Within a larger automation application, the function block can be used to split a common bus signal to several downstream function blocks.

Comparison with Similar Function Blocks

Similar splitter function blocks exist for other adapter types or for data-based forwarding. The `AB_SPLIT_4` is characterized by its specific fit for the adapter type `AB` and its unidirectional design. Unlike function blocks with event or data interfaces, it requires no additional clocking or synchronization – the distribution is implicit in the connection topology.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AB_SPLIT_4` is a simple yet useful generic function block for multiplying a unidirectional adapter connection. It simplifies the structuring of control applications by avoiding redundant wiring and enabling a clear distribution of signal pins. Its generic implementation makes it flexible and usable in various contexts.

AB_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AB_SPLIT_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

The `AB_SPLIT_4_UNGATED` is a simple yet useful generic function block for multiplying a unidirectional adapter connection. It simplifies the structuring of control applications by avoiding redundant wiring and enabling a clear distribution of signal pins. Its generic implementation makes it flexible and usable in various contexts.

AB_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AB_SPLIT_5` is used to distribute one unidirectional AB adapter input (socket) to five identical AB adapter outputs (plugs). It is a generic function block designed for signal distribution in automation systems.

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs
None. Data transmission occurs exclusively via the adapter interfaces.

Data Outputs
None.

Adapters

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AB`	Unidirectional AB adapter providing the input signal.
Plug (Output)	`OUT1`	`adapter::types::unidirectional::AB`	First unidirectional AB adapter output.
Plug (Output)	`OUT2`	`adapter::types::unidirectional::AB`	Second unidirectional AB adapter output.
Plug (Output)	`OUT3`	`adapter::types::unidirectional::AB`	Third unidirectional AB adapter output.
Plug (Output)	`OUT4`	`adapter::types::unidirectional::AB`	Fourth unidirectional AB adapter output.
Plug (Output)	`OUT5`	`adapter::types::unidirectional::AB`	Fifth unidirectional AB adapter output.

Functionality
The module receives a unidirectional AB signal via socket `IN`. This signal is forwarded without modification to all five plugs (`OUT1` to `OUT5`). This creates five identical copies of the input signal, which can be connected in parallel to various subsequent components or systems.

Since the component has no event or data inputs, all communication takes place exclusively via the adapter interfaces. Distribution is static and without delay or buffering.

Technical Features
- **Generic Component**: `AB_SPLIT_5` uses the generic class name `GEN_AB_SPLIT` and enables type-safe instantiation in the 4diac IDE.
- **Unidirectional**: All participating adapters are of type `unidirectional::AB`, meaning data flows only in one direction (from the socket to the plugs).
- **No State Logic**: The function block has no internal state diagram or event processing – it is purely structural and does not perform any data transformation.

State Overview
There is no state machine. The function block operates continuously and permanently passes the received signal to all five outputs.

Application Scenarios
- **Signal Distribution in Fieldbus Systems**: When a sensor value or control signal (as an AB adapter) needs to be sent to multiple actuators or controllers.
- **Multiplexing in Modular Machines**: Distribution of a central AB signal to different modules of a system.

- **Testing and Simulation**: Simultaneously connecting multiple monitoring or logging units to a data source.

Comparison with Similar Function Blocks

Function Block	Number of Outputs	Special Features
`AB_SPLIT_2`	2	Simple 1:2 distribution
`AB_SPLIT_3`	3	1:3 distribution
`AB_SPLIT_5`	5	1:5 distribution (this block)
`AB_SPLIT_N` (generic)	configurable	Individual number via GenericClassName

Compared to a configurable split block, `AB_SPLIT_5` offers a fixed, yet simple and type-safe solution without additional configuration effort.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AB_SPLIT_5` is a lean, specialized function block for the 1:5 distribution of unidirectional AB adapter signals. Thanks to its generic implementation and clear interface structure, it is ideally suited for the modular design of automation systems where a signal is required multiple times.

AB_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_SPLIT_6** is a generic adapter splitter. It serves to distribute an incoming unidirectional adapter data stream (type `AB`) simultaneously to six separate outputs. This allows the data from a single adapter to be made available to multiple downstream blocks without data loss.

Interface Structure

Event Inputs
The block has no event inputs. Data is passed exclusively via the adapter interface.

Event Outputs
There are no event outputs. Output is provided solely via the adapters.

Data Inputs
The block has no separate data inputs. The actual user data is transported via the adapter input `IN`.

Data Outputs
There are no explicit data outputs. The distributed data is provided via the adapter outputs `OUT1` to `OUT6`.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AB`	`IN`	Socket	Input adapter that supplies the data to be distributed.
`adapter::types::unidirectional::AB`	`OUT1`	Plug	First output adapter – receives a copy of the input data.
adapter::types::unidirectional::AB`	`OUT2`	Plug	Second output adapter.
adapter::types::unidirectional::AB`	`OUT3`	Plug	Third output adapter.
adapter::types::unidirectional::AB`	`OUT4`	Plug	Fourth output adapter.
adapter::types::unidirectional::AB`	`OUT5`	Plug	Fifth output adapter.
adapter::types::unidirectional::AB`	`OUT6`	Plug	Sixth output adapter.

Functionality
The function block reads the data arriving from adapter `IN` and forwards it identically to all six output adapters `OUT1` to `OUT6`. This is a pure 1:6 distribution without buffering or data processing. As soon as data is present at the input, it is immediately and simultaneously transferred to all outputs. The number of outputs is fixed at six.

Technical Features
- **Generic Function Block**: The function block is implemented as a generic type (`GEN_AB_SPLIT`) and can be used multiple times within the 4diac IDE framework.
- **Unidirectional Interface**: All adapters are of type `unidirectional::AB`, meaning that data flow is only in one direction (from the input to the outputs).
- **No State Dependency**: Since neither events nor trigger mechanisms exist, the function block operates continuously and without an internal state.
- **License**: The function block is licensed under the Eclipse Public License 2.0 (EPL-2.0).

State Overview
The function block has no internal state machine or discrete states. Its operation is purely continuous – there is no initialization, no error states, and no time dependencies.

Application Scenarios
- **Data Distribution in Control Applications**: When a sensor or data source (e.g., an IO-Link master via a `AB` adapter) needs to provide its measured values to several function blocks operating in parallel.
- **Redundant Processing**: An input signal is simultaneously forwarded to multiple independent calculation or monitoring logics.
- **Prototyping**: Easily duplicate an adapter signal during the development phase without having to write your own splitter logic.

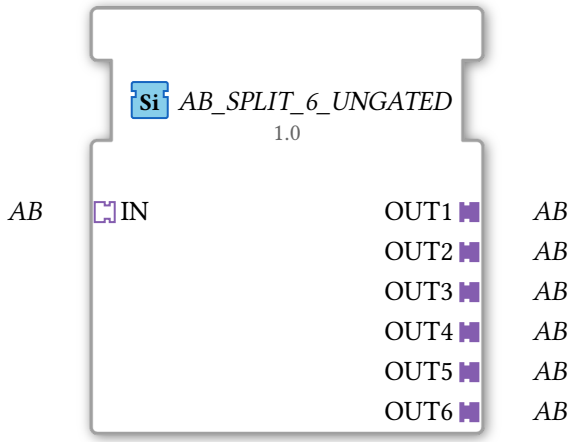
Comparison with similar components

- **AB_SPLIT_2 / AB_SPLIT_4**: Analogous design, but with two or four outputs, respectively. This component offers the maximum of six outputs.
- **Generic Splits with Events**: Some splitters operate in an event-driven manner (e.g., `E_SPLIT`), but then require additional triggers. In contrast, `AB_SPLIT_6` operates continuously and without events via the adapter interface.
- **Data Splitters (e.g., `F_SPLIT`)**: These split individual data values (e.g., an array), while `AB_SPLIT_6` copies the entire adapter data stream unchanged.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The `AB_SPLIT_6` is a simple yet useful generic function block for multiplying a unidirectional adapter signal to up to six outputs. It is easy to understand, requires no configuration, and is ideally suited for the rapid distribution of adapter data in industrial control applications.

AB_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_SPLIT_7** is used to split a single incoming adapter of type `adapter::types::unidirectional::AB` into seven identical output adapters. It is implemented as a generic block (`GEN_AB_SPLIT`) and can therefore be instantiated for various specific adapter types that conform to the unidirectional AB protocol. It was developed under the Eclipse Public License 2.0.

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Data Outputs

None available.

Adapters

Name	Type	Direction	Description

IN	`adapter::types::unidirectional::AB`	Socket (Input)	Incoming adapter that is distributed to the outputs.
OUT1	`adapter::types::unidirectional::AB`	Plug (Output)	First outgoing adapter, identical to the input.
OUT2	`adapter::types::unidirectional::AB`	Plug (Output)	Second outgoing adapter.
OUT3	`adapter::types::unidirectional::AB`	Plug (Output)	Third outgoing adapter.
OUT4	`adapter::types::unidirectional::AB`	Plug (Output)	Fourth outgoing adapter.
OUT5	`adapter::types::unidirectional::AB`	Plug (Output)	Fifth outgoing adapter.
OUT6	`adapter::types::unidirectional::AB`	Plug (Output)	Sixth outgoing adapter.
OUT7	`adapter::types::unidirectional::AB`	Plug (Output)	Seventh outgoing adapter.

Functionality

This component functions purely as a signal distributor for adapter connections. Every data or event flow arriving via socket `IN` is forwarded unchanged and in parallel to all seven output plugs (`OUT1` – `OUT7`). No processing, buffering, or state changes take place. Therefore, this component should be understood as a passive "splitter."

Since these are unidirectional adapters, communication only occurs in one direction – from the socket to the plugs. The outputs are logically identical and can be connected independently to subsequent function blocks.

Technical Features

- **Generic Type**: The function block is declared as a generic FB (GenericClassName `'GEN_AB_SPLIT'`). This allows reuse for different implementations of the unidirectional AB adapter without having to redefine the interface.
- **No Internal Logic**: There are no event triggers, data operations, or state machines. The FB is completely defined by its adapter wiring.
- **Unidirectionality**: The adapter type `unidirectional::AB` supports only one direction of data flow. There are no return channels.

State Overview

The function block does not have an internal state machine (ECC). It is static and does not execute any sequential logic. There are no distinguishable operating states.

Application Scenarios

- **Distributing control information** to multiple parallel consumers (e.g., controlling several identical actuators).
- **Splitting a feedback signal** for separate evaluation in different branches of an automation application.
- **Generating multiple identical adapter strings** for redundancy or separate monitoring.

Due to its generic design, the function block can be used in various contexts once the specific adapter type is defined.

Comparison with Similar Function Blocks

- **AB_MERGE**: Merges multiple incoming adapters into one output – the opposite function to AB_SPLIT_7.
- **AB_SPLIT_N**: Generalization with a configurable number of outputs, if available. AB_SPLIT_7 is a fixed 1:7 split.
- **Direct wiring without a splitter**: If multiple identical copies are needed, the source function block would have to be instantiated multiple times, which increases the design complexity. The splitter reduces redundancy at the adapter connection level.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AB_SPLIT_7** is a simple yet useful function block for multiplying a unidirectional adapter connection. Its generic nature and clear separation of inputs and outputs make it a reusable tool in the 4diac IDE, especially in scenarios requiring parallel signal distribution. It contributes to the modularity and clarity of industrial control applications.

Functionality

This component functions purely as a signal distributor for adapter connections. Every data or event flow arriving via socket `IN` is forwarded unchanged and in parallel to all seven output plugs (`OUT1` – `OUT7`). No processing, buffering, or state changes take place. Therefore, this component should be understood as a passive "splitter."

Since these are unidirectional adapters, communication only occurs in one direction – from the socket to the plugs. The outputs are logically identical and can be connected independently to subsequent function blocks.

Technical Features

- **Generic Type**: The function block is declared as a generic FB (GenericClassName `'GEN_AB_SPLIT'`). This allows reuse for different implementations of the unidirectional AB adapter without having to redefine the interface.
- **No Internal Logic**: There are no event triggers, data operations, or state machines. The FB is completely defined by its adapter wiring.
- **Unidirectionality**: The adapter type `unidirectional::AB` supports only one direction of data flow. There are no return channels.

State Overview

The function block does not have an internal state machine (ECC). It is static and does not execute any sequential logic. There are no distinguishable operating states.

Application Scenarios

- **Distributing control information** to multiple parallel consumers (e.g., controlling several identical actuators).
- **Splitting a feedback signal** for separate evaluation in different branches of an automation application.
- **Generating multiple identical adapter strings** for redundancy or separate monitoring.

Due to its generic design, the function block can be used in various contexts once the specific adapter type is defined.

Comparison with Similar Function Blocks

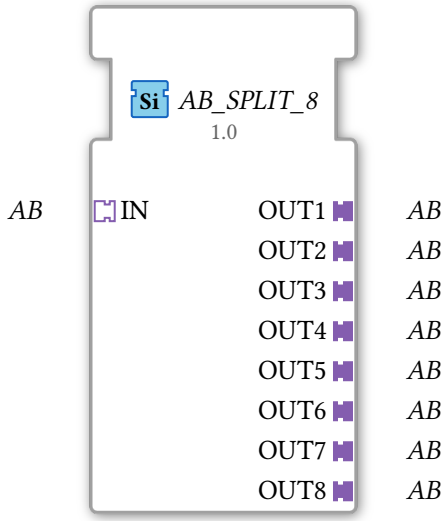
- **AB_MERGE**: Merges multiple incoming adapters into one output – the opposite function to AB_SPLIT_7_UNGATED.

- **AB_SPLIT_N**: Generalization with a configurable number of outputs, if available. AB_SPLIT_7_UNGATED is a fixed 1:7 split.
- **Direct wiring without a splitter**: If multiple identical copies are needed, the source function block would have to be instantiated multiple times, which increases the design complexity. The splitter reduces redundancy at the adapter connection level.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The **AB_SPLIT_7_UNGATED** is a simple yet useful function block for multiplying a unidirectional adapter connection. Its generic nature and clear separation of inputs and outputs make it a reusable tool in the 4diac IDE, especially in scenarios requiring parallel signal distribution. It contributes to the modularity and clarity of industrial control applications.

AB_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_SPLIT_8** is used to multiply an incoming adapter signal of type `AB` into eight identical outputs. It functions as a passive splitter for unidirectional data exchange via the standardized interface `adapter::types::unidirectional::AB`. The block is designed as a generic function block and is typically used in automation technology to forward an AB signal in parallel to multiple downstream components.

Interface Structure

Event Inputs

None. The function block has no event-driven inputs; data is passed solely via the adapter interface.

Event Outputs

None. No events are explicitly output.

Data Inputs

No direct data inputs. All incoming information is transmitted via the socket adapter.

Data Outputs

No direct data outputs. Outgoing information is provided via the plug adapters.

Adapters

Name	Type	Direction	Description
IN	adapter::types::unidirectional::AB	Socket	Input adapter that receives the signal to be distributed.
OUT1	adapter::types::unidirectional::AB	Plug	First output adapter (identical to the input signal).
OUT2	adapter::types::unidirectional::AB	Plug	Second output adapter.
OUT3`	adapter::types::unidirectional::AB	Plug	Third output adapter.
OUT4`	adapter::types::unidirectional::AB	Plug	Fourth output adapter.
OUT5`	adapter::types::unidirectional::AB	Plug	Fifth output adapter.
OUT6`	adapter::types::unidirectional::AB	Plug	Sixth output adapter.
OUT7`	adapter::types::unidirectional::AB	Plug	Seventh output adapter.
OUT8`	adapter::types::unidirectional::AB	Plug	Eighth Output Adapter.

Functionality

The **AB_SPLIT_8** functions purely as a signal distributor without internal logic or state machine. The AB signal arriving via socket `IN` is forwarded identically and simultaneously to all eight plug outputs `OUT1` to `OUT8`. No buffering or delay occurs. The function block is completely passive – it reacts solely to data changes from the connected adapter and forwards them unchanged.

The distribution is independent of the internal structure of the AB adapter (e.g., data and event connections). The function block itself has no execution state and does not require sequential control.

Technical Features

- **Generic Type**: The function block (FB) is declared as a generic block (`GenericClassName = 'GEN_AB_SPLIT'`), enabling flexible use in various projects.
- **No State Machine**: There is no Execution Control Chart (ECC); the FB is fully data flow controlled.
- **Adapter Type**: The adapter used, `adapter::types::unidirectional::AB`, is standardized and provides a uniform interface.
- **License**: The block is licensed under the **Eclipse Public License 2.0 (EPL-2.0)** and is designed for the **4diac IDE**.

State Overview

The **AB_SPLIT_8** has no internal states or state machines. Signal transmission occurs without delay and without dependence on sequential logic.

Application Scenarios

- **Distributing a single AB sensor signal** to multiple actuators or controllers.
- **Parallel connection of monitoring units** in agricultural technology (e.g., distributing an acknowledge signal).
- **Extension of control cabinet wiring** through software-based signal multiplication.
- **Test environments** where an AB signal is to be sent simultaneously to multiple analysis function blocks (FBs).

Comparison with similar function blocks

- **`AB_SPLIT_2`, `AB_SPLIT_4`**: These function blocks distribute the signal to two or four outputs, respectively. The `AB_SPLIT_8` offers the maximum of eight outputs in a single FB.

- **`DATA_SPLIT`**: Distributes arbitrary data types (e.g., `INT`, `BOOL`). The `AB_SPLIT_8` function block is specifically designed for the `AB` adapter type and retains the complete adapter structure.
- **`EC_SPLIT`**: An event splitter that only multiplies events, but not data. In contrast, `AB_SPLIT_8` operates at the adapter level, including all data and events it contains.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AB_SPLIT_8** function block is a simple yet effective block for multiplying a unidirectional AB adapter signal. Its generic design and passive operation make it ideal for parallelizing control and monitoring signals in automation technology. The absence of state logic ensures low runtime complexity and high reliability. This function block is a valuable addition to any 4diac library that relies on adapter communication.

AB_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_SPLIT_9** is used to split a single incoming adapter of type **AB** into nine identical outgoing adapters (**OUT1** to **OUT9**). It is implemented as a generic block (GenericClassName = `'GEN_AB_SPLIT'`) and can be used in any 4diac project to establish a point-to-multipoint connection via the adapter interface. The block has no event-driven or data-driven inputs/outputs – all communication takes place exclusively via the adapter interfaces. This enables clean, task-oriented coupling of modules.

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Data Outputs

None available.

Adapters

Interface	Direction	Type	Description
IN	Socket	`adapter::types::unidirectional::AB`	Incoming adapter (source)
OUT1 – OUT9	Plug	`adapter::types::unidirectional::AB`	Nine identical outgoing adapters (sinks)

Functionality

This function block copies all data and event traffic from the incoming adapter **IN** to the nine output adapters **OUT1** to **OUT9**. Each output receives exactly the same information as the input – no filtering, transformation, or delay takes place.

The function block thus behaves like a **passive distributor** (splitting node) at the adapter level. Changes to the input adapter (e.g., new values or events) are immediately propagated to all outputs, provided the connected modules allow this.

Technical Features

- **Generic Type**: The function block is declared as a generic FB (`GenericClassName = 'GEN_AB_SPLIT'`). This allows it to be reused in different contexts, as long as the adapter type `unidirectional::AB` is compatible.
- **No State Logic**: There is no ECC (Execution Control Chart) – the function block is completely declarative and does not require sequential processing.
- **Easy Extensibility**: The principle can be applied to other numbers of outputs (e.g., `AB_SPLIT_4`, `AB_SPLIT_16`) by adapting the XML structure accordingly.

State Overview

The function block has **no** states of its own. Its behavior is purely combinatorial – distribution occurs continuously and without delay. Therefore, a state machine is not required.

Application Scenarios

- **Control of Multiple Parallel Actuators**: A sensor (e.g., a pressure sensor) delivers its measured value via an AB adapter. This value is to be simultaneously transmitted to several actuators (valves, motors) – the split function block distributes the information to all of them.
- **Signal Coupling in Modular Systems**: In a distributed automation solution, multiple subsystems can receive the same data stream without each subsystem having to establish a separate connection to the source.
- **Test and Simulation Environments**: An incoming data stream can be split across multiple monitoring or logging modules without affecting the original connection.

Comparison with Similar Components

Component	Outputs	Special Feature
AB_SPLIT_9	9	Standard split for 1⟶9, generic
AB_SPLIT_4	4	Same functionality, fewer outputs
AB_MERGE	–	Combines multiple inputs into one output (opposite direction)

While AB_SPLIT_9 distributes a single source to multiple sinks, AB_MERGE combines several sources into a single output. Therefore, AB_SPLIT_9 is the ideal choice when a signal needs to be routed to many consumers.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AB_SPLIT_9** offers a simple yet powerful way to split a single adapter-based data stream into nine parallel paths. Its generic nature allows it to be used in any 4diac project, requires no state programming, and enables a clean, modular architecture. It is a fundamental building block for the serial or parallel distribution of adapter signals in automation technology.

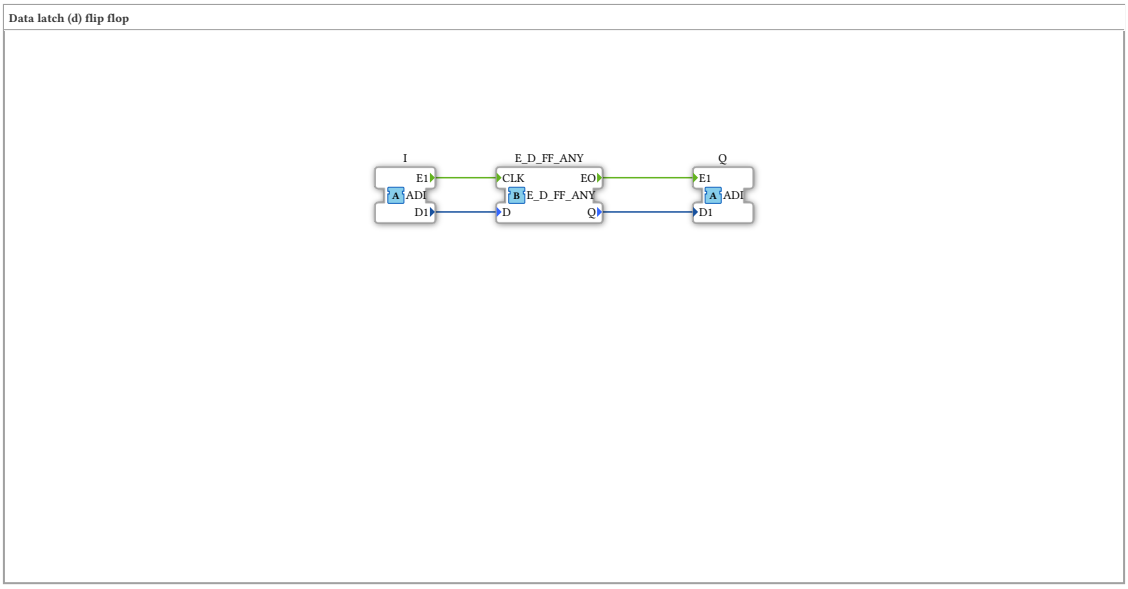
Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ADI_D_FF

Value to latch – *ADI*

ADI – Latched value

• — ○ • — ○ • — ○ •

Introduction

The function block `ADI_D_FF` implements a data latch (D flip-flop) based on adapters. It serves to store and output a Boolean value when an event occurs. The block encapsulates the industrial standard function block `E_D_FF_ANY` and communicates exclusively via the unidirectional adapters `ADI`.

Interface Structure

Event Inputs

The function block has no separate event inputs. Event control is handled exclusively via the adapter `I`.

Event Outputs

The function block has no separate event outputs. Event output is exclusively via the `Q` adapter.

Data Inputs

The FB has no separate data inputs. Data is acquired via the `I` adapter.

Data Outputs

The FB has no separate data outputs. Data is output via the `Q` adapter.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::ADI`	`I`	Input (Socket)	Outputs the clock signal (`E1`) and the data value to be latched (`D1`).
`adapter::types::unidirectional::ADI`	`Q`	Output (Plug)	Outputs the stored data value (`D1`) and an acknowledgment event (`E1`).

Functionality

The `ADI_D_FF` operates on the principle of an edge-triggered D flip-flop. Each event arriving at the adapter `I` (`E1`) is interpreted as a clock signal (CLK). At each clock cycle, the current data value `D1` is received from the input, stored internally, and output at the adapter `Q` both as a new data value (`D1`) and as an acknowledgment event (`E1`).

Internally, the standardized IEC 61499 function block `E_D_FF_ANY` is used, which provides precisely this functionality. The adapters serve as uniform, reusable interfaces for events and data.

Technical Features

- All data and event exchange takes place via adapters of type `ADI` (unidirectional event and data transmission). This makes the function block easy to integrate into adapter-based architectures.
- No independent state machine is implemented; The entire logic is implemented by the internal function block `E_D_FF_ANY`.
- The implementation follows the IEC 61499-1 (Annex A) standard and uses the Eclipse 4diac IDE.

State Overview

The function block does not have explicit states in the sense of a state machine. Its behavior corresponds to a simple flip-flop:

- At each clock cycle (event at `I.E1`), the current value is taken from `I.D1` and passed to `Q.D1`.
- The stored value remains constant until the next clock cycle.
- The output `Q.E1` signals the transfer of a new value.

Application Scenarios

- **Synchronization:** Holding an asynchronously arriving Boolean signal at a defined clock time.
- **Latch:** Holding a data value for further processing in subsequent function block networks.
- **Buffering:** Decoupling event and data sources from further processing (e.g., in time-critical processes).

Comparison with Similar Function Blocks

Function Block	Function	Differences
`ADI_SR_FF`	Set-Reset Flip-Flop	Stores based on set/reset behavior, not clock-driven.
`ADI_T_FF`	T Flip-Flop	Toggles the state on every clock cycle.
`ADI_D_FF`	D flip-flop	Stores the incoming data value on the clock edge (as described here).

Conclusion

The `ADI_D_FF` is a compact, adapter-based D flip-flop component for the 4diac IDE. It offers a clean separation of clock and data and is ideally suited for use in event-driven automation solutions. The adapter encapsulation increases reusability and simplifies integration into existing projects.

ADI_D_FF_HYS

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_D_FF_HYS** implements a data-timed (D) flip-flop with adjustable hysteresis. It receives values via a unidirectional adapter input `I` and outputs the state, including hysteresis, via the adapter output `Q`. The hysteresis bandwidth is set during the initialization event `INIT`.

Interface Structure

Event Inputs

Event	Type	Description
`INIT`	EInit	Sets the hysteresis bandwidth (in conjunction with `HYSTERESIS`).

Event Outputs

Event	Type	Description
`INITO`	EInit	Confirms the execution of `INIT`.

Data Inputs

Variable	Type	Description
`HYSTERESIS`	DINT	Hysteresis bandwidth (integer value).

Data Outputs

This function block does not have direct data outputs; The latched value is provided via the adapter `Q`.

Adapter

Interface	Type	Direction	Description
`I`	`adapter::types::unidirectional::ADI`	Socket	Input value (consisting of Event `E1` and Data `D1`).
`Q`	`adapter::types::unidirectional::ADI`	Plug	Latched output value (consisting of Event `E1` and Data `D1`).

Note: The `ADI` (unidirectional) adapter provides one event channel (E1) and one data channel (D1) by default.

Functionality

1. **Initialization**

An event at `INIT` transfers the value to `HYSTERESIS` and sets the internal hysteresis bandwidth for the flip-flop. The initialization event is then passed directly to `INITO`.

1. **Data Transfer**

The input adapter `I` delivers the current data value to `I.D1` with each event at `I.E1`.
The internal function block `E_D_FF_ANY_HYS` adopts this value according to the configured hysteresis:

- If the input value is **above** the upper threshold (stored value + hysteresis), the output is set to `1`.
- If the input value is **below** the lower threshold (stored value - hysteresis), the output is set to `0`.
- If the value remains within the hysteresis range, the output does not change.

1. **Output**

The internally latched value is passed to the data output `Q.D1`. Simultaneously, an event is triggered at `Q.E1` to signal data processing to downstream logic blocks.

Technical Features

- **Parameterizable Hysteresis:** The hysteresis bandwidth can be adjusted at runtime via `INIT` and `HYSTERESIS` (integer value, data type `DINT`).
- **Adapter-Based Communication:** The function block uses fully unidirectional adapters, enabling a clean separation of signal flow and event control. This makes it particularly suitable for modular and distributed signal processing.
- **Internal Implementation:** The hysteresis logic is implemented using the standardized function block `E_D_FF_ANY_HYS` from the library `logiBUS::signalprocessing::hysteresis`.
- **No Delay Due to INIT:** The initialization (`INIT → INITO`) is passed through in the same cycle; the hysteresis is available from the following cycle.

State Overview

The component does not have an explicit state machine, but is based on the internal state of the D flip-flop `E_D_FF_ANY_HYS`. This stores:

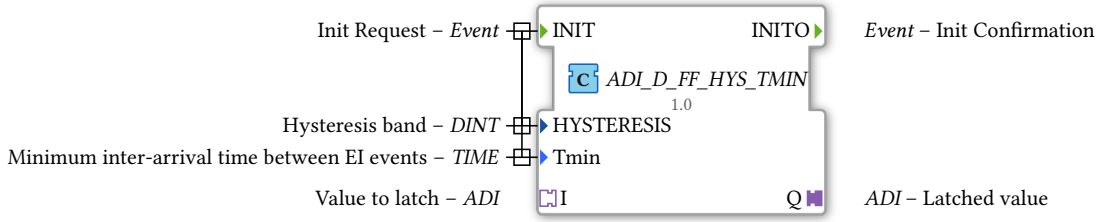
- The current output value (latched).
- The last input value received (for hysteresis analysis).

The output only changes when the new input value leaves the hysteresis band.

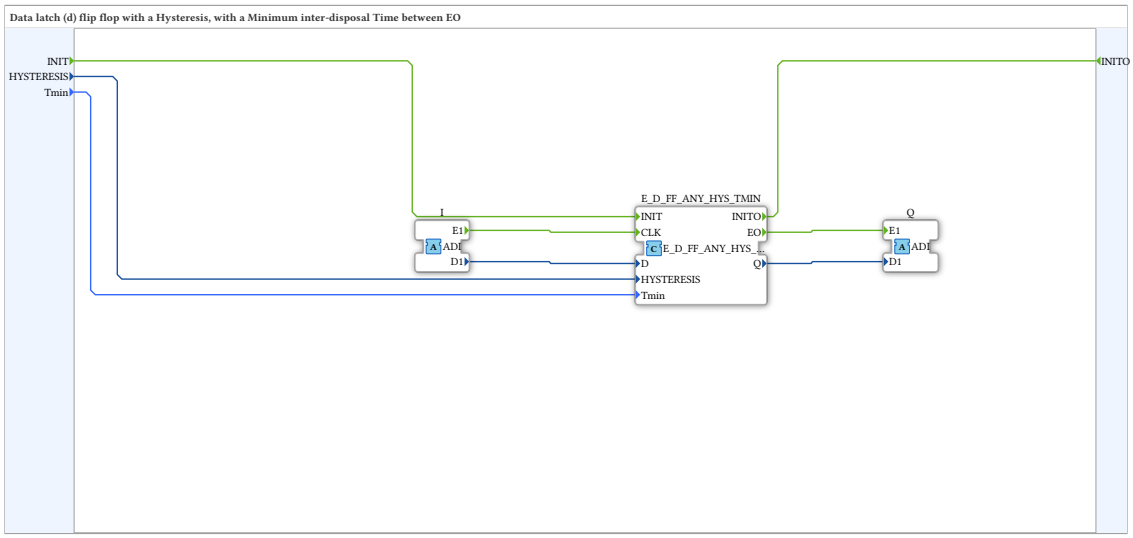
Application Scenarios

- **Debouncing of Sensor Switches:** Turn-on and turn-off thresholds with hysteresis prevent edge noise.
- **Threshold Monitoring with Delayed Release:** Temperature, pressure, or level control with defined turn-on and turn-off points.
- **Digitization of Analog Signals:** Conversion of a continuous range of values into a stable binary value (Schmitt trigger behavior).
- **Control of actuators with hysteresis:** Prevents rapid on/off switching, e.g., with thermostats or pumps.

Comparison with similar function blocks



Function block	Properties
E_D_FF	Standard D flip-flop without hysteresis (direct transfer).
E_D_FF_ANY_HYS	Identical function, but with direct data ports instead of adapters.
Schmitt trigger	Similar behavior, but hysteresis cannot be configured at runtime.



The **ADI_D_FF_HYS** offers particularly flexible integration into heterogeneous systems thanks to its adapter interface, while the hysteresis can be configured at runtime.

Conclusion

The **ADI_D_FF_HYS** is a robust, configurable D flip-flop with hysteresis, ideally suited for signal processing with stable switching thresholds. The use of unidirectional adapters facilitates integration into process-level control applications and enables a clear separation of data transport and event control.

ADI_D_FF_HYS_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_D_FF_HYS_TMIN** implements a data latch (D flip-flop) with hysteresis and a minimal time delay between successive output events. It serves for stable and interference-free signal transmission in industrial control applications based on unidirectional adapters.

Interface Structure

Event Inputs

- **INIT** (EInit): Initialization request. This event input initializes the block with the parameters `HYSTERESIS` and `Tmin`.

Event Outputs

- **INITO** (EInit): Initialization confirmation. Outputted after successful initialization.

Data Inputs

- **HYSTERESIS** (DINT): Hysteresis band. Defines the switching threshold to prevent output chatter.
- **Tmin** (TIME): Minimum time between two output events (Inter-Arrival Time). Prevents excessively rapid switching.

Data Outputs

This module does not have its own data outputs. The output data is provided via an adapter.

Adapters

- **I** (Socket, Type: `adapter::types::unidirectional::ADI`): The value to be latched is received via this adapter input (event and data).
- **Q** (Plug, Type: `adapter::types::unidirectional::ADI`): The latched value is output via this adapter output (event and data).

Functionality

The function block internally uses the FB `E_D_FF_ANY_HYS_TMIN`. It processes the events (`I.E1`) and data (`I.D1`) received via the adapter **I**. The actual latching function uses hysteresis, which is defined by the parameter `HYSTERESIS`. Additionally, a minimum waiting time `Tmin` is maintained between two output events to suppress an excessively high event frequency. Output is provided via the adapter **Q** (`Q.E1` and `Q.D1`). Initialization (`INIT`) sets the parameters and activates the internal FB.

Technical Features

- **Adapter-Based Communication:** The function block uses unidirectional adapters (`ADI`) for data exchange. This enables loose coupling of data and events.
- **Configurable Hysteresis:** The hysteresis width can be set application-specifically to suppress noise or bounce effects.
- **Minimum Event Interval Time:** The maximum output frequency can be limited using `Tmin`, which helps to reduce the load on subsequent processing units.

State Overview

The function block has two stable internal states (e.g., HIGH/LOW or TRUE/FALSE) that represent the latched output value. A state change only occurs if the incoming value (via **I**) exceeds the hysteresis threshold and the time elapsed since the last output event is at least `Tmin`. Otherwise, the event is suppressed.

State	Description
LOW	Output value is logic 0 or low
HIGH	Output value is logic 1 or high

Changes between states occur according to the hysteresis and timing conditions.

Application Scenarios

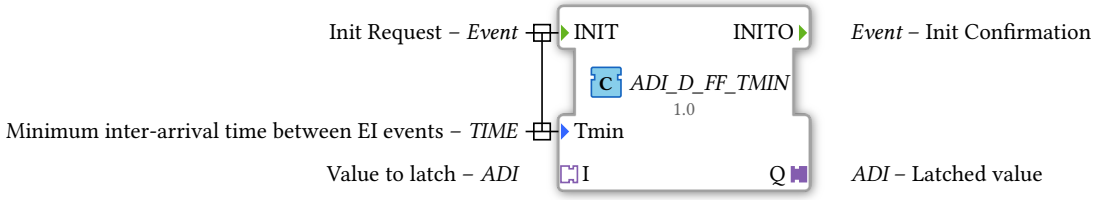
- **Debouncing of switches or sensors:** Prevents multiple switching cycles due to mechanical bouncing.
- **Signal smoothing in process automation:** Suppresses small disturbances or noise on analog or digital signals.
- **Event rate limiting:** Protects subsequent functions from excessively rapid event sequences, e.g., in counters or communication interfaces.

Comparison with Similar Components

A conventional D flip-flop (e.g., `E_D_FF`) switches on every clock cycle without hysteresis or time delay. The `ADI_D_FF_HYS_TMIN`, on the other hand, offers:

- **Hysteresis:** Prevents oscillations with slowly changing or noisy signals.
- **Minimal Inter-Arrival Time:** Reduces the event rate and enables precise timing control.
- **Adapter Interface:** Specifically designed for use in complex, adapter-based function block networks.

Conclusion



The `ADI_D_FF_HYS_TMIN` is a robust functional block for reliable signal processing with hysteresis and timing control. It is particularly suitable for applications requiring noise-free, filtered, and rate-limited transmission of events and data—typically in industrial control systems based on the 4diac framework and unidirectional adapters.

ADI_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **ADI_D_FF_TMIN** implements a data latch (D flip-flop) with a configurable minimum dwell time between two consecutive transfer events. It serves to save a data value at a specific event time and only update it again when a predefined time interval (Tmin) has elapsed since the last transfer.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request; Passes the parameter Tmin

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirmation

Data Inputs

Name	Type	Comment
Tmin	TIME	Minimum time between two events at input I.E1

Data Outputs

No direct data outputs – the latched value is provided via the adapter output Q.

Adapter

Direction	Name	Type	Comment

Socket (Input)	I	adapter::types::unidirectional::ADI	Value and event to latch
Plug (Output)	Q	adapter::types::unidirectional::ADI	Latched Value and Associated Output Event

Functionality

The function block receives an event (I.E1) along with a data value (I.D1) via the adapter socket **I**. After this event, the value is transferred and output as Q.D1 at the adapter plug **Q** simultaneously, an event is sent to Q.E1.

However, at least the time specified in **Tmin** must elapse between two consecutive transfers. As long as this minimum period has not expired, an incoming event at I.E1 is ignored (the value remains unchanged).

The INIT input sets the parameter Tmin and confirms this via INITO, without affecting the flip-flop itself.

The function block (FB) internally uses the block `iec61499::events::E_D_FF_ANY_TMIN`, which encapsulates the actual logic (a D flip-flop with time control).

Technical Features

- **Adapter-based interface:** Instead of directly connected event and data ports, the inputs and outputs are implemented via unidirectional adapters (type `ADI`). This simplifies the reuse and separation of control and data flows.
- **Minimum time guarantee:** The Tmin time is measured from the moment of the last valid output event. If an input event occurs too early, the output remains unchanged – the old value is retained.
- **Initialization required:** The function block must first be initialized with a Tmin value via INIT before it responds to incoming adapter events.

State Overview

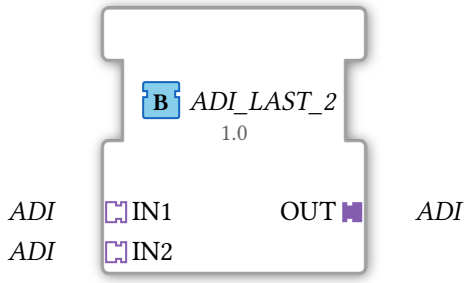
The function block (FB) has implicit state logic, which is represented by the internal `E_D_FF_ANY_TMIN`:

- **Idle:** Waiting for the first valid event at I.E1 after initialization.
- **Latched:** A value has been transferred; the timer for Tmin is running. New events at I.E1 are ignored until Tmin has expired.
- **Ready:** Tmin has expired; the function block is ready for the next transfer.

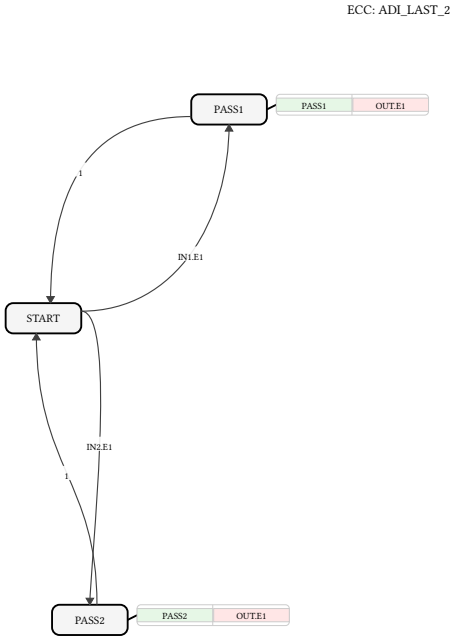
The state transitions are controlled by the events at I.E1 and the internal timer. Initialization returns the function block to the idle state.

Application Scenarios

- **Clock Decoupling in Industrial Applications:** Ensuring that data is transferred only at defined minimum intervals (e.g., for sensor queries with a fixed interval).
- **Event Debouncing:** Prevents duplicate evaluations for closely spaced events (e.g., push-button or switching signals with bounce time).
- **Data Storage in Safety-Critical Systems:** Once latched, values remain valid until the minimum time has elapsed – protecting against noise or transient disturbances.



Comparison with Similar Function Blocks



- **Standard D Flip-Flop (without Tmin):** A simple D flip-flop, such as `E_D_FF`, immediately adopts any value upon each event. This function block extends this functionality with a time lock.
- **E_D_FF_ANY_TMIN:** This is the direct internal base function block. `ADI_D_FF_TMIN` encapsulates its functionality and offers an adapter interface instead of separate event/data ports – this increases flexibility when connecting to other adapter-based components.

Conclusion

The `ADI_D_FF_TMIN` is a useful functional block for applications requiring reliable data acquisition with adjustable time decoupling. The use of adapters makes it particularly suitable for modular, adapter-based architectures according to IEC 61499. The minimum time enhances the overall system stability in environments with sporadic or bouncy events.

ADI_LAST_2

Introduction

The ADI_LAST_2 function block merges two same-type DINT adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: DINT adapter (unidirectional) - first signal source
- **IN2**: DINT adapter (unidirectional) - second signal source

Output adapter (Plug):

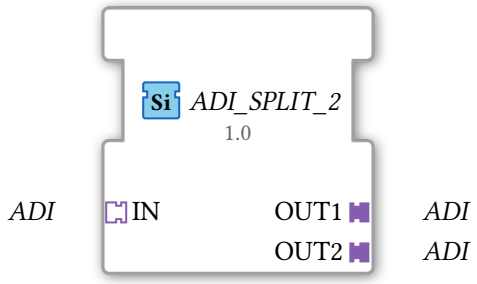
- **OUT**: DINT adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid DINT signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same DINT value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

ADI_LAST_2 is the inverse of `ADI_SPLIT_2`: ADI_SPLIT_2 distributes 1 input to 2 outputs, ADI_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

ADI_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_SPLIT_2` is used to distribute an incoming ADI adapter (socket) to two identical ADI output adapters (plugs). It is designed as a generic building block and enables simple signal bundling in adapter-based architectures.

Interface Structure

Event Inputs

None – this function block has no event inputs.

Event Outputs

None – this function block has no event outputs.

Data Inputs

None – this function block has no separate data inputs. All data is transported via the ADI adapter.

Data Outputs

None – This function block has no separate data outputs. All data is output via the ADI adapters.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::ADI`	`IN`	Socket	Incoming ADI adapter that is distributed to the two outputs.
`adapter::types::unidirectional::ADI`	`OUT1`	Plug	First output adapter (duplicate of the input).

adapter::types::unidirectional::ADI	OUT2	Plug	Second output adapter (duplicate of the input).

Functionality

The function block forwards the ADI adapter received via socket IN to both plugs OUT1 and OUT2 without modification. This makes the data and events provided by the input adapter available at both outputs simultaneously. No processing, delay, or transformation of the data takes place.

Technical Features

- **Generic Function Block:** The function block is declared as a generic type (GEN_ADI_SPLIT) and can be reused in different ADI environments.
- **No State Machine:** Due to its pure signal forwarding function, the function block does not have its own state machine (ECC).
- **Adapter-based:** All data exchange occurs exclusively via adapters, not via individual data or event ports.

State Overview

This functional block does not have an internal state machine. The routing is static and without time dependencies.

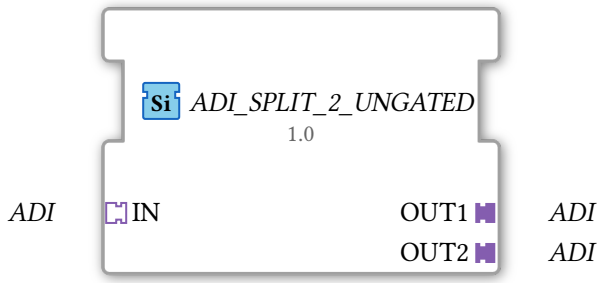
Application Scenarios

- **Signal Multiplication:** When an ADI adapter supplied by a sensor or controller needs to be distributed to multiple downstream functional units (e.g., for display, logging, or parallel processing).
- **Architecture Decoupling:** In systems where an output signal is required multiple times without the source component needing to know the number of destinations.
- **Prototypes and Test Setups:** Rapid expansion of an existing adapter circuit by adding a second branch.

Comparison with Similar Function Blocks

- **Event/Data Splitter:** Conventional splitter function blocks (e.g., SPLIT for BOOL) operate on individual data and event channels. ADI_SPLIT_2, on the other hand, copies an entire adapter, including all its data and events.
- **Mux/Demux Function Blocks:** Multiplexers and demultiplexers perform merging or distribution with selection; ADI_SPLIT_2 distributes rigidly without selection.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

ADI_SPLIT_2` is a simple yet useful function block for distributing an ADI adapter to two identical outputs. It simplifies the design of adapter-based controllers and avoids redundant source blocks. Its generic nature and lack of internal logic make it a flexible component in IEC 61499 applications.

ADI_SPLIT_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of ADI_SPLIT_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_SPLIT_2_UNGATED` is used to distribute an incoming ADI adapter (socket) to two identical ADI output adapters (plugs). It is designed as a generic building block and enables simple signal bundling in adapter-based architectures.

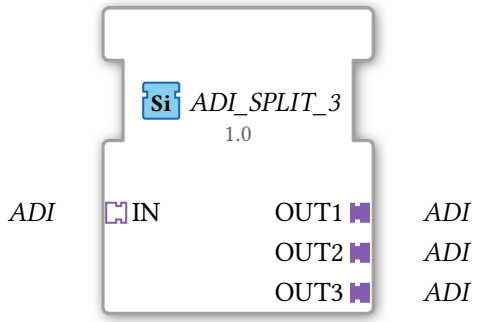
- **Prototypes and Test Setups:** Rapid expansion of an existing adapter circuit by adding a second branch.

Comparison with Similar Function Blocks

- **Event/Data Splitter:** Conventional splitter function blocks (e.g., `SPLIT` for `BOOL`) operate on individual data and event channels. `ADI_SPLIT_2_UNGATED`, on the other hand, copies an entire adapter, including all its data and events.
- **Mux/Demux Function Blocks:** Multiplexers and demultiplexers perform merging or distribution with selection; `ADI_SPLIT_2_UNGATED` distributes rigidly without selection.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

ADI_SPLIT_2_UNGATED` is a simple yet useful function block for distributing an ADI adapter to two identical outputs. It simplifies the design of adapter-based controllers and avoids redundant source blocks. Its generic nature and lack of internal logic make it a flexible component in IEC 61499 applications.

ADI_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ADI_SPLIT_3** is used to distribute an incoming ADI data stream (adapter interface) to three identical outputs. It is designed as a generic function block and enables simple signal multiplication in adapter-based 4diac applications.

Interface Structure

The function block has only adapter interfaces – neither event nor data inputs/outputs are present.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Name	Type	Direction	Description
IN	adapter::types::unidirectional::ADI	Socket (Input)	Incoming ADI data stream that is split.
OUT1	adapter::types::unidirectional::ADI	Plug (Output)	First outgoing ADI data stream (copy of the input).
OUT2	adapter::types::unidirectional::ADI	Plug (Output)	Second outgoing ADI data stream.
OUT3	adapter::types::unidirectional::ADI	Plug (Output)	Third outgoing ADI data stream.

Functionality

The function block forwards all ADI data packets arriving at its socket `IN` unchanged to the three output plugs `OUT1`, `OUT2`, and `OUT3`. No processing or buffering takes place – distribution occurs directly and without delay. This behavior corresponds to passive signal multiplication (1:N splitter).

Technical Features

- **Generic Type:** The function block is defined using a generic class name (`GEN_ADI_SPLIT`), allowing it to be reused for any ADI-compliant data type.
- **Type Hash:** An empty type hash is stored, indicating a simple, unparameterized implementation.
- **No Runtime Logic:** Since neither event nor data interfaces exist, the function block is entirely controlled by the adapter connections and does not require its own ECC (Execution Control Chart).

State Overview

The function block has no internal states. Its functionality is limited to passively passing through adapter data – therefore, there is no state machine.

Application Scenarios

- **Signal Distribution in Control Systems:** When an ADI sensor value needs to be sent simultaneously to multiple consumers (e.g., visualization, control, logging).
- **Test and Simulation Environments:** A real ADI signal can be distributed to various test modules or simulation components using `ADI_SPLIT_3` without having to access the source multiple times.
- **Redundancy and Safety Concepts:** Distribution of a safety-critical signal to multiple independent evaluation units.

Comparison with Similar Components

- **`ADI_SPLIT_2`** – Splits to two outputs, otherwise identical functionality.
- **`ADI_MERGE`** – Combines multiple ADI inputs into one output (counterpart to the splitter).
- **`ADI_SELECT`** – Selects one of several ADI inputs based on a control signal (not pure distribution).

The `ADI_SPLIT_3` is specifically optimized for situations where exactly three identical copies of an ADI signal are required. If more or fewer outputs are needed, other splitter variants or combinations can be used.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ADI_SPLIT_3** is a simple yet useful generic building block for multiplying ADI data streams in three directions. Its pure adapter interface allows for seamless integration into existing 4diac projects without requiring additional event or data processing. It is particularly well-suited for passive signal distribution in modular, adapter-based automation solutions.

ADI_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ADI_SPLIT_4** serves as a generic splitter for a single ADI data stream. It receives one ADI input via the socket interface `IN` and makes it available to four identical ADI outputs via the plug interfaces `OUT1`, `OUT2`, `OUT3`, and `OUT4`. This block is ideal when an ADI signal needs to be forwarded in parallel to several subsequent components.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Type	Name	Direction	Description
`ADI` (unidirectional)	`IN`	Socket	Receives the ADI data stream to be distributed.
`ADI` (unidirectional)	`OUT1`	Plug	First output – identical copy of the input signal.
`ADI` (unidirectional)	`OUT2`	Plug	Second output – identical copy of the input signal.
`ADI` (unidirectional)	`OUT3`	Plug	Third output – identical copy of the input signal.
`ADI` (unidirectional)	`OUT4`	Plug	Fourth output – identical copy of the input signal.

Functionality

This module functions as a simple **replication** of the ADI signal. As soon as a valid ADI data stream is present at socket `IN`, it is passed on unchanged and without delay to all four plugs (`OUT1` … `OUT4`). No logic, filtering, or data manipulation takes place – the behavior is that of a passive signal distributor.

Since this is a generic function block (FB), the underlying ADI type is only determined at runtime or when it is integrated into a project. The interface definition itself is type-independent.

Technical Features

- **Generic Type** – The function block is declared as `GEN_ADI_SPLIT` and can be instantiated with any specific ADI adapter type.

- **No Events** – Signal distribution occurs purely via the adapter interfaces; there are no event inputs or outputs.
- **Scalability** – The function block is fixed at exactly four outputs. Alternative versions (e.g., `ADI_SPLIT_2`) are available for other numbers.

State Overview

The function block does not have an explicit state machine (ECC). Since it only implements passive signal transmission, no internal state is required.

Application Scenarios

- **Parallel Operation** – An ADI data stream provided by a sensor or predecessor function block is to be used simultaneously by multiple actuators, logic blocks, or visualization components.
- **Prototyping** – During the development phase, the splitter allows for easy testing of multiple paths of the same signal.
- **Redundancy** – The ADI signal can be distributed to multiple redundant evaluation paths.

Comparison with Similar Function Blocks

- **ADI_SPLIT_2** – Distributes one ADI signal to two outputs. Identical functionality, but fewer outputs.
- **ADI_MERGE** – Combines multiple ADI inputs into one output (counterpart to the splitter).
- **Manual Wiring** – Alternatively, distribution could be achieved by connecting multiple outputs to the same output; however, the splitter in the 4diac IDE is the cleaner and reusable solution.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ADI_SPLIT_4** is a simple yet useful generic function block for multiplying an ADI data stream. It requires no configuration and integrates seamlessly into modular automation projects. Its adapter-based interface ensures flexibility and allows it to be integrated into different environments without modifications to its internal logic.

ADI_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ADI_SPLIT_5** is used to split an incoming ADI adapter (unidirectional) into five identical output adapters. It is designed as a generic function block (Generic FB) and can be used in IEC 61499-based systems to forward a signal or data stream to multiple subsequent function blocks.

Interface Structure

Event Inputs
None

Event Outputs
None

Data Inputs
- **IN** (Socket, Type: `adapter::types::unidirectional::ADI`)

Input adapter that provides the signal to be distributed.

Data Outputs
- **OUT1** (Plug, Type: `adapter::types::unidirectional::ADI`)
- **OUT2** (Plug, Type: `adapter::types::unidirectional::ADI`)
- **OUT3** (Plug, Type: `adapter::types::unidirectional::ADI`)
- **OUT4** (Plug, Type: `adapter::types::unidirectional::ADI`)
- **OUT5** (Plug, Type: `adapter::types::unidirectional::ADI`)

All outputs are independent instances of the same adapter type and receive identical data.

Adapters
This module operates exclusively via adapter interfaces. No event or data inputs/outputs in the traditional sense are used. All communication takes place via the ADI adapters, which implicitly control signal and data forwarding.

Functionality
The function block **ADI_SPLIT_5** receives an ADI adapter via the socket **IN** and forwards the data and events it contains in parallel to the five plugs **OUT1** to **OUT5**. No processing or transformation of the data takes place – the block functions as a passive distributor (fan-out).

Since these are unidirectional ADI adapters, the signal is only passed from the input side to the output side; feedback from the outputs is not intended.

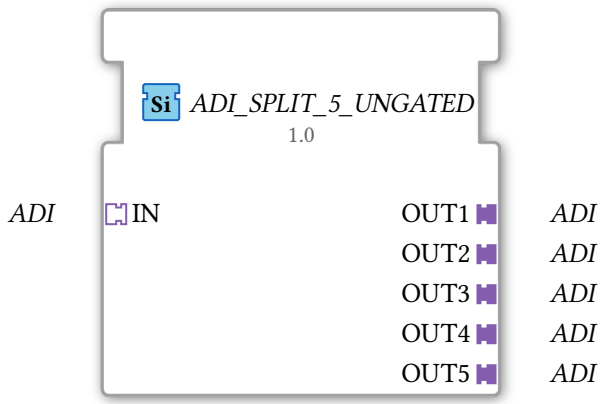
Technical Features
- **Generic Function Block**: The class `GEN_ADI_SPLIT` allows for flexible reuse, e.g., by parameterizing the type or number of outputs (here fixed at five).
- **Adapter-based**: No direct event or data inputs/outputs – all signal transmission occurs via the adapter interfaces.
- **Unidirectional**: The adapters are defined as `unidirectional`, meaning data flows only in one direction (from IN to OUT1-5).
- The function block contains no internal state logic or timing control.

State Overview
The **ADI_SPLIT_5** has no states of its own. It is a purely combinational function block that reacts immediately to incoming adapter data and passes it on unchanged to all outputs.

Application Scenarios
- **Signal Cascade**: Distribution of a sensor signal (e.g., temperature, pressure) to multiple evaluation and control blocks.
- **Diagnostics and Monitoring**: Simultaneous distribution of a data stream to processing and logging modules.
- **Load Balancing**: Parallel processing of the same input using different algorithms (e.g., filters, limit monitoring, visualization).

Comparison with Similar Components
In the IEC 61499 environment, variants such as **SPLIT_2**, **SPLIT_3**, or **SPLIT_N** are common, providing a different number of outputs. **ADI_SPLIT_5** is a specific implementation for exactly five outputs using unidirectional ADI adapter interfaces. Unlike event-based split components (e.g., `E_SPLIT`), distribution here is achieved via adapters, enabling type-based and typically data-oriented communication.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ADI_SPLIT_5** is a simple yet useful function block for distributing a unidirectional ADI signal to up to five subsequent function blocks. It is particularly suitable for modular automation solutions where an input signal needs to be used multiple times without requiring additional control logic. Its generic implementation allows it to be reused in various contexts.

ADI_SPLIT_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ADI_SPLIT_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Event Outputs

None

Data Inputs

- **IN** (Socket, Type: `adapter::types::unidirectional::ADI`)

Input adapter that provides the signal to be distributed.

Data Outputs

- **OUT1** (Plug, Type: `adapter::types::unidirectional::ADI`)
- **OUT2** (Plug, Type: `adapter::types::unidirectional::ADI`)
- **OUT3** (Plug, Type: `adapter::types::unidirectional::ADI`)
- **OUT4** (Plug, Type: `adapter::types::unidirectional::ADI`)

- **OUT5** (Plug, Type: `adapter::types::unidirectional::ADI`)

All outputs are independent instances of the same adapter type and receive identical data.

Adapters

This module operates exclusively via adapter interfaces. No event or data inputs/outputs in the traditional sense are used. All communication takes place via the ADI adapters, which implicitly control signal and data forwarding.

Functionality

The function block **ADI_SPLIT_5_UNGATED** receives an ADI adapter via the socket **IN** and forwards the data and events it contains in parallel to the five plugs **OUT1** to **OUT5**. No processing or transformation of the data takes place – the block functions as a passive distributor (fan-out).

Since these are unidirectional ADI adapters, the signal is only passed from the input side to the output side; feedback from the outputs is not intended.

Technical Features

- **Generic Function Block**: The class `GEN_ADI_SPLIT` allows for flexible reuse, e.g., by parameterizing the type or number of outputs (here fixed at five).
- **Adapter-based**: No direct event or data inputs/outputs – all signal transmission occurs via the adapter interfaces.
- **Unidirectional**: The adapters are defined as `unidirectional`, meaning data flows only in one direction (from IN to OUT1-5).
- The function block contains no internal state logic or timing control.

State Overview

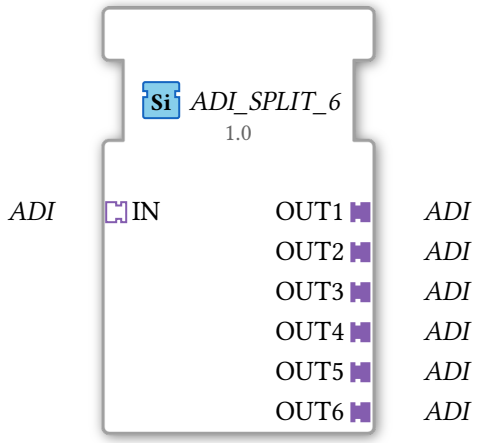
The **ADI_SPLIT_5_UNGATED** has no states of its own. It is a purely combinational function block that reacts immediately to incoming adapter data and passes it on unchanged to all outputs.

Application Scenarios

- **Signal Cascade**: Distribution of a sensor signal (e.g., temperature, pressure) to multiple evaluation and control blocks.
- **Diagnostics and Monitoring**: Simultaneous distribution of a data stream to processing and logging modules.
- **Load Balancing**: Parallel processing of the same input using different algorithms (e.g., filters, limit monitoring, visualization).

Comparison with Similar Components

In the IEC 61499 environment, variants such as **SPLIT_2**, **SPLIT_3**, or **SPLIT_N** are common, providing a different number of outputs. **ADI_SPLIT_5_UNGATED** is a specific implementation for exactly five outputs using unidirectional ADI adapter interfaces. Unlike event-based split components (e.g., `E_SPLIT`), distribution here is achieved via adapters, enabling type-based and typically data-oriented communication.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **ADI_SPLIT_5_UNGATED** is a simple yet useful function block for distributing a unidirectional ADI signal to up to five subsequent function blocks. It is particularly suitable for modular automation solutions where an input signal needs to be used multiple times without requiring additional control logic. Its generic implementation allows it to be reused in various contexts.

ADI_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The ADI_SPLIT_6 function block is used to distribute a single (unidirectional) ADI adapter input to six identical ADI adapter outputs. It is designed as a generic building block for the Eclipse 4diac framework and is typically used when an ADI signal needs to be forwarded to multiple downstream components.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

The module communicates exclusively via adapter interfaces:
Socket (Input):

- `IN`: Type `adapter::types::unidirectional::ADI` – receives a unidirectional ADI signal.

Plugs (Outputs):

- `OUT1` to `OUT6`: each type `adapter::types::unidirectional::ADI` – pass the incoming signal identically to six parallel outputs.

Functionality

The module performs a simple 1:6 distribution of the ADI adapter signal. All data and events arriving at socket `IN` are passed on unchanged and simultaneously to all six plugs `OUT1`…`OUT6`. No buffering, filtering, or delay occurs. The function block thus operates as a passive splitter at the adapter level.

Technical Features

- **Generic Implementation:** The function block is implemented as a generic block (`eclipse4diac::core::GenericClassName = 'GEN_ADI_SPLIT'`) and can be reused in various projects.
- **Unidirectional Adapters:** The ADI adapters used are unidirectional; feedback via the outputs is not provided.
- **No Internal States:** Since the function block does not perform any event or data processing, it does not have an internal state machine.

- **Performance:** Due to the direct forwarding without logic or memory, there is virtually no latency.

State Overview

This function block does not have a state machine or explicit operating states. It is always active and immediately passes the input signal to all outputs.

Application Scenarios

- **Signal Distribution in Control Systems:** An ADI signal provided by a sensor or central logic unit is to be sent in parallel to multiple actuators, displays, or downstream functions.
- **Test Environments:** During simulation or debugging, a single signal can be split across multiple receivers to test different components simultaneously.
- **Redundancy Mapping:** If a signal is needed multiple times (e.g., for monitoring and control paths), this splitter can provide clean decoupling of the outputs.

Comparison with Similar Function Blocks

- **SPLIT for Standard Data Types:** Many frameworks offer splitters for simple data types (e.g., `SPLIT_INT`). The `ADI_SPLIT_6` function block is specifically designed for the `ADI` adapter type and operates at a higher level of abstraction (adapters instead of individual data points).
- **ADI_MERGE / ADI_COMBINE:** While this function block distributes a signal, other function blocks combine multiple adapter inputs into a single output.
- **Other Splitter Variants:** Splitters may exist for other adapter types (e.g., bidirectional ADI). This function block is limited to unidirectional signals.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `ADI_SPLIT_6` function block is a simple yet effective function block for multiplying unidirectional ADI adapter signals. Its generic design and low complexity make it ideally suited for the modular development of control applications in the Eclipse 4diac environment. Its applications range from simple signal distribution to testing and redundancy scenarios.

ADI_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ADI_SPLIT_7** is used to split an incoming **ADI** adapter signal into seven identical outputs. It is implemented as a generic function block (Generic FB) and enables the unidirectional distribution of data via one adapter socket to seven adapter plugs.

Interface Structure

Event Inputs

None – the function block has no event inputs. Data is transmitted exclusively via the adapter interface.

Event Outputs

None – the function block has no event outputs. The output adapters are supplied directly with the received data.

Data Inputs

None – the data is not provided via separate data inputs, but rather via the adapter socket IN.

Data Outputs

None – the data is not output via separate data outputs, but rather via the adapter plugs OUT1 ... OUT7.

Adapters

Name	Direction	Type	Description
IN	Socket	adi (unidirectional)	Input adapter that receives the data to be distributed.
OUT1	Plug	adi (unidirectional)	First output adapter (identical to IN).
OUT2	Plug	adi (unidirectional)	Second output adapter (identical to IN).
OUT3	Plug	adi (unidirectional)	Third output adapter (identical to IN).
OUT4	Plug	adi (unidirectional)	Fourth output adapter (identical to IN).
OUT5	Plug	ADI (unidirectional)	Fifth output adapter (identical to IN).
OUT6	Plug	ADI (unidirectional)	Sixth output adapter (identical to IN).
OUT7	Plug	ADI (unidirectional)	Seventh output adapter (identical to IN).

Functionality

This component functions as a **1-to-7 splitter** for ADI adapter signals. When the signal is set at the input adapter **IN**, it is copied to all seven output adapters **OUT1** to **OUT7** without further processing or delay. The component has no internal logic or state machine – it simply passes the data on passively.

- **Generic component** – the type is instantiated as `GEN_ADI_SPLIT` and can be reused in various applications.
- **No Event Control** – Data transmission is purely data-driven without event inputs/outputs.
- **1:1 Copy** – The data at the input is transferred unchanged to all outputs.

The module has **no state machine** (ECC). It is stateless, meaning it does not react to events and has no internal states. The output data directly follows the input data.

- **Signal Distribution** – A single ADI signal (e.g., sensor value, control signal) must be distributed to multiple consumers (e.g., control blocks, visualizations).
- **Redundancy** – A signal is required for redundant processing paths.
- **Test and Simulation Environments** – an incoming signal is split for different test instances.

Function Block	Number of Outputs	Properties
ADI_SPLIT_2	2	Distributes 1 ADI to 2 outputs
ADI_SPLIT_4	4	Distributes 1 ADI to 4 outputs
ADI_SPLIT_7	7	Distributes 1 ADI to 7 outputs

ADI_MERGE	1 (Input: multiple)	Combines multiple ADI inputs into one output

Compared to manually connecting multiple ADI_Split function blocks in parallel, the `ADI_SPLIT_7` reduces configuration effort and improves network clarity.

The `ADI_SPLIT_7` is a simple yet powerful component for distributing a unidirectional ADI signal to seven identical outputs. Thanks to its generic implementation and the absence of event-driven control, it is ideally suited for pure distribution in automation and control environments based on the ADI adapter protocol.

ADI_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_SPLIT_8` is used to split a single unidirectional ADI (Application Data Interface) adapter into eight identical output adapters. It is implemented as a generic block that can be adapted to different ADI contexts by specifying a `GenericClassName` attribute. The function block simplifies signal distribution in control applications by distributing an incoming adapter path to multiple receivers without data loss.

Interface Structure

Event Inputs

There are no event inputs. Data is passed continuously and without events via a direct adapter connection.

Event Outputs

There are no event outputs.

Data Inputs

No data inputs in the conventional sense are defined. Information is transmitted exclusively via the adapter interfaces.

Data Outputs

No data outputs are available.

Adapters

Direction	Name	Type	Description
Socket	IN	ADI (unidirectional)	Input interface distributed to eight outputs.
Plug	OUT1	ADI (unidirectional)	First outgoing adapter (identical to IN).
Plug	OUT2	ADI (unidirectional)	Second outgoing adapter.
Plug	OUT3	ADI (unidirectional)	Third outgoing adapter.
Plug	OUT4	ADI (unidirectional)	Fourth outgoing adapter.
Plug	OUT5	ADI (unidirectional)	Fifth outgoing adapter.
Plug	OUT6	ADI (unidirectional)	Sixth outgoing adapter.
Plug	OUT7	ADI (unidirectional)	Seventh outgoing adapter.
Plug	OUT8	ADI (unidirectional)	Eighth outgoing adapter.

Functionality

The function block forwards the ADI adapter arriving via socket `IN` unchanged to all eight `OUT` plugs. Each output represents an independent, but identical copy of the incoming adapter. Distribution occurs directly – there is no buffering, delay, or transformation. Changes to the `IN` adapter are immediately propagated to all `OUT` adapters. The function block operates purely combinatorially and requires no clocking or initialization.

Technical Features

- **Generic Type**: The FB can be parameterized to various specific ADI implementations using the attribute `eclipse4diac::core::GenericClassName`. By default, the class name is set to `'GEN_ADI_SPLIT'`.
- **No State Management**: The FB has no internal memory or state machines; it acts as a simple signal distributor.
- **Unidirectionality**: All adapters are unidirectional – data flows only from the socket to the plugs. Feedback is not provided.
- **No Event Control**: Distribution occurs without events, which increases runtime determinism.

State Overview

The `ADI_SPLIT_8` FB has no internal states or an ECC (Execution Control Chart). It behaves statically and performs the same function at all times. Therefore, a state overview is unnecessary.

Application Scenarios

- **Signal Broadcasting**: Distributing a measured value or control signal (e.g., temperature, speed) to multiple parallel control loops.
- **Adapter Multiplexing**: Providing a central ADI path for multiple subsystems that require the same data stream.
- **Test and Simulation Environments**: Feeding a simulated signal to multiple receiver blocks simultaneously.
- **Modular Automation Architectures**: Creating redundant or parallel processing paths by simply duplicating adapter connections.

Comparison with Similar Components

- **SPLIT (Data-Event Variant)**: Classic split components (e.g., `E_SPLIT`) distribute events or data values, but not entire adapter paths. `ADI_SPLIT_8` operates at a higher level of abstraction (adapter level).
- **FORK FBs**: Some IEC 61499 implementations offer fork blocks for adapters, but these are often event-driven. This FB is distinguished by its absence of events and its fixed number of eight outputs.
- **Manual Wiring**: Without this FB, each destination connection would have to be implemented individually via coupling adapters or manual branching – more complex and prone to errors.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

ADI_SPLIT_8` is a powerful, generic split block for unidirectional ADI adapters in IEC 61499 applications. It significantly reduces wiring effort, improves clarity, and allows for the easy duplication of an adapter path. Thanks to its generic parameterization and event-free operation, it is particularly well-suited for data-driven automation systems that require reliable, low-latency signal distribution.

ADI_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_SPLIT_9` is a generic component that splits an incoming ADI signal (adapter) into nine identical output signals. It functions purely as a splitter at the adapter level.

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs
None.

Data Outputs
None.

Adapter
- **IN** (Socket): Adapter type `adapter::types::unidirectional::ADI` – Input signal.
- **OUT1** to **OUT9** (Plugs): Nine adapters of the same type – outputs that pass the input signal on unchanged.

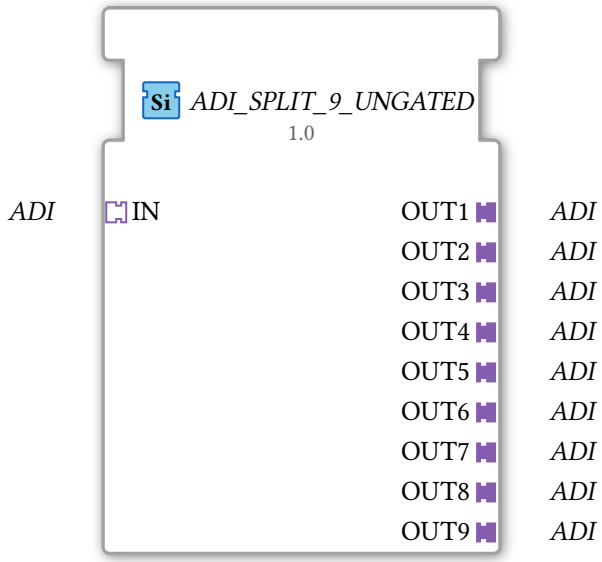
Functionality
The function block forwards the ADI signal present at socket `IN` to all nine plugs `OUT1` to `OUT9`. No signal processing or conversion takes place; the distribution is purely structural via the adapter connections. Due to the unidirectional adapter type, the data flow direction from the socket to the plugs is fixed.

Technical Features
- The function block is defined as a generic function block (attribute `eclipse4diac::core::GenericClassName = 'GEN_ADI_SPLIT'`) and can therefore be reused in different projects.
- It has neither events nor data inputs/outputs; all functionality resides in the adapter topology.
- The type hash attribute is empty, indicating a simple, non-versioned execution.

State Overview
The function block has no state machines or algorithms. It is purely passive and does not react to events.

Application Scenarios
- Distributing an analog or digital sensor signal (as ADI) to multiple downstream function blocks.
- Splitting a control signal in an automation system to control identical actuators in parallel.
- Generating signal copies for monitoring, testing, or diagnostic purposes.

Comparison with Similar Function Blocks
- Unlike data- or event-based splitters, `ADI_SPLIT_9` operates at the higher adapter level, enabling clean architectural separation.
- Similar function blocks exist with a variable number of outputs (e.g., `ADI_SPLIT_M`), while this function block offers a fixed number of nine outputs.



Change Detection
Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion
ADI_SPLIT_9` is a simple, generic function block for 1-to-9 distribution of a unidirectional ADI signal. It is suitable for applications that require multiple, identical forwarding of adapter signals without additional logic.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADI_SPLIT_9_UNGATED` is a generic component that splits an incoming ADI signal (adapter) into nine identical output signals. It functions purely as a splitter at the adapter level.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

- **IN** (Socket): Adapter type `adapter::types::unidirectional::ADI` – Input signal.
- **OUT1** to **OUT9** (Plugs): Nine adapters of the same type – outputs that pass the input signal on unchanged.

Functionality

The function block forwards the ADI signal present at socket `IN` to all nine plugs `OUT1` to `OUT9`. No signal processing or conversion takes place; the distribution is purely structural via the adapter connections. Due to the unidirectional adapter type, the data flow direction from the socket to the plugs is fixed.

Technical Features

- The function block is defined as a generic function block (attribute `eclipse4diac::core::GenericClassName = 'GEN_ADI_SPLIT'`) and can therefore be reused in different projects.
- It has neither events nor data inputs/outputs; all functionality resides in the adapter topology.
- The type hash attribute is empty, indicating a simple, non-versioned execution.

State Overview

The function block has no state machines or algorithms. It is purely passive and does not react to events.

Application Scenarios

- Distributing an analog or digital sensor signal (as ADI) to multiple downstream function blocks.
- Splitting a control signal in an automation system to control identical actuators in parallel.
- Generating signal copies for monitoring, testing, or diagnostic purposes.

Comparison with Similar Function Blocks

- Unlike data- or event-based splitters, `ADI_SPLIT_9_UNGATED` operates at the higher adapter level, enabling clean architectural separation.
- Similar function blocks exist with a variable number of outputs (e.g., `ADI_SPLIT_M`), while this function block offers a fixed number of nine outputs.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

ADI_SPLIT_9_UNGATED` is a simple, generic function block for 1-to-9 distribution of a unidirectional ADI signal. It is suitable for applications that require multiple, identical forwarding of adapter signals without additional logic.

AD_D_FF

• – ○ • – ○ • – ○ •

The function block **AD_D_FF** implements a **data latch (D flip-flop)**. It receives a data value upon an incoming event and holds this value until the next data transfer. The interface is defined exclusively via standardized **adapters**, which allows for flexible wiring in complex automation systems.

No direct event inputs. The function block uses only the **input adapter `I`**, which provides the clock signal via its internal event channel.

No direct event outputs. The FB uses only the **output adapter `Q`**, which signals via its internal event channel that a new data value is available.

No direct data inputs. The value to be latched is provided via the **data channel of the input adapter `I`**.

No direct data outputs. The latched value is provided via the **data channel of the output adapter `Q`**.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

Adapter	Direction	Type	Description
`I` (Socket)	Input	`adapter::types::unidirectional::AD`	Provides the clock signal (E1) and the data value to be stored (D1).
`Q` (Plug)	Output	`adapter::types::unidirectional::AD`	Outputs the stored data value after the clock event (E1 as acknowledgment, D1 as data).

The adapters of type `unidirectional::AD` each define one event channel (`E1`) and one data channel (`D1`). The exact data types are defined by the adapter definition (usually `ANY`).

The adapters of type `unidirectional::AD` define one event channel (`E1`) and one data channel (`D1`). The exact data types are defined by the adapter definition (usually `ANY`).

Functionality

The function block (FB) internally uses the elementary block `E_D_FF_ANY` (from the IEC 61499 standard library). Its behavior is as follows:

1. **Upon each event at the clock input (CLK)**, the current data value at input `D` is transferred to output `Q`. This transfer is triggered by an edge (rising edge of the event).
2. Output `Q` remains unchanged until a new clock event arrives.

The connection in the FB network:

- The event `I.E1` is connected to `CLK`.
- The date `I.D1` is linked to `D`.
- The event output `EO` of the internal function block is forwarded to `Q.E1`.
- The data output `Q` of the internal function block is forwarded to `Q.D1`.

Thus, with each event at the input adapter, the incoming data value is received and immediately output via the output adapter. The value is retained until the next event.

- **Pure Adapter Interface:** The function block does not have traditional event/data ports but communicates exclusively via adapters. This enables its use in systems with standardized connections (e.g., via specific fieldbus adapter profiles).
- **Type Transparency:** Since the adapters are generic (`ANY`), the function block (FB) can work with different data types – provided that both the input and output adapters use the same data type.
- **No Internal State Machine:** The FB implements the flip-flop behavior through the pure data/event wiring of the internal `E_D_FF_ANY`. It does not have its own state machine.

The FB does not have an explicit state machine. The internal block `E_D_FF_ANY` internally stores the saved value (state). However, from the perspective of event processing, the FB is stateless: Every event at the input immediately triggers an output.

- **Signal Buffering:** A data value should be "frozen" upon a specific event and made available for subsequent processing steps.
- **Standardized data coupling:** In architectures that rely on adapter interfaces (e.g., in agricultural machinery), the function block can be used as a universal latch component.
- **RS flip-flop (AD_RS_FF):** Stores two states (Set/Reset) and requires two event/data channels. The AD_D_FF operates with only one clock signal and one data point – simpler and more deterministic.
- **E_D_FF_ANY (direct):** Offers the same functionality, but with classic event/data ports instead of adapters. The AD_D_FF encapsulates this logic in an adapter interface, which facilitates reuse in adapter-based environments.
- **Toggle FF (AD_T_FF)** or **JK FF:** More complex flip-flops with multiple inputs; the AD_D_FF is the simplest form of a data-controlled memory.

The **AD_D_FF** is a lightweight, adapter-based D flip-flop device for the 4diac IDE. It takes a data value on each clock event and outputs it. Thanks to its simple adapter interfaces, it integrates seamlessly into architectures that rely on standardized connections. Its straightforward functionality makes it the ideal choice for data buffering and synchronization tasks without the need for additional logic.

The **AD_D_FF** is a lightweight, adapter-based D flip-flop device for the 4diac IDE. —

AD_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AD_D_FF_TMIN** implements a data-retaining flip-flop (D-latch) based on adapters with a unidirectional interface. It features a configurable minimum inter-disposal time (MDR) between two consecutive events, making it suitable for time-critical signal processing.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request (Passing the Minimum Time)

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirmation

Data Inputs

Name	Data Type	Comment
Tmin	TIME	Minimum time between two consecutive events on socket *I*

Data Outputs

No direct data outputs are available; output is exclusively via the adapter *Q*.

Adapters

Type	Direction	Name	Comment
adapter::types::unidirectional::AD	**Plug** (Output)	Q	Returns the latched value
adapter::types::unidirectional::AD	**Socket** (Input)	I	Receives the value to be latched and the clock event

Functionality

This component encapsulates an internal instance of the function block `iec61499::events::E_D_FF_ANY_TMIN`. The socket *I* returns both the clock event (via the adapter event output `E1`) and the data value (via the adapter data output `D1`). At each clock cycle, the internal flip-flop updates the current value from `I.D1` to its output `Q`. This signal is output via the plug *Q* (event `E1` and data `D1`).

The minimum dwell time `Tmin` is passed to the internal block during initialization and limits the frequency of clock events: Events arriving before the elapsed time of `Tmin` since the last clock cycle are suppressed.

Technical Features

- **Adapter-based I/O**: The block uses unidirectional adapters (type `adapter::types::unidirectional::AD`) that combine events and data in a structured interface.
- **Event-driven minimum dwell time**: The configurable time `Tmin` prevents excessively fast clocking and protects downstream logic from overload.
- **Reuse**: The internal logic is implemented as a separate function block (`E_D_FF_ANY_TMIN`), which facilitates modular maintenance and testing.

State Overview

The function block itself does not have an explicit state machine (no ECC definition). Its behavior is entirely determined by the embedded function block `E_D_FF_ANY_TMIN`. This operates as a **D flip-flop with a time filter**:

- **Idle State**: Waiting for the next clock event.
- **Clock Processing**: Checking whether the time interval `Tmin` has elapsed since the last clock cycle. If yes → Data transfer and generation of an output event. If no → Event ignored.
- **Initialization State**: Only when `INIT` is `Tmin` set and the internal timer reset.

Application Scenarios

- **Data Acquisition with Minimum Interval**:

Sensor data should only be acquired if a specific time interval from the previous value is maintained (e.g., debouncing or sampling rate limiting).

- **Pulse Shaping / Trigger Management**:

The function block can be used as a "debounced" flip-flop in controllers to smooth signal edges and filter out interference pulses.

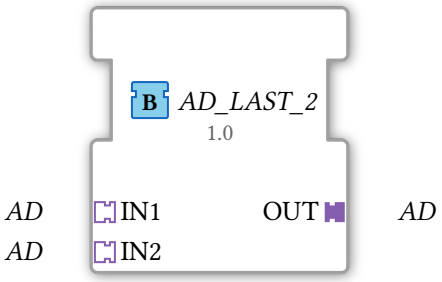
- **Adapter-Oriented Bus Architectures**:

Thanks to the adapter interface, the function block can be seamlessly integrated into existing unidirectional data flows, e.g., in sensor-actuator networks.

Comparison with Similar Function Blocks

Function Block	Feature	Difference
E_D_FF	Standard D Flip-Flop	No time constraint; every clock event is processed.
E_CTD / E_CTU	Counter	Different basic function; counts events.
AD_D_FF_TMIN	D Flip-Flop with *Minimum Inter-disposal Time*	Prevents excessively fast clock sequences through configurable lock time.

Conclusion



The **AD_D_FF_TMIN** extends the classic D Flip-Flop with a time-based filter function, which is configured via the parameter `Tmin`. Its adapter interface allows for clean encapsulation of events and data in a single connector, simplifying integration into complex automation systems. The module is ideal for applications requiring a minimal event distance.

]

AD_LAST_2

Introduction

The AD_LAST_2 function block merges two same-type DWORD adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: DWORD adapter (unidirectional) - first signal source
- **IN2**: DWORD adapter (unidirectional) - second signal source

Output adapter (Plug):

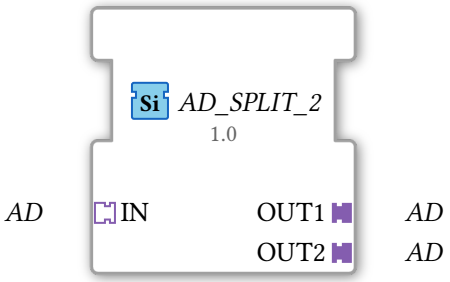
- **OUT**: DWORD adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid DWORD signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same DWORD value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AD_LAST_2 is the inverse of `AD_SPLIT_2`: AD_SPLIT_2 distributes 1 input to 2 outputs, AD_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

AD_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The AD_SPLIT_2 function block is used to split an incoming unidirectional adapter (AD) into two identical output adapters. It is implemented as a generic function block and allows for the simple branching of an adapter signal into two parallel paths.

Interface Structure

Event Inputs
None

Event Outputs
None

Data Inputs
None

Data Outputs
None

Adapter

Name	Type	Direction
IN	adapter::types::unidirectional::AD	Socket (Input)
OUT1	adapter::types::unidirectional::AD	Plug (Output)
OUT2	adapter::types::unidirectional::AD	Plug (Output)

Functionality
The function block receives a unidirectional adapter via socket `IN`. All data and events transmitted via this adapter are passed unchanged to both output adapters `OUT1` and `OUT2`. No processing or filtering takes place – the signals are simply duplicated. The distribution occurs without any time delay and without internal buffering.

Technical Features
- **Generic Implementation**: The function block uses the generics mechanisms of Eclipse 4diac (`GenericClassName`). This allows the specific adapter type to be parameterized at design time or runtime, as long as it conforms to the adapter schema `unidirectional::AD`.
- **Type purity**: The output adapters are of the same type as the input adapter; no type conversion takes place.
- **No state logic**: The function block has no internal state machine (ECC) and reacts to adapter communication in an event-driven manner.

State overview
The function block has no explicit states. It operates continuously and immediately forwards each incoming signal to both outputs.

Application scenarios
- Splitting a sensor data stream to two independent control or monitoring units.
- Parallelizing adapter signals in industrial automation systems (e.g., distributing a fieldbus adapter value across two control loops).
- Test and simulation setups where a signal must be sent to different devices simultaneously.

Comparison with Similar Function Blocks
- **AD_SPLIT_3, AD_SPLIT_4**: Extensions with multiple outputs, based on the same mechanism.
- **AD_MERGE**: Combines multiple adapter inputs into one output – the inverse function of AD_SPLIT_2.
- **AD_SELECT**: Selects one of several adapter inputs and passes it on, but requires control logic.

Change Detection
Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AD_SPLIT_2 is a simple yet effective function block for signal distribution in adapter-based architectures. Its generic nature and lack of state logic make it easy to configure and resource-efficient. It is particularly suitable for modular automation projects where an adapter signal needs to be distributed to multiple downstream components.

AD_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AD_SPLIT_3` serves as a generic splitter for a unidirectional adapter (AD). It receives an incoming AD and forwards it to three separate outputs. This allows multiple uses of the same data or signal path.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Type	Direction	Name	Description
Socket (Input)	Input	IN	Unidirectional adapter input, which is distributed to the three outputs.
Plug (Output)	Output	OUT1	First output with duplicated adapter signal.
Plug (Output)	Output	OUT2	Second output with duplicated adapter signal.
Plug (Output)	Output	OUT3	Third output with duplicated adapter signal.

All adapters are of type `adapter::types::unidirectional::AD`.

Functionality

The module functions as a pure splitter: The adapter (data or event stream) connected to socket `IN` is identically duplicated to the three plugs `OUT1`, `OUT2`, and `OUT3`. Changes or events at the input affect all three outputs instantly. No transformation, buffering, or logic is performed – signal distribution is transparent.

Technical Features

- **Generic Type**: The function block is designed as a generic adapter splitter (`GenericClassName = 'GEN_AD_SPLIT'`) and can be used with any unidirectional adapter of type `adapter::types::unidirectional::AD`.
- **Pure Adapter Interface**: The function block has neither event nor data inputs/outputs in the traditional sense, but communicates exclusively via adapter plugs and sockets.
- **Unidirectional**: Communication occurs only in one direction (from the socket to the plugs), therefore no feedback or handshake mechanism is required.
- **No Runtime Dependence**: Distribution occurs instantaneously and without delay.

State Overview

The `AD_SPLIT_3` does not have its own state diagram (ECC). The outputs follow the input without any internal logic or memory behavior. Therefore, there is only a single, passive state in which the current input is constantly passed on to the outputs.

Application Scenarios

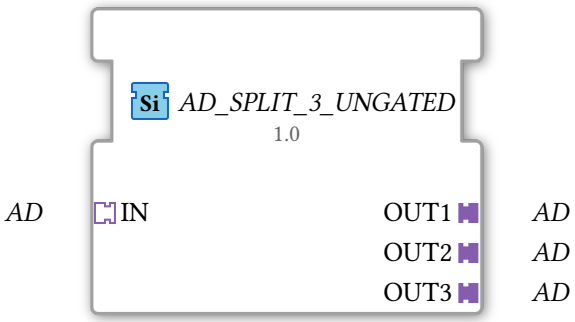
1. **Signal Fan-Out**: A sensor signal or a command (e.g., control word or status) is to be sent to multiple parallel consumers.
2. **Logging**: A data stream is processed once and then forwarded a second time for recording or monitoring.

3. **Redundancy**: A critical adapter path is distributed across multiple independent systems.
4. **Test Environments**: In simulation or test setups, a signal can be mirrored to multiple test points.

Comparison with Similar Function Blocks

- **AD_SPLIT_2**: Distributes the input to only two outputs. `AD_SPLIT_3` extends this to three outputs.
- **AD_MERGE**: Combines multiple adapter inputs into one output – functionally the opposite.
- **Specific Data Splitters**: Function blocks like `SPLIT_INT` or `SPLIT_BOOL` operate at the data level, not the adapter level. `AD_SPLIT_3` is designed for complete adapter structures (data plus events).

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AD_SPLIT_3` is a simple yet useful generic function block for multiplying unidirectional adapters. Due to its pure adapter interface and lack of logic, it is particularly suitable for modular architectures where a signal needs to be distributed to multiple receivers without introducing additional complexity.

AD_SPLIT_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_SPLIT_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AD_SPLIT_3_UNGATED` is a simple yet useful generic function block for multiplying unidirectional adapters. Due to its pure adapter interface and lack of logic, it is particularly suitable for modular architectures where a signal needs to be distributed to multiple receivers without introducing additional complexity.

AD_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_SPLIT_4** is used to distribute an incoming unidirectional AD adapter (adapter definition) to four identical outputs. It is a generic function block specifically designed for splitting a single AD signal into up to four separate paths.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available. Data transmission occurs exclusively via the incoming AD adapter.

Data Outputs

No data outputs available. Output occurs exclusively via the four outgoing AD adapters.

Adapters

This component uses only adapters of type `adapter::types::unidirectional::AD`:

- **Socket (Input)**

IN` – A unidirectional analog-to-digital input that receives the signal to be split.

- **Plugs (Outputs)**

OUT1, OUT2, OUT3, OUT4` – Four unidirectional analog-to-digital outputs that pass the signal received from the input onward identically.

Functionality

The **AD_SPLIT_4** function block copies the AD data stream arriving at its socket `IN` (without event handling) and makes it available in parallel at all four plugs `OUT1` to `OUT4`. Distribution occurs without delay or buffering – any change at the input is immediately propagated to all outputs. The function block is designed generically, so the specific data type of the AD adapter is only determined at runtime (GenericClassName = `'GEN_AD_SPLIT'`).

Technical Features

- **Generic Type**: The function block is implemented as a generic function block. The actual AD data type is determined by the attribute `eclipse4diac::core::GenericClassName` (`'GEN_AD_SPLIT'`).
- **Unidirectional Communication**: The adapter used, `adapter::types::unidirectional::AD`, only allows data transmission from the socket to the plugs – feedback is not supported.
- **No Event Control**: The module does not require events, as data transmission is purely data-driven (or by the underlying adapter logic).

State Overview

Since the module has no event inputs/outputs, there is no state machine. The behavior is deterministic: The outputs always reflect the current state of the input.

Application Scenarios

- **Signal Distribution**: When a single A/D signal (e.g., a measured value or a control signal) needs to be forwarded to multiple subsequent function blocks or hardware components.
- **Monitoring and Control**: Simultaneous monitoring of a signal in different logic units without requiring multiple copies of the signal source.
- **Redundancy Paths**: Splitting a signal for parallel, independent processing paths.

Comparison with Similar Function Blocks

- **AD_SPLIT_2**, **AD_SPLIT_8**: Related function blocks with identical functionality, but for two or eight outputs, respectively. The choice depends on the number of distributions required.
- **AD_MERGE_4**: A counterpart that combines multiple AD inputs into a single output, as opposed to splitting them.
- **Pure Data Split Function Blocks (e.g., D_SPLIT_4)**: These split individual data values (e.g., INT, REAL), while AD_SPLIT_4 is specifically designed for the complex AD adapter type.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AD_SPLIT_4** function block is a compact, generic tool for easily replicating a unidirectional AD signal. Its clean, event-free interface makes it particularly suitable for data flow-oriented applications in automation technology where a signal needs to be distributed to multiple receivers. Its generic design allows it to be flexibly adapted to various adapter data types.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_SPLIT_4_UNGATED** is used to distribute an incoming unidirectional AD adapter (adapter definition) to four identical outputs. It is a generic function block specifically designed for splitting a single AD signal into up to four separate paths.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available. Data transmission occurs exclusively via the incoming AD adapter.

Data Outputs

No data outputs available. Output occurs exclusively via the four outgoing AD adapters.

Adapters

This component uses only adapters of type `adapter::types::unidirectional::AD`:

- **Socket (Input)**

IN` – A unidirectional analog-to-digital input that receives the signal to be split.

- **Plugs (Outputs)**

OUT1, OUT2, OUT3, OUT4` – Four unidirectional analog-to-digital outputs that pass the signal received from the input onward identically.

Functionality

The **AD_SPLIT_4_UNGATED** function block copies the AD data stream arriving at its socket `IN` (without event handling) and makes it available in parallel at all four plugs `OUT1` to `OUT4`. Distribution occurs without delay or buffering – any change at the input is immediately propagated to all outputs. The function block is designed generically, so the specific data type of the AD adapter is only determined at runtime (GenericClassName = `'GEN_AD_SPLIT'`).

Technical Features

- **Generic Type**: The function block is implemented as a generic function block. The actual AD data type is determined by the attribute `eclipse4diac::core::GenericClassName` (`'GEN_AD_SPLIT'`).
- **Unidirectional Communication**: The adapter used, `adapter::types::unidirectional::AD`, only allows data transmission from the socket to the plugs – feedback is not supported.
- **No Event Control**: The module does not require events, as data transmission is purely data-driven (or by the underlying adapter logic).

State Overview

Since the module has no event inputs/outputs, there is no state machine. The behavior is deterministic: The outputs always reflect the current state of the input.

Application Scenarios

- **Signal Distribution**: When a single A/D signal (e.g., a measured value or a control signal) needs to be forwarded to multiple subsequent function blocks or hardware components.
- **Monitoring and Control**: Simultaneous monitoring of a signal in different logic units without requiring multiple copies of the signal source.
- **Redundancy Paths**: Splitting a signal for parallel, independent processing paths.

Comparison with Similar Function Blocks

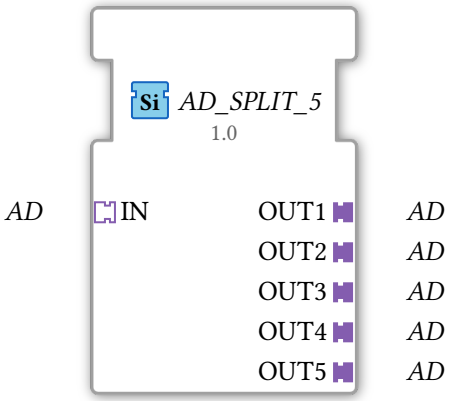
- **AD_SPLIT_2**, **AD_SPLIT_8**: Related function blocks with identical functionality, but for two or eight outputs, respectively. The choice depends on the number of distributions required.

- **AD_MERGE_4**: A counterpart that combines multiple AD inputs into a single output, as opposed to splitting them.
- **Pure Data Split Function Blocks (e.g., D_SPLIT_4)**: These split individual data values (e.g., INT, REAL), while AD_SPLIT_4_UNGATED is specifically designed for the complex AD adapter type.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The **AD_SPLIT_4_UNGATED** function block is a compact, generic tool for easily replicating a unidirectional AD signal. Its clean, event-free interface makes it particularly suitable for data flow-oriented applications in automation technology where a signal needs to be distributed to multiple receivers. Its generic design allows it to be flexibly adapted to various adapter data types.

AD_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AD_SPLIT_5` is a generic function block that splits an incoming unidirectional adapter (type `adapter::types::unidirectional::AD`) into five identical output adapters. It serves to forward an adapter signal in parallel to multiple subsequent function blocks without requiring the input to be connected multiple times.

Interface Structure

Event Inputs

No direct event inputs are available. All communication takes place via the adapter socket.

Event Outputs

No direct event outputs are available. Outputs are exclusively via the adapter plugs.

Data Inputs

No direct data inputs are available. Data is received via the adapter socket.

Data Outputs

No direct data outputs are available. Data is provided via the adapter plugs.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AD`	`IN`	Socket (Input)	Incoming adapter signal, which is distributed to all outputs.
`adapter::types::unidirectional::AD`	`OUT1`	Plug (Output)	First outgoing adapter, identical to the input signal.
`adapter::types::unidirectional::AD`	`OUT2`	Plug (Output)	Second outgoing adapter.
`adapter::types::unidirectional::AD`	`OUT3`	Plug (Output)	Third outgoing adapter.
`adapter::types::unidirectional::AD`	`OUT4`	Plug (Output)	Fourth outgoing adapter.
`adapter::types::unidirectional::AD`	`OUT5`	Plug (Output)	Fifth outgoing adapter.

Functionality

This component does not have event or data ports in the conventional sense. Instead, an incoming adapter `IN` is passed through to all five outgoing adapters `OUT1` to `OUT5`. This means that changes or events transmitted via the input adapter are passed to all five outputs simultaneously. This multiplication occurs without any logical processing or delay.

- **Generic Type**: The function block is implemented as a generic component (attribute `eclipse4diac::core::GenericClassName = 'GEN_AD_SPLIT'`). This allows it to be used in various contexts with the adapter type `adapter::types::unidirectional::AD`.
- **No State Machine**: The block does not have an ECC (Execution Control Chart) and operates purely in a data flow-driven manner. It does not perform any data storage operations.
- **Unidirectional Adapters**: All adapters are unidirectional, meaning data flows in only one direction – from the socket to the plugs.

The function block has no internal states or steps. It is a pure splitter without its own behavior. Therefore, a state overview is not available.

- **Signal Distribution**: When an adapter signal is needed multiple times, e.g., to feed several parallel calculations or outputs.
- **Modular Chaining**: In complex automation systems where a sensor value (as an adapter) needs to be passed on to different subsystems.
- **Prototyping**: Rapid setup of test environments where a signal needs to reach multiple locations simultaneously.
- **AD_SPLIT_2, AD_SPLIT_3, AD_SPLIT_4**: The same functionality with two, three, or four outputs, respectively. `AD_SPLIT_5` is the five-output version.
- **Manual Wiring**: Without this block, the output of the source block would have to be connected multiple times, which is not directly possible in the 4diac IDE (a port can only have one connection). The splitter solves this problem.
- **Event-Based Splitters**: There are also splitters for events (e.g., `E_SPLIT`), but these are based on event and data ports. In contrast, `AD_SPLIT_5` operates exclusively at the adapter level.

The function block `AD_SPLIT_5` is a simple yet useful tool for multiplying adapter signals in the 4diac development environment. Its generic design and the absence of a state machine provide an efficient way to distribute an adapter signal across five parallel paths without requiring any code changes. It is ideal for modular and scalable automation applications.

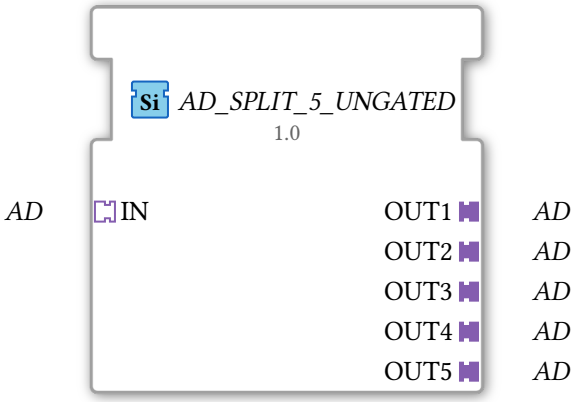
Technical Features

State Overview

Application Scenarios

Comparison with Similar Function Blocks

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AD_SPLIT_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_SPLIT_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AD_SPLIT_5_UNGATED` is a generic function block that splits an incoming unidirectional adapter (type `adapter::types::unidirectional::AD`) into five identical output adapters. It serves to forward an adapter signal in parallel to multiple subsequent function blocks without requiring the input to be connected multiple times.

Interface Structure

Event Inputs

No direct event inputs are available. All communication takes place via the adapter socket.

Event Outputs

No direct event outputs are available. Outputs are exclusively via the adapter plugs.

Data Inputs

No direct data inputs are available. Data is received via the adapter socket.

Data Outputs

No direct data outputs are available. Data is provided via the adapter plugs.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AD`	`IN`	Socket (Input)	Incoming adapter signal, which is distributed to all outputs.
`adapter::types::unidirectional::AD`	`OUT1`	Plug (Output)	First outgoing adapter, identical to the input signal.
`adapter::types::unidirectional::AD`	`OUT2`	Plug (Output)	Second outgoing adapter.
`adapter::types::unidirectional::AD`	`OUT3`	Plug (Output)	Third outgoing adapter.
`adapter::types::unidirectional::AD`	`OUT4`	Plug (Output)	Fourth outgoing adapter.
`adapter::types::unidirectional::AD`	`OUT5`	Plug (Output)	Fifth outgoing adapter.

Functionality

This component does not have event or data ports in the conventional sense. Instead, an incoming adapter `IN` is passed through to all five outgoing adapters `OUT1` to `OUT5`. This means that changes or events transmitted via the input adapter are passed to all five outputs simultaneously. This multiplication occurs without any logical processing or delay.

- **Generic Type**: The function block is implemented as a generic component (attribute `eclipse4diac::core::GenericClassName = 'GEN_AD_SPLIT'`). This allows it to be used in various contexts with the adapter type `adapter::types::unidirectional::AD`.
- **No State Machine**: The block does not have an ECC (Execution Control Chart) and operates purely in a data flow-driven manner. It does not perform any data storage operations.

AD_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_SPLIT_6** distributes an incoming adapter of type `adapter::types::unidirectional::AD` to six separate output adapters of the same type. It is designed as a generic function block that implements a simple 1:6 split without additional logic or state management.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AD`	IN	Socket	Input adapter that distributes the signal to the six outputs.

`adapter::types::unidirectional::AD`	OUT1	Plug	First output adapter (identical to IN).
`adapter::types::unidirectional::AD`	OUT2	Plug	Second output adapter.
`adapter::types::unidirectional::AD`	OUT3	Plug	Third output adapter.
`adapter::types::unidirectional::AD`	OUT4	Plug	Fourth output adapter.
`adapter::types::unidirectional::AD`	OUT5	Plug	Fifth output adapter.
`adapter::types::unidirectional::AD`	OUT6	Plug	Sixth output adapter.

Functionality

The function block forwards the adapter received via socket **IN** unchanged to all six plugs (**OUT1** to **OUT6**). No data manipulation, filtering, or delay occurs. The adapter is multiplied by reference or by direct coupling (depending on the runtime environment) to the outputs. Thus, all connected subsequent function blocks receive the same adapter content.

Technical Features

- **Generic Function Block**: The attribute `eclipse4diac::core::GenericClassName` is set to `'GEN_AD_SPLIT'`, enabling reuse in various type configurations.
- **No Events or Data**: The function block operates exclusively via adapter interfaces; events or direct data connections are not required.
- **Simple Topology**: The 1:6 distribution is hard-coded and cannot be dynamically adjusted.

State Overview

The function block has no internal states or state machines. It behaves passively and continuously passes the input value to all outputs. There are no time constraints or mode switching.

Application Scenarios

- **Signal distribution** in control applications where an AD adapter interface needs to be distributed to multiple downstream components.
- **Test and simulation setups** for monitoring and processing a data stream in parallel.
- **Bus-like architectures** where multiple devices need to receive identical adapter information.

Comparison with Similar Components

Other split components such as `AD_SPLIT_2`, `AD_SPLIT_4`, or `AD_SPLIT_8` differ only in the number of outputs. `AD_SPLIT_6`, with six outputs, offers a middle ground between these variants. Components with additional logic (e.g., conditional distribution) also exist, but this is not the case here.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AD_SPLIT_6` is a simple yet useful generic function block for 1:6 distribution of an AD adapter. Its clear interface and lack of state logic make it easy to understand and efficient for distribution tasks in IEC 61499-based applications.

AD_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_SPLIT_7** is a generic function block for splitting an incoming adapter of type `AD` (unidirectional) into seven separate output adapters. It allows a single adapter signal to be forwarded in parallel to multiple downstream components without modifying or buffering the data. The function block is specifically designed for use in control engineering (e.g., agricultural machinery) and is licensed under the Eclipse Public License 2.0.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AD`	Receives the adapter signal to be distributed.
Plug (Output) 1	`OUT1`	`adapter::types::unidirectional::AD`	First output – identical copy of the input signal.
Plug (Output) 2	`OUT2`	`adapter::types::unidirectional::AD`	Second output.
Plug (Output) 3	`OUT3`	`adapter::types::unidirectional::AD`	Third output.
Plug (Output) 4	`OUT4`	`adapter::types::unidirectional::AD`	Fourth output.
Plug (Output) 5	`OUT5`	`adapter::types::unidirectional::AD`	Fifth output.
Plug (Output) 6	`OUT6`	`adapter::types::unidirectional::AD`	Sixth output.
Plug (Output) 7	`OUT7`	`adapter::types::unidirectional::AD`	Seventh output.

Functionality

The function block forwards the adapter signal (type `AD`) present at socket `IN` unchanged to all seven plugs (`OUT1` … `OUT7`). No data manipulation, synchronization, or buffering takes place. The outputs are always simultaneous and identical to the input. The function block operates purely on a data flow basis without events or state logic.

–

Technical Features

- **Generic Function Block**: The function block is declared as a generic type (GenericClassName = `'GEN_AD_SPLIT'`), which allows reuse with different adapter variants.
- **Unidirectional Adapters**: All adapters used are unidirectional (direction from the socket to the plugs).
- **No Internal States**: There is no state machine – the outputs are continuously derived from the input.
- **Type Hash**: An empty type hash (`''`) is set, but can be used for version control if needed.

State Overview

The function block has no states or state machines. Its behavior is purely combinatorial: As soon as a valid signal is present at the input, it is immediately mirrored to all outputs.

Application Scenarios

- **Distributing Sensor Data**: A single sensor (e.g., speed, pressure) should supply several independent evaluation units in parallel.
- **Parallel Operation of Actuators**: A control signal is simultaneously transmitted to several identical actuators (e.g., valves, motors).
- **Redundancy Setup**: The same data stream is sent to multiple redundant processing paths.
- **Test and Simulation Environments**: A simulated adapter signal is distributed across various test modules.

Comparison with Similar Components

Component	Number of Outputs	Special Feature
`AD_SPLIT_2`	2	Simple 1:2 distribution
`AD_SPLIT_4`	4	Typical for 4-channel systems
`AD_SPLIT_7`	**7**	Extended distribution for seven parallel paths
`AD_MERGE`	–	Combines multiple inputs into one output

Unlike a merge function block, `AD_SPLIT_7` is used exclusively for duplicating a signal without combining data.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AD_SPLIT_7` is a simple yet useful function block for passive signal duplication in adapter-based 4diac applications. Its generic nature and independence from events make it ideal for pure dataflow architectures. For applications requiring a higher number of parallel outputs, the function block can be extended by adjusting the GenericClassName.

AD_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_SPLIT_8** is a generic function block for splitting an incoming unidirectional AD adapter signal into eight separate outputs. It enables the distribution of an analog or digital signal to multiple downstream components without altering the signal.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

Direction	Name	Type	Description
Socket	**IN**	`adapter::types::unidirectional::AD`	Input Adapter – Signal to be Split
Plug	**OUT1**	`adapter::types::unidirectional::AD`	First Output
Plug	**OUT2**	`adapter::types::unidirectional::AD`	Second Output
Plug	**OUT3**	`adapter::types::unidirectional::AD`	Third Output
Plug	**OUT4**	`adapter::types::unidirectional::AD`	Fourth Output
Plug	**OUT5**	`adapter::types::unidirectional::AD`	Fifth Output
Plug	**OUT6**	`adapter::types::unidirectional::AD`	Sixth Output
Plug	**OUT7**	`adapter::types::unidirectional::AD`	Seventh Output
Plug	**OUT8**	`adapter::types::unidirectional::AD`	Eighth Output

Functionality

This function block forwards the signal present at socket **IN** unchanged to all eight plugs **OUT1** through **OUT8**. No signal processing, delay, or logical modification takes place. Distribution occurs continuously and without event triggering.

Technical Features

- **Generic Type**: Depending on the project definition, the adapter type `adapter::types::unidirectional::AD` can represent any unidirectional signal (e.g., analog value, byte, structure).
- **No Event Control**: The function block operates purely data-driven (adapter flow) – no INIT, RSP, or other events are required.
- **Compatibility**: Required import declarations for `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash` are included in the CompilerInfo.
- **Scalability**: By adjusting the generic parameters, similar function blocks with different output numbers can be created.

State Overview

This function block does not have a state machine (ECC). It operates statically and does not adapt its output behavior to different operating modes.

Application Scenarios

- **Sensor Distribution**: A single analog sensor value (e.g., temperature) is passed on to multiple control modules in parallel.
- **Signal Provision for Visualization and Control**: The same A/D signal is sent simultaneously to a higher-level controller and an operator panel.
- **Redundant Data Supply**: In safety-critical applications, the signal can be split across multiple independent paths.

Comparison with Similar Function Blocks

- **AD_SPLIT_2, AD_SPLIT_4** – Function blocks with similar functionality but fewer outputs.
- **AD_ROUTER** – A function block that selectively routes the incoming signal to one of several outputs.
- **AD_MULTIPLEXER** – Combines multiple inputs into one output (in reverse direction).

Unlike these function blocks, **AD_SPLIT_8** does not perform any selection – all outputs always receive the same signal.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AD_SPLIT_8 is a simple yet essential function block in IEC 61499 systems that implements signal distribution via adapter interfaces without additional logic or runtime costs. Its generic nature makes it flexible and facilitates the modular structuring of automation projects.

IN	adapter::types::unidirectional::AD	Socket (Input)
OUT1	adapter::types::unidirectional::AD	Plug (Output)
OUT2	adapter::types::unidirectional::AD	Plug (Output)
OUT3	adapter::types::unidirectional::AD	Plug (Output)
OUT4	adapter::types::unidirectional::AD	Plug (Output)
OUT5	adapter::types::unidirectional::AD	Plug (Output)
OUT6	adapter::types::unidirectional::AD	Plug (Output)
OUT7	adapter::types::unidirectional::AD	Plug (Output)
OUT8	adapter::types::unidirectional::AD	Plug (Output)

OUT9	adapter::types::unidirectional::AD	Plug (Output)

Functionality

The function block (FB) performs a **1:n distribution** of the incoming adapter signal. Each of the nine output adapters (OUT1 … OUT9) provides exactly the same data as the input adapter (IN). Since the FB has neither event nor data inputs, signal transmission is purely structural: the connection between IN and all OUTs is defined at configuration time and transparently passed on at runtime.

Technical Features

- **Generic Block**: The FB carries the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AD_SPLIT'`, thus serving as a placeholder for type-specific instantiation.
- **Type Binding**: All adapters are of type `adapter::types::unidirectional::AD` – a standardized unidirectional adapter interface.
- **No Event Control**: Distribution occurs without time synchronization or events; changes to the input signal are immediately passed on to all outputs.

State Overview

The FB has no internal state machine and executes no sequential logic. Its behavior is **purely combinatorial**.

Application Scenarios

- **Signal Multiplexing**: An adapter provided by a sensor or controller is to be connected to multiple independent evaluation units (e.g., visualization, logging, alarm generation).
- **Modular Architecture**: In an IEC 61499-based application, a central data provider can distribute its information via `AD_SPLIT_9` to up to nine different submodules without duplicating the source logic.

Comparison with Similar Function Blocks

- **AD_SPLIT_2 / AD_SPLIT_4 / AD_SPLIT_8**: These function blocks offer the same functionality, but with fewer outputs (2, 4, 8). `AD_SPLIT_9` complements the portfolio for applications requiring exactly nine parallel outputs.
- **Other Split Function Blocks**: Data type-oriented split function blocks (e.g., for INTEGER or BOOL) split individual data values, while `AD_SPLIT_9` replicates complete adapter structures. The adapter can bundle multiple related data and events.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AD_SPLIT_9` is a simple yet useful generic function block for unidirectionally splitting an adapter signal into nine identical outputs. It helps avoid redundancy in system design and facilitates the modular structuring of IEC 61499 applications.

AD_SPLIT_9_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AD_SPLIT_9`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AD_SPLIT_9_UNGATED** distributes an incoming unidirectional adapter (AD) signal to nine identical outputs. It is implemented as a generic function block and is suitable for reusing an adapter signal in various downstream components.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Name	Type	Direction
IN	adapter::types::unidirectional::AD	Socket (Input)
OUT1	adapter::types::unidirectional::AD	Plug (Output)
OUT2	adapter::types::unidirectional::AD	Plug (Output)
OUT3	adapter::types::unidirectional::AD	Plug (Output)
OUT4	adapter::types::unidirectional::AD	Plug (Output)
OUT5	adapter::types::unidirectional::AD	Plug (Output)
OUT6	adapter::types::unidirectional::AD	Plug (Output)
OUT7	adapter::types::unidirectional::AD	Plug (Output)
OUT8	adapter::types::unidirectional::AD	Plug (Output)

OUT9	adapter::types::unidirectional::AD	Plug (Output)

Functionality

The function block (FB) performs a **1:n distribution** of the incoming adapter signal. Each of the nine output adapters (OUT1 … OUT9) provides exactly the same data as the input adapter (IN). Since the FB has neither event nor data inputs, signal transmission is purely structural: the connection between IN and all OUTs is defined at configuration time and transparently passed on at runtime.

Technical Features

- **Generic Block**: The FB carries the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AD_SPLIT'`, thus serving as a placeholder for type-specific instantiation.
- **Type Binding**: All adapters are of type `adapter::types::unidirectional::AD` – a standardized unidirectional adapter interface.
- **No Event Control**: Distribution occurs without time synchronization or events; changes to the input signal are immediately passed on to all outputs.

State Overview

The FB has no internal state machine and executes no sequential logic. Its behavior is **purely combinatorial**.

Application Scenarios

- **Signal Multiplexing**: An adapter provided by a sensor or controller is to be connected to multiple independent evaluation units (e.g., visualization, logging, alarm generation).
- **Modular Architecture**: In an IEC 61499-based application, a central data provider can distribute its information via `AD_SPLIT_9_UNGATED` to up to nine different submodules without duplicating the source logic.

Comparison with Similar Function Blocks

- **AD_SPLIT_2 / AD_SPLIT_4 / AD_SPLIT_8**: These function blocks offer the same functionality, but with fewer outputs (2, 4, 8). `AD_SPLIT_9_UNGATED` complements the portfolio for applications requiring exactly nine parallel outputs.
- **Other Split Function Blocks**: Data type-oriented split function blocks (e.g., for INTEGER or BOOL) split individual data values, while `AD_SPLIT_9_UNGATED` replicates complete adapter structures. The adapter can bundle multiple related data and events.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AD_SPLIT_9_UNGATED` is a simple yet useful generic function block for unidirectionally splitting an adapter signal into nine identical outputs. It helps avoid redundancy in system design and facilitates the modular structuring of IEC 61499 applications.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AE_AX_SWITCH

• – ○ • – ○ • – ○ •

Introduction

The function block **AE_AX_SWITCH** implements event-driven switching (demultiplexing). An incoming event is forwarded to one of two event outputs – depending on the Boolean value of a separate data input.

Interface Structure

Event Inputs

The function block has no direct event inputs. Events are received via the **adapter `EI`** (type `adapter::types::unidirectional::AE`).

Event Outputs

The function block has no direct event outputs. Events are output via the **adapters `EO0` and `EO1`** (both type `adapter::types::unidirectional::AE`).

Data Inputs

- **`G`** (adapter type `adapter::types::unidirectional::AX`) – Boolean value that controls the switching.
- `G=0` ⟶ Event is routed to `EO0`
- `G=1` ⟶ Event is routed to `EO1`

Data Outputs

No direct data outputs. Output is exclusively via the event adapters.

Adapters

Name	Type	Direction	Description
EI	AE (Event Adapter)	Socket	Receives the event to be switched.
G	AX (Data Adapter)	Socket	Returns the switching state (boolean).
EO0	AE	Plug	Outputs the event if G=0 was present.
EO1	AE	Plug	Outputs the event if G=1 was present.

Functionality

The function block (FB) is always in state START. As soon as an event arrives at adapter EI (signal EI.E1), the current value of the Boolean adapter G.D1 is evaluated:

- **G.D1 = 0** → The FB switches to state G0 and sends an event via adapter EO0.E1. It then immediately returns to state START.
- **G.D1 = 1** → The function block (FB) switches to state G1 and sends an event via adapter EO1.E1. It then immediately returns to state START.

An additional event at adapter G (signal G.E1) does not trigger any action – the FB remains in state START. This prevents unwanted switching operations when the data value changes.

Technical Features

- **Adapter-based interface** – The FB uses loosely coupled adapters of types AE (event) and AX (data). This enables flexible integration with other function blocks in the 4diac framework.
- **Deterministic Switching** – The decision as to which output is activated is made in the same step as the event is received, thus eliminating any additional delay.
- **No Memory Behavior** – After outputting, the function block immediately returns to its initial state. The state G is not cached – it is read anew with each event.

State Overview

State	Description	Output Action
START	Waiting for an event at EI.	–
G0	Event from EI processed at G.D1=0.	EO0.E1
G1	Event from EI processed at G.D1=1.	EO1.E1

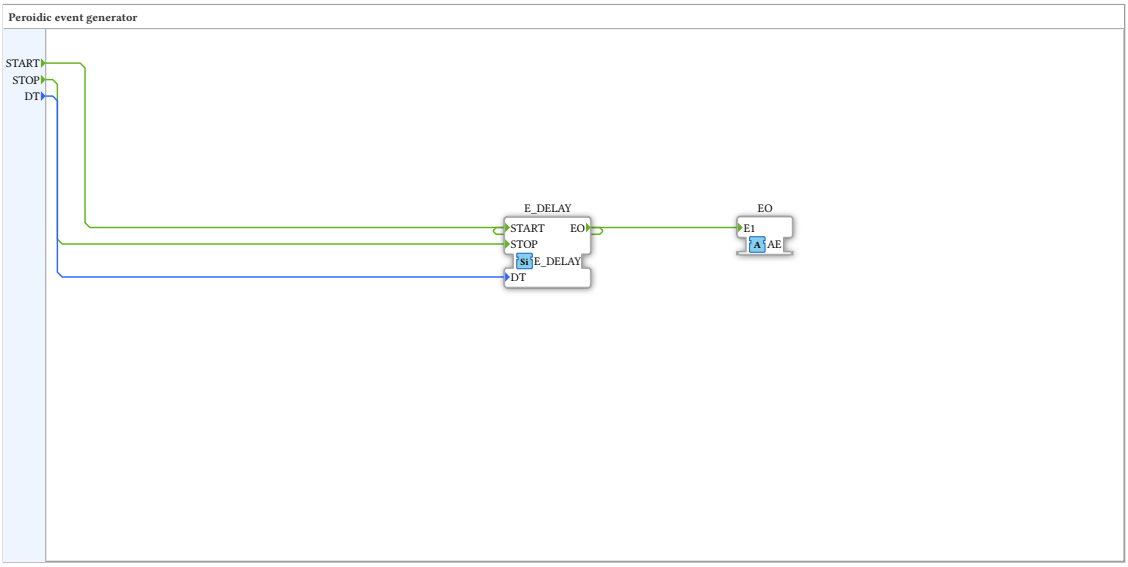
States G0 and G1 are exited immediately after output (automatic transition to START).

Application Scenarios

- **Event Routing** – Forwarding an event to different downstream logic branches, depending on a condition.
- **State-Dependent Control** – In automation systems, a sensor event can be sent to different processing blocks depending on the operating mode.
- **Multiplexing Reversal** – As a demultiplexer for asynchronous event streams, e.g., in communication protocols.

Comparison with Similar Function Blocks

- **E_SWITCH** – The standard function block E_SWITCH uses direct event inputs/outputs. AE_AX_SWITCH extends this concept with adapters, enabling looser coupling and reusability in different contexts.
- **E_DEMUX** – Other demultiplexer function blocks often use multiple inputs or states. AE_AX_SWITCH focuses on the simple, Boolean switching of a single event – without buffering or delay.



Conclusion

The AE_AX_SWITCH is a compact, efficient demultiplexer for events based on a Boolean switching signal. Its adapter-based interface allows for flexible integration into IEC 61499 systems, while its deterministic behavior ensures reliable routing. It is particularly suitable for applications where an event needs to be sent to different processing paths depending on the state of a condition.

AE_CYCLE

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_CYCLE** (Adapter Event Cycle) serves as a periodic event generator. It generates an output event at regular intervals, defined by a timer. Unlike the standard `E_CYCLE` block, this function block uses an adapter for signal output, making it particularly suitable for architectural patterns based on event adapters.

Interface Structure

Event Inputs

- **START**: Starts the periodic generation of events. When this event is triggered, the timer is activated.
- **STOP**: Stops the generation of events and interrupts the current cycle.

Event Outputs

- *No direct event outputs are available (see adapters).*

Data Inputs

- **DT** (TIME): The cycle time. This value determines the interval between two consecutive events.

Data Outputs

- *No data outputs available.*

Adapter

- **EO** (Plug): An adapter of type `adapter::types::unidirectional::AE`. The periodically generated event is output via this adapter (specifically via the adapter event `E1`).

Functionality

The **AE_CYCLE** is implemented as a Composite Function Block. Internally, its logic is based on the standard block `E_DELAY`.

1. **Start**: When the `START` event occurs, the internal `E_DELAY` block is started with a duration of `DT`.
2. **Delay & Trigger**: After the time specified by `DT` has elapsed, the internal module generates an output event.
3. **Feedback (Loop)**: This internal event performs two functions:

- It is forwarded to the adapter **EO** to output the signal.
- It is fed directly back to the `START` input of the internal `E_DELAY`.

1. **Cycle**: This feedback immediately restarts the timer, creating a continuous loop.
2. **Stop**: The `STOP` event immediately interrupts the internal `E_DELAY` module and ends the loop.

Technical Features

- **Encapsulation**: The function block encapsulates the logic of an oscillator circuit (feedback loop) and makes it available via a simplified interface.
- **Adapter Usage**: The use of the `AE` adapter (Adapter Event) enables clean separation and grouping of event flows, compatible with the `adapter::events::unidirectional` package.

State Overview

Since this is a Composite Function Block, it does not have its own state machine (ECC). The implicit state is determined by the internal `E_DELAY`:

- **Inactive**: After initialization or `STOP`.
- **Running**: After `START`, while the timer is running or being retriggered.

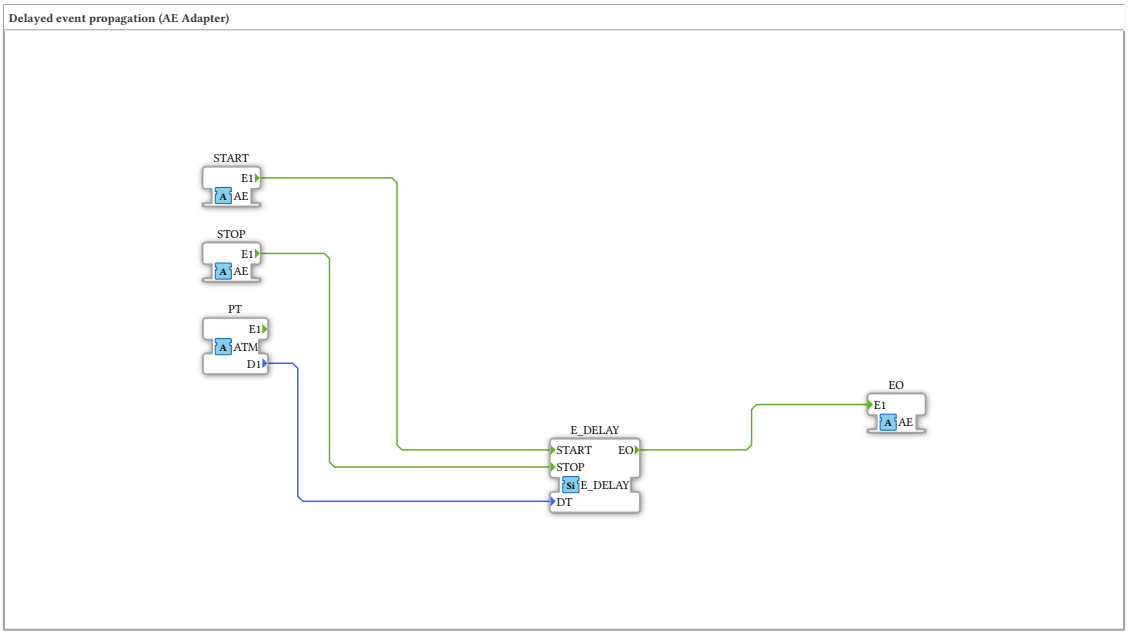
Application Scenarios

- **Heartbeat Signals**: Generating a status signal for higher-level systems or watchdogs.
- **Polling**: Periodically querying sensor data (trigger for `READ` operations).
- **Blinking**: Controlling indicator lights (in combination with toggle logic).
- **Timed Sequences**: Generating a clock signal for step sequences or periodic calculations.

⚖️ Comparison with Similar Function Blocks

- **E_CYCLE**: This is the direct standard counterpart from the IEC 61499 library. `E_CYCLE` offers the same functionality but uses a direct `EO` event output instead of an adapter.
- **E_DELAY**: `AE_CYCLE` is based on `E_DELAY`. While `E_DELAY` only forwards an event with a single delay, `AE_CYCLE`, due to its internal circuitry, ensures an endless repetition.
- **E_TRAIN**: Generates a limited number of pulses (pulse train), while `AE_CYCLE` runs indefinitely until stopped.

Conclusion



The **AE_CYCLE** is a useful utility block for developers working with event adapters within the 4diac environment. It abstracts the necessary feedback logic for generating periodic signals and integrates seamlessly into adapter-based software architectures.

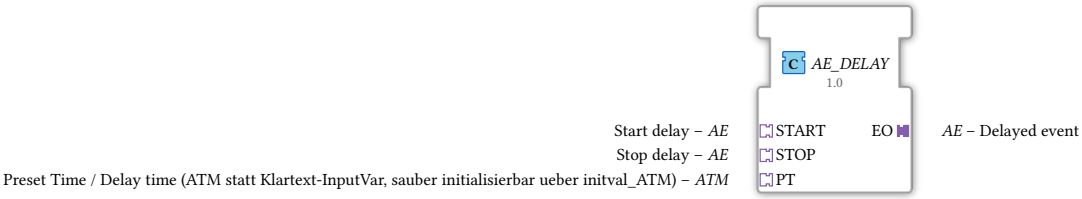
]



AE_DELAY

• — ○ • — ○ • — ○ •

Introduction

The **AE_DELAY** function block is a wrapper for the standard IEC 61499 function block `E_DELAY`, specifically designed for use with **Event Adapters (AE)**. It enables the delayed forwarding of events within an adapter-based architecture. Instead of conventional event pins, this function block uses adapter sockets and plugs to receive start and stop signals and output the delayed event.

Interface Structure

The function block encapsulates the functionality of an on-delay timer in adapter interfaces.

Event Inputs

This function block does not have direct event inputs. All input events are routed via the adapters `START` and `STOP`.

Event Outputs

This function block does not have direct event outputs at the main level. All output events are routed via the adapter `EO`.

Data Inputs

This function block does not have direct data inputs. The delay time is provided via the adapter `PT`.

Data Outputs

This function block does not have any data outputs.

Adapter

Name	Type	Kind	Comment

START	adapter::types::unidirectional::AE	Socket (Input)	Starts the time delay (internally triggers `START`).
STOP	adapter::types::unidirectional::AE	Socket (Input)	Stops/cancels the time delay (internally triggers `STOP`).
PT	adapter::types::unidirectional::ATM	Socket (Input)	**Preset Time**: Delay time (`PT.D1`, TIME).
EO	adapter::types::unidirectional::AE	Plug (Output)	**Event Output**: Outputs the event after the specified time elapses, `PT`.

Functionality

The **AE_DELAY** block acts as a bridge between the adapter world and the classic `E_DELAY` timer:

1. **Initialization:** The desired delay time is set via the adapter socket `PT` (data value `PT.D1`).
2. **Starting the Timer:** When an event (usually `E1`) arrives at the adapter socket **START**, it is internally forwarded to the `START` input of the embedded `E_DELAY` block. The timer then starts running.
3. **Time Expiration:** Once the time `PT` has elapsed, the internal timer generates an event. This is forwarded to the adapter plug **EO** (event `E1`).
4. **Stopping:** When an event arrives at the adapter socket **STOP**, the running timer is immediately stopped and reset. No event is generated at output `EO`.

Technical Details

- **Package Membership:** The function block is part of the package `adapter::events::unidirectional::timers`.
- **Encapsulation:** It contains an instance of `iec61499::events::E_DELAY`.
- **Adapter Type:** Uses the unidirectional event adapter `AE` (`adapter::types::unidirectional::AE`), which typically carries a single event (`E1`).

State Overview

The function block itself does not have an explicit state machine (ECC) because it is a composite network (FB). The behavior is entirely determined by the internal `E_DELAY`:

- **Idle:** Waiting for an event at the `START` adapter.
- **Timing:** After receiving a signal at `START`, the timer `PT` starts.
- **Triggered:** After `PT` expires, the signal is sent to `EO`, and the block returns to the idle state.
- **Reset:** A signal at `STOP` during the *Timing* phase immediately resets the block to the idle state.

Application Scenarios

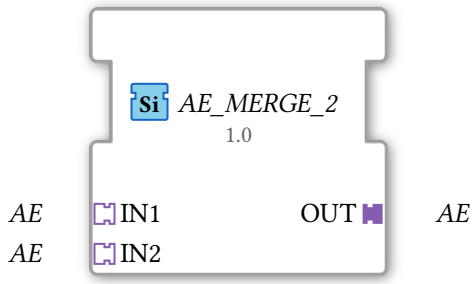
- **Adapter-Based Controllers:** Ideal for systems that rely heavily on adapter connections to reduce the "spaghetti code" of individual connections.
- **Delayed Signal Chains:** Inserting delays into an event chain that is logically grouped by adapters.
- **Process Control:** Delayed start of units or processes controlled via standardized AE interfaces.

⚖️ Comparison with Similar Function Blocks

Function Block	Difference
E_DELAY	The standard function block with direct event pins (START, STOP, EO). **AE_DELAY** is the wrapper for this.
E_CYCLE	Generates periodic events, while **AE_DELAY** forwards an event only once with a delay.
AE_SPLIT	Used to split adapter events, but does not offer time delay.

Conclusion

The **AE_DELAY** is an indispensable tool for developers who want to leverage the advantages of 4diac adapters (reduced connection complexity, clear interface definitions) without sacrificing fundamental



timing functions like delays. It seamlessly integrates the proven `E_DELAY` into modern, adapter-based application designs.

AE_MERGE_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_MERGE_2** merges two unidirectional AE adapters (pure event, no payload data) into one common output adapter. It is the reverse of AE_SPLIT_2: instead of distributing one event to two outputs, it merges two independent event sources into a common output. The block is implemented as a generic FB (`GenericClassName: 'GEN_AE_MERGE'`).

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::AE`	First event source.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::AE`	Second event source.
Plug (Output)	`OUT`	`adapter::types::unidirectional::AE`	Merged event.

Functionality

Whenever an event arrives at `IN1` **or** `IN2`, it is forwarded unchanged to `OUT`. Since `AE` carries no data value, there is nothing to arbitrate when merging beyond the event itself – every single incoming event appears at the output immediately, regardless of which socket it came from. The order in which both sockets are checked for a simultaneous arrival is `IN1` before `IN2` in the implementation, which can matter if both events arrive within the same execution cycle.

Technical Features

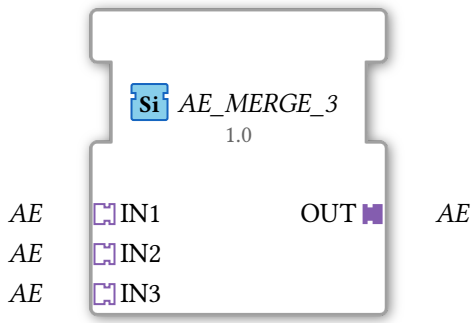
- **Generic type**: Implemented via the generic base class `CGenUnidirectMergeBase` (N sockets, 1 plug) – the same C++ base underlying `GEN_ASR_MERGE` and `GEN_ASRT_MERGE`. The number of input sockets is fixed at compile time via the generic suffix (_2).
- **No states / algorithms**: Since `AE` carries no data value, there is no change detection and no ECC – the block is pure event forwarding.
- **No data loss on simultaneous events**: Unlike a plain data connection (which only allows one source), every event from `IN1` and `IN2` can be forwarded independently; no event is "lost" just because the other socket fired shortly before.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at `IN1` or `IN2` is forwarded to `OUT` immediately.

Application Scenarios

- **Event merging**: Two independent event sources (e.g. two buttons or two sensor triggers) should trigger the same follow-up action, without wiring the downstream logic twice.
- **Redundant trigger paths**: An event can be triggered via two independent sources (e.g. a manual and an automatic path) that both feed into the same output.
- **Simplifying networks** that would otherwise need two separate event connections to the same destination.



Comparison with Similar Components

- AE_SPLIT_2: the reverse direction – distributes one incoming event to two outputs, instead of merging two inputs.
- ASR_MERGE_2: the same merge logic for the set/reset event adapter `ASR` (2 events instead of 1).
- ASRT_MERGE_2: the same merge logic for the set/reset/toggle event adapter `ASRT` (3 events instead of 1).

Conclusion

AE_MERGE_2 is a minimal generic function block for merging two pure event sources into a common AE adapter output. Its lack of logic ensures minimal latency, while the generic implementation keeps it consistent with the other `GEN_*_MERGE` blocks in the family.

AE_MERGE_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_MERGE_3** merges 3 unidirectional AE adapters (pure event adapter, no payload data) into one common output adapter. It is the 3-input variant of AE_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_AE_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 3 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::AE`	Source 1.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::AE`	Source 2.
Socket (Input 3)	`IN3`	`adapter::types::unidirectional::AE`	Source 3.
Plug (Output)	`OUT`	`adapter::types::unidirectional::AE`	Merged signal.

Functionality

Whenever `E1` arrives at any of the 3 sockets (`IN1`, `IN2`, `IN3`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 3 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN3`, which only matters if several events arrive within the same execution cycle. Since `AE` carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

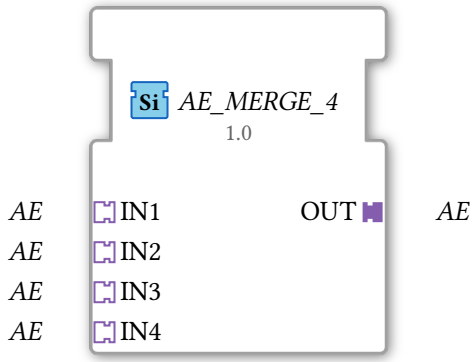
- **Generic type**: Implemented via the generic base class `CGenUnidirectMergeBase` (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (`_3`).
- **No states / algorithms**: Since `AE` carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers AE_MERGE_2 through AE_MERGE_7; for other input counts see `AE_MERGE_2`, `AE_MERGE_4`, `AE_MERGE_5`, `AE_MERGE_6`, `AE_MERGE_7`.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 3 sockets is forwarded to `OUT` immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 3 redundant or alternative trigger paths) into a common AE adapter output.
- **Simplifying networks** that would otherwise need 3 separate event connections to the same destination.



Comparison with Similar Components

- **AE_SPLIT_2**: the reverse direction for 2 outputs (for ASRT, AE_SPLIT_3 through AE_SPLIT_9 are also available).
- **`AE_MERGE_2`, `AE_MERGE_4`, `AE_MERGE_5`, `AE_MERGE_6`, `AE_MERGE_7`**: the same generic implementation with a different input count.
- ASR_MERGE_3, ASRT_MERGE_3: the same merge logic for the other unidirectional event adapters.

Conclusion

`AE_MERGE_3` provides a generically implemented merge of 3 `AE` event sources into a common adapter output, completing the `GEN_AE_MERGE` family with the 3-input variant.

AE_MERGE_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_MERGE_4** merges 4 unidirectional AE adapters (pure event adapter, no payload data) into one common output adapter. It is the 4-input variant of AE_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_AE_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 4 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::AE`	Source 1.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::AE`	Source 2.
Socket (Input 3)	`IN3`	`adapter::types::unidirectional::AE`	Source 3.
Socket (Input 4)	`IN4`	`adapter::types::unidirectional::AE`	Source 4.
Plug (Output)	`OUT`	`adapter::types::unidirectional::AE`	Merged signal.

Functionality

Whenever `E1` arrives at any of the 4 sockets (`IN1`, `IN2`, `IN3`, `IN4`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 4 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN4`, which only matters if several events arrive within the same execution cycle. Since `AE` carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

- **Generic type**: Implemented via the generic base class `CGenUnidirectMergeBase` (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_4).
- **No states / algorithms**: Since `AE` carries no data value, there is no change detection and no ECC.

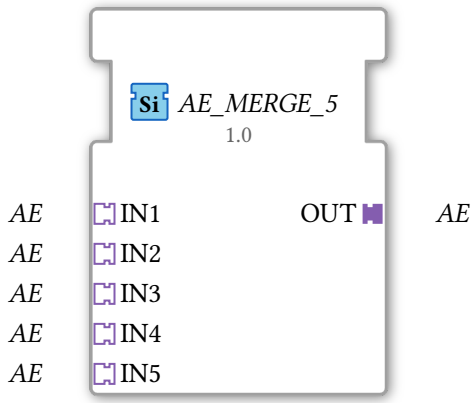
- **Arbitrary input count**: The same implementation covers AE_MERGE_2 through AE_MERGE_7; for other input counts see `AE_MERGE_2`, `AE_MERGE_3`, `AE_MERGE_5`, `AE_MERGE_6`, `AE_MERGE_7`.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 4 sockets is forwarded to `OUT` immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 4 redundant or alternative trigger paths) into a common AE adapter output.
- **Simplifying networks** that would otherwise need 4 separate event connections to the same destination.



Comparison with Similar Components

- AE_SPLIT_2: the reverse direction for 2 outputs (for ASRT, AE_SPLIT_3 through AE_SPLIT_9 are also available).
- **`AE_MERGE_2`, `AE_MERGE_3`, `AE_MERGE_5`, `AE_MERGE_6`, `AE_MERGE_7`**: the same generic implementation with a different input count.
- ASR_MERGE_4, ASRT_MERGE_4: the same merge logic for the other unidirectional event adapters.

Conclusion

`AE_MERGE_4` provides a generically implemented merge of 4 `AE` event sources into a common adapter output, completing the `GEN_AE_MERGE` family with the 4-input variant.

AE_MERGE_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_MERGE_5** merges 5 unidirectional AE adapters (pure event adapter, no payload data) into one common output adapter. It is the 5-input variant of AE_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_AE_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 5 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	IN1	adapter::types::unidirectional::AE	Source 1.
Socket (Input 2)	IN2	adapter::types::unidirectional::AE	Source 2.
Socket (Input 3)	IN3	adapter::types::unidirectional::AE	Source 3.
Socket (Input 4)	IN4	adapter::types::unidirectional::AE	Source 4.
Socket (Input 5)	IN5	adapter::types::unidirectional::AE	Source 5.
Plug (Output)	OUT	adapter::types::unidirectional::AE	Merged signal.

Functionality

Whenever E1 arrives at any of the 5 sockets (IN1, IN2, IN3, IN4, IN5), it is forwarded unchanged to OUT as the matching event type. All event types are handled independently, and all 5 sockets are treated equally — the order in which sockets are checked follows IN1 … IN5, which only matters if several events arrive within the same execution cycle. Since AE carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

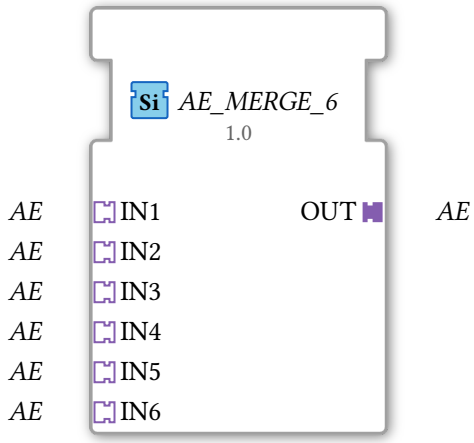
- **Generic type**: Implemented via the generic base class CGenUnidirectMergeBase (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_5).
- **No states / algorithms**: Since AE carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers AE_MERGE_2 through AE_MERGE_7; for other input counts see AE_MERGE_2, AE_MERGE_3, AE_MERGE_4, AE_MERGE_6, AE_MERGE_7.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 5 sockets is forwarded to OUT immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 5 redundant or alternative trigger paths) into a common AE adapter output.
- **Simplifying networks** that would otherwise need 5 separate event connections to the same destination.



Comparison with Similar Components

- **AE_SPLIT_2**: the reverse direction for 2 outputs (for ASRT, AE_SPLIT_3 through AE_SPLIT_9 are also available).
- **AE_MERGE_2, AE_MERGE_3, AE_MERGE_4, AE_MERGE_6, AE_MERGE_7**: the same generic implementation with a different input count.
- ASR_MERGE_5, ASRT_MERGE_5: the same merge logic for the other unidirectional event adapters.

Conclusion

AE_MERGE_5 provides a generically implemented merge of 5 AE event sources into a common adapter output, completing the GEN_AE_MERGE family with the 5-input variant.

AE_MERGE_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_MERGE_6** merges 6 unidirectional AE adapters (pure event adapter, no payload data) into one common output adapter. It is the 6-input variant of AE_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_AE_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 6 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::AE`	Source 1.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::AE`	Source 2.
Socket (Input 3)	`IN3`	`adapter::types::unidirectional::AE`	Source 3.
Socket (Input 4)	`IN4`	`adapter::types::unidirectional::AE`	Source 4.
Socket (Input 5)	`IN5`	`adapter::types::unidirectional::AE`	Source 5.
Socket (Input 6)	`IN6`	`adapter::types::unidirectional::AE`	Source 6.
Plug (Output)	`OUT`	`adapter::types::unidirectional::AE`	Merged signal.

Functionality

Whenever `E1` arrives at any of the 6 sockets (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 6 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN6`, which only matters if several events

arrive within the same execution cycle. Since AE carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

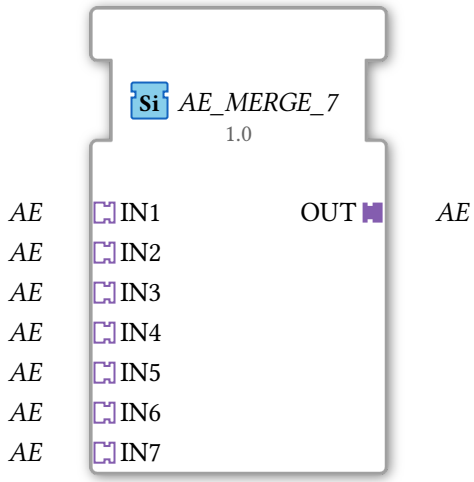
- **Generic type**: Implemented via the generic base class CGenUnidirectMergeBase (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_6).
- **No states / algorithms**: Since AE carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers AE_MERGE_2 through AE_MERGE_7; for other input counts see AE_MERGE_2, AE_MERGE_3, AE_MERGE_4, AE_MERGE_5, AE_MERGE_7.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 6 sockets is forwarded to OUT immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 6 redundant or alternative trigger paths) into a common AE adapter output.
- **Simplifying networks** that would otherwise need 6 separate event connections to the same destination.



Comparison with Similar Components

- AE_SPLIT_2: the reverse direction for 2 outputs (for ASRT, AE_SPLIT_3 through AE_SPLIT_9 are also available).
- **AE_MERGE_2, AE_MERGE_3, AE_MERGE_4, AE_MERGE_5, AE_MERGE_7**: the same generic implementation with a different input count.
- ASR_MERGE_6, ASRT_MERGE_6: the same merge logic for the other unidirectional event adapters.

Conclusion

AE_MERGE_6 provides a generically implemented merge of 6 AE event sources into a common adapter output, completing the GEN_AE_MERGE family with the 6-input variant.

AE_MERGE_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_MERGE_7** merges 7 unidirectional AE adapters (pure event adapter, no payload data) into one common output adapter. It is the 7-input variant of AE_MERGE_2 and, like it, is implemented as a generic FB (GenericClassName: 'GEN_AE_MERGE') — the same C++ base (CGenUnidirectMergeBase), just with 7 instead of 2 sockets.

Interface Structure

Event Inputs
None. Events are received exclusively via the adapter sockets.

Event Outputs
None. Events are forwarded exclusively via the adapter plug.

Data Inputs
None.

Data Outputs
None.

Adapters

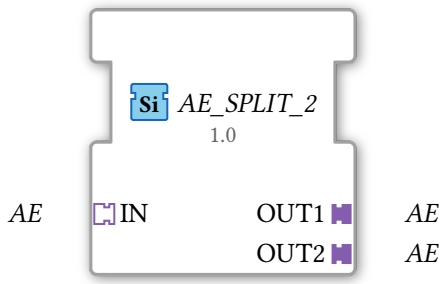
Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::AE`	Source 1.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::AE`	Source 2.
Socket (Input 3)	`IN3`	`adapter::types::unidirectional::AE`	Source 3.
Socket (Input 4)	`IN4`	`adapter::types::unidirectional::AE`	Source 4.
Socket (Input 5)	`IN5`	`adapter::types::unidirectional::AE`	Source 5.
Socket (Input 6)	`IN6`	`adapter::types::unidirectional::AE`	Source 6.
Socket (Input 7)	`IN7`	`adapter::types::unidirectional::AE`	Source 7.
Plug (Output)	`OUT`	`adapter::types::unidirectional::AE`	Merged signal.

Functionality
Whenever `E1` arrives at any of the 7 sockets (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 7 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN7`, which only matters if several events arrive within the same execution cycle. Since `AE` carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features
- **Generic type**: Implemented via the generic base class `CGenUnidirectMergeBase` (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (`_7`).
- **No states / algorithms**: Since `AE` carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers AE_MERGE_2 through AE_MERGE_7; for other input counts see `AE_MERGE_2`, `AE_MERGE_3`, `AE_MERGE_4`, `AE_MERGE_5`, `AE_MERGE_6`.

State Overview
The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 7 sockets is forwarded to `OUT` immediately.

Application Scenarios
- **Merging several equivalent signal sources** (e.g. 7 redundant or alternative trigger paths) into a common AE adapter output.
- **Simplifying networks** that would otherwise need 7 separate event connections to the same destination.



Comparison with Similar Components
- AE_SPLIT_2: the reverse direction for 2 outputs (for ASRT, AE_SPLIT_3 through AE_SPLIT_9 are also available).

- **AE_MERGE_2, AE_MERGE_3, AE_MERGE_4, AE_MERGE_5, AE_MERGE_6**: the same generic implementation with a different input count.
- ASR_MERGE_7, ASRT_MERGE_7: the same merge logic for the other unidirectional event adapters.

Conclusion

AE_MERGE_7 provides a generically implemented merge of 7 AE event sources into a common adapter output, completing the GEN_AE_MERGE family with the 7-input variant.

AE_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_SPLIT_2** serves as a generic distributor for an incoming adapter event (AE). It receives a unidirectional event via socket IN and forwards it without delay or modification to the two output plugs OUT1 and OUT2. The block is implemented as a generic FB (GenericClassName: 'GEN_AE_SPLIT'), so it can theoretically be used for various adapter types – provided they conform to the unidirectional AE protocol.

Interface Structure

Event Inputs

None. The FB does not have any traditional event inputs. Event forwarding occurs exclusively via the adapter socket.

Event Outputs

None. Event forwarding occurs via the adapter plugs.

Data Inputs

None.

Data Outputs

None.

Adapter

Role	Name	Type	Description
Socket (Input)	IN	adapter::types::unidirectional::AE	Receives a unidirectional event, which is distributed to both outputs.
Plug (Output 1)	OUT1	adapter::types::unidirectional::AE	First output for the duplicated event.
Plug (Output 2)	OUT2	adapter::types::unidirectional::AE	Second output for the duplicated event.

Functionality

As soon as an event arrives at the adapter socket IN, it is forwarded **immediately and in parallel** to both output plugs OUT1 and OUT2. The function block performs no logic, filtering, or delay – it functions purely

as a splitter at the adapter level. The distribution is event-based: Every single incoming event appears at both outputs.

Technical Features

- **Generic Type**: The function block is declared as a generic function block (`GenericClassName = 'GEN_AE_SPLIT'`). This allows adaptation to other user-defined adapter types, as long as they use the unidirectional event interface. In the current configuration, the specific type `adapter::types::unidirectional::AE` is defined.
- **No States / Algorithms**: Since no logic or memory behavior is implemented, the function block (FB) has no Execution Control Chart (ECC) and no internal states.
- **Latency**: Forwarding occurs instantaneously within one execution cycle.

State Overview

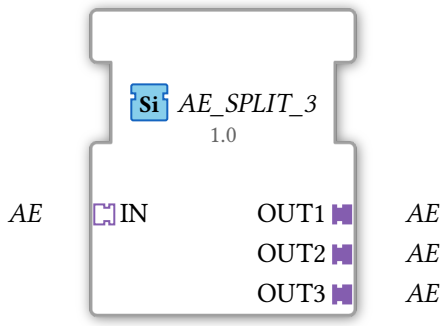
The FB has **no state machine**. Its behavior is purely combinatorial: Every incoming adapter event is immediately duplicated and output to both outputs.

Application Scenarios

- **Event Distribution**: A sensor or controller delivers an event (e.g., "Start" or "Alarm") that must be processed by two independent subsystems.
- **Parallel Circuit**: Splitting a signal to simultaneously control two actuators or for parallel data acquisition.
- **Prototyping**: Temporary branching of an event stream during the development and testing phase.

Comparison with Similar Components

- **AE_SPLIT_1**: A splitter with only one output (i.e., pure pass-through) – usually unnecessary.
- **E_SPLIT_2**: Classic event splitter for standard event inputs/outputs. Unlike `AE_SPLIT_2`, this one operates at the event level without adapter coupling.
- **AE_ROUTER**: An adapter-based distributor that can selectively route events to specific outputs (e.g., based on data values). `AE_SPLIT_2` is simpler and always distributes to all outputs.



Conclusion

The **AE_SPLIT_2** is a minimal yet useful function block for easily distributing adapter events. Its generic nature makes it versatile, while the lack of logic ensures low latency and high reliability. It is ideal for all scenarios where an event needs to be forwarded to multiple receivers.

AE_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_SPLIT_3** is used to distribute an incoming adapter data stream (of type `AE`) to three identical outputs. It is implemented as a generic function block and allows for the flexible use of different adapter types through design-time configuration.

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs
None.

Data Outputs
None.

Adapter

Direction	Name	Type	Description
Socket (Input)	IN	adapter::types::unidirectional::AE	Incoming adapter data stream, distributed to the three outputs.
Connector (Output)	OUT1	adapter::types::unidirectional::AE	First output – receives the same data as the input.
Connector (Output)	OUT2	adapter::types::unidirectional::AE	Second output – receives the same data as the input.
Connector (Output)	OUT3	adapter::types::unidirectional::AE	Third output – receives the same data as the input.

Functionality
The function block accepts a unidirectional adapter data stream of type `AE` via socket `IN`. Each incoming data packet or event is forwarded without modification to all three adapter plugs (`OUT1`, `OUT2`, `OUT3`). No processing or preparation of the data takes place – the function block acts purely as a **signal distributor** for adapter connections.

The function block accepts a unidirectional adapter data stream of type `AE` via socket `OUT1`, `OUT2`, and `OUT3`. Thanks to the generic design (`eclipse4diac::core::GenericClassName = 'GEN_AE_SPLIT'`), the specific adapter type (e.g., a user-defined AE subtype) can be defined at design time for `IN`, `OUT1`–`OUT3`. At runtime, all instances are identically typed.

Technical Features
- **Generic Component** – The adapter type is only defined during instantiation in the project, which increases reusability and type safety.
- **Unidirectional Communication** – Data flows only from the input to the outputs; reverse communication is not supported.
- **License** – The component is licensed under the **Eclipse Public License 2.0 (EPL-2.0)**, which permits free use, modification, and distribution.
- No event- or data-based inputs/outputs – all communication takes place exclusively via the adapter interfaces.

State Overview
The function block does not have an internal state diagram (ECC). It operates **combinatorically**: Any change at the input is immediately and without delay passed on to all outputs.

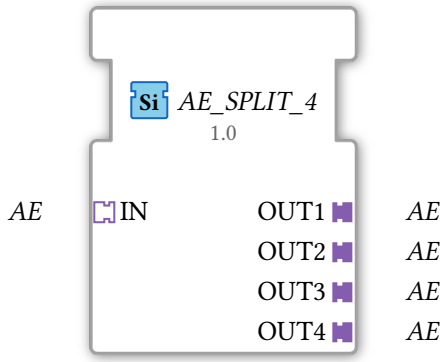
Application Scenarios
- **Signal Multiplication** – An adapter data stream provided by a sensor (e.g., `AE_Temperature`) is to be sent in parallel to three different evaluation units.
- **Distribution of Event Adapters** – In automation systems that rely on adapter-based communication, this allows multiple receivers to be served.
- **Test and Simulation Environments** – A data stream is distributed across multiple monitoring or logging modules.

Comparison with Similar Function Blocks

Function Block	Number of Outputs	Special Features
`AE_SPLIT_2`	2	Distributed to two outputs.
`AE_SPLIT_3`	3	Distributed to three outputs (existing FB).
`AE_SPLIT_N` (hypothetical)	variable	Flexible number via parameters – requires more configuration effort.

All variants have in common that they operate solely at the adapter level and do not manipulate any data.

Conclusion



The **AE_SPLIT_3** is a simple yet indispensable function block for duplicating adapter connections in the 4diac IDE. Its generic design and clear, unidirectional structure make it a maintainable tool for signal distribution without additional logic. Thanks to the EPL 2.0 license, it can be used in your own projects without restrictions.

]

AE_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_SPLIT_4** distributes an incoming event from a unidirectional **AE adapter** to four identical output adapters. It is executed as a generic function block (Generic FB) and can therefore be used for any data type of the adapter. The distribution occurs without delay or state change – the incoming event is forwarded to all four outputs simultaneously.

Interface Structure

Event Inputs

The function block has no explicit event inputs. Event control is handled exclusively via the **IN** socket (see section Adapter).

Event Outputs

The function block has no explicit event outputs. Event propagation is handled via the **OUT1** to **OUT4** plugs (see section Adapter).

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket (Input)	**IN**	`adapter::types::unidirectional::AE`	Receives a unidirectional adapter event (event + associated data).
Plug (Output)	**OUT1**	`adapter::types::unidirectional::AE`	First output – receives the same event and data as the input.
Plug (Output)	**OUT2**	`adapter::types::unidirectional::AE`	Second output.
Plug (Output)	**OUT3**	`adapter::types::unidirectional::AE`	Third output.
Plug (Output)	**OUT4**	`adapter::types::unidirectional::AE`	Fourth output.

Functionality

As soon as an event from the AE adapter is received at socket **IN** (with all data associated with that event), this event is immediately and simultaneously passed on to all four plugs **OUT1**, **OUT2**, **OUT3**, and **OUT4**. The output is simultaneous – there are no priorities or sequences. Due to the generic design of the function block, the data types of the adapters are freely selectable (e.g., `INT`, `REAL`, `BOOL`, etc.), as long as all participating adapters use the same data type.

Technical Features

- **Generic Function Block** – The function block is implemented as a generic type (`GenericClassName = 'GEN_AE_SPLIT'`). This allows the specific data type of the adapter to be defined during the project planning phase.
- **Unidirectional Adapters** – The function block works exclusively with adapters of type `unidirectional::AE`. Return channels or bidirectional communication are not supported.
- **License** – The source code is subject to the **Eclipse Public License 2.0** (EPL-2.0).

State Overview

The **AE_SPLIT_4** is a purely combinational function block and has no internal states. The output signal depends solely on the current input signal – there is no storage or delay.

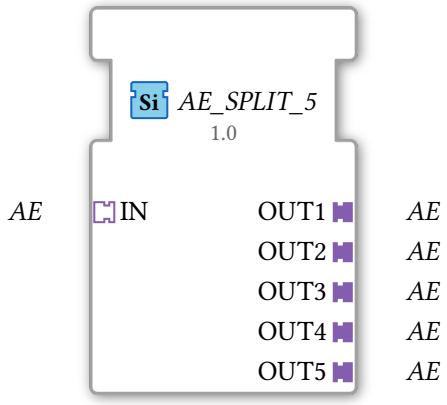
Application Scenarios

- **Sensor Distribution** – A single sensor (e.g., temperature, speed) provides data via an AE adapter; this data is to be distributed to several control functions operating in parallel.
- **Signal Propagation in a Control Chain** – An event must reach several downstream function blocks in parallel, e.g., for triggering alarms and logging.
- **Event Source Multiplexing** – (in conjunction with a preceding AE-MUX) different sources can be routed to the same four outputs.

Comparison with Similar Function Blocks

- **E_SPLIT** – Standard 4diac function block for distributing an event to multiple event outputs without data transmission. **AE_SPLIT_4** extends this functionality by also enabling the transmission of adapter data associated with the event.
- **F_SPLIT** – Data splitters (e.g., for IEC 61131-3 “MUX”) typically do not operate in an event-driven manner. **AE_SPLIT_4** is specifically optimized for event-based adapter communication.
- **AE_MERGE** – The reverse function block: combines multiple AE inputs into a single output.

Conclusion



The **AE_SPLIT_4** is a simple yet powerful function block that enables the event-driven distribution of adapter data to up to four equal outputs. Thanks to its generic design, it can be used for any data type without modification and is ideally suited for modular, parallel control architectures.

]

AE_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_SPLIT_5** is used to duplicate an incoming adapter event. It receives an adapter event (AE) at its socket `IN` and forwards it identically to five separate output plugs (`OUT1` … `OUT5`). The block is implemented as a generic FB (GenericClassName `'GEN_AE_SPLIT'`), thus enabling easy reuse in different contexts.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AE`	A unidirectional adapter event whose content is forwarded to all outputs.
Plug (Output 1)	`OUT1`	`adapter::types::unidirectional::AE`	First output that provides the incoming event.
Plug (Output 2)	`OUT2`	`adapter::types::unidirectional::AE`	Second output providing the incoming event.
Plug (Output 3)	`OUT3`	`adapter::types::unidirectional::AE`	Third output providing the incoming event.
Plug (Output 4)	`OUT4`	`adapter::types::unidirectional::AE`	Fourth output providing the incoming event.
Plug (Output 5)	`OUT5`	`adapter::types::unidirectional::AE`	Fifth output providing the incoming event.

Functionality

The FB **AE_SPLIT_5** is a pure distribution block. As soon as an adapter event arrives at socket `IN`, this event is sent – without delay or data manipulation – in parallel to all five output plugs `OUT1` to `OUT5`. No internal storage or state modification occurs; the function block (FB) is entirely combinatorial.

Technical Features

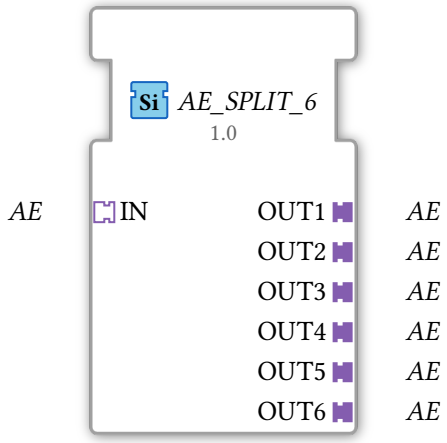
- **Generic Implementation**: The function block is declared as a generic FB (`GenericClassName = 'GEN_AE_SPLIT'`), so it can be used with different adapter types if needed, provided they are of type `adapter::types::unidirectional::AE`.
- **Unidirectionality**: All adapters involved are unidirectional. There is no communication back to the sender.
- **No Additional Logic**: The FB has neither event nor data inputs/outputs. The forwarding is done entirely via adapters.

State Overview

This function block has no defined state machine or sequence control. Its behavior is static: Upon receiving an event at `IN`, all outputs are activated simultaneously. There is no latency or intermediate states.

Application Scenarios

- **Event Distribution in Control Systems**: A sensor event (e.g., "Position Reached") is to be sent to multiple independent control components.
- **Multicast in Modular Architectures**: In a distributed automation environment, a central function block can distribute its event to up to five downstream modules.
- **Prototyping and Test Environments**: For simultaneously testing multiple receivers with the same event.



Comparison with Similar Function Blocks

- **Event Splitter (E_SPLIT)**: These function blocks distribute **events** (event inputs) to multiple event outputs. **AE_SPLIT_5**, on the other hand, distributes **adapter events** (complex data objects that communicate via adapters), thus offering a higher level of abstraction.
- **Data Splitter (F_SPLIT)**: Splits data streams but does not have an adapter interface. **AE_SPLIT_5** focuses on distributing adapter-based event messages.

Conclusion

The **AE_SPLIT_5** is a simple yet effective component for replicating a unidirectional adapter event to five outputs. Due to its generic nature and its pure adapter interface, it is particularly suitable for modular and scalable control applications where information needs to be sent to multiple receivers in parallel.

AE_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_SPLIT_6** distributes an incoming AE adapter (type `adapter::types::unidirectional::AE`) to six identical outputs. It is a generic function block that can be reused for various AE types. The name derives from the 1:6 split: one input is split into six outputs.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Direction	Name	Type	Description
Socket (Input)	IN	`adapter::types::unidirectional::AE`	Incoming AE adapter, whose signal is duplicated to all outputs.
Plug (Output)	OUT1	`adapter::types::unidirectional::AE`	First output, identical copy of the input signal.
Plug (Output)	OUT2	`adapter::types::unidirectional::AE`	Second output, identical copy of the input signal.
Plug (Output)	OUT3	`adapter::types::unidirectional::AE`	Third output, identical copy of the input signal.
Plug (Output)	OUT4	`adapter::types::unidirectional::AE`	Fourth output, identical copy of the input signal.
Plug (Output)	OUT5	`adapter::types::unidirectional::AE`	Fifth output, identical copy of the input signal.
Plug (Output)	OUT6	`adapter::types::unidirectional::AE`	Sixth output, identical copy of the input signal.

Functionality

The function block forwards the adapter signal present at socket **IN** unchanged to all six plugs (**OUT1** … **OUT6**). No logical processing, filtering, or delay takes place – the distribution is passive and instantaneous. Thus, the function block behaves like a pure 1:6 splitter for the unidirectional adapter type `AE`.

Technical Features

- **Generic Block**: The function block (FB) is marked with the attribute `eclipse4diac::core::GenericClassName` as `'GEN_AE_SPLIT'`. This allows it to be used in different projects with different, but structurally identical, AE adapter types – the specific type is only determined at project runtime.
- **Unidirectionality**: All adapters are declared as unidirectional, meaning that data/event transfer only occurs from the input (socket) to the outputs (plugs). Feedback is not provided.
- **No State Logic**: The function block has no internal states, no events, and no data inputs/outputs. It is entirely defined by its adapter interfaces.

State Overview

The FB **AE_SPLIT_6** is a purely combinational function block without a state machine. There are no internal steps, transitions, or actions – distribution is direct and permanent.

Application Scenarios

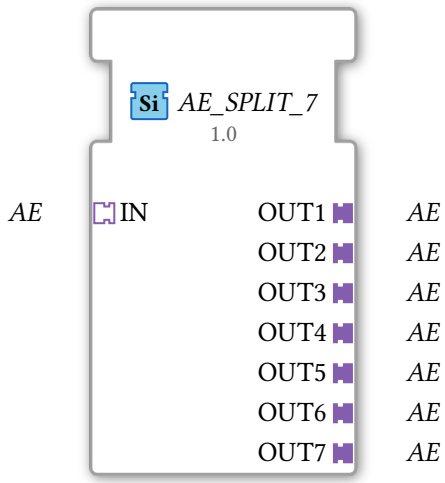
- **Signal Distribution**: Several downstream function blocks should receive the same AE signal, e.g., to start parallel calculations or parallel output.
- **Bus Structure**: In a control architecture where an event must be sent to multiple components (actuators, displays, loggers) without burdening the source.
- **Adapter Networks**: When an AE adapter is provided by a sender and multiple receivers need to access it independently.

Comparison with Similar Function Blocks

- **E_SPLIT Function Blocks**: These split an event signal (e.g., into **E_SPLIT** or **E_F_SPLIT**) across multiple event outputs. The **AE_SPLIT_6**, on the other hand, operates at the adapter level and distributes the entire adapter network, which can contain both events and data – depending on the specific adapter instantiation.
- **AE_SPLIT_2 / AE_SPLIT_4**: Variants with two or four outputs. The **AE_SPLIT_6** offers the maximum number of outputs in this family: six.
- **MUX/DEMUX blocks**: These select or combine signals. The **AE_SPLIT_6**, however, duplicates the signal without selection.

Conclusion

The **AE_SPLIT_6** is a simple yet useful generic function block for the 1:6 distribution of a unidirectional AE adapter. Its generic design allows it to be used in a wide variety of automation and control environments where a signal is required multiple times. It operates without delay and without its own logic, making it particularly efficient and reliable.



AE_SPLIT_6 –

]

AE_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_SPLIT_7** is used to distribute a single incoming adapter event (AE) to seven identical output adapters. It is a generic function block designed for unidirectional adapters of type `adapter::types::unidirectional::AE`. The function block enables star-shaped routing of an event signal to multiple downstream function blocks without modifying or delaying the events.

Interface Structure

Event Inputs
None – communication occurs exclusively via adapters.

Event Outputs
None – output occurs via adapters.

Data Inputs
None.

Data Outputs
None.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AE`	**IN**	Socket	Input adapter that receives the event to be distributed.
`adapter::types::unidirectional::AE`	**OUT1**	Plug	First output adapter; the received event is forwarded here.
`adapter::types::unidirectional::AE`	**OUT2**	Plug	Second output adapter.
`adapter::types::unidirectional::AE`	**OUT3**	Plug	Third output adapter.
`adapter::types::unidirectional::AE`	**OUT4**	Plug	Fourth output adapter.
`adapter::types::unidirectional::AE`	**OUT5**	Plug	Fifth output adapter.
`adapter::types::unidirectional::AE`	**OUT6**	Plug	Sixth output adapter.
`adapter::types::unidirectional::AE`	**OUT7**	Plug	Seventh output adapter.

Functionality
This function block is passive and forwards an incoming event at the input adapter **IN** unchanged to all seven output adapters **OUT1** to **OUT7**. The forwarding occurs simultaneously (logically parallel), meaning that after an event is received, all outputs are supplied with the same event. No buffering, prioritization, or data manipulation takes place. Since these are unidirectional adapters, data flow is only possible in one direction (from the socket to the plug).

Technical Features
- **Generic Function Block:** The function block is declared as a generic type (`GEN_AE_SPLIT`) and can be used in various contexts with the corresponding adapter type. Type checking is performed at design time.
- **No Latency:** The event is passed through without delay; the runtime depends solely on the infrastructure of the IEC 61499 runtime system.
- **Type Identity:** All participating adapters must be of the same type (`AE` – unidirectional). Mixing different adapter types is not permitted.
- **No State Storage:** The function block (FB) has no internal memory – it only performs a one-to-many (1:n) forwarding.

State Overview
Since the FB does not have its own state machine and operates solely reactively to incoming events, there is only one implicit state: **Ready**. In this state, input events are immediately passed to all outputs. There are no error states or start/stop logic.

Application Scenarios
- **Event Distribution in Control Applications:** A single sensor or bus participant triggers an event that should simultaneously reach multiple actuators, alarms, or monitoring blocks.

- **Parallel Processing:** An event should be processed simultaneously in several independent function blocks, e.g., for redundancy or different evaluations.
- **Application Structuring:** Replaces multiple manual connection nodes and improves clarity in the network diagram.

Comparison with Similar Function Blocks

- **AE_SPLIT_2, AE_SPLIT_3, ... :** These function blocks offer the same functionality but with fewer outputs. The choice depends on the required number.
- **E_SPLIT (Event Splitter, Dataless):** A pure event splitter (without adapter encapsulation) distributes events but cannot handle adapter interfaces. The AE_SPLIT_7 is specifically designed for use with adapter types such as `AE`.
- **Adapter Merger (e.g., AE_MERGE):** Combines multiple adapter events into one – the opposite of this function block.

Conclusion

The **AE_SPLIT_7** is a simple yet useful function block for duplicating adapter events in IEC 61499 applications. Its generic nature, full event fidelity, and ease of use make it a fundamental tool for structured event distribution. It is ideally suited when an event needs to be forwarded to multiple similar target adapters and no data content is being transferred.

AE_SPLIT_8

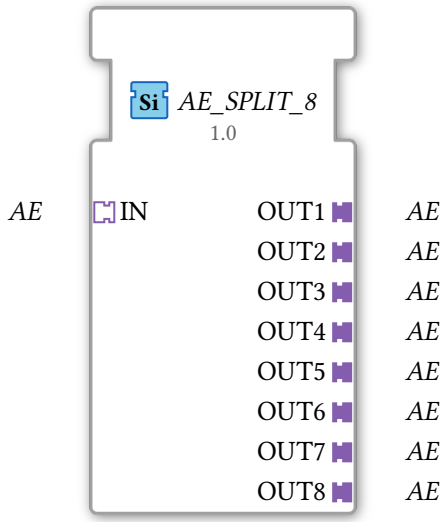

Image of the function block: [Insert here if available]

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AE_SPLIT_8** serves as a generic distributor for one unidirectional adapter input (AE) to eight identical adapter outputs. It allows the multiple use of an incoming signal without modifying it.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AE`	Incoming unidirectional AE adapter
Plug	`OUT1`	`adapter::types::unidirectional::AE`	First outgoing AE adapter
Plug	`OUT2`	`adapter::types::unidirectional::AE`	Second outgoing AE adapter
Plug	`OUT3`	`adapter::types::unidirectional::AE`	Third Outgoing AE Adapter
Plug	`OUT4`	`adapter::types::unidirectional::AE`	Fourth Outgoing AE Adapter
Plug	`OUT5`	`adapter::types::unidirectional::AE`	Fifth Outgoing AE Adapter
Plug	`OUT6`	`adapter::types::unidirectional::AE`	Sixth Outgoing AE Adapter
Plug	`OUT7`	`adapter::types::unidirectional::AE`	Seventh Outgoing AE Adapter
Plug	`OUT8`	`adapter::types::unidirectional::AE`	Eighth Outgoing AE Adapter

Functionality

This function block forwards the adapter signal present at socket `IN` to all eight plugs (`OUT1` to `OUT8`) without delay or modification. No logical or timing processing takes place – the incoming adapter is duplicated one-to-one.

Technical Features

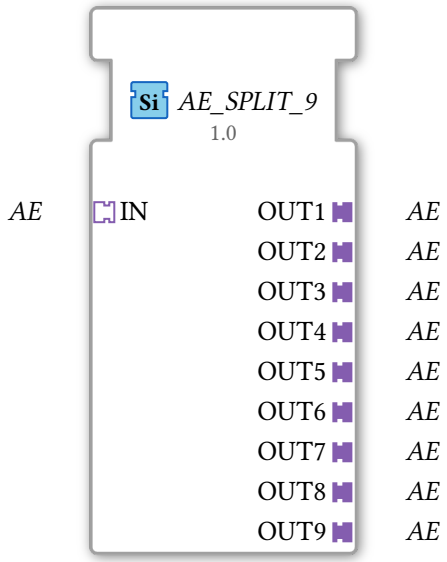
- **Generic Type**: The function block is defined as a generic function block (`GenericClassName: GEN_AE_SPLIT`) and can be reused in various contexts.
- **Unidirectionality**: Both the input and output adapters are unidirectional. Feedback from the outputs to the input is not possible.
- **No Event Control**: The function block has no event inputs and operates purely passively. Forwarding occurs immediately upon connection establishment.
- **Scalability**: With a fixed number of eight outputs, the function block is optimized for applications requiring a precise 1:8 distribution.

State Overview

The function block has no internal states or sequence control. There is no ECC (Execution Control Chart) – functionality is purely combinatorial.

Application Scenarios

- **Signal Distribution in Control Networks**: An AE adapter signal from a sensor or a higher-level controller is to be simultaneously passed on to several downstream function blocks.
- **Test and Simulation Environments**: Multiple receivers are to receive the same adapter signal to observe parallel responses.
- **Redundant Connection**: The same signal can be processed in parallel on multiple paths, for example, for safety or monitoring functions.



Comparison with Similar Function Blocks

- **AE_SPLIT_2/AE_SPLIT_4**: Function blocks with a smaller number of outputs (2 or 4, respectively) for smaller distributions. **AE_SPLIT_8** extends this to eight outputs.
- **Data Splitters (e.g., SPLIT_INT, SPLIT_BOOL)**: These distribute data values, while **AE_SPLIT_8** distributes adapter signals. Adapters can bundle complex composite interfaces (events and data).
- **Event Splitters (e.g., E_SPLIT)**: Distribute only events. **AE_SPLIT_8** transmits the entire adapter context, including all data and event connections it contains.

Conclusion

The **AE_SPLIT_8** is a simple and efficient function block for 1:8 distribution of unidirectional adapter signals. Due to its generic nature and the absence of event control, it is particularly suitable for applications where a signal needs to be forwarded to multiple receivers in parallel without delay.

AE_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The AE_SPLIT_9 function block is used to split an incoming unidirectional adapter event (AE) into nine identical outputs. It is implemented as a generic function block and allows events to be distributed to multiple downstream function blocks.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

- **IN** (Socket): Unidirectional AE adapter (input)
- **OUT1 ... OUT9** (Plugs): Unidirectional AE adapters (outputs)

Functionality

The function block receives an adapter event via the “IN” socket. Each incoming event is duplicated to all nine plug outputs (OUT1 to OUT9) without delay or further logic. Thus, the function block behaves like a 1:9 splitter for AE signals.

Technical Features

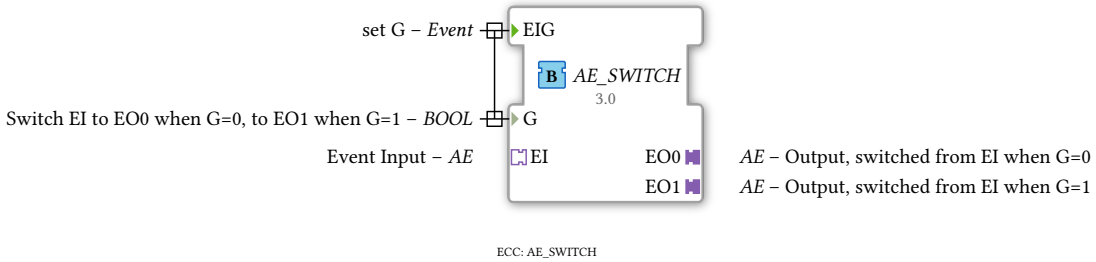
- The function block is implemented as a generic function block (GenericClassName = ‘GEN_AE_SPLIT’), which allows for flexible reuse in different contexts.
- No data is processed; only the adapter interface is passed through.
- The outputs are independent of each other; a fault on one output does not affect the others.

State Overview

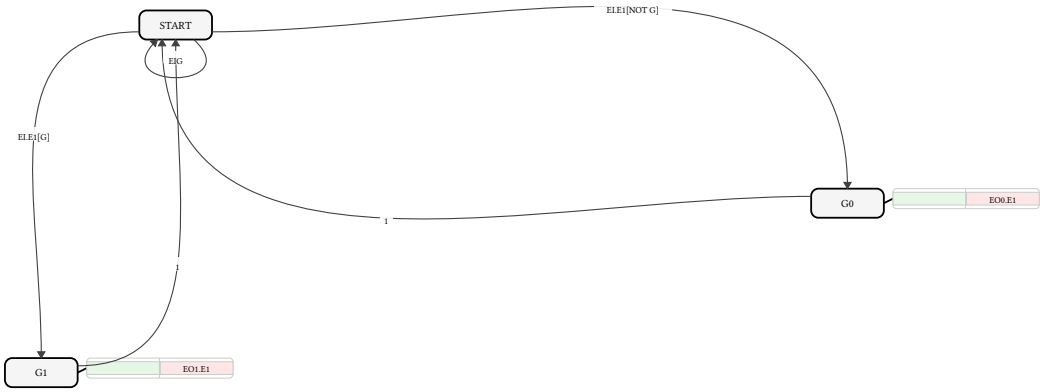
The function block has no internal state. It operates purely combinatorially: An event at the input immediately triggers events at all outputs.

Application Scenarios

- Distribution of a sensor event to multiple control logics.
- Broadcast of an alarm to various monitoring units.
- Splitting a trigger signal for parallel processing paths.



Comparison with Similar Function Blocks



- AE_SPLIT_2, AE_SPLIT_4: same functionality with fewer outputs.
- Unlike data splitters (e.g., SPLIT_INT), this function block only replicates events (without data).

Conclusion

AE_SPLIT_9 is a simple yet useful function block for event distribution in IEC 61499 systems. Its generic nature and clear 1:9 split make it ideal for applications requiring a wide distribution of adapter events.

AE_SWITCH

• – ○ • – ○ • – ○ •

Introduction

The **AE_SWITCH** function block acts as an event demultiplexer. It forwards an incoming event to one of two unidirectional event adapter outputs, depending on the value of a Boolean input `G`.

Interface Structure

Event Inputs

- **EIG** (Event): Sets the value of `G`. When this event is triggered, the corresponding data input `G` is used – no forwarding to the outputs occurs.

Event Outputs

- No independent event outputs are available. Output is exclusively via the adapters `EO0` and `EO1`.

Data Inputs

Name	Type	Comment
`G`	BOOL	Switch: 0 ⟶ Output via `EO0`, 1 ⟶ Output via `EO1`

Data Outputs

- No data outputs.

Adapters

Direction	Name	Type (unidirectional)	Comment
Socket (Input)	`EI`	`adapter::types::unidirectional::AE`	Event input that is switched.
Plug (Output)	`EO0`	`adapter::types::unidirectional::AE`	Event output, active at `G = 0`
Plug (Output)	`EO1`	`adapter::types::unidirectional::AE`	Event output, active at `G = 1`

Functionality

The function block is initially in the **START** state.

1. **Setting the Switch**: An event at `EIG` inherits the current value from `G`. The block then remains in the **START** state.
2. **Forwarding the Input Event**: If an event arrives via the adapter input `EI`, the value of `G` is evaluated:

- If `G = 0` ⟶ state change to **G0**: The adapter output `EO0` is triggered with its event `E1`.
- If `G = 1` ⟶ State change to **G1**: The adapter output `EO1` is triggered by its event `E1`.

1. After the respective output is triggered, the function block automatically returns to the **START** state.

Technical Features

- Event forwarding occurs exclusively via **unidirectional adapters** of type `AE`. This ensures a clean separation of event sources and sinks.
- The function block implements **demultiplexing** (1-to-2) at the event level: An incoming event is routed to one of two outputs depending on a Boolean condition.
- The set input `EIG` allows the switching value to be changed independently of any pending event at input `EI`.

State Overview

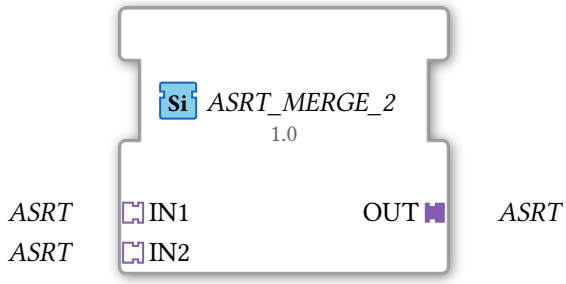
State	Description	Action on Entry
START	Wait for an event at `EI` or `EIG`	–
G0	Event at `EI` with `G = 0` – forward to `EO0`	`EO0.E1`
G1	Event at `EI` with `G = 1` – forward to `EO1`	`EO1.E1`

Transitions:

- START ⟶ G0 : `EI.E1[NOT G]`
- START ⟶ G1 : `EI.E1[G]`
- G0 ⟶ START : `1` (immediate)
- G1 ⟶ START : `1` (immediate)
- START ⟶ START : `EIG` (only sets G, no forwarding)

Application Scenarios

- **Event Routing** in automation systems, where a central trigger (e.g., a sensor event) controls different actuators depending on the operating mode.
- **State-Dependent Processing**: An incoming event should only be processed in a specific operating mode; the other operating mode receives a separate event.
- **Test and Diagnostic Tasks**: Switching between normal operation and test mode by setting `G`.



Comparison with Similar Function Blocks

- **E_SWITCH** (Standard 61499): Similar functionality, but via regular event outputs. `AE_SWITCH` uses adapters, which allows for better encapsulation and reusability in components with standardized interfaces.
- **E_MUX** (Multiplexer): Combines multiple events into one output – in the opposite direction. `AE_SWITCH` demultiplexes an input event to two outputs.

Conclusion

The `AE_SWITCH` offers a lean, adapter-based solution for conditional event forwarding. Its use of unidirectional adapters makes it ideal for modular and type-safe IEC 61499 applications. Its simple state machine makes it efficient and easy to understand.

ASRT_MERGE_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_MERGE_2** merges two unidirectional ASRT adapters (a set/reset/toggle event triple, no payload data) into one common output adapter. `ASRT` extends `ASR` with a third event `TOGGLE` (see `AX_T_FF_SR`). The block is the reverse of ASRT_SPLIT_2 and is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_MERGE'`).

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::ASRT`	First SET/RESET/TOGGLE source.

Socket (Input 2)	IN2	adapter::types::unidirectional::ASRT	Second SET/RESET/TOGGLE source.
Plug (Output)	OUT	adapter::types::unidirectional::ASRT	Merged SET/RESET/TOGGLE signal.

Functionality

Whenever a SET, RESET, or TOGGLE event arrives at IN1 **or** IN2, it is forwarded to OUT as the matching event type. All three event types are handled independently – which event arrives on which socket has no effect on the other two event types or on the other socket. Since ASRT carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

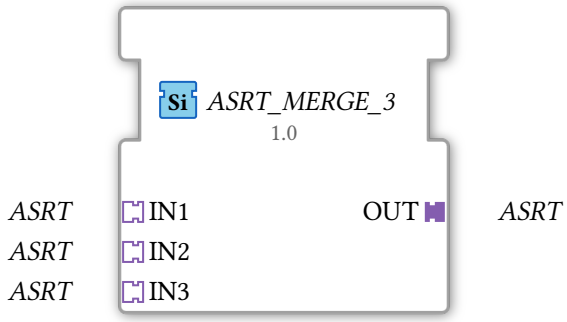
- **Generic type**: Implemented via the generic base class CGenUnidirectMergeBase (N sockets, 1 plug) – the same C++ base underlying GEN_AE_MERGE and GEN_ASR_MERGE.
- **Three independent event channels**: SET, RESET, and TOGGLE are checked and forwarded separately.
- **No states / algorithms**: Since ASRT carries no data value, there is no change detection and no ECC.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming SET, RESET, or TOGGLE event at IN1 or IN2 is forwarded to OUT immediately as the matching event type.

Application Scenarios

- **Merging redundant set/reset/toggle sources**: e.g. two operator stations that should both drive the same AX_T_FF_SR-controlled element via a common ASRT adapter.
- **Simplifying networks** that would otherwise need three separate event connection pairs (SET, RESET, TOGGLE) per source to the same destination.



Comparison with Similar Components

- ASRT_SPLIT_2: the reverse direction – distributes one incoming set/reset/toggle signal to two outputs, instead of merging two inputs.
- ASR_MERGE_2: the same merge logic for the set/reset event adapter ASR (no TOGGLE).
- AE_MERGE_2: the same merge logic for the pure event adapter AE (1 event instead of SET/RESET/TOGGLE).

Conclusion

ASRT_MERGE_2 is a minimal generic function block for merging two set/reset/toggle event sources into a common ASRT adapter output, completing the GEN_*_MERGE family for all three unidirectional event adapters (AE, ASR, ASRT).

ASRT_MERGE_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_MERGE_3** merges 3 unidirectional ASRT adapters (set/reset/toggle event adapter, no payload data) into one common output adapter. It is the 3-input variant of ASRT_MERGE_2

and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 3 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::ASRT`	Source 1.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::ASRT`	Source 2.
Socket (Input 3)	`IN3`	`adapter::types::unidirectional::ASRT`	Source 3.
Plug (Output)	`OUT`	`adapter::types::unidirectional::ASRT`	Merged signal.

Functionality

Whenever `SET` or `RESET` or `TOGGLE` arrives at any of the 3 sockets (`IN1`, `IN2`, `IN3`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 3 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN3`, which only matters if several events arrive within the same execution cycle. Since `ASRT` carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

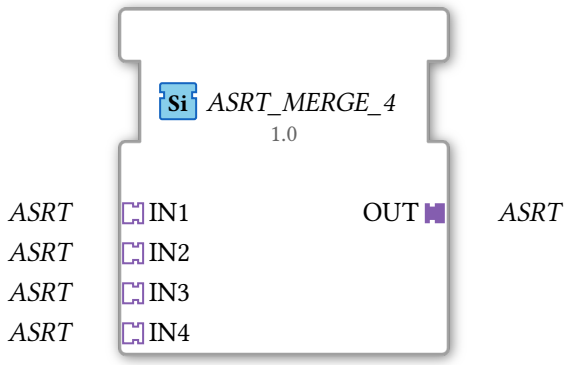
- **Generic type**: Implemented via the generic base class `CGenUnidirectMergeBase` (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (`_3`).
- **No states / algorithms**: Since `ASRT` carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASRT_MERGE_2 through ASRT_MERGE_7; for other input counts see `ASRT_MERGE_2`, `ASRT_MERGE_4`, `ASRT_MERGE_5`, `ASRT_MERGE_6`, `ASRT_MERGE_7`.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 3 sockets is forwarded to `OUT` immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 3 redundant or alternative trigger paths) into a common ASRT adapter output.
- **Simplifying networks** that would otherwise need 3 separate event connections to the same destination.



Comparison with Similar Components

- ASRT_SPLIT_2: the reverse direction for 2 outputs (for ASRT, ASRT_SPLIT_3 through ASRT_SPLIT_9 are also available).
- **`ASRT_MERGE_2`, `ASRT_MERGE_4`, `ASRT_MERGE_5`, `ASRT_MERGE_6`, `ASRT_MERGE_7`**: the same generic implementation with a different input count.
- AE_MERGE_3, ASR_MERGE_3: the same merge logic for the other unidirectional event adapters.

Conclusion

`ASRT_MERGE_3` provides a generically implemented merge of 3 `ASRT` event sources into a common adapter output, completing the `GEN_ASRT_MERGE` family with the 3-input variant.

ASRT_MERGE_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_MERGE_4** merges 4 unidirectional ASRT adapters (set/reset/toggle event adapter, no payload data) into one common output adapter. It is the 4-input variant of ASRT_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 4 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::ASRT`	Source 1.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::ASRT`	Source 2.
Socket (Input 3)	`IN3`	`adapter::types::unidirectional::ASRT`	Source 3.
Socket (Input 4)	`IN4`	`adapter::types::unidirectional::ASRT`	Source 4.
Plug (Output)	`OUT`	`adapter::types::unidirectional::ASRT`	Merged signal.

Functionality

Whenever `SET` or `RESET` or `TOGGLE` arrives at any of the 4 sockets (`IN1`, `IN2`, `IN3`, `IN4`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 4 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN4`, which only matters if several events arrive within the same execution cycle. Since `ASRT` carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

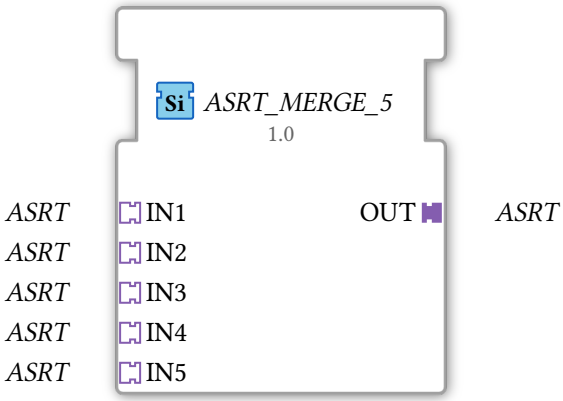
- **Generic type**: Implemented via the generic base class `CGenUnidirectMergeBase` (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_4).
- **No states / algorithms**: Since `ASRT` carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASRT_MERGE_2 through ASRT_MERGE_7; for other input counts see `ASRT_MERGE_2`, `ASRT_MERGE_3`, `ASRT_MERGE_5`, `ASRT_MERGE_6`, `ASRT_MERGE_7`.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 4 sockets is forwarded to `OUT` immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 4 redundant or alternative trigger paths) into a common ASRT adapter output.
- **Simplifying networks** that would otherwise need 4 separate event connections to the same destination.



Comparison with Similar Components

- **ASRT_SPLIT_2**: the reverse direction for 2 outputs (for ASRT, ASRT_SPLIT_3 through ASRT_SPLIT_9 are also available).
- **`ASRT_MERGE_2`, `ASRT_MERGE_3`, `ASRT_MERGE_5`, `ASRT_MERGE_6`, `ASRT_MERGE_7`**: the same generic implementation with a different input count.
- AE_MERGE_4, ASR_MERGE_4: the same merge logic for the other unidirectional event adapters.

Conclusion

`ASRT_MERGE_4` provides a generically implemented merge of 4 `ASRT` event sources into a common adapter output, completing the `GEN_ASRT_MERGE` family with the 4-input variant.

ASRT_MERGE_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_MERGE_5** merges 5 unidirectional ASRT adapters (set/reset/toggle event adapter, no payload data) into one common output adapter. It is the 5-input variant of ASRT_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 5 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	IN1	adapter::types::unidirectional::ASRT	Source 1.
Socket (Input 2)	IN2	adapter::types::unidirectional::ASRT	Source 2.
Socket (Input 3)	IN3	adapter::types::unidirectional::ASRT	Source 3.
Socket (Input 4)	IN4	adapter::types::unidirectional::ASRT	Source 4.
Socket (Input 5)	IN5	adapter::types::unidirectional::ASRT	Source 5.
Plug (Output)	OUT	adapter::types::unidirectional::ASRT	Merged signal.

Functionality

Whenever SET or RESET or TOGGLE arrives at any of the 5 sockets (IN1, IN2, IN3, IN4, IN5), it is forwarded unchanged to OUT as the matching event type. All event types are handled independently, and all 5 sockets are treated equally — the order in which sockets are checked follows IN1 … IN5, which only matters if several events arrive within the same execution cycle. Since ASRT carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

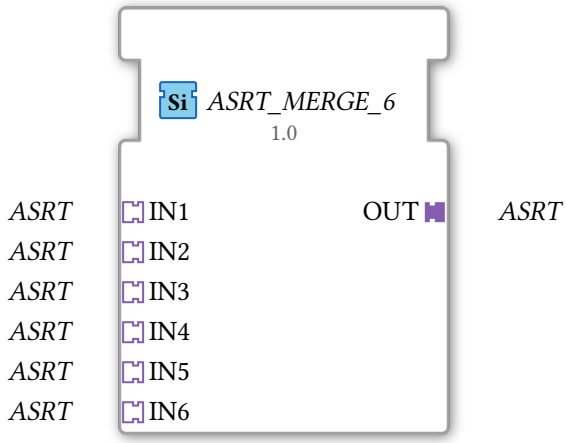
- **Generic type**: Implemented via the generic base class CGenUnidirectMergeBase (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_5).
- **No states / algorithms**: Since ASRT carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASRT_MERGE_2 through ASRT_MERGE_7; for other input counts see ASRT_MERGE_2, ASRT_MERGE_3, ASRT_MERGE_4, ASRT_MERGE_6, ASRT_MERGE_7.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 5 sockets is forwarded to OUT immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 5 redundant or alternative trigger paths) into a common ASRT adapter output.
- **Simplifying networks** that would otherwise need 5 separate event connections to the same destination.



Comparison with Similar Components

- **ASRT_SPLIT_2**: the reverse direction for 2 outputs (for ASRT, ASRT_SPLIT_3 through ASRT_SPLIT_9 are also available).
- **ASRT_MERGE_2, ASRT_MERGE_3, ASRT_MERGE_4, ASRT_MERGE_6, ASRT_MERGE_7**: the same generic implementation with a different input count.
- AE_MERGE_5, ASR_MERGE_5: the same merge logic for the other unidirectional event adapters.

Conclusion

ASRT_MERGE_5 provides a generically implemented merge of 5 ASRT event sources into a common adapter output, completing the GEN_ASRT_MERGE family with the 5-input variant.

ASRT_MERGE_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_MERGE_6** merges 6 unidirectional ASRT adapters (set/reset/toggle event adapter, no payload data) into one common output adapter. It is the 6-input variant of ASRT_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 6 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Socket (Input 6)	`IN6`	`adapter::types::unidirectional::ASRT`	Source 6.
Plug (Output)	`OUT`	`adapter::types::unidirectional::ASRT`	Merged signal.

Functionality

Whenever `SET` or `RESET` or `TOGGLE` arrives at any of the 6 sockets (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 6 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN6`, which only

matters if several events arrive within the same execution cycle. Since ASRT carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

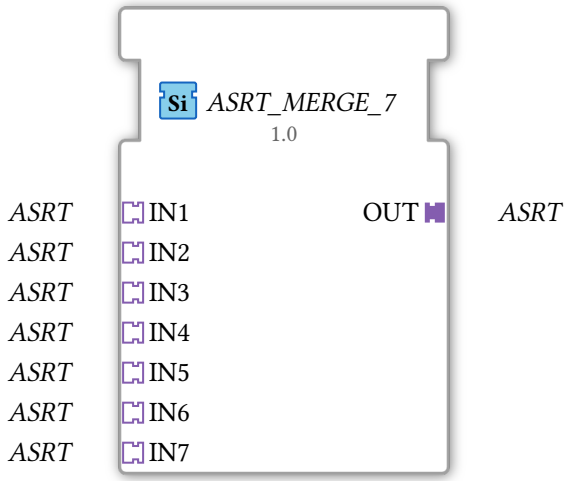
- **Generic type**: Implemented via the generic base class CGenUnidirectMergeBase (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_6).
- **No states / algorithms**: Since ASRT carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASRT_MERGE_2 through ASRT_MERGE_7; for other input counts see ASRT_MERGE_2, ASRT_MERGE_3, ASRT_MERGE_4, ASRT_MERGE_5, ASRT_MERGE_7.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 6 sockets is forwarded to OUT immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 6 redundant or alternative trigger paths) into a common ASRT adapter output.
- **Simplifying networks** that would otherwise need 6 separate event connections to the same destination.



Comparison with Similar Components

- ASRT_SPLIT_2: the reverse direction for 2 outputs (for ASRT, ASRT_SPLIT_3 through ASRT_SPLIT_9 are also available).
- **ASRT_MERGE_2, ASRT_MERGE_3, ASRT_MERGE_4, ASRT_MERGE_5, ASRT_MERGE_7**: the same generic implementation with a different input count.
- AE_MERGE_6, ASR_MERGE_6: the same merge logic for the other unidirectional event adapters.

Conclusion

ASRT_MERGE_6 provides a generically implemented merge of 6 ASRT event sources into a common adapter output, completing the GEN_ASRT_MERGE family with the 6-input variant.

ASRT_MERGE_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_MERGE_7** merges 7 unidirectional ASRT adapters (set/reset/toggle event adapter, no payload data) into one common output adapter. It is the 7-input variant of ASRT_MERGE_2 and, like it, is implemented as a generic FB (GenericClassName: 'GEN_ASRT_MERGE') — the same C++ base (CGenUnidirectMergeBase), just with 7 instead of 2 sockets.

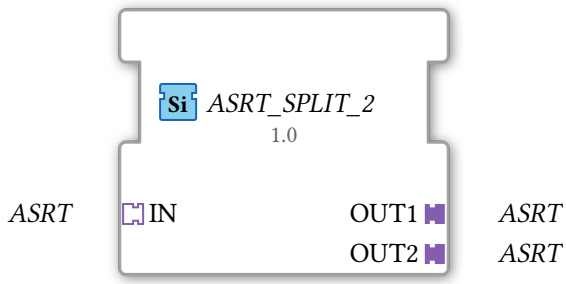
Socket (Input 7)	`IN7`	`adapter::types::unidirectional::ASRT`	Source 7.
Plug (Output)	`OUT`	`adapter::types::unidirectional::ASRT`	Merged signal.

Functionality
Whenever `SET` or `RESET` or `TOGGLE` arrives at any of the 7 sockets (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`, `IN6`, `IN7`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 7 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN7`, which only matters if several events arrive within the same execution cycle. Since `ASRT` carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features
- **Generic type**: Implemented via the generic base class `CGenUnidirectMergeBase` (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (`_7`).
- **No states / algorithms**: Since `ASRT` carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASRT_MERGE_2 through ASRT_MERGE_7; for other input counts see `ASRT_MERGE_2`, `ASRT_MERGE_3`, `ASRT_MERGE_4`, `ASRT_MERGE_5`, `ASRT_MERGE_6`.

State Overview
The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 7 sockets is forwarded to `OUT` immediately.

Application Scenarios
- **Merging several equivalent signal sources** (e.g. 7 redundant or alternative trigger paths) into a common ASRT adapter output.
- **Simplifying networks** that would otherwise need 7 separate event connections to the same destination.



Comparison with Similar Components
- ASRT_SPLIT_2: the reverse direction for 2 outputs (for ASRT, ASRT_SPLIT_3 through ASRT_SPLIT_9 are also available).

- **ASRT_MERGE_2, ASRT_MERGE_3, ASRT_MERGE_4, ASRT_MERGE_5, ASRT_MERGE_6**: the same generic implementation with a different input count.
- AE_MERGE_7, ASR_MERGE_7: the same merge logic for the other unidirectional event adapters.

Conclusion

ASRT_MERGE_7 provides a generically implemented merge of 7 ASRT event sources into a common adapter output, completing the GEN_ASRT_MERGE family with the 7-input variant.

ASRT_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_SPLIT_2** distributes an incoming unidirectional ASRT adapter (a set/reset/toggle event triple, no payload data) to two identical output adapters. ASRT extends ASR with a third event TOGGLE (see AX_T_FF_SR). It is implemented as a generic FB (GenericClassName: 'GEN_ASRT_SPLIT') and completes the SPLIT family alongside AE_SPLIT_2 and ASR_SPLIT_2.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter socket.

Event Outputs

None. Events are forwarded exclusively via the adapter plugs.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input)	IN	adapter::types::unidirectional::ASRT	Receives a SET, RESET, or TOGGLE event, which is distributed to both outputs.
Plug (Output 1)	OUT1	adapter::types::unidirectional::ASRT	First output for the duplicated event.
Plug (Output 2)	OUT2	adapter::types::unidirectional::ASRT	Second output for the duplicated event.

Functionality

As soon as a SET, RESET, or TOGGLE event arrives at adapter socket IN, it is forwarded **immediately and in parallel** as a matching event to both output plugs OUT1 and OUT2. The block performs no logic, filtering, or delay – it acts as a pure splitter at the adapter level, regardless of which of the three event types arrives.

Technical Features

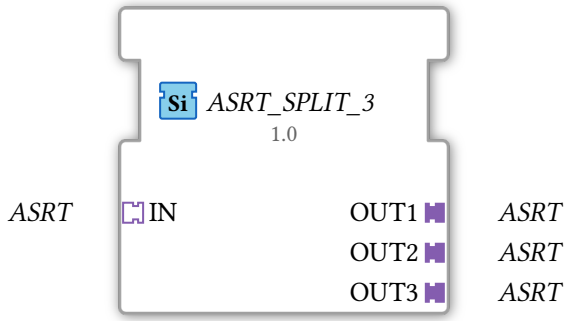
- **Generic type**: Implemented via the generic base class `CGenUnidirectSplitBase` (1 socket, N plugs) – the same C++ base underlying `GEN_AE_SPLIT` and `GEN_ASR_SPLIT`.
- **Three independent event channels**: `SET`, `RESET`, and `TOGGLE` are checked separately and each distributed to both outputs.
- **No states / algorithms**: Since `ASRT` carries no data value, there is no change detection and no ECC.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming `SET`, `RESET`, or `TOGGLE` event at socket `IN` is duplicated to both outputs immediately.

Application Scenarios

- **Event distribution**: A set/reset/toggle signal (e.g. driven by `AX_T_FF_SR`) needs to be processed by two independent subsystems.
- **Parallel wiring**: Splitting an ASRT signal to simultaneously drive two actuators.



Comparison with Similar Components

- ASRT_MERGE_2: the reverse direction – merges two incoming set/reset/toggle signals into one common output, instead of distributing one signal.
- ASR_SPLIT_2: the same distribution logic for the set/reset event adapter `ASR` (no `TOGGLE`).
- AE_SPLIT_2: the same distribution logic for the pure event adapter `AE` (1 event instead of SET/RESET/TOGGLE).

Conclusion

ASRT_SPLIT_2 is a minimal generic function block for distributing a set/reset/toggle event to two ASRT adapter outputs, closing the last remaining gap in the `GEN_*_SPLIT` family for all three unidirectional event adapters (`AE`, `ASR`, `ASRT`).

ASRT_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_SPLIT_3** distributes an incoming unidirectional ASRT adapter (set/reset/toggle event adapter, no payload data) to 3 identical output adapters. It is the 3-output variant of ASRT_SPLIT_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_SPLIT'`) — the same C++ base (`CGenUnidirectSplitBase`), just with 3 instead of 2 plugs.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter socket.

Event Outputs

None. Events are forwarded exclusively via the adapter plugs.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input)	IN	adapter::types::unidirectional::ASRT	Receives SET or RESET or TOGGLE, distributed to all 3 outputs.
Plug (Output 1)	OUT1	adapter::types::unidirectional::ASRT	Output 1 for the duplicated event.
Plug (Output 2)	OUT2	adapter::types::unidirectional::ASRT	Output 2 for the duplicated event.
Plug (Output 3)	OUT3	adapter::types::unidirectional::ASRT	Output 3 for the duplicated event.

Functionality

As soon as SET or RESET or TOGGLE arrives at adapter socket IN, it is forwarded **immediately and in parallel** as a matching event to all 3 output plugs (OUT1, OUT2, OUT3). The block performs no logic, filtering, or delay – it acts as a pure splitter at the adapter level.

Technical Features

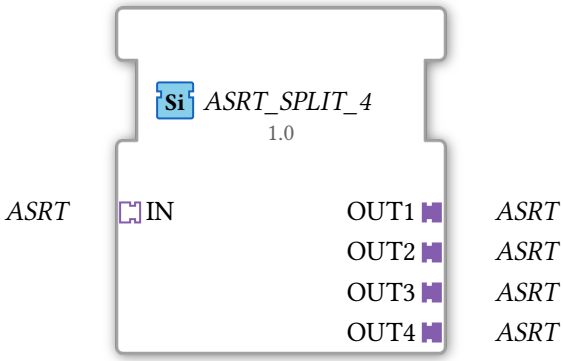
- **Generic type**: Implemented via the generic base class CGenUnidirectSplitBase (1 socket, N plugs); the number of output plugs is fixed at compile time via the generic suffix (_3).
- **No states / algorithms**: Since ASRT carries no data value, there is no change detection and no ECC.
- **Arbitrary output count**: The same implementation covers ASRT_SPLIT_2 through ASRT_SPLIT_9; for other output counts see ASRT_SPLIT_2, ASRT_SPLIT_4, ASRT_SPLIT_5, ASRT_SPLIT_6, ASRT_SPLIT_7, ASRT_SPLIT_8, ASRT_SPLIT_9.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at socket IN is duplicated to all 3 outputs immediately.

Application Scenarios

- **Event distribution**: A signal needs to be processed by 3 independent subsystems.
- **Parallel wiring**: Splitting a ASRT signal to simultaneously drive several actuators.



Comparison with Similar Components

- ASRT_MERGE_2: the reverse direction for 2 inputs (for ASRT, ASRT_MERGE_3 through ASRT_MERGE_7 are also available).
- **ASRT_SPLIT_2, ASRT_SPLIT_4, ASRT_SPLIT_5, ASRT_SPLIT_6, ASRT_SPLIT_7, ASRT_SPLIT_8, ASRT_SPLIT_9**: the same generic implementation with a different output count.

Conclusion

ASRT_SPLIT_3 provides a generically implemented distribution of a ASRT event to 3 adapter outputs, completing the GEN_ASRT_SPLIT family with the 3-output variant.

ASRT_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_SPLIT_4** distributes an incoming unidirectional ASRT adapter (set/reset/toggle event adapter, no payload data) to 4 identical output adapters. It is the 4-output variant of ASRT_SPLIT_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_SPLIT'`) — the same C++ base (`CGenUnidirectSplitBase`), just with 4 instead of 2 plugs.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter socket.

Event Outputs

None. Events are forwarded exclusively via the adapter plugs.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::ASRT`	Receives `SET` or `RESET` or `TOGGLE`, distributed to all 4 outputs.
Plug (Output 1)	`OUT1`	`adapter::types::unidirectional::ASRT`	Output 1 for the duplicated event.
Plug (Output 2)	`OUT2`	`adapter::types::unidirectional::ASRT`	Output 2 for the duplicated event.
Plug (Output 3)	`OUT3`	`adapter::types::unidirectional::ASRT`	Output 3 for the duplicated event.
Plug (Output 4)	`OUT4`	`adapter::types::unidirectional::ASRT`	Output 4 for the duplicated event.

Functionality

As soon as `SET` or `RESET` or `TOGGLE` arrives at adapter socket `IN`, it is forwarded **immediately and in parallel** as a matching event to all 4 output plugs (`OUT1`, `OUT2`, `OUT3`, `OUT4`). The block performs no logic, filtering, or delay – it acts as a pure splitter at the adapter level.

Technical Features

- **Generic type**: Implemented via the generic base class `CGenUnidirectSplitBase` (1 socket, N plugs); the number of output plugs is fixed at compile time via the generic suffix (_4).
- **No states / algorithms**: Since `ASRT` carries no data value, there is no change detection and no ECC.
- **Arbitrary output count**: The same implementation covers ASRT_SPLIT_2 through ASRT_SPLIT_9; for other output counts see `ASRT_SPLIT_2`, `ASRT_SPLIT_3`, `ASRT_SPLIT_5`, `ASRT_SPLIT_6`, `ASRT_SPLIT_7`, `ASRT_SPLIT_8`, `ASRT_SPLIT_9`.

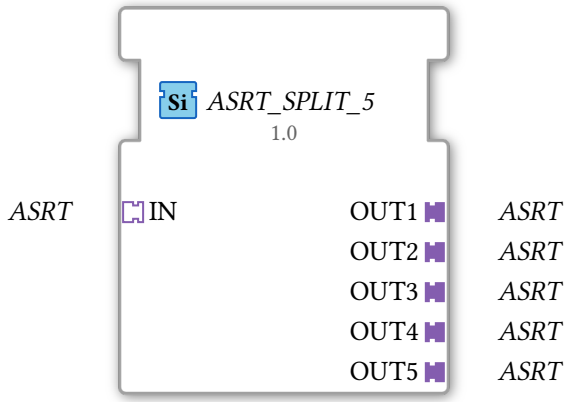
State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at socket `IN` is duplicated to all 4 outputs immediately.

Application Scenarios

- **Event distribution**: A signal needs to be processed by 4 independent subsystems.
- **Parallel wiring**: Splitting a ASRT signal to simultaneously drive several actuators.

Comparison with Similar Components



- **ASRT_MERGE_2**: the reverse direction for 2 inputs (for ASRT, ASRT_MERGE_3 through ASRT_MERGE_7 are also available).

- **ASRT_SPLIT_2, ASRT_SPLIT_3, ASRT_SPLIT_5, ASRT_SPLIT_6, ASRT_SPLIT_7, ASRT_SPLIT_8, ASRT_SPLIT_9**: the same generic implementation with a different output count.

Conclusion

`ASRT_SPLIT_4` provides a generically implemented distribution of a `ASRT` event to 4 adapter outputs, completing the `GEN_ASRT_SPLIT` family with the 4-output variant.

ASRT_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_SPLIT_5** distributes an incoming unidirectional ASRT adapter (set/reset/toggle event adapter, no payload data) to 5 identical output adapters. It is the 5-output variant of ASRT_SPLIT_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_SPLIT'`) — the same C++ base (`CGenUnidirectSplitBase`), just with 5 instead of 2 plugs.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter socket.

Event Outputs

None. Events are forwarded exclusively via the adapter plugs.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::ASRT`	Receives `SET` or `RESET` or `TOGGLE`, distributed to all 5 outputs.
Plug (Output 1)	`OUT1`	`adapter::types::unidirectional::ASRT`	Output 1 for the duplicated event.
Plug (Output 2)	`OUT2`	`adapter::types::unidirectional::ASRT`	Output 2 for the duplicated event.
Plug (Output 3)	`OUT3`	`adapter::types::unidirectional::ASRT`	Output 3 for the duplicated event.
Plug (Output 4)	`OUT4`	`adapter::types::unidirectional::ASRT`	Output 4 for the duplicated event.
Plug (Output 5)	`OUT5`	`adapter::types::unidirectional::ASRT`	Output 5 for the duplicated event.

Functionality

As soon as `SET` or `RESET` or `TOGGLE` arrives at adapter socket `IN`, it is forwarded **immediately and in parallel** as a matching event to all 5 output plugs (`OUT1`, `OUT2`, `OUT3`, `OUT4`, `OUT5`). The block performs no logic, filtering, or delay – it acts as a pure splitter at the adapter level.

Technical Features

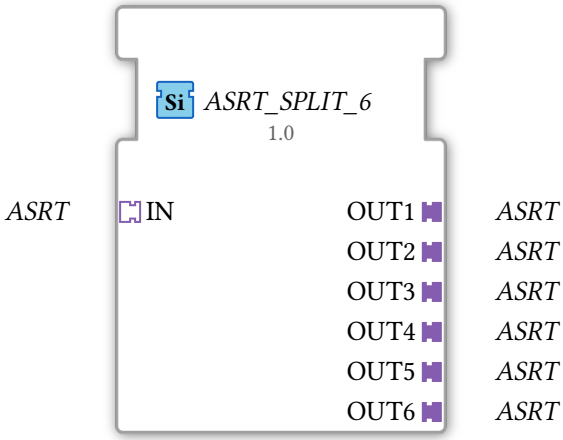
- **Generic type**: Implemented via the generic base class `CGenUnidirectSplitBase` (1 socket, N plugs); the number of output plugs is fixed at compile time via the generic suffix (`_5`).
- **No states / algorithms**: Since `ASRT` carries no data value, there is no change detection and no ECC.
- **Arbitrary output count**: The same implementation covers ASRT_SPLIT_2 through ASRT_SPLIT_9; for other output counts see `ASRT_SPLIT_2`, `ASRT_SPLIT_3`, `ASRT_SPLIT_4`, `ASRT_SPLIT_6`, `ASRT_SPLIT_7`, `ASRT_SPLIT_8`, `ASRT_SPLIT_9`.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at socket `IN` is duplicated to all 5 outputs immediately.

Application Scenarios

- **Event distribution**: A signal needs to be processed by 5 independent subsystems.
- **Parallel wiring**: Splitting a ASRT signal to simultaneously drive several actuators.



Comparison with Similar Components

- ASRT_MERGE_2: the reverse direction for 2 inputs (for ASRT, ASRT_MERGE_3 through ASRT_MERGE_7 are also available).
- **`ASRT_SPLIT_2`, `ASRT_SPLIT_3`, `ASRT_SPLIT_4`, `ASRT_SPLIT_6`, `ASRT_SPLIT_7`, `ASRT_SPLIT_8`, `ASRT_SPLIT_9`**: the same generic implementation with a different output count.

Conclusion

`ASRT_SPLIT_5` provides a generically implemented distribution of a `ASRT` event to 5 adapter outputs, completing the `GEN_ASRT_SPLIT` family with the 5-output variant.

ASRT_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_SPLIT_6** distributes an incoming unidirectional ASRT adapter (set/reset/toggle event adapter, no payload data) to 6 identical output adapters. It is the 6-output variant of ASRT_SPLIT_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_SPLIT'`) — the same C++ base (`CGenUnidirectSplitBase`), just with 6 instead of 2 plugs.

Interface Structure

None.

Data Outputs
None.

Adapters

Role	Name	Type	Description
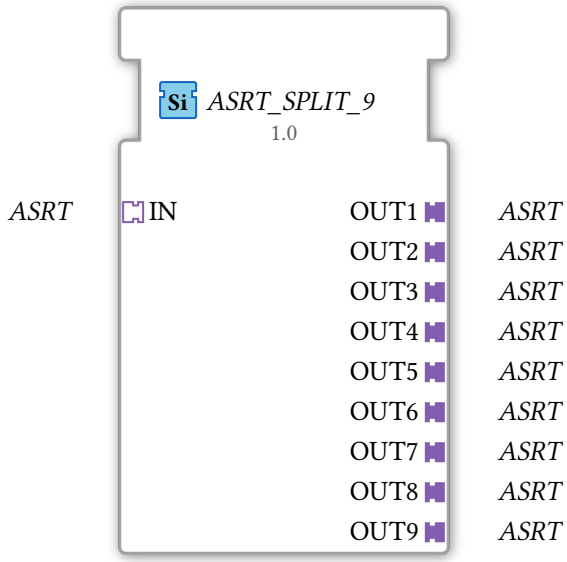
Socket (Input)	`IN`	`adapter::types::unidirectional::ASRT`	Receives `SET` or `RESET` or `TOGGLE`, distributed to all 8 outputs.
Plug (Output 1)	`OUT1`	`adapter::types::unidirectional::ASRT`	Output 1 for the duplicated event.
Plug (Output 2)	`OUT2`	`adapter::types::unidirectional::ASRT`	Output 2 for the duplicated event.
Plug (Output 3)	`OUT3`	`adapter::types::unidirectional::ASRT`	Output 3 for the duplicated event.
Plug (Output 4)	`OUT4`	`adapter::types::unidirectional::ASRT`	Output 4 for the duplicated event.
Plug (Output 5)	`OUT5`	`adapter::types::unidirectional::ASRT`	Output 5 for the duplicated event.
Plug (Output 6)	`OUT6`	`adapter::types::unidirectional::ASRT`	Output 6 for the duplicated event.
Plug (Output 7)	`OUT7`	`adapter::types::unidirectional::ASRT`	Output 7 for the duplicated event.
Plug (Output 8)	`OUT8`	`adapter::types::unidirectional::ASRT`	Output 8 for the duplicated event.

Functionality
As soon as `SET` or `RESET` or `TOGGLE` arrives at adapter socket `IN`, it is forwarded **immediately and in parallel** as a matching event to all 8 output plugs (`OUT1`, `OUT2`, `OUT3`, `OUT4`, `OUT5`, `OUT6`, `OUT7`, `OUT8`). The block performs no logic, filtering, or delay – it acts as a pure splitter at the adapter level.

Technical Features
- **Generic type**: Implemented via the generic base class `CGenUnidirectSplitBase` (1 socket, N plugs); the number of output plugs is fixed at compile time via the generic suffix (`_8`).
- **No states / algorithms**: Since `ASRT` carries no data value, there is no change detection and no ECC.
- **Arbitrary output count**: The same implementation covers ASRT_SPLIT_2 through ASRT_SPLIT_9; for other output counts see `ASRT_SPLIT_2`, `ASRT_SPLIT_3`, `ASRT_SPLIT_4`, `ASRT_SPLIT_5`, `ASRT_SPLIT_6`, `ASRT_SPLIT_7`, `ASRT_SPLIT_9`.

State Overview
The function block has **no state machine**. Its behavior is purely combinational: every incoming event at socket `IN` is duplicated to all 8 outputs immediately.

Application Scenarios
- **Event distribution**: A signal needs to be processed by 8 independent subsystems.
- **Parallel wiring**: Splitting a ASRT signal to simultaneously drive several actuators.



Comparison with Similar Components

- ASRT_MERGE_2: the reverse direction for 2 inputs (for ASRT, ASRT_MERGE_3 through ASRT_MERGE_7 are also available).
- **ASRT_SPLIT_2**, **ASRT_SPLIT_3**, **ASRT_SPLIT_4**, **ASRT_SPLIT_5**, **ASRT_SPLIT_6**, **ASRT_SPLIT_7**, **ASRT_SPLIT_9**: the same generic implementation with a different output count.

Conclusion

`ASRT_SPLIT_8` provides a generically implemented distribution of a `ASRT` event to 8 adapter outputs, completing the `GEN_ASRT_SPLIT` family with the 8-output variant.

ASRT_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASRT_SPLIT_9** distributes an incoming unidirectional ASRT adapter (set/reset/toggle event adapter, no payload data) to 9 identical output adapters. It is the 9-output variant of ASRT_SPLIT_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASRT_SPLIT'`) — the same C++ base (`CGenUnidirectSplitBase`), just with 9 instead of 2 plugs.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter socket.

Event Outputs

None. Events are forwarded exclusively via the adapter plugs.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::ASRT`	Receives `SET` or `RESET` or `TOGGLE`, distributed to all 9 outputs.

Plug (Output 1)	OUT1	adapter::types::unidirectional::ASRT Output 1 for the duplicated event.
Plug (Output 2)	OUT2	adapter::types::unidirectional::ASRT Output 2 for the duplicated event.
Plug (Output 3)	OUT3	adapter::types::unidirectional::ASRT Output 3 for the duplicated event.
Plug (Output 4)	OUT4	adapter::types::unidirectional::ASRT Output 4 for the duplicated event.
Plug (Output 5)	OUT5	adapter::types::unidirectional::ASRT Output 5 for the duplicated event.
Plug (Output 6)	OUT6	adapter::types::unidirectional::ASRT Output 6 for the duplicated event.
Plug (Output 7)	OUT7	adapter::types::unidirectional::ASRT Output 7 for the duplicated event.
Plug (Output 8)	OUT8	adapter::types::unidirectional::ASRT Output 8 for the duplicated event.
Plug (Output 9)	OUT9	adapter::types::unidirectional::ASRT Output 9 for the duplicated event.

Functionality

As soon as SET or RESET or TOGGLE arrives at adapter socket IN, it is forwarded **immediately and in parallel** as a matching event to all 9 output plugs (OUT1, OUT2, OUT3, OUT4, OUT5, OUT6, OUT7, OUT8, OUT9). The block performs no logic, filtering, or delay – it acts as a pure splitter at the adapter level.

Technical Features

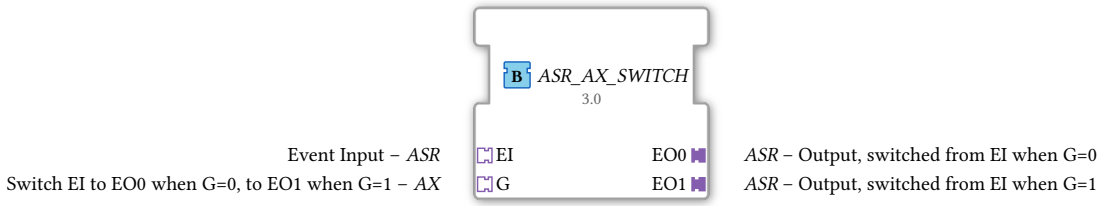
- **Generic type**: Implemented via the generic base class CGenUnidirectSplitBase (1 socket, N plugs); the number of output plugs is fixed at compile time via the generic suffix (_9).
- **No states / algorithms**: Since ASRT carries no data value, there is no change detection and no ECC.
- **Arbitrary output count**: The same implementation covers ASRT_SPLIT_2 through ASRT_SPLIT_9; for other output counts see ASRT_SPLIT_2, ASRT_SPLIT_3, ASRT_SPLIT_4, ASRT_SPLIT_5, ASRT_SPLIT_6, ASRT_SPLIT_7, ASRT_SPLIT_8.

State Overview

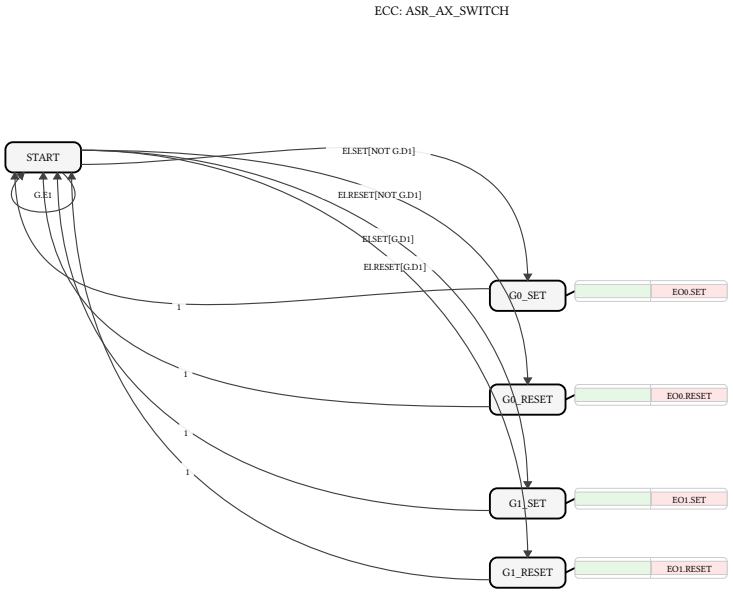
The function block has **no state machine**. Its behavior is purely combinational: every incoming event at socket IN is duplicated to all 9 outputs immediately.

Application Scenarios

- **Event distribution**: A signal needs to be processed by 9 independent subsystems.
- **Parallel wiring**: Splitting a ASRT signal to simultaneously drive several actuators.



Comparison with Similar Components



- ASRT_MERGE_2: the reverse direction for 2 inputs (for ASRT, ASRT_MERGE_3 through ASRT_MERGE_7 are also available).
- **ASRT_SPLIT_2, ASRT_SPLIT_3, ASRT_SPLIT_4, ASRT_SPLIT_5, ASRT_SPLIT_6, ASRT_SPLIT_7, ASRT_SPLIT_8**: the same generic implementation with a different output count.

Conclusion

ASRT_SPLIT_9 provides a generically implemented distribution of a ASRT event to 9 adapter outputs, completing the GEN_ASRT_SPLIT family with the 9-output variant.

ASR_AX_SWITCH

• – ○ • – ○ • – ○ •

Introduction

The function block **ASR_AX_SWITCH** serves as a demultiplexer for asynchronous set/reset events (ASR). It forwards an incoming SET or RESET event, based on the state of a binary control input **G**, to either one of two outputs (**EO0** or **EO1**). This block enables demand-based distribution of control signals in automation applications.

Interface Structure

Event Inputs

The function block does not have traditional event inputs via *EventInputs* – events are received via the **Socket Adapter `EI`** of type `ASR`. This adapter provides the two events `SET` and `RESET`.

Event Outputs

The event outputs are provided via the **plug adapters `EO0`** and **`EO1`** (both type `ASR`). Each of these adapters has the outputs `SET` and `RESET`:

Adapter	Event	Description
`EO0.SET`	SET	Triggered when a `EI.SET` event occurs and `G.D1 == 0`
`EO0.RESET`	RESET	Triggered when a `EI.RESET` event occurs and `G.D1 == 0`
`EO1.SET`	SET	Triggered when a `EI.SET` event occurs and `G.D1 == 1`
`EO1.RESET`	RESET	Triggered when a `EI.RESET` event occurs and `G.D1 == 1`

Data Inputs

The FB has no separate data inputs. The control variable **G** is obtained via the **Socket Adapter `G`** of type `AX` – the logical signal is present at the data output `D1` of the adapter.

Data Outputs

There are no explicit data outputs. Control information is transmitted exclusively via the event outputs of the ASR adapters.

Adapters

Name	Direction	Type	Description
EI	Socket (Input)	adapter::types::unidirectional::ASR	Receives the SET/RESET events to be distributed
G	Socket (Input)	adapter::types::unidirectional::AX	Provides the binary toggle signal via D1 (0 ⟶ Channel 0, 1 ⟶ Channel 1)
EO0	Plug (Output)	adapter::types::unidirectional::ASR	Output for Channel 0 (with G.D1 = 0)
EO1	Plug (Output)	adapter::types::unidirectional::ASR	Output for Channel 1 (with G.D1 = 1)

Functionality

The function block operates in an event-driven manner. After startup, it is in the **START** state and waits for incoming events via the EI adapter:

- **EI.SET** and **EI.RESET** are only processed if a valid binary value is simultaneously present at G.D1 via the G adapter.
- The condition for the transition is:
- EI.SET[NOT G.D1] ⟶ **G0_SET** ⟶ Output EO0.SET
- EI.SET[G.D1] ⟶ **G1_SET** ⟶ Output EO1.SET
- EI.RESET[NOT G.D1] ⟶ **G0_RESET** ⟶ Output EO0.RESET
- EI.RESET[G.D1] ⟶ **G1_RESET** ⟶ Output EO1.RESET
- After the initial event is triggered, the function block immediately returns to the **START** state (unconditional transition with 1).
- Additionally, there is a transition from **START** to **START** at **G.E1** – this allows for asynchronous updating of the control signal without immediate event propagation (serves, for example, for synchronization or initialization).

Processing is deterministic without intermediate event storage.

Technical Features

- **Adapter-based communication**: The function block uses only adapters (sockets/plugs) for event and data exchange – this enables flexible integration within the 4diac IDE.
- **No state storage**: The selection of the target channel is purely combinatorial at the time of the incoming event. No internal state is maintained.
- **Full synchronicity**: After each output event, the function block returns to its initial state – events cannot be stacked.
- **Embedded license**: The code is released under the Eclipse Public License 2.0.

Status Overview

Status	Description	Action
START	Waiting for incoming SET/RESET event	–
G0_SET	Receive EI.SET at G.D1=0	Output EO0.SET
G1_SET	Receive EI.SET at G.D1=1	Output EO1.SET
G0_RESET	Receive EI.RESET at G.D1=0	Output EO0.RESET
G1_RESET	Receive EI.RESET at G.D1=1	Output EO1.RESET

State transitions follow the ECC scheme: A condition leads from START to the action state, and from there, without further conditions, immediately back to START.

Application Scenarios

- **Channel Switching**: In a modular controller, a central set/reset command should be forwarded to different actuators (e.g., valves, motors) depending on the operating mode.
- **Safety Logic**: Depending on an enable signal (G), resets are only routed to the active channel.

- **Redundancy Control**: The signal `G` selects between the main and backup channels.
- **Sequential Processes**: Multiple processing stations are controlled sequentially by switching `G`.

Comparison with Similar Function Blocks

Property	ASR_AX_SWITCH	Simple event multiplexer (e.g., SELECT)
Event Type	SET/RESET (ASR Adapter)	Any single event
Control	Binary via AX adapter (with `D1`)	Boolean data input
Output Type	Two ASR adapters	Depending on the type, single or multiple events
Stateful	No (no storage)	Mostly stateless
Adapter interface	Yes	Often directly via event/data ports

The ASR_AX_SWITCH is specifically optimized for asynchronous set/reset signals and integrates seamlessly into the ASR adapter world of the 4diac library. Compared to generic multiplexers, there is no need to manually extract the adapter events.

Conclusion

The **ASR_AX_SWITCH** is a compact, efficient demultiplexer for the directed routing of ASR control events. Thanks to its adapter-based interface and clear decision logic, it is ideally suited for modular automation projects where a single control signal needs to be selectively routed to different paths. The simple state machine guarantees fast, deterministic response times without side effects.

ASR_MERGE_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_MERGE_2** merges two unidirectional ASR adapters (a set/reset event pair, no payload data) into one common output adapter. It is the reverse of ASR_SPLIT_2: instead of distributing a set/reset signal to two outputs, it merges two independent set/reset sources into a common output. The block is implemented as a generic FB (`GenericClassName: 'GEN_ASR_MERGE'`).

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	IN1	adapter::types::unidirectional::ASR	First SET/RESET source.
Socket (Input 2)	IN2	adapter::types::unidirectional::ASR	Second SET/RESET source.
Plug (Output)	OUT	adapter::types::unidirectional::ASR	Merged SET/RESET signal.

Functionality

Whenever a SET event arrives at IN1 **or** IN2, a SET is forwarded to OUT; likewise, a RESET at IN1/IN2 is forwarded to OUT as a RESET. Both event types are handled independently – a SET at IN1 has no effect on whether a RESET at IN2 is forwarded. Since ASR carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

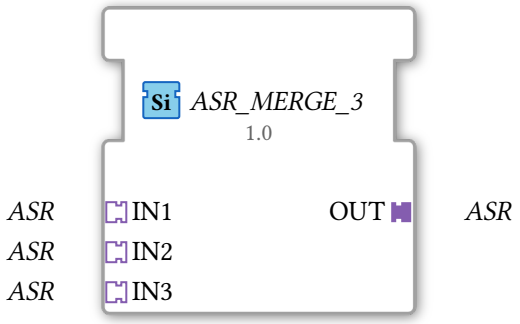
- **Generic type**: Implemented via the generic base class CGenUnidirectMergeBase (N sockets, 1 plug) – the same C++ base underlying GEN_AE_MERGE and GEN_ASRT_MERGE.
- **Two independent event channels**: SET and RESET are checked and forwarded separately; one socket could, for example, only ever deliver SET events while the other only delivers RESET, without the two interfering with each other.
- **No states / algorithms**: Since ASR carries no data value, there is no change detection and no ECC.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming SET or RESET event at IN1 or IN2 is forwarded to OUT immediately as the matching event type.

Application Scenarios

- **Merging redundant set/reset sources**: Two independent operator stations or safety paths should both be able to set or reset the same ASR output.
- **Simplifying networks** that would otherwise need two separate SET/RESET event connection pairs to the same destination.



Comparison with Similar Components

- ASR_SPLIT_2: the reverse direction – distributes one incoming set/reset signal to two outputs, instead of merging two inputs.
- AE_MERGE_2: the same merge logic for the pure event adapter AE (1 event instead of SET/RESET).
- ASRT_MERGE_2: the same merge logic for the set/reset/toggle event adapter ASRT (adds TOGGLE).

Conclusion

ASR_MERGE_2 is a minimal generic function block for merging two set/reset event sources into a common ASR adapter output, closing the gap previously noted as "hypothetical" next to ASR_SPLIT_2.

ASR_MERGE_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_MERGE_3** merges 3 unidirectional ASR adapters (set/reset event adapter, no payload data) into one common output adapter. It is the 3-input variant of ASR_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASR_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 3 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::ASR`	Source 1.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::ASR`	Source 2.
Socket (Input 3)	`IN3`	`adapter::types::unidirectional::ASR`	Source 3.
Plug (Output)	`OUT`	`adapter::types::unidirectional::ASR`	Merged signal.

Functionality

Whenever `SET` or `RESET` arrives at any of the 3 sockets (`IN1`, `IN2`, `IN3`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 3 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN3`, which only matters if several events arrive within the same execution cycle. Since `ASR` carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

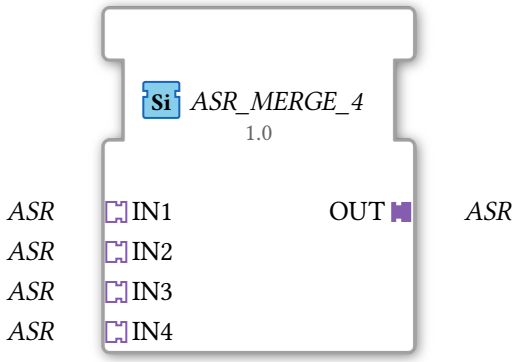
- **Generic type**: Implemented via the generic base class `CGenUnidirectMergeBase` (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (`_3`).
- **No states / algorithms**: Since `ASR` carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASR_MERGE_2 through ASR_MERGE_7; for other input counts see `ASR_MERGE_2`, `ASR_MERGE_4`, `ASR_MERGE_5`, `ASR_MERGE_6`, `ASR_MERGE_7`.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 3 sockets is forwarded to `OUT` immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 3 redundant or alternative trigger paths) into a common ASR adapter output.
- **Simplifying networks** that would otherwise need 3 separate event connections to the same destination.



Comparison with Similar Components

- **ASR_SPLIT_2**: the reverse direction for 2 outputs (for ASRT, ASR_SPLIT_3 through ASR_SPLIT_9 are also available).
- **`ASR_MERGE_2`, `ASR_MERGE_4`, `ASR_MERGE_5`, `ASR_MERGE_6`, `ASR_MERGE_7`**: the same generic implementation with a different input count.
- AE_MERGE_3, ASRT_MERGE_3: the same merge logic for the other unidirectional event adapters.

Conclusion

`ASR_MERGE_3` provides a generically implemented merge of 3 `ASR` event sources into a common adapter output, completing the `GEN_ASR_MERGE` family with the 3-input variant.

ASR_MERGE_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_MERGE_4** merges 4 unidirectional ASR adapters (set/reset event adapter, no payload data) into one common output adapter. It is the 4-input variant of ASR_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASR_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 4 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	IN1	adapter::types::unidirectional::ASR	Source 1.
Socket (Input 2)	IN2	adapter::types::unidirectional::ASR	Source 2.
Socket (Input 3)	IN3	adapter::types::unidirectional::ASR	Source 3.
Socket (Input 4)	IN4	adapter::types::unidirectional::ASR	Source 4.
Plug (Output)	OUT	adapter::types::unidirectional::ASR	Merged signal.

Functionality

Whenever SET or RESET arrives at any of the 4 sockets (IN1, IN2, IN3, IN4), it is forwarded unchanged to OUT as the matching event type. All event types are handled independently, and all 4 sockets are treated equally — the order in which sockets are checked follows IN1 … IN4, which only matters if several events arrive within the same execution cycle. Since ASR carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

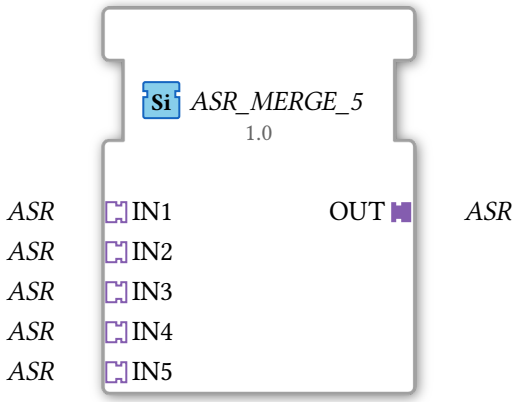
- **Generic type**: Implemented via the generic base class CGenUnidirectMergeBase (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_4).
- **No states / algorithms**: Since ASR carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASR_MERGE_2 through ASR_MERGE_7; for other input counts see ASR_MERGE_2, ASR_MERGE_3, ASR_MERGE_5, ASR_MERGE_6, ASR_MERGE_7.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 4 sockets is forwarded to OUT immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 4 redundant or alternative trigger paths) into a common ASR adapter output.
- **Simplifying networks** that would otherwise need 4 separate event connections to the same destination.



Comparison with Similar Components

- ASR_SPLIT_2: the reverse direction for 2 outputs (for ASRT, ASR_SPLIT_3 through ASR_SPLIT_9 are also available).
- **ASR_MERGE_2, ASR_MERGE_3, ASR_MERGE_5, ASR_MERGE_6, ASR_MERGE_7**: the same generic implementation with a different input count.
- AE_MERGE_4, ASRT_MERGE_4: the same merge logic for the other unidirectional event adapters.

Conclusion

ASR_MERGE_4 provides a generically implemented merge of 4 ASR event sources into a common adapter output, completing the GEN_ASR_MERGE family with the 4-input variant.

ASR_MERGE_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_MERGE_5** merges 5 unidirectional ASR adapters (set/reset event adapter, no payload data) into one common output adapter. It is the 5-input variant of ASR_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASR_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 5 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

None.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::ASR`	Source 1.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::ASR`	Source 2.
Socket (Input 3)	`IN3`	`adapter::types::unidirectional::ASR`	Source 3.
Socket (Input 4)	`IN4`	`adapter::types::unidirectional::ASR`	Source 4.
Socket (Input 5)	`IN5`	`adapter::types::unidirectional::ASR`	Source 5.
Plug (Output)	`OUT`	`adapter::types::unidirectional::ASR`	Merged signal.

Functionality

Whenever `SET` or `RESET` arrives at any of the 5 sockets (`IN1`, `IN2`, `IN3`, `IN4`, `IN5`), it is forwarded unchanged to `OUT` as the matching event type. All event types are handled independently, and all 5 sockets are treated equally — the order in which sockets are checked follows `IN1` … `IN5`, which only matters if several events arrive within the same execution cycle. Since `ASR` carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

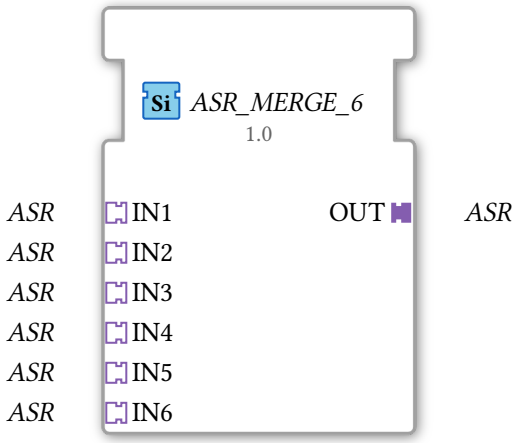
- **Generic type**: Implemented via the generic base class `CGenUnidirectMergeBase` (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_5).
- **No states / algorithms**: Since `ASR` carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASR_MERGE_2 through ASR_MERGE_7; for other input counts see `ASR_MERGE_2`, `ASR_MERGE_3`, `ASR_MERGE_4`, `ASR_MERGE_6`, `ASR_MERGE_7`.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 5 sockets is forwarded to `OUT` immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 5 redundant or alternative trigger paths) into a common ASR adapter output.
- **Simplifying networks** that would otherwise need 5 separate event connections to the same destination.



Comparison with Similar Components

- **ASR_SPLIT_2**: the reverse direction for 2 outputs (for ASRT, ASR_SPLIT_3 through ASR_SPLIT_9 are also available).
- **`ASR_MERGE_2, ASR_MERGE_3, ASR_MERGE_4, ASR_MERGE_6, ASR_MERGE_7`**: the same generic implementation with a different input count.
- AE_MERGE_5, ASRT_MERGE_5: the same merge logic for the other unidirectional event adapters.

Conclusion

`ASR_MERGE_5` provides a generically implemented merge of 5 `ASR` event sources into a common adapter output, completing the `GEN_ASR_MERGE` family with the 5-input variant.

ASR_MERGE_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_MERGE_6** merges 6 unidirectional ASR adapters (set/reset event adapter, no payload data) into one common output adapter. It is the 6-input variant of ASR_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASR_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 6 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Inputs

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	IN1	adapter::types::unidirectional::ASR	Source 1.
Socket (Input 2)	IN2	adapter::types::unidirectional::ASR	Source 2.
Socket (Input 3)	IN3	adapter::types::unidirectional::ASR	Source 3.
Socket (Input 4)	IN4	adapter::types::unidirectional::ASR	Source 4.
Socket (Input 5)	IN5	adapter::types::unidirectional::ASR	Source 5.
Socket (Input 6)	IN6	adapter::types::unidirectional::ASR	Source 6.
Plug (Output)	OUT	adapter::types::unidirectional::ASR	Merged signal.

Functionality

Whenever SET or RESET arrives at any of the 6 sockets (IN1, IN2, IN3, IN4, IN5, IN6), it is forwarded unchanged to OUT as the matching event type. All event types are handled independently, and all 6 sockets are treated equally — the order in which sockets are checked follows IN1 … IN6, which only matters if several events arrive within the same execution cycle. Since ASR carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

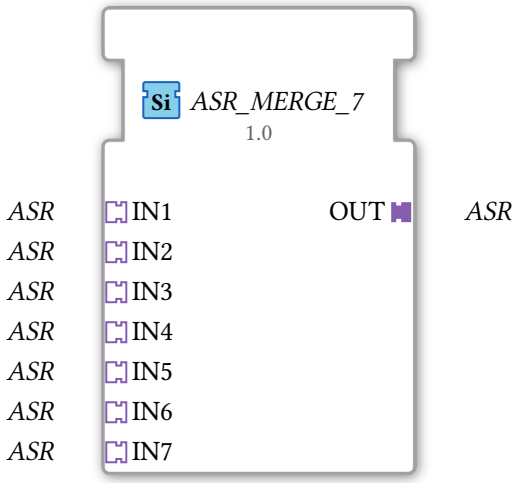
- **Generic type**: Implemented via the generic base class CGenUnidirectMergeBase (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_6).
- **No states / algorithms**: Since ASR carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASR_MERGE_2 through ASR_MERGE_7; for other input counts see ASR_MERGE_2, ASR_MERGE_3, ASR_MERGE_4, ASR_MERGE_5, ASR_MERGE_7.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 6 sockets is forwarded to OUT immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 6 redundant or alternative trigger paths) into a common ASR adapter output.
- **Simplifying networks** that would otherwise need 6 separate event connections to the same destination.



Comparison with Similar Components

- ASR_SPLIT_2: the reverse direction for 2 outputs (for ASRT, ASR_SPLIT_3 through ASR_SPLIT_9 are also available).
- **ASR_MERGE_2, ASR_MERGE_3, ASR_MERGE_4, ASR_MERGE_5, ASR_MERGE_7**: the same generic implementation with a different input count.
- AE_MERGE_6, ASRT_MERGE_6: the same merge logic for the other unidirectional event adapters.

Conclusion

ASR_MERGE_6 provides a generically implemented merge of 6 ASR event sources into a common adapter output, completing the GEN_ASR_MERGE family with the 6-input variant.

ASR_MERGE_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_MERGE_7** merges 7 unidirectional ASR adapters (set/reset event adapter, no payload data) into one common output adapter. It is the 7-input variant of ASR_MERGE_2 and, like it, is implemented as a generic FB (`GenericClassName: 'GEN_ASR_MERGE'`) — the same C++ base (`CGenUnidirectMergeBase`), just with 7 instead of 2 sockets.

Interface Structure

Event Inputs

None. Events are received exclusively via the adapter sockets.

Event Outputs

None. Events are forwarded exclusively via the adapter plug.

Data Outputs

None.

Adapters

Role	Name	Type	Description
Socket (Input 1)	`IN1`	`adapter::types::unidirectional::ASR`	Source 1.
Socket (Input 2)	`IN2`	`adapter::types::unidirectional::ASR`	Source 2.
Socket (Input 3)	`IN3`	`adapter::types::unidirectional::ASR`	Source 3.
Socket (Input 4)	`IN4`	`adapter::types::unidirectional::ASR`	Source 4.
Socket (Input 5)	`IN5`	`adapter::types::unidirectional::ASR`	Source 5.
Socket (Input 6)	`IN6`	`adapter::types::unidirectional::ASR`	Source 6.
Socket (Input 7)	`IN7`	`adapter::types::unidirectional::ASR`	Source 7.
Plug (Output)	`OUT`	`adapter::types::unidirectional::ASR`	Merged signal.

Functionality

Whenever SET or RESET arrives at any of the 7 sockets (IN1, IN2, IN3, IN4, IN5, IN6, IN7), it is forwarded unchanged to OUT as the matching event type. All event types are handled independently, and all 7 sockets are treated equally — the order in which sockets are checked follows IN1 ... IN7, which only matters if several events arrive within the same execution cycle. Since ASR carries no data value, there is nothing to arbitrate beyond the respective event type itself.

Technical Features

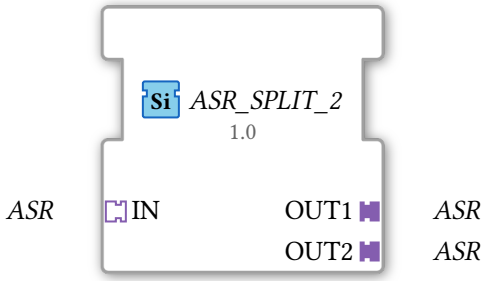
- **Generic type**: Implemented via the generic base class CGenUnidirectMergeBase (N sockets, 1 plug); the number of input sockets is fixed at compile time via the generic suffix (_7).
- **No states / algorithms**: Since ASR carries no data value, there is no change detection and no ECC.
- **Arbitrary input count**: The same implementation covers ASR_MERGE_2 through ASR_MERGE_7; for other input counts see ASR_MERGE_2, ASR_MERGE_3, ASR_MERGE_4, ASR_MERGE_5, ASR_MERGE_6.

State Overview

The function block has **no state machine**. Its behavior is purely combinational: every incoming event at any of the 7 sockets is forwarded to OUT immediately.

Application Scenarios

- **Merging several equivalent signal sources** (e.g. 7 redundant or alternative trigger paths) into a common ASR adapter output.
- **Simplifying networks** that would otherwise need 7 separate event connections to the same destination.



Comparison with Similar Components

- ASR_SPLIT_2: the reverse direction for 2 outputs (for ASRT, ASR_SPLIT_3 through ASR_SPLIT_9 are also available).
- **ASR_MERGE_2, ASR_MERGE_3, ASR_MERGE_4, ASR_MERGE_5, ASR_MERGE_6**: the same generic implementation with a different input count.
- AE_MERGE_7, ASRT_MERGE_7: the same merge logic for the other unidirectional event adapters.

Conclusion

ASR_MERGE_7 provides a generically implemented merge of 7 ASR event sources into a common adapter output, completing the GEN_ASR_MERGE family with the 7-input variant.

ASR_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_SPLIT_2** splits an incoming unidirectional ASR (Application Service Request) adapter into two identical output adapters. It is designed as a generic function block and allows an ASR signal to be forwarded to two separate consumers or subsequent function blocks without changing the logic.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Type	Direction	Name	Description
`adapter::types::unidirectional::ASR`	Input (Socket)	**IN**	Incoming ASR signal
`adapter::types::unidirectional::ASR`	Output (Plug)	**OUT1**	First outgoing ASR path
`adapter::types::unidirectional::ASR`	Output (Plug)	**OUT2**	Second outgoing ASR path

Functionality

This module passes the ASR signal received via socket **IN** unchanged to both plugs **OUT1** and **OUT2**. No processing, filtering, or delay occurs – the signal is passively split into two paths. Each output provides the exact same information as the input.

Technical Features

- The function block is implemented as a **Generic Function Block (FB)**. The actual type instance is determined at runtime by configuring the generic class attribute (`eclipse4diac::core::GenericClassName = 'GEN_ASR_SPLIT'`).
- No event or data inputs/outputs are used – all communication takes place exclusively via the adapter interfaces.
- The outputs are independent of each other; an error or blockage at one output does not affect the other.

State Overview

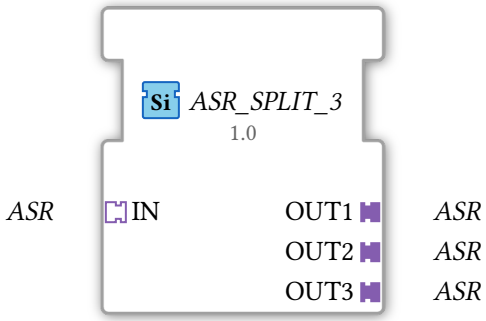
The function block does not have its own state diagram, as it operates purely passively. Its behavior corresponds to a static branch.

Application Scenarios

- **Parallelization of Service Requests:** An ASR (e.g., a service request) should be sent to two independent components, e.g., to a logging component and simultaneously to an execution service.
- **Redundancy:** Distribution of a signal across two redundant paths to increase fault tolerance.
- **Adapter Bridge:** Used in systems where an ASR connection needs to be split across two adapter points without copying the logic.

Comparison with Similar Components

- ASR_MERGE_2: Merges two ASR inputs into one output (every SET/RESET event is forwarded unchanged, no priority arbitration). The **ASR_SPLIT_2** does the opposite.
- **SPLIT_1_to_N** (generic split components): A general splitter that operates with a configurable number of outputs. The **ASR_SPLIT_2** is a specialized version with two fixed outputs.



Conclusion

The **ASR_SPLIT_2** is a simple yet useful generic component for multiplying ASR signals. Thanks to its platform-independent adapters and purely passive operation, it is suitable for all scenarios where a service signal needs to be distributed across multiple paths. Integration requires no configuration and has no side effects on the transmitted data.

ASR_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASR_SPLIT_3` is used to distribute an incoming ASR (Application-Specific Resource) adapter to three identical outgoing ASR adapters. It is designed as a generic block and enables simple signal distribution within an adapter-based communication structure.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Type	Direction	Name	Description
Socket	Input	IN	Incoming ASR signal adapter.
Plug	Output	OUT1	First outgoing ASR signal adapter.
Plug	Output	OUT2	Second outgoing ASR signal adapter.
Plug	Output	OUT3	Third outgoing ASR signal adapter.

All adapters are of type `adapter::types::unidirectional::ASR`. ...

Functionality

This function block forwards all signals and events arriving via socket `IN` from the ASR adapter unchanged to the three plug channels `OUT1`, `OUT2`, and `OUT3`. No logical processing or buffering takes place – the distribution is passive and instantaneous. The function block acts as a simple splitter for ASR connections.

Technical Features

- The function block is generic (attribute `eclipse4diac::core::GenericClassName = 'GEN_ASR_SPLIT'`), allowing it to be reused for different instances of the ASR type.
- No Execution Control Chart (ECC) is required, as the forwarding occurs directly through the adapter coupling.
- All three outputs are separately addressable, allowing different target modules to be connected independently.

State Overview

Since the module does not process events and operates without a state, there is no state diagram. Its functionality is limited to passive signal pass-through.

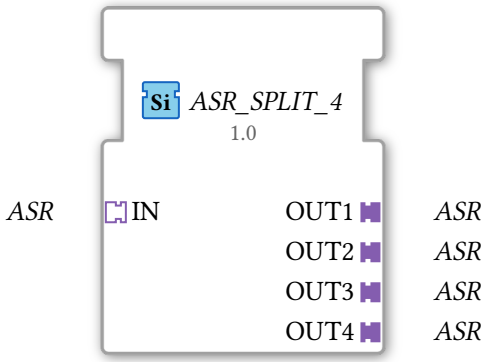
Application Scenarios

- **Distributing control signals** to multiple parallel components in an automation system, e.g., to three drives or sensors.
- **Splitting ASR communication** across different subsystems that expect the same adapter interface.
- **Test and debugging setups** where a signal needs to be forwarded to multiple monitoring points simultaneously.

Comparison with Similar Modules

- `ASR_SPLIT_2` splits an ASR signal across two outputs; `ASR_SPLIT_3` extends this functionality to three outputs.
- `ASR_MERGE` (if present) combines multiple ASR signals, while `ASR_SPLIT_3` separates them.
- Unlike generic data splitters, this component operates directly at the adapter level and requires no additional data type conversions.

Conclusion



The `ASR_SPLIT_3` is a simple yet effective component for duplicating an ASR signal to three identical outputs. It is particularly well-suited for modular structures where a central signal is needed multiple times. Its generic design increases reusability and reduces configuration effort.

ASR_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_SPLIT_4** is a generic block that distributes an incoming unidirectional ASR adapter (actuator-control adapter) signal to four separate, identical ASR outputs. It enables the simultaneous control of up to four independent actuators or subsystems with the same signal without compromising signal integrity. The block is designed for use in distributed automation systems according to IEC 61499.

Interface Structure

Adapter Inputs (Sockets)

Name	Type	Description
IN	`adapter::types::unidirectional::ASR`	Input adapter providing the ASR connection to be distributed.

Adapter Outputs (Plugs)

Name	Type	Description
OUT1	`adapter::types::unidirectional::ASR`	First output adapter (identical copy of the input).
OUT2	`adapter::types::unidirectional::ASR`	Second output adapter.
OUT3	`adapter::types::unidirectional::ASR`	Third output adapter.
OUT4	`adapter::types::unidirectional::ASR`	Fourth output adapter.

Note: The specific structure of the ASR adapter (event/data elements) is not defined within the function block itself, but is determined by the associated adapter type `adapter::types::unidirectional::ASR`. Typically, this includes control and feedback signals for drives.

Functionality

The ASR_SPLIT_4 function block operates as a pure signal distributor: All ASR connection elements (events and data) received via the `IN` socket are replicated **1:1** to all four output plugs (OUT1–OUT4). No signal amplification, filtering, or logical processing takes place. As soon as the input adapter establishes an active connection, it is immediately passed through to all outputs. The function block does not require its own state logic – it operates entirely combinationally.

Technical Features

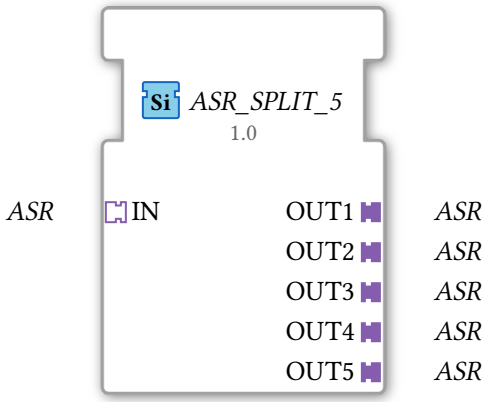
- **Generic Function Block:** The function block is declared as a generic type (`GEN_ASR_SPLIT`), which means that the interface definition of the ASR adapter is resolved at compile time. It can be used with various versions of the ASR adapter, as long as they conform to the unidirectional protocol.
- **Unidirectional Signal Direction:** The adapters are designed as unidirectional, meaning data flows only from the input to the outputs (no return channel from output to input).
- **No Latency Buffering:** All outputs are supplied with the same signal simultaneously; there is no staggered timing or buffering.

State Overview

The function block has **no explicit internal states**. The outputs always follow the input signals directly. There is no state machine. The behavior can be described as a single "switching" operation.

Application Scenarios

- **Control of Multiple Parallel Drives:** A central drive command transmitter (e.g., an AGV control block) distributes the speed or direction signal to four independent motor controllers.
- **Redundant Signal Distribution:** In safety-critical systems, the same command can be sent to multiple redundant actuators to ensure fail-safe operation.
- **Test and Simulation Environments:** A simulated ASR signal is simultaneously applied to multiple test instances.



Comparison with Similar Function Blocks

- **ASR_SPLIT_2 / ASR_SPLIT_N:** These function blocks split the ASR input into two or any number of outputs, respectively. The `ASR_SPLIT_4` is a special, four-channel variant.
- **Signal Multiplexer:** Unlike a true multiplexer, which selects from multiple sources, the split function block distributes the *same* source to multiple sinks.
- **Adapter Coupler:** Some libraries offer coupling blocks for adapter routing; the Split block extends this functionality to include multiplication.

Conclusion

The **ASR_SPLIT_4** is a simple yet useful function block that enables the modular and reusable coupling of ASR adapter connections in IEC 61499 systems. Its generic implementation allows it to be used in various contexts where an input signal needs to be distributed to multiple identical output interfaces. Thanks to its adaptive, stateless design, it integrates seamlessly into event-driven automation architectures.

ASR_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_SPLIT_5** is used to split a single unidirectional ASR adapter (Agricultural Standardized Interface) into five identical ASR outputs. It is designed as a generic module, thus enabling the simple distribution of an ASR signal to multiple downstream components or controllers.

Interface Structure

The module does not have any traditional event or data inputs/outputs. All communication takes place via adapter interfaces of type `adapter::types::unidirectional::ASR`.

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

Name	Type	Direction
`IN`	`adapter::types::unidirectional::ASR`	Socket (Input)
`OUT1`	`adapter::types::unidirectional::ASR`	Plug (Output)
`OUT2`	`adapter::types::unidirectional::ASR`	Plug (Output)
`OUT3`	`adapter::types::unidirectional::ASR`	Plug (Output)
`OUT4`	`adapter::types::unidirectional::ASR`	Plug (Output)
`OUT5`	`adapter::types::unidirectional::ASR`	Plug (Output)

Functionality

This component is a simple multiplexer at the adapter level. The ASR signal present at socket `IN` is passed through unchanged and without delay to all five output plugs (`OUT1` … `OUT5`). Thus, each connected receiver receives the identical signal from the input adapter. No active signal processing or conditioning takes place.

Technical Features

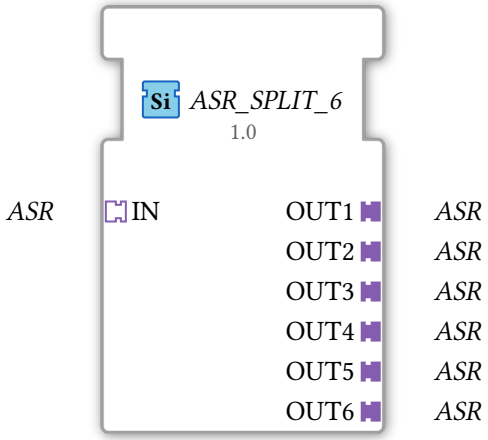
- **Generic Type**: The component is implemented as a generic function block (`GEN_ASR_SPLIT`) and can be automatically adapted to the specific data types of the ASR adapter used.
- **Unidirectional Communication**: All adapters are unidirectional (`adapter::types::unidirectional::ASR`), meaning data flows only from the input to the outputs; feedback is not provided.
- **No State Logic**: Since no events or algorithms are present, the module does not have an ECC state diagram and operates exclusively in a data flow-oriented manner.

State Overview

The functional block has no internal state machine. It behaves like a passive signal distributor and does not require state control.

Application Scenarios

- **Signal Distribution**: An ASR signal (e.g., sensor data, control commands) must be simultaneously transmitted to multiple consumers (e.g., multiple actuators or higher-level controllers).
- **Test and Simulation Environments**: Parallel injection of a test signal into multiple independent system paths.
- **Redundancy**: Supplying multiple identical control units with the same input information.



Comparison with Similar Function Blocks

- **ASR_SPLIT_2 / ASR_SPLIT_3 / ASR_SPLIT_4**: These function blocks split an ASR signal into two, three, or four outputs, respectively – the appropriate number can be selected as needed.
- **ASR_MERGE**: Unlike a splitter, a MERGE combines multiple ASR inputs into a single output.

Conclusion

The **ASR_SPLIT_5** is a simple yet useful routing function block for multiplying a unidirectional ASR adapter. Thanks to its generic implementation and pure adapter interface, it integrates seamlessly into IEC 61499 applications and facilitates structured signal distribution in complex automation systems.

ASR_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASR_SPLIT_6` distributes an incoming ASR signal (Generic Adapter Type) to six identical ASR outputs. It serves as a pure signal splitter and is provided as a generic function block in the 4diac IDE.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Adapter	Direction	Type	Description
IN	Socket	adapter::types::unidirectional::ASR	Input adapter – the ASR signal to be distributed
OUT1 – OUT6	Plug	adapter::types::unidirectional::ASR	Six output adapters – identical copies of the input signal

Functionality

This component does not perform any data processing or state logic. It forwards the adapter (unidirectional ASR) connected to socket IN directly and without delay to all six plugs (OUT1 to OUT6). Thus, the same signal is present at each output as at the input. The distribution occurs purely at the adapter level, without the involvement of events or data inputs/outputs.

Technical Features

- **Generic Function Block**: The function block uses the generic type definition GEN_ASR_SPLIT (attribute eclipse4diac::core::GenericClassName). This allows for flexible reuse with different ASR adapter types.
- **Unidirectional Adapter**: Both the input and outputs are of type adapter::types::unidirectional::ASR, meaning the data flows only in one direction (from the socket to the plugs).
- **No State Logic**: The component has no ECC (Execution Control Chart) and no internal states – it is a pure connection without any temporal behavior.
- **Scalability**: Due to the generic concept, similar splitters with any number of outputs (e.g., 2, 4, 8) can be created.

State Overview

There is no state diagram (ECC) because the component does not execute any sequential logic. Signal distribution is static and continuous.

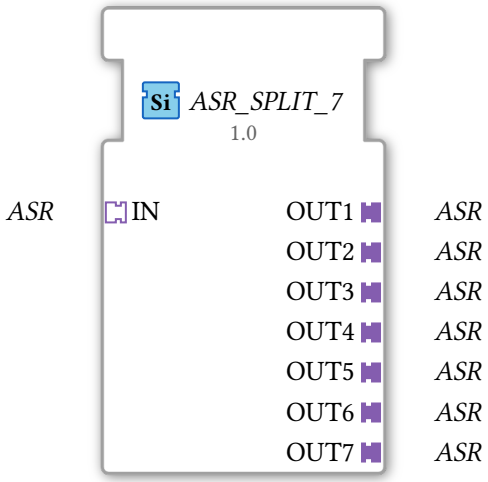
Application Scenarios

- **Distribution of a sensor signal** to multiple control units or subsystems.
- **Provision of the same ASR communication channel** for parallel processing branches.
- **Test and simulation environments** where an input signal is required multiple times.

Comparison with Similar Components

Component	Outputs	Special Features
ASR_SPLIT_2	2	Dual Split
ASR_SPLIT_4	4	Quad Split
ASR_SPLIT_6	**6**	**Six-Way Split (this module)**
Generic Split (e.g., via template)	Variable	Requires individual parameterization

The ASR_SPLIT_6 offers a fixed number of six outputs and is therefore specifically designed for applications that require exactly this number.



Conclusion

The `ASR_SPLIT_6` function block is a simple yet useful function block for signal duplication at the adapter level. Its generic nature and clear, uneventful operation make it ideal for modular control architectures that require multiple uses of an ASR signal.

ASR_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_SPLIT_7** is a generic function block that distributes a single ASR adapter input to seven ASR adapter outputs. It acts as a 1:7 splitter for ASR data and enables the parallel transmission of a signal to multiple downstream components.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Direction	Name	Type	Description
Input (Socket)	**IN**	`adapter::types::unidirectional::ASR`	Source adapter whose data is distributed to all outputs.
Output (Plug)	**OUT1**	`adapter::types::unidirectional::ASR`	First output, receives the duplicated data from `IN`.
Output (Plug)	**OUT2**	`adapter::types::unidirectional::ASR`	Second output.

Output (Plug)	**OUT3**	`adapter::types::unidirectional::ASR`	Third output.
Output (Plug)	**OUT4**	`adapter::types::unidirectional::ASR`	Fourth output.
Output (Plug)	**OUT5**	`adapter::types::unidirectional::ASR`	Fifth output.
Output (Plug)	**OUT6**	`adapter::types::unidirectional::ASR`	Sixth output.
Output (Plug)	**OUT7**	`adapter::types::unidirectional::ASR`	Seventh output.

Functionality

The module receives an ASR signal via socket `IN`. This signal is internally duplicated to all seven plugs (`OUT1` ... `OUT7`) and forwarded without modification. No data manipulation or filtering takes place – the incoming signal is copied one-to-one to each output.

Technical Features

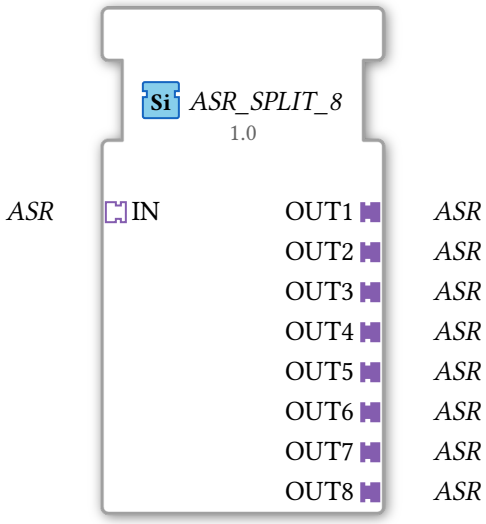
- **Generic Type**: The function block is declared as a generic block with the class name `GEN_ASR_SPLIT`. This allows it to be used in various contexts where an ASR splitter is required.
- **Pure Adapter Interface**: Only adapters (no events or data inputs/outputs) are used. Communication takes place via the unidirectional ASR adapter protocol.
- **No Internal State**: The block has no state management; signal distribution is continuous and instantaneous.

State Overview

The block has no explicit states. Its functionality is limited to the static duplication of the input signal.

Application Scenarios

- **Signal Distribution**: An ASR signal (e.g., a control command or a configuration message) is to be sent to multiple independent receivers.
- **Parallel Processing**: In an automated control system, information must reach multiple subsystems simultaneously, each designed for the ASR protocol.
- **Test Environments**: A test adapter is connected to `IN`, and the outputs are connected to various monitoring or logging modules.



Comparison with Similar Modules

Other splitter modules exist, such as `ASR_SPLIT_2`, `ASR_SPLIT_4`, and `ASR_SPLIT_n`, which distribute the input signal to 2, 4, and `n` outputs, respectively. `ASR_SPLIT_7` represents a specific variant with seven outputs. All of them share the common feature of duplicating the incoming ASR signal without modification.

Conclusion

The `ASR_SPLIT_7` is a simple yet useful component for distributing an ASR signal across seven parallel paths. Its generic definition and the absence of events or states make it flexible and robust in operation.

ASR_SPLIT_8

(Insert image of function block here)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ASR_SPLIT_8` is used to distribute a single incoming **ASR** adapter signal unchanged to eight identical outputs. It is defined as a generic function block and is particularly suitable for applications where a sensor or control signal is required multiple times – for example, in agricultural automation technology.

Interface Structure

Event Inputs

No event inputs are available. The function block operates purely on an adapter basis without event-driven execution.

Event Outputs

No event outputs are available.

Data Inputs

No data inputs are available. All signal transmissions take place via the **adapter** interfaces.

Data Outputs

No data outputs available.

Adapters

Direction	Name	Type	Description
Socket	IN	`adapter::types::unidirectional::ASR`	Incoming ASR signal distributed to all outputs.
Plug	OUT1	`adapter::types::unidirectional::ASR`	First output with the signal from IN.
Plug	OUT2	`adapter::types::unidirectional::ASR`	Second output with the signal from IN.
Plug	OUT3	`adapter::types::unidirectional::ASR`	Third output with the signal from IN.
Plug	OUT4	`adapter::types::unidirectional::ASR`	Fourth output with the signal from IN.
Plug	OUT5	`adapter::types::unidirectional::ASR`	Fifth output with the signal from IN.
Plug	OUT6	`adapter::types::unidirectional::ASR`	Sixth output with the signal from IN.

Plug	OUT7	`adapter::types::unidirectional::ASR`	Seventh output with the signal from IN.
Plug	OUT8	`adapter::types::unidirectional::ASR`	Eighth output with the signal from IN.

Functionality

The `ASR_SPLIT_8` block represents a **1-to-8 signal distribution** for the ASR adapter type. The ASR signal present at socket `IN` is forwarded to all eight plug outputs (`OUT1`...`OUT8`) without delay or state change. No signal conditioning, filtering, or logical processing takes place – the block operates purely passively and without any inherent behavior.

Since the adapter type `ASR` is defined as unidirectional, data flows only from the socket to the plugs. Changes to the input signal immediately affect all outputs.

Technical Features

- **Generic Type Parameterization**: The function block (FB) has the attributes `eclipse4diac::core::GenericClassName` (value `'GEN_ASR_SPLIT'`) and `eclipse4diac::core::TypeHash`, which enable the use of a generic ASR data type. This allows the block to be reused for various ASR subtypes.
- **No Event Control**: The block contains no event inputs or outputs; signal transmission occurs exclusively via the adapter interfaces. This simplifies integration into static data flows.
- **No Internal Behavior**: There is no state machine or algorithm – functionality is limited to the pure wiring logic of the 4diac IDE.

State Overview

The `ASR_SPLIT_8` has **no internal states**. The output is a direct function of the input signal at any given time. The block behaves like passive wiring (sterile splitter) without any memory or delay effects.

Application Scenarios

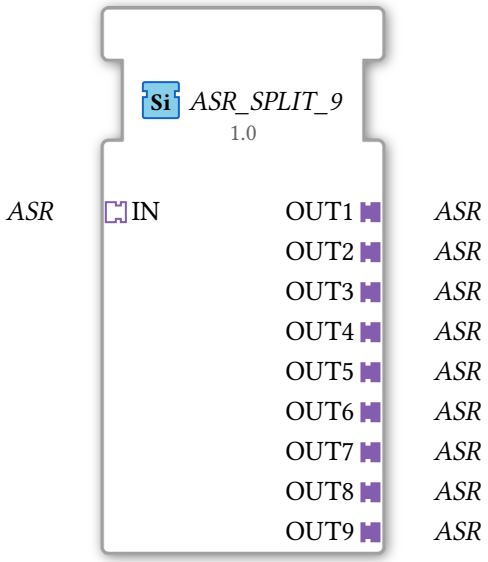
- **Distribution of a sensor signal** (e.g., speed, pressure, or position) to multiple parallel control loops or display units.
- **Dividing a control command** to multiple actuators in an agricultural machine, such as the simultaneous control of several valves or drives.
- **Monitoring and Logging**: A signal can be routed to a controller via one output and to a diagnostic system via a second output.

Comparison with Similar Blocks

Block	Outputs	Special Features
`ASR_SPLIT_8`	8	Provides the maximum possible number of ASR copies in one block.
`ASR_SPLIT_4`	4	More compact alternative for smaller distribution systems.
`ASR_SPLIT_2`	2	Minimal splitter for point-to-point transmission.

The **8-way version** is the most comprehensive and allows the connection of many devices without additional cascading. Compared to cascading multiple 2-way or 4-way splitters, `ASR_SPLIT_8` reduces the number of required blocks and simplifies engineering.

Conclusion



The `ASR_SPLIT_8` is a simple yet efficient component for distributing an ASR signal across eight independent paths. Its generic design and the absence of states and events make it robust, resource-efficient, and ideally suited for unidirectional data transmission in agricultural and industrial automation systems. It complements the ASR splitter family and addresses the need for a high number of parallel outputs.

]

ASR_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ASR_SPLIT_9** is used to split a single incoming ASR adapter (Application Specific Resource) into nine separate ASR outputs. It is implemented as a generic function block (Generic FB) and allows the distribution of an ASR signal to up to nine independent receivers.

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

No separate data inputs. All data exchange takes place via the ASR adapter **IN**.

Data Outputs

No separate data outputs. The data is output via the ASR adapters **OUT1** to **OUT9**.

Adapter

Socket (Input):

Name	Type	Direction
IN	`adapter::types::unidirectional::ASR`	Socket

Plugs (Outputs):

Name	Type	Direction
OUT1	`adapter::types::unidirectional::ASR`	Plug
OUT2	`adapter::types::unidirectional::ASR`	Plug
OUT3	`adapter::types::unidirectional::ASR`	Plug
OUT4	`adapter::types::unidirectional::ASR`	Plug
OUT5	`adapter::types::unidirectional::ASR`	Plug

OUT6	`adapter::types::unidirectional::ASR`	Plug
OUT7	`adapter::types::unidirectional::ASR`	Plug
OUT8	`adapter::types::unidirectional::ASR`	Plug
OUT9	`adapter::types::unidirectional::ASR`	Plug

Functionality

The module receives an ASR signal via the socket adapter **IN**. This signal is internally routed to all nine output adapters (**OUT1** to **OUT9**). Thus, the identical ASR signal is present at each output. No delay or buffering occurs. The module is purely passive and does not perform any data transformation.

Technical Features

- **Generic Function Block:** This type is designed as a generic FB (GenericClassName `'GEN_ASR_SPLIT'`), allowing it to be parameterized with different ASR types depending on the project context.
- **Unidirectional Adapters:** All adapters used are of type `unidirectional::ASR`, ensuring a clear data flow direction from the input to the outputs.
- **No Events:** The function block has no event inputs or outputs. Data is transmitted solely via the adapter interfaces.
- **Platform-Neutral:** By using the IEC 61499-2 standard, the function block can be used in various 4diac IDE projects.

State Overview

The function block does not have an internal state machine (ECC). It operates statically and passes the incoming signal to all outputs without any temporal or logical dependencies.

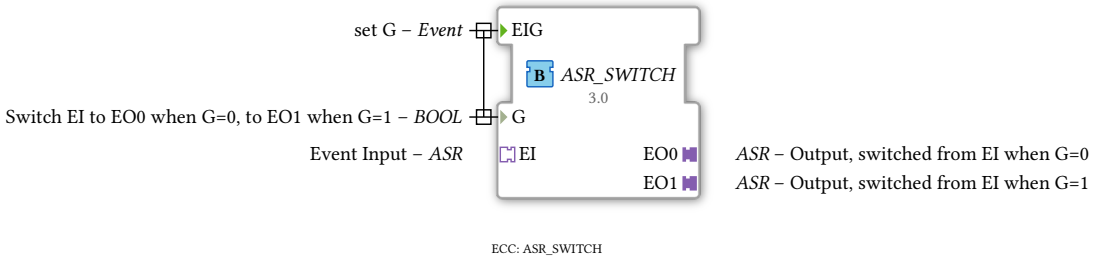
Application Scenarios

- **Distribution of an ASR signal** to multiple parallel-operating resources or functional units.
- **Monitoring or parallel control** when multiple components require the same ASR data (e.g., one sensor value to multiple evaluation modules).
- **Simple bus-like structures** in automated control systems, without complex multicast mechanisms.

Comparison with Similar Modules

- **ASR_SPLIT_4 / ASR_SPLIT_2:** Modules with a smaller number of outputs (4 or 2, respectively). `ASR_SPLIT_9` offers the maximum distribution across nine channels.
- **ASR_MERGE:** Combines multiple ASR signals into one, while `ASR_SPLIT_9` performs the exact opposite function.
- **Data Distributor:** Data type-oriented function blocks (e.g., `DATA_SPLIT`) tend to use simpler data types. `ASR_SPLIT_9` is specifically optimized for complex adapter structures.

Conclusion



The **ASR_SPLIT_9** function block is a compact and efficient solution for distributing an ASR signal to nine identical outputs. Its generic nature and clear, event-free adapter coupling make it particularly suitable for modular, reusable automation systems based on IEC 61499.

ASR_SWITCH

• – ○ • – ○ • – ○ •

Introduction

The **ASR_SWITCH** function block acts as a demultiplexer for **ASR events** (SET/RESET). It forwards events received via the adapter socket `EI` to either the adapter plug `EO0` or `EO1`, depending on the Boolean value of the input `G`. This allows switching between two different signal paths in an automation application.

Interface Structure

Event Inputs

Event	Data Link	Description
`EIG`	`G`	Sets the switching value `G` to the Boolean value present at input `G`.

Event Outputs

This function block does not have any independent event outputs. Output is exclusively via the **adapter plugs**.

Data Inputs

Variable	Type	Description
`G`	`BOOL`	Switch position: `FALSE` ⟶ Events are forwarded to `EO0`, `TRUE` ⟶ to `EO1`.

Data Outputs

None.

Adapters

Adapter	Direction	Type	Description
EI	Socket	adapter::types::unidirectional::ASR	Receives incoming ASR events (SET/RESET).
EO0	Plug	adapter::types::unidirectional::ASR	Output for the case G = FALSE.
EO1	Plug	adapter::types::unidirectional::ASR	Output for the case G = TRUE.

Functionality

The **ASR_SWITCH** is activated by an incoming event from the adapter socket EI or by the event EIG. The processing takes place in **Event-driven Control (ECC)**:

1. **Switching G:**

When the event EIG occurs, the value of G is adopted. The function block remains in the start state START and waits for the next events.

1. **Forwarding EI.SET:**

- EI.SET and G = FALSE: Transition to the state G0_SET, where EO0.SET is output.
- EI.SET and G = TRUE: Transition to state G1_SET, where EO1.SET is output.

1. **Forwarding from EI.RESET:**

- EI.RESET and G = FALSE: Transition to state G0_RESET, where EO0.RESET is output.
- EI.RESET and G = TRUE: Transition to state G1_RESET, where EO1.RESET is output.

1. **Return:**

After the action is output, the ECC immediately (condition = 1) returns to the start state START to process the next event.

Technical Features

- The function block works exclusively with the **unidirectional adapter type ASR**, meaning it can transport both SET and RESET events via the same adapter.
- The switchover is **event-triggered** via EIG (non-cyclically).
- No data outputs are required – all signaling is handled via the adapter plugs.
- Due to the immediate reset to the start state, the module is ready to restart **deterministically and quickly**.

State Overview

The following table summarizes the ECC states and the actions performed:

State	Description	Action(s)
START	Waiting for events	–
G0_SET	EI.SET at G = FALSE	Output EO0.SET
G1_SET	EI.SET at G = TRUE	Output EO1.SET
G0_RESET	EI.RESET at G = FALSE	Output EO0.RESET
G1_RESET	EI.RESET at G = TRUE	Output EO1.RESET

All states (except START) return to START with an unconditional transition (1).

Application Scenarios

- **Control of two parallel process paths:** Depending on the position of a switch, SET/RESET signals are distributed to different parts of the system.
- **Operating mode switching:** For example, between automatic and manual operation – a logical variable G determines which events affect which logic.

- **Test environments:** A test frame can send the same events to different test objects by switching `G`.

Comparison with Similar Function Blocks

- **`SELECT` Function Block:** A classic multiplexer/demultiplexer usually works with data, not events. The **ASR_SWITCH** specializes in ASR event forwarding.
- **`F_TRIG` / `R_TRIG` / `SR`:** These function blocks set or reset a memory function, but do not forward events. The **ASR_SWITCH** does not create states itself, but only channels existing events.
- **Adapter-Based Solutions:** In the 4diac IDE, the use of adapters is typical for modular communication – the **ASR_SWITCH** is a prime example of the flexible coupling of function blocks.

**

Conclusion

The **ASR_SWITCH** is a simple yet effective function block for demultiplexing SET/RESET events. Its adapter interface allows for seamless integration into event-based automation solutions. Its clear state logic and minimal interface make it a reliable component for switching between two signal paths.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. ...

AI_D_FF

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_D_FF** implements a data latch (D flip-flop) for the temporary storage of a data value. It serves as an adapter-encapsulated implementation of an edge-triggered D flip-flop according to IEC 61499, which, upon an event at the input, takes the incoming data value and makes it available at the output.

Interface Structure

Event Inputs

No direct event inputs.

Event Outputs

No direct event outputs.

Data Inputs

No direct data inputs.

Data Outputs

No direct data outputs.

Adapter

Name	Direction	Type	Description
I	Socket	`adapter::types::unidirectional::AI`	Returns the input event (E1) and the data value to be latched (D1).
Q	Plug	`adapter::types::unidirectional::AI`	After the latch is closed, outputs the result event (E1) and the stored data value (D1).

The `AI` adapter is unidirectional, meaning that data and event flows only in one direction. Socket **I** serves as the input, and Plug **Q** as the output.

Functionality

The internal component is a `E_D_FF_ANY` function block (IEC 61499 D flip-flop). The wiring connects:

- `I.E1` ⟶ `E_D_FF_ANY.CLK` (clock edge)
- `I.D1` ⟶ `E_D_FF_ANY.D` (data input)
- `E_D_FF_ANY.EO` ⟶ `Q.E1` (output event)
- `E_D_FF_ANY.Q` ⟶ `Q.D1` (latching data value)

Process:

An event at `I.E1` triggers a rising edge at the clock input of the internal flip-flop. The current value of `I.D1` is transferred and is available at `Q.D1` after processing is complete. Simultaneously, an event is output to `Q.E1`, signaling the validity of the new data value.

Technical Features

- **Adapter Encapsulation:** The function block (FB) has no direct inputs/outputs, but only adapter interfaces. This facilitates reuse in modular architectures where multiple signals are bundled and transmitted.
- **Unidirectional Data Flow:** The adapters are designed as pure sources (plugs) or sinks (sockets), which clearly defines the signal direction.
- **Edge-Triggered:** The transfer occurs only upon an event (rising edge), not upon level changes. Therefore, the function block is suitable for clocked systems.
-

State Overview

The internal state of the flip-flop is determined by the stored value `Q`. Two stable states exist:

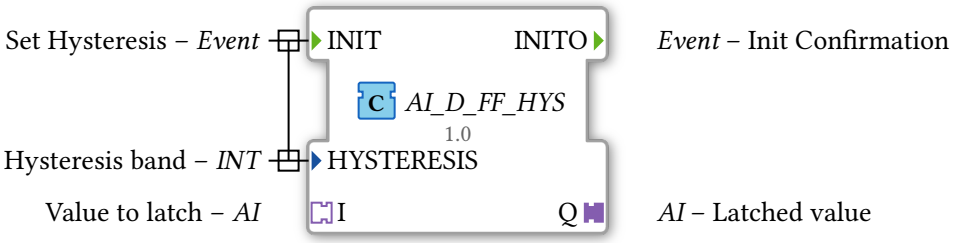
Clock (CLK)	D (Input)	Q (Output) before	Q (Output) after
No event	-	Q_old	Q_old

Event (rising edge)	0	X	0
Event (rising edge)	1	X	1

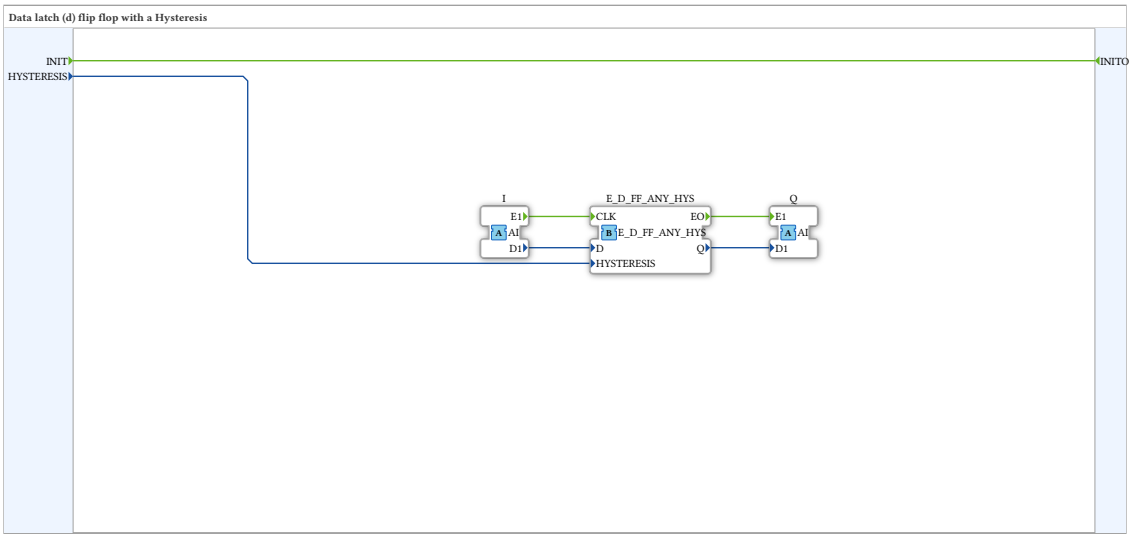
For each event at `I.E1`, the current D value is adopted, regardless of the previous Q value.

Application Scenarios

- **Analog Value Sampling:** A sensor (e.g., temperature, pressure) periodically delivers a measured value via the `I` adapter. The function block stores this value upon a trigger event and passes it on to the subsequent logic.
- **Cable Storage in Data Paths:** In conveyor belt or pipeline structures, `AI_D_FF` can be used as a data hold to buffer values for one clock cycle.
- **Debouncing / Edge Processing:** Combined with a clock generator, the function block can be used to process incoming signals only at specific times.



Comparison with Similar Function Blocks



- **E_D_FF** (without adapter): Offers direct event and data inputs/outputs but is less abstract. `AI_D_FF`, on the other hand, encapsulates the signals in adapters, which simplifies composition in higher hierarchies.
- **SR Flip-Flop (S/R dominant):** Stores state via set/reset, while `AI_D_FF` only takes over on clock edges and has no reset function.
- **Latch (level-controlled):** Unlike a latch, `AI_D_FF` only reacts to edges, making it better suited for synchronized systems.

Conclusion

The **AI_D_FF** is a compact, adapter-based D flip-flop device that stores and outputs a data value on an edge-triggered basis. By using unidirectional adapters, it integrates seamlessly into modern, modular automation concepts and enables a clean separation of data and event signals. Its application is particularly suitable for clocked sampling and buffering tasks in IEC-61499 systems.

AI_D_FF_HYS

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_D_FF_HYS** implements a clock-controlled D flip-flop (data latch) with configurable hysteresis. It serves to stably lock a binary or analog input signal and filter out disturbances in the signal waveform. The hysteresis prevents constant switching due to minor signal changes (bouncing, noise), thus ensuring a clean, latency-free output state.

Interface Structure

Event Inputs

Event	Type	With Variables	Description
INIT	EInit	HYSTERESIS	Initialization and Hysteresis Band Setting

Event Outputs

Event	Type	Description
INITO	EInit	Initialization Confirmation

Data Inputs

Name	Type	Description
HYSTERESIS	INT	Hysteresis Bandwidth (e.g., in digital steps)

Data Outputs

This function block does not have direct data outputs. The locked value is provided via the **Adapter Plug Q**.

Adapter

Name	Type	Direction	Description
I	AI	Socket	Input adapter: Clock signal (**E1**) and data (**D1**)
Q	AI	Plug	Output adapter: Latched value (**D1**) and associated event (**E1**)

The adapter type used, `adapter::types::unidirectional::AI`, is a unidirectional data and event channel. The clock (E1) and data (D1) values are received via socket **I** the latched value (D1) is output via plug **Q** along with an acknowledgment event (E1).

Functionality

1. **Initialization**

The module is activated by the **INIT** event. The passed value **HYSTERESIS** is stored as the hysteresis band. After successful initialization, **INITO** is triggered.

1. **Data Latching**

After initialization, the module waits for a clock signal at adapter **I** (event **I.E1**). With each clock event, the current data value **I.D1** is read.

The internal function block `E_D_FF_ANY_HYS` compares the incoming value with the last latched value, taking the hysteresis into account:

- If the new value exceeds the old value by more than half the hysteresis, the new value is adopted (set).
- If it falls short of the old value by more than half the hysteresis, the new value is adopted (reset).
- For smaller differences, the output remains unchanged.

The latched value determined in this way is provided at adapter **Q**: **Q.D1** contains the digital value, and event **Q.E1** signals the update.

Technical Features

- **Adapter-Based Communication**

All data and event exchange occurs via adapters. This enables loose coupling between the flip-flop and the connected components and facilitates reuse in different contexts.

- **Hysteresis for Noise Suppression**

Hysteresis prevents flip-flop behavior in the presence of noise or bouncing signals. The bandwidth is passed as an integer (INT) and can be reset at runtime via **INIT**.

- **No Direct Data Outputs**

The latched value is only accessible via the **Q** adapter. This enforces structured signal routing within the overall system.

- **Embedded Function Block**

The actual flip-flop with hysteresis is implemented by the internal function block `E_D_FF_ANY_HYS`, which encapsulates complexity and simplifies maintenance.

State Overview

The function block (FB) does not have explicit states in the sense of a finite automaton. After the **INIT** operation, it is in an operating state where it waits for clock events. A subsequent **INIT** call resets the hysteresis and initializes the internal logic.

State	Description
Initialized	Ready for processing after a successful **INIT**
Waiting for Clock	Expecting an **I.E1** event at the input adapter
Data Processing	Upon **I.E1**: Hysteresis comparison and, if necessary, acceptance

Application Scenarios

- **Debouncing of Switches and Sensors**

A mechanical contact produces bouncing signals. Hysteresis suppresses short-term changes and only passes on stable states.

- **Noise Reduction for Analog Signals**

An analog-to-digital converter (ADC) delivers noisy values. Hysteresis prevents constant switching between adjacent quantization levels.

- **State Memory in Controllers**

This component can be used as a simple D flip-flop to clock a digital value and hold it until the next clock signal.

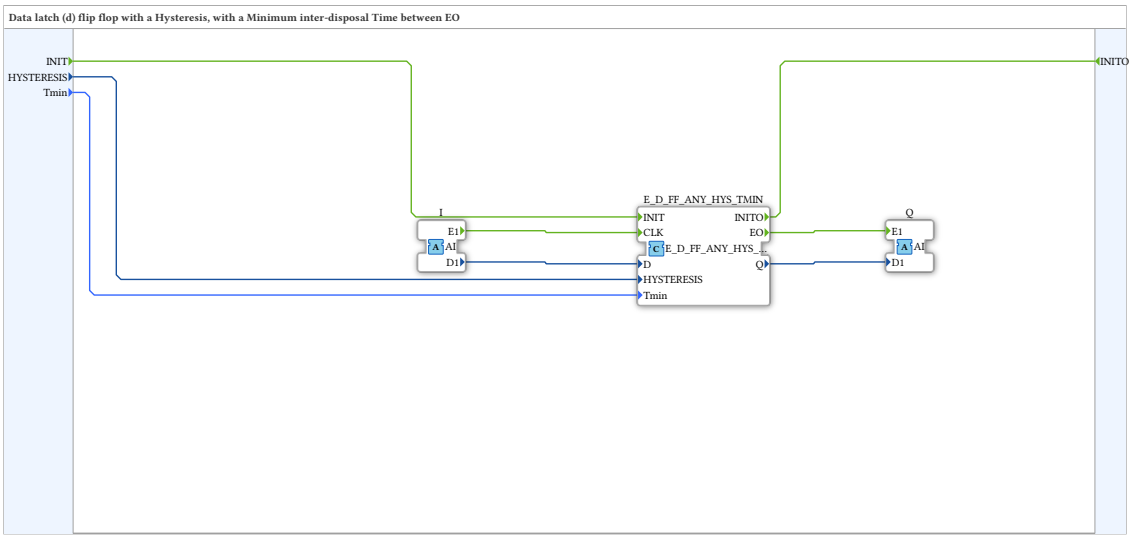
- **Interface Between Asynchronous and Synchronous Systems**

This adapter allows the connection of components with different event clocks by using the flip-flop as a buffer.

Comparison with Similar Components

Compo-nent	Hys-teresis	Clock Input	Output Type	Special Feature					
AI_D_FF_HYS	Yes	Yes	Adapter (AI)	Flexible Adapter Cou-pling	... Stan-dard D-FF (61499)	No	Yes	Direct Data Outputs	No Noise Sup-pression
SR Flip-Flop	No	No	Direct	Set/Re-set, No Clock					
Schmitt Trigger	Yes	No	Analog Thresh-old	Thresh-old Only,					

				No Memory					



The AI_D_FF_HYS combines the features of a clocked D flip-flop with adjustable hysteresis and offers platform-independent integration into IEC 61499 systems via its adapter interface.

Conclusion

The **AI_D_FF_HYS** is a robust and flexible functional block for clocked signal locking with hysteresis. It is particularly suitable for applications where noise needs to be filtered out of the input signal without sacrificing the functionality of a simple clock flip-flop. The adapter-based interface promotes modular, reusable designs and makes the component a valuable element in automation technology and signal processing.

AI_D_FF_HYS_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_D_FF_HYS_TMIN** implements a data latch (D flip-flop) with a hysteresis band and a minimum time between successive event outputs. It serves as a robust signal processing component that suppresses noise and fast edge transitions and only passes on stable state changes.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Initialization Request (sets hysteresis band and Tmin)

Event Outputs

Event	Type	Comment

INITO	EInit	Initialization Confirmation

Data Inputs

Variable	Type	Comment
HYSTERESIS	INT	Hysteresis Band (value in the same unit as the input signal)
Tmin	TIME	Minimum time between two event outputs (E1 on the Q adapter)

Data Outputs

This function block does not have its own data outputs. The latched value is provided via the output adapter **Q**.

Adapters

Adapter	Type	Comment
I	adapter::types::unidirectional::AI	Input adapter: provides the signal to be processed (via event E1 and data D1)
Q	adapter::types::unidirectional::AI	Output adapter: outputs the latched value (via event E1 and data D1)

Functionality

The function block internally uses the subroutine **E_D_FF_ANY_HYS_TMIN** from the *logiBUS::signal-processing::hysteresis* library. Overview of its functionality:

1. **Initialization**

The parameters `HYSTERESIS` and `Tmin` are received via the **INIT** event input. After successful initialization, **INITO** is sent.

1. **Signal Processing**

- A new value is received via the **I** adapter (event **E1** with the corresponding data value **D1**).
- The function block compares the new value with the currently stored (latched) value, taking the hysteresis band into account:
- A change is only accepted if the difference between the new value and the old value is greater than `HYSTERESIS`.
- Additionally, the time elapsed since the last event output must be at least `Tmin`. Only when both conditions are met is the new value accepted and output via the **Q** adapter (event **E1** and data **D1**).

1. **Output**

The currently valid latched value is provided via the **Q** adapter. An event is sent to **Q.E1** for every valid state change.

Technical Features

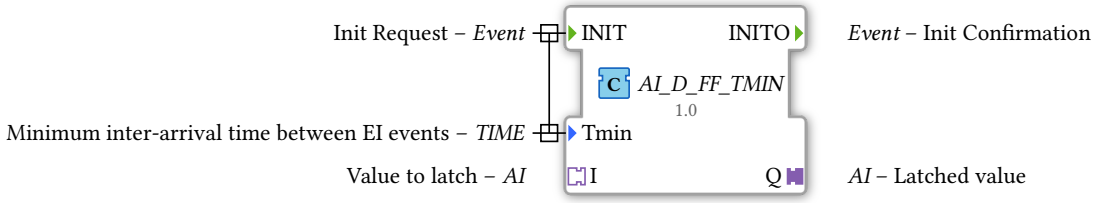
- **Hysteresis** – Suppresses noise and rapid fluctuations by only accepting a change if it exceeds the hysteresis band.
- **Minimum Time Between Events (Tmin)** – Prevents overly frequent outputs (e.g., due to high-frequency signals or bouncing). Events are only released after a period of `Tmin` has elapsed since the last event.
- **Adapter-Based Interface** – Input and output are handled via unidirectional adapters, allowing for flexible integration with other components.

State Overview

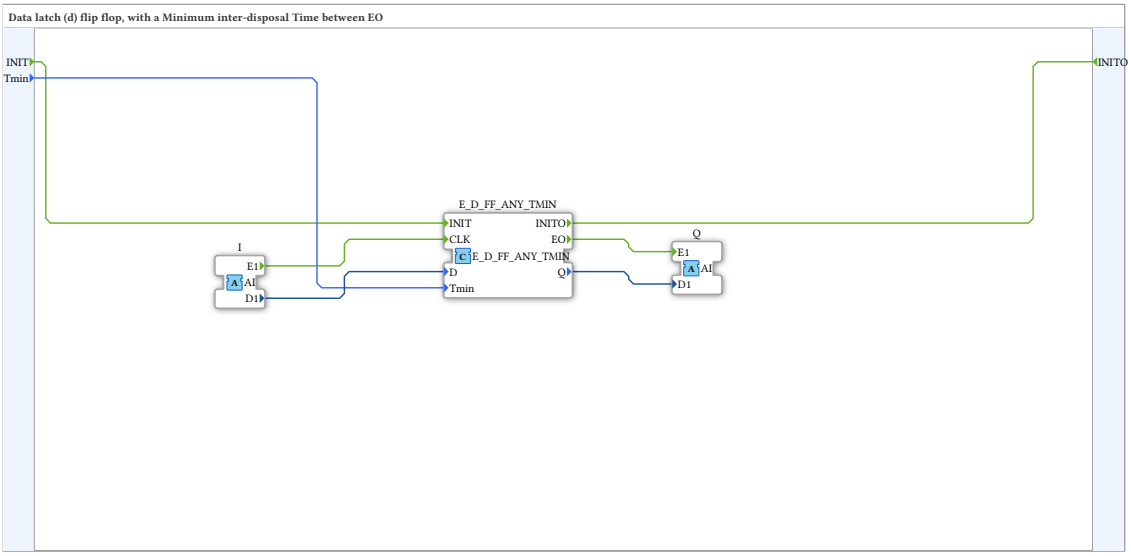
The component does not have explicitly named states. The internal flip-flop operates as a bistable element with two stable states (high/low or the last valid value). State transitions are controlled by the hysteresis and timing conditions.

Application Scenarios

- **Sensor Value Debouncing** – Smoothing of analog or digital input signals (e.g., temperature, pressure, level) when thresholds are exceeded.
- **Noise Peak Filtering** – Prevention of false triggers caused by short-term disturbances.
- **Time-controlled signal monitoring** – When changes should only be reported at specific intervals (e.g., for logging or update rates).
- **Interface decoupling** – Used as a stabilized intermediate between a fast signal transmitter and a slow-moving actuator.



Comparison with similar components



Component	Key difference
E_D_FF (simple D flip-flop)	No hysteresis band, no minimum time – accepts every change immediately.
AI_D_FF_HYS (without Tmin)	Includes hysteresis, but no time limit for the output.
AI_D_FF_TMIN (without hysteresis)	Includes only the minimum time, but no hysteresis.
AI_D_FF_HYS_TMIN (this one)	Combines both filters: hysteresis and time limiting.

Conclusion

The **AI_D_FF_HYS_TMIN** is a versatile function block for robust signal conditioning. Its combination of hysteresis and minimum interval makes it ideal for applications requiring both noise-resistant and time-controlled state changes. The adapter-based interface facilitates integration into modular automation systems.

AI_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AI_D_FF_TMIN** implements a D flip-flop (data latch) with a minimum inter-disposal time between successive output events. It serves as an adapter-encapsulated component that receives an

asynchronously incoming data value via a socket, temporarily stores it during an active event, and passes it on via a plug. Output is only released again when the configured minimum time (T_{\text{min}}) has elapsed since the last output.

Interface Structure

Event Inputs

Name	Type	With Variable	Comment
`INIT`	EInit	`Tmin`	Initialization Request

Event Outputs

Label	Type	With Variable	Comment	
`INITO`	EInit	–	Initialization Confirmation	

Data Inputs

Label	Type	Comment
`Tmin`	TIME	Minimum time interval between two EO events

Data Outputs

This function block does not have its own data outputs; output is exclusively via the adapter `Q`.

Adapter

Name	Type (Adapter)	Direction	Comment
`I`	`adapter::types::unidirectional::AI`	Socket	Input data for latching
`Q`	`adapter::types::unidirectional::AI`	Plug	Latched Output Value

Functionality

This function block encapsulates the internal function block `E_D_FF_ANY_TMIN`, which implements the actual D flip-flop with timing control. The interconnection is as follows:

- The initialization event `INIT` is passed to the internal function block along with the parameter `Tmin`.
- A data latch is triggered by an event on socket `I` (adapter event `I.E1`). This event serves as the clock signal (`CLK`) for the flip-flop.
- The current data value of `I.D1` is taken at each clock cycle and made available at the output of the internal function block.
- The internal function block generates an event at output `EO`, which is passed on via the adapter `Q` as `Q.E1`.
- There must be at least `EO` time between two consecutive events. If another clock cycle occurs during this lock time, the data value is latched, but the output is only released after the lock time has expired.
- The event `INITO` confirms the completion of the initialization process.

Technical Features

- **Adapter Interface:** Input and output are handled via unidirectional adapters of type `AI`. These enable loose coupling and easy reuse of the function block in different environments.
- **Minimum Output Time:** The parameter `Tmin` allows for targeted limitation of the event rate at the output. This prevents downstream components from being overloaded by excessively rapid event sequences.
- **Initialization Required:** Before first use, the function block must be initialized via `INIT`, as the internal state is set and `Tmin` is adopted during this phase.

State Overview

The function block does not have an explicitly visible state machine; the timing behavior is entirely controlled by the internal function block `E_D_FF_ANY_TMIN`. The function block essentially goes through the following phases:

1. **Initialization** – After receiving `INIT`, the internal function block is configured.
2. **Waiting for Clock** – The function block waits for an event at socket `I`.
3. **Latching** – Upon receiving a clock signal, the data value is acquired and an output event is generated.
4. **Lockout Phase** – After the output, any further output event is delayed for the duration of `Tmin`.
5. **Ready** – After the lockout period expires, another clock signal can be processed.

Application Scenarios

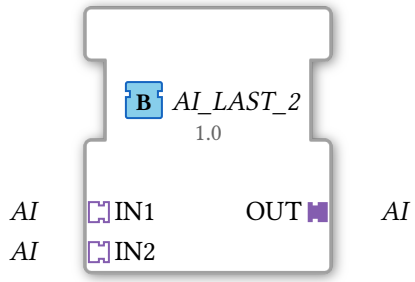
- **Sensor Data Acquisition:** An asynchronously operating sensor provides measured values that should only be transmitted to a control system at a defined minimum interval (e.g., temperature measurement with debouncing).
- **Buffering of Time-Critical Signals:** In automation applications where downstream processing modules tolerate a limited event rate, this module is used as a "rate limiter."
- **Synchronization:** This module can be used to synchronize cyclic processes by limiting the maximum update rate of an output signal.

Comparison with Similar Modules

Module	Description	Difference to AI_D_FF_TMIN
`E_D_FF`	Simple D flip-flop without a time limit	No minimum time between output events
`E_D_FF_ANY`	D flip-flop for arbitrary data types	Also without time control
`AI_D_FF`	D-Flip-Flop with Adapter Interface	Missing `Tmin` Option
`E_CYCLE`	Clock Generator with Adjustable Period	Generates Periodic Events, No Latch

The `AI_D_FF_TMIN` combines the functionality of an adapter-encapsulated flip-flop with a freely configurable output lock – a combination not found in standard flip-flops.

Conclusion



AI_D_FF_TMIN` offers a compact solution for buffering and time-controlled data transmission via adapter interfaces. The integrated minimum output time protects downstream components from overload and enables robust signal processing in industrial control systems. Thanks to its modular adapter interface, the component can be flexibly integrated into a wide variety of 4diac networks.

AI_LAST_2

Introduction

The AI_LAST_2 function block merges two same-type INT adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: INT adapter (unidirectional) - first signal source
- **IN2**: INT adapter (unidirectional) - second signal source

Output adapter (Plug):

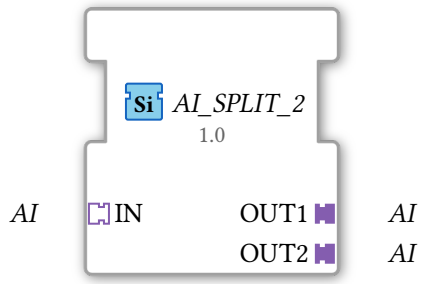
- **OUT**: INT adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid INT signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same INT value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AI_LAST_2 is the inverse of AI_SPLIT_2: AI_SPLIT_2 distributes 1 input to 2 outputs, AI_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use AX_AE_MERGE instead, which merges only the event without altering the data value.

AI_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The AI_SPLIT_2 function block is used to distribute an analog input signal (AI) to two identical analog outputs. It is designed as a generic function block and allows for flexible further processing of the signal in two independent paths.

Interface Structure

The function block does not have event or data inputs/outputs in the traditional sense, but communicates exclusively via adapter interfaces of type `adapter::types::unidirectional::AI`.

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AI	Input (Socket)	Receives an analog input signal.
OUT1	adapter::types::unidirectional::AI	Output (Plug)	Passes the signal present at IN unchanged.
OUT2	adapter::types::unidirectional::AI	Output (Plug)	Passes the signal present at IN unchanged.

Functionality

The module passes the analog signal (AI) received via socket `IN` simultaneously to both outputs (`OUT1` and `OUT2`). No signal processing or modification takes place. The partitioning is purely passive and takes effect immediately. The adapters ensure the necessary interface compatibility.

Technical Features

- **Generic Structure**: The function block is implemented as a generic FB (`GEN_AI_SPLIT`) and can be used with various AI adapters that conform to the unidirectional AI protocol.

- **No State Logic**: There is no ECC (Execution Control Chart), therefore the behavior is purely combinatorial.
- **Platform Independence**: The function block is specified according to IEC 61499-2 and can be used in environments that support the adapter concept.

State Overview

The function block has no internal state behavior. The outputs follow the input signal directly and without delay.

Application Scenarios

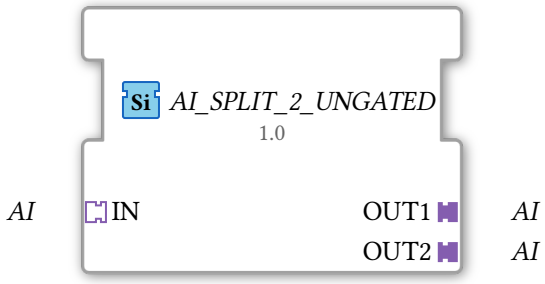
- **Signal Distribution**: A single analog sensor (e.g., pressure sensor, temperature sensor) is to be evaluated by two independent control components.
- **Redundancy**: Splitting a signal for parallel monitoring and control paths.
- **Simulation**: Generating a second identical signal channel for testing or analysis purposes.

Comparison with similar function blocks

- **AI_SPLIT_3**: Extended to three outputs.
- **AI_SELECT**: Selects one of several inputs instead of distributing them.
- **AI_MERGE**: Combines multiple AI signals into one (e.g., average).

AI_SPLIT_2 is specialized for simple 1:2 distribution without logic or configuration.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AI_SPLIT_2 is a simple yet useful function block for passively splitting an analog input signal. Its generic adapter approach makes it flexible and facilitates the modular structuring of applications according to IEC 61499.

AI_SPLIT_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_SPLIT_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

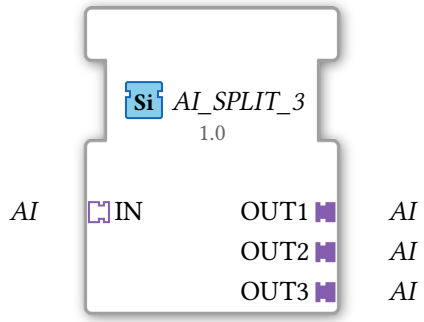
- **AI_SELECT**: Selects one of several inputs instead of distributing them.
- **AI_MERGE**: Combines multiple AI signals into one (e.g., average).

AI_SPLIT_2_UNGATED is specialized for simple 1:2 distribution without logic or configuration.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AI_SPLIT_2_UNGATED is a simple yet useful function block for passively splitting an analog input signal. Its generic adapter approach makes it flexible and facilitates the modular structuring of applications according to IEC 61499.

AI_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_SPLIT_3** is a generic function block for duplicating an analog input signal (AI). It splits an incoming AI signal into three separate, identical output signals. The function block is entirely defined via adapters of type `AI` and operates purely in a data flow-oriented manner without its own event or data point interfaces.

Interface Structure

The function block does not offer any direct event or data inputs/outputs. All communication takes place via **adapters**.

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

No direct data inputs – the AI signal is received via the socket adapter `IN`.

Data Outputs

No direct data outputs – the three identical AI signals are provided via the plug adapters `OUT1`, `OUT2`, and `OUT3`.

Adapters

Direction	Designation	Type	Description
Socket	`IN`	`ADAPTER_AI`	Incoming analog signal (source)
Plug	`OUT1`	`ADAPTER_AI`	First output – identical to the input signal
Plug	`OUT2`	`ADAPTER_AI`	Second output – identical to the input signal
Plug	`OUT3`	`ADAPTER_AI`	Third output – identical to the input signal

The adapters are of type `adapter::types::unidirectional::AI`. The component is generic, meaning that the specific data structure of the AI signal (e.g., value, unit, status) is only defined during instantiation by the connected adapters. ...|ADAPTER_AI` | qzmsdocs00009qz |

Functionality

The functional block forwards the analog signal received via socket `IN` unchanged and simultaneously to all three plug adapters `OUT1`, `OUT2`, and `OUT3`. No signal transformation, amplification, or delay takes place. The component functions purely as a **1-to-3 splitter**.

Since no events or state machines are present, the signal is passed purely via data flow. As soon as a new AI signal is present at `IN`, it is available at all three outputs.

Technical Features

- **Generic Function Block:** The function block is identified as `eclipse4diac::core::GenericClassName` using `'GEN_AI_SPLIT'`. This allows it to be used in various applications for different AI data types without requiring modification of the function block itself.
- **Pure Adapter Interface:** No direct event or data inputs/outputs are required. All data transmission occurs via the adapters, enabling flexible coupling with other function blocks.
- **No State Logic:** The function block does not have its own state machine (ECC) – its functionality is purely data flow-based and therefore very lightweight.

State Overview

The function block has **no** state machine or internal states. Signals are passed directly and without delay. Therefore, a state overview is not required.

Application Scenarios

- **Signal Distribution in Automation Systems:** An analog measured value (e.g., pressure sensor, temperature) is to be transmitted to multiple control or monitoring units.
- **Redundancy and Parallel Processing:** The same AI signal is required in parallel for different algorithms (e.g., control, alarming, logging).
- **Test Environments:** A simulated analog value can be distributed simultaneously to multiple components under test.

Comparison with Similar Components

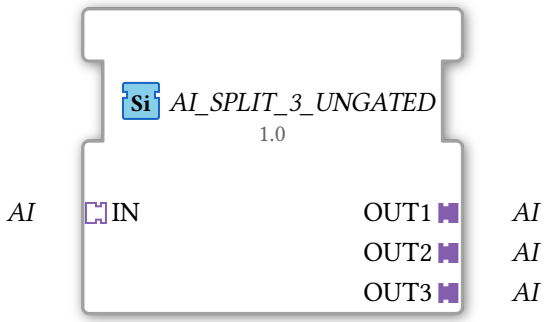
- **AI_SPLIT_2:** Distributes the input signal to two outputs instead of three.
- **AI_SPLIT_4 / AI_SPLIT_N:** Extended versions with four or more outputs (if available).
- **AI_SELECT:** Selects one input from multiple inputs instead of duplicating a signal.
- **AI_MERGE:** Combines multiple AI inputs into one output (counterpart to the splitter).

All split blocks share the common feature of passing the input signal to all outputs without modification. The AI_SPLIT_3 represents a typical 3-way split.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The **AI_SPLIT_3** is a simple yet effective block for multiplying an analog signal to three outputs. Its generic nature and the use of adapters allow it to integrate seamlessly into adapter-based 4diac applications. It is ideally suited for applications where an AI value needs to be distributed to multiple devices without requiring additional logic or configuration.

AI_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_SPLIT_4** is a generic block that splits a unidirectional analog input (AI) into four separate analog outputs. It serves as a signal distributor for analog signals and allows a single AI signal to be passed on to various subsequent blocks. The block is entirely adapter-based and has no built-in event or data interfaces. It is available under the Eclipse Public License 2.0.

Interface Structure

Event Inputs

- None

Event Outputs

- None

Data Inputs

- None

Data Outputs

- None

Adapters

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AI`	Input of the analog signal to be distributed
Plug (Output)	`OUT1`	`adapter::types::unidirectional::AI`	First output (copy of the input signal)
Plug (Output)	`OUT2`	`adapter::types::unidirectional::AI`	Second output (copy of the input signal)
Plug (Output)	`OUT3`	`adapter::types::unidirectional::AI`	Third output (copy of the input signal)
Plug (output)	`OUT4`	`adapter::types::unidirectional::AI`	Fourth output (copy of the input signal)

Functionality

This module provides a simple 1:4 distribution of an analog signal. The signal present at adapter `IN` is passed unchanged to all four output adapters (`OUT1` … `OUT4`). No scaling, filtering, or conversion takes place – the signal is copied 1:1 at the fieldbus level. The number of channels is fixed at four.

Technical Features

- **Pure Adapter Block**: The function block contains no event or data interfaces; all communication takes place via adapters.
- **Generic Type**: The block is identified as generic via the attribute `GenericClassName` (`'GEN_AI_SPLIT'`). A specific type can be derived from this in the 4diac IDE.
- **Unidirectional**: The adapter type used, `unidirectional::AI`, only transmits data in one direction (from the socket to the plugs).
- **No State Machine**: Since there are no events, there is no ECC (Execution Control Chart). The function block is purely data flow-oriented.

State Overview

The function block does not have a state machine – it is event-free and continuously passes the input signal to all outputs. Therefore, a state overview is not available.

Application Scenarios

- **Analog Signal Distribution**: A single sensor value (e.g., temperature, pressure, fill level) is to be sent to multiple control logics or visualization components simultaneously.

- **Redundancy or Monitoring**: The signal is forwarded in parallel to a main controller and an independent monitoring module.
- **Decoupling of Subsystems**: In a modular control system, different subsystems can receive the same analog value without requiring multiple access to the sensor.

Comparison with Similar Modules

- **AI_SPLIT_2 / AI_SPLIT_8**: Similar modules with 2 or 8 outputs, respectively. The choice depends on the required number of parallel signals.
- **AI_SELECT** or **AI_MUX**: These modules select one input from several, while the AI_SPLIT multiplies the input signal.
- **Standard Adapter Split**: Some libraries offer generic split function blocks, but these often require additional event or data interfaces. The AI_SPLIT_4, with its pure adapter approach, is particularly easy to integrate into adapter chains.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AI_SPLIT_4** function block is a specialized yet easy-to-use function block for multiplying analog signals. Thanks to its pure adapter interface, it can be seamlessly integrated into 4diac projects without additional event logic. It is particularly suitable for modular and scalable automation solutions where a single measured value needs to be distributed to multiple devices.

AI_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_SPLIT_5** is used to distribute an incoming analog signal (AI) to five identical outputs. It is a generic function block specifically designed for splitting an analog value into multiple parallel paths. It is implemented using unidirectional adapters of type `AI`.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No direct data inputs available. Signal transmission occurs exclusively via the adapter input.

Data Outputs

No direct data outputs available. Signal transmission occurs exclusively via the adapter outputs.

Adapter

Direction	Name	Type	Description
Socket	IN	`adapter::types::unidirectional::AI`	Receives the incoming analog signal.
Plug	OUT1	`adapter::types::unidirectional::AI`	First output, provides the same signal as the input.
Plug	OUT2	`adapter::types::unidirectional::AI`	Second output, provides the same signal as the input.
Plug	OUT3	`adapter::types::unidirectional::AI`	Third output, provides the same signal as the input.
Plug	OUT4	`adapter::types::unidirectional::AI`	Fourth output provides the same signal as IN.
Plug	OUT5	`adapter::types::unidirectional::AI`	Fifth output provides the same signal as IN.

Functionality

The function block forwards the analog signal present at the adapter input *IN* unchanged to all five adapter outputs *OUT1* to *OUT5*. No signal processing or buffering takes place; the distribution is purely topological at the connection level. This makes the function block ideal for distributing a single analog signal to multiple subsequent functions or devices without requiring any duplication at the application level.

Technical Features

- **Generic Type**: The function block is implemented as a generic function block (`GEN_AI_SPLIT`) and can be adapted to different analog signal types by assigning appropriate type codes.
- **Unidirectional Adapters**: All adapters are unidirectional, meaning data flows only from the input to the outputs.
- **No Internal State Behavior**: The function block (FB) does not have its own state model (ECC) because it operates purely combinatorially.
- **Scalability**: The function block is designed for five outputs. For other numbers, similar function blocks (e.g., AI_SPLIT_2, AI_SPLIT_3) can be used or created by adapting the generic pattern.

State Overview

The FB does not have an explicit state diagram. Since no events are processed, the behavior is static: the signal at the input is permanently passed through to the outputs. Initialization or special behavior during commissioning is not required.

Application Scenarios

- **Distribution of a Measured Value**: An analog sensor (e.g., temperature, pressure) provides a value that must be transmitted in parallel to several control, monitoring, or visualization components.
- **Parallel Processing**: In a control application, the same analog value is processed differently in different branches (e.g., in both a PID controller and a limit value monitor).
- **Redundancy**: The signal is sent to multiple independent evaluation units to ensure fault tolerance.

Comparison with Similar Function Blocks

- **AI_SPLIT_2, AI_SPLIT_3, AI_SPLIT_N**: These function blocks split an analog signal to a different number of outputs. AI_SPLIT_5 is specifically optimized for five outputs.
- **Analog Splitters in Other Libraries**: Often, such functions are implemented using adapter coupling or data copiers. AI_SPLIT_5 offers a clean, reusable structure within the 4diac framework.
- **Difference to Data-Event-Based Splitters**: Since the function block does not use events, it is purely signal-flow oriented and requires no synchronization or sequence control.

AI_SPLIT_5 is not a data-event-based splitter.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AI_SPLIT_5 is a simple yet useful function block for duplicating an analog signal. Its generic nature and clear adapter interface make it an ideal building block for modular automation solutions where an analog value is needed multiple times. The lack of event-driven control reduces complexity and enables direct signal transmission without time delays.

No event outputs available.

Data Inputs

No direct data inputs available. Signal transmission occurs exclusively via the adapter input.

Data Outputs

No direct data outputs available. Signal transmission occurs exclusively via the adapter outputs.

Adapter

Direction	Name	Type	Description
Socket	IN	`adapter::types::unidirectional::AI`	Receives the incoming analog signal.
Plug	OUT1	`adapter::types::unidirectional::AI`	First output, provides the same signal as the input.
Plug	OUT2	`adapter::types::unidirectional::AI`	Second output, provides the same signal as the input.
Plug	OUT3	`adapter::types::unidirectional::AI`	Third output, provides the same signal as the input.
Plug	OUT4	`adapter::types::unidirectional::AI`	Fourth output provides the same signal as IN.
Plug	OUT5	`adapter::types::unidirectional::AI`	Fifth output provides the same signal as IN.

Functionality

The function block forwards the analog signal present at the adapter input *IN* unchanged to all five adapter outputs *OUT1* to *OUT5*. No signal processing or buffering takes place; the distribution is purely topological at the connection level. This makes the function block ideal for distributing a single analog signal to multiple subsequent functions or devices without requiring any duplication at the application level.

Technical Features

- **Generic Type**: The function block is implemented as a generic function block (`GEN_AI_SPLIT`) and can be adapted to different analog signal types by assigning appropriate type codes.
- **Unidirectional Adapters**: All adapters are unidirectional, meaning data flows only from the input to the outputs.
- **No Internal State Behavior**: The function block (FB) does not have its own state model (ECC) because it operates purely combinatorially.
- **Scalability**: The function block is designed for five outputs. For other numbers, similar function blocks (e.g., AI_SPLIT_2, AI_SPLIT_3) can be used or created by adapting the generic pattern.

State Overview

The FB does not have an explicit state diagram. Since no events are processed, the behavior is static: the signal at the input is permanently passed through to the outputs. Initialization or special behavior during commissioning is not required.

Application Scenarios

- **Distribution of a Measured Value**: An analog sensor (e.g., temperature, pressure) provides a value that must be transmitted in parallel to several control, monitoring, or visualization components.
- **Parallel Processing**: In a control application, the same analog value is processed differently in different branches (e.g., in both a PID controller and a limit value monitor).
- **Redundancy**: The signal is sent to multiple independent evaluation units to ensure fault tolerance.

Comparison with Similar Function Blocks

- **AI_SPLIT_2, AI_SPLIT_3, AI_SPLIT_N**: These function blocks split an analog signal to a different number of outputs. AI_SPLIT_5_UNGATED is specifically optimized for five outputs.
- **Analog Splitters in Other Libraries**: Often, such functions are implemented using adapter coupling or data copiers. AI_SPLIT_5_UNGATED offers a clean, reusable structure within the 4diac framework.
- **Difference to Data-Event-Based Splitters**: Since the function block does not use events, it is purely signal-flow oriented and requires no synchronization or sequence control.

AI_SPLIT_5_UNGATED is not a data-event-based splitter.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The AI_SPLIT_5_UNGATED is a simple yet useful function block for duplicating an analog signal. Its generic nature and clear adapter interface make it an ideal building block for modular automation solutions where an analog value is needed multiple times. The lack of event-driven control reduces complexity and enables direct signal transmission without time delays.

AI_SPLIT_6

Introduction

The function block **AI_SPLIT_6** serves as a generic splitter that distributes an analog input value (AI) to six identical outputs. It implements a 1:6 distribution of an AI adapter without modifying any data or events. The block is defined as a generic FB (GenericClassName: `GEN_AI_SPLIT`) and operates purely on an adapter basis.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Direction	Name	Type	Description
Input (Socket)	IN	`adapter::types::unidirectional::AI`	Single Analog Input Adapter (Source)
Output (Plug)	OUT1	`adapter::types::unidirectional::AI`	First Output (1:1 pass-through from IN)
Output (Plug)	OUT2	`adapter::types::unidirectional::AI`	Second Output

Output (Plug)	OUT3	`adapter::types::unidirectional::AI`	Third Output
Output (Plug)	OUT4	`adapter::types::unidirectional::AI`	Fourth Output
Output (Plug)	OUT5	`adapter::types::unidirectional::AI`	Fifth Output
Output (Plug)	OUT6	`adapter::types::unidirectional::AI`	Sixth Output

Functionality

This function block has no internal logic or state machines. It functions as a passive splitter: The AI adapter connected to socket **IN** is duplicated unchanged to all six plug outputs **OUT1** to **OUT6**. Changes to the AI value (e.g., measured value or status) at the source are immediately and simultaneously visible at all outputs.

Technical Features

- **Generic Function Block**: The function block is marked as `eclipse4diac::core::GenericClassName`. This allows it to be parameterized or instantiated depending on the runtime environment without changing its basic splitter function.
- **Pure Adapter Coupling**: Neither events nor data port variables are used; only unidirectional adapters of type `adapter::types::unidirectional::AI` are employed. This reduces overhead and enables direct interconnection with other AI adapter blocks.
- **No States**: Since no ECC (Execution Control Chart) is present, the function block requires no algorithms or state transitions. The routing is purely structural.

State Overview

The function block does not have a state machine (ECC) and does not perform any active operations. There are no distinguishable operating states.

Application Scenarios

- **Distribution of an Analog Sensor Signal**: A single analog input (e.g., a 4-20 mA transmitter) is to be passed on in parallel to multiple control functions or display units.
- **Redundancy / Plausibility Check**: The same measured value is routed to several parallel evaluation blocks, which perform tasks such as averaging or error detection.
- **Simulation and Testing**: A simulated AI adapter is distributed across multiple test blocks to verify system behavior under load.

Comparison with Similar Blocks

- **AI_SPLIT_2 / AI_SPLIT_4**: These blocks split one AI input into two or four outputs, respectively. **AI_SPLIT_6** represents the variant with six outputs. All splitters function identically and differ only in the number of output adapters.
- **AI_DUPLICATE (hypothetical)**: A block that duplicates the value for copying purposes, but usually uses data ports. AI_SPLIT_6, on the other hand, uses adapters exclusively, allowing direct coupling without additional event control.
- `AI_SPLIT_6_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AI_SPLIT_6** is a minimal yet useful component for distributing analog adapter signals in the 4diac IDE. Its generic definition and pure adapter interface make it particularly suitable for architectures requiring loose coupling and easy extensibility. The distribution across six outputs enables flexible multiple use of a single analog input value.

AI_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_SPLIT_7** is used to distribute a single analog input (AI) to seven identical analog outputs. It is a generic function block that passes the incoming analog value unchanged to all seven output adapters. This allows multiple devices to be powered from a single signal source without having to acquire or duplicate the signal multiple times.

Interface Structure

Event Inputs

The function block has no event inputs. Data is passed exclusively via adapters.

Event Outputs

There are no event outputs.

Data Inputs

Direct data inputs are not defined. The analog value is read exclusively via the **IN** (socket) adapter.

Data Outputs

Direct data outputs are not available. The analog values are output via the seven adapters **OUT1** to **OUT7** (plugs).

Adapters

- **IN** (Socket): Type `adapter::types::unidirectional::AI` – Input for the analog signal.
- **OUT1** to **OUT7** (plugs): Type `adapter::types::unidirectional::AI` – Seven outputs that forward the incoming value identically.

Technical Features

AI_SPLIT_7 operates as a pure data distributor. An analog value present at the **IN** adapter is copied to all seven output adapters (**OUT1** to **OUT7**) without delay or transformation. This ensures that all connected components receive the same analog value. The internal logic is designed for unidirectional data transmission.

State Overview

- **Generic Function Block:** The function block is implemented as a generic type (`GEN_AI_SPLIT`) and can be flexibly integrated into various applications.
- **Adapter-Based:** The interfaces are implemented as IEC 61499 adapters, enabling loose coupling between function blocks.

- **No Event Control:** Since no events are used, data transmission occurs exclusively via the adapter connections and is driven by the runtime environment.

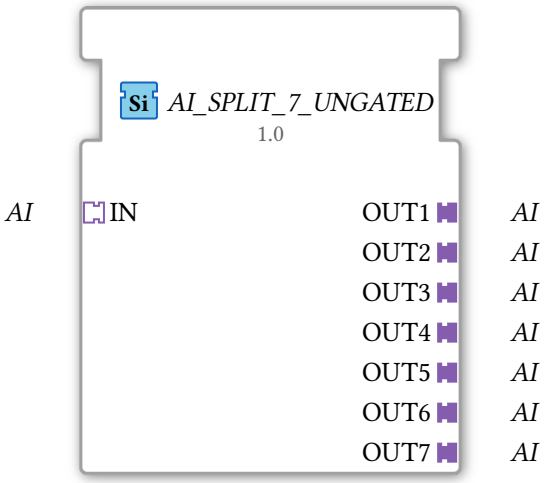
Application Scenarios

The function block has no explicit states because it contains no sequential or event-driven logic. It operates continuously as a pure signal distributor.

Comparison with Similar Function Blocks

- **Distributing a Sensor Signal:** An analog sensor (e.g., temperature, pressure) is to be transmitted to multiple control logics or displays.
- **Redundant Processing:** The same measured value is required in parallel by different algorithms or monitoring units.
- **AI_SPLIT_N:** Function blocks such as `AI_SPLIT_2` or `AI_SPLIT_3` differ only in the number of output adapters. `AI_SPLIT_7` offers the maximum distribution across seven channels.
- **Other splitters:** Unlike event-driven splitters (e.g., `E_SPLIT`), this function block operates purely analogously without event triggering. It is optimized for continuous analog signals.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AI_SPLIT_7 is a simple yet effective function block for multiplying analog signals in IEC 61499 systems. Through the use of adapters and its generic implementation, it can be easily integrated into various automation and control applications. Its clear, event-free structure makes it particularly suitable for unidirectional data transfer without additional control logic.

AI_SPLIT_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AI_SPLIT_7`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Change Detection
This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion
AI_SPLIT_7_UNGATED is a simple yet effective function block for multiplying analog signals in IEC 61499 systems. Through the use of adapters and its generic implementation, it can be easily integrated into

various automation and control applications. Its clear, event-free structure makes it particularly suitable for unidirectional data transfer without additional control logic.

AI_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_SPLIT_8** is used to distribute an analog input signal (type *AI*) to eight identical analog output signals. The block is implemented as a generic FB (GenericClassName: `GEN_AI_SPLIT`) and is used in the 4diac IDE to make a single analog signal usable multiple times.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Name	Type	Direction	Description
IN	`adapter::types::unidirectional::AS`	Socket (Input)	Receives the analog signal, which is distributed to all outputs.
OUT1 – OUT8	`adapter::types::unidirectional::AP`	Plug (Output)	Eight identical outputs that provide the signal present at the input.

Functionality

The FB has no processing logic of its own (no state machine, no ECC). The analog signal present at the adapter socket **IN** is passed directly and without delay to all eight adapter plugs (**OUT1** to **OUT8**). No signal conversion or amplification takes place – the signal is duplicated one-to-one.

Technical Features

- **Generic Function Block:** The function block is declared as a generic type (`GEN_AI_SPLIT`) and can therefore be parameterized with a specific analog data type at runtime.
- **Unidirectional Adapters:** All adapters used are unidirectional, meaning that data flows exclusively from the socket to the plugs.
- **No Event Control:** Distribution is eventless; an incoming signal is immediately forwarded to all outputs.

State Overview

The function block does not have an internal state machine (ECC). There are no defined states – the function block operates continuously and without its own behavior.

Application Scenarios

- **Signal Distribution:** An analog sensor signal (e.g., temperature, pressure) is to be sent to multiple control modules or monitoring units simultaneously.
- **Redundancy:** Multiple parallel evaluations of the same signal in different parts of a system.
- **Prototyping:** Quickly deploy a signal to multiple test points in a development or simulation environment.

Comparison with similar function blocks

- **AI_SPLIT_2, AI_SPLIT_4:** These function blocks distribute an analog signal to two or four outputs, respectively. The present function block offers a higher number of parallel connections with eight outputs.
- **DIO_SPLIT (digital):** A similar splitter for digital signals, but based on DI/DO adapter types. The AI_SPLIT_8 is specifically designed for analog signals.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AI_SPLIT_8** is a simple, generic function block for multiplying an analog signal. Its clear structure—one input, eight outputs, no events—makes it ideal for straightforward signal distribution in automation applications. Its generic nature allows for flexible adaptation to various analog data types.

AI_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AI_SPLIT_9** is a generic component that distributes a single analog input signal (adapter type `AI`) to nine identical outputs (OUT1 to OUT9). It serves as a signal distributor, allowing an AI signal to be used multiple times in a control application without having to link the source multiple times.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Direction	Name	Type	Description
Input (Socket)	`IN`	`adapter::types::unidirectional::AI`	Single analog input distributed to all outputs.
Output (Plug)	`OUT1`	`adapter::types::unidirectional::AI`	First outgoing AI channel.
Output (Plug)	`OUT2`	`adapter::types::unidirectional::AI`	Second outgoing AI channel.
Output (Plug)	`OUT3`	`adapter::types::unidirectional::AI`	Third outgoing AI channel.
Output (Plug)	`OUT4`	`adapter::types::unidirectional::AI`	Fourth outgoing AI channel.
Output (Plug)	`OUT5`	`adapter::types::unidirectional::AI`	Fifth outgoing AI channel.
Output (Plug)	`OUT6`	`adapter::types::unidirectional::AI`	Sixth outgoing AI channel.
Output (Plug)	`OUT7`	`adapter::types::unidirectional::AI`	Seventh outgoing AI channel.
Output (Plug)	`OUT8`	`adapter::types::unidirectional::AI`	Eighth outgoing AI channel.
Output (Plug)	`OUT9`	`adapter::types::unidirectional::AI`	Ninth outgoing AI channel.

Functionality

The module operates as a pure signal distributor: The AI value present at adapter socket `IN` is passed on unchanged and simultaneously to all nine adapter plugs `OUT1` … `OUT9`. No signal processing, scaling, or other manipulation takes place. The distribution is continuous and without internal state behavior – the output follows the input without delay.

Technical Features

- **Generic Block:** The function block is typed as `GEN_AI_SPLIT` and utilizes the generics mechanisms of Eclipse 4diac (`GenericClassName`, `TypeHash`). This allows for flexible use in type hierarchies and libraries.
- **Adapter-Based Interface:** Instead of individual data ports, adapters are used that provide an encapsulated, reusable interface for analog inputs (`AI`). This simplifies the interconnection concept in 4diac applications.
- **Zero Latency:** Since there is no internal logic or processes, signal transmission is instantaneous.

State Overview

The block does not have an internal state machine (no ECC). It operates purely on a data flow basis: The input value is continuously passed through to the outputs.

Application Scenarios

- **Signal Multiplication:** A single analog sensor (e.g., temperature, pressure) is to be evaluated in parallel across multiple function blocks.
- **Redundant Processing:** An AI signal is routed to multiple independent paths to enable failover or plausibility checks.
- **Modular Distribution:** In a large control application, an analog input signal is routed to various modules (e.g., control, monitoring, visualization).

Comparison with Similar Components

- **AI_SPLIT_2 / AI_SPLIT_4 / ...**: Analog components with 2 or 4 outputs, respectively. `AI_SPLIT_9` extends the concept to nine outputs and is therefore suitable for applications with many receivers.
- **AI_MERGE**: Combines multiple AI inputs into a single output – the opposite operation.
- **Direct Adapter Linking**: In 4diac, a single adapter port can theoretically be connected multiple times, but the explicit splitting with this function block is more documented and clearly structured.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AI_SPLIT_9** is a simple yet useful function block for signal multiplication of analog inputs in IEC 61499 applications. Its generic structure and adapter interface allow it to integrate seamlessly into the 4diac ecosystem and facilitate the structured routing of signals. Its use is recommended wherever an AI signal needs to be simultaneously passed to multiple processing units.

State Overview

The block does not have an internal state machine (no ECC). It operates purely on a data flow basis: The input value is continuously passed through to the outputs.

Application Scenarios

- **Signal Multiplication:** A single analog sensor (e.g., temperature, pressure) is to be evaluated in parallel across multiple function blocks.
- **Redundant Processing:** An AI signal is routed to multiple independent paths to enable failover or plausibility checks.
- **Modular Distribution:** In a large control application, an analog input signal is routed to various modules (e.g., control, monitoring, visualization).

Comparison with Similar Components

- **AI_SPLIT_2 / AI_SPLIT_4 / ...**: Analog components with 2 or 4 outputs, respectively. `AI_SPLIT_9_UNGATED` extends the concept to nine outputs and is therefore suitable for applications with many receivers.
- **AI_MERGE**: Combines multiple AI inputs into a single output – the opposite operation.
- **Direct Adapter Linking**: In 4diac, a single adapter port can theoretically be connected multiple times, but the explicit splitting with this function block is more documented and clearly structured.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **AI_SPLIT_9_UNGATED** is a simple yet useful function block for signal multiplication of analog inputs in IEC 61499 applications. Its generic structure and adapter interface allow it to integrate seamlessly into the 4diac ecosystem and facilitate the structured routing of signals. Its use is recommended wherever an AI signal needs to be simultaneously passed to multiple processing units.

ALI_D_FF

• – ○ • – ○ • – ○ •

Introduction

The **ALI_D_FF** function block implements a clock-controlled D flip-flop (data latch) via adapter interfaces. It stores a data value on the rising edge of a clock signal and outputs it until the next clock edge. This function block is suitable for synchronous data storage in event-driven automation environments.

Interface Structure

Event Inputs

- **I.E1** (via adapter I): Clock input – the data is stored on a rising edge.

Event Outputs

- **Q.E1** (via adapter Q): Confirmation of data storage – output after successful edge detection and value assignment.

Data Inputs

- **I.D1** (via adapter I): Data input – the value to be stored (any data type, depending on the adapter type `ALI`).

Data Outputs

- **Q.D1** (via adapter Q): Data output – the currently stored (latched) value.

Adapters

Name	Type	Direction	Description
I	`adapter::types::unidirectional::ALI`	Socket	Provides event and data input.
Q	`adapter::types::unidirectional::ALI`	Plug	Provides event and data output.

Functionality

The function block internally uses the standard function `E_D_FF_ANY` from the IEC 61499 library.

- On a rising edge at the event input **I.E1**, the current value of **I.D1** is transferred to the internal state.
- Subsequently, an event is generated at the output **Q.E1**, signaling that the new value is present at **Q.D1**.
- The data output **Q.D1** retains the stored value until a new rising edge occurs.

Technical Features

- **Adapter-based interface**: The function block does not have direct event/data inputs but uses two adapters (`I` and `Q`). This allows for flexible encapsulation of the connections and facilitates reuse in complex networks.
- **Internal Implementation**: The core of the function block is the FB `E_D_FF_ANY`, which operates independently of data type. The data type is determined by the adapters used.
- **Event-driven**: State changes occur exclusively upon events, allowing integration into event-driven processes.

State Overview

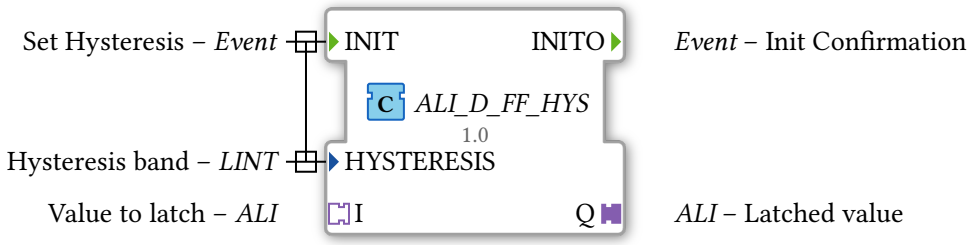
The FB has two logical states:

- **State 0**: Output `Q.D1` contains the last latched value, which can be, for example, logical 0.
- **State 1**: Output `Q.D1` contains a valid value other than 0 (provided the data type allows this).

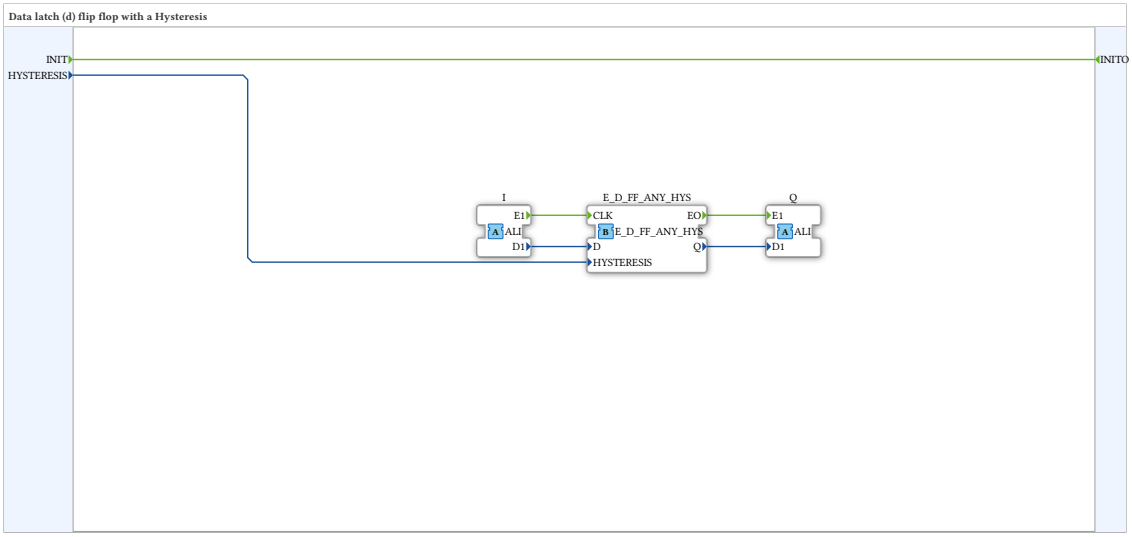
A state change occurs only on a rising edge of `I.E1`. Without a clock signal, the output remains stable.

Application Scenarios

- **Data Synchronization**: Buffering a sensor signal until the next clock cycle of a controller.
- **State Memory**: Maintaining a switching state in sequence controllers.
- **Feedback-Free Delay**: Temporarily storing values in data paths to avoid asynchronous concurrent execution.



Comparison with Similar Components



- **ALI_D_FF vs. Simple D-FF (e.g., `E_D_FF_ANY`)**: The ALI_D_FF encapsulates event and data connections in adapters, making it more modular and easier to integrate into predefined interfaces.
- **ALI_D_FF vs. RS Flip-Flop**: An RS flip-flop allows setting and resetting (asynchronously), while the D flip-flop operates purely clock-driven and does not offer direct set/reset inputs.
- **ALI_D_FF vs. T-Flip-Flop**: The T-FF toggles on every clock cycle, while the D-FF takes an external value.

Conclusion

The **ALI_D_FF** offers a clean, adapter-based solution for synchronous data storage. It combines the proven functionality of a D-flip-flop with the flexibility of IEC 61499 adapters. This makes it particularly suitable for modular, reusable automation components in distributed systems.

ALI_D_FF_HYS

• – ◦ • – ◦ • – ◦ •

Introduction

The **ALI_D_FF_HYS** function block implements a data latch (D flip-flop) with a hysteresis function. It serves for the stable and debounced transmission of a binary signal: An incoming data signal is received and output on a rising clock edge, with configurable hysteresis preventing small signal changes (noise) from causing unwanted output changes. The component is specifically designed for use with the unidirectional **ALI** adapter structure in IEC 61499 environments.

Interface Structure

Event Inputs

Event	Type	Comment
`INIT`	EInit	Sets the hysteresis value for the switching threshold.

Event Outputs

Event	Type	Comment
`INITO`	EInit	Confirmation of successful initialization.

Data Inputs

Variable	Type	Comment
`HYSTERESIS`	LINT	Hysteresis bandwidth (e.g., as an integer)

Data Outputs

No direct data outputs – output is via the adapter `Q`.

Adapters

Direction	Name	Type	Comment
Socket	`I`	`adapter::types::unidirectional::ALI`	Input value (data + clock)
Plug	`Q`	`adapter::types::unidirectional::ALI`	Output value (latched value)

The adapter `I` provides two signals:

- **`I.E1`** – Clock signal (event)
- **`I.D1`** – Data input (e.g., BOOL or numeric)

The adapter `Q` provides the latched value as **`Q.D1`**.

Functionality

The function block works internally with another function block **E_D_FF_ANY_HYS** (from the library `logiBUS::signalprocessing::hysteresis`), which implements the core logic. Overview of how it works:

1. **Initialization**

When the event `INIT` arrives, the value of `HYSTERESIS` is passed to the inner component, and the event is immediately acknowledged as `INITO`.

1. **Data Processing**

The event and data connections are directly connected between the adapters and the internal module:

- `I.E1` ⟶ **CLK** (Clock signal)
- `I.D1` ⟶ **D** (Input data)
- **Q** ⟶ `Q.D1` (Lagged output signal)

1. **Hysteresis Behavior**

At each clock cycle (`CLK`), the current data value `D` is evaluated. If `D` lies within the hysteresis band around the current output value `Q`, the output remains unchanged. If `D` exceeds the upper or lower threshold, the new value is adopted. This suppresses interference and ensures a clean, debounced signal.

Technical Features

- **Pure Adapter Communication**: The function block uses only unidirectional adapters (`ALI`) for event and data transmission. This makes it easy to integrate into modular, adapter-based architectures.
- **Indirect Hysteresis Implementation**: Hysteresis is not implemented directly in the function block body, but rather through the internal block `E_D_FF_ANY_HYS`. This allows for flexible reuse of the logic.
- **Immediate INIT Acknowledgement**: The `INIT` event is acknowledged immediately via a direct connection (`INIT → INITO`) without waiting for the hysteresis logic.
- **Hysteresis Parameter Type**: `HYSTERESIS` is defined as `LINT`, thus allowing large integer values.

State Overview

The function block itself has no visible states, as all state logic is encapsulated within the internal function block. Behavior of the D flip-flop with hysteresis:

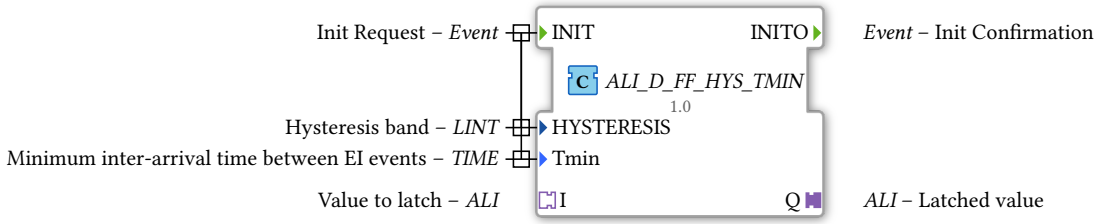
- **Idle State**: Output values remain stable as long as no clock signal is applied.
- **Clock Edge (Rising)**:
- If D > Q + HYSTERESIS ⟶ Q = D (Set)
- If D < Q - HYSTERESIS ⟶ Q = D (Reset)
- Otherwise ⟶ Q remains unchanged (hysteresis range)

Application Scenarios

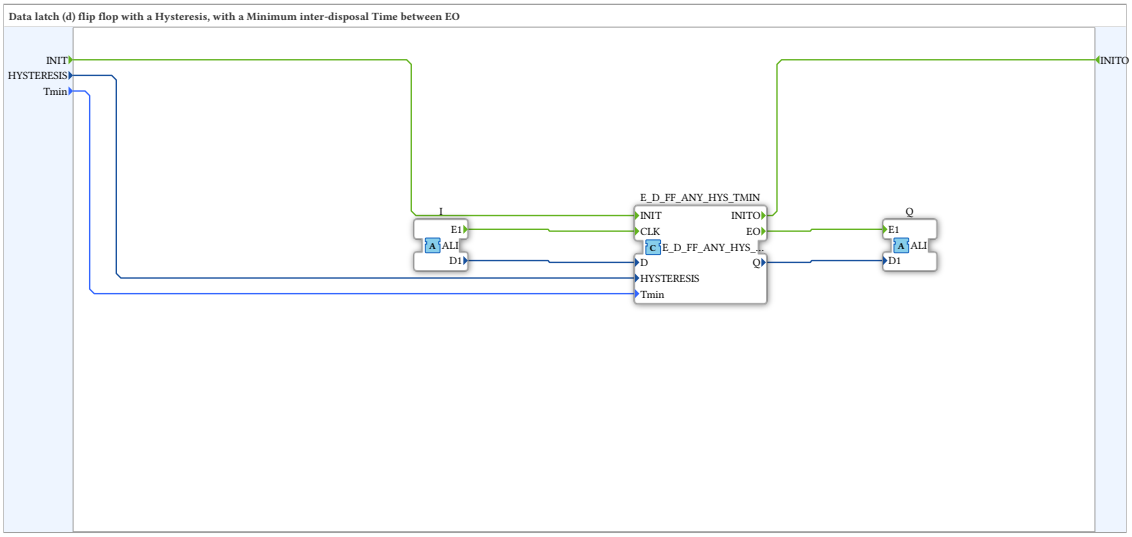
Typical applications for this function block include:

- **Debouncing of switch signals** in automation technology (e.g., limit switches, proximity sensors).
- **Signal conditioning in harsh environments** (agricultural technology, mechanical engineering) – the hysteresis prevents oscillations caused by vibrations or noise.
- **Basic building block for more complex logic** with adapter-based data transmission, e.g., as an input stage of a state machine.

Comparison with Similar Function Blocks



Function Block	Feature
ALI_D_FF (without hysteresis)	Simple D flip-flop without noise suppression
ALI_D_FF_HYS (this one)	D flip-flop with configurable hysteresis for noise filtering
Schmitt trigger function block	Similar function, but often with fixed thresholds
E_D_FF_ANY_HYS	Internal logic, generic type (no adapter format)



The advantage of **ALI_D_FF_HYS** lies in its direct adapter connection, enabling seamless integration into existing IEC 61499 adapter networks.

Conclusion

The **ALI_D_FF_HYS** function block offers a proven combination of a D flip-flop and adjustable hysteresis, packaged in a standards-compliant IEC 61499 adapter interface. It is particularly suitable for applications where signals must be processed reliably under real-world conditions (noise, bounce). The clear separation of initialization and data processing, as well as the use of a proven sub-component, makes it robust, maintainable and flexible in its application.

ALI_D_FF_HYS_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **ALI_D_FF_HYS_TMIN** implements a data-driven D flip-flop with an adjustable hysteresis width (threshold band) and a minimum waiting time between two consecutive output events. It is used for debouncing and stabilizing signal transitions in industrial automation, particularly when a signal should only be considered valid after it has left a defined tolerance range and a minimum time has elapsed since the last valid edge.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization request – sets the hysteresis width and the minimum time.

Event Outputs

Name	Type	Comment
INITO	EInit	Confirmation of successful initialization.

Data Inputs

Name	Type	Comment
HYSTERESIS	LINT	Hysteresis band as an integer value (LINT).
Tmin	TIME	Minimum time between two output events (Inter-Disposal Time).

Data Outputs

No direct data outputs available.

The function block outputs its status via the adapter **Q** (see Adapters).

Adapters

| Type | Name | Direction | Comment | | `adapter::types::unidirectional::ALI` | I | Socket | Input adapter – provides the signal to be received (event and data value). | | `adapter::types::unidirectional::ALI` | Q | Plug | Output adapter – outputs the last valid data value and an event. |

The adapter type `ALI` includes an event (E1) and a data value (D1) and is used for unidirectional communication between function blocks.

Functionality

The function block **ALI_D_FF_HYS_TMIN** is implemented as a composition and internally uses the function block `logiBUS::signalprocessing::hysteresis::E_D_FF_ANY_HYS_TMIN`. Its operation can be described as follows:

1. **Initialization** – The **INIT** event sets the **HYSTERESIS** and **Tmin** parameters. After successful initialization, **INITO** is triggered.
2. **Signal Acquisition** – Every event at socket **I** (event **I.E1**) is interpreted as a clock edge. The corresponding data value **I.D1** is only transferred to internal memory if it is outside the hysteresis band around the currently stored value (i.e., the change exceeds the hysteresis).
3. **Minimum Time Control** – After a valid value is acquired, output via plug **Q** (event **Q.E1** and value **Q.D1**) is only enabled after at least **Tmin** has elapsed since the last output event. This suppresses unwanted rapid signal changes.
4. **Signal Acquisition** – After a valid value is acquired, output via plug **Q** (event **Q.E1** and value **Q.D1**) is only enabled after at least **Tmin** has elapsed since the last output event. This suppresses unwanted rapid signal changes.
5. **Output** – Once the minimum time has elapsed, the new value is output via the output adapter **Q**. The function block then waits for the next input event.

Technical Features

- **Hysteresis Data Width** – The hysteresis is defined as a LINT (64-bit integer); this allows for the processing of very large value ranges.
- **Time Parameters** – The minimum inter-disposal time **Tmin** is specified as IEC-61499-`TIME` (e.g., `T#10ms`).
- **Adapter-Based Coupling** – The use of the adapters `ALI` allows loose coupling between signal-generating and signal-processing function blocks. The socket **I** receives the data, and the plug **Q** provides it.
- **Type of Dependency** – The function block is based on the internal FB `E_D_FF_ANY_HYS_TMIN`, which implements the actual hysteresis and timing logic. The outer function block merely encapsulates the adapter interface.

State Overview

The function block goes through the following states:

1. **INIT** – Waiting for initialization parameters.
2. **IDLE** – Ready; waiting for an event on socket **I**.
3. **SAMPLE** – An event has arrived; the data value is checked for exceeding the hysteresis.

- *Hysteresis violated:* The value is ignored, returning to **IDLE**.
- *Hysteresis satisfied:* Transition to state **WAIT_TMIN**.

1. **WAIT_TMIN** – The new value is saved; release is delayed by **Tmin**.

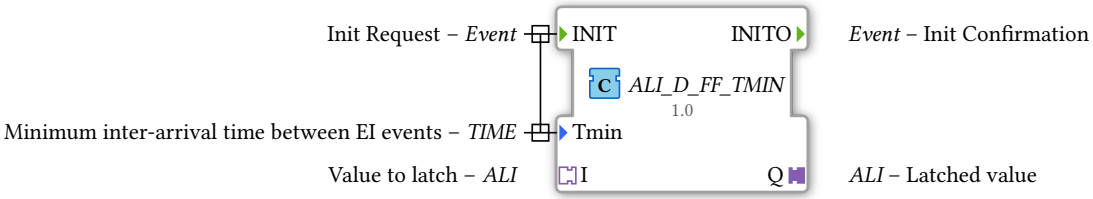
- After the time has elapsed, output is made via **Q**, and the data returns to **IDLE**.

A formal state machine is not visible via the XML interface, but it can be deduced from the behavior of the internal flip-flop.

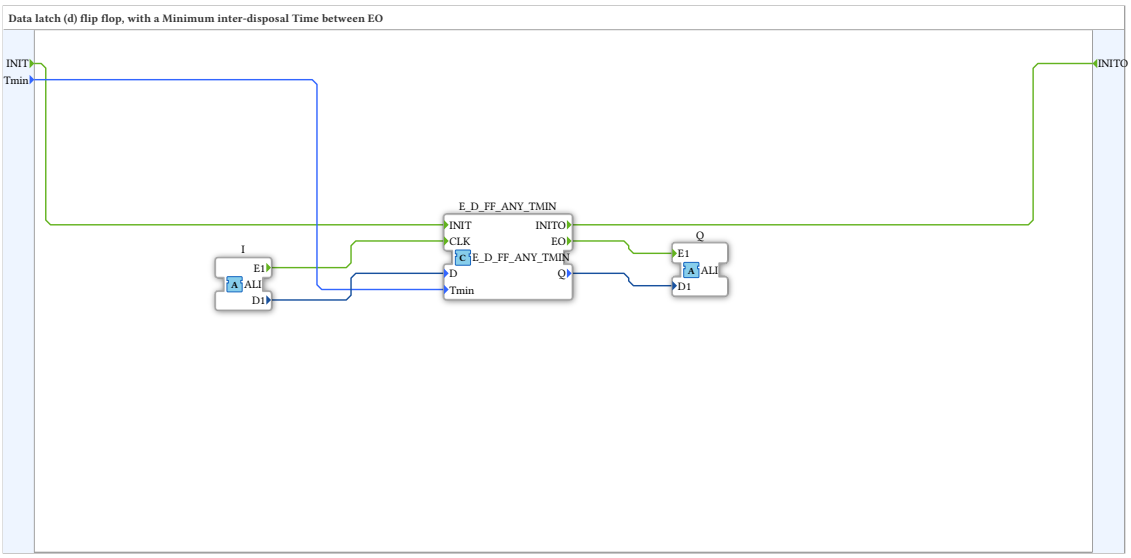
Application Scenarios

- **Sensor Value Smoothing** – A digital sensor (e.g., rotary encoder) delivers values that fluctuate briefly due to vibrations or noise. Hysteresis prevents small fluctuations from being interpreted as valid changes.
- **Button Debouncing** – For mechanical contacts, **Tmin** ensures that bouncing events within a specific time do not result in multiple output events.
- **Measurement Acquisition with Dead Time** – In dosing or positioning systems, the minimum time between two valid measurements must be maintained to avoid overloading the system dynamics.

Comparison with Similar Components



Component	Hysteresis	Minimum Time	Adapter Interface
`E_D_FF` (simple)	No	No	No (direct I/O)
`E_D_FF_HYS`	Yes	No	No
`ALI_D_FF_HYS_TMIN`	Yes	Yes	Yes (adapter usage)



The function block described here combines the advantages of hysteresis and minimum time intervals and, thanks to its adapter interface, is particularly well-suited for a modular, event-driven architecture according to IEC 61499.

Conclusion

The **ALI_D_FF_HYS_TMIN** module provides a robust solution for the stable acquisition of signals in harsh environments. The combination of hysteresis and minimal output time effectively suppresses both amplitude fluctuations and time bounces. Its adapter-based input and output capabilities make it flexible for use in complex automation networks.

ALI_D_FF_TMIN

• – ○ • – ○ • – ○ •

The function block **ALI_D_FF_TMIN** implements a data storage (D flip-flop) with an adapter-based input and output and a configurable minimum dwell time between output events. It serves to accept an incoming data value on a rising edge at the input and release it after a minimum time to avoid cyclical conditions or timing issues in communication.

Event	Type	With Variables	Comment
INIT	EInit	Tmin	Initialization request, sets the minimum dwell time
Event	Type	With Variables	Comment
–––––	––	–––––	–––––
INITO	EInit	–	Initialization Confirmation
Variable	Type	Comment	
–––––	–––	–––––	
Tmin	TIME	Minimum time between two output events (EO)	

No direct data outputs. The latched value is provided via the **Q-Adapter**.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

| Label | Type | Direction | Comment | | I | ALI (unidirectional) | Socket (Input) | Value to be transferred | | Q | ALI (unidirectional) | Plug (Output) | Stored value |

Functionality

The **ALI_D_FF_TMIN** encapsulates an internal function block of type `E_D_FF_ANY_TMIN`. Its functionality:

- Upon an event at the input adapter **I.E1** (rising edge), the data value **I.D1** is transferred.
- However, the output event **EO** is only triggered if at least the time **Tmin** has elapsed since the last **EO**.
- Initialization (INIT) sets the internal timer and prepares the function block.

The function block operates asynchronously; timing is controlled via the internal function block.

- The logic is completely outsourced to the internal function block `E_D_FF_ANY_TMIN`, which has its own state machine and timer.
- The **Tmin** time is set only once during INIT and remains valid for the entire lifetime.
- Adapters **I** (input) and **Q** (output) are unidirectional of type `ALI`; they transmit both events and data.
- The function block does not implement its own top-level behavior but delegates all functions.

Since the function block uses `E_D_FF_ANY_TMIN` internally, it implicitly has the following states:

1. **Initialized**: After INIT, ready for the first edge.
2. **Edge Received**: Value has been stored; the output will be sent after **Tmin**.
3. **Wait for Minimum Time**: No new EO (Event End) is possible until Tmin has expired.
4. **Ready**: After the waiting time has elapsed, the next EO can be triggered.

The exact state machine is located in the internal function block and is not shown here.

- **Data Backup in Time-Controlled Bus Systems**: Buffering of values at a clock signal, which may only be passed on at defined intervals.

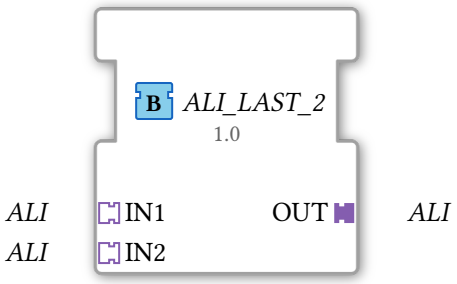
- **Signal Debouncing**: Prevents rapid switching on and off from resulting in numerous events at the logic level.
- **Sequential Processing with Minimum Interval**: Ensures that subsequent function blocks have sufficient processing time.

Function Block	Difference
`ALI_D_FF` (without TMIN)	No minimum time between output events, immediate forwarding on every edge.
`E_D_FF` (Standard-61499)	Direct event inputs and outputs, without adapters or timing.
`E_D_FF_ANY_TMIN`	Same functionality, but with dedicated data and event ports, not via adapters.

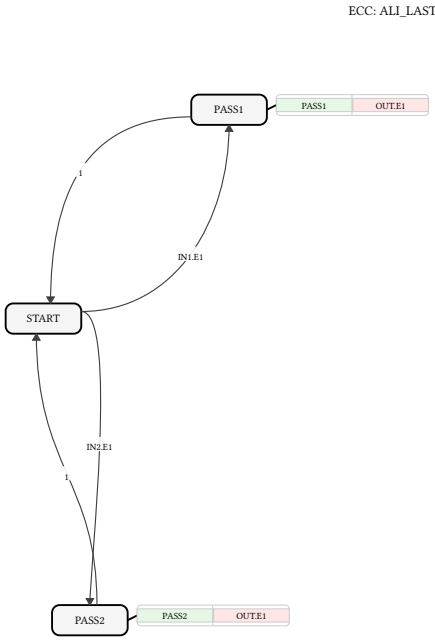
The **ALI_D_FF_TMIN** extends the adapter interface with convenient encapsulation and adds timing control, which is lacking in simple flip-flops.

The **ALI_D_FF_TMIN** is a useful component for applications that require delayed or timed data transmission via adapters. Its configurable minimum time between output events makes it particularly suitable for time-critical or debounced communication links. The internal implementation using a proven function block ensures robustness and reusability.

Technical Features



State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

ALI_LAST_2

Introduction

The ALI_LAST_2 function block merges two same-type LINT adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: LINT adapter (unidirectional) - first signal source
- **IN2**: LINT adapter (unidirectional) - second signal source

Output adapter (Plug):

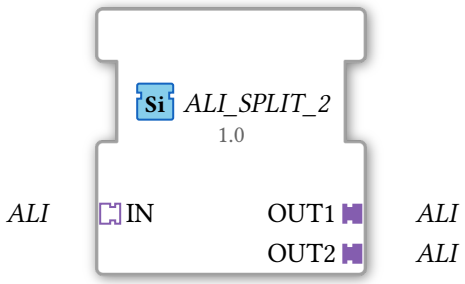
- **OUT**: LINT adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid LINT signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same LINT value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

ALI_LAST_2 is the inverse of `ALI_SPLIT_2`: ALI_SPLIT_2 distributes 1 input to 2 outputs, ALI_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

ALI_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The **ALI_SPLIT_2** function block serves as a generic distributor for a unidirectional ALI (Application Layer Interface) adapter. It copies all incoming data and events from a single input socket to two output plugs. This allows a signal or data source to be passed on to two independent receivers.

Interface Structure

Event Inputs

No event inputs are available. Data is passed solely via the adapter interface.

Event Outputs

No event outputs are available. Event control is handled via the adapter connections.

Data Inputs

No dedicated data inputs. All data is provided via the incoming adapter **IN**.

Data Outputs

No dedicated data outputs. The distributed data is provided via the two outgoing adapters **OUT1** and **OUT2**.

Adapters

Type	Name	Direction	Description
Socket	`IN`	Input	Unidirectional ALI adapter that receives incoming data/events.
Plug	`OUT1`	Output	First unidirectional ALI adapter to which the data/events are forwarded.
Plug	`OUT2`	Output	Second unidirectional ALI adapter to which the data/events are forwarded.

All adapters are of type `adapter::types::unidirectional::ALI`.

Functionality

The module implements a 1:2 split at the adapter level. As soon as data or events are present at socket **IN**, they are passed on unchanged and simultaneously to both plugs **OUT1** and **OUT2**. No buffering or processing of the data takes place – the module operates purely as a signal distributor.

Technical Features

- **Generic Module**: The attribute `eclipse4diac::core::GenericClassName` marks the module as a generic instance `GEN_ALI_SPLIT`. It can therefore be used with different ALI types or parameters, as long as the underlying adapter definition is compatible.
- **No State Management**: The module has no internal states or variables – its functionality is purely combinatorial.
- **Unidirectionality**: The adapters are defined as unidirectional, meaning data flows only from the input to the outputs; reverse communication is not supported.

State Overview

Since the module has no event inputs/outputs or internal states, there is no state machine. Data transmission is continuous and instantaneous.

Application Scenarios

- **Distributing a Sensor Signal**: An analog or digital ALI sensor is connected to two control units that need to access the measurement data independently.
- **Parallel Processing**: A data stream should be processed simultaneously by two different function blocks without requiring manual branching in the application.
- **Redundancy**: An application requires duplicate ALI communication to increase reliability.

Comparison with Similar Function Blocks

Function Block	Function	Difference
ALI_SPLIT_2	Distributes one ALI input to two ALI outputs.	–
ALI_SPLIT_3 (hypothetical)	Distributes to three outputs.	Higher number of outputs.
ALI_MERGE_2	Combines two ALI inputs into one ALI output.	Opposite function (Join).
ALI_FILTER	Passes on only specific data/events.	Contains filter logic.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

ALI_SPLIT_2 is a simple but essential function block for distributing unidirectional ALI interfaces. Its generic nature and lean implementation make it a universal tool in IEC 61499 component development when a signal or data stream needs to be passed to multiple subsequent blocks.

]

ALI_SPLIT_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_SPLIT_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The **ALI_SPLIT_2_UNGATED** function block serves as a generic distributor for a unidirectional ALI (Application Layer Interface) adapter. It copies all incoming data and events from a single input socket to two output plugs. This allows a signal or data source to be passed on to two independent receivers.

Interface Structure

Event Inputs

No event inputs are available. Data is passed solely via the adapter interface.

Event Outputs

No event outputs are available. Event control is handled via the adapter connections.

Data Inputs

No dedicated data inputs. All data is provided via the incoming adapter **IN**.

Data Outputs

No dedicated data outputs. The distributed data is provided via the two outgoing adapters **OUT1** and **OUT2**.

Adapters

Type	Name	Direction	Description
Socket	`IN`	Input	Unidirectional ALI adapter that receives incoming data/events.
Plug	`OUT1`	Output	First unidirectional ALI adapter to which the data/events are forwarded.
Plug	`OUT2`	Output	Second unidirectional ALI adapter to which the data/events are forwarded.

All adapters are of type `adapter::types::unidirectional::ALI`.

Functionality

The module implements a 1:2 split at the adapter level. As soon as data or events are present at socket **IN**, they are passed on unchanged and simultaneously to both plugs **OUT1** and **OUT2**. No buffering or processing of the data takes place – the module operates purely as a signal distributor.

Technical Features

- **Generic Module**: The attribute `eclipse4diac::core::GenericClassName` marks the module as a generic instance `GEN_ALI_SPLIT`. It can therefore be used with different ALI types or parameters, as long as the underlying adapter definition is compatible.
- **No State Management**: The module has no internal states or variables – its functionality is purely combinatorial.
- **Unidirectionality**: The adapters are defined as unidirectional, meaning data flows only from the input to the outputs; reverse communication is not supported.

State Overview

Since the module has no event inputs/outputs or internal states, there is no state machine. Data transmission is continuous and instantaneous.

Application Scenarios

- **Distributing a Sensor Signal**: An analog or digital ALI sensor is connected to two control units that need to access the measurement data independently.
- **Parallel Processing**: A data stream should be processed simultaneously by two different function blocks without requiring manual branching in the application.
- **Redundancy**: An application requires duplicate ALI communication to increase reliability.

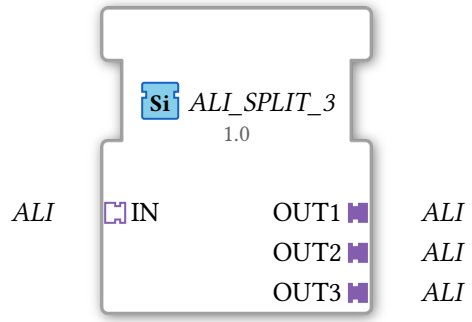
Comparison with Similar Function Blocks

Function Block	Function	Difference
ALI_SPLIT_2_UNGATED	Distributes one ALI input to two ALI outputs.	–
ALI_SPLIT_3 (hypothetical)	Distributes to three outputs.	Higher number of outputs.
ALI_MERGE_2	Combines two ALI inputs into one ALI output.	Opposite function (Join).
ALI_FILTER	Passes on only specific data/events.	Contains filter logic.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



ALI_SPLIT_2_UNGATED is a simple but essential function block for distributing unidirectional ALI interfaces. Its generic nature and lean implementation make it a universal tool in IEC 61499 component development when a signal or data stream needs to be passed to multiple subsequent blocks.

ALI_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALI_SPLIT_3** is used to distribute an incoming unidirectional adapter of type **ALI** (Application Layer Interface) to three identical output adapters of the same type. It is designed as a generic component and enables signal multiplication without data modification.

Interface Structure

Event Inputs
– None –

Event Outputs
– None –

Data Inputs
– None (all communication takes place via the adapter interfaces)

Adapter

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::ALI`	Receives the incoming ALI signal.
Plug (Output)	`OUT1`	`adapter::types::unidirectional::ALI`	First output copy of the signal.
Plug (Output)	`OUT2`	`adapter::types::unidirectional::ALI`	Second output copy of the signal.
Plug (Output)	`OUT3`	`adapter::types::unidirectional::ALI`	Third output copy of the signal.

Note: The adapter type `ALI` is a unidirectional interface adapter that typically encapsulates data and event flow in one direction. The exact internal structure is defined application-specifically.

Functionality
The function block performs a pure 1:3 distribution of the ALI adapter connected to socket `IN`. All information received at the input (e.g., data values, events, or states) is forwarded in parallel to the three outputs `OUT1`, `OUT2`, and `OUT3` without delay or transformation. No buffering or logic takes place – the function block operates purely synchronously with the data flow.

Technical Features
- **Generic Type:** The function block is declared as a generic function block (`eclipse4diac::core::GenericClassName = 'GEN_ALI_SPLIT'`). This allows the actual adapter type to be defined at configuration time, provided the underlying system supports this.
- **No Internal Dynamics:** The function block has no event or data inputs/outputs outside of the adapters. All communication takes place exclusively via the adapter interfaces.
- **Low Latency:** By eliminating internal processing, signal distribution is virtually delay-free.

State Overview
The function block has no state machines or state memory. Its behavior is deterministic and purely combinatorial: The current input state is immediately mapped to all outputs.

Application Scenarios
- **Signal Multiplication in Control Systems:** If an ALI signal (e.g., a sensor data stream) is required multiple times by different downstream function blocks, ALI_SPLIT_3 can handle the distribution.
- **Test and Simulation Environments:** Multiple components are supplied with the same input signal to observe parallel responses.
- **Redundancy:** A signal is split across three paths, which are processed independently (e.g., for comparison or fault detection).

Comparison with Similar Function Blocks
- **ALI_SPLIT_2:** Distributes an ALI signal to two outputs instead of three. ALI_SPLIT_3 extends this number to three.
- **ALI_MERGE (hypothetical):** Combines multiple ALI inputs into one output – functionally the opposite.
- **Event-Based Splitters (e.g., E_SPLIT):** Work with pure events, while ALI_SPLIT_3 distributes data and event components together via a single adapter.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

ALI_SPLIT_3 is a simple yet useful function block for multiplying ALI adapter connections. Its generic nature and pure signal transmission make it a flexible tool in automation and control engineering, especially when a signal is needed multiple times.

ALI_SPLIT_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_SPLIT_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALI_SPLIT_3_UNGATED** is used to distribute an incoming unidirectional adapter of type **ALI** (Application Layer Interface) to three identical output adapters of the same type. It is designed as a generic component and enables signal multiplication without data modification.

Interface Structure

Event Inputs

– None –

Event Outputs

– None –

Data Inputs

– None (all communication takes place via the adapter interfaces)

Adapter

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::ALI`	Receives the incoming ALI signal.

Plug (Output)	`OUT1`	`adapter::types::unidirectional::ALI`	First output copy of the signal.
Plug (Output)	`OUT2`	`adapter::types::unidirectional::ALI`	Second output copy of the signal.
Plug (Output)	`OUT3`	`adapter::types::unidirectional::ALI`	Third output copy of the signal.

Note: The adapter type `ALI` is a unidirectional interface adapter that typically encapsulates data and event flow in one direction. The exact internal structure is defined application-specifically.

Functionality

The function block performs a pure 1:3 distribution of the ALI adapter connected to socket `IN`. All information received at the input (e.g., data values, events, or states) is forwarded in parallel to the three outputs `OUT1`, `OUT2`, and `OUT3` without delay or transformation. No buffering or logic takes place – the function block operates purely synchronously with the data flow.

Technical Features

- **Generic Type:** The function block is declared as a generic function block (`eclipse4diac::core::GenericClassName = 'GEN_ALI_SPLIT'`). This allows the actual adapter type to be defined at configuration time, provided the underlying system supports this.
- **No Internal Dynamics:** The function block has no event or data inputs/outputs outside of the adapters. All communication takes place exclusively via the adapter interfaces.
- **Low Latency:** By eliminating internal processing, signal distribution is virtually delay-free.

State Overview

The function block has no state machines or state memory. Its behavior is deterministic and purely combinatorial: The current input state is immediately mapped to all outputs.

Application Scenarios

- **Signal Multiplication in Control Systems:** If an ALI signal (e.g., a sensor data stream) is required multiple times by different downstream function blocks, ALI_SPLIT_3_UNGATED can handle the distribution.
- **Test and Simulation Environments:** Multiple components are supplied with the same input signal to observe parallel responses.
- **Redundancy:** A signal is split across three paths, which are processed independently (e.g., for comparison or fault detection).

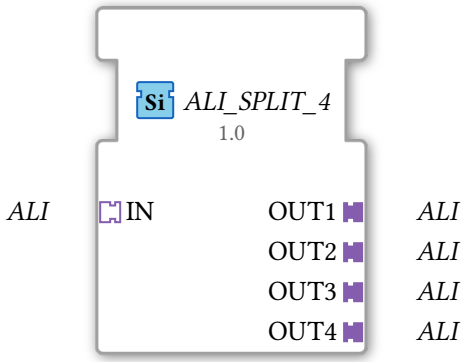
Comparison with Similar Function Blocks

- **ALI_SPLIT_2:** Distributes an ALI signal to two outputs instead of three. ALI_SPLIT_3_UNGATED extends this number to three.
- **ALI_MERGE (hypothetical):** Combines multiple ALI inputs into one output – functionally the opposite.
- **Event-Based Splitters (e.g., E_SPLIT):** Work with pure events, while ALI_SPLIT_3_UNGATED distributes data and event components together via a single adapter.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



ALI_SPLIT_3_UNGATED is a simple yet useful function block for multiplying ALI adapter connections. Its generic nature and pure signal transmission make it a flexible tool in automation and control engineering, especially when a signal is needed multiple times.

ALI_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALI_SPLIT_4** is used to distribute a single ALI adapter input (type: `adapter::types::unidirectional::ALI`) to four separate ALI adapter outputs. It is designed as a generic function block (FB) and enables unidirectional signal transmission from one source to up to four destinations.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Direction	Name	Type	Description
Socket	IN	adapter::types::unidirectional::ALI	Unidirectional ALI Input (Source)
Plug	OUT1	adapter::types::unidirectional::ALI	First ALI Output (Destination)
Plug	OUT2	adapter::types::unidirectional::ALI	Second ALI Output (Destination)
Plug	OUT3	adapter::types::unidirectional::ALI	Third ALI Output (Destination)
Plug	OUT4	adapter::types::unidirectional::ALI	Fourth ALI Output (Destination)

Functionality

The function block receives an ALI adapter connection via socket **IN** and forwards the incoming signals unchanged to all four plugs **OUT1** to **OUT4**. No data processing, filtering, or logical operation takes place – the distribution is purely passive. Due to its generic implementation, the function block can be used in various contexts where an ALI signal is required multiple times.

Technical Features

- The function block is declared as a generic function block (`GEN_ALI_SPLIT`), which allows for flexible type customization in the 4diac IDE development environment.
- No events or data points are required – all communication occurs exclusively via the adapter interfaces.
- The function block is unidirectional: feedback from the outputs to the input is not provided.

- The attributes `GenericClassName` and `TypeHash` serve for the unique identification and versioning of the generic type.

State Overview

The function block has no states or control logic of its own. Its behavior is deterministic and consists solely of forwarding the adapter signal. Therefore, a separate state machine is not required.

Application Scenarios

- **Signal Distribution**: A central ALI data stream (e.g., from a sensor or control unit) is to be sent in parallel to several downstream components.
- **Prototyping**: In early development phases, the function block can be used to quickly distribute a signal to multiple test units.
- **Redundancy**: Multiple identical outputs allow for the connection of backup systems or separate monitoring units.

Comparison with Similar Function Blocks

- **ALI_SPLIT_2**: Distributes the input signal to two outputs instead of four. The ALI_SPLIT_4 offers twice the number of output channels.
- **ALI_MERGE**: Combines multiple ALI inputs into one output – the inverse function of the split function.
- **ALI_SELECT**: Selects one of several inputs based on a control signal and routes it to an output (no parallel distribution).

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ALI_SPLIT_4** is a simple yet useful function block for passively distributing a unidirectional ALI signal to four identical outputs. Its generic design and the absence of event or data logic make it particularly suitable for rapid signal multiplication in automation technology without incurring additional processing load.

ALI_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALI_SPLIT_5` is a generic adapter split block. It accepts a single incoming ALI adapter (`adapter::types::unidirectional::ALI`) and provides the same ALI signals at five outgoing

ALI adapter interfaces. This allows an ALI connection to be distributed to multiple subsequent blocks or devices without interrupting the logical signal chain.

Interface Structure

Event Inputs
- None

Event Outputs
- None

Data Inputs
- None

Data Outputs
- None

Adapters

Direction	Name	Type	Description
Input (Socket)	`IN`	`adapter::types::unidirectional::ALI`	Single input: contains the ALI data to be distributed to the five outputs.
Output (Plug)	`OUT1`	`adapter::types::unidirectional::ALI`	First output (identical signals as at the input).
Output (Plug)	`OUT2`	`adapter::types::unidirectional::ALI`	Second output.
Output (Plug)	`OUT3`	`adapter::types::unidirectional::ALI`	Third output.
Output (Plug)	`OUT4`	`adapter::types::unidirectional::ALI`	Fourth output.
Output (Plug)	`OUT5`	`adapter::types::unidirectional::ALI`	Fifth output.

Functionality

As soon as the module is connected to socket `IN` via a valid ALI connection, all data and event traffic from the incoming adapter is forwarded **unchanged** and **in parallel** to the five plug adapters `OUT1` to `OUT5`. No logical processing, filtering, or delay takes place – the function block acts as a passive distribution unit ("splitter") for the ALI channel.

The forwarding is bidirectional according to the ALI adapter definition: Both events and data (as defined in the ALI type) are made available synchronously at all outputs. The function block has no internal runtime logic or state.

Technical Features
- **Generic Function Block** – The specific implementation is controlled by the meta attributes `GenericClassName` and `TypeHash`. This allows the same function block definition to be reused for different ALI variants (e.g., with different data structures).
- **No Delay** – The signals are replicated to the outputs without any significant delay.
- **Easily Expandable** – The principle of this splitter can be transferred to other adapter types; the generic architecture eliminates the need to modify the basic logic.
- **Direct Coupling** – The output state always corresponds to the current input state; there is no buffering or intermediate storage.

State Overview

The component has **no internal state machine**. It operates directly and without delay as a pure connection switch ("wired split"). State changes occur only through the connected adapter partners, and these are passed on transparently.

Application Scenarios
- **Distributing a sensor signal** to multiple evaluation units or controllers that require the same ALI data stream.

- **Parallelizing ALI communication paths** in a machine controller to supply redundant or independent processing chains.
- **Test and debugging environments** where an ALI signal needs to be simultaneously monitored and recorded.

Comparison with similar components

Other split or fanout components usually offer a fixed number of outputs or are restricted to specific data types. The `ALI_SPLIT_5` is specifically designed for the unidirectional ALI adapter, but its generic template allows for flexible application. Unlike a **multiplexer** or **router**, this component always forwards the signal to all outputs **without switching**.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `ALI_SPLIT_5` is a simple yet essential component for multiplying an ALI signal. Due to its generic nature, it can be easily integrated into various 4diac projects and simplifies signal distribution in complex automation architectures. It requires little maintenance because it contains no internal logic and contributes to the modularization and reusability of ALI connections.

ALI_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The ALI_SPLIT_6 function block is used to distribute an incoming unidirectional ALI (Application Layer Interface) adapter signal to six identical outputs. It is designed as a generic function block and enables simple signal multiplication without additional logic.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

Type	Name	Direction	Description
adapter::types::unidirectional::ALI	IN	Socket (Input)	An ALI adapter whose signal is distributed to all outputs.
adapter::types::unidirectional::ALI	OUT1	Plug (Output)	First output carrying the input signal.
adapter::types::unidirectional::ALI	OUT2	Plug (Output)	Second output carrying the input signal.
adapter::types::unidirectional::ALI	OUT3	Plug (Output)	Third output carrying the input signal.
adapter::types::unidirectional::ALI	OUT4	Plug (Output)	Fourth output with the input signal.
adapter::types::unidirectional::ALI	OUT5	Plug (Output)	Fifth output with the input signal.
adapter::types::unidirectional::ALI	OUT6	Plug (Output)	Sixth output with the input signal.

Functionality

The ALI_SPLIT_6 implements a simple 1:6 distribution. The ALI adapter signal received via socket `IN` is forwarded unchanged and simultaneously to all six plugs (`OUT1` to `OUT6`). No signal processing, delay, or state changes occur. The distribution is purely structural via the adapter connections.

Technical Features

- **Generic Function Block:** The FB is defined as a generic function block. The specific class name (e.g., `eclipse4diac::core::GenericClassName`) can be defined via the attribute `'GEN_ALI_SPLIT'`. The attribute `eclipse4diac::core::TypeHash` can be used to identify the specific configuration.
- **No State Machines:** The FB has no ECC (Execution Control Chart) and no internal logic. It operates purely passively.
- **Unidirectional ALI Adapter Interface:** Both inputs and outputs use the type `adapter::types::unidirectional::ALI`, which enables simple and standardized communication.

State Overview

The FB does not have its own states or behavior modes, as it only performs structural routing. Therefore, state analysis is not required.

Application Scenarios

- **Controlling Multiple Actuators:** An ALI signal, e.g., a enable or control signal, is to be simultaneously transmitted to six receivers (e.g., servo motors or valve manifolds).
- **Signal Distribution in Modular Systems:** In an industrial control system, a central ALI signal can be distributed to multiple decentralized units.
- **Replacing Manual Wiring:** The FB replaces the physical distribution of a signal with a software-defined, maintainable solution.

Comparison with Similar Function Blocks

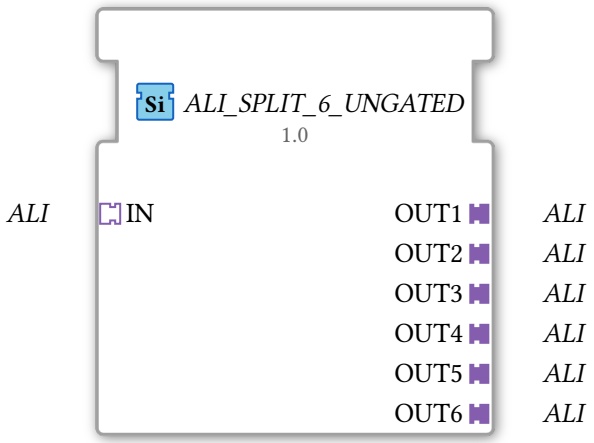
Function Block	Outputs	Special Features
ALI_SPLIT_2	2	Dual Distribution
ALI_SPLIT_4	4	Quadruple Distribution
ALI_SPLIT_6	**6**	**Six-Way Distributor, Generic**
ALI_SPLIT_8	8	Eight-Way Distributor

The ALI_SPLIT_6 differs from other split variants only in the number of outputs. All function blocks in this family operate on the same passive distribution principle. The function block described here is implemented as a generic block, while other variants may be implemented as simple function block types without genericity.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The ALI_SPLIT_6 is a simple yet useful function block for multiplying a unidirectional ALI adapter signal to six identical outputs. Thanks to its generic properties, it can be flexibly integrated into various control systems. Due to the lack of processing logic, it is particularly resource-efficient and easy to understand. It is ideally suited for applications where a signal needs to be provided to multiple receivers simultaneously.

ALI_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALI_SPLIT_7** is a generic splitter that distributes one incoming ALI adapter (socket `IN`) to seven outgoing ALI adapters (plugs `OUT1`…`OUT7`). It is used for a 1:7 distribution of data and events within a unidirectional ALI communication path.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket (Input)	IN	adapter::types::unidirectional::ALI	Input adapter whose data and events are distributed.
Plug (Output)	OUT1	adapter::types::unidirectional::ALI	First output adapter.
Plug (Output)	OUT2	adapter::types::unidirectional::ALI	Second output adapter.
Plug (Output)	OUT3	adapter::types::unidirectional::ALI	Third output adapter.
Plug (Output)	OUT4	adapter::types::unidirectional::ALI	Fourth Output Adapter.
Plug (Output)	OUT5	adapter::types::unidirectional::ALI	Fifth Output Adapter.
Plug (Output)	OUT6	adapter::types::unidirectional::ALI	Sixth Output Adapter.
Plug (Output)	OUT7	adapter::types::unidirectional::ALI	Seventh Output Adapter.

Functionality

The function block forwards all incoming ALI signals (both data and events) via socket `IN` unchanged to all seven output adapters `OUT1`…`OUT7`. This results in a strict 1:7 parallel distribution without delay or buffering. The function block behaves purely combinatorially; no processing or filtering of the contents takes place.

Technical Features

- **Generic Type**: The function block is declared as a generic function block (`GenericClassName = 'GEN_ALI_SPLIT'`). This allows it to be used with different ALI adapter variants, provided they support the same interface protocol (unidirectional adapters).
- **No States**: The function block does not have a state machine (ECC) and does not store any data. Each iteration is deterministic and has no side effects.
- **Flexible Distribution**: With its fixed number of seven outputs, the FB is particularly suitable for applications requiring distribution across exactly seven paths.

State Overview

The FB has **no explicit states**. Its functionality is purely passive and data flow-driven.

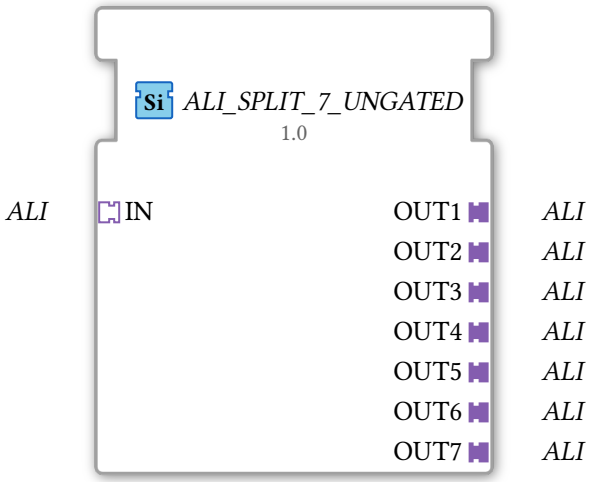
Application Scenarios

- **Parallel Signal Distribution**: An ALI data stream sent by a higher-level control module is to be simultaneously passed on to several downstream modules (e.g., actuators, visualizations, or logging systems).
- **Redundancy or Load Balancing**: Several identical processing units receive the same ALI input data and operate independently.
- **Adapter Conversion**: In combination with specialized ALI adapters, the splitter can be used to multiply a data path across different logic or hardware interfaces.

Comparison with Similar Function Blocks

- **ALI_SPLIT_2 / ALI_SPLIT_4**: These function blocks offer splits to two or four outputs, respectively. `ALI_SPLIT_7` is the extension to seven outputs for specific requirements.
- **ALI_MERGE**: The counterpart that combines multiple ALI inputs into one output. A splitter like `ALI_SPLIT_7` operates in the opposite direction (fan-out).

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ALI_SPLIT_7** is a specialized, generic function block for the clean and lossless 1:7 distribution of unidirectional ALI signals. Its simple structure, lack of state logic, and generic design make it ideal for modular control architectures where a signal needs to be passed to multiple receivers in parallel.

ALI_SPLIT_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_SPLIT_7`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::ALI`	Input adapter whose data and events are distributed.
Plug (Output)	`OUT1`	`adapter::types::unidirectional::ALI`	First output adapter.

Plug (Output)	OUT2	adapter::types::unidirectional::ALI	Second output adapter.
Plug (Output)	OUT3	adapter::types::unidirectional::ALI	Third output adapter.
Plug (Output)	OUT4	adapter::types::unidirectional::ALI	Fourth Output Adapter.
Plug (Output)	OUT5	adapter::types::unidirectional::ALI	Fifth Output Adapter.
Plug (Output)	OUT6	adapter::types::unidirectional::ALI	Sixth Output Adapter.
Plug (Output)	OUT7	adapter::types::unidirectional::ALI	Seventh Output Adapter.

Functionality

The function block forwards all incoming ALI signals (both data and events) via socket `IN` unchanged to all seven output adapters `OUT1`...`OUT7`. This results in a strict 1:7 parallel distribution without delay or buffering. The function block behaves purely combinatorially; no processing or filtering of the contents takes place.

Technical Features

- **Generic Type**: The function block is declared as a generic function block (`GenericClassName = 'GEN_ALI_SPLIT'`). This allows it to be used with different ALI adapter variants, provided they support the same interface protocol (unidirectional adapters).
- **No States**: The function block does not have a state machine (ECC) and does not store any data. Each iteration is deterministic and has no side effects.
- **Flexible Distribution**: With its fixed number of seven outputs, the FB is particularly suitable for applications requiring distribution across exactly seven paths.

State Overview

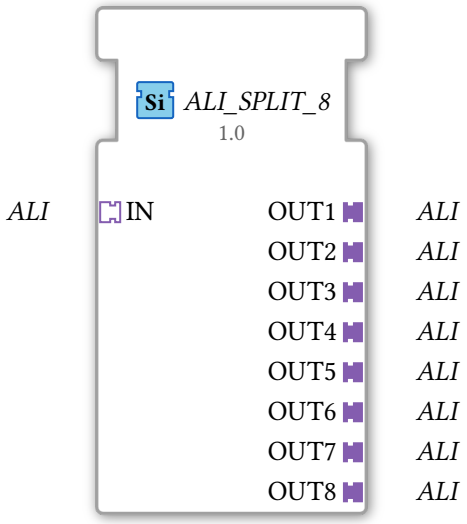
The FB has **no explicit states**. Its functionality is purely passive and data flow-driven.

Application Scenarios

- **Parallel Signal Distribution**: An ALI data stream sent by a higher-level control module is to be simultaneously passed on to several downstream modules (e.g., actuators, visualizations, or logging systems).
- **Redundancy or Load Balancing**: Several identical processing units receive the same ALI input data and operate independently.
- **Adapter Conversion**: In combination with specialized ALI adapters, the splitter can be used to multiply a data path across different logic or hardware interfaces.

Comparison with Similar Function Blocks

- **ALI_SPLIT_2 / ALI_SPLIT_4**: These function blocks offer splits to two or four outputs, respectively. `ALI_SPLIT_7_UNGATED` is the extension to seven outputs for specific requirements.
- **ALI_MERGE**: The counterpart that combines multiple ALI inputs into one output. A splitter like `ALI_SPLIT_7_UNGATED` operates in the opposite direction (fan-out).



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **ALI_SPLIT_7_UNGATED** is a specialized, generic function block for the clean and lossless 1:7 distribution of unidirectional ALI signals. Its simple structure, lack of state logic, and generic design make it ideal for modular control architectures where a signal needs to be passed to multiple receivers in parallel.

ALI_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALI_SPLIT_8` serves as a generic splitter for the **Agricultural Light Interface (ALI)**. It distributes an incoming ALI signal unchanged to eight parallel outputs. This allows multiple downstream devices or controllers to be supplied with the same signal without compromising signal integrity.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

- **Socket (Input):**

IN– `of type`adapter::types::unidirectional::ALI` Receives the incoming ALI signal.

- **Plugs (Outputs):**

OUT1…OUT8– `each of type`adapter::types::unidirectional::ALI` Provide the eight identical copies of the input signal.

Functionality

The module forwards the ALI signal present at socket `IN` unchanged and without delay to all eight plugs (`OUT1` … `OUT8`). Since this is purely signal distribution, no processing, buffering, or status changes occur. All events and data transmitted via the ALI adapter are replicated to each output.

Technical Features

- **Generic Function Block:** The function block is defined as a generic type (`GEN_ALI_SPLIT`) and can be used in various contexts within the ALI ecosystem.
- **No ECC:** There is no execution state machine (ECC); distribution is purely combinatorial.

- **Unidirectional:** The adapter type is unidirectional – the signal flows only from the socket to the plugs; feedback is not provided.
- **Scalability:** Due to its modular design, similar splitters for other output numbers (e.g., `ALI_SPLIT_2`) can be derived.

State Overview

The function block has no internal states or sequential logic. Signal distribution operates continuously and without delay.

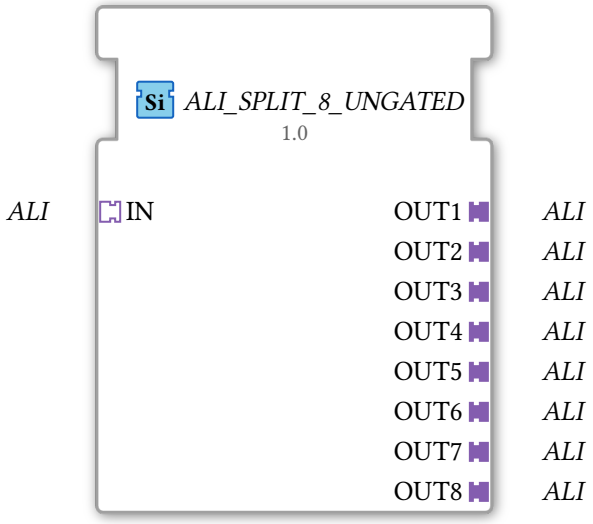
Application Scenarios

- **Distribution Circuits:** An ALI signal (e.g., from a control unit) must be simultaneously transmitted to multiple actuators or sensors.
- **Redundancy:** Parallel control of identical components without requiring separate signal sources.
- **Bus Structures:** Construction of star-shaped ALI networks with a central splitter.

Comparison with Similar Components

Other splitter components such as `ALI_SPLIT_2`, `ALI_SPLIT_4`, or `ALI_SPLIT_N` differ only in the number of outputs. The `ALI_SPLIT_8` offers the maximum distribution in the standard family. Unlike a multiplexer (`ALI_MUX`) or a switch (`ALI_SWITCH`), here **each output is supplied with the same signal** – no selection or switching takes place.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `ALI_SPLIT_8` is a simple yet essential component for multiplying ALI signals. Its generic definition and the absence of state logic make it particularly suitable for robust, low-latency distributions in agricultural automation.

ALI_SPLIT_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALI_SPLIT_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

ALI_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The **ALI_SPLIT_9** is a generic function block (FB) within the 4diac IDE, used to split an incoming **ALI** adapter signal (unidirectional) into up to nine separate output adapters. The block is implemented as a generic type ("Generic FB") and is typically customized using the type parameters `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash`. The goal is flexible signal distribution without additional logic, purely at the adapter level.

Interface Structure

Event Inputs

Data Outputs

None

Adapters

Direction	Name	Type	Description
Socket (Input)	IN	`ALI` (unidirectional)	Input of the ALI signal to be distributed
Plug (Output 1)	OUT1	`ALI` (unidirectional)	First output – identical copy of the input signal

Plug (Output 2)	OUT2	`ALI` (unidirectional)	Second output
Plug (Output 3)	OUT3	`ALI` (unidirectional)	Third output
Plug (Output 4)	OUT4	`ALI` (unidirectional)	Fourth exit
Plug (output 5)	OUT5	`ALI` (unidirectional)	Fifth exit
Plug (output 6)	OUT6	`ALI` (unidirectional)	Sixth exit
Plug (output 7)	OUT7	`ALI` (unidirectional)	Seventh exit
Plug (output 8)	OUT8	`ALI` (unidirectional)	Eighth exit
Plug (output 9)	OUT9	`ALI` (unidirectional)	Ninth exit

Functionality

The function block operates passively as a pure **signal distributor**. The ALI adapter protocol applied to socket **IN** is duplicated unchanged to all nine plug outputs **OUT1…OUT9**. No data processing, event generation, or filtering takes place. Each output provides an identical logical and temporal copy of the incoming signal.

The internal implementation uses the generic type mechanisms of the 4diac IDE (`GenericClassName` and `TypeHash`), allowing the function block to be specifically adapted to the project requirements at runtime.

Technical Features

- **Generic Function Block**: The function block is declared as `GEN_ALI_SPLIT` (according to the attribute `eclipse4diac::core::GenericClassName`). Specific instances receive a unique type identifier via `TypeHash`.
- **No Events or Data**: The interface consists exclusively of adapters; there are no event inputs/outputs or data inputs/outputs.
- **Unidirectional ALI Adapters**: All adapters used are of type `adapter::types::unidirectional::ALI`, meaning communication is one-way (input → outputs). Feedback from the outputs to the input is not supported.
- **Simple Topology**: The module implements a 1:9 star distribution without additional buffers or synchronization.

State Overview

The module does not have its own state machine. Its behavior is determined solely by the adapter interfaces: As long as socket **IN** provides a signal, all nine plugs are active. As soon as **IN** becomes inactive (no signal), all outputs also provide no signal.

Application Scenarios

- **Distributing an ALI bus signal** to multiple downstream subsystems (e.g., sensor data to multiple controllers).
- **Splitting a master signal** for redundancy or parallel processing in plant control.
- **Test and debugging environments**: An ALI signal can be simultaneously routed to an analyzer and multiple target systems.
- **Generic interface extension**: When a system has only one ALI output but needs to serve multiple devices.

Comparison with similar components

- **ALI_SPLIT_2 / ALI_SPLIT_4 / ALI_SPLIT_8**: Variants with 2, 4, or 8 outputs. The component described here offers the maximum split to 9 channels.
- **ALI_MERGE** (hypothetical): Combines multiple ALI inputs into one output – the opposite function.
- **Event-based splitters**: Other components use events to control the signal flow; this adapter splitter operates in a signal-driven manner without event logic.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ALI_SPLIT_9** is a specialized, generic adapter function block (FB) that enables the simple and reliable distribution of a unidirectional ALI signal to up to nine separate receivers in industrial automation using the 4diac IDE. Its pure adapter interface makes it particularly resource-efficient and ideally suited for star network topologies in IEC 61499-based systems. Its generic nature allows for flexible adaptation to specific requirements without changing the block structure.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ALR_D_FF

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_D_FF** implements a data-driven flip-flop (D-latch) with an adapter-based interface. It takes a data value on a clock event and makes it available at the output. The block encapsulates the IEC 61499 standard function `E_D_FF_ANY` and offers a unidirectional adapter connection for modular system integration.

Interface Structure

The function block has no direct event or data inputs/outputs. All communication takes place via two adapters:

Event Inputs

- **I.E1** (via socket `I`): Clock event – the current data value is taken on a rising edge.

Event Outputs

- **Q.E1** (via plug `Q`): Acknowledge event – sent after successful data value transfer.

Data Inputs

- **I.D1** (via socket `I`): Data input – the value to be latched (data type is defined by adapter `ALR`).

Data Outputs

- **Q.D1** (via plug `Q`): Data output – the stored, latched value.

Adapters

Adapter	Type	Direction	Description
`I`	adapter::types::unidirectional::ALR	Socket (Input)	Returns the clock event and the data value.
`Q`	adapter::types::unidirectional::ALR	Plug (Output)	Outputs the output event and the latched value.

Functionality

1. The function block expects a clock event at the adapter input `I.E1`.
2. Simultaneously, the data value from `I.D1` is read.
3. The internal function block `E_D_FF_ANY` receives the data value on the rising edge of the clock signal.
4. The received value is output unchanged to `Q.D1`.
5. An output event on `Q.E1` signals that the new value is ready.

This process repeats with each subsequent clock event. The output value remains stable between clock cycles (latch behavior).

Technical Features

- **Adapter-based interface**: The function block (FB) uses the unidirectional adapter `ALR`, which carries exactly one event and one data value. This enables loose coupling and easy interconnection with other adapter blocks.
- **Delegation to IEC 61499 standard**: The actual flip-flop logic is implemented by the standard FB `E_D_FF_ANY`, which is designed for any data type ("ANY"). `ALR_D_FF` therefore inherits its robustness and type neutrality.
- **No dedicated state machine**: The function block (FB) does not have an internal state machine – state management is handled entirely within the embedded `E_D_FF_ANY`.

State Overview

The function block has no explicit states. The internal logic (flip-flop) only recognizes two implicit states:

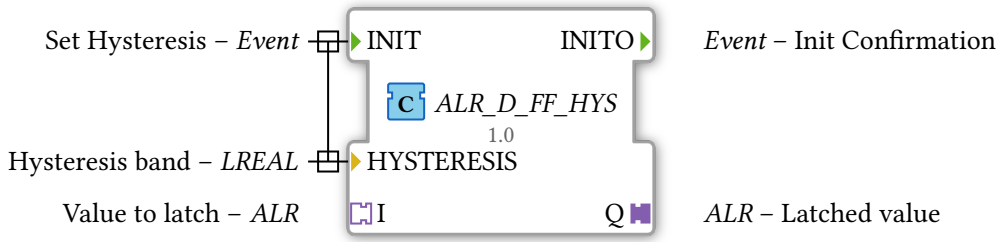
- **Waiting for clock event**: The output retains the last latched value.
- **Latch moment**: Upon a clock event, the input value is adopted and the output is updated.

Application Scenarios

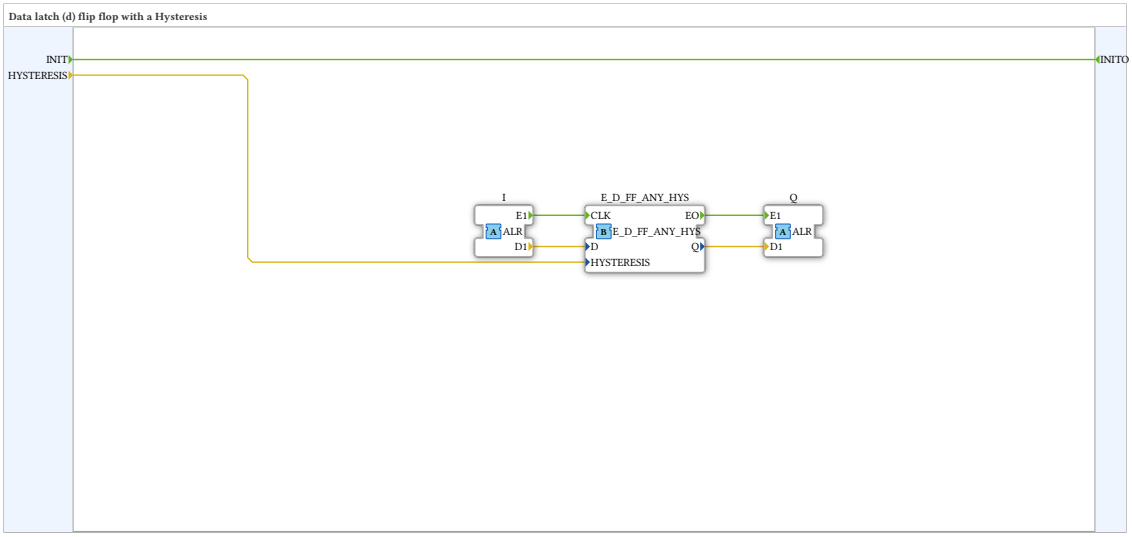
- **Data storage**: Holding a digital signal (e.g., switch position) until the next query.
- **Synchronization**: Transferring asynchronous data into a clocked context.
- **Buffering**: Temporarily storing values in control sequences, e.g., in state machines or sequence controllers.

Comparison with Similar Components

- **`ALR_SR_FF`** (Set-Reset Flip-Flop): Offers two control inputs (Set/Reset) instead of a clock input. Suitable for priority-driven applications.
- **`ALR_JK_FF`** (JK Flip-Flop): More complex switching behavior with toggling and holding. More flexible, but more expensive.
- **`E_D_FF_ANY`** (Direct): Offers the same functionality, but with separate event and data inputs/outputs instead of an adapter. The `ALR_D_FF` simplifies coupling in adapter-based frameworks.



Conclusion



The `ALR_D_FF` is a lean yet reliable D flip-flop component for use in adapter-oriented 4diac applications. It combines proven IEC 61499 standard logic with a clearly structured adapter interface and is particularly suitable for modular, reusable control systems.

ALR_D_FF_HYS

• – ◦ • – ◦ • – ◦ •

Introduction

The **ALR_D_FF_HYS** function block implements a data latch (D flip-flop) with adjustable hysteresis. It receives a data value via an adapter socket and outputs the latched value via an adapter plug. The hysteresis is set during the initialization event and serves to suppress noise or small fluctuations in the input signal.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Sets the hysteresis (with the data value `HYSTERESIS`) and starts the initialization.

Event Outputs

Event	Type	Description
INITO	EInit	Confirms successful initialization.

Data Inputs

Variable	Type	Description
HYSTERESIS	LREAL	Size of the hysteresis band (passed on the `INIT` event).

Data Outputs

The FB has no direct data outputs. The latched value is output exclusively via the adapter plug `Q`.

Adapter

Name	Type	Direction	Description
I (Socket)	`adapter::types::unidirectional::ALR`	Input	Receives the value to be latched via the event `I.E1` and the associated data value `I.D1`.
Q (Plug)	`adapter::types::unidirectional::ALR`	Output	Outputs the latched value via the event `Q.E1` and the data value `Q.D1`.

The adapter used, **ALR**, is a unidirectional data adapter with one event (`E1`) and one data value (`D1`).

Functionality

The function block (FB) works internally with the block `E_D_FF_ANY_HYS`, which implements the actual latch and hysteresis logic. The sequence of events is as follows:

1. **Initialization**: Upon arrival of `INIT`, the value of `HYSTERESIS` is forwarded to the internal block, and the output event `INITO` is immediately acknowledged.
2. **Latch Operation**: On each rising edge of the event `I.E1` (from the socket), the current data value `I.D1` is adopted. However, the latched value is only output when it leaves the band defined by the hysteresis. This suppresses small changes around the current latch value.
3. **Output**: As soon as the latched value leaves the hysteresis band, the internal function block generates an event on `E0`, which is output externally as `Q.E1`, and the new value is available on `Q.D1`.

Technical Features

- The hysteresis is set exclusively on the `INIT` event and remains constant during operation.
- The function block (FB) does not use its own state machine, but delegates all logic to the internal block `E_D_FF_ANY_HYS`.
- The initial state of the latch is undefined; initialization with `INIT` is mandatory before valid latch operations can occur.

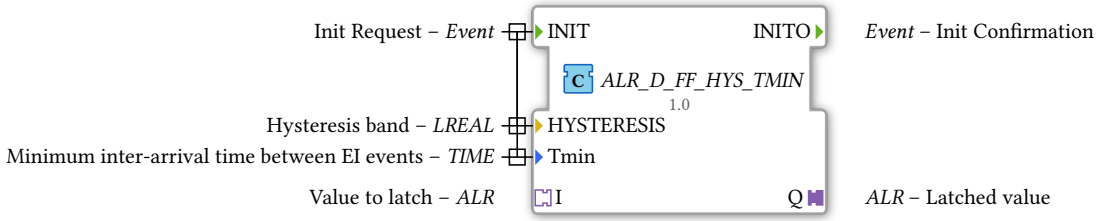
State Overview

Since the FB implements the behavior via an internal block, there is no separate state diagram. The internal block `E_D_FF_ANY_HYS` typically operates with the following states:

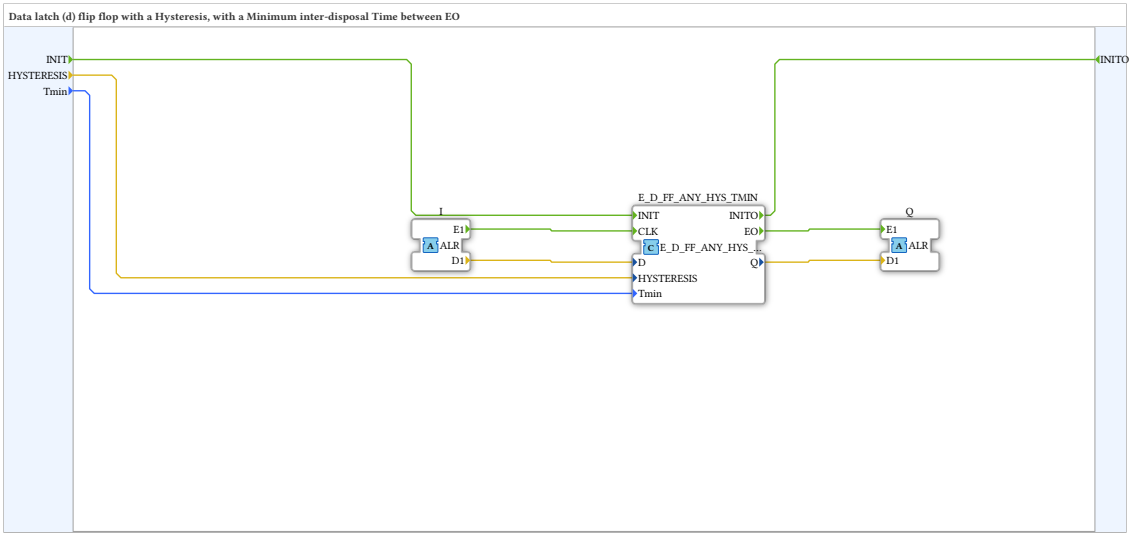
- **Initial** – Waiting for the hysteresis setting.
- **Normal** – Latch operation with hysteresis band check (delayed output update).
- **Output** – Sending the newly latched value via the output adapter.

Application Scenarios

- **Signal Conditioning**: Latching of measured values with noise suppression in automation technology.
- **Debouncing**: Processing of switching signals where short pulses or bouncing need to be suppressed.
- **Threshold Monitoring**: Detection of analog values that only assume a new valid state above or below a hysteresis band.



Comparison with Similar Components



Component	Property
Simple D flip-flop (e.g., `E_D_FF`)	Latch without hysteresis – any change at the input is immediately registered.
D flip-flop with deadband (`E_D_FF_TOTBAND`)	It has a deadband that blocks changes as long as the value remains within the band.
ALR_D_FF_HYS	Hysteresis is only effective in one direction (threshold behavior), typically used to prevent flutter.

Conclusion

The ALR_D_FF_HYS is a specialized function block for applications where a data value needs to be latched and hysteresis applied simultaneously for noise suppression. Encapsulating the logic in an internal block keeps the interface simple and allows for flexible use via the adapter interface.

ALR_D_FF_HYS_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_D_FF_HYS_TMIN** implements a clock-controlled D-latch (flip-flop) with adjustable hysteresis for data acquisition and a minimal time delay between successive output events. It processes an analog or Boolean value via an adapter input and outputs the buffered value via an adapter output. The hysteresis prevents unintended switching due to fluctuating input values, while the minimum time (Tmin) limits the event frequency at the output.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Initialization Request (sets hysteresis and Tmin)

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization Acknowledgement

Data Inputs

Name	Type	Comment
HYSTERESIS	LREAL	Hysteresis band for data transfer
Tmin	TIME	Minimum time between two output events

Data Outputs

The FB does not have its own data outputs. The latched value is provided via the adapter output `Q`.

Adapter

Direction	Name	Type (unidirectional)	Comment
Socket	I	ALR	Input value to be latched
Plug	Q	ALR	Output value (latched)

Functionality

The function block (FB) is implemented as a composite block that internally uses an FB of type `E_D_FF_ANY_HYS_TMIN` (from the library `logiBUS::signalprocessing::hysteresis`). The functionality in detail:

1. **Initialization (INIT)**: Upon the event `INIT`, the parameters `HYSTERESIS` and `Tmin` are passed to the internal FB. The internal FB is initialized and acknowledged with `INITO`.
2. **Data Transfer**: An event at the adapter input `I.E1` triggers the clock (`CLK`) of the internal flip-flop. Simultaneously, the data value `I.D1` is transferred as a new input `D`.
3. **Hysteresis**: The value is only transferred if the deviation from the currently latched value is greater than or equal to the set hysteresis. This prevents constant switching due to small fluctuations.
4. **Minimum Time (Tmin)**: After each output event (`EO`), a delay of `Tmin` is observed before another output event can be generated. Events arriving within this delay period are ignored.
5. **Output**: The latched value is provided via the adapter output `Q.D1`, and an event (`Q.E1`) signals the update.

Technical Features

- **Hysteresis**: The function block operates with an adjustable hysteresis band. The actual implementation (whether symmetrical or with thresholds) depends on the internal function block. A Schmitt trigger characteristic is common.
- **Time-Controlled Output**: `Tmin` limits the maximum output frequency. This is useful for reducing the load on downstream components or ensuring a minimum signal duration.
- **Adapter Interface**: The use of adapters (`ALR`) enables loose coupling between the data value and the event – an event implicitly carries the corresponding data value.
- **Reusability**: The FB is built from a standardized hysteresis flip-flop and can be easily adapted to other data formats.

State Overview

Since the function block consists of several internal states (e.g., waiting for clock signal, hysteresis check, waiting for minimum time), a simplified state description is given here:

1. **Initialized** (after INIT and INITO)
2. **Ready** – waits for an event at input `I.E1`
3. **Hysteresis Check** – compares the new value with the latched value

- If the hysteresis limit is exceeded: the new value is adopted, and the process transitions to **Waiting for Minimum Time**
- Otherwise: returns to **Ready** without output

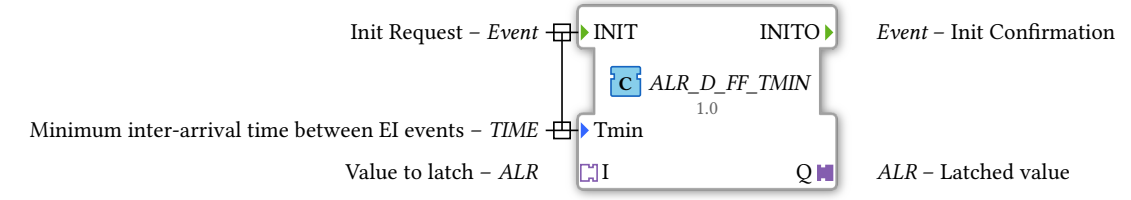
1. **Waiting for Minimum Time** – after the minimum time has elapsed, the output event `Q.E1` is generated, and the latched value is displayed at `Q.D1`Output; then return to **Ready**

Application Scenarios

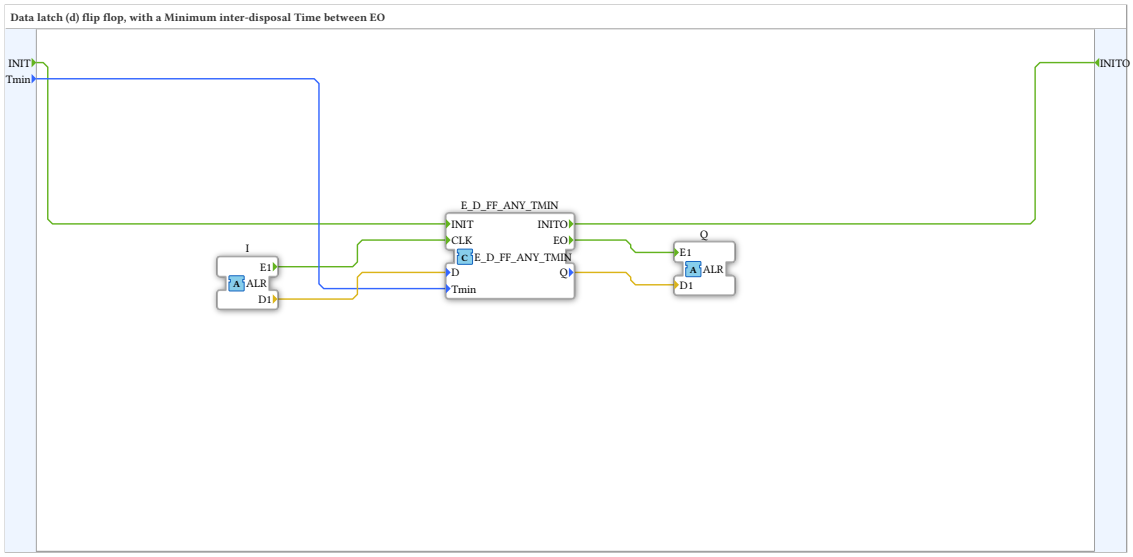
- **Analog Switching Thresholds**: Monitoring of sensors (e.g., temperature, pressure) with adjustable hysteresis and a minimum switching pause to suppress bounce or noise.
- **Digital Signal Conditioning**: Processing of square wave signals with noise, where hysteresis stabilizes the edges and Tmin enforces a defined pulse duration.
- **Stepper Motor Control**: Latching of position values with hysteresis to counter mechanical vibrations, accompanied by time-debouncing of the output commands.
- **Safety-Critical Systems**: Minimum time between output changes prevents excessively rapid state transitions and protects subsequent actuators.

Comparison with Similar Function Blocks

Function Block	Properties	Difference to ALR_D_FF_HYS_TMIN
Simple D flip-flop (D_FF)	No hysteresis, no timing	No signal stabilization or frequency limiting
Schmitt trigger (e.g., S_TRIG)	Hysteresis only, no timing, often only binary	Differs with analog values and forced pauses



Edge-triggered latch with dead time	Timing (dead time) present, but usually without hysteresis	Combination of both effects (hysteresis + Tmin)
Filter block (e.g., FILTER)	Noise reduction, e.g., as a low-pass filter, no discrete state change	Explicit latch with event output and adjustable hysteresis



This block combines the advantages of hysteresis with a minimal event spacing function, making it particularly suitable for harsh industrial environments.

Conclusion

The **ALR_D_FF_HYS_TMIN** is a robust, configurable function block for reliable signal processing with hysteresis and time-based debouncing. It is suitable for all applications requiring a soft threshold and limiting the output event frequency. The adapter-based interface facilitates integration into complex control architectures.

ALR_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **ALR_D_FF_TMIN** implements a clock-edge-triggered data latch flip-flop (D flip-flop) with a minimum inter-disposal time (MIT) between two consecutive event outputs. It enables the latching of a data value upon receiving an event and ensures that the output event pulse does not occur faster than a definable time interval. This is particularly useful for protecting downstream systems from overload or for maintaining minimum time intervals in event communication.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Initialization Request; Sets the minimum time `Tmin`

Event Outputs

Event	Type	Comment
INITO	EInit	Confirmation of successful initialization

Data Inputs

Name	Type	Comment
Tmin	TIME	Minimum wait time between two EO events

Data Outputs

No dedicated data outputs available – the latched value is provided via the adapter output.

Adapter

| Adapter | Direction | Type | Comment | | Tmin | TIME | Minimum wait time between two EO events | | Adapter | Direction | Type | Comment | | Adapter | | ... |–––|–––––|––––––|–––––––––––––| | I | Socket | ALR (unidirectional) | Input value (`D1`) and clock (`E1`) | | Q | Plug | ALR (unidirectional) | Output value (`D1`) and acknowledgement (`E1`) |

The unidirectional adapter `ALR` has an event input `E1` and a data input `D1` (socket side) and an event output `E1` and a data output `D1` (plug side). The exact semantics of `E1` and `D1` are application-specific; here, `E1` serves as the clock signal and `D1` as the data value to be latched.

Functionality

After initialization (INIT), the function block operates as follows:

1. An **event at the input adapter `I.E1`** triggers the latch operation. The current value `I.D1` is internally adopted.
2. The latched value is immediately output at the output adapter `Q.D1`.
3. Simultaneously, an event `Q.E1` is triggered – but only after at least `Tmin` has elapsed since the last output event.

If another `I.E1` event arrives within the waiting time, it is ignored (or processed only after `Tmin` has elapsed). The minimum delay is implemented by the internal function block `E_D_FF_ANY_TMIN`.

The data value is updated on every valid clock cycle, but the event output is delayed.

Technical Features

- **Composite Function Block**: The function block is implemented as a composite function block and internally uses the function block `iec61499::events::E_D_FF_ANY_TMIN`. The logic of the actual flip-flop and the timing control are encapsulated there.
- **Universal Time Interval**: `Tmin` can be set at runtime via INIT and is not fixed.
- **Buffered Events**: Since the event output is delayed, incoming clock events can be lost during the waiting period unless the internal function block buffers them (not specified here). Typically, they are simply ignored.
- **Adapter-based interface**: The use of adapters enables flexible interconnection in modular control applications without the need for hardwiring.

State overview

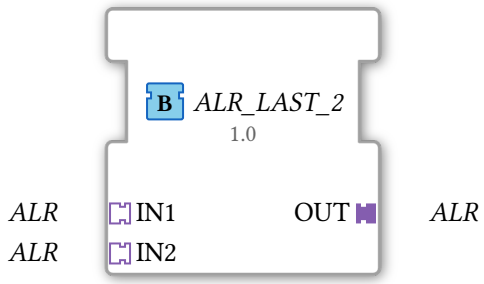
The function block does not have explicit states but operates event-driven:

- **Idle**: Waiting for `I.E1` (after INIT).
- **Latching**: The data value is transferred upon `I.E1`, and `Q.E1` is triggered after `Tmin` has expired.
- **Blocked**: While `Tmin` has not yet expired, further `I.E1` are ignored.
- After the waiting period expires, the function block returns to the idle state.

Application Scenarios

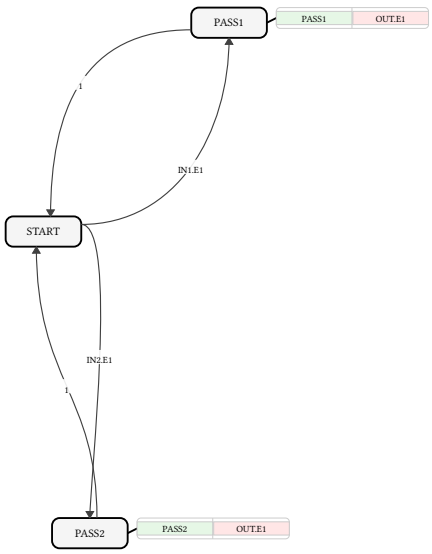
- **Sensor Signal Debouncing**: A sensor delivers events faster than the subsequent controller can process them. `Tmin` defines the minimum interval.
- **Pulse Width Limiting**: Ensures that actuator controls are not switched too quickly in succession (e.g., valves, motors).

- **Clock Synchronization**: When a data value is latched with an asynchronous clock and only passed on after a defined dead time.
- **Safety Functions**: Prevents “rapid-fire” commands in critical applications.



Comparison with Similar Function Blocks

- **E_D_FF_ANY_TMIN**: This is the internal function block – it offers the same functionality, but without the adapter interface. `ALR_D_FF_TMIN` encapsulates this in a more user-friendly, adapter-based form.
- **Standard IEC 61499 D flip-flops**: These often lack time-based control of output events. The function block described here extends this functionality with the `Tmin` delay.
- **Function block with TON/Timer**: A simple timer would only trigger after a delay but would not hold a data value. The combination with a latch is specific.



Conclusion

The function block `ALR_D_FF_TMIN` combines the features of a D flip-flop with an adjustable minimum time between event outputs. Thanks to its adapter technology and simple initialization, it can be flexibly deployed in IoT, automation, or control environments. It is particularly suitable for applications that require temporal decoupling between data acquisition and event transmission.

ALR_LAST_2

ECC: ALR_LAST_2

Introduction

The ALR_LAST_2 function block merges two same-type LREAL adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event

wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: LREAL adapter (unidirectional) - first signal source
- **IN2**: LREAL adapter (unidirectional) - second signal source

Output adapter (Plug):

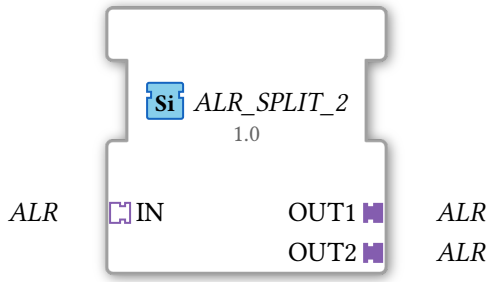
- **OUT**: LREAL adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid LREAL signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same LREAL value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

ALR_LAST_2 is the inverse of `ALR_SPLIT_2`: ALR_SPLIT_2 distributes 1 input to 2 outputs, ALR_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

ALR_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The ALR_SPLIT_2 function block splits an incoming ALR adapter signal into two identical output signals. It is designed generically (`GEN_ALR_SPLIT`) and is suitable for distributing alarm or lifecycle signals.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

- **IN** (Socket): Type `adapter::types::unidirectional::ALR` – Input adapter for the ALR signal.
- **OUT1** (Plug): Type `adapter::types::unidirectional::ALR` – first output adapter.
- **OUT2** (Plug): Type `adapter::types::unidirectional::ALR` – second output adapter.

Functionality

The function block forwards the ALR signal received via socket `IN` unchanged to both plugs `OUT1` and `OUT2`. No transformation or delay occurs. The signal is passively split.

Technical Features

- The function block is implemented as a generic function block (attribute `GenericClassName = 'GEN_ALR_SPLIT'`).
- Unidirectional adapters of type `ALR` are used, which only support one direction of data flow.
- No internal timers, states, or events – pure signal distribution.

State Overview

This function block has no state machines. Its behavior is determined solely by the adapter definition.

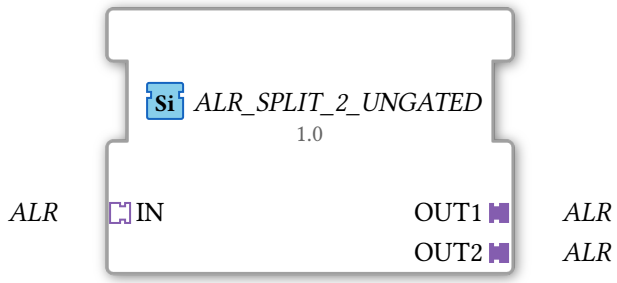
Application Scenarios

- Distribution of an ALR signal (e.g., alarm, temperature limit) to two different receivers.
- As part of a logic circuit that needs to evaluate an alarm signal multiple times.
- Use in control systems that forward a signal in parallel to two function blocks.

Comparison with Similar Function Blocks

- **ALR_SPLIT_2** splits an ALR signal to two outputs; comparable to event splitters like `E_SWITCH` or `E_SPLIT`, but for ALR adapters.
- Unlike data-based splitters (`MUX`, `F_SPLIT`), no data manipulation takes place here.
- Variants with more outputs may exist (e.g., `ALR_SPLIT_4`), allowing for a higher number of distributions.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

ALR_SPLIT_2` is a simple and effective component for splitting an incoming ALR adapter signal to two outputs. Due to its generic nature and lack of logic, it is ideally suited for clean signal distribution in IEC 61499 systems.

ALR_SPLIT_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of ALR_SPLIT_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

Adapter

- **IN** (Socket): Type `adapter::types::unidirectional::ALR` – Input adapter for the ALR signal.
- **OUT1** (Plug): Type `adapter::types::unidirectional::ALR` – first output adapter.
- **OUT2** (Plug): Type `adapter::types::unidirectional::ALR` – second output adapter.

Functionality

The function block forwards the ALR signal received via socket `IN` unchanged to both plugs `OUT1` and `OUT2`. No transformation or delay occurs. The signal is passively split.

Technical Features

- The function block is implemented as a generic function block (attribute `GenericClassName = 'GEN_ALR_SPLIT'`).
- Unidirectional adapters of type `ALR` are used, which only support one direction of data flow.
- No internal timers, states, or events – pure signal distribution.

State Overview

This function block has no state machines. Its behavior is determined solely by the adapter definition.

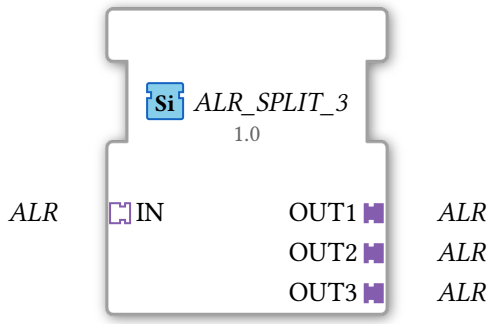
Application Scenarios

- Distribution of an ALR signal (e.g., alarm, temperature limit) to two different receivers.
- As part of a logic circuit that needs to evaluate an alarm signal multiple times.
- Use in control systems that forward a signal in parallel to two function blocks.

Comparison with Similar Function Blocks

- **ALR_SPLIT_2_UNGATED** splits an ALR signal to two outputs; comparable to event splitters like `E_SWITCH` or `E_SPLIT`, but for ALR adapters.
- Unlike data-based splitters (`MUX`, `F_SPLIT`), no data manipulation takes place here.

- Variants with more outputs may exist (e.g., `ALR_SPLIT_4`), allowing for a higher number of distributions.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

ALR_SPLIT_2_UNGATED` is a simple and effective component for splitting an incoming ALR adapter signal to two outputs. Due to its generic nature and lack of logic, it is ideally suited for clean signal distribution in IEC 61499 systems.

ALR_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALR_SPLIT_3** serves as a generic SPLIT function block that splits an incoming ALR signal (alarm or event signal) into three identical outputs. It is primarily used in automation systems where a single signal needs to be distributed in parallel to multiple downstream components without altering the signal quality or logic.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

- **IN** – *Socket* (Input) of type `adapter::types::unidirectional::ALR` Receives the ALR signal to be distributed.
- **OUT1** – *Plug* (Output 1) of type `adapter::types::unidirectional::ALR` Passes the incoming signal on unchanged.
- **OUT2** – *Plug* (Output 2) of type `adapter::types::unidirectional::ALR`
- **OUT3** – *Plug* (Output 3) of type `adapter::types::unidirectional::ALR`

Functionality

This module functions purely as a signal distributor. As soon as an ALR signal is present at the adapter socket **IN** (e.g., an alarm state, an event, or an activation), this signal is forwarded to all three adapter

plugs **OUT1**, **OUT2**, and **OUT3** without delay or manipulation. No logical processing or filtering takes place. Distribution is handled passively via the connection logic of the 4diac IDE.

Technical Features

- **Generic Function Block** – The block can be created as a generic instance using the attributes `eclipse4diac::core::GenericClassName` and `eclipse4diac::core::TypeHash`. This allows for easy reuse and parameterization in different projects.
- **No State Machine** – The block does not have an ECC (Execution Control Chart), as its behavior is defined solely by the adapter connectivity.
- **Unidirectional Adapters** – All ALR adapters used are of type `unidirectional`; the signal direction is fixed (input ⟶ outputs).

State Overview

The function block does not define any internal states. The output signal always corresponds instantaneously to the input signal. A separate state description is therefore not required.

Application Scenarios

- **Alarm Distribution** – A central alarm detector (e.g., a higher-level control system) is connected to three independent control units that are intended to react to the alarm in parallel.
- **Signal Multiplexing** – A Boolean or value-based signal from a sensor is distributed to multiple actuators or visualizations.
- **Redundancy Architectures** – The same signal is sent to two or three independent paths to achieve fault tolerance.

Comparison with Similar Function Blocks

- **ALR_SPLIT_2** – Distributes a signal to two outputs (identical function, but fewer outputs).
- **ALR_SPLIT_4** – Distributes one signal to four outputs.
- **Manual Coupling** – Without the SPLIT function block, the signal would have to be tapped multiple times in the application or distributed via a common line, which reduces clarity and maintainability.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ALR_SPLIT_3** is a simple yet useful generic function block for multiplying an ALR signal. It facilitates structured and reusable interconnection in automation solutions where a signal needs to be passed on to multiple receivers without additional logic or latency.

ALR_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALR_SPLIT_4** splits an incoming ALR adapter signal into four identical outputs. It is a generic function block (FB) that can be used with various ALR adapter types.

Interface Structure

Event Inputs

No event inputs are available. Event control is handled via the input adapter.

Event Outputs

No event outputs are available. Events are forwarded via the output adapters.

Data Inputs

No data inputs are available. Data is provided via the input adapter.

Data Outputs

No data outputs are available. Data is output via the output adapters.

Adapters

- **Socket (Input)**:
- **IN**: Unidirectional ALR adapter (type `adapter::types::unidirectional::ALR`). Receives the incoming signal.
- **Plugs (Outputs)**:
- **OUT1**, **OUT2**, **OUT3**, **OUT4**: Each a unidirectional ALR adapter (same type). Outputs the distributed signal.

Functionality

The module features direct pass-through: All events and data arriving at the input adapter **IN** are passed on unchanged and simultaneously to the four output adapters **OUT1** to **OUT4**. No processing, buffering, or filtering takes place. The module operates purely combinationally.

Technical Features

- **Generic Type**: The specific ALR adapter type can be defined at design time using the attribute `eclipse4diac::core::GenericClassName` (e.g., `'GEN_ALR_SPLIT'`).
- **Unidirectional**: The data flow direction is fixed from input to output. Backward communication is not supported.
- **No State Logic**: The function block does not contain an event-driven state machine (ECC) and does not include any time delays.

State Overview

The function block does not have its own states. Signal transmission is continuous and instantaneous.

Application Scenarios

- Distribution of an ALR signal (e.g., control commands, status messages) to multiple parallel modules or actuators.
- Creation of branches in adapter-based communication when multiple downstream components require the same information.
- Use in modular automation systems where a common signal needs to be split across multiple identical units.

Comparison with similar components

- **ALR_SPLIT_2 / ALR_SPLIT_N**: Split components with a different number of outputs (e.g., 2 or 8).
- **Event Splitters**: Split events but operate at the event level only. ALR_SPLIT_4, on the other hand, distributes complete adapter signals (events and data encapsulated).
- **Data Splitters**: Distribute individual data values, but without adapter encapsulation. ALR_SPLIT_4 is specifically optimized for use with unidirectional ALR adapter types.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

ALR_SPLIT_4 is a simple yet essential component for multiplying adapter connections. Its generic design allows it to be used with various ALR adapter types without requiring any modification to the block logic. It is particularly suitable for modular architectures where a signal needs to be distributed to multiple receivers in parallel.

ALR_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALR_SPLIT_5** is used to distribute an incoming ALR signal to five identical outputs. It is implemented as a generic function block (Generic FB) and enables simple signal multiplication in control systems based on the adapter concept of IEC 61499.

Interface Structure

Event Inputs

No event inputs are available.

Event Outputs

No event outputs are available.

Data Inputs

No data inputs are available. All data transmission occurs exclusively via adapters.

Data Outputs

No data outputs are available.

Adapter

The module has one socket (input) and five plugs (outputs):

Direction	Name	Type	Description
Input	IN	`adapter::types::unidirectional::ALR`	Receives the ALR signal to be distributed
Output	OUT1	`adapter::types::unidirectional::ALR`	First output with the identical ALR signal
Output	OUT2	`adapter::types::unidirectional::ALR`	Second output with the identical ALR signal
Output	OUT3	`adapter::types::unidirectional::ALR`	Third output with the identical ALR signal
Output	OUT4	`adapter::types::unidirectional::ALR`	Fourth output with the identical ALR signal
Output	OUT5	`adapter::types::unidirectional::ALR`	Fifth output with the identical ALR signal

Functionality

This function block forwards the ALR signal received from socket `IN` unchanged to all five plugs `OUT1` to `OUT5`. This is a purely combinational forwarding process – no logic, delay, or data manipulation takes place. The block operates without requiring an event or state; as soon as a signal is present at the input, it is available at all outputs.

This function block forwards the ALR signal received from socket `IN` unchanged to all five plugs `OUT1` to `OUT5`.

- **Generic Function Block:** The function block is defined as a Generic FB and uses the Eclipse 4diac Generics mechanisms (`eclipse4diac::core::GenericClassName`). This allows it to be used in various contexts without modifying the core logic.
- **Pure Adapter Communication:** No traditional event or data inputs/outputs are used. All communication takes place via adapters of type `ALR`, which enable unidirectional data exchange.
- **Simple Structure:** No state machines or time dependencies – the function block is deterministic and resource-efficient.

The function block has no explicit state logic or state machine. It operates entirely combinatorially, meaning the output signal is derived directly from the input signal without delay.

- **Signal Distribution in Automation:** A sensor delivers an ALR signal that must be forwarded in parallel to several actuators (e.g., valves, drives).

- **Redundancy:** The signal can be distributed to various control units or monitoring modules.
- **Test and Simulation Environments:** A central ALR signal is split across multiple test points to enable parallel evaluations.
- **ALR_SPLIT_2, ALR_SPLIT_3, ALR_SPLIT_4:** These function blocks split an ALR signal across two, three, and four outputs, respectively. This function block extends this to five outputs.
- **General Split Function Blocks (e.g., DATA_SPLIT):** Similar function blocks exist for other data types. Their functionality is identical; only the adapter type used differs. The advantage of ALR_SPLIT_5 lies in its direct use of the ALR adapter protocol without additional type conversion.

The **ALR_SPLIT_5** is a simple yet valuable component for multiplying ALR signals in IEC 61499 systems. Its generic and combinatorial implementation makes it easy to integrate and resource-efficient. It is particularly suitable for applications where a signal needs to be distributed to multiple receivers without requiring additional logic or timing.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALR_SPLIT_5_UNGATED** is used to distribute an incoming ALR signal to five identical outputs. It is implemented as a generic function block (Generic FB) and enables simple signal multiplication in control systems based on the adapter concept of IEC 61499.

Interface Structure

Event Inputs

No event inputs are available.

Event Outputs

No event outputs are available.

Data Inputs

No data inputs are available. All data transmission occurs exclusively via adapters.

Data Outputs

No data outputs are available.

Adapter

The module has one socket (input) and five plugs (outputs):

Direction	Name	Type	Description
Input	IN	`adapter::types::unidirectional::ALR`	Receives the ALR signal to be distributed
Output	OUT1	`adapter::types::unidirectional::ALR`	First output with the identical ALR signal
Output	OUT2	`adapter::types::unidirectional::ALR`	Second output with the identical ALR signal
Output	OUT3	`adapter::types::unidirectional::ALR`	Third output with the identical ALR signal
Output	OUT4	`adapter::types::unidirectional::ALR`	Fourth output with the identical ALR signal
Output	OUT5	`adapter::types::unidirectional::ALR`	Fifth output with the identical ALR signal

Functionality

This function block forwards the ALR signal received from socket `IN` unchanged to all five plugs `OUT1` to `OUT5`. This is a purely combinational forwarding process – no logic, delay, or data manipulation takes place. The block operates without requiring an event or state; as soon as a signal is present at the input, it is available at all outputs.

This function block forwards the ALR signal received from socket `IN` unchanged to all five plugs `OUT1` to `OUT5`.

- **Generic Function Block:** The function block is defined as a Generic FB and uses the Eclipse 4diac Generics mechanisms (`eclipse4diac::core::GenericClassName`). This allows it to be used in various contexts without modifying the core logic.
- **Pure Adapter Communication:** No traditional event or data inputs/outputs are used. All communication takes place via adapters of type `ALR`, which enable unidirectional data exchange.
- **Simple Structure:** No state machines or time dependencies – the function block is deterministic and resource-efficient.

The function block has no explicit state logic or state machine. It operates entirely combinatorially, meaning the output signal is derived directly from the input signal without delay.

- **Signal Distribution in Automation:** A sensor delivers an ALR signal that must be forwarded in parallel to several actuators (e.g., valves, drives).

- **Redundancy:** The signal can be distributed to various control units or monitoring modules.
- **Test and Simulation Environments:** A central ALR signal is split across multiple test points to enable parallel evaluations.
- **ALR_SPLIT_2, ALR_SPLIT_3, ALR_SPLIT_4:** These function blocks split an ALR signal across two, three, and four outputs, respectively. This function block extends this to five outputs.
- **General Split Function Blocks (e.g., DATA_SPLIT):** Similar function blocks exist for other data types. Their functionality is identical; only the adapter type used differs. The advantage of ALR_SPLIT_5_UNGATED lies in its direct use of the ALR adapter protocol without additional type conversion.

The **ALR_SPLIT_5_UNGATED** is a simple yet valuable component for multiplying ALR signals in IEC 61499 systems. Its generic and combinatorial implementation makes it easy to integrate and resource-efficient. It is particularly suitable for applications where a signal needs to be distributed to multiple receivers without requiring additional logic or timing.

ALR_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The ALR_SPLIT_6 function block is a generic 1:6 splitter for the adapter type `adapter::types::unidirectional::ALR`. It distributes an incoming ALR signal unchanged to six outputs and serves as a passive signal distributor without data manipulation.

Interface Structure

Event Inputs
None

Event Outputs
None

Data Inputs
None

Data Outputs
None

Adapter

Name	Type	Direction	Description
IN	adapter::types::unidirectional::ALR	Socket (Input)	ALR input signal copied to all outputs
OUT1	adapter::types::unidirectional::ALR	Plug (Output)	First ALR output
OUT2	adapter::types::unidirectional::ALR	Plug (Output)	Second ALR output
OUT3	adapter::types::unidirectional::ALR	Plug (Output)	Third ALR output
OUT4	adapter::types::unidirectional::ALR	Plug (Output)	Fourth ALR output
OUT5	adapter::types::unidirectional::ALR	Plug (Output)	Fifth ALR output
OUT6	adapter::types::unidirectional::ALR	Plug (Output)	Sixth ALR Output

Functionality
This function block forwards the adapter signal present at Socket IN unchanged to all six plugs OUT1–OUT6. No transformation, delay, or selection takes place – all outputs always receive the identical signal copy. The function block is declared as a generic function block (`GEN_ALR_SPLIT`) and can be typed by specifying the concrete adapter type.

Technical Features
- Purely passive splitter without events, data ports, or state machines.
- Generic implementation via the metadata `eclipse4diac::core::GenericClassName = 'GEN_ALR_SPLIT'`.
- All adapter interfaces are unidirectional; there are no return channels.
- No runtime dependencies or initialization are required.

State Overview
The function block has no ECC (Execution Control Chart) and no internal states. It operates continuously and immediately forwards every incoming adapter signal to all outputs.

Application Scenarios
- Duplication of an ALR signal for parallel loads in control networks.
- Signal distribution in agricultural automation systems (based on the ALR adapter context).
- Easy provision of an identical reference for multiple downstream logic blocks.

Comparison with Similar Blocks
- **ALR_SPLIT_2 / ALR_SPLIT_3 / …** – same functionality, but with fewer outputs.
- **Event-based splitters (e.g., E_SPLIT)** – operate with event/data separation, while ALR_SPLIT_6 uses adapters exclusively.
- **Data multiplexers** – select one output; ALR_SPLIT_6 always activates all outputs.

- `ALR_SPLIT_6_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

ALR_SPLIT_6 is a minimalist and reliable block for signal duplication at the adapter level. Its generic design facilitates reuse in different projects, and the absence of complex logic keeps the data flow model clear and simple.

ALR_SPLIT_7

(No image available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ALR_SPLIT_7` is used to split an incoming ALR (Agricultural Logic Resource) signal into seven identical output signals. It is designed as a generic block and enables the parallel distribution of an alarm or control signal to up to seven downstream components or subsystems.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapters

Name	Type	Direction	Description
IN	`adapter::types::unidirectional::ALR`	Socket (Input)	Incoming ALR signal, which is distributed to the outputs.
OUT1	`adapter::types::unidirectional::ALR`	Plug (Output)	First output of the split signal.
OUT2	`adapter::types::unidirectional::ALR`	Plug (Output)	Second output of the split signal.

OUT3	adapter::types::unidirectional::ALR	Plug (Output)	Third output of the split signal.
OUT4	adapter::types::unidirectional::ALR	Plug (Output)	Fourth output of the split signal.
OUT5	adapter::types::unidirectional::ALR	Plug (Output)	Fifth output of the split signal.
OUT6	adapter::types::unidirectional::ALR	Plug (Output)	Sixth output of the split signal.
OUT7	adapter::types::unidirectional::ALR	Plug (Output)	Seventh output of the split signal.

Functionality

The ALR_SPLIT_7 module forwards the ALR signal present at its socket IN unchanged to all seven plugs (OUT1 to OUT7). No transformation, delay, or filtering of the signal takes place. The module functions purely as a splitter for a unidirectional ALR data stream.

Technical Features

- **Generic FB:** The function block is implemented as a generic function block (GenericClassName = 'GEN_ALR_SPLIT') and can be parameterized or instantiated depending on the application.
- **Unidirectional:** All adapters are of type adapter::types::unidirectional::ALR, meaning data flows in only one direction – from the input to the outputs.
- **No Event Control:** The function block has no event inputs or outputs; signal transmission is continuous (data-driven).

State Overview

The function block does not have an internal state machine. There are no states in the sense of an ECC (Execution Control Chart). It operates purely combinationally and always outputs the input signal to all outputs.

Application Scenarios

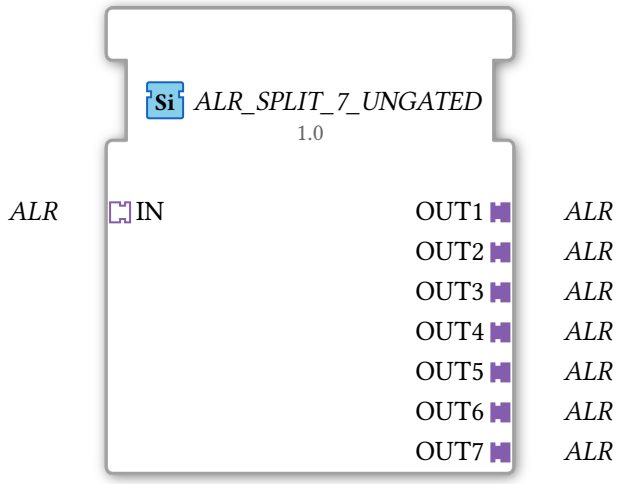
- **Distributing an Alarm to Multiple Units:** A central alarm signal (e.g., a fault) is to be forwarded to seven different controllers or display elements.
- **Parallel Processing:** An ALR signal is required to trigger or monitor multiple independent subsystems simultaneously.
- **Redundancy and Testing:** The signal is sent to multiple test or logging components without interfering with each other.

Comparison with Similar Components

Component	Number of Outputs	Special Feature
ALR_SPLIT_2	2	Simple Dual Distribution
ALR_SPLIT_4	4	Quad Distribution
ALR_SPLIT_7	7	Seven-Way Distribution (this module)
ALR_SPLIT_N (generic)	Configurable	Flexible splitter with adjustable number of paths

All variations are based on the same principle: unidirectional distribution without signal modification.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The ALR_SPLIT_7 is a simple yet useful function block for splitting a single ALR signal into seven parallel paths. Its generic implementation allows it to be used in various industrial or agricultural automation scenarios where a signal is needed multiple times. It does not offer complex logic but reliably fulfills its function as a passive splitter.

ALR_SPLIT_7_UNGATED

i UNGATED variant: This block is the ungated version of `ALR_SPLIT_7`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). It does not offer complex logic but reliably fulfills its function as a passive splitter.

ALR_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **ALR_SPLIT_8** is used to split a single ALR signal (via a socket) into eight identical ALR outputs (plugs). This block is designed as a generic function block and enables signal distribution within an IEC 61499-based controller.

Interface Structure

Event Inputs

No direct event inputs are available. Control is integrated into the input adapter.

Event Outputs

No direct event outputs are available. Control is integrated into the output adapters.

Data Inputs

No direct data inputs are available. Data is received via the input adapter.

Data Outputs

No direct data outputs are available. Data is provided via the output adapters.

Adapter

Name	Type	Direction	Description
IN	`adapter::types::unidirectional::ALR`	Socket	Input signal that is routed to all outputs
OUT1	`adapter::types::unidirectional::ALR`	Plug	Output 1 – duplicated signal
OUT2	`adapter::types::unidirectional::ALR`	Plug	Output 2 – duplicated signal
OUT3	`adapter::types::unidirectional::ALR`	Plug	Output 3 – duplicated signal
OUT4	`adapter::types::unidirectional::ALR`	Plug	Output 4 – duplicated signal
OUT5	`adapter::types::unidirectional::ALR`	Plug	Output 5 – duplicated signal
OUT6	`adapter::types::unidirectional::ALR`	Plug	Output 6 – Duplicated Signal
OUT7	`adapter::types::unidirectional::ALR`	Plug	Output 7 – Duplicated Signal
OUT8	`adapter::types::unidirectional::ALR`	Plug	Output 8 – Duplicated Signal

Functionality

The function block forwards the ALR signal received via socket **IN** unchanged to all eight output adapters **OUT1** to **OUT8**. No data processing or time delay occurs – the signals are passed through directly. This allows multiple subsequent function blocks to be supplied with the same signal in parallel.

Technical Features

- **Generic Type:** The function block is implemented as a generic function block (`GenericClassName = 'GEN_ALR_SPLIT'`), so the underlying ALR type can be specified during instantiation.
- **Adapter-Based:** All communication occurs via adapters, ensuring loose coupling and easy reuse.

State Overview

The function block has no events and no internal state machine. Execution is strictly data flow-driven: If the signal at the input changes, it is immediately propagated to all outputs.

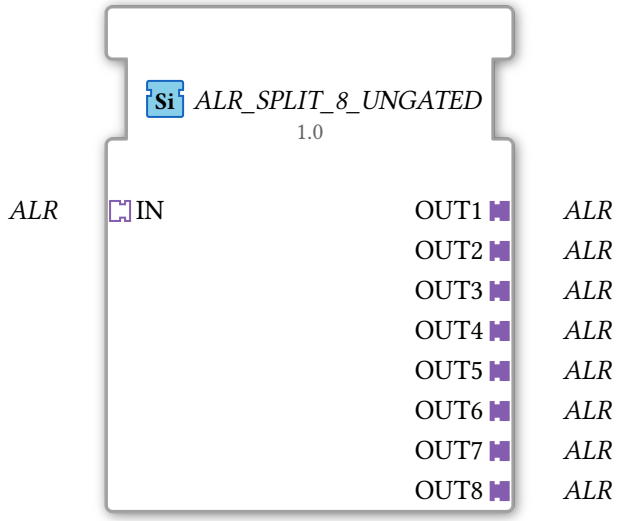
Application Scenarios

- **Signal Splitting** in control architectures when an ALR signal is needed multiple times (e.g., for parallel evaluations or redundancy).
- **Interconnecting multiple subsystems** with identical control data, without multiple signal generation.
- **Test setups** for simultaneously stimulating multiple receivers with the same value.

Comparison with Similar Function Blocks

Other splitter function blocks (e.g., SPLIT_4 or SPLIT_16) differ only in the number of outputs. The ALR_SPLIT_8 is specifically designed for the ALR adapter type, while generic splitters (e.g., ANY_SPLIT) can be used for any data type. This component provides an optimized, type-safe solution for ALR distribution applications.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ALR_SPLIT_8** is a simple yet effective functional block for multiplying an ALR signal to eight outputs. Its generic nature, adapter-based interface, and passive operation make it a robust and flexible component for IEC 61499 applications.

ALR_SPLIT_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of ALR_SPLIT_8. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

ALR_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The **ALR_SPLIT_9** is a generic function block that splits an incoming ALR signal (unidirectional adapter) into exactly nine identical outputs. It functions as a 1:9 splitter for the adapter type `ALR` from the package `adapter::types::unidirectional`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Direction	Name	Type
Socket	`IN`	`ALR` (unidirectional) – The input that is distributed to the nine outputs.
Plug	`OUT1` ... `OUT9`	`ALR` (unidirectional) – The nine outputs to which the incoming signal is provided.

Functionality

The module forwards the ALR signal present at socket `IN` unchanged and without delay to all nine plugs (`OUT1` to `OUT9`). No processing, conversion, or state logic takes place – the function block (FB) implements pure signal distribution at the adapter level.

Technical Features

- The FB is generic and has the attributes `GenericClassName` (value: `'GEN_ALR_SPLIT'`) and `TypeHash`.
- It uses only adapter interfaces; no events or input/output data are defined.
- Since no algorithm or state machine is implemented, the FB operates passively and efficiently.

State Overview

The FB has no state machine because it has no internal logic or memory behavior.

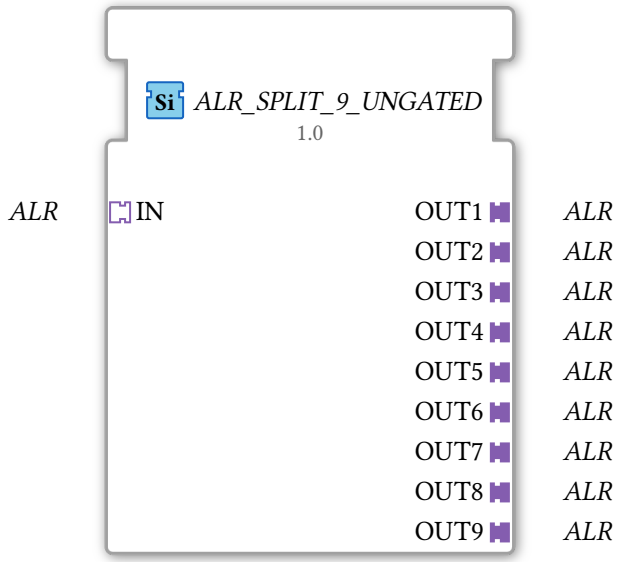
Application Scenarios

- **Signal Distribution:** An ALR event generated by a controller should reach multiple actuators or components simultaneously.
- **Redundant Control:** Several identical devices must receive the same output signal (e.g., parallel hydraulic valves in agricultural machinery).
- **Monitoring:** A signal should be passed to a monitoring unit and simultaneously to the actual device without interference.

Comparison with Similar Function Blocks

- **ALR_SPLIT_4 / ALR_SPLIT_8:** Analog function blocks with a different number of outputs.
- **Data Type Splitters (e.g., `SPLIT_INT`):** These operate at the data level, while `ALR_SPLIT_9` operates at the adapter level (signal/event forwarding).
- **Adapter Multiplexers/Demultiplexers:** Unlike these, `ALR_SPLIT_9` does not select or combine signals, but simply forwards the incoming signal 1:9.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ALR_SPLIT_9** is a simple yet practical function block for distributing a unidirectional ALR signal across nine parallel paths. It is easy to understand, requires no resources for logic or states, and can be directly integrated into control programs that require signal duplication.

ALR_SPLIT_9_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ALR_SPLIT_9`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

AL_D_FF

Value to latch – *AL*

AL – Latched value

• – ○ • – ○ • – ○ •

Introduction

The function block **AL_D_FF** implements a data latch flip-flop (D flip-flop). It serves to store a digital data value upon each incoming event and make the stored value available via an adapter output. The block encapsulates the recurring task of a D flip-flop and provides a clean, typed interface for event and data exchange via adapters.

Interface Structure

Event Inputs

No direct event inputs. The event for transferring the data value is provided via the adapter socket **I** (E1).

Event Outputs

No direct event outputs. The output event is provided via the adapter plug **Q** (E1).

Data Inputs

No direct data inputs. The data value to be stored is supplied via the adapter socket **I** (D1).

Data Outputs

No direct data outputs. The stored data value is output via the adapter plug **Q** (D1).

Adapters

Name	Type	Direction	Comment
I	`adapter::types::unidirectional::AL`	Socket	Value to be latched
Q	`adapter::types::unidirectional::AL`	Plug	Latched value

The adapters are unidirectional and of type `AL`. Each adapter contains an event input/output (E1) and a data input/output (D1). Socket **I** serves as the input interface, and plug **Q** as the output interface.

Functionality

The function block internally uses the standard function block `iec61499::events::E_D_FF_ANY`.

Upon each event at the adapter input **I** (E1), the data value from **I.D1** is taken and stored at the adapter output **Q.D1**. Simultaneously, an event is generated at output **Q.E1** to signal the availability of the new value to the downstream logic.

The takeover is edge-triggered (rising edge) – the behavior corresponds to a clocked D-latch or D-flip-flop, depending on the definition of the internally used function block.

Technical Features

- **Adapter-based interface**: Instead of individual inputs/outputs, the entire signal group (event + data) is combined via an adapter. This simplifies the connection in the application and ensures clear semantic encapsulation.
- **Reusing Existing Logic**: The function block delegates the core function to the IEC 61499 standard function block `E_D_FF_ANY`, thus using a proven and portable implementation.
- **Type Safety**: By using a defined adapter type (`AL`), it is ensured that only compatible signals can be connected.

State Overview

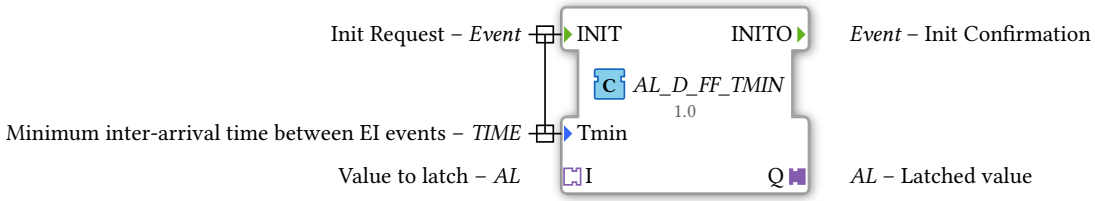
The function block does not have its own ECC state machine. Its internal behavior is entirely determined by the embedded function block `E_D_FF_ANY`. This implements a D flip-flop with two logical states:

- **State 0**: The stored value is `false` (or the adapter's data value is 0).
- **State 1**: The stored value is `true` (or the adapter's data value is 1).

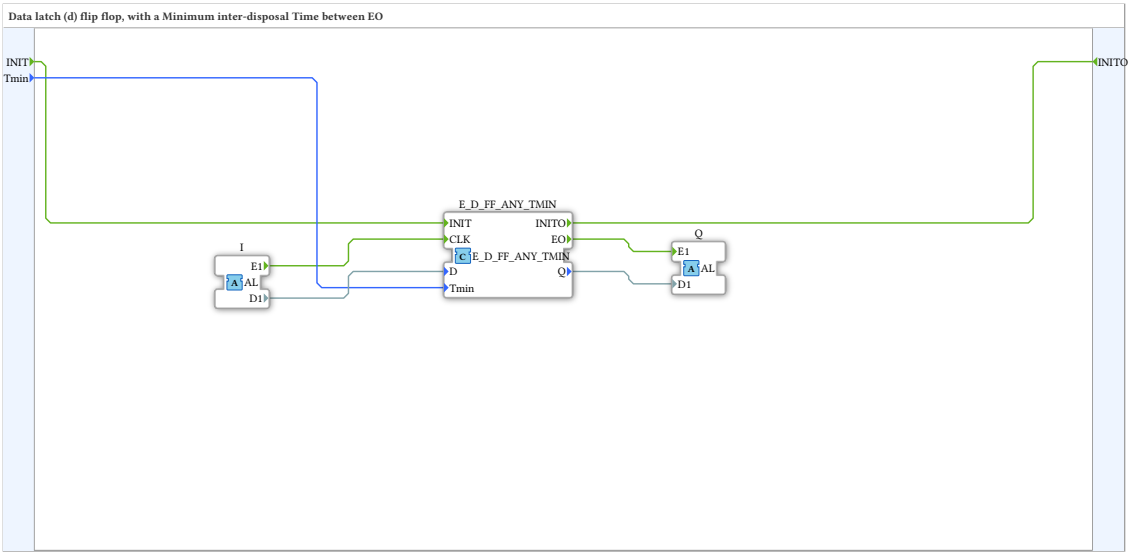
A state change occurs only upon an event at **I.E1** the value present at **I.D1** is then adopted.

Application Scenarios

- **Signal Delay and Synchronization**: A data value should only be passed on upon a defined event (e.g., clock edge).
- **Storage of a Binary State**: e.g., as part of a shift register, a state register, or marker logic.
- **Coupling with Adapter-Based Components**: Easy integration into applications that already use the adapter type `adapter::types::unidirectional::AL`.



Comparison with Similar Components



- **E_D_FF_ANY**: Standard D flip-flop with single event and data inputs. `AL_D_FF` encapsulates this function block and provides an adapter interface.
- **SR_FF or JK_FF**: Other flip-flop types with multiple control inputs. `AL_D_FF` is limited to basic D functionality.
- **AL_D_LATCH**: A simple latch without event control? (Not available). `AL_D_FF` operates on an edge and is therefore suitable for clock-synchronous systems.

Conclusion

The function block `AL_D_FF` offers an encapsulated, adapter-based solution for basic D flip-flop functionality. It simplifies the handling of signal and event groups in IEC 61499 applications, increases reusability, and remains reliable and traceable through traceability to a standardized core component.

AL_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The AL_D_FF_TMIN function block implements an edge-triggered D flip-flop (data latch) with an adjustable minimum inter-disposal time. It receives a data value upon an incoming event, stores it, and outputs it—along with its own event—only after the specified minimum time has elapsed. This limits the output event rate.

Interface Structure

Event Inputs

- **INIT**: Initialization request; sets the parameter Tmin for the minimum time between output events.

Event Outputs

- **INITO**: Confirmation of successful initialization.

Data Inputs

- **Tmin** (TIME): Minimum time interval that must be maintained between two consecutive output events (EO).

Data Outputs

- No direct data outputs – the latched values are transmitted exclusively via the output adapter Q.

Adapters

- **I** (Socket, Type: `adapter::types::unidirectional::AL`): Input adapter for the value to be latched. The latch pulse is received via the event interface (E1), and the data value to be latched is provided via the data interface (D1).
- **Q** (Plug, Type: `adapter::types::unidirectional::AL`): Output adapter for the stored value. An event (E1) is sent and the currently stored data value (D1) is output for each successful latch operation.

Functionality

The module internally uses the predefined flip-flop module `E_D_FF_ANY_TMIN`.

As soon as an event arrives at the input adapter (I.E1), the simultaneously present data value (I.D1) is received and stored internally. However, the output event (Q.E1) is only generated if at least the time interval specified by Tmin has elapsed since the last output event. Only then is the stored value passed on to the output adapter (Q.D1). Initialization with INIT sets the parameter Tmin and must be performed before first use.

Technical Features

- **Minimum time between output events**: The delay Tmin limits the frequency of output events – useful for preventing bus overloads or limiting the actuator control rate.
- **Adapter Interfaces**: Coupling is achieved via standardized, unidirectional adapters (`adapter::types::unidirectional::AL`). This allows the function block to be flexibly integrated into various applications.
- **Edge-Triggered**: The internal flip-flop reacts to the rising edge of the event at the input adapter (I.E1).

State Overview

The function block does not have an explicitly displayed state machine. Its behavior is determined by the internal D flip-flop with time control:

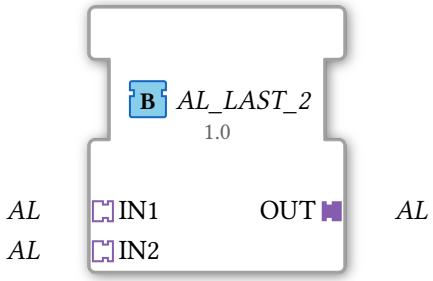
- After successful initialization (INIT ⟶ INITO), the function block waits for an event at the input adapter I.
- Upon an event, the incoming data value is latched. Immediately afterward, it is checked whether the time elapsed since the last output event has already exceeded Tmin.
- If yes: The output event is generated immediately.
- If no: The output is blocked until the waiting time has expired; then the output is generated.
- Events received during the wait time may be ignored or buffered (depending on the internal implementation of the underlying function block) – typically, only the most recent data value is considered for the next output.

Application Scenarios

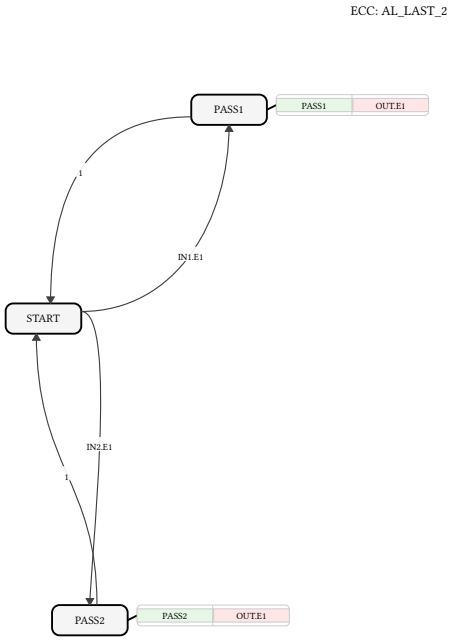
- **Synchronization of time-critical controllers** where data must not be updated more frequently than at a predefined interval.
- **Debouncing of signals** or throttling of event sequences in communication networks.
- **Simple state machines** that react to external events and must maintain a minimum response time (e.g., in automation technology or the control of physical actuators).

Comparison with Similar Function Blocks

- **AL_D_FF**: A simple D flip-flop without a minimum time between output events – AL_D_FF_TMIN extends this with the Tmin control and adapter interfaces.



AL_D_FF_TMIN - **E_D_FF_ANY_TMIN**: The underlying generic flip-flop that can be used directly (without adapter encapsulation). AL_D_FF_TMIN encapsulates this in a plug-and-play adapter format.



- **R_TRIG / F_TRIG**: Detect rising and falling edges, respectively, but do not store data values and do not offer an adjustable output delay.

Conclusion

The AL_D_FF_TMIN function block provides a reliable, edge-triggered D-latch function with an adjustable minimum time between output events. By using standardized adapter interfaces, it is easily integrated into IEC 61499 applications and is particularly suitable for applications that require limiting the event rate or time-controlled data release.

AL_LAST_2

Introduction

The AL_LAST_2 function block merges two same-type LWORD adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: LWORD adapter (unidirectional) - first signal source
- **IN2**: LWORD adapter (unidirectional) - second signal source

Output adapter (Plug):

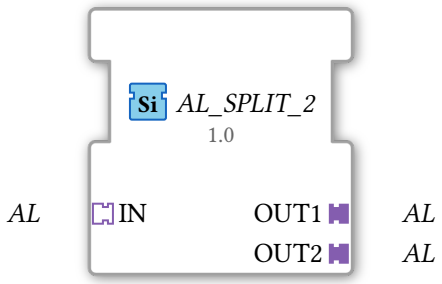
- **OUT**: LWORD adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid LWORD signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same LWORD value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AL_LAST_2 is the inverse of `AL_SPLIT_2`: AL_SPLIT_2 distributes 1 input to 2 outputs, AL_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

AL_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_SPLIT_2** is used to split an incoming unidirectional adapter signal into two identical outputs. It is designed as a generic function block, so the specific adapter type is only determined during use.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

Type	Direction	Name	Description
`adapter::types::unidirectional::AL`	**Socket** (Input)	`IN`	Input signal distributed to both outputs
`adapter::types::unidirectional::AL`	**Plug** (Output)	`OUT1`	First output with the same adapter signal as `IN`
`adapter::types::unidirectional::AL`	**Plug** (Output)	`OUT2`	Second output with the same adapter signal as `IN`

Functionality

The function block forwards the unidirectional adapter signal present at socket `IN` unchanged to both plugs `OUT1` and `OUT2`. No data processing or transformation takes place – the function block operates purely passively and by passing the signal through. As soon as a signal is present at the input, it is simultaneously available at both outputs.

Technical Features

- **Generic Type**: The function block is defined as a generic function block (attributes `GenericClassName` and `TypeHash`). This allows it to be used with different unidirectional adapter instances without requiring any modifications to the source code.
- **Adapters instead of Data Points**: Signal transmission occurs exclusively via adapters, not via discrete event or data inputs/outputs. This enables structured and reusable encapsulation of communication interfaces.
- **No State Dependency**: The function block has no internal memory and no state machine. The output signals follow the input signal directly.

State Overview

The function block does not have its own state management. It can be considered a **combinatorial** block where the outputs are always assigned the current input value. There is no explicit state machine.

Application Scenarios

- **Signal Distribution**: When an adapter signal needs to be passed from one source to multiple independent receivers (e.g., a control command to two actuators).
- **Logging / Monitoring**: An adapter signal can be split into a path for actual processing and simultaneously into a monitoring or logging path.
- **Modular Architectures**: In complex systems that use adapters, the `AL_SPLIT_2` simplifies the topological distribution of signals without requiring manual connections or duplicates.

Comparison with Similar Components

The 4diac IDE offers various splitter components for different signal types:

Component	Signal Type	Outputs	Special Feature
`AL_SPLIT_2`	Adapter (unidirectional)	2	Generic, no data/events
`SPLIT`	Events	2	Distributes events without data
`E_SPLIT`	Events (with data)	2	Distributes events along with accompanying data
`F_SPLIT`	Data (any type)	n	Distributes a data value to multiple outputs

The `AL_SPLIT_2` is specifically optimized for adapter interfaces, providing a clean way to split complex, adapter-based connections without interfering with the data or event layer.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AL_SPLIT_2` is a simple yet useful generic function block for splitting unidirectional adapter signals. It enables flexible and structured signal distribution in modular automation solutions without additional logic or state dependencies. Its generic nature makes it universally applicable.

AL_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_SPLIT_3** is used to split an incoming unidirectional adapter signal (AL – Adapter Label) into three identical output adapters. It is designed as a generic building block and enables the multiple forwarding of an adapter-based data or event flow within an IEC 61499 application.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AL`	IN	Socket	Input adapter that provides the signal to be distributed.
`adapter::types::unidirectional::AL`	OUT1	Plug	First output adapter – identical copy of the input signal.
`adapter::types::unidirectional::AL`	OUT2	Plug	Second output adapter – identical copy of the input signal.
`adapter::types::unidirectional::AL`	OUT3	Plug	Third output adapter – identical copy of the input signal.

Functionality

The function block (FB) forwards the unidirectional adapter signal present at socket **IN unchanged and without delay** to the three plugs **OUT1**, **OUT2**, and **OUT3**. No logical or timing manipulation takes place – the distribution is purely structural. This behavior corresponds to passive wiring (“fan-out”) at the adapter level.

Technical Features

- **Generic Implementation:** The function block uses the generic class name `'GEN_AL_SPLIT'`, allowing it to be reused for various instances of the unidirectional AL type, as long as the specific type is defined at design time.
- **No State Logic:** There are no internal states, events, or data variables. The FB is completely passive and requires no active processing.
- **No Runtime Dependencies:** The functionality is implemented at design time by the interconnection system of the 4diac IDE.

State Overview

The function block (FB) has **no internal state** and no state machine. It does not execute any sequential processes. The output signal is always a direct copy of the input signal.

Application Scenarios

- **Multiple Use of an Adapter:** A unidirectional AL signal provided by a component is to be distributed to several subsequent function blocks (e.g., a sensor signal to different evaluation units).
- **Architectural Structuring:** Splitting a data stream for parallel processing or monitoring without the source component needing to know the number of sinks.
- **Testing and Diagnostic Purposes:** Connecting additional monitoring or logging blocks to an existing adapter connection.

Comparison with Similar Function Blocks

- **Event-Based Splitters (e.g., E_SPLIT):** These split events, while AL_SPLIT_3 distributes adapter objects (complex data structures). Event splitters often require handling of event sequences.
- **Adapter Merger (e.g., AL_MERGE):** Combines multiple adapter signals into one – the opposite of the function described here.
- **Individual AL Splitters:** Generic versions also exist for other output numbers (e.g., AL_SPLIT_2, AL_SPLIT_4), differing only in the number of plugs.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AL_SPLIT_3 is a simple yet useful generic function block for duplicating a unidirectional adapter signal to three independent outputs. Due to its passive nature, it is resource-efficient and ideally suited for the flexible design of IEC 61499 applications where a signal is needed multiple times without altering the source logic.

AL_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_SPLIT_4** is a generic function block that splits a single adapter input (socket) of type `adapter::types::unidirectional::AL` into four separate outputs (plugs) of the same type. It serves to distribute an incoming adapter data stream to multiple parallel consumers without modifying the data itself.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Type	Name	Direction	Description
`adapter::types::unidirectional::AL`	**IN**	Socket (Input)	Incoming adapter data stream, distributed to all outputs.
`adapter::types::unidirectional::AL`	**OUT1**	Plug (Output)	First output – receives an identical copy of the input data stream.
`adapter::types::unidirectional::AL`	**OUT2**	Plug (Output)	Second output – receives an identical copy of the input data stream.

adapter::types::unidirectional::AL	**OUT3**	Plug (Output)	Third output – receives an identical copy of the input data stream.
adapter::types::unidirectional::AL	**OUT4**	Plug (Output)	Fourth output – receives an identical copy of the input data stream.

Functionality

This component is a pure signal distributor. It has internal logic that – as soon as the adapter input **IN** is connected to a data source – forwards the incoming data packets (events and data) directly and unchanged to all four output adapters **OUT1** to **OUT4**. No buffering, delay, or logical processing takes place. Each output receives exactly the same information as the input.

Technical Features

- **Generic Component:** The class `GEN_AL_SPLIT` is defined in the attribute `eclipse4diac::core::GenericClassName`, which means that the component can be reused as a template for various implementations of the adapter type `AL`.
- **No states or timing:** Since the function block operates exclusively on a line-based basis and has no processing logic, there are no internal states or concurrent execution sequences.
- **Adapter type:** The adapter used, `adapter::types::unidirectional::AL`, is a standardized, unidirectional adapter from the library `adapter::types::unidirectional`. Its exact interface (included events and data) is defined by the adapter definition and is not influenced by the split block itself.

State overview

The function block does not have a state machine. It operates statically and permanently distributes the input signal to all outputs.

Application scenarios

- **Distributing a control signal** to multiple parallel actuator units, e.g., in agricultural technology (as indicated in the copyright notice of HR Agrartechnik GmbH).
- **Splitting a measurement data source** across multiple analysis or logging modules.
- **Testing and Debugging:** An original adapter signal can be routed to multiple outputs to be sent to different test instances simultaneously.

Comparison with Similar Function Blocks

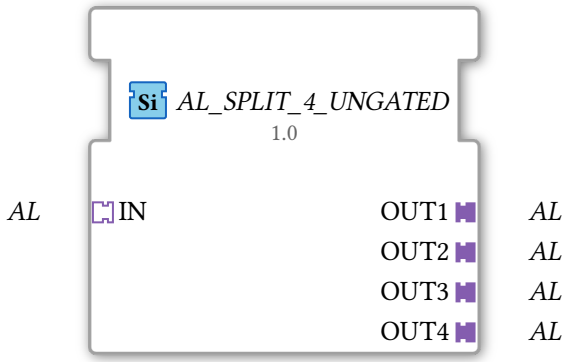
- **AL_SPLIT_2** – splits an AL signal across two outputs (fewer outputs, lower fan-out capacity).
- **AL_MERGE** – combines multiple AL inputs into one output (inverse function).
- **Event-based split function blocks (e.g., SPLIT_EVENT)** – split only events without duplicating the associated data adapters.

Unlike these function blocks, `AL_SPLIT_4` operates exclusively at the adapter level and copies complete adapter communication streams.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The **AL_SPLIT_4** function block is a simple, efficient signal fan for the `AL` adapter type. It is ideally suited for all applications where a single adapter data stream needs to be distributed to multiple consumers without additional logic or delays. Its generic nature allows its use in various automation contexts, particularly in agricultural machinery control, as intended by the manufacturer.

AL_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_SPLIT_5** serves as a generic splitter for a unidirectional adapter of type `AL`. It splits an incoming signal (via the `IN` socket) into five separate outputs (`OUT1` to `OUT5`). The block is marked as generic, which allows the specific adapter type to be defined when using it.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Type	Direction	Name	Description
Socket	Input	IN	Unidirectional `AL` adapter input
Plug	Output	OUT1	First output (unidirectional `AL`)
Plug	Output	OUT2	Second output (unidirectional `AL`)
Plug	Output	OUT3	Third output (unidirectional `AL`)
Plug	Output	OUT4	Fourth output (unidirectional `AL`)
Plug	Output	OUT5	Fifth output (unidirectional `AL`)

Functionality

The function block receives a signal of type `AL` via socket `IN` and forwards it unchanged to all five plugs `OUT1` to `OUT5`. No data processing or event handling takes place; the distribution occurs purely at the adapter level. This allows multiple downstream components to be supplied with the same adapter signal in parallel.

The function block is designed as a generic function block (`GEN_AL_SPLIT`). The specific adapter type `AL` can be defined via an attribute during instantiation.

Technical Features

- **No Events or Data**: The function block has only adapter interfaces, no event or data ports.
- **Generic Design**: The type of the `AL` adapter is configurable (generic class), allowing different implementations of the same adapter type to be used.
- **Pure Signal Distribution**: This is a pure 1:5 distribution without any logic, delay, or transformation.

State Overview

The function block does not have an internal state machine, as it does not process any events. It behaves statically and permanently passes the input signal to all outputs.

Application Scenarios

- **Signal Distribution**: If several components require the same adapter signal of a `AL` type, e.g., For example, to send a sensor value to different control logics.
- **Test and debugging environments**: An incoming adapter signal can be passed on to multiple monitor or logging blocks simultaneously.
- **Redundancy**: The signal can be distributed to parallel processing paths.

Comparison with similar blocks

Other splitter blocks exist in the 4diac ecosystem, such as `SPLIT` for event or data flows. The advantage of `AL_SPLIT_5` lies in its exclusive adapter interface. While a `SPLIT` block separates events or data, this block operates directly at the adapter level and requires no conversion between events and data. Similar function blocks with a different number of outputs (e.g., `AL_SPLIT_2`, `AL_SPLIT_3`) are conceivable, but are not included in this generic form by default.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AL_SPLIT_5** is a simple yet useful generic function block for duplicating a unidirectional adapter signal to five outputs. Due to its pure adapter interface and lack of event/data logic, it is particularly suitable for applications that need to distribute a signal to multiple receivers without processing. The generic design increases flexibility for reuse in different projects.

AL_SPLIT_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AL_SPLIT_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_SPLIT_5_UNGATED** serves as a generic splitter for a unidirectional adapter of type `AL`. It splits an incoming signal (via the `IN` socket) into five separate outputs (`OUT1` to `OUT5`). The block is marked as generic, which allows the specific adapter type to be defined when using it.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Type	Direction	Name	Description
Socket	Input	IN	Unidirectional `AL` adapter input
Plug	Output	OUT1	First output (unidirectional `AL`)
Plug	Output	OUT2	Second output (unidirectional `AL`)
Plug	Output	OUT3	Third output (unidirectional `AL`)
Plug	Output	OUT4	Fourth output (unidirectional `AL`)
Plug	Output	OUT5	Fifth output (unidirectional `AL`)

Functionality

The function block receives a signal of type `AL` via socket `IN` and forwards it unchanged to all five plugs `OUT1` to `OUT5`. No data processing or event handling takes place; the distribution occurs purely at the adapter level. This allows multiple downstream components to be supplied with the same adapter signal in parallel.

The function block is designed as a generic function block (`GEN_AL_SPLIT`). The specific adapter type `AL` can be defined via an attribute during instantiation.

Technical Features

- **No Events or Data**: The function block has only adapter interfaces, no event or data ports.

- **Generic Design**: The type of the `AL` adapter is configurable (generic class), allowing different implementations of the same adapter type to be used.
- **Pure Signal Distribution**: This is a pure 1:5 distribution without any logic, delay, or transformation.

State Overview

The function block does not have an internal state machine, as it does not process any events. It behaves statically and permanently passes the input signal to all outputs.

Application Scenarios

- **Signal Distribution**: If several components require the same adapter signal of a `AL` type, e.g., For example, to send a sensor value to different control logics.
- **Test and debugging environments**: An incoming adapter signal can be passed on to multiple monitor or logging blocks simultaneously.
- **Redundancy**: The signal can be distributed to parallel processing paths.

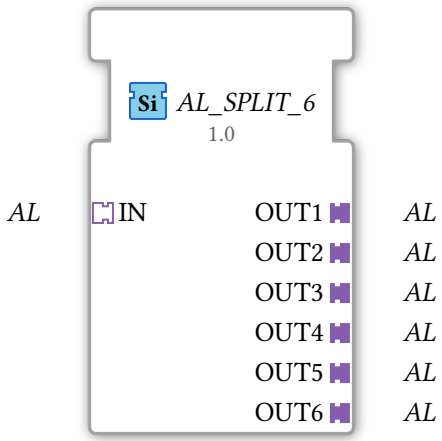
Comparison with similar blocks

Other splitter blocks exist in the 4diac ecosystem, such as `SPLIT` for event or data flows. The advantage of `AL_SPLIT_5_UNGATED` lies in its exclusive adapter interface. While a `SPLIT` block separates events or data, this block operates directly at the adapter level and requires no conversion between events and data. Similar function blocks with a different number of outputs (e.g., `AL_SPLIT_2`, `AL_SPLIT_3`) are conceivable, but are not included in this generic form by default.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The **AL_SPLIT_5_UNGATED** is a simple yet useful generic function block for duplicating a unidirectional adapter signal to five outputs. Due to its pure adapter interface and lack of event/data logic, it is particularly suitable for applications that need to distribute a signal to multiple receivers without processing. The generic design increases flexibility for reuse in different projects.

AL_SPLIT_6

• − ◦ • − ◦ • − ◦ •

Introduction

The function block **AL_SPLIT_6** is used to split a single unidirectional AL adapter input (socket) into six identical AL adapter outputs (plugs). It enables simple signal distribution within a 4diac application without requiring additional logic or a state machine.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Direction	Identifier	Type	Description
In	IN	adapter::types::unidirectional::AL	Unidirectional AL adapter as input signal.
Out	OUT1	adapter::types::unidirectional::AL	First output channel (identical to IN).
Out	OUT2	adapter::types::unidirectional::AL	Second output channel.
Out	OUT3	adapter::types::unidirectional::AL	Third output channel.
Out	OUT4	adapter::types::unidirectional::AL	Fourth output channel.
Out	OUT5	adapter::types::unidirectional::AL	Fifth output channel.
Out	OUT6	adapter::types::unidirectional::AL	Sixth output channel.

Functionality

This function block has no internal logic or state machine. It forwards the AL signal arriving at socket **IN** unchanged to all six plugs **OUT1** … **OUT6**. Any change or event at the input is thus transmitted simultaneously to all outputs. The function block operates purely structurally as a splitter and does not require event activation.

Technical Features

- **Generic Function Block:** The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `GEN_AL_SPLIT`. This allows it to be treated as a generic type in the 4diac IDE and enables clean type system integration.
- **No Data/Event Interface:** Distribution occurs exclusively via the adapter interface. No additional data or event ports are required.
- **No Runtime Dependencies:** Since no algorithms or states exist, the function block is resource-efficient and requires no specific initialization.

State Overview

The function block has no state machine (no ECC) and therefore no defined state machine. Its behavior is entirely determined by the interface structure and the simple forwarding of the adapter signal.

Application Scenarios

- **Signal Distribution in Agricultural Engineering or Automation:** A central AL adapter (e.g., a control command) is to be sent to several downstream components simultaneously.
- **Tests and Simulations:** A test signal can be distributed in parallel to different modules to verify system behavior.

- **Redundant Paths:** The same AL adapter can be routed to different processing units via multiple channels.

Comparison with Similar Function Blocks

- **AL_SPLIT_2, AL_SPLIT_4 … AL_SPLIT_N**: These function blocks differ only in the number of output channels. The functionality is identical – a simple 1:N split.
- **Other split blocks with events or data:** Unlike these, **AL_SPLIT_6** has no data or event interfaces, but works purely via adapters. This simplifies configuration but limits the variety of types.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AL_SPLIT_6** is a compact and efficient function block for multiplying a unidirectional AL adapter signal. Due to its generic nature and simple structure, it is ideally suited for all applications where an input signal needs to be distributed to multiple outputs without additional logic or event control.

AL_SPLIT_7

(Image of function block not available)

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_SPLIT_7** serves as a generic distributor (splitter) for a unidirectional adapter of type `AL`. It accepts a single adapter at its socket `IN` and forwards the incoming data and events unchanged to seven identical adapter outputs (`OUT1` … `OUT7`). The block is implemented as a generic type (`GEN_AL_SPLIT`), thus enabling flexible use in control and automation applications.

Interface Structure

Event Inputs

This function block has no explicit event inputs. All event control is handled via the connected adapter `IN`.

Event Outputs

There are no direct event outputs. Events are passed on via the seven adapter outputs (`OUT1` … `OUT7`).

Data Inputs

This function block has no independent data inputs. Data is transferred exclusively via the adapter `IN`.

Data Outputs

Accordingly, there are no direct data outputs. The data is replicated via the seven adapter outputs.

Adapters

Direction	Name	Type	Description

Socket	IN	adapter::types::unidirectional::AL	Adapter input that provides the AL connection to be distributed.
Plug	OUT1 … OUT7	adapter::types::unidirectional::AL	Seven adapter outputs that provide an identical copy of the input adapter.

Functionality

The **AL_SPLIT_7** is a pure distribution module. When an adapter of type AL is connected to socket IN, all data and events received via this adapter are forwarded unchanged to each of the seven plugs (OUT1 … OUT7). No logical or temporal processing takes place – the distribution is one-to-seven without delay or buffering. Due to its generic implementation, the function block can be used with different AL adapter instances that have the same data type and event schema.

Technical Features

- **Generic Implementation:** The function block is declared as a generic type (GEN_AL_SPLIT). This allows it to be used in different projects without modifying the source code, as long as the underlying adapter type AL corresponds to the expected interface.
- **Unidirectionality:** The module operates exclusively unidirectionally – data and events flow from the socket to the plugs. Feedback or bidirectional communication is not supported.
- **No State Logic:** The module does not have its own state machine; it is transparent.

State Overview

The module has no internal states. It is always ready to distribute incoming adapter connections. An active state results solely from the presence of a valid adapter at the IN socket.

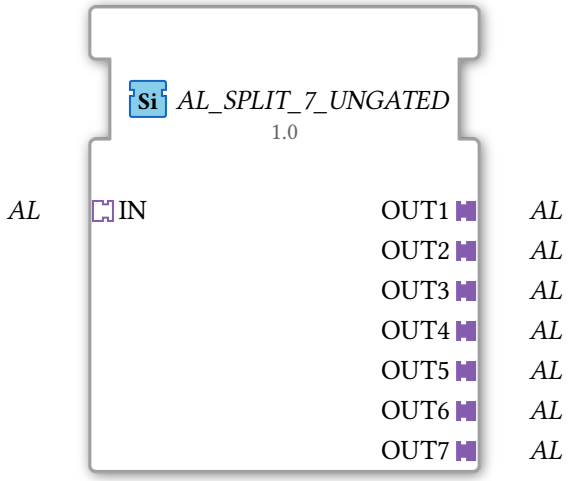
Application Scenarios

- **Control Distribution:** A higher-level control adapter (e.g., for controlling an axis or sensor) should send identical signals to multiple parallel components.
- **Test Environments:** In simulation or test setups, one adapter can supply several similar subsystems.
- **Signal Bundling:** This function block can be used as a distributor in a hierarchy of adapters when a signal needs to be split across multiple downstream function blocks.

Comparison with Similar Function Blocks

Compared to an **AL_SPLIT_2** or **AL_SPLIT_4**, **AL_SPLIT_7** offers a higher number of outputs (seven instead of two or four). While smaller splitters are sufficient for low-demand applications, this function block enables direct distribution to seven receivers without the need to cascade multiple splitters. Its function is the exact opposite of an **AL_MERGE** (which combines multiple inputs).

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AL_SPLIT_7** is a simple yet useful generic function block for replicating unidirectional AL adapter connections. Thanks to its generic nature and clear interface, it can be flexibly integrated into automation and control systems where a signal needs to be distributed across multiple paths. Its inherent transparency ensures lossless transmission without additional latency.

AL_SPLIT_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of AL_SPLIT_7. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Thanks to its generic nature and clear interface, it can be flexibly integrated into automation and control systems where a signal needs to be distributed across multiple paths. Its inherent transparency ensures lossless transmission without additional latency.

AL_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block AL_SPLIT_8 distributes an incoming unidirectional AL signal (socket IN) to eight identical outputs (plugs OUT1 to OUT8). It is declared as a generic block and serves for simple signal multiplication in 4diac applications.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapters

Type	Name	Direction	Description
adapter::types::unidirectional::AL	IN	Socket (Input)	Incoming AL signal
adapter::types::unidirectional::AL	OUT1 ... OUT8	Plugs (Output)	Eight outgoing AL signals

Functionality

The component has no internal logic or state machine. An AL adapter signal applied to IN is forwarded unchanged and simultaneously to all eight output adapters. This multiplication is purely data-flow controlled, without delay or buffering.

Technical Features

- **Generic Type**: The function block is declared as a generic block (GenericClassName = 'GEN_AL_SPLIT'), but due to the fixed adapter definition, it can only be used with the type AL.
- **No Event Control**: There is neither an ECC nor an event interface; data is passed passively via the data flow.
- **Unidirectional**: The adapter is designed for only one direction (input → outputs).

State Overview

The function block has no internal states. It is completely stateless and performs no processing.

Application Scenarios

- **Alarm Distribution**: A central alarm signal is passed on to multiple subsystems (e.g., display, logging, control).
- **Redundant Signaling**: The same signal can be sent in parallel to multiple receivers to increase fault tolerance.
- **Controlling multiple actuators**: A sensor or control signal is split across multiple independent actuators.

Comparison with similar function blocks

- **Standard SPLIT function blocks** (e.g., SPLIT for simple data types) distribute individual values, while AL_SPLIT_8 is specifically designed for the unidirectional adapter AL.
- **Adapter mergers** (such as a hypothetical AL_MERGE) combine multiple signals into one; AL_SPLIT_8 implements the reverse 1:n functionality.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AL_SPLIT_8` is a simple yet important function block for multiplying AL adapter signals. Its passive, stateless operation allows it to integrate seamlessly into data-flow-oriented 4diac applications and facilitates the structured distribution of alarm or control signals.

AL_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AL_SPLIT_9** is a generic function block that splits an incoming adapter of type `AL` into nine identical outgoing adapters. It is used to distribute a signal or data flow arriving via a single adapter to multiple downstream components. The function block is defined as a generic type (`GEN_AL_SPLIT`) and must be bound to the specific adapter type before use.

Interface Structure

Event Inputs

The function block has no event inputs. Data is passed exclusively via adapter connections.

Event Outputs

There are no event outputs.

Data Inputs

No separate data inputs – the actual data is transmitted via the incoming adapter.

Data Outputs

No separate data outputs – the output data is provided via the nine outgoing adapters.

Adapters

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AL`	An incoming adapter that provides the signal or data to be distributed.
Plug (Output)	`OUT1` … `OUT9`	`adapter::types::unidirectional::AL`	Nine outgoing adapters, each outputting a copy of the input signal.

Functionality

The function block acts as a passive distributor. As soon as the incoming adapter `IN` receives a signal or data packet, the function block forwards it to all nine output adapters (`OUT1` … `OUT9`). This forwarding occurs without buffering or delay – it is a pure 1:9 distribution.

Since the function block is generic, a specific adapter type must be assigned to it before use. This is done in the development environment by specifying the adapter type, which defines the actual data fields and events.

Technical Features

- **Generic Function Block:** The function block is declared as `GEN_AL_SPLIT` and requires binding to a specific `AL` adapter type (e.g., `SimpleData_AL`). The binding is controlled by the attribute `eclipse4diac::core::GenericClassName`.
- **Type Safety:** All nine outputs use the same adapter type as the input. This ensures that the data structure remains identical.
- **Stateless:** The function block has no internal states or memory – distribution occurs instantaneously with each new data iteration.
- **No Event Control:** Since no event inputs are defined, distribution is triggered solely by data changes at the input adapter.

State Overview

The function block has no internal state machine. It operates statelessly and is purely data-flow driven.

Application Scenarios

- **Signal Distribution:** A sensor value (e.g., temperature, pressure) is to be sent simultaneously to multiple evaluation units or controllers.
- **Data Replication:** A control command is to be distributed to multiple actuators in parallel.
- **Modular Architectures:** Splitting a data stream in a pipeline to feed different processing branches.

Comparison with Similar Components

- **AL_SPLIT_2, AL_SPLIT_4:** Components with analog functionality that distribute the input signal to 2 or 4 outputs, respectively. `AL_SPLIT_9` covers a larger number of outputs, which is particularly useful in complex distribution structures.
- **Simple Coupling (e.g., Direct Connection):** Without the Split component, the sender would have to provide multiple adapter connections themselves. The Split component encapsulates this logic and simplifies the overall architecture.

AL_SPLIT_2, AL_SPLIT_4: Components with analog functionality that distribute the input signal to 2 or 4 outputs, respectively. `AL_SPLIT_9` covers a larger number of outputs, which is particularly useful in complex distribution structures.

Simple Coupling (e.g., Direct Connection): Without the Split component, the sender would have to provide multiple adapter connections themselves. The Split component encapsulates this logic and simplifies the overall architecture.

**

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AL_SPLIT_9` is a simple yet powerful generic distribution block for adapter interfaces of type `AL`. It enables clean, maintainable distribution of a data flow across nine independent paths. Thanks to its generic nature and stateless operation, it is ideally suited for modular and scalable automation solutions.

Since the function block is generic, a specific adapter type must be assigned to it before use. This is done in the development environment by specifying the adapter type, which defines the actual data fields and events.

Technical Features

- **Generic Function Block:** The function block is declared as `GEN_AL_SPLIT` and requires binding to a specific `AL` adapter type (e.g., `SimpleData_AL`). The binding is controlled by the attribute `eclipse4diac::core::GenericClassName`.
- **Type Safety:** All nine outputs use the same adapter type as the input. This ensures that the data structure remains identical.
- **Stateless:** The function block has no internal states or memory – distribution occurs instantaneously with each new data iteration.
- **No Event Control:** Since no event inputs are defined, distribution is triggered solely by data changes at the input adapter.

State Overview

The function block has no internal state machine. It operates statelessly and is purely data-flow driven.

Application Scenarios

- **Signal Distribution:** A sensor value (e.g., temperature, pressure) is to be sent simultaneously to multiple evaluation units or controllers.
- **Data Replication:** A control command is to be distributed to multiple actuators in parallel.
- **Modular Architectures:** Splitting a data stream in a pipeline to feed different processing branches.

Comparison with Similar Components

- **AL_SPLIT_2, AL_SPLIT_4:** Components with analog functionality that distribute the input signal to 2 or 4 outputs, respectively. `AL_SPLIT_9_UNGATED` covers a larger number of outputs, which is particularly useful in complex distribution structures.
- **Simple Coupling (e.g., Direct Connection):** Without the Split component, the sender would have to provide multiple adapter connections themselves. The Split component encapsulates this logic and simplifies the overall architecture.

AL_SPLIT_2, AL_SPLIT_4: Components with analog functionality that distribute the input signal to 2 or 4 outputs, respectively. `AL_SPLIT_9_UNGATED` covers a larger number of outputs, which is particularly useful in complex distribution structures.

Simple Coupling (e.g., Direct Connection): Without the Split component, the sender would have to provide multiple adapter connections themselves. The Split component encapsulates this logic and simplifies the overall architecture.

**

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The `AL_SPLIT_9_UNGATED` is a simple yet powerful generic distribution block for adapter interfaces of type `AL`. It enables clean, maintainable distribution of a data flow across nine independent paths. Thanks to its generic nature and stateless operation, it is ideally suited for modular and scalable automation solutions.

AQ_D_FF

Value to latch – *AQ*

AQ – Latched value

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AQ_D_FF` implements a data storage element (D-latch) based on the adapter concept of IEC 61499. It receives an incoming data value upon an event and makes it available at the output until the next event. The block fully encapsulates the latch functionality in an adapter interface, thus enabling modular integration into system-wide data and event paths.

Interface Structure

Event Inputs

No direct event inputs are available. Event control is handled exclusively via the adapter `I`.

Event Outputs

No direct event outputs are available. Event output is handled exclusively via the adapter `Q`.

Data Inputs

No direct data inputs are available. The data value to be latched is provided via the adapter `I`.

Data Outputs

No direct data outputs are available. The latched data value is output via the adapter `Q`.

Adapters

Adapter	Direction	Type	Description
`I`	Socket (Input)	`adapter::types::unidirectional::AQ`	Provides the data value to be latched and the triggering event.

Q	Plug (Output)	adapter::types::unidirectional::AQ	Outputs the latched data value and an acknowledgment event.

The adapter type used, adapter::types::unidirectional::AQ, provides a unidirectional connection: One event channel and one data channel are transmitted from the socket to the plug.

Functionality

The AQ_D_FF operates on the principle of an edge-triggered D-latch. Internally, the function block iec61499::events::E_D_FF_ANY is used:

- As soon as an event arrives at the I adapter, the currently available data value, D1 (from the I adapter), is retrieved.
- The received value is output as D1 at adapter Q, and simultaneously, event E1 is triggered at the output adapter.
- The output value remains constant between two events. With each new event at the input, the output is updated to the then-current input value.

Technical Features

- **Pure Adapter Interface**: The module has no direct event or data inputs/outputs. All communication takes place via adapters I and Q.
- **Unidirectional Data Transmission**: The adapters are of type adapter::types::unidirectional::AQ, meaning that data and events flow only from input to output. Feedback or bidirectional communication is not supported.
- **Internal Implementation**: The latch function is implemented using the universal function block E_D_FF_ANY from the IEC 61499 event library, ensuring robust and standards-compliant processing.
- **No Initialization**: The initial state of the latched value is undefined until the first event arrives at the input.

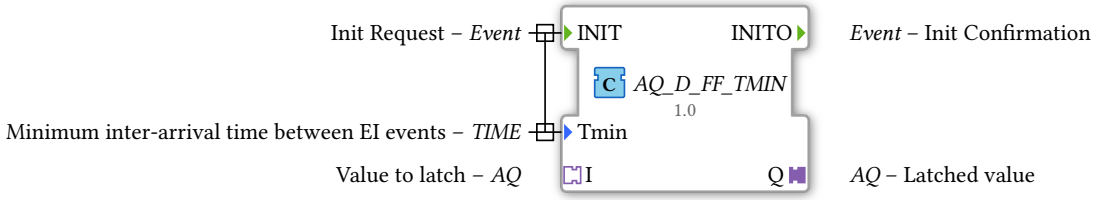
State Overview

The AQ_D_FF does not have an explicit state machine. However, its behavior can be described by two logical states:

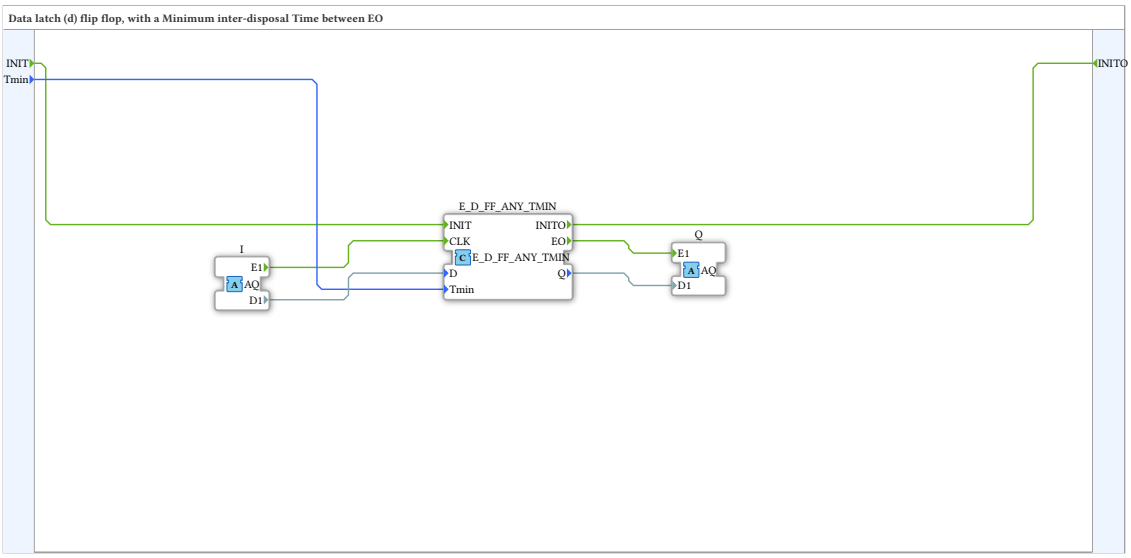
State	Description
Waiting for Event	The output Q holds the last latched value. No event is pending at I.
Accept/Output	When an event arrives at I, the new value is transferred from I, output to Q, and an event is generated on E1 by Q. The function block then returns to its wait state.

Application Scenarios

- **Cache Storage of Sensor Values**: A measured value is captured upon a trigger event (e.g., clock cycle or query) and is then available for further processing.
- **Synchronization of Asynchronous Data Streams**: If data arrives asynchronously, AQ_D_FF can hold the last valid value until a subsequent process retrieves it.
- **Event-driven data forwarding**: The function block can be used as a simple "data holder" in an adapter-based communication path to forward data only upon specific events.



Comparison with similar function blocks



Function block	Properties
E_D_FF (direct I/Os)	Same latch functionality, but with separate event and data inputs/outputs. No adapters.
E_SR_FF	Set/reset flip-flop with two separate input events. Binary states, not data values.
AQ_D_FF	Enables embedding the latch function into existing adapter interfaces without additional wiring at the function block level.

Conclusion

The function block `AQ_D_FF` offers a compact, adapter-based implementation of a D-latch. It integrates seamlessly into system-wide adapter paths, thus reducing wiring effort at the function block level. Its operation is simple and reliable, especially for applications where a data value needs to be transferred upon an event and held until the next event.

AQ_D_FF_TMIN

• – ○ • – ○ • – ○ •

The function block **AQ_D_FF_TMIN** implements a data-locking D flip-flop with a minimum inter-disposal time (MIT) between two consecutive output events (EOs). It serves as an extension of a simple D flip-flop, adding time-based debouncing or minimum-distance control, and is connected to the signal transmitter and receiver via adapters.

Event	Type	With Variable	Comment
INIT	EInit	Tmin	Initialization request, sets the minimum MIT.
Event	Type	Comment	
–––––	––	–––––	
INITO	EInit	Initialization confirmation.	
Variable	Type	Comment	
–––––	––	–––––	
Tmin	TIME	Minimum waiting time between two output events (EO).	

No dedicated data outputs; the latched signal is output via the adapter `Q`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

| Type | Label | Direction | Comment | | `adapter::types::unidirectional::AQ` | I | Socket (Input) | Latching value, containing one data signal (D1) and one event signal (E1). | | `adapter::types::unidirectional::AQ` | Q | Plug (Output) | Latched value, containing one data signal (D1) and one event signal (E1). |

Functionality

This function block encapsulates an internal function block of type `iec61499::events::E_D_FF_ANY_TMIN`. This functions like an edge-triggered D flip-flop, where the event `I.E1` serves as the clock signal and `I.D1` as the data input. The output event `EO` is only output at adapter `Q.E1` if at least the time specified in `Tmin` has elapsed since the last output event. The data value at output `Q.D1` corresponds to the value `I.D1` present at the time of the rising edge at `I.E1`.

The initialization (`INIT`) passes the parameter `Tmin` to the internal function block, thus defining the timing condition.

- **Minimum Interval Time (Tmin):** Prevents excessively rapid succession of output events, e.g., for debouncing or limiting the update rate.
- **Adapter-Based Communication:** The function block (FB) uses unidirectional adapters (`AQ`) that bundle both data and events, enabling loose coupling between the signal source and sink.
- **IEC 61499-Compliant:** Complies with the 61499-1 Annex A standard and utilizes the event/data flows of the standard.

The FB does not have an explicit public state machine. Its behavior is determined by the internal FB `E_D_FF_ANY_TMIN`, which has the last latched value as its state and a wait logic. Simplified representation:

State	Meaning
Initialized	Ready after INIT, Tmin is set
Ready	Waiting for clock (I.E1)
Latched	Data value has been accepted; output event will be released after Tmin has elapsed
Waiting	Tmin is running – output event is blocked

A detailed state representation can be found in the source code of the internal function block.

- **Signal Smoothing/Debouncing:** Preventing multiple triggers with mechanical pushbuttons or rapid signal changes.
- **Data Rate Limiting:** Limiting the output frequency of measured values in monitoring systems.
- **Synchronization of Asynchronous Signals:** Forwarding a data value with a defined minimum time interval.
- **Control of Slow Actuators:** Ensuring that actuators are not controlled faster than their mechanical response time allows.

Function Block	Special Feature
`AQ_D_FF` / `E_D_FF`	Simple D flip-flop without a time limit on the output.
AQ_D_FF_TMIN` (this FB)	Extended by a minimum delay Tmin between output events.
AQ_D_FF_TMAX` (hypothetical)	Limits the maximum time between two output events.

Compared to a standard D flip-flop, `AQ_D_FF_TMIN` offers additional protection against excessively rapid succession of output events, which is often necessary in practice.

The function block `AQ_D_FF_TMIN` combines the functionality of a D flip-flop with an adjustable minimum delay at the output. Thanks to its adapter interfaces and IEC 61499 compliance, it can be easily integrated into industrial control applications where both data acquisition and temporal decoupling of events are required. It offers a robust solution for signal processing and actuator control with defined temporal constraints.

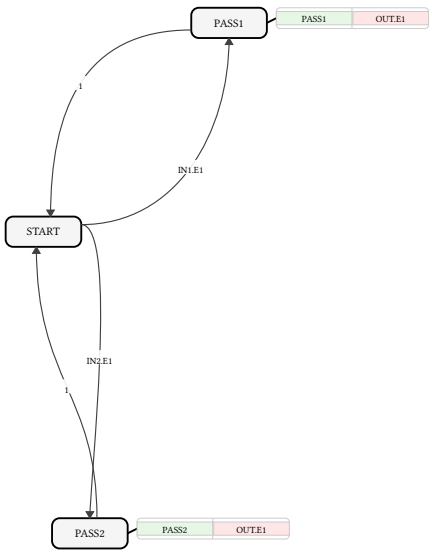
State Overview

Application Scenarios



Comparison with Similar Function Blocks

Conclusion

AQ_LAST_2

ECC: AQ_LAST_2

Introduction

The AQ_LAST_2 function block merges two same-type QUARTER adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: QUARTER adapter (unidirectional) - first signal source
- **IN2**: QUARTER adapter (unidirectional) - second signal source

Output adapter (Plug):

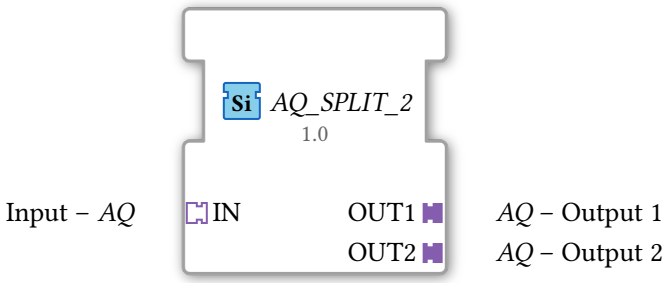
- **OUT**: QUARTER adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid QUARTER signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same QUARTER value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AQ_LAST_2 is the inverse of `AQ_SPLIT_2`: AQ_SPLIT_2 distributes 1 input to 2 outputs, AQ_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

AQ_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AQ_SPLIT_2` serves as a fan-out block. It distributes an incoming AQ (Analog Quantity) signal unidirectionally to two identical outputs. It thus implements a simple 1:2 signal multiplication for analog quantities.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Type	Name	Direction	Description
adapter::types::unidirectional::AQ	IN	Socket (Input)	Input adapter for the AQ signal to be split.
adapter::types::unidirectional::AQ	OUT1	Plug (Output)	First output – provides the unaltered input signal.
adapter::types::unidirectional::AQ	OUT2	Plug (Output)	Second output – also provides the unaltered input signal.

Functionality

The module receives an analog signal via the adapter socket `IN`. This signal is passed internally without delay or conversion to both adapter plugs `OUT1` and `OUT2`. No signal processing takes place – the function block acts purely as a splitter.

Technical Features

- **Generic Implementation**: The function block is declared as the generic type `GEN_AQ_SPLIT` and can be used with any AQ adapter, as long as it conforms to the unidirectional AQ interface.
- **No Event Control**: The function block operates purely data-driven without events – a change in state at the input immediately affects both outputs.
- **Unidirectional**: The adapters are designed for one direction only (input ⟶ outputs).

State Overview

The function block has no internal states. It is stateless (combinatory) and outputs the currently present input signal at both outputs at any given time.

Application Scenarios

- **Signal Distribution** in Control Systems: An analog signal provided by a sensor is to be passed on in parallel to two different devices (e.g., two controllers or display units).
- **Test and Simulation Setups**: A reference signal is split across multiple test points without affecting the signal flow.
- **Redundant Transmission**: The signal is sent to two independent paths to increase reliability.

Comparison with Similar Components

- **`AQ_SPLIT_N`** (hypothetical): A comparable component with outputs like `N` – `AQ_SPLIT_2` is a specialized 1:2 version.
- **Event-Driven Split Components**: These often require trigger events and then perform signal transmission. In contrast, `AQ_SPLIT_2` operates purely signal-driven without events.
- **Bus-based splitters**: These distribute multiple signals over a shared bus (e.g., via multicast). `AQ_SPLIT_2` operates selectively and individually via adapters.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AQ_SPLIT_2` is a simple yet useful component for distributing an analog signal to two identical outputs. Thanks to its generic nature, it can be used in various 4diac projects without modification. Its stateless operation minimizes complexity and makes it ideal for real-time applications requiring immediate signal transmission.

AQ_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AQ_SPLIT_3` implements a 1-to-3 split (fan-out) of a unidirectional AQ adapter signal. An incoming AQ adapter signal is copied to three identical output adapters and made available in parallel.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Socket (Input)

Name	Type	Description
`IN`	`adapter::types::unidirectional::AQ`	Input adapter whose signal is distributed to three outputs

Plug (Outputs)

Name	Type	Description
`OUT1`	`adapter::types::unidirectional::AQ`	First output (copy of the input signal)
`OUT2`	`adapter::types::unidirectional::AQ`	Second Output (Copy of Input Signal)
`OUT3`	`adapter::types::unidirectional::AQ`	Third Output (Copy of Input Signal)

Functionality

The module forwards the AQ signal present at socket `IN` to all three plugs (`OUT1`, `OUT2`, `OUT3`) without delay or data manipulation. This is a pure signal distribution (fan-out) – the incoming adapter interface is mirrored to three identical output interfaces. Since no events or data outside the adapter are processed, the forwarding is passive and transparent.

Technical Features

- **Generic Type**: The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AQ_SPLIT'`. This allows it to be used as a generic AQ splitter in various contexts.
- **Unidirectional**: The adapters are defined as unidirectional AQ interfaces – data flows only from the input to the outputs.
- **No State Logic**: The function block has no event I/O, no internal state, and no data I/O. It functions purely as connection logic.

State Overview

The function block is stateless. It does not execute any time-dependent or sequential processes. The output signals always directly correspond to the current input signal.

Application Scenarios

- **Signal Distribution in Automation**: When an AQ signal (e.g., a quality value, a measurement, or status adapter) needs to be simultaneously distributed to multiple consumers.
- **Multicasting of Adapters**: In architectures where a service sends its result to multiple downstream components via an AQ adapter.

- **Generic Coupling**: Used as a generic splitter in libraries or frameworks based on the `GEN_AQ_SPLIT` type.

Comparison with Similar Components

- **AQ_SPLIT_2**: Distributes to only two outputs – `AQ_SPLIT_3` offers an additional third output.
- **Manual Triple Wiring**: Instead of a single component, the input signal could be manually connected to three sockets. However, the splitter improves the clarity and maintainability of the network.
- **Generic Splitters for Other Adapter Types**: Similar components exist, for example, for data or event signals (e.g., `DATA_SPLIT_3`). `AQ_SPLIT_3` is specifically designed for the AQ adapter type.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AQ_SPLIT_3` is a simple, functional fan-out component for unidirectional AQ adapters. Thanks to its generic design and clear 1:3 distribution, it is ideally suited for all applications that need to provide an AQ signal multiple times. The absence of event and data I/O makes it lightweight and usable in any process context.

AQ_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AQ_SPLIT_4` serves as a fan-out component for distributing an incoming AQ adapter to four identical output adapters. It is used to forward an analog signal or control variable (AQ – Analog Quantity) from a sender to multiple independent receivers without compromising signal integrity.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Type	Direction	Name	Description
`adapter::types::unidirectional::AQ`	Socket (Input)	`IN`	Incoming AQ adapter, which is distributed to the four outputs.
`adapter::types::unidirectional::AQ`	Plug (Output)	`OUT1`	First outgoing AQ adapter.
`adapter::types::unidirectional::AQ`	Plug (Output)	`OUT2`	Second outgoing AQ adapter.

`adapter::types::unidirectional::AQ`	Plug (Output)	`OUT3`	Third outgoing AQ adapter.
`adapter::types::unidirectional::AQ`	Plug (Output)	`OUT4`	Fourth outgoing AQ adapter.

Functionality

The `AQ_SPLIT_4` forwards all data and events arriving via socket `IN` from the AQ adapter unchanged to the four plug adapters `OUT1` to `OUT4`. No processing, filtering, or delay of the signals takes place. Distribution occurs purely at the connection level, so all outputs always have the same state as the input.

- **Generic Typing**: The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AQ_SPLIT'`. This allows it to be addressed as a generic function block in the 4diac IDE, increasing its reusability in various application contexts.
- **No State Logic**: The function block has no internal state machine (ECC) and no input/output events. It acts purely as a "wiring aid" for adapter connections.
- **Unidirectional Adapter**: All adapters used are of type `unidirectional::AQ`, meaning data flows only in one direction (from the socket to the plugs).

Technical Features

- **Generic Typing**: The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AQ_SPLIT'`. This allows it to be addressed as a generic function block in the 4diac IDE, increasing its reusability in various application contexts.
- **No State Logic**: The function block has no internal state machine (ECC) and no input/output events. It acts purely as a "wiring aid" for adapter connections.
- **Unidirectional Adapter**: All adapters used are of type `unidirectional::AQ`, meaning data flows only in one direction (from the socket to the plugs).

State Overview

The function block has no state machine. It is passive and does not perform any time- or event-driven operations. Signal transmission is continuous and without intermediate storage.

Application Scenarios

- **Distributing a Measured Value**: An analog sensor (e.g., temperature, pressure, flow rate) is connected via an AQ adapter and its signal needs to be sent to multiple control or monitoring units.
- **Multiple Use of a Control Signal**: An analog control signal output by a controller is transmitted in parallel to multiple actuators (e.g., valves, frequency converters).
- **Signal Monitoring**: The original signal is sent unchanged to the end devices, while an additional output is used for diagnostics or logging.

Comparison with Similar Function Blocks

- **AQ_SPLIT_2**: Distributes an AQ signal to two outputs instead of four – saving space and reducing requirements.
- **IQ_SPLIT_4**: Analog function block for digital adapters (e.g., `adapter::types::unidirectional::IQ`), otherwise identical functionality.
- **Manual Parallel Connection**: Theoretically, one could manually connect an AQ socket to multiple plugs, but the `AQ_SPLIT_4` offers a clear and reusable encapsulation.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AQ_SPLIT_4` is a simple yet useful function block for signal distribution in industrial automation with 4diac. Its generic design and lack of internal logic make it easy to understand, robust, and flexible. It contributes to the structuring and reusability of function block networks.

It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AQ_SPLIT_4_UNGATED` serves as a fan-out component for distributing an incoming AQ adapter to four identical output adapters. It is used to forward an analog signal or control variable (AQ – Analog Quantity) from a sender to multiple independent receivers without compromising signal integrity.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Type	Direction	Name	Description
`adapter::types::unidirectional::AQ`	Socket (Input)	`IN`	Incoming AQ adapter, which is distributed to the four outputs.
`adapter::types::unidirectional::AQ`	Plug (Output)	`OUT1`	First outgoing AQ adapter.
`adapter::types::unidirectional::AQ`	Plug (Output)	`OUT2`	Second outgoing AQ adapter.
`adapter::types::unidirectional::AQ`	Plug (Output)	`OUT3`	Third outgoing AQ adapter.
`adapter::types::unidirectional::AQ`	Plug (Output)	`OUT4`	Fourth outgoing AQ adapter.

Functionality

The `AQ_SPLIT_4_UNGATED` forwards all data and events arriving via socket `IN` from the AQ adapter unchanged to the four plug adapters `OUT1` to `OUT4`. No processing, filtering, or delay of the signals takes place. Distribution occurs purely at the connection level, so all outputs always have the same state as the input.

- **Generic Typing**: The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AQ_SPLIT'`. This allows it to be addressed as a generic function block in the 4diac IDE, increasing its reusability in various application contexts.
- **No State Logic**: The function block has no internal state machine (ECC) and no input/output events. It acts purely as a "wiring aid" for adapter connections.
- **Unidirectional Adapter**: All adapters used are of type `unidirectional::AQ`, meaning data flows only in one direction (from the socket to the plugs).

Technical Features

- **Generic Typing**: The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AQ_SPLIT'`. This allows it to be addressed as a generic function block in the 4diac IDE, increasing its reusability in various application contexts.
- **No State Logic**: The function block has no internal state machine (ECC) and no input/output events. It acts purely as a "wiring aid" for adapter connections.
- **Unidirectional Adapter**: All adapters used are of type `unidirectional::AQ`, meaning data flows only in one direction (from the socket to the plugs).

State Overview

The function block has no state machine. It is passive and does not perform any time- or event-driven operations. Signal transmission is continuous and without intermediate storage.

Application Scenarios

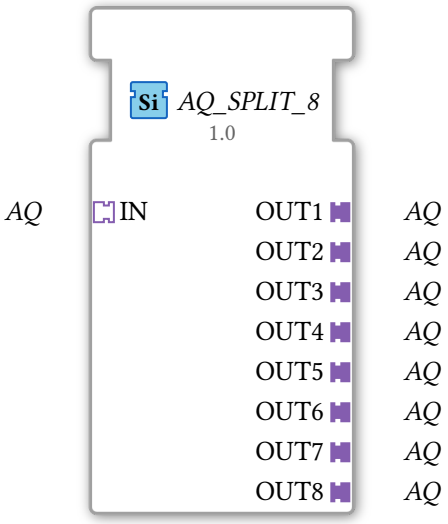
- **Distributing a Measured Value**: An analog sensor (e.g., temperature, pressure, flow rate) is connected via an AQ adapter and its signal needs to be sent to multiple control or monitoring units.
- **Multiple Use of a Control Signal**: An analog control signal output by a controller is transmitted in parallel to multiple actuators (e.g., valves, frequency converters).
- **Signal Monitoring**: The original signal is sent unchanged to the end devices, while an additional output is used for diagnostics or logging.

Comparison with Similar Function Blocks

- **AQ_SPLIT_2**: Distributes an AQ signal to two outputs instead of four – saving space and reducing requirements.
- **IQ_SPLIT_4**: Analog function block for digital adapters (e.g., `adapter::types::unidirectional::IQ`), otherwise identical functionality.
- **Manual Parallel Connection**: Theoretically, one could manually connect an AQ socket to multiple plugs, but the `AQ_SPLIT_4_UNGATED` offers a clear and reusable encapsulation.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.



Conclusion

The `AQ_SPLIT_4_UNGATED` is a simple yet useful function block for signal distribution in industrial automation with 4diac. Its generic design and lack of internal logic make it easy to understand, robust, and flexible. It contributes to the structuring and reusability of function block networks.

AQ_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AQ_SPLIT_8** is a fan-out function block that distributes a single AQ adapter input to eight identical AQ adapter outputs. It serves to multiply signals in analog output paths, thus enabling the parallel control of multiple identical actuators or subsystems. The implementation is based on the generic mechanism `GEN_AQ_SPLIT` and is designed for unidirectional AQ interfaces.

Interface Structure

Event Inputs

None – the function block operates purely on an adapter basis without event control.

Event Outputs

None – the function block has no event outputs.

Data Inputs

None – all signal transmission occurs via AQ adapters.

Data Outputs

None – see Data Inputs.

Adapters

Adapter	Type	Direction	Description
IN	`adapter::types::unidirectional::AQ`	Socket (Input)	Receives the AQ signal to be distributed.
OUT1 – OUT8	`adapter::types::unidirectional::AQ`	Plug (Output)	Identical outputs that forward the signal from `IN`.

Functionality

The module forwards the AQ signal present at socket `IN` to all eight plug outputs `OUT1` to `OUT8` via internal wiring. No signal processing or modification takes place – it is a simple 1:8 distribution (fan-out). The adapters are unidirectional, meaning data and events flow only from the input to the outputs.

Technical Features

- **No Clocked Logic**: The module does not require event I/Os, as the forwarding occurs directly via the adapter interface level.

- **Generic Type**: The module is declared as a generic instance (`GEN_AQ_SPLIT`) – the specific adapter type can be adapted depending on the system environment.
- **Expandability**: The 8 outputs are hardwired; dynamic numbering or configuration is not supported.

State Overview

The module does not have an explicit state machine (ECC). Its functionality is purely static: As soon as the `IN` adapter is active, all outputs output the same signal. There are no operating modes, error states, or lifecycle events.

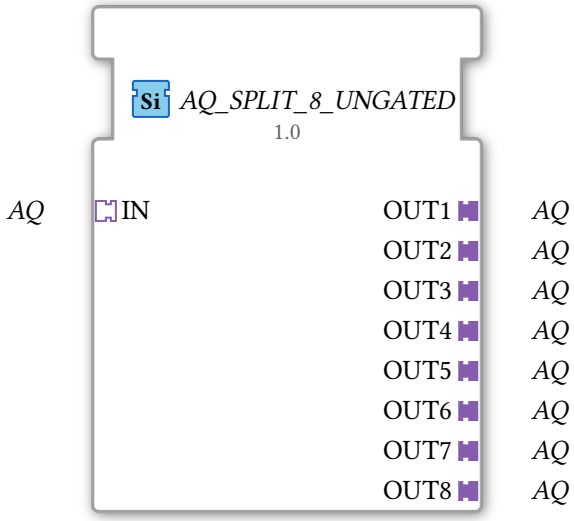
Application Scenarios

- **Parallel Wiring**: Distribute an analog output signal simultaneously to multiple actuators or measuring points.
- **Test and Simulation Environments**: A signal generator feeds the signal via `IN`, and multiple simulated components are supplied via `OUT1`–`OUT8`.
- **Redundant Control**: For situations where multiple subsystems need to receive the same setpoint without requiring a bus or software branching.

Comparison with Similar Components

- **AQ_SPLIT_4**: Offers only 4 outputs – suitable for lower distribution requirements.
- **AQ_SELECT**: A multiplexer that selects one input from multiple inputs – the opposite of a split function.
- **DQ_SPLIT_8**: Analog component for digital signals (DQ type) – structurally identical, but for a different signal type.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AQ_SPLIT_8** is a simple, reliable fan-out component for the 1:8 distribution of analog output signals via adapter interfaces. It does not use event logic or state machines and is therefore particularly suitable for clearly defined, static signal distributions in automation systems. Its generic basis facilitates reuse in different projects.

AQ_SPLIT_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AQ_SPLIT_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

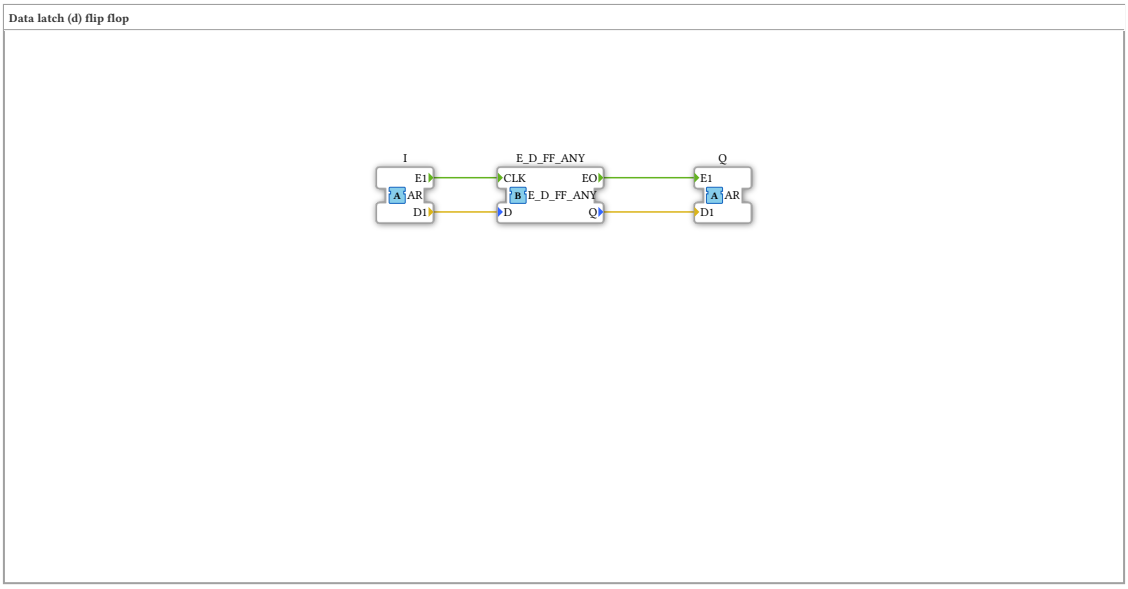
Conclusion



The **AQ_SPLIT_8_UNGATED** is a simple, reliable fan-out component for the 1:8 distribution of analog output signals via adapter interfaces. It does not use event logic or state machines and is therefore particularly suitable for clearly defined, static signal distributions in automation systems. Its generic basis facilitates reuse in different projects.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AR_D_FF

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_D_FF** implements a data-controlled flip-flop (D-latch) according to the IEC 61499-1 Annex A specification. It serves as an encapsulation for the standard function block `iec61499::events::E_D_FF_ANY` and provides its functionality via two unidirectional adapters. The block accepts a data value on a rising edge of the clock signal and holds it until the next rising edge.

Interface Structure

The AR_D_FF has no direct event or data inputs/outputs; all communication takes place via its two adapters.

Event Inputs

- **No direct inputs.**

The clock event is provided via the input adapter **I** (see Adapter section).

Event Outputs

- **No direct outputs.**

The acknowledgment event is provided via the output adapter **Q** (see Adapters section).

Data Inputs

- **No direct outputs.**

The data value to be latched is provided via the input adapter **I** (see Adapters section).

Data Outputs

- **No direct outputs.**

The latched data value is provided via the output adapter **Q** (see Adapters section).

Adapters

Adapter	Direction / Type	Description	Included Elements
I	Socket (`adapter::types::unidirectional::AR`)	Value to be latched.	**E1** (Event Input) – Clock Signal (CLK) **D1** (Data Input) – Data Value
Q	Plug (`adapter::types::unidirectional::AR`)	Latched Value.	**E1** (Event Output) – Acknowledgement after Successful Latch

			D1 (Data Output) – Latched Data Value

Functionality

The component operates on the principle of an edge-triggered D flip-flop:

1. An event at the clock input **I.E1** activates the latch.
2. At the time of the rising edge, the current data value **I.D1** is stored internally.
3. The stored value is immediately output to **Q.D1**.
4. Simultaneously, an event is triggered on **Q.E1** to acknowledge the processing.

The internal state remains unchanged between two clock edges (memory behavior).

Technical Features

- **Adapter-based encapsulation:** The AR_D_FF uses only unidirectional adapters (type `AR`) for input and output. This enables modular, standardized integration into larger adapter networks.
- **Use of the standard component `E_D_FF_ANY`:** The actual flip-flop logic is implemented using the IEC 61499 standard component. Changes to the internal implementation do not affect the externally visible interface.
- **No reset input:** Unlike other flip-flop variants, this component has no reset function. The state can only be changed by a new data value and a clock pulse.

State overview

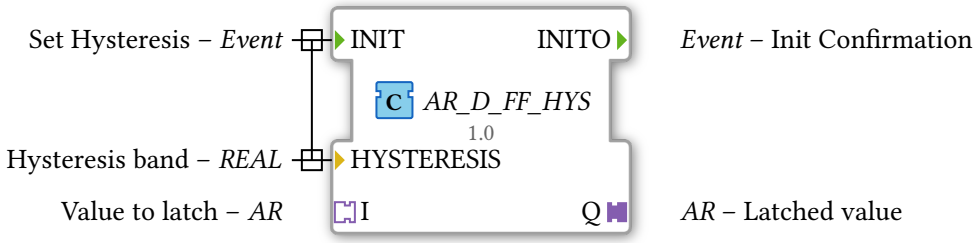
The component has a single internal memory (the latched data value). State transitions occur exclusively on a rising edge at the clock input **I.E1**:

Old State	Input D1 (current)	New State	Output D1	Event Q.E1
any	*any*	Value of D1	Value of D1	is triggered

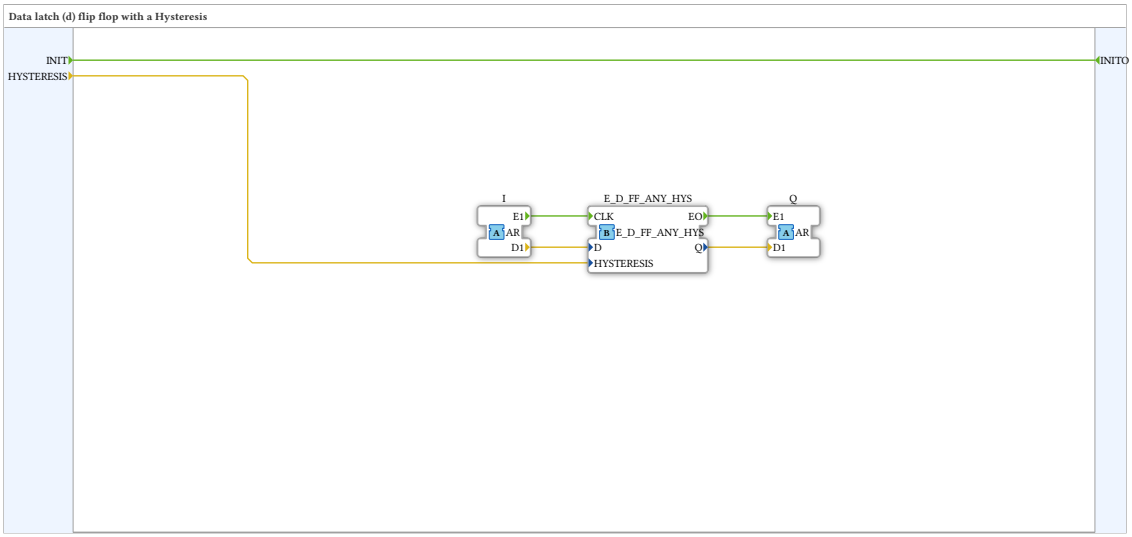
There are no other internal states or branches.

Application Scenarios

- **Data Synchronization:** Transfer of a data word at a defined time, e.g., in a cyclic control system.
- **Buffering:** Intermediate storage of a value between two calculation steps.
- **Event-driven signal propagation:** Applications where a value may only be updated when a specific event occurs.



Comparison with similar components



Component	Property	Difference to AR_D_FF
AR_SR_FF	Set-Reset Flip-Flop	Does not latch a data value, but is set/reset via Set/Reset. Has two event inputs.
E_D_FF_ANY	Standard D Flip-Flop without adapter	Same core logic, but direct event/data connections; no adapter encapsulation.
AR_T_FF	Toggle Flip-Flop	Toggles the output on each clock pulse; no data input.

Conclusion

The **AR_D_FF** is a simple, reliable D flip-flop that, thanks to its adapter interface, is particularly suitable for modular and reusable IEC 61499 applications. The encapsulation of this standard component increases its robustness and facilitates integration into larger systems. Specialized flip-flop variants are available for applications requiring a reset or other logic functions.

AR_D_FF_HYS

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_D_FF_HYS** implements a data latch (D) flip-flop with hysteresis. It serves for the stable acquisition and transmission of an analog (real) value, with a hysteresis band suppressing unwanted fluctuations at the output. The block is designed for use in industrial signal processing.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initializes the block and sets the hysteresis band.

Event Outputs

Event	Type	Description
INITO	EInit	Confirms successful initialization.

Data Inputs

Name	Type	Description
HYSTERESIS	REAL	Hysteresis band size.

Data Outputs

(No direct data outputs; the latent value is output via adapter Q)

Adapter

Name	Type	Direction	Description
I	adapter::types::unidirectional::AR	Socket (Input)	Receives the value to be latched (trigger event on E1, data on D1).
Q	adapter::types::unidirectional::AR	Plug (Output)	Outputs the latched value (event on E1, data on D1).

Functionality

The function block internally contains a sub-FB `E_D_FF_ANY_HYS` from the library `logiBUS::signalprocessing::hysteresis`.

- On each rising edge at the event input `I.E1`, the current data value from `I.D1` is taken.
- The received value is only passed on to `Q.D1` if it differs from the last issued value by more than the configured hysteresis (`HYSTERESIS`).
- The event `I.E1` is synchronously forwarded as `Q.E1` to inform the receiver of a new value.
- Initialization (`INIT`) sets the hysteresis band and immediately confirms it with `INITO`. Changing `HYSTERESIS` during operation is not supported; the hysteresis is only applied during the INIT event.
- Initialization (`INIT`) sets the hysteresis band and immediately confirms it with `INITO`. Modifying `HYSTERESIS` during operation is not supported; the hysteresis is only applied during the INIT event.
-

Technical Features

- **Adapter-Based Interface**: Both the input and output use the generic adapter `adapter::types::unidirectional::AR`, allowing the block to be flexibly integrated into existing adapter chains.
- **Hysteresis Function**: Suppresses noise and oscillations at threshold values, ensuring a clean, stable output.
- **EPL 2.0**: The block is licensed under the Eclipse Public License 2.0 and can be freely used and modified.
- **Internal Implementation**: The actual hysteresis logic is executed by a specialized sub-block (`E_D_FF_ANY_HYS`), improving maintainability and reusability.

State Overview

The block has an implicit memory state for the last output value. Since this is a D flip-flop with hysteresis, three logical ranges can be distinguished:

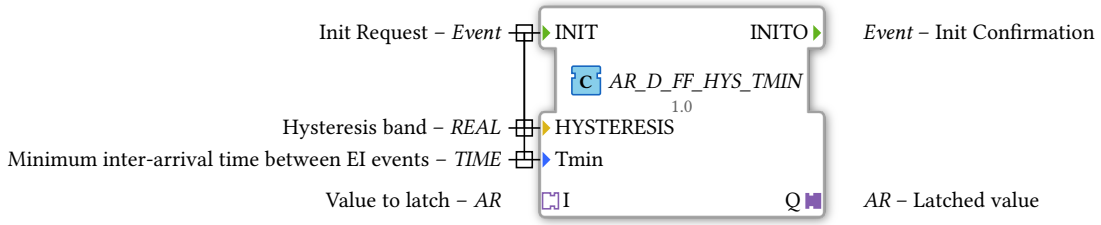
- **Input ≥ (Output + Hysteresis/2)** ⟶ Output is set to the new input.
- **Input ≤ (Output – Hysteresis/2)** ⟶ Output is set to the new input.
- **Value within the hysteresis range** ⟶ Output remains unchanged (history).

There are no explicit state machines; the component operates purely event-driven.

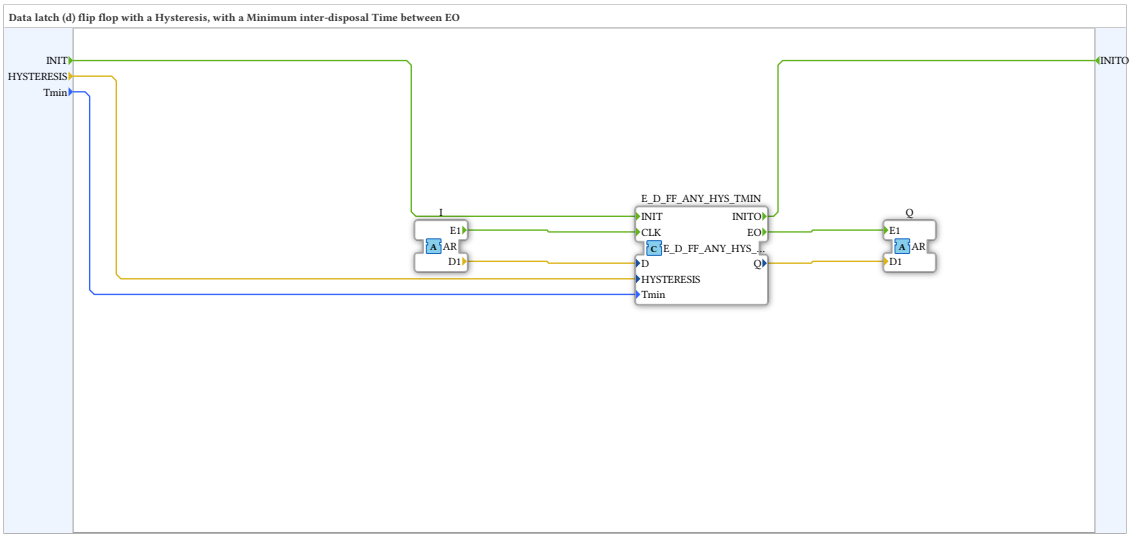
Application Scenarios

- **Signal Smoothing**: Removal of high-frequency noise from analog measured values.
- **Threshold Switch**: Defined on and off points for binary decisions (e.g., temperature control).
- **Edge Detection with Hysteresis**: Reliable detection of rising or falling edges of an analog signal.
- **Level Adjustment**: Stable tracking of an output value to a fluctuating input.

Comparison with Similar Function Blocks



Function Block	Feature
AR_D_FF (without hysteresis)	Instantly adopts any new value; sensitive to noise.
AR_D_FF_HYS (this function block)	Uses a hysteresis band to suppress flicker.



Schmitt Trigger	Implements similar hysteresis, but usually for binary (Boolean) signals. This function block operates with analog (REAL) values.

Conclusion

The **AR_D_FF_HYS** is a robust, adapter-based function block for the reliable transmission of analog values with adjustable hysteresis. It is particularly suitable for applications where interference occurs on the signal line or where defined switching behavior is required. Its simple initialization and clear interface structure facilitate integration into automation systems.

AR_D_FF_HYS_TMIN

• – ○ • – ○ • – ○ •

Introduction

The **AR_D_FF_HYS_TMIN** function block implements a data latch (D flip-flop) with a hysteresis function and a minimal delay between successive output events at the output adapter. It serves for the stable acquisition and transmission of analog values via unidirectional AR adapters, suppressing edge noise and limiting the output frequency.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initialization request; passes the parameters HYSTERESIS and Tmin to the internal logic.

Event Outputs

Event	Type	Description

INITO	EInit	Confirmation of successful initialization.

Data Inputs

Variable	Type	Description
HYSTERESIS	REAL	Hysteresis band: A change in the input value must exceed this amount for a new value to be latched.
Tmin	TIME	Minimum time between two output events (inter-disposal time). Prevents overly rapid switching.

Data Outputs

The FB does not have its own data outputs; the output data is provided via the **Q** adapter.

Adapter

Name	Type	Direction	Description
I	adapter::types::unidirectional::AR (Socket)	Input	Provides the value to be latched via **I.D1** and the clock signal via **I.E1**.
Q	adapter::types::unidirectional::AR (Plug)	Output	Provides the latched value via **Q.D1** and signals an update via **Q.E1**.

Functionality

The function block works internally with a sub-function block of type `logiBUS::signalprocessing::hysteresis::E_D_FF_ANY_HYS_TMIN`.

1. **Initialization**: During the **INIT** event, the parameters **HYSTERESIS** and **Tmin** are passed to the internal logic. After successful initialization, **INITO** is output.
2. **Data Acquisition**: At each clock event on adapter **I.E1**, the currently present value **I.D1** is compared with the last stored value.

- A change is only made if the absolute difference between **I.D1** and the stored value is greater than **HYSTERESIS**.
- If the difference is smaller, the old value remains unchanged (hysteresis function).

1. **Time-Limited Output**: As soon as the new value has been acquired, the output signal **Q.D1** is updated. However, the corresponding event **Q.E1** is only sent if at least the time interval **Tmin** has elapsed since the last **Q.E1**. This limits the maximum output frequency.

- A change is only made if the time interval **Tmin** has elapsed since the last **Q.E1**. The entire behavior can be viewed as a clock-controlled, hysteresis-enabled signal-hold block with output blocking.

Technical Features

- **Hysteresis**: Suppresses noise and small fluctuations in the input signal. A new state is only assumed when the change exceeds the **HYSTERESIS** value.
- **Minimum Interval Time (Tmin)**: Prevents an excessively high event rate at the output. This is particularly advantageous for downstream, computationally intensive, or communication-limited systems.
- **Adapter-Based Interfaces**: Both input and output use the unidirectional AR adapter, which combines data and events. This simplifies the modular chaining of signal processing blocks.

State Overview

The function block (FB) does not have an explicit finite state machine (FSM) at the top level, as the state logic is encapsulated in the internal sub-FB. The logical behavior, however, corresponds to a D flip-flop with extended conditions:

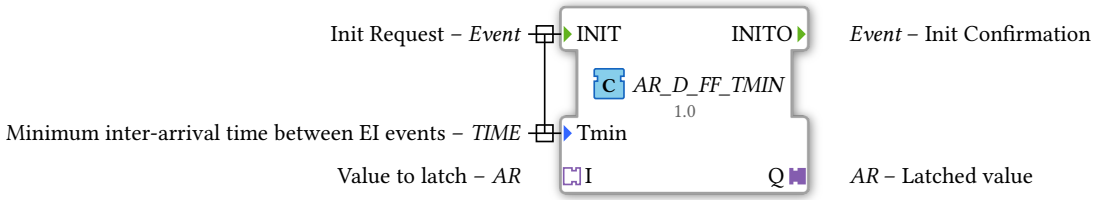
- **Idle State**: Waiting for the next clock cycle (I.E1).
- **Check State**: Comparison of the new value with the stored value, taking hysteresis into account.
- **Output State**: Update of **Q.D1** and, if **Tmin** has expired, send of **Q.E1**.

A graphical state machine can be derived from the internal sub-FB if required.

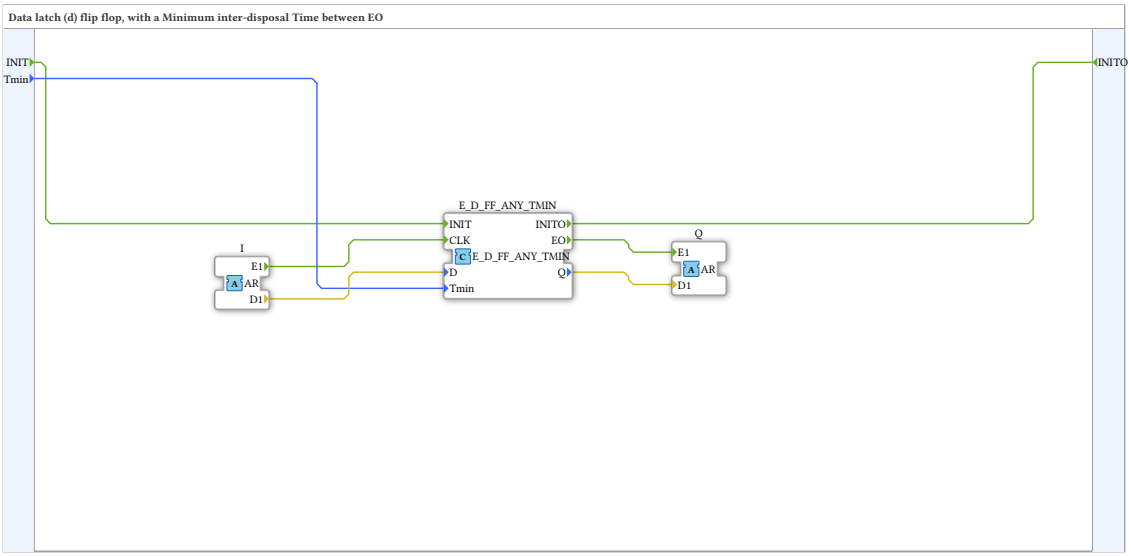
Application Scenarios

- **Measurement Acquisition with Noise Suppression**: Smoothing of sensor signals (e.g., temperature, pressure) and transmission only when significant changes occur.
- **Time-Controlled Process Outputs**: Control of actuators that must not be driven faster than a predefined clock frequency.
- **Signal Conditioning in Fieldbus Systems**: Reduction of bus load by limiting the event rate without information loss due to hysteresis.
- **Cascading Flip-Flops**: Used as a stabilized intermediate stage in data chains with multiple sampling stages.

Comparison with Similar Components



- **Simple D Flip-Flop (e.g., E_D_FF)**: Has neither hysteresis nor an output time limit. Changes its output on every clock cycle, regardless of the change magnitude or frequency.
- **Hysteresis Flip-Flop (e.g., E_D_FF_HYS)**: Includes hysteresis but no minimum interval time. Events can follow each other very quickly if the hysteresis is constantly exceeded.
- **Limited-Time Flip-Flop (No Hysteresis)**: Only the minimum output time is observed; small value changes are still processed immediately, which can lead to oscillations.



The **AR_D_FF_HYS_TMIN** combines both mechanisms, thus offering a robust solution for practical measurement and control tasks.

Conclusion

The **AR_D_FF_HYS_TMIN** function block is a versatile tool for reliable signal routing in automation systems. By combining hysteresis and minimal inter-disposal time, typical problems such as noise, flicker, and overload of downstream processing stages are effectively avoided. The adapter-based interface facilitates integration into existing modular architectures.

AR_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AR_D_FF_TMIN** implements a data latch (D flip-flop) with one input and one output adapter. It is characterized by the optional specification of a minimum time (`Tmin`) between successive

event outputs. The core of the function block is based on the standard function block `E_D_FF_ANY_TMIN`, which handles the actual flip-flop logic and the timing.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request (with parameter `Tmin`)

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement

Data Inputs

Name	Type	Comment
Tmin	TIME	Minimum Delay Between Two EO Events

Data Outputs

No standalone data outputs; the value is output via the `Q` adapter.

Adapter

Direction	Name	Type	Comment
Socket	I	`adapter::types::unidirectional::AR`	Value to be transferred
Plug	Q	`adapter::types::unidirectional::AR`	Latched value

The adapter `adapter::types::unidirectional::AR` combines one event (`E1`) and one data word (`D1`) per direction.

Functionality

The function block works internally with the function block `E_D_FF_ANY_TMIN`:

1. **Initialization**: An event at `INIT` passes the parameter `Tmin` to the internal function block. Then, `INITO` is output.

The adapter `INITO` is output. 2. **Flip-flop operation**: An event at the adapter input `I.E1` (socket) is forwarded to the **CLK** input of the internal flip-flop. Simultaneously, the data value `I.D1` is passed to the **D** input of the flip-flop.

1. **Output**: The internally generated state (`Q`) and the associated event (`EO`) are passed to the adapter output `Q` (plug) – after adhering to the set minimum time `Tmin`. The event `Q.E1` and the data value `Q.D1` represent the latched value.
2. **Timing**: The parameter `Tmin` defines the minimum time that must elapse between two consecutive `EO` events. If the frequency of input events exceeds this limit, the output is delayed or blocked accordingly.

Technical Features

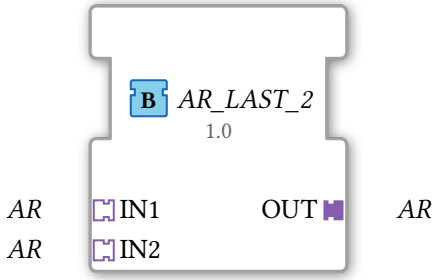
- **Adapter-Based Communication**: The function block uses only unidirectional AR adapters, making it suitable for loosely coupled or distributed systems.
- **Reuse of a Standard Function Block**: The core logic is provided by the IEC 61499 standard function block `E_D_FF_ANY_TMIN` – thus, the functionality is standards-compliant and extensible.
- **Configurable Lockout Time**: The minimum time `Tmin` is passed for initialization and cannot be changed during runtime (except via a new INIT cycle).

State Overview

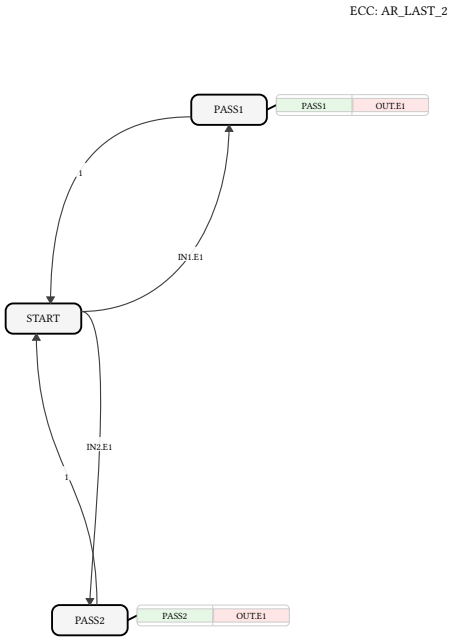
The FB itself does not have its own state diagram. Its behavior is entirely determined by the embedded standard function block `E_D_FF_ANY_TMIN`. After the INIT phase, this block is in a wait state and switches to an output state with each CLK event, provided the `Tmin` time has elapsed.

Application Scenarios

- **Signal Debouncing**: When a sensor signal (e.g., via `I`) should only be passed on with a minimum pause to suppress bounce or noise.
- **Event Rate Limitation**: In control or monitoring systems where downstream components must not be operated faster than a defined rate.
- **Secure Data Transfer**: The latched value remains stable until the next CLK event (at the adapter input) arrives.



Comparison with Similar Function Blocks



- **AR_D_FF** (without TMIN): A pure D flip-flop function block without a time limit on the output events. It is suitable for real-time applications without delay requirements.
- **AR_D_FF_TMIN**: Extends the basic function block with the ability to limit the event rate, which is often necessary in industrial control systems with time constraints.
- **AR_SR_FF**: Implements set-reset logic – unlike the D flip-flop implemented here, the output is not clock-controlled.

Conclusion

The `AR_D_FF_TMIN` is a functionally enhanced D flip-flop device that combines latch functionality with a configurable minimum time between output events. Its adapter-based interface and the use of a standardized core make it a flexible and standards-compliant component for time-critical control applications in the IEC 61499 environment.

AR_LAST_2

Introduction

The AR_LAST_2 function block merges two same-type REAL adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: REAL adapter (unidirectional) - first signal source
- **IN2**: REAL adapter (unidirectional) - second signal source

Output adapter (Plug):

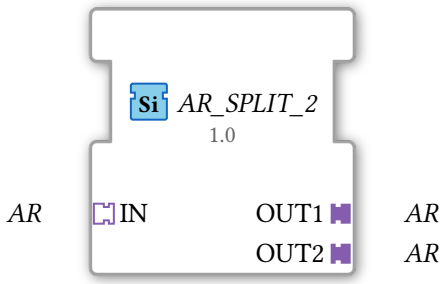
- **OUT**: REAL adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid REAL signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same REAL value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AR_LAST_2 is the inverse of AR_SPLIT_2: AR_SPLIT_2 distributes 1 input to 2 outputs, AR_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use AX_AE_MERGE instead, which merges only the event without altering the data value.

AR_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The **AR_SPLIT_2** is a generic function block that splits an incoming adapter of type `adapter::types::unidirectional::AR` into two separate outputs (OUT1, OUT2). It serves to forward a signal to two subsequent function blocks without modifying the data. The function block is implemented as a generic type (`GEN_AR_SPLIT`) and is parameterized at runtime.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AR`	IN	Socket	Input signal (AR)
`adapter::types::unidirectional::AR`	OUT1	Plug	First output (identical to IN)
`adapter::types::unidirectional::AR`	OUT2	Plug	Second output (identical to IN)

Functionality

This module forwards the AR signal present at socket **IN** unchanged to both plugs **OUT1** and **OUT2**. No data manipulation, filtering, or delay occurs. The distribution is purely structural: Each output receives its own copy of the reference to the underlying AR object.

Technical Features

- **Generic Implementation**: The function block uses the generic class name attribute (`eclipse4diac::core::GenericClassName`) with the value `'GEN_AR_SPLIT'`, allowing for application-specific configuration.
- **Unidirectional Adapters**: All adapters are of type `adapter::types::unidirectional::AR` (forward direction only).

- **No State Automation**: The function block does not have an explicit ECC (Execution Control Chart); signal routing is direct and event-independent.

State Overview

The function block does not implement state automation. Its functionality is limited to passively routing the input signal to both outputs. Therefore, state visualization is not required.

Application Scenarios

- **Signal Distribution**: Splitting an AR-based sensor signal to two parallel-operating control components.
- **Redundancy**: Providing the same AR data stream for a primary and a redundant system.
- **Debugging**: Connecting an analysis or logging module in parallel to the existing path without interrupting the original signal chain.

Comparison with Similar Modules

Modules such as `AR_SPLIT_3` or `AR_SPLIT_N` offer similar functionality, distributing a signal to three or N outputs, respectively. The choice depends on the required number of outputs. Cascading multiple `AR_SPLIT_2` instances is also possible, but increases complexity compared to a dedicated multi-output splitter.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AR_SPLIT_2** is a simple yet essential module for multiplying an AR signal in IEC 61499-based control systems. Its generic design and clear interface make it the first choice when a signal needs to be passed between two independent target components.

AR_SPLIT_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AR_SPLIT_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The **AR_SPLIT_2_UNGATED** is a generic function block that splits an incoming adapter of type `adapter::types::unidirectional::AR` into two separate outputs (OUT1, OUT2). It serves to forward a signal to two subsequent function blocks without modifying the data. The function block is implemented as a generic type (`GEN_AR_SPLIT`) and is parameterized at runtime.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AR`	IN	Socket	Input signal (AR)
`adapter::types::unidirectional::AR`	OUT1	Plug	First output (identical to IN)
`adapter::types::unidirectional::AR`	OUT2	Plug	Second output (identical to IN)

Functionality

This module forwards the AR signal present at socket **IN** unchanged to both plugs **OUT1** and **OUT2**. No data manipulation, filtering, or delay occurs. The distribution is purely structural: Each output receives its own copy of the reference to the underlying AR object.

Technical Features

- **Generic Implementation**: The function block uses the generic class name attribute (`eclipse4diac::core::GenericClassName`) with the value `'GEN_AR_SPLIT'`, allowing for application-specific configuration.
- **Unidirectional Adapters**: All adapters are of type `adapter::types::unidirectional::AR` (forward direction only).
- **No State Automation**: The function block does not have an explicit ECC (Execution Control Chart); signal routing is direct and event-independent.

State Overview

The function block does not implement state automation. Its functionality is limited to passively routing the input signal to both outputs. Therefore, state visualization is not required.

Application Scenarios

- **Signal Distribution**: Splitting an AR-based sensor signal to two parallel-operating control components.
- **Redundancy**: Providing the same AR data stream for a primary and a redundant system.
- **Debugging**: Connecting an analysis or logging module in parallel to the existing path without interrupting the original signal chain.

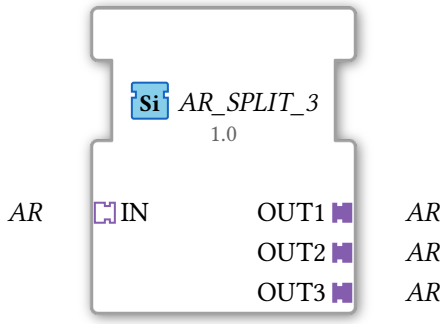
Comparison with Similar Modules

Modules such as `AR_SPLIT_3` or `AR_SPLIT_N` offer similar functionality, distributing a signal to three or N outputs, respectively. The choice depends on the required number of outputs. Cascading multiple `AR_SPLIT_2_UNGATED` instances is also possible, but increases complexity compared to a dedicated multi-output splitter.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The **AR_SPLIT_2_UNGATED** is a simple yet essential module for multiplying an AR signal in IEC 61499-based control systems. Its generic design and clear interface make it the first choice when a signal needs to be passed between two independent target components.

AR_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_SPLIT_3** serves as a generic splitter for adapter connections. It distributes an incoming data and event stream (via a `AR` adapter) to three separate, identically structured output adapters. This enables efficient reuse of information in automation processes without duplicating the logic.

Interface Structure

Event Inputs

None – the block has only adapter interfaces. Events are transmitted implicitly via the socket `IN` (of type `AR`).

Event Outputs

None – Events are passed via the plugs `OUT1`, `OUT2`, and `OUT3` (type `AR`).

Data Inputs

None – All data is provided via the adapter `IN`.

Data Outputs

None – All data is output via the three output adapters (`OUT1`, `OUT2`, `OUT3`).

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AR`	Incoming adapter as the source of the data/events.
Plug	`OUT1`	`adapter::types::unidirectional::AR`	First outgoing adapter (Destination 1).
Plug	`OUT2`	`adapter::types::unidirectional::AR`	Second outgoing adapter (Destination 2).

Plug	OUT3	adapter::types::unidirectional::AR	Third outgoing adapter (Destination 3).

Functionality

This function block implements a **1:3 distribution** at the adapter level. A AR adapter (unidirectional) connected to IN is internally routed to the three output adapters OUT1, OUT2, and OUT3.

Every event or data packet received at IN is simultaneously forwarded to all three outputs. The distribution occurs without delay and without data modification. The function block is generic and can be used with any AR adapter profile – its internal logic automatically adapts to the structure of the adapter type used.

…

Technical Features

- **Generic Type**: The function block (FB) is designed as a generic block (GEN_AR_SPLIT) and can be used with different AR adapter definitions (unidirectional), provided the interfaces are compatible.
- **Unidirectional Adapters**: Both inputs and outputs are unidirectional, meaning the data/event direction is fixed (from sender to receiver). Feedback is not possible with this block.
- **Easy Scaling**: The outputs are split without additional configuration. For different numbers of outputs, variants such as AR_SPLIT_2 or a configurable splitter (AR_SPLIT_N) can be used.
- **No State Change**: The block has no internal memory and no state machine – every event is replicated immediately and completely.

State Overview

The function block is **stateless** (combinatorial). There are no internal states or sequential processes. Distribution occurs purely through the connection of the adapter signals.

Application Scenarios

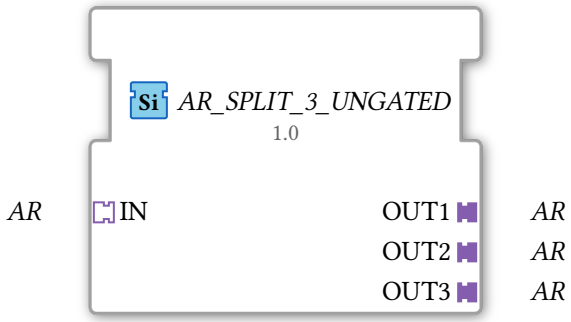
- **Distributing sensor data** to multiple parallel processing logics (e.g., evaluation, visualization, logging).
- **Controlling multiple actuator groups** with an identical control signal (e.g., parallel valve or motor control).
- **Splitting a control event** into different function blocks without copying the source logic.
- **Debugging and Monitoring**: A signal can be routed to a physical receiver and, in parallel, to a monitoring component.

Comparison with Similar Function Blocks

Function Block	Description
AR_SPLIT_2	Distribution to two outputs – more compact for smaller applications.
AR_SPLIT_N	Distribution to a configurable number of outputs (generic).
AR_CONNECT	Simple 1:1 connection (no distribution).

Unlike dedicated splitters with data or event inputs/outputs, the AR_SPLIT_3 operates exclusively via adapters, making it particularly flexible and type-independent.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AR_SPLIT_3 is a simple yet useful generic function block for distributing adapter signals to multiple outputs. It reduces the effort required for signal duplication in IEC 61499 applications and, due to its generic nature, contributes to the reusability and clarity of control logic. Thanks to its pure adapter approach, it can be integrated into a wide variety of environments without modification.

AR_SPLIT_3_UNGATED

i UNGATED variant: This block is the ungated version of AR_SPLIT_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_SPLIT_3_UNGATED** serves as a generic splitter for adapter connections. It distributes an incoming data and event stream (via a AR adapter) to three separate, identically structured output adapters. - **Controlling multiple actuator groups** with an identical control signal (e.g., parallel valve or motor control).
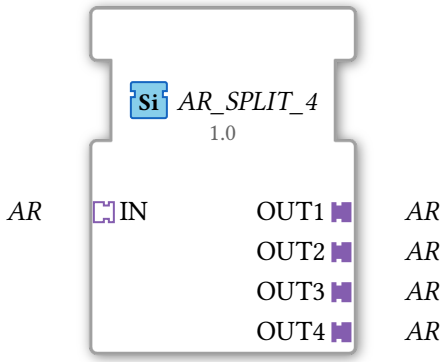
- **Splitting a control event** into different function blocks without copying the source logic.
- **Debugging and Monitoring**: A signal can be routed to a physical receiver and, in parallel, to a monitoring component.

Comparison with Similar Function Blocks

Function Block	Description
AR_SPLIT_2	Distribution to two outputs – more compact for smaller applications.
AR_SPLIT_N	Distribution to a configurable number of outputs (generic).
AR_CONNECT	Simple 1:1 connection (no distribution).

Unlike dedicated splitters with data or event inputs/outputs, the AR_SPLIT_3_UNGATED operates exclusively via adapters, making it particularly flexible and type-independent.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AR_SPLIT_3_UNGATED is a simple yet useful generic function block for distributing adapter signals to multiple outputs. It reduces the effort required for signal duplication in IEC 61499 applications and, due to its generic nature, contributes to the reusability and clarity of control logic. Thanks to its pure adapter approach, it can be integrated into a wide variety of environments without modification.

AR_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_SPLIT_4** is used to split one incoming AR adapter (unidirectional) into four outgoing AR adapters. It is implemented as a generic function block (`GenericClassName = 'GEN_AR_SPLIT'`) and enables simple signal multiplication for adapter-based communication in control systems.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

Name	Type	Comment
(none)	–	–

Data Outputs

Name	Type	Comment
(none)	–	–

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AR`	**IN**	Socket (Input)	Incoming AR adapter signal, which is distributed to the four outputs.
`adapter::types::unidirectional::AR`	**OUT1**	Plug (Output)	First outgoing AR channel.
`adapter::types::unidirectional::AR`	**OUT2**	Plug (Output)	Second outgoing AR channel.
`adapter::types::unidirectional::AR`	**OUT3**	Plug (Output)	Third outgoing AR channel.
`adapter::types::unidirectional::AR`	**OUT4**	Plug (Output)	Fourth outgoing AR channel.

Functionality

The function block receives an AR adapter signal via socket **IN** and forwards it unchanged to all four plugs **OUT1** to **OUT4**. Distribution occurs in parallel – every event or data value received via **IN** is simultaneously available on all outputs. The function block itself does not perform any logical processing or transformation; it functions purely as a splitter for unidirectional AR adapters.

Technical Features

- **Generic Type**: The function block is defined as a generic function block (`GenericClassName`), which means that the specific AR adapter type is determined at compile time. This increases reusability in various applications.
- **No State Machine**: The function block (FB) has no Execution Control Chart (ECC) and no internal states. All operations are purely combinatorial or event-driven.
- **Unidirectional**: The adapter type is specified as unidirectional; feedback from the target block is not provided.

State Overview

Since the FB has no state machine, no explicit states exist. The behavior is deterministic: An incoming trigger at socket **IN** is immediately forwarded to all outputs.

Application Scenarios

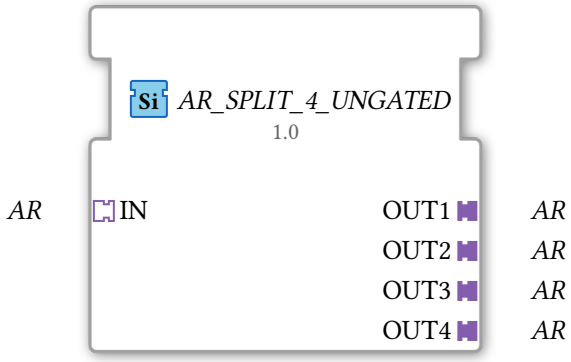
- **Signal Multiplication**: A control signal (e.g., "Start" or "Reset") should reach several parallel function blocks simultaneously.
- **Monitoring and Parallel Processing**: A measured value or an alarm is distributed to several independent evaluation blocks.
- **Testing and Simulation**: During development, a signal can be recorded or simulated while simultaneously being sent to the actual target block.

Comparison with Similar Function Blocks

- **AR_SPLIT_2**: Splits an AR signal into two outputs – suitable for smaller distributions.
- **AR_SPLIT_N**: A non-standard, configurable splitter (e.g., via parameters) designed for any number of outputs.
- **AR_MERGE**: Merges multiple AR signals into one – the inverse function of AR_SPLIT_4.

Compared to these alternatives, AR_SPLIT_4 offers a fixed number of four outputs, enabling a compact and clear implementation without configuration overhead.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AR_SPLIT_4** is a simple yet useful generic function block for distributing a unidirectional AR adapter signal across four parallel paths. Due to its streamlined design (no event/data interfaces, no state machine), it is ideally suited for all applications where a signal is needed multiple times without introducing additional logic.

AR_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AR_SPLIT_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

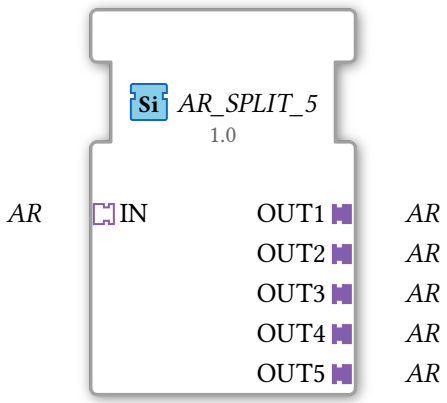
- **AR_MERGE**: Merges multiple AR signals into one – the inverse function of AR_SPLIT_4_UNGATED.

Compared to these alternatives, AR_SPLIT_4_UNGATED offers a fixed number of four outputs, enabling a compact and clear implementation without configuration overhead.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **AR_SPLIT_4_UNGATED** is a simple yet useful generic function block for distributing a unidirectional AR adapter signal across four parallel paths. Due to its streamlined design (no event/data interfaces, no state machine), it is ideally suited for all applications where a signal is needed multiple times without introducing additional logic.

AR_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The AR_SPLIT_5 function block is used to split an incoming AR adapter into five identical AR adapter outputs. It is a generic function block specifically designed for distributing unidirectional adapters (type: `adapter::types::unidirectional::AR`).

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Data Outputs

None available.

Adapter

- **Socket (Input)**:
- `IN`: Type `adapter::types::unidirectional::AR` – Receives a single AR adapter.
- **Plugs (Outputs)**:
- `OUT1`: Type `adapter::types::unidirectional::AR`
- `OUT2`: Type `adapter::types::unidirectional::AR`
- `OUT3`: Type `adapter::types::unidirectional::AR`
- `OUT4`: Type `adapter::types::unidirectional::AR`
- `OUT5`: Type `adapter::types::unidirectional::AR`

All outputs are identical and pass the incoming AR adapter through unchanged.

Functionality

The function block operates as a passive distributor: As soon as an AR adapter is connected to the input `IN`, it is duplicated to the five outputs `OUT1` to `OUT5`. Each connection receives an independent but identical copy of the adapter. No data processing or modification takes place.

Technical Features

- **Unidirectionality**: The adapters of type `AR` are exclusively unidirectional, meaning signals flow only from the input to the outputs.
- **Generic Implementation**: The function block is implemented as a generic type (`GEN_AR_SPLIT`), which allows for easy reuse and adaptation to other adapter types.
- **No State Logic**: The function block has no internal states or events; The splitting is achieved purely through interconnection technology.

State Overview

The AR_SPLIT_5 does not have its own state machine. Its behavior is static and purely structural: The input is directly passed through to all outputs.

Application Scenarios

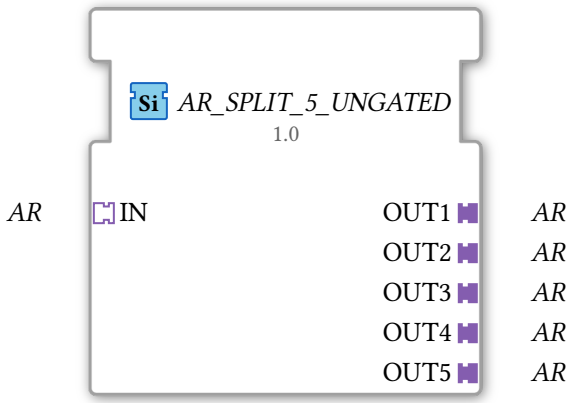
- **Signal Distribution**: When an AR adapter provides a control or data signal that needs to be passed on to several downstream components (e.g., actuators, sensors).
- **Module Cascading**: In complex automation systems where an AR signal needs to be split to different subsystems.

Comparison with Similar Function Blocks

- **AR_SPLIT_2, AR_SPLIT_3, AR_SPLIT_4**: These function blocks split an AR adapter into two, three, or four outputs, respectively. The AR_SPLIT_5 is the extension to five outputs.

- **AR_MERGE_***: Unlike split function blocks, merge function blocks combine multiple AR adapters into one.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AR_SPLIT_5 is a simple yet useful function block for distributing a unidirectional AR adapter across five independent outputs. Its generic and eventless structure makes it a fundamental tool for adapter-based communication in IEC 61499 systems.

AR_SPLIT_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AR_SPLIT_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The AR_SPLIT_5_UNGATED function block is used to split an incoming AR adapter into five identical AR adapter outputs. It is a generic function block specifically designed for distributing unidirectional adapters (type: `adapter::types::unidirectional::AR`).

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Adapter

- **Socket (Input)**:

- `IN`: Type `adapter::types::unidirectional::AR` – Receives a single AR adapter.
- **Plugs (Outputs)**:
- `OUT1`: Type `adapter::types::unidirectional::AR`
- `OUT2`: Type `adapter::types::unidirectional::AR`
- `OUT3`: Type `adapter::types::unidirectional::AR`
- `OUT4`: Type `adapter::types::unidirectional::AR`
- `OUT5`: Type `adapter::types::unidirectional::AR`

All outputs are identical and pass the incoming AR adapter through unchanged.

Functionality

The function block operates as a passive distributor: As soon as an AR adapter is connected to the input `IN`, it is duplicated to the five outputs `OUT1` to `OUT5`. Each connection receives an independent but identical copy of the adapter. No data processing or modification takes place.

Technical Features

- **Unidirectionality**: The adapters of type `AR` are exclusively unidirectional, meaning signals flow only from the input to the outputs.
- **Generic Implementation**: The function block is implemented as a generic type (`GEN_AR_SPLIT`), which allows for easy reuse and adaptation to other adapter types.
- **No State Logic**: The function block has no internal states or events; The splitting is achieved purely through interconnection technology.

State Overview

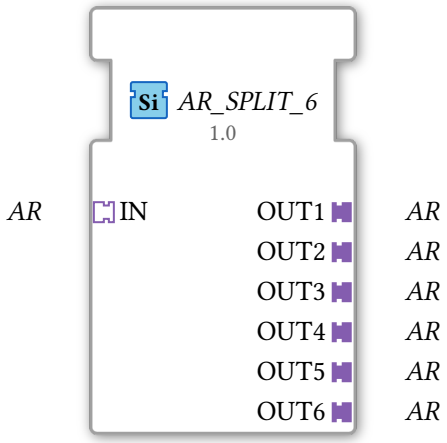
The AR_SPLIT_5_UNGATED does not have its own state machine. Its behavior is static and purely structural: The input is directly passed through to all outputs.

Application Scenarios

- **Signal Distribution**: When an AR adapter provides a control or data signal that needs to be passed on to several downstream components (e.g., actuators, sensors).
- **Module Cascading**: In complex automation systems where an AR signal needs to be split to different subsystems.

Comparison with Similar Function Blocks

- **AR_SPLIT_2, AR_SPLIT_3, AR_SPLIT_4**: These function blocks split an AR adapter into two, three, or four outputs, respectively. The AR_SPLIT_5_UNGATED is the extension to five outputs.
- **AR_MERGE_***: Unlike split function blocks, merge function blocks combine multiple AR adapters into one.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The AR_SPLIT_5_UNGATED is a simple yet useful function block for distributing a unidirectional AR adapter across five independent outputs. Its generic and eventless structure makes it a fundamental tool for adapter-based communication in IEC 61499 systems.

AR_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_SPLIT_6** is used to distribute a single AR adapter input to six separate AR adapter outputs. It is designed as a generic function block (Generic FB) and allows for the simple duplication of an AR interface without data loss or protocol-specific conversion.

Interface Structure

Event Inputs

No event inputs are available. Functionality is controlled solely via the adapter interface.

Event Outputs

No event outputs are available.

Data Inputs

No data inputs are available.

Data Outputs

No data outputs are available.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AR`	**IN**	Socket (Input)	An incoming AR adapter that is distributed to all outputs.
`adapter::types::unidirectional::AR`	**OUT1**	Plug (Output)	First outgoing AR adapter (identical to IN).
`adapter::types::unidirectional::AR`	**OUT2**	Plug (Output)	Second outgoing AR adapter (identical to IN).
`adapter::types::unidirectional::AR`	**OUT3**	Plug (Output)	Third outgoing AR adapter (identical to IN).
`adapter::types::unidirectional::AR`	**OUT4**	Plug (Output)	Fourth outgoing AR adapter (identical to IN).
`adapter::types::unidirectional::AR`	**OUT5**	Plug (Output)	Fifth outgoing AR adapter (identical to IN).
`adapter::types::unidirectional::AR`	**OUT6**	Plug (Output)	Sixth outgoing AR adapter (identical to IN).

Functionality

The function block forwards the signals from the incoming AR adapter (socket **IN**) unchanged to all six output adapters (**OUT1** … **OUT6**). No logical or timing processing takes place – any change at the input is immediately visible on all outputs. The function block operates purely passively and does not require event control.

Technical Features

- **Generic Function Block (FB):** The FB is declared as a generic type (`eclipse4diac::core::GenericClassName = 'GEN_AR_SPLIT'`), allowing it to be reused in different contexts without having to redefine the underlying AR type.
- **Unidirectional Adapters:** All adapters used are of type `adapter::types::unidirectional::AR`, meaning data flows only from the socket to the plugs.
- **No State Machine:** Since the FB has no events or internal logic, there is no ECC (Execution Control Chart).

State Overview

This FB does not contain a state machine. It operates in a data-driven manner and establishes the input/output relationship continuously and without delay.

Application Scenarios

- **Distributing an AR signal to multiple devices:** If a sensor or actuator provides its data via an AR adapter, this function block (FB) can supply multiple downstream modules in parallel (e.g., several controllers or displays).
- **Test and simulation environments:** This FB is suitable for switching a single test signal to multiple evaluation units simultaneously.
- **Redundancy or parallelization:** In controllers that require multiple identical processing chains, the input is simply duplicated.

Comparison with similar function blocks

- **AR_SPLIT_2 / AR_SPLIT_4:** These function blocks split the input into two or four outputs, respectively, and differ only in the number of outputs. AR_SPLIT_6 extends this to six outputs.
- **General split function blocks:** Other split function blocks exist for data types (e.g., INT_SPLIT), but these are designed for specific data formats. This function block operates exclusively at the adapter level, making it more flexible when data exchange occurs via adapters.
- **Custom Implementation:** Alternatively, the distribution could also be achieved by manually wiring multiple adapter nodes, but this reduces clarity and maintainability.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AR_SPLIT_6** is a simple yet useful generic function block for multiplying an AR adapter signal into six parallel outputs. It is characterized by minimal complexity, a clear structure, and high reusability in automation projects based on the 4diac IDE and the IEC 61499 standard.

`adapter::types::unidirectional::AR`	**OUT3**	Plug (Output)	Third outgoing AR adapter (identical to IN).
`adapter::types::unidirectional::AR`	**OUT4**	Plug (Output)	Fourth outgoing AR adapter (identical to IN).
`adapter::types::unidirectional::AR`	**OUT5**	Plug (Output)	Fifth outgoing AR adapter (identical to IN).
`adapter::types::unidirectional::AR`	**OUT6**	Plug (Output)	Sixth outgoing AR adapter (identical to IN).

Functionality

The function block forwards the signals from the incoming AR adapter (socket **IN**) unchanged to all six output adapters (**OUT1** ... **OUT6**). No logical or timing processing takes place – any change at the input is immediately visible on all outputs. The function block operates purely passively and does not require event control.

Technical Features

- **Generic Function Block (FB):** The FB is declared as a generic type (`eclipse4diac::core::GenericClassName = 'GEN_AR_SPLIT'`), allowing it to be reused in different contexts without having to redefine the underlying AR type.
- **Unidirectional Adapters:** All adapters used are of type `adapter::types::unidirectional::AR`, meaning data flows only from the socket to the plugs.
- **No State Machine:** Since the FB has no events or internal logic, there is no ECC (Execution Control Chart).

State Overview

This FB does not contain a state machine. It operates in a data-driven manner and establishes the input/output relationship continuously and without delay.

Application Scenarios

- **Distributing an AR signal to multiple devices:** If a sensor or actuator provides its data via an AR adapter, this function block (FB) can supply multiple downstream modules in parallel (e.g., several controllers or displays).
- **Test and simulation environments:** This FB is suitable for switching a single test signal to multiple evaluation units simultaneously.
- **Redundancy or parallelization:** In controllers that require multiple identical processing chains, the input is simply duplicated.

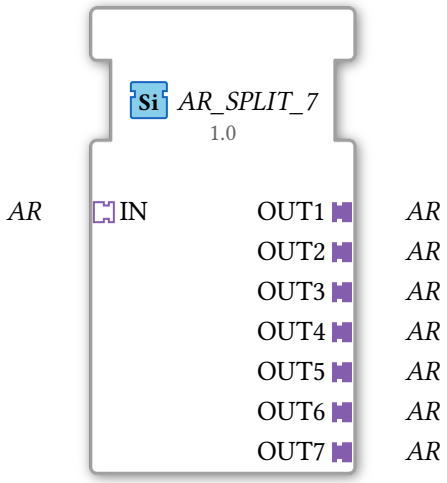
Comparison with similar function blocks

- **AR_SPLIT_2 / AR_SPLIT_4:** These function blocks split the input into two or four outputs, respectively, and differ only in the number of outputs. AR_SPLIT_6_UNGATED extends this to six outputs.
- **General split function blocks:** Other split function blocks exist for data types (e.g., INT_SPLIT), but these are designed for specific data formats. This function block operates exclusively at the adapter level, making it more flexible when data exchange occurs via adapters.
- **Custom Implementation:** Alternatively, the distribution could also be achieved by manually wiring multiple adapter nodes, but this reduces clarity and maintainability.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The **AR_SPLIT_6_UNGATED** is a simple yet useful generic function block for multiplying an AR adapter signal into six parallel outputs. It is characterized by minimal complexity, a clear structure, and high reusability in automation projects based on the 4diac IDE and the IEC 61499 standard.

AR_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The **AR_SPLIT_7** is a generic function block that distributes an incoming AR adapter socket (of type `adapter::types::unidirectional::AR`) to seven separate AR adapter plugs. It serves to forward an AR signal to up to seven different receivers without requiring the data to be provided multiple times.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AR`	IN	Socket	Incoming AR adapter, which is distributed to the seven outputs.
`adapter::types::unidirectional::AR`	OUT1 ... OUT7	Plug	Seven output adapters to which the incoming AR adapter is passed on unchanged.

Functionality

The function block receives an AR adapter via socket `IN`. As soon as a connection to this socket is established, the function block forwards the complete adapter – including all data and events it contains – to all seven plug adapters (`OUT1` to `OUT7`). No data transformation, filtering, or buffering takes place; the AR adapter is mirrored **1:1 across all outputs**.

The function block (FB) is implemented as a **generic block** (see attribute `eclipse4diac::core::GenericClassName = 'GEN_AR_SPLIT'`), so it operates independently of the specific AR adapter parameters.

Technical Features

- **Generic Design** – The FB does not require specific type information from the AR adapter; it operates purely via the adapter interface.
- **No State Machine** – The FB does not have an ECC (Execution Control Chart) and is purely data flow-related; it reacts directly to adapter connections.
- **Copyright & License** – The function block is subject to the Eclipse Public License 2.0 (EPL-2.0) and was provided by HR Agrartechnik GmbH (Version 1.0, 2025-01-24).

State Overview

The function block (FB) does not have a state machine (ECC). Distribution is static and without runtime logic.

Application Scenarios

- **Signal Distribution in Automation Systems** – One sensor or control adapter (AR) must supply several downstream function blocks in parallel.
- **Monitor or Diagnostic Connection** – An AR signal is simultaneously passed on to a control branch and a monitoring branch.
- **Test and Simulation Environments** – One adapter is distributed to several test or mock function blocks without instantiating the source multiple times.

Comparison with Similar Function Blocks

- **AR_SPLIT_2, AR_SPLIT_3, ...** – These function blocks offer the same functionality with a different number of outputs (2, 3, ...). The `AR_SPLIT_7` is the variant with exactly seven outputs.
- **AR_MERGE** – Merging multiple AR adapters into one, i.e., the inverse operation.
- **AR_COPY** – Often used as a dedicated function block for a single 1:1 distribution, while `AR_SPLIT_7` handles multiple outputs at once.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AR_SPLIT_7** is a lean, generic function block for easily distributing one AR adapter to up to seven target adapters. Thanks to its generic nature, it can be used immediately without modifying the type information and is particularly suitable for loosely coupled, dataflow-oriented architectures in automation technology.

AR_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The AR_SPLIT_8 function block is used to split a single unidirectional AR adapter signal into eight identical AR outputs. It is implemented as a generic function block and enables simple signal distribution without additional logic.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Name	Type	Direction
IN	`adapter::types::unidirectional::AR`	Socket (Input)
OUT1 – OUT8	`adapter::types::unidirectional::AR`	Plug (Output)

Functionality

The function block receives the complete interface of a unidirectional AR adapter via the **IN** socket. Events and data present at this interface are replicated to all eight output adapters (**OUT1** to **OUT8**) without delay or modification. Thus, a single data/event stream can be distributed in parallel to up to eight downstream components.

Technical Features

- The function block is generic (generic FB) and is identified as such by the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AR_SPLIT'`.
- There is no internal state diagram (ECC) – the forwarding is direct and stateless at all times.

- The implementation is designed for unidirectional AR adapters; use with bidirectional adapters is not supported.

State Overview

The function block has no explicit state diagram and operates statelessly. Adapter distribution occurs continuously, without any time dependencies or internal logic.

Application Scenarios

- **Distribution of Control Signals**: A central control algorithm (e.g., a PID controller) distributes its output via AR to several parallel actuators.
- **Broadcast in Star-Shaped Plant Sections**: Signals from a higher-level controller are distributed to eight identical substations.
- **Test and Simulation Environments**: A signal generator feeds several test objects simultaneously with the same adapter signal.

Comparison with Similar Function Blocks

- **AR_SPLIT_2, AR_SPLIT_4**: Analog function blocks with 2 and 4 outputs, respectively; AR_SPLIT_8 extends the number to eight outputs.
- **AR_MERGE_X**: Combines multiple AR signals into one – opposite function.
- SPLIT_ *for other adapter types**: Split blocks exist for other unidirectional and bidirectional adapter definitions that implement a similar splitting logic.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AR_SPLIT_8 is a simple yet extremely useful block for distributing unidirectional AR adapter signals across up to eight parallel paths. Its generic implementation allows for flexible use in various automation projects without requiring the implementation of additional signal multiplication logic.

AR_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AR_SPLIT_9** splits an incoming AR adapter (type `unidirectional`) into nine separate AR outputs. It serves as a distributor for an AR signal to multiple downstream components. The block is designed to be completely generic.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Direction	Adapter	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AR`	Incoming AR signal that is distributed.
Plug (Output)	`OUT1` ... `OUT9`	`adapter::types::unidirectional::AR`	Nine identical outputs that forward the incoming AR signal.

Functionality

The module forwards the AR signal present at the **IN** socket unchanged to all nine outputs **OUT1** to **OUT9**. No delay, filtering, or conversion takes place. Signal propagation is purely combinatorial.

Technical Features

- **Generic Function Block**: The function block uses a generic class name attribute (`eclipse4diac::core::GenericClassName` with the value `'GEN_AR_SPLIT'`) and a type hash attribute to enable flexible type adaptation in the IEC 61499 model.
- **Unidirectional Adapters**: Both the input and all outputs are defined as unidirectional AR adapters. Feedback or bidirectional communication is not provided.
- **No Events or Data**: All logic is handled exclusively via adapter interfaces – there are no event or data inputs/outputs.

State Overview

The function block has no internal state (no state machine). The output signal corresponds to the current input signal at any given time. There are no initialization or error states.

Application Scenarios

- **Distribution of a Start/Stop Signal**: A central AR command (e.g., "Start") is distributed to multiple actuators or machine parts.
- **Multicast Coupling**: An AR signal originating from a higher-level controller is simultaneously sent to multiple subordinate modules.
- **Parallel Control** of nine identical or different components using the same AR protocol.

Comparison with Similar Function Blocks

Function Block	Number of Outputs	Remarks
`AR_SPLIT_4`	4	Same functionality, but only four outputs.
`AR_SPLIT_9`	9	Presented function block (nine outputs).

AR_SPLIT_2	2	Minimal splitter for two paths.

The function blocks differ only in the number of outputs; the functionality and generic properties are identical.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AR_SPLIT_9** is a simple yet useful splitter function block for unidirectional AR signals. Due to its generic design, it can be flexibly used in different control architectures without requiring manual type adaptation. It is particularly suitable for scenarios where a signal needs to be duplicated to multiple paths simultaneously.

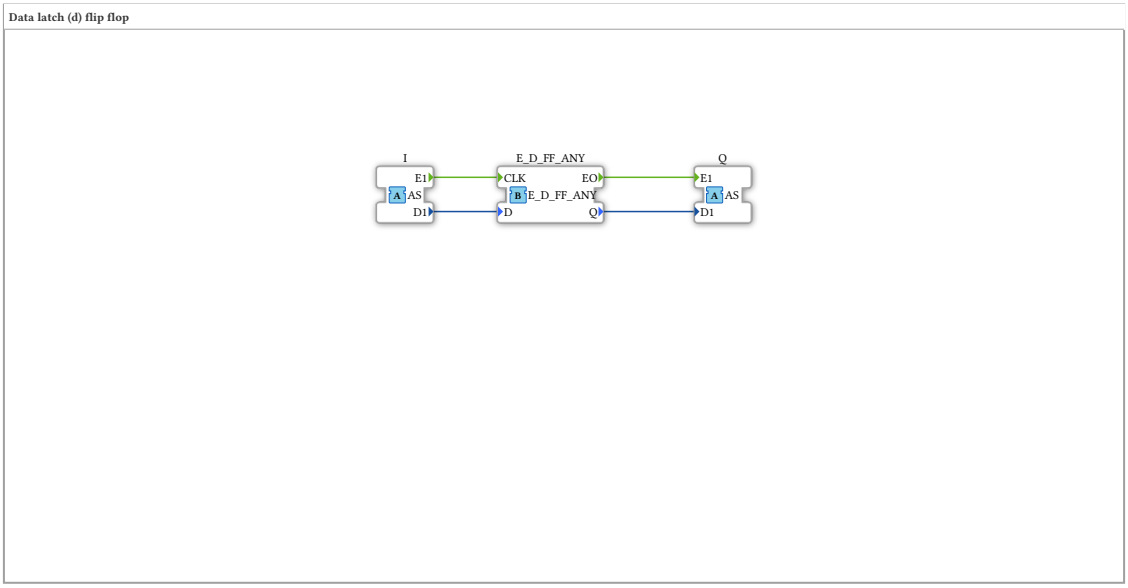
Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AS_D_FF

Value to latch – *AS*

AS – Latched value

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_D_FF** implements a simple data latch (D flip-flop) based on adapters. It stores an incoming data value with each incoming event and outputs the stored value as a signal. The block encapsulates the logic of the 4diac standard block `E_D_FF_ANY` and provides its interfaces exclusively via unidirectional adapters of type `adapter::types::unidirectional::AS`. This enables modular and standardized integration into more complex systems.

Interface Structure

Event Inputs

No direct event inputs. The block receives events exclusively via the adapter **I** (socket). The event is provided at the adapter input `I.E1`.

Event Outputs

No direct event outputs. The function block sends events exclusively via the **Q** (Plug) adapter. The output event appears at the adapter output `Q.E1`.

Data Inputs

No direct data inputs. The data value to be stored is provided via the **I** (Socket) adapter as `I.D1`.

Data Outputs

No direct data outputs. The stored data value is output via the **Q** (Plug) adapter as `Q.D1`.

Adapters

Adapter	Direction	Type	Description
I	Socket (Input)	`adapter::types::unidirectional::AS`	Provides the input event (`E1`) and the data value to be latched (`D1`).
Q	Plug (Output)	`adapter::types::unidirectional::AS`	Outputs an output event (`E1`) and the stored data value (`D1`).

Functionality

The **AS_D_FF** function block operates as an asynchronous data latch.

Upon each positive event on `I.E1`, the current value of `I.D1` is transferred to the block's internal memory. Immediately afterwards, an event is triggered on `Q.E1`, and the stored value is available on `Q.D1`.

This logic is implemented by the internally used component `E_D_FF_ANY`:

- `I.E1` ⟶ `E_D_FF_ANY.CLK`
- `I.D1` ⟶ `E_D_FF_ANY.D`
- `E_D_FF_ANY.EO` ⟶ `Q.E1`
- `E_D_FF_ANY.Q` ⟶ `Q.D1`

The component thus behaves like a classic D flip-flop, but with a standardized adapter interface instead of direct inputs/outputs.

…

Technical Features

- **Adapter-based encapsulation**: All data exchange occurs exclusively via unidirectional adapters of type `adapter::types::unidirectional::AS`. This facilitates reuse in different contexts and ensures a clear separation between event and data flows.
- **Internal use of `E_D_FF_ANY`**: The component utilizes the standard function block `iec61499::events::E_D_FF_ANY`, which offers a proven and efficient implementation of a D flip-flop.
- **No direct I/O pins**: The component itself does not define any event or data inputs/outputs; all communication is handled via the adapters.
- **Unidirectional adapters**: Both adapters (I and Q) are defined as unidirectional, meaning that event and data flow occurs only in one direction (from the socket to the plug).

State Overview

The component does not have an explicit state machine. Its behavior is determined by the internal D flip-flop, which has two logical states:

- **State 0**: The stored data value is 0 (or `FALSE`).
- **State 1**: The stored data value is 1 (or `TRUE`).

The state is switched to `I.E1` by an event (if the data value has changed) and remains in this state until the next event.

Application Scenarios

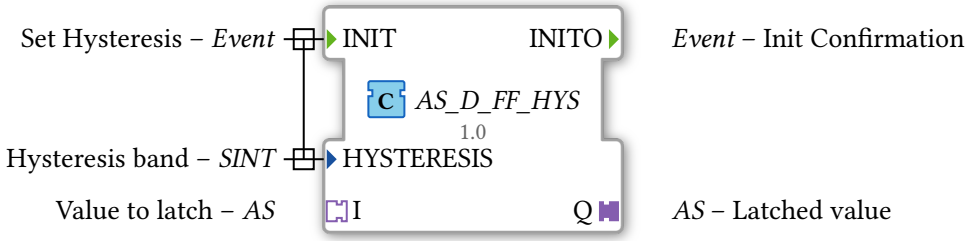
- **Signal Buffering**: Temporarily storing a digital signal that is to be retrieved at specific times (e.g., sample-and-hold).
- **Synchronization**: Adapting asynchronous data streams to a clock-driven sequence by holding a value at an event.
- **Modular Interconnection**: Used in systems based on adapter communication to maintain a uniform interface (e.g., in a chain of processing blocks).
- **Simple State Storage**: Implements simple memory functions in automation applications without relying on complex memory modules.

Comparison with Similar Modules

Module	Property	Difference from AS_D_FF
SR_FF	Set-Reset Flip-Flop	Has separate set and reset inputs, no clock signal.
E_D_FF_ANY	Pure D flip-flop with direct I/O	Does not offer an adapter interface; requires direct connections.
AS_FF_RS (hypothetical)	RS flip-flop with adapters	Uses two adapters for set and reset, no clock signal.

The **AS_D_FF** combines the clear logic of a D flip-flop with the flexibility of an adapter-based interface. It is particularly suitable for systems that prefer standardized, unidirectional communication.

Conclusion



The **AS_D_FF** function block represents a practical encapsulation of a D flip-flop that communicates exclusively via adapters. Its internal behavior corresponds to a reliable data latch that responds to every incoming event. The use of adapters increases modularity and reusability, while the implementation is based on the proven `E_D_FF_ANY`. The block is ideal for all applications that require simple, event-driven data storage with a standardized interface.

]

AS_D_FF_HYS

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_D_FF_HYS** implements a data-triggered flip-flop (D-latch) with **hysteresis** (switching hysteresis). This component is typically used in signal processing to smooth noisy or fluctuating input signals and create defined switching points. It features an event input `INIT` to set the hysteresis value, as well as two adapter interfaces: an input adapter `I` for the signal to be latched and an output adapter `Q` for the latched and hysteresis-filtered output signal.

Interface Structure

Event Inputs

Name	Type	Comment	With Data
`INIT`	EInit	Sets the hysteresis value	`HYSTERESIS`

Event Outputs

Name	Type	Comment
`INITO`	EInit	Confirmation of INIT processing

Data Inputs

Name	Type	Comment
`HYSTERESIS`	SINT	Hysteresis Bandwidth (Integer Value)

Data Outputs

No direct data outputs – the output value is provided via the `Q` adapter.

Adapters

Direction	Name	Type	Comment
Socket	`I`	`adapter::types::unidirectional::AS`	Input Signal (Value and Clock)
Plug	`Q`	`adapter::types::unidirectional::AS`	Output signal (latched with hysteresis)

The `AS` (unidirectional) adapters typically have an event port `E1` and a data port `D1`. The socket `I` provides the clock signal via `I.E1` and the data value to be latched via `I.D1`. The plug `Q` outputs an event via `Q.E1` and the filtered output value via `Q.D1`.

The socket `I` provides the clock signal via `I.E1` and the data value to be latched via `I.D1`.

Functionality

The FB receives a clock signal (event `I.E1`) and a data value (`I.D1`) via the adapter `I`. With each clock cycle, the current data value is compared to the last output value, taking the hysteresis band into account. The output `Q.D1` only changes if the new input value is outside the interval `[letzter Ausgangswert - HYSTERESIS , letzter Ausgangswert + HYSTERESIS]`. This suppresses small fluctuations (noise) around the set operating point.

The event `INIT` is used for the one-time configuration of the hysteresis value. The hysteresis value from the data input `HYSTERESIS` is used for this purpose. After successful initialization, the event `INITO` is triggered.

The function block (FB) internally uses the block `E_D_FF_ANY_HYS` from the library `logiBUS::signalprocessing::hysteresis`, which implements the actual flip-flop logic with hysteresis.

Technical Features

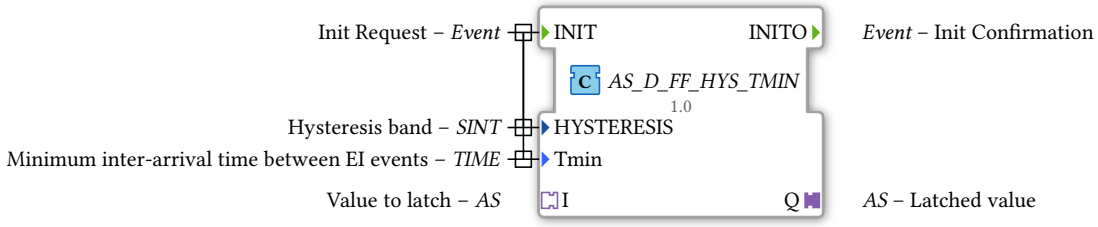
- The hysteresis value is defined as `SINT` (signed integer).
- The actual signal processing is implemented by a subordinate FB (`E_D_FF_ANY_HYS`), which is not directly accessible to the user.
- The adapter interface allows loose coupling of the function block to other components.
- The event `INIT` does not process a value – the hysteresis parameters can only be set before initial operation. Subsequent changes are only possible by resending `INIT`.

State Overview

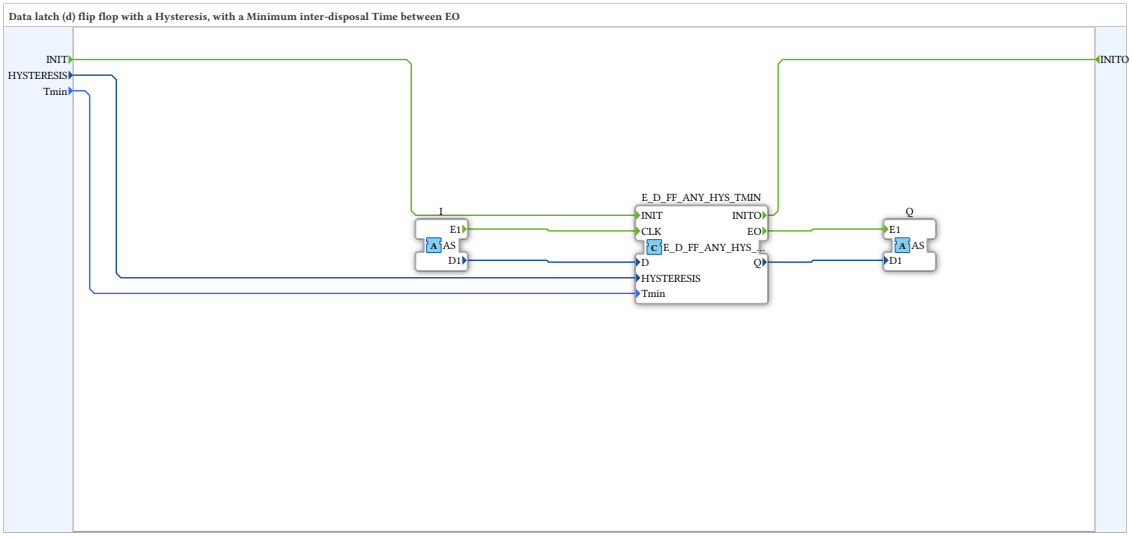
The function block (FB) has **no explicit state machine** that is externally visible. Internally, the current output value is stored. Hysteresis creates a state memory: The output does not change with every input change, but only when the hysteresis thresholds are exceeded or fallen below.

Application Scenarios

- **Debouncing of Switch Contacts** – Suppression of bounce and short interference pulses.
- **Threshold Switches with Hysteresis** – e.g., temperature controllers that separate on and off points.
- **Signal Smoothing in Sensors** – Processing noisy analog values into discrete states.
- **Data Latch with Noise Suppression** – for slow but noisy data signals.



Comparison with Similar Function Blocks



Function Block	Property	Difference to AS_D_FF_HYS
`E_D_FF`	Classic D flip-flop without hysteresis	No filtering; output follows each clock cycle.
`E_D_FF_HYS`	D flip-flop with hysteresis (same logic)	No dedicated `INIT` input; hysteresis is set via data if necessary.
`AS_FF_HYS`	Flip-flop with hysteresis and dedicated adapter interface	Possibly different coupling, similar function.

Conclusion

The `AS_D_FF_HYS` combines a D flip-flop with adjustable hysteresis and encapsulates the complex logic in an easy-to-use, adapter-based component. It is particularly suitable for applications where noisy discrete signals need to be processed cleanly and with defined switching points. Initial configuration via `INIT` allows for flexible adaptation to various noise environments.

AS_D_FF_HYS_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AS_D_FF_HYS_TMIN** implements a data-triggered flip-flop (D flip-flop) with hysteresis and a minimal time delay between successive events. It serves for stable, debounced signal transmission in time-critical control sequences. The block uses adapters for unidirectional communication, with an input signal received via socket **I** and the latching output signal provided via plug **Q**.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization request; sets hysteresis and minimum time

Event Outputs

Name	Type	Comment
INITO	EInit	Confirmation of completed initialization

Data Inputs

Name	Type	Comment
HYSTERESIS	SINT	Hysteresis band (integer value, e.g., 8 bits)
Tmin	TIME	Minimum time between two events (e.g., for debouncing)

Data Outputs

No direct data outputs – the output signal is provided via the **Q** adapter.

Adapters

Type	Name	Direction	Comment
AS	I (Socket)	Input	Unidirectional adapter for the signal to be latched (e.g., data + event line)
AS	Q (Plug)	Output	Unidirectional adapter for the latching output signal

Functionality

The function block operates internally with a predefined function block **E_D_FF_ANY_HYS_TMIN**. Upon the **INIT** event, the parameters **HYSTERESIS** and **Tmin** are transferred. The incoming event (via the **I** adapter, line **E1**) triggers the flip-flop clock, while the corresponding data value (via **I.D1**) is transferred. Output **Q.D1** is updated only if:

- the new data value differs from the currently stored value by at least the **hysteresis**, and
- at least the time **Tmin** has elapsed since the last event.

The output event (via **Q.E1**) signals a valid update. The module thus suppresses noise and prevents excessively rapid edge transitions.

Technical Features

- **Adapter-Based Input/Output** – Signal transmission via adapters **I** and **Q** enables easy integration into complex adapter networks and increases reusability.
- **Hysteresis** – Prevents oscillations with fluctuating or noisy input signals by only registering significant changes.
- **Minimum Event Time (Tmin)** – Enforces a minimum pause between two triggers; serves as an additional debouncing mechanism.
- **Internal use of a proven flip-flop component** – The implementation delegates the core logic to **E_D_FF_ANY_HYS_TMIN**, which is designed for generic data types.

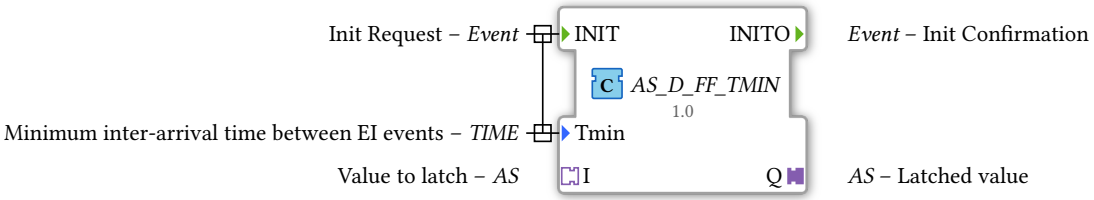
State Overview

The component does not have any explicit, externally visible states. Internally, the flip-flop maintains a stored value (last valid output) that is only updated when the hysteresis and timing conditions are met. After initialization (INIT/INITO), the stored value is undefined until the first valid signal arrives.

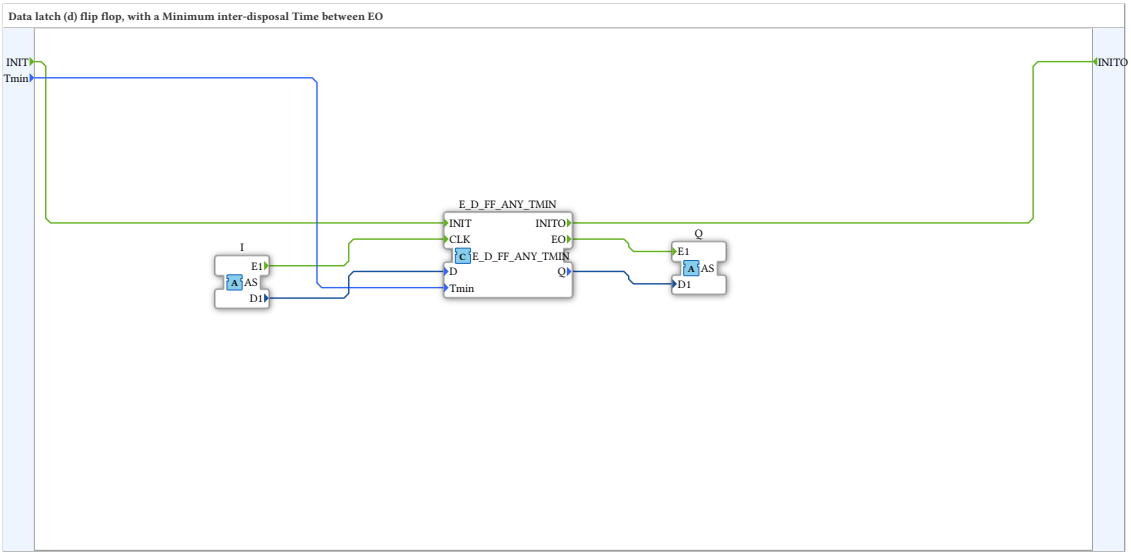
Application Scenarios

- **Debouncing of sensor signals** – e.g., limit switches or proximity sensors with mechanical bouncing.
- **Frequency limiting** – Preventing excessively fast switching operations in downstream actuators or communication interfaces.
- **Hysteresis-based threshold detection** – e.g., temperature or pressure control with a reset band.
- **Signal transmission in time-critical, interference-prone environments** (e.g., agricultural machinery controls).

Comparison with similar components



- **Simple D flip-flop (e.g., E_D_FF)** – without hysteresis or time delay; accepts every clock signal without filtering.
- **Schmitt trigger component** – also with hysteresis, but usually without asynchronous event control and without an adjustable minimum time.
- **Delay component (e.g., E_DELAY)** – only delays the signal, but has no hysteresis or latch function.



AS_D_FF_HYS_TMIN combines latch function, hysteresis, and timing in a single component and is therefore specifically optimized for robust, time-controlled signal processing.

Conclusion

The **AS_D_FF_HYS_TMIN** is a specialized function block for industrial controllers that require reliable, noise-insensitive signal transmission with adjustable dead time. The combination of a D flip-flop, hysteresis, and minimum time makes it a valuable tool for automation solutions, especially in environments with high levels of interference or tight timing requirements.

AS_D_FF_TMIN

• – ○ • – ○ • – ○ •

The function block **AS_D_FF_TMIN** implements a data-locking D flip-flop that takes over a data value supplied via an adapter upon the arrival of an event and outputs it via another adapter. Its special feature is a configurable minimum time (`Tmin`) between two consecutive take-over events. This suppresses excessively rapid event sequences, which can be used, for example, for debouncing or to enforce process constraints.

Event	Type	Comment
INIT	EInit	Initialization Request (reads `Tmin`)
Event	Type	Comment
–––––	–––	–––––––––––––––
INITO	EInit	Initialization Confirmation
Name	Type	Comment
––	––	–––––––––––––––––––––––
Tmin	TIME	Minimum time between two consecutive CLK events

This block has no explicit data outputs; output is exclusively via the **Q** adapter.

Daten-Ausgänge

Daten-Eingänge

Ereignis-Ausgänge

Ereignis-Eingänge

Interface Structure

Introduction

Adapters

| Direction | Adapter | Type | Comment | | Socket | I | adapter::types::unidirectional::AS | Input data (D1) and clock (E1) | | Plug | Q | adapter::types::unidirectional::AS | Output data (D1) and event (E1) |

The adapters of type `AS` each provide one event input/output (E1) and one data input/output (D1).

Functionality

After successful initialization (INIT with a valid `Tmin`), the block operates like a clocked D flip-flop with a time filter:

- An event at the adapter input **I.E1** is interpreted as a clock signal (CLK).
- The data value **I.D1** is adopted upon the arrival of I.E1, **provided the time interval to the last CLK event is at least `Tmin`**. Otherwise, the event is ignored.
- If the adoption is successful, the stored value is output at data output **Q.D1**, and an event **Q.E1** is triggered.

Time filtering is implemented by the internally used block `E_D_FF_ANY_TMIN`, which delays or discards the clock event if the minimum time is not met.

- **Adapter-based I/O**: Data and events are not exchanged as separate variables, but via unidirectional adapters (`AS`). This allows for modular connection with other blocks.
- **Parameterizable Minimum Time**: The time `Tmin` is set for initialization and cannot be changed during operation (another INIT call is required).
- **Event Suppression**: Clock events that occur too close together are silently ignored – no error message is generated.

The block does not have explicit state machines in the sense of a statechart. However, its behavior can be described in two phases:

1. **Initialization Phase**: After the INIT event, `Tmin` is set internally. Only then is the block ready to process CLK events.
2. **Operation Phase**: The block waits for CLK events. When one arrives, it checks whether the time lock (since the last CLK) has expired. If so, the data value is taken and output. If no, the event is discarded.

- **Digital Signal Debouncing**: A sensor delivers fast, bouncing signals; the minimum pulse width is set using `Tmin`.
- **Clock Synchronization in Time-Critical Systems**: Prevents data transfers faster than a predefined system clock threshold.
- **Rate Limiting for Communication Interfaces**: A new value is only accepted every `Tmin` seconds (e.g., for bus accesses).

Function Block	Time Filtering	Additional Features
AS_D_FF	No (immediate transfer)	Simple D flip-flop without time limit
AS_D_FF_TMIN (this one)	Yes, configurable via `Tmin`	Suppresses excessively fast clock sequences
AS_D_FF_TMAX	Yes, maximum time between clock cycles	Enforces regular takeovers

The **AS_D_FF_TMIN** function block extends a simple D flip-flop by adding an adjustable minimum time between two takeover events. Thanks to its adapter interface and the clear separation of initialization and operation, it is particularly suitable for industrial control systems and discrete-time processing applications where excessively fast switching must be avoided.

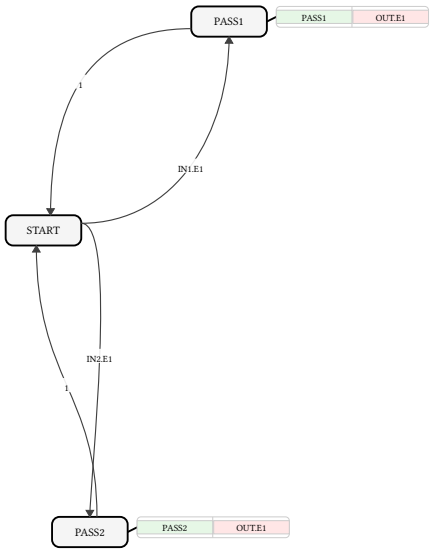
State Overview

Application Scenarios



Comparison with Similar Function Blocks

Conclusion

AS_LAST_2

ECC: AS_LAST_2

Introduction

The AS_LAST_2 function block merges two same-type SINT adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: SINT adapter (unidirectional) - first signal source
- **IN2**: SINT adapter (unidirectional) - second signal source

Output adapter (Plug):

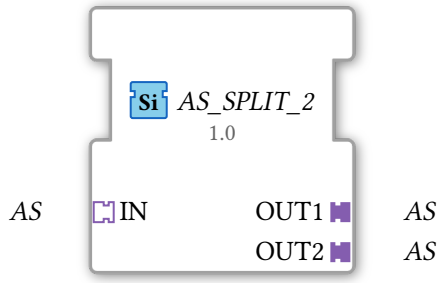
- **OUT**: SINT adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid SINT signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same SINT value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AS_LAST_2 is the inverse of `AS_SPLIT_2`: AS_SPLIT_2 distributes 1 input to 2 outputs, AS_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

AS_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_SPLIT_2** splits an incoming adapter signal of type `adapter::types::unidirectional::AS` into two identical output adapters. It is designed as a generic function block and is suitable for applications where an adapter data stream needs to be distributed to multiple downstream components without altering the original signal.

Interface Structure

Event Inputs

None. The function block operates purely data-driven via the adapters.

Event Outputs

None.

Data Inputs

None. All data transmission occurs via the adapter input `IN`.

Data Outputs

None. The output data is provided via the adapters `OUT1` and `OUT2`.

Adapters

Direction	Name	Type	Description
Socket	IN	adapter::types::unidirectional::AS	Input adapter whose data is distributed to both outputs.
Plug	OUT1	adapter::types::unidirectional::AS	First output adapter – receives a copy of the incoming data.
Plug	OUT2	adapter::types::unidirectional::AS	Second output adapter – also receives a copy of the incoming data.

Functionality

The module functions as a passive distributor: An adapter data stream present at socket `IN` is forwarded unchanged to both plugs `OUT1` and `OUT2`. No data manipulation, buffering, or filtering takes place. The distribution is signal-accurate, so the data present at `OUT1` and `OUT2` corresponds exactly in time and content to the data at `IN`.

Technical Features

- **Generic Type:** The module is declared as a generic function block (`GenericClassName = GEN_AS_SPLIT`). This allows for use in various contexts, provided the connected adapters are of type `AS`.
- **No Event Control:** Data flows solely through the adapter interfaces. There are no event inputs or outputs, meaning the module has no independent sequence control.
- **No Data Buffer:** Since neither memory nor delay is implemented, the module is particularly suitable for low-latency, real-time applications.

State Overview

The module has no internal states or sequential logic. It behaves like a pure wiring component and operates continuously without an explicit state machine.

Application Scenarios

- **Signal Fan-out:** Distributing a sensor adapter to multiple evaluation units connected in parallel.
- **Redundancy:** Feeding a control signal into two independent actuator circuits.
- **Monitoring:** Connecting an analysis or logging adapter in parallel to the existing data path.

Comparison with Similar Function Blocks

Unlike a simple connection node (which only implements a 1:1 connection), `AS_SPLIT_2` enables clean, configurable distribution across two outputs. Compared to an **AS_MUX** or **AS_DEMUX**, this function block lacks selection or prioritization logic – it always distributes all incoming data to all outputs. Similar blocks like `AS_SPLIT_3` or `AS_SPLIT_N` expand the number of outputs accordingly.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AS_SPLIT_2** is a simple yet useful function block for duplicating adapter data streams. Its generic definition and the absence of complex logic make it ideally suited as a universal distribution element in 4diac-based automation systems where signal splitting without data modification is required.

AS_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The AS_SPLIT_3 function block distributes an incoming adapter data stream to three identical outputs. It is implemented as a generic function block and designed for use with the `adapter::types::unidirectional::AS` adapter type.

Interface Structure

Event Inputs

None

Event Outputs

None

Data Inputs

None

Data Outputs

None

Adapter

Name	Type	Direction	Description
IN	`adapter::types::unidirectional::AS`	Socket	Input adapter – Data source distributed to three outputs.
OUT1	`adapter::types::unidirectional::AS`	Plug	First output – receives the unchanged data from IN.
OUT2	`adapter::types::unidirectional::AS`	Plug	Second output – receives the unchanged data from IN.
OUT3	`adapter::types::unidirectional::AS`	Plug	Third output – receives the unchanged data from IN.

Functionality

The module forwards the adapter data received via socket `IN` identically and without delay to all three adapter plugs `OUT1`, `OUT2`, and `OUT3`. No data manipulation, filtering, or buffering takes place. Distribution occurs in a pure pass-through mode.

Technical Features

- **Generic Type**: The function block uses the attribute `eclipse4diac::core::GenericClassName` with the value `'GEN_AS_SPLIT'` to enable generic instantiation. The specific adapter type (`adapter::types::unidirectional::AS`) is defined during project configuration.
- **Eventless**: Since no events (event inputs/outputs) are defined, data transmission is purely data-driven – changes to the input adapter are immediately propagated to all outputs.
- **Registered Copyright**: The function block is copyrighted under the Eclipse Public License 2.0.

State Overview

The function block does not have an internal state machine or an ECC (Execution Control Chart). The behavior is purely combinatorial: As soon as the input adapter data changes, the output data is updated accordingly.

Application Scenarios

- **Data Distribution in Control Systems**: Splitting a sensor data stream (e.g., AS-i bus data) across multiple parallel processing blocks.
- **Signal Copying for Diagnostic Purposes**: Connecting a separate monitor or logging path without affecting the main data.
- **Control Signal Multiplication**: Distributing a single instruction set to multiple actuators or subsystems.

Comparison with Similar Function Blocks

- **AS_SPLIT_2**: An analog function block with only two outputs. AS_SPLIT_3 extends the number to three outputs.
- **AS_MERGE (Theoretical)**: Unlike a merge function block, which combines multiple inputs into one output, AS_SPLIT_3 performs the reverse function (1 ⟶ N).
- **Generic Split Function Blocks**: Similar concepts exist for data inputs (e.g., SPLIT_INT), but these work with elementary data, while AS_SPLIT_3 processes adapters (complex data types).

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AS_SPLIT_3 is a simple yet useful function block for duplicating adapter data in the 4diac IDE. Its generic design and the absence of event traffic make it particularly lightweight and usable in many scenarios. The documented license (EPL 2.0) ensures that the block can be legally integrated into your own projects.

AS_SPLIT_4

No image available.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_SPLIT_4** splits an incoming unidirectional AS adapter into four identical outputs. It acts as a generic splitter, forwarding the signal received via socket `IN` unchanged to the four plugs `OUT1` to `OUT4`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AS`	IN	Socket	Incoming AS signal path (input)
`adapter::types::unidirectional::AS`	OUT1	Plug	First output (identical to IN)
`adapter::types::unidirectional::AS`	OUT2	Plug	Second output (identical to IN)
`adapter::types::unidirectional::AS`	OUT3	Plug	Third output (identical to IN)
`adapter::types::unidirectional::AS`	OUT4	Plug	Fourth output (identical to IN)

Functionality

The function block (FB) operates purely passively: Every signal received via the `IN` adapter is forwarded to all four plugs (`OUT1`–`OUT4`) without delay or transformation. No data buffering, logical processing, or state changes occur. Distribution is deterministic and takes place at compile time or runtime according to the adapter contracts.

Technical Features

- **No Event/Data Interfaces:** All communication occurs exclusively via adapters.
- **Uniform Type:** All five adapters are of the same unidirectional type, `AS`.

- **Generic Parameterization:** The function block (FB) has the attributes `GenericClassName` (value: `'GEN_AS_SPLIT'`) and `TypeHash`, allowing it to be adapted to specific applications (e.g., through refactoring or model transformation).
- **Stateless:** No ECC, no internal variables – the behavior is completely defined by the adapter contracts.

State Overview

The FB has no state machines. Its behavior is timeless and constant: The input signal is always immediately duplicated to all outputs.

Application Scenarios

- **Signal Distribution in Controllers:** Distributing a speed or position command across multiple parallel axes.
- **Sensor Value Multiplexing:** Distributing a measured value to multiple evaluation or monitoring instances.
- **Modular Connection:** Used in hierarchical systems where an adapter signal is needed multiple times without instantiating the sender multiple times.

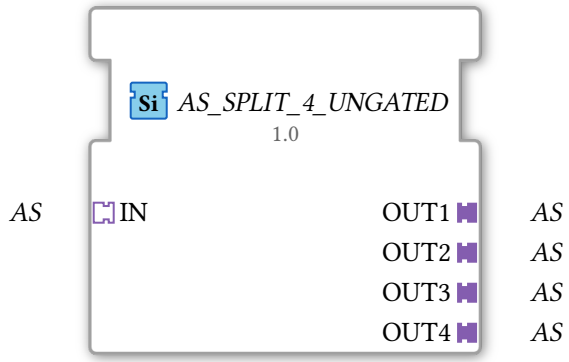
Comparison with Similar Components

- **AS_MERGE:** Combines multiple AS inputs into one output – the functional counterpart to Split.
- **AS_SPLIT_2:** Same functionality, but only two outputs. `AS_SPLIT_4` extends this to four.
- **Event-Based Splitters (e.g., E_SPLIT):** Work with event and data inputs/outputs and distribute events. `AS_SPLIT_4`, on the other hand, operates at the adapter level and forwards the entire adapter contract (including all events and data contained within it).

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



AS_SPLIT_4` is a simple yet essential building block for structurally replicating unidirectional AS adapter connections in 4diac applications. Its generic design and pure adapter interface make it ideal for modular and scalable control architectures.

AS_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The AS_SPLIT_5 function block is a generic function block that distributes one incoming adapter of type “AS” (unidirectional) to five separate output adapters of the same type. It is used for signal multiplication in control and automation systems, based on the IEC 61499-2 standard.

Interface Structure

Event Inputs

No event inputs defined.

Event Outputs

No event outputs defined.

Data Inputs

No data inputs defined.

Data Outputs

No data outputs defined.

Adapters

Role	Name	Type	Description
Socket	IN	adapter::types::unidirectional::AS	Input adapter that receives the AS signal to be distributed.
Plug	OUT1	adapter::types::unidirectional::AS	First output adapter for the distributed signal.
Plug	OUT2	adapter::types::unidirectional::AS	Second output adapter.
Plug	OUT3	adapter::types::unidirectional::AS	Third output adapter.
Plug	OUT4	adapter::types::unidirectional::AS	Fourth output adapter.
Plug	OUT5	adapter::types::unidirectional::AS	Fifth output adapter.

Functionality

The AS_SPLIT_5 block functions as a passive distributor. The AS signal present at socket "IN" is forwarded identically to all five output plugs (OUT1 to OUT5) without delay or modification. Distribution strictly follows the broadcast principle – each outgoing signal corresponds to the original signal. The implementation is purely adapter-based and requires no additional event or data port connections.

Technical Features

- The block is defined as a generic type (GenericClassName = 'GEN_AS_SPLIT') and can therefore be parameterized using the 4diac IDE.
- A type hash is used to ensure the block's uniqueness within the project.
- The number of outputs is fixed at five; dynamic configuration is not supported.
- The runtime environment must support the unidirectional adapter interface "adapter::types::unidirectional::AS".

State Overview

The block does not have an internal state machine. Signal distribution is continuous and without sequential logic. Therefore, a status overview is not required.

Application Scenarios

- **Control Wiring**: Splitting an AS signal from a higher-level controller to multiple substations or actuators.
- **Simulation and Testing**: Multiplying a test signal for parallel control of multiple simulated components.
- **Redundancy**: Providing the same signal on different paths to enable redundancy or load balancing.

Comparison with Similar Components

Since AS_SPLIT_5 is designed for a specific adapter architecture (unidirectional AS), similar components typically exist, such as "AS_SPLIT_2", "AS_SPLIT_3", or generalized splitters with a variable number of outputs. This component differs in its fixed number of five outputs and its pure adapter interface without data or event ports.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AS_SPLIT_5 is a simple yet effective function block for multiplying an AS adapter signal into five parallel outputs. Its generic implementation and clear interface make it well-suited for modular automation solutions according to IEC 61499.

AS_SPLIT_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of AS_SPLIT_5. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The AS_SPLIT_5_UNGATED function block is a generic function block that distributes one incoming adapter of type "AS" (unidirectional) to five separate output adapters of the same type. It is used for signal multiplication in control and automation systems, based on the IEC 61499-2 standard.

Interface Structure

Event Inputs

No event inputs defined.

Event Outputs

No event outputs defined.

Data Inputs

No data inputs defined.

Data Outputs

No data outputs defined.

Adapters

Role	Name	Type	Description
Socket	IN	adapter::types::unidirectional::AS	Input adapter that receives the AS signal to be distributed.
Plug	OUT1	adapter::types::unidirectional::AS	First output adapter for the distributed signal.
Plug	OUT2	adapter::types::unidirectional::AS	Second output adapter.
Plug	OUT3	adapter::types::unidirectional::AS	Third output adapter.
Plug	OUT4	adapter::types::unidirectional::AS	Fourth output adapter.

Plug	OUT5	adapter::types::unidirectional::AS	Fifth output adapter.

Functionality

The AS_SPLIT_5_UNGATED block functions as a passive distributor. The AS signal present at socket “IN” is forwarded identically to all five output plugs (OUT1 to OUT5) without delay or modification. Distribution strictly follows the broadcast principle – each outgoing signal corresponds to the original signal. The implementation is purely adapter-based and requires no additional event or data port connections.

Technical Features

- The block is defined as a generic type (GenericClassName = ‘GEN_AS_SPLIT’) and can therefore be parameterized using the 4diac IDE.
- A type hash is used to ensure the block’s uniqueness within the project.
- The number of outputs is fixed at five; dynamic configuration is not supported.
- The runtime environment must support the unidirectional adapter interface “adapter::types::unidirectional::AS”.

State Overview

The block does not have an internal state machine. Signal distribution is continuous and without sequential logic. Therefore, a status overview is not required.

Application Scenarios

- **Control Wiring**: Splitting an AS signal from a higher-level controller to multiple substations or actuators.
- **Simulation and Testing**: Multiplying a test signal for parallel control of multiple simulated components.
- **Redundancy**: Providing the same signal on different paths to enable redundancy or load balancing.

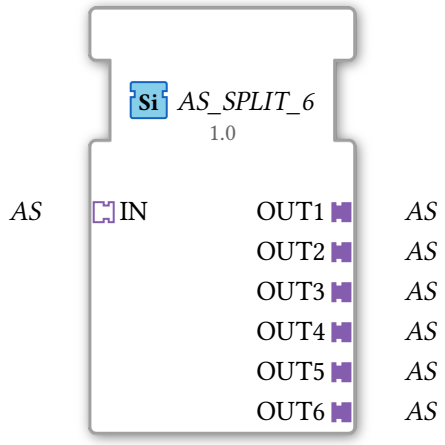
Comparison with Similar Components

Since AS_SPLIT_5_UNGATED is designed for a specific adapter architecture (unidirectional AS), similar components typically exist, such as “AS_SPLIT_2”, “AS_SPLIT_3”, or generalized splitters with a variable number of outputs. This component differs in its fixed number of five outputs and its pure adapter interface without data or event ports.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The AS_SPLIT_5_UNGATED is a simple yet effective function block for multiplying an AS adapter signal into five parallel outputs. Its generic implementation and clear interface make it well-suited for modular automation solutions according to IEC 61499.

AS_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_SPLIT_6** is used to split a single incoming AS adapter signal into six separate AS adapter outputs. It is implemented as a generic block and can be used with various unidirectional AS adapter types (e.g., sensor or actuator adapters).

Interface Structure

Event Inputs

– None –

Event Outputs

– None –

Data Inputs

– None –

Data Outputs

– None –

Adapter

Direction	Name	Type
SOCKET	IN	unidirectional::AS (generic)
PLUG	OUT1	unidirectional::AS (generic)
PLUG	OUT2	unidirectional::AS (generic)
PLUG	OUT3	unidirectional::AS (generic)
PLUG	OUT4	unidirectional::AS (generic)
PLUG	OUT5	unidirectional::AS (generic)
PLUG	OUT6	unidirectional::AS (generic)

Functionality

This component forwards all adapter signals present at the SOCKET **IN** unchanged to all six PLUGs (**OUT1** to **OUT6**). No data processing or conversion takes place – the distribution is purely structural. Therefore, all outputs behave identically to the inputs.

Technical Features

- **Generic Block:** The specific AS adapter type is only defined during instantiation (e.g., by specifying a GenericClassName such as `'GEN_AS_SPLIT'`). This allows the block to be used with various protocols or data structures.
- **No State Logic:** The block has no state machine, no algorithms, and no events – it operates purely passively and immediately.
- **Unidirectional:** The adapters are of type `unidirectional::AS`, meaning data flows only from the input to the outputs.

State Overview

The block does not have an End-Centre Conditioning (ECC) function, as no sequential processes or processing steps are defined. Signal distribution is static and continuous.

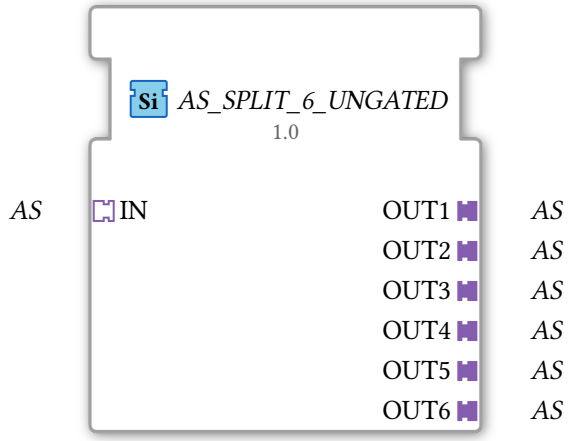
Application Scenarios

- **Signal Multiplication:** A single sensor adapter (e.g., temperature measurement) is provided to multiple processing units.
- **Data Bus Coupling:** A common signal is passed on to six parallel control modules or displays.
- **Prototyping and Testing:** Simplified generation of multiple identical interfaces from a single source.

Comparison with Similar Function Blocks

- **AS_SPLIT_2 / AS_SPLIT_4** – Identical functionality, but with only two or four outputs, respectively. This function block is suitable for applications with exactly six destinations.
- **AS_MERGE_...** – Combines multiple adapter inputs into one output – the opposite task.
- **Manual Wiring** – Could be implemented using multiple adapter couplings, but increases the configuration effort.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AS_SPLIT_6** is a simple yet effective generic function block for splitting a unidirectional AS signal into six separate outputs. Its generic nature allows for flexible use in various automation environments where fast and clear signal duplication is required.

AS_SPLIT_6_UNGATED

> **i UNGATED variant:** This block is the ungated version of AS_SPLIT_6. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Adapters

Name	Type	Direction	Description
IN	`adapter::types::unidirectional::AS`	Socket	Receives the AS signal to be distributed.
OUT1	`adapter::types::unidirectional::AS`	Plug	First output – same signal as the input.
OUT2	`adapter::types::unidirectional::AS`	Plug	Second output – same signal as the input.
OUT3	`adapter::types::unidirectional::AS`	Plug	Third output – same signal as the input.
OUT4	`adapter::types::unidirectional::AS`	Plug	Fourth output – same signal as the input.
OUT5	`adapter::types::unidirectional::AS`	Plug	Fifth output – same signal as the input.
OUT6	`adapter::types::unidirectional::AS`	Plug	Sixth output – same signal as the input.
OUT7	`adapter::types::unidirectional::AS`	Plug	Seventh output – same signal as the input.

Functionality
The function block forwards the AS signal present at socket `IN` unchanged to all seven plug outputs. No signal conditioning, amplification, or processing takes place. The function block operates purely passively and without any time delay – as soon as a signal is present at the input, it is available at all outputs simultaneously.

Technical Features
- **Generic Function Block:** The function block is implemented as a generic type (`GEN_AS_SPLIT`) and can be used in various contexts by configuring its parameters.
- **Adapter-Based Interface:** Communication occurs exclusively via unidirectional adapters of type `adapter::types::unidirectional::AS`. This makes the function block particularly suitable for modular architectures where signals are exchanged via clearly defined interfaces.
- **No State Logic:** The function block has no internal states, events, or processing logic – distribution is purely combinatorial.
- **Easy Extensibility:** Due to the generic nature of the function block, analog splitter variants (e.g., `AS_SPLIT_2`, `AS_SPLIT_4`) can be easily derived or created by adjusting the parameters.

State Overview
The **AS_SPLIT_7** has no state machines, as it operates purely passively. There are no start, stop, or error states. Its behavior is determined solely by the current value of the input signal at all times.

Application Scenarios

- **Signal Distribution in Control Systems:** An analog measurement signal (e.g., pressure, temperature) is distributed to multiple displays, controllers, or data loggers.
- **Parallel Connection of Actuators:** A control signal (e.g., 0-10V) is intended to control multiple actuators simultaneously.
- **Redundant Signal Paths:** The same signal is provided to multiple independent processing units to create redundancy.
- **Test and Simulation Environments:** A generated test signal is distributed across multiple simulation components.

Comparison with Similar Function Blocks

The **AS_SPLIT_7** belongs to a family of splitter function blocks that differ only in the number of outputs (e.g., `AS_SPLIT_2`, `AS_SPLIT_3`, ..., `AS_SPLIT_N`). Compared to manual wiring, the function block offers the advantages of reusability, clear interface definition, and easy parameterization. Unlike active signal distributors (e.g., with amplification), the function block has no effect on the signal and is therefore ideal for passive applications.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AS_SPLIT_7** is a simple yet useful function block for passively distributing a unidirectional AS signal to seven outputs. Thanks to its generic implementation and adapter interface, it integrates seamlessly into modern, component-based automation solutions. For applications requiring simple signal multiplication without processing, it offers a reliable and easy-to-understand solution.

AS_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_SPLIT_8** is used to split an incoming *Application Specific* (AS) adapter data stream into eight identical outputs. It is provided as a generic function block (generic FB) and is specifically designed for distributing adapter data within an IEC 61499-based control application.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapter

Type	Name	Direction	Description
adapter::types::unidirectional::AS`	IN	Socket (Input)	Receives the AS data stream to be distributed.
adapter::types::unidirectional::AS`	OUT1	Plug (Output)	First copy of the incoming AS data stream.
adapter::types::unidirectional::AS`	OUT2	Plug (Output)	Second copy of the incoming AS data stream.
adapter::types::unidirectional::AS`	OUT3	Plug (Output)	Third copy.
adapter::types::unidirectional::AS`	OUT4	Plug (Output)	Fourth copy.
adapter::types::unidirectional::AS`	OUT5	Plug (Output)	Fifth copy.
adapter::types::unidirectional::AS`	OUT6	Plug (Output)	Sixth Copy.
`adapter::types::unidirectional::AS`	OUT7	Plug (Output)	Seventh Copy.
`adapter::types::unidirectional::AS`	OUT8	Plug (Output)	Eighth Copy.

Functionality

The module operates purely on an adapter basis, without using events or data inputs/outputs. The adapter data stream present at socket `IN` is internally mirrored to all eight output plugs (`OUT1` … `OUT8`). Each output passes on exactly the same data that is present at the input. No delay, filtering, or modification takes place. Branching occurs passively and without active runtime logic (no state machine).

Technical Features

- **Pure Adapter Block**: The function block (FB) has neither event nor data interfaces in the traditional sense; all data transmission occurs via the adapter connections.
- **Generic Implementation**: By declaring it as a generic FB (`GenericClassName = 'GEN_AS_SPLIT'`), the block can be used for any AS adapter type, provided the underlying adapter type is `unidirectional::AS`.
- **No State Machine**: Due to the lack of events, an Execution Control Chart (ECC) is not required. Distribution is continuous.
- **Simple 1:8 Splitting**: Optimized for situations where a signal needs to be distributed to multiple subsequent modules.

State Overview

Not applicable – the block has no internal states or sequence control.

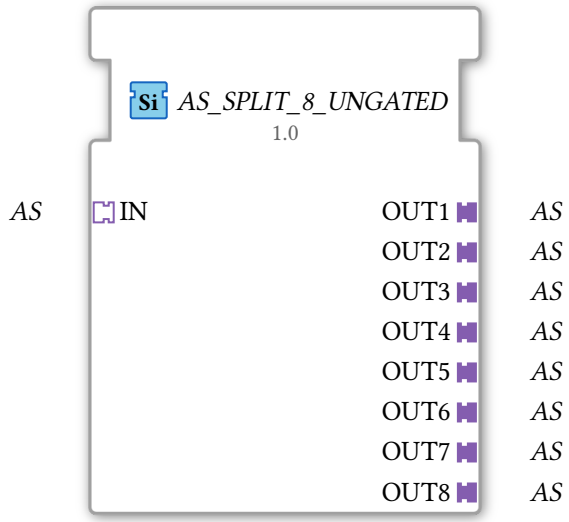
Application Scenarios

- **Parallel Distribution of Sensor Data**: A single adapter that… B. If a tank's fill level data is provided, it is distributed across eight monitoring or controlling functional units.
- **Signal Multicasting in Industry 4.0**: Distribution of a control command to multiple actuators or subsystems.
- **Test Environments** for simulating multiple receivers of a data stream.

Comparison with Similar Function Blocks

- **AS_SPLIT_2 / AS_SPLIT_4**: Analog function blocks with fewer outputs. AS_SPLIT_8 offers maximum distribution in one step with eight outputs.
- **Event-based splitters (e.g., E_SPLIT)**: These operate with events and distribute them according to a time-controlled process. In contrast, this function block continuously distributes all adapter data without event control.
- **Data-based splitters (e.g., ANY_DISTRIBUTE)**: Split data values but require additional events. AS_SPLIT_8 is optimized for simple adapter forwarding.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AS_SPLIT_8** is a simple yet useful adapter distributor that duplicates an incoming AS data stream to eight outputs without requiring any additional logic. Its generic nature and clear structure make it a robust solution for scenarios where an adapter signal needs to be used multiple times. The module's documentation does not claim to be exhaustive regarding implementation details; the exact functionality may vary depending on the runtime environment used.

AS_SPLIT_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AS_SPLIT_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/ frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

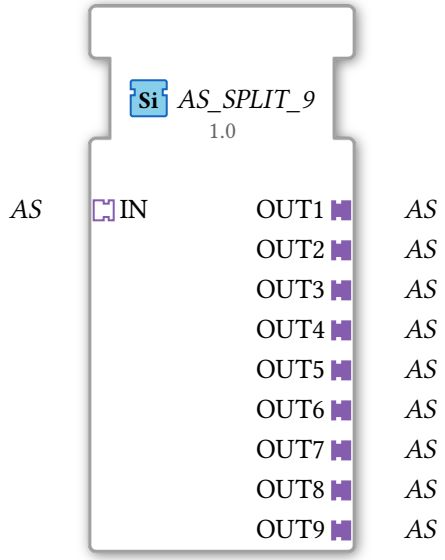
- **Signal Multicasting in Industry 4.0**: Distribution of a control command to multiple actuators or subsystems.
- **Test Environments** for simulating multiple receivers of a data stream.

Comparison with Similar Function Blocks

- **AS_SPLIT_2 / AS_SPLIT_4**: Analog function blocks with fewer outputs. AS_SPLIT_8_UNGATED offers maximum distribution in one step with eight outputs.
- **Event-based splitters (e.g., E_SPLIT)**: These operate with events and distribute them according to a time-controlled process. In contrast, this function block continuously distributes all adapter data without event control.
- **Data-based splitters (e.g., ANY_DISTRIBUTE)**: Split data values but require additional events. AS_SPLIT_8_UNGATED is optimized for simple adapter forwarding.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **AS_SPLIT_8_UNGATED** is a simple yet useful adapter distributor that duplicates an incoming AS data stream to eight outputs without requiring any additional logic. Its generic nature and clear structure make it a robust solution for scenarios where an adapter signal needs to be used multiple times. The module's documentation does not claim to be exhaustive regarding implementation details; the exact functionality may vary depending on the runtime environment used.

AS_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_SPLIT_9** is used to split an incoming **AS adapter** (unidirectional) into nine separate output adapters. It is implemented as a generic function block and distributes the AS signal present at socket `IN` identically to all nine plug outputs (`OUT1` ... `OUT9`). This makes it ideal for routing a single AS signal multiple times to different downstream components.

Interface Structure

Event Inputs
- None

Event Outputs
- None

Data Inputs
- None

Data Outputs
- None

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AS`	Input Adapter (AS Interface)
Plug	`OUT1`	`adapter::types::unidirectional::AS`	First Output Adapter
Plug	`OUT2`	`adapter::types::unidirectional::AS`	Second Output Adapter
Plug	`OUT3`	`adapter::types::unidirectional::AS`	Third Output Adapter
Plug	`OUT4`	`adapter::types::unidirectional::AS`	Fourth Output Adapter
Plug	`OUT5`	`adapter::types::unidirectional::AS`	Fifth Output Adapter
Plug	`OUT6`	`adapter::types::unidirectional::AS`	Sixth Output Adapter
Plug	`OUT7`	`adapter::types::unidirectional::AS`	Seventh Output Adapter
Plug	`OUT8`	`adapter::types::unidirectional::AS`	Eighth Output Adapter
Plug	`OUT9`	`adapter::types::unidirectional::AS`	Ninth Output Adapter

Functionality

The module receives an AS connection via socket `IN`. Internal logic forwards this incoming signal without modification to all nine plug outputs (`OUT1` … `OUT9`). This ensures that the same AS data and/or events are always available at all outputs. There is no separate state machine or internal processing – distribution occurs directly and without delay.

Technical Features

- **Generic Function Block** – The function block is classified as **GEN_AS_SPLIT** and can be parameterized as needed (e.g., for a variable number of outputs).
- **Unidirectional Adapters** – Both inputs and outputs use the type `adapter::types::unidirectional::AS`. This ensures that the data/event direction from IN to OUT is strictly maintained.
- No dedicated event or data inputs are required – the entire interface consists exclusively of adapters.

State Overview

The function block does not have an explicit state machine (ECC). Distribution occurs purely combinatorially as soon as the input adapter provides valid data or events.

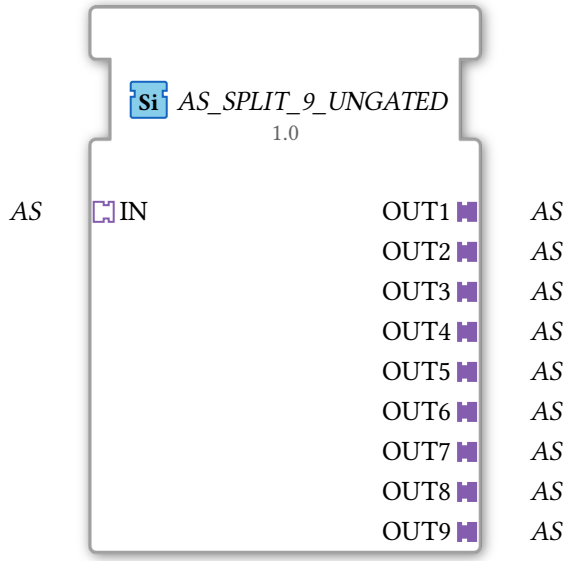
Application Scenarios

- **Signal Distribution** – An AS sensor or controller must supply several actuators or monitored components simultaneously.
- **Parallel Operation** – Multiple devices are to be connected to an AS network without requiring active replication.
- **Test and Simulation Environments** – An outgoing AS signal is split across multiple test modules or analysis tools.

Comparison with Similar Components

- **AS_SPLIT_2**, **AS_SPLIT_4**, etc. – These components offer a smaller number of outputs (2, 4, etc.) and are optimized for smaller distributions.
- **AS_MUX** – A multiplexer that combines multiple inputs into one output; the opposite of a splitter.
- **AS_COPY** – Copies a signal to a second output; equivalent to a 1:2 split.
- **AS_SPLIT_9**, with nine outputs, is the largest standard variant and covers extensive distribution requirements.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AS_SPLIT_9** is a straightforward, reliable function block for duplicating an AS signal. Its simple adapter interface and lack of internal logic make it particularly suitable for applications where an output signal needs to be distributed to multiple receivers. Its generic nature also allows for easy adaptation to specific project requirements.

AS_SPLIT_9_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AS_SPLIT_9`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AS_SPLIT_9_UNGATED** is used to split an incoming **AS adapter** (unidirectional) into nine separate output adapters. It is implemented as a generic function block and distributes the AS signal present at socket `IN` identically to all nine plug outputs (`OUT1` … `OUT9`). This makes it ideal for routing a single AS signal multiple times to different downstream components.

Interface Structure

Event Inputs

- None

Event Outputs

- None

Data Inputs

- None

Data Outputs

- None

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AS`	Input Adapter (AS Interface)
Plug	`OUT1`	`adapter::types::unidirectional::AS`	First Output Adapter
Plug	`OUT2`	`adapter::types::unidirectional::AS`	Second Output Adapter
Plug	`OUT3`	`adapter::types::unidirectional::AS`	Third Output Adapter
Plug	`OUT4`	`adapter::types::unidirectional::AS`	Fourth Output Adapter
Plug	`OUT5`	`adapter::types::unidirectional::AS`	Fifth Output Adapter
Plug	`OUT6`	`adapter::types::unidirectional::AS`	Sixth Output Adapter
Plug	`OUT7`	`adapter::types::unidirectional::AS`	Seventh Output Adapter
Plug	`OUT8`	`adapter::types::unidirectional::AS`	Eighth Output Adapter
Plug	`OUT9`	`adapter::types::unidirectional::AS`	Ninth Output Adapter

Functionality

The module receives an AS connection via socket `IN`. Internal logic forwards this incoming signal without modification to all nine plug outputs (`OUT1` … `OUT9`). This ensures that the same AS data and/or events are always available at all outputs. There is no separate state machine or internal processing – distribution occurs directly and without delay.

Technical Features

- **Generic Function Block** – The function block is classified as **GEN_AS_SPLIT** and can be parameterized as needed (e.g., for a variable number of outputs).
- **Unidirectional Adapters** – Both inputs and outputs use the type `adapter::types::unidirectional::AS`. This ensures that the data/event direction from IN to OUT is strictly maintained.
- No dedicated event or data inputs are required – the entire interface consists exclusively of adapters.

State Overview

The function block does not have an explicit state machine (ECC). Distribution occurs purely combinatorially as soon as the input adapter provides valid data or events.

Application Scenarios

- **Signal Distribution** – An AS sensor or controller must supply several actuators or monitored components simultaneously.
- **Parallel Operation** – Multiple devices are to be connected to an AS network without requiring active replication.
- **Test and Simulation Environments** – An outgoing AS signal is split across multiple test modules or analysis tools.

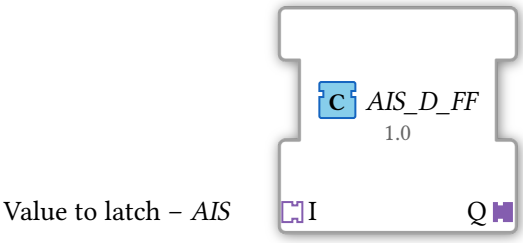
Comparison with Similar Components

- **AS_SPLIT_2**, **AS_SPLIT_4**, etc. – These components offer a smaller number of outputs (2, 4, etc.) and are optimized for smaller distributions.
- **AS_MUX** – A multiplexer that combines multiple inputs into one output; the opposite of a splitter.

- **AS_COPY** – Copies a signal to a second output; equivalent to a 1:2 split.
- **AS_SPLIT_9_UNGATED**, with nine outputs, is the largest standard variant and covers extensive distribution requirements.

Change Detection

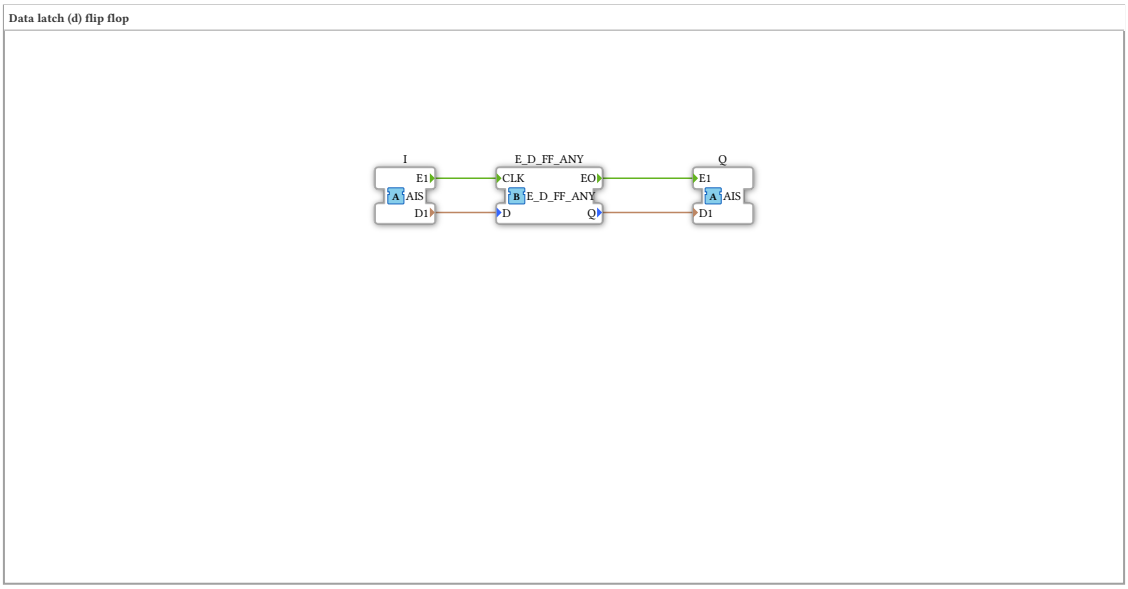
This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.



Conclusion

The **AS_SPLIT_9_UNGATED** is a straightforward, reliable function block for duplicating an AS signal. Its simple adapter interface and lack of internal logic make it particularly suitable for applications where an output signal needs to be distributed to multiple receivers. Its generic nature also allows for easy adaptation to specific project requirements.

Numeric Index (unidirectional)



Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AIS_D_FF

Value to latch – *AIS*

AIS – Latched value

• – ○ • – ○ • – ○ •

Introduction

The `AIS_D_FF` function block implements a clock-edge-triggered D flip-flop (data latch). It is used to store and output a data value upon receiving a clock event. Communication is exclusively via AIS adapters (unidirectional), allowing the function block to be integrated into adapter-based component architectures.

Interface Structure

Event Inputs

No direct event inputs. The clock signal is provided via the socket adapter **I** (event port `E1`).

Event Outputs

No direct event outputs. The output event is sent via the plug adapter **Q** (event port `E1`).

Data Inputs

No direct data inputs. The data value to be received is received via the socket adapter **I** (data port `D1`).

Data Outputs

No direct data outputs. The stored value is output via the plug adapter **Q** (data port `D1`).

Adapters

Adapter	Type	Direction	Description
I	`adapter::types::unidirectional::AIS`	Socket	Input adapter: Clock signal (event `E1`) and data input (data `D1`)
Q	`adapter::types::unidirectional::AIS`	Plug	Output adapter: Acknowledge event (event `E1`) and stored data value (data `D1`)

Functionality

This component encapsulates the IEC 61499 standard component `E_D_FF_ANY`. On a rising edge of the clock signal (event `I.E1`), the current value of `I.D1` is taken and stored internally in the flip-flop. An event is then triggered at output `Q.E1`, and the stored value is made available at port `Q.D1`. The output value remains until the next clock event arrives.

Technical Features

- **Pure Adapter Interface**: The module has no direct event or data ports but uses only AIS adapters. This allows for flexible integration with other adapter-based components.
- **Generic Data Type**: The internal `E_D_FF_ANY` module supports any data type. The data width and type are determined by the adapter implementation used.
- **Event-Driven Data Pass-Through**: The output is only updated upon an incoming clock event. Without a clock event, the output remains unchanged.

State Overview

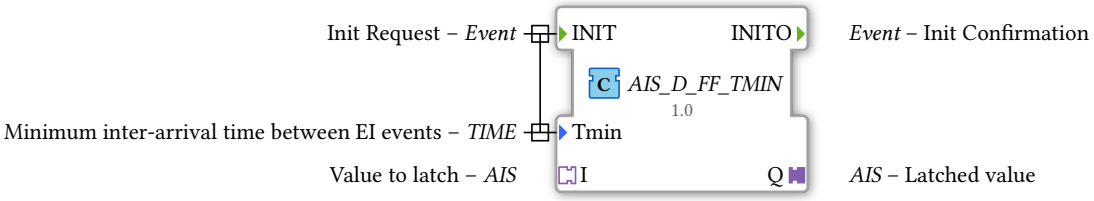
Since the component implements the behavior of a D flip-flop, two states can be distinguished:

State	Description
Idle State	The stored value remains constant. No output event is generated.
Takeover	Upon the arrival of a clock event, the current input value is taken, the output is updated, and an output event is sent.

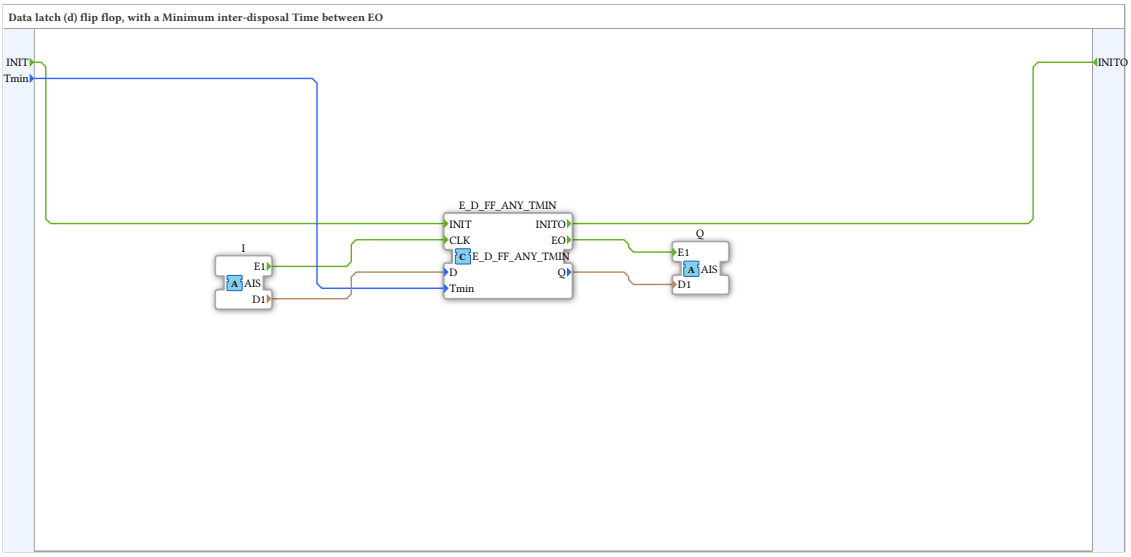
The flip-flop is edge-triggered (rising edge) and not level-triggered.

Application Scenarios

- **Data Buffer in Adapter Networks**: Temporarily storing values that are only valid for specific events (e.g., clock signals from sensors).
- **Synchronization**: Synchronizing data between components that communicate via asynchronous events.
- **Registers in Control Applications**: Construction of shift registers or simple memory cells in IEC 61499 systems using AIS adapters.



Comparison with Similar Devices



- **`E_D_FF_ANY`** – The direct function block equivalent with standard event and data ports. `AIS_D_FF` encapsulates this device in an adapter-based interface.
- **SR Flip-Flop** – Stores a binary state via set and reset inputs, while `AIS_D_FF` stores an arbitrary data value via a clock signal.
- **Latch (Level-Controlled)** – A latch holds the input value as long as the clock signal is active; In contrast, `AIS_D_FF` only reacts to an edge and is therefore less susceptible to noise and glitches.

Conclusion

AIS_D_FFis a useful component for implementing an edge-triggered D flip-flop in adapter-based architectures. By encapsulating the provenE_D_FF_ANY` functional block, it offers reliable memory functionality and can be seamlessly integrated into existing AIS communication structures.

AIS_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AIS_D_FF_TMIN** implements a data-dependent flip-flop (D flip-flop) with a minimum inter-disposal time (MIT) between two consecutive output events (EOs). It latches an incoming data value via an AIS adapter and outputs it only when the minimum time specified by the parameter `Tmin` has elapsed since the last EO. This suppresses excessively rapid signal changes and ensures a defined signal delay.

Interface Structure

Event Inputs

Event	Type	Comment
`INIT`	EInit	Initialization Request (with `Tmin`)

Event Outputs

Event	Type	Comment
`INITO`	EInit	Initialization Acknowledgement

Data Inputs

Variable	Type	Comment
`Tmin`	TIME	Minimum time interval between two EO events

Data Outputs

The FB has no data outputs of its own. Output is exclusively via the adapter plug (see below).

Adapter

Direction	Label	Adapter Type	Comment
Plug (Output)	`Q`	`adapter::types::unidirectional::AIS`	Latched output value
Socket (Input)	`I`	`adapter::types::unidirectional::AIS`	Input value to be latched

The adapter `AIS` is unidirectional and delivers the actual signals via the event/data interfaces `E1` and `D1`.

Functionality

Internally, the function block consists of a nested function block `E_D_FF_ANY_TMIN` (from the IEC 61499 library).

Processing proceeds as follows:

1. **Initialization**: Upon the event `INIT`, the parameter `Tmin` is forwarded to the internal function block, which is then initialized. Subsequently, `INITO` is triggered.
2. **Latch Operation**: An event `E1` arriving at **socket `I`** (connected to the internal `CLK`) transfers the simultaneously received data value `D1` (connected to `D`) into the flip-flop.
3. **Minimum Delay**: The internal function block checks whether at least the time `Tmin` has elapsed since the last output event (`EO`).

- If the condition is met, the latched data is output via the **plug `Q`** (event `E1` and data value `D1`).
- Otherwise, the value is held back until the required waiting time has elapsed.

This ensures that output events do not occur faster than specified by `Tmin`.

Technical Features

- **Adaptor-based I/O**: The signals are not routed as separate input/output variables, but rather via standardized unidirectional AIS adapters. This allows for flexible interconnection with other components or subsystems.
- **Maintaining a minimum delay**: The delay prevents "noise" or excessively rapid signal changes, which can lead to malfunctions in time-critical systems.
- **Internal IEC 61499 Standard Function Block (FB)**: The implementation uses the library's own `E_D_FF_ANY_TMIN`, ensuring high reliability and reusability.

State Overview

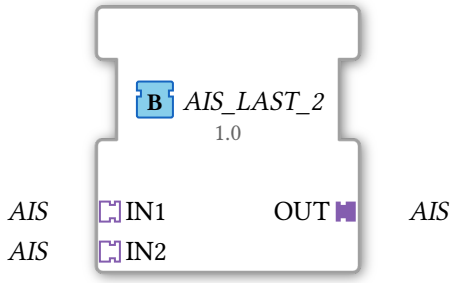
The FB itself does not have any explicitly modeled states in the XML definition. Its behavior is entirely determined by the internal FB `E_D_FF_ANY_TMIN`. This typically goes through the following phases (simplified):

- **Idle**: Waiting for a clock event at input `I.E1`.
- **Sampling**: Upon a clock event, the current data value `I.D1` is taken.
- **Delay**: After the takeover, the time elapsed since the last `EO` is compared to `Tmin`. If the time falls below the minimum, the system enters a wait state.
- **Output**: After the minimum time has elapsed, the latched data is output via `Q.E1` and `Q.D1`.

Application Scenarios

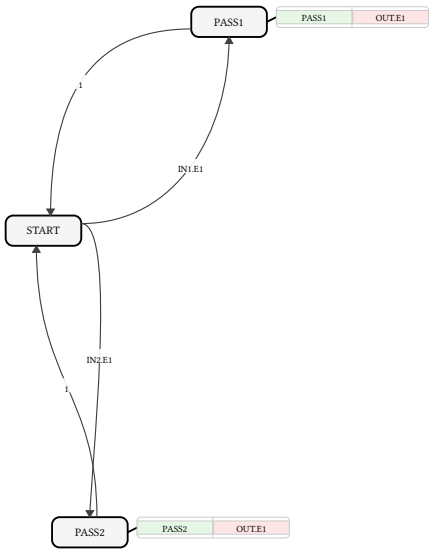
- **Signal Smoothing**: Suppression of bounces or short pulses at digital inputs.
- **Cycle Control**: Ensuring that an output signal is updated only at a defined minimum interval (e.g., every 100 ms).
- **Interface Buffering**: Buffering values between system components with different speeds, while maintaining a minimum update rate.
- **Automation Technology**: Control of actuators that require mechanical dead times or minimum switching intervals.

Comparison with Similar Function Blocks



- **Simple D Flip-Flop (without timing)**: A standard D flip-flop outputs the latched value immediately with the next clock event – without a delay limit. `AIS_D_FF_TMIN` adds the additional timing condition.

- **Monostable Flip-Flop**: A monostable function block generates a pulse of fixed duration; the function block described here, however, does not maintain a pulse duration but rather a minimum interval between outputs.
- **IEC-61499 `E_D_FF_ANY`**: This is the basic version without a time limit. `E_D_FF_ANY_TMIN` extends this variant with the `Tmin` parameter.



Conclusion

The `AIS_D_FF_TMIN` offers a robust way to latch digital signals with an adjustable minimum output delay. Thanks to the use of AIS adapters and internal IEC 61499 standard components, it is both flexible and reliable. It is particularly suitable for automation tasks where rapid signal changes need to be suppressed or defined minimum pauses between output events must be maintained.

AIS_LAST_2

ECC: AIS_LAST_2

Introduction

The AIS_LAST_2 function block merges two same-type STRING adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: STRING adapter (unidirectional) - first signal source
- **IN2**: STRING adapter (unidirectional) - second signal source

Output adapter (Plug):

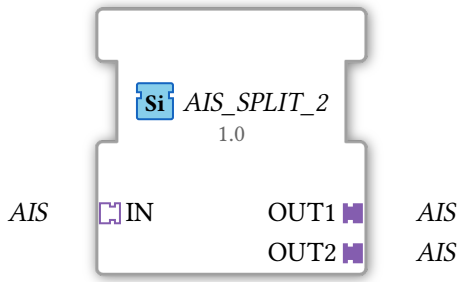
- **OUT**: STRING adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid STRING signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same STRING value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AIS_LAST_2 is the inverse of `AIS_SPLIT_2`: AIS_SPLIT_2 distributes 1 input to 2 outputs, AIS_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

AIS_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_SPLIT_2** is a generic adapter module that splits an incoming unidirectional AIS adapter (Application Interface Socket) into two identical outgoing AIS adapters. It serves as a passive splitter without its own logic or event processing.

Interface Structure

Event Inputs

Not present.

Event Outputs

Not present.

Data Inputs

Not present.

Data Outputs

Not present.

Adapter

- **IN** (Socket): Type `adapter::types::unidirectional::AIS` – Input interface for the adapter to be distributed.
- **OUT1** (Plug): Type `adapter::types::unidirectional::AIS` – first output, receives all data/events from IN.
- **OUT2** (Plug): Type `adapter::types::unidirectional::AIS` – second output, receives identical data/events as OUT1.

Functionality

The function block forwards the adapter connected to socket **IN** unchanged and without delay to both plugs **OUT1** and **OUT2**. All events and data defined via the AIS adapter are copied to both outputs in parallel. The function block itself has no processing logic, states, or timing behavior.

Technical Features

- **Generic Parameterization**: The specific AIS adapter type is only defined during project configuration via the attribute `eclipse4diac::core::GenericClassName` (default value: `'GEN_AIS_SPLIT'`). This allows the function block to be reused for different AIS variants.
- **No Eigenstates**: Since there is no ECC state machine or data/event inputs/outputs, the function block is purely passive and behaves like a "wiring aid."
- **Unidirectional**: The adapters are declared as unidirectional – a data flow direction from IN to OUT1/OUT2 is implicit.

State Overview

The AIS_SPLIT_2 does not have its own state machine. The operating state is determined exclusively by the connected AIS adapters.

Application Scenarios

- **Parallel Processing**: An AIS signal is to be processed simultaneously by two subsequent function blocks (e.g., visualization and control).
- **Monitoring**: Branching off an AIS signal to a monitoring instance without affecting the original signal.
- **Generic Splitting**: Used in libraries where the exact AIS structure is only defined at runtime or configuration time.

Comparison with Similar Function Blocks

- **AIS_SPLIT_4**: Offers four outputs instead of two; otherwise, identical functionality.
- **Event/Data Splitter**: Other splitters work with simple events or data (e.g., F_SPLIT), while AIS_SPLIT_2 splits complete adapter interfaces.
- **AIS_MERGE**: The counterpart that combines two AIS inputs into one output.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The AIS_SPLIT_2 is a minimalist, generically applicable adapter splitter that enables the flexible branching of AIS interfaces in 4diac projects. By configuring it via the GenericClassName attribute, it can be used for different AIS types without modifying the source code.

AIS_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_SPLIT_3** is used to distribute an incoming AIS data stream to three identical outputs. It is implemented as a generic function block and enables the simple duplication of AIS information in control systems according to IEC 61499.

Interface Structure

Event Inputs

Not present – the function block operates purely data- and adapter-driven.

Event Outputs

Not present.

Data Inputs

Not present – input data is provided exclusively via the adapter socket.

Data Outputs

Not present – output data is provided exclusively via the adapter plugs.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::AIS`	IN	Socket (Input)	Receives an AIS data stream.
`adapter::types::unidirectional::AIS`	OUT1	Plug (Output)	First output channel – identical copy of the input.
`adapter::types::unidirectional::AIS`	OUT2	Plug (Output)	Second output channel – identical copy of the input.
`adapter::types::unidirectional::AIS`	OUT3	Plug (Output)	Third output channel – identical copy of the input.

Functionality

The module receives an AIS data stream via the **IN** socket and forwards it without delay or manipulation to the three output adapters **OUT1**, **OUT2**, and **OUT3**. Each output receives identical data. No buffering, filtering, or protocol conversion takes place – the module functions purely as a splitter at the adapter level.

Technical Features

- **Generic Type**: The module is assigned the generic class name `GEN_AIS_SPLIT`, allowing it to be reused in various contexts and with different AIS data types.
- **Unidirectional Adapters**: Both inputs and outputs use the unidirectional adapter `adapter::types::unidirectional::AIS`, ensuring a clear data flow direction.
- **No Event-Driven Synchronization**: Since there are no event inputs/outputs, data transmission occurs immediately and without triggering by external events.

State Overview

This function block does not have an explicit state machine. Its behavior is that of a continuously active pass-through connection: As long as the input adapter is supplying data, it is output on all three outputs. There are no internal states or modes.

Application Scenarios

- **Distributing AIS data to multiple consumers** – e.g., simultaneous visualization, logging, and further processing.
- **Redundant data provision** – feeding data into different subsystems without placing an additional load on the data source.
- **Test and diagnostic setups** – parallel monitoring of an AIS stream at multiple points.

Comparison with similar function blocks

Function block	Number of outputs	Special feature
AIS_SPLIT_2	2	Distributed across two channels.
AIS_SPLIT_3	**3**	**Standard splitter with three outputs.**
AIS_SPLIT_N	variable	Generic version with configurable number of outputs (where available).

The AIS_SPLIT_3 fills the gap between a simple 2-way splitter and a fully configurable splitter.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AIS_SPLIT_3** is a simple yet effective component for multiplying an AIS data stream. Thanks to its generic nature and clear, adapter-based interface, it can be easily integrated into larger 4diac projects. It offers a robust and maintainable solution for applications requiring multiple distributions without data modification.

AIS_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_SPLIT_4** is used to distribute an incoming AIS adapter signal (type `adapter::types::unidirectional::AIS`) to four separate outputs. It implements a 1-to-4 split without modifying the data. The block is implemented generically and can be adapted to different signal types via the generic class name.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

- **Socket (Input):** `IN` – Type `adapter::types::unidirectional::AIS`
- **Plugs (Outputs):**
- `OUT1` – Type `adapter::types::unidirectional::AIS`
- `OUT2` – Type `adapter::types::unidirectional::AIS`
- `OUT3` – Type `adapter::types::unidirectional::AIS`
- `OUT4` – Type `adapter::types::unidirectional::AIS`

Functionality

The module forwards the adapter signal present at socket `IN` unchanged to all four output adapters. (`OUT1` … `OUT4`). No data manipulation, filtering, or buffering takes place. Each output corresponds exactly to the input signal. Distribution is asynchronous and without event control – the adapter interface handles data transmission according to its communication logic.

Technical Features

- **Generic Type:** The function block is implemented as a generic function block. The actual signal type can be defined at creation time via the attribute `eclipse4diac::core::GenericClassName` (value `'GEN_AIS_SPLIT'`).
- **Type Hash:** An empty string (`''`) for the attribute `eclipse4diac::core::TypeHash` indicates that the function block is dynamically configured as needed.
- **Compactness:** Since there are neither event nor data inputs/outputs, the module is purely adapter-based and free of timing dependencies.

State Overview

The module does not have a state machine – it operates continuously and without a state. There are no internal states or events that need to be switched. Its functionality is limited to passively passing through the adapter signal.

Application Scenarios

- **Signal Distribution in Control Architectures:** An AIS signal provided by a source (e.g., a sensor) is to be made available to several downstream processing units or displays.
- **Redundant Data Transmission:** In safety-critical systems, the input signal can be routed to multiple independent paths without duplicating it.
- **Test and Debugging Environments:** A signal is routed in parallel to the actual logic and to an analysis/logging tool.

Comparison with Similar Function Blocks

- **AIS_SPLIT_2 / AIS_SPLIT_8:** These function blocks represent variants with two and eight outputs, respectively. Their functionality is identical; only the number of output adapters differs.
- **Data-Based Splitters (e.g., SPLIT_INT):** Unlike adapter-based splitters, data-based splitters work with specific data types (e.g., integers) and usually require events for triggering. The AIS_SPLIT_4 is a pure adapter splitter and does not require explicit triggering.
- **Adapter Multiplexers (e.g., AIS_MUX):** A multiplexer selects one input from several, while the splitter distributes one input to multiple outputs.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AIS_SPLIT_4** is a simple yet practical function block for reliably distributing an AIS signal to four identical outputs. Its generic design and pure adapter logic make it flexible and eliminate the need for additional event control. It is ideally suited for applications where a signal is needed multiple times without data processing or synchronization.

AIS_SPLIT_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_SPLIT_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_SPLIT_4_UNGATED** is used to distribute an incoming AIS adapter signal (type `adapter::types::unidirectional::AIS`) to four separate outputs. It implements a 1-to-4 split without modifying the data. The block is implemented generically and can be adapted to different signal types via the generic class name.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

- **Socket (Input):** `IN` – Type `adapter::types::unidirectional::AIS`
- **Plugs (Outputs):**
- `OUT1` – Type `adapter::types::unidirectional::AIS`
- `OUT2` – Type `adapter::types::unidirectional::AIS`
- `OUT3` – Type `adapter::types::unidirectional::AIS`
- `OUT4` – Type `adapter::types::unidirectional::AIS`

Functionality

The module forwards the adapter signal present at socket `IN` unchanged to all four output adapters. (`OUT1` … `OUT4`). No data manipulation, filtering, or buffering takes place. Each output corresponds exactly to the input signal. Distribution is asynchronous and without event control – the adapter interface handles data transmission according to its communication logic.

Technical Features

- **Generic Type:** The function block is implemented as a generic function block. The actual signal type can be defined at creation time via the attribute `eclipse4diac::core::GenericClassName` (value `'GEN_AIS_SPLIT'`).
- **Type Hash:** An empty string (`''`) for the attribute `eclipse4diac::core::TypeHash` indicates that the function block is dynamically configured as needed.
- **Compactness:** Since there are neither event nor data inputs/outputs, the module is purely adapter-based and free of timing dependencies.

State Overview

The module does not have a state machine – it operates continuously and without a state. There are no internal states or events that need to be switched. Its functionality is limited to passively passing through the adapter signal.

Application Scenarios

- **Signal Distribution in Control Architectures:** An AIS signal provided by a source (e.g., a sensor) is to be made available to several downstream processing units or displays.
- **Redundant Data Transmission:** In safety-critical systems, the input signal can be routed to multiple independent paths without duplicating it.
- **Test and Debugging Environments:** A signal is routed in parallel to the actual logic and to an analysis/logging tool.

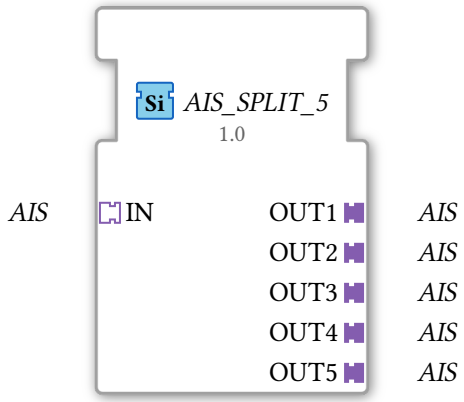
Comparison with Similar Function Blocks

- **AIS_SPLIT_2 / AIS_SPLIT_8:** These function blocks represent variants with two and eight outputs, respectively. Their functionality is identical; only the number of output adapters differs.
- **Data-Based Splitters (e.g., SPLIT_INT):** Unlike adapter-based splitters, data-based splitters work with specific data types (e.g., integers) and usually require events for triggering. The AIS_SPLIT_4_UNGATED is a pure adapter splitter and does not require explicit triggering.
- **Adapter Multiplexers (e.g., AIS_MUX):** A multiplexer selects one input from several, while the splitter distributes one input to multiple outputs.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion



The **AIS_SPLIT_4_UNGATED** is a simple yet practical function block for reliably distributing an AIS signal to four identical outputs. Its generic design and pure adapter logic make it flexible and eliminate the need for additional event control. It is ideally suited for applications where a signal is needed multiple times without data processing or synchronization.

AIS_SPLIT_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_SPLIT_5** serves as a generic splitter for adapters of type `AIS` (unidirectional). It receives an incoming AIS signal via a socket and forwards it to five separate AIS plugs. This allows a single adapter signal to be distributed to multiple target blocks.

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs
None.

Data Outputs
None.

Adapter

Direction	Name	Type	Description
Socket (Input)	IN	adapter::types::unidirectional::AIS	Incoming AIS adapter signal
Plug (Output 1)	OUT1	adapter::types::unidirectional::AIS	First outgoing AIS adapter port
Plug (Output 2)	OUT2	adapter::types::unidirectional::AIS	Second outgoing AIS adapter port
Plug (Output 3)	OUT3	adapter::types::unidirectional::AIS	Third outgoing AIS adapter port
Plug (Output 4)	OUT4	adapter::types::unidirectional::AIS	Fourth Outgoing AIS Adapter Port
Plug (Output 5)	OUT5	adapter::types::unidirectional::AIS	Fifth Outgoing AIS Adapter Port

Functionality
This function block operates as a pure broadcast without its own logic or states. As soon as an event or data change arrives via socket `IN`, this signal is passed unchanged to all five plugs (`OUT1`–`OUT5`). Each plug can be connected to a different receiver function block, allowing the original signal to be processed simultaneously by multiple components.

Technical Features
- **Generic Function Block**: The function block is marked as a generic function block (`eclipse4diac::core::GenericClassName = 'GEN_AIS_SPLIT'`). This allows it to be instantiated in various contexts with appropriate AIS adapter types.
- **No Event or Data Inputs/Outputs**: All communication takes place exclusively via the adapter interfaces. This makes it particularly simple and efficient.
- **Unidirectional**: The adapter type `AIS` is unidirectional, meaning the signal direction is fixed (from the socket to the plugs). Feedback is not provided.

State Overview
The module has no internal state logic (no ECC). There is no internal state machine or delay. Its operation is based on a rigid, combinational routing.

Application Scenarios
- **Signal Distribution in Control Systems**: An AIS signal supplied by a source (e.g., sensor or communication module) is to be passed on to several independent processing blocks.
- **Test and Simulation Environments**: A test signal can be sent simultaneously to various monitoring or analysis modules.
- **Redundant Processing**: The same signal is evaluated multiple times to detect errors or compare different algorithms.

Comparison with Similar Components
Other splitter components, such as `AIS_SPLIT_2`, `AIS_SPLIT_3`, and `AIS_SPLIT_4`, offer fewer outputs. All of them distribute a single AIS input signal to multiple outputs. The `AIS_SPLIT_5` offers the maximum

of five outputs in this family. The appropriate splitter can be selected based on requirements to avoid unnecessary cabling.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AIS_SPLIT_5` is a simple yet effective generic function block for multiplying a unidirectional AIS adapter signal. It reduces cabling effort in the 4diac IDE and enables clean, modular structuring of control applications. It represents an optimal solution for applications requiring the distribution of a signal to up to five receivers.

AIS_SPLIT_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_SPLIT_6** is used to distribute an incoming AIS (Automation Interface Signal) signal to six separate AIS outputs. It acts as a generic splitter, forwarding the incoming signal to all connected outputs without delay or manipulation.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available (data transmission occurs exclusively via the adapter).

Data Outputs

No data outputs available (data transmission occurs exclusively via the adapter).

Adapter

Type	Direction	Name	Description
adapter::types::unidirectional::AIS	Input (Socket)	IN	Incoming AIS signal, which is distributed to all outputs.
adapter::types::unidirectional::AIS	Output (Plug)	OUT1	First output with the split AIS signal.
adapter::types::unidirectional::AIS	Output (Plug)	OUT2	Second output with the split AIS signal.
adapter::types::unidirectional::AIS	Output (Plug)	OUT3	Third output with the split AIS signal.
adapter::types::unidirectional::AIS	Output (Plug)	OUT4	Fourth output with the split AIS signal.
adapter::types::unidirectional::AIS	Output (Plug)	OUT5	Fifth output with the split AIS signal.

adapter::types::unidirectional::AIS	Output (Plug)	OUT6	Sixth output with the split AIS signal.

Functionality

The module receives an AIS signal via socket `IN` and forwards it simultaneously and identically to all six plugs `OUT1` to `OUT6`. No data processing, filtering, or intermediate storage takes place – the distribution is purely signal-based. The function block operates unidirectionally (only from the input to the outputs) and thus represents a simple 1:6 multiplication of the AIS signal.

Technical Features

- **Generic Type**: The function block is implemented as a generic function block (`GEN_AIS_SPLIT`), meaning it can be used with various AIS types as long as the adapter definition (`adapter::types::unidirectional::AIS`) matches.
- **Unidirectional**: Data exchange occurs only in one direction – from the input to the outputs. Feedback from the outputs to the input is not supported.
- **No Internal Logic**: Since there are neither events nor data inputs/outputs, the function block operates purely passively and requires no state machine or algorithms.
- **Easy Scalability**: Due to the fixed number of six outputs, the function block is optimized for typical applications requiring exactly six parallel AIS connections.

State Overview

This function block does not have its own state machine (ECC). Its behavior is deterministic and timeless: An incoming AIS signal is immediately passed on to all outputs. There are no internal states or steps.

Application Scenarios

- **Distributing Control Signals**: An AIS signal from a central controller (e.g., a higher-level function block) must be forwarded to several subordinate components.
- **Monitoring and Parallel Operation**: A signal should be used simultaneously for control, monitoring, and logging.
- **Test Setups**: A uniform test signal is distributed to several simulated or real modules.
- **Redundant Wiring**: Signal distribution via multiple paths to increase fault tolerance.

Comparison with Similar Function Blocks

Other split function blocks may exist in the 4diac framework that differ in the number of outputs or data type. `AIS_SPLIT_6` is specifically designed for the AIS adapter interface and six outputs. Other splitters might have additional events or configuration parameters (e.g., selective routing), while this module is intentionally simple and requires no configuration.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The `AIS_SPLIT_6` is a useful and minimalist module for signal splitters in AIS-based control systems. It reliably distributes an incoming signal to six outputs and is characterized by its simplicity, generic design, and clear interface separation. This makes it particularly suitable for modular, transparent control architectures.

AIS_SPLIT_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_SPLIT_7** is used to distribute an incoming AIS data stream to seven identical outputs. It is implemented as a generic block and allows the division of a unidirectional AIS adapter (Socket IN) into seven identical adapter plugs (OUT1 ... OUT7). The term "AIS" here refers to an application-specific, abstract data type in the adapter context of IEC 61499.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

Direction	Name	Type	Description
Socket (Input)	IN	`adapter::types::unidirectional::AIS`	Incoming AIS data stream, distributed to all outputs.
Plug (Output)	OUT1 ... OUT7	`adapter::types::unidirectional::AIS`	Seven identical outputs, each forwarding the incoming AIS data stream unchanged.

Functionality

This module functions as a splitter for AIS adapter connections. Every incoming data or event at socket `IN` is replicated **without delay or processing** to all seven adapter plugs OUT1 to `OUT7`. The data is forwarded in parallel, meaning all outputs receive the same information simultaneously. No internal logic or state machine is required, as this is a passive, connection-oriented data transfer.

Technical Features

- **Generic Function Block** – The function block is declared as a generic instance (`GEN_AIS_SPLIT`) and can be parameterized for any AIS type.

- **Unidirectional Adapters** – Both inputs and outputs use only unidirectional adapters, ensuring a pure flow from input to output.
- **No Event or Data Inputs/Outputs** – All communication occurs exclusively via adapters, enabling clean encapsulation and reuse.
- **Scalability** – The principle can easily be adapted to different numbers of outputs (e.g., AIS_SPLIT_2, AIS_SPLIT_8).

State Overview

This function block does not have an explicit state machine (ECC) because it does not execute any sequential logic or delayed operations. Its function is reduced to static, continuous forwarding. Therefore, an operating state is not defined.

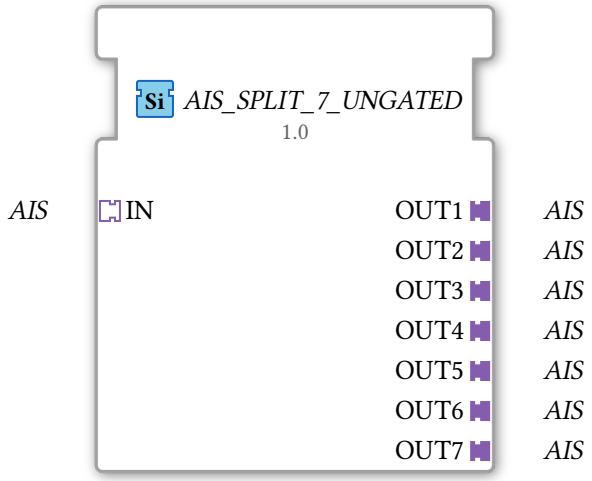
Application Scenarios

- **Distribution of AIS signals** to multiple parallel processing units, e.g., in automation systems, when a sensor value needs to be simultaneously passed to several control loops, displays, or analysis tools.
- **Redundant Signal Forwarding** – Used to feed an AIS data stream into multiple independent paths for testing or monitoring purposes.
- **Modular System Architecture** – As a component in a library of generic adapter function blocks to increase the reuse and interchangeability of connections.

Comparison with Similar Function Blocks

- **Data Splitters (e.g., SPLIT_1_to_N)** – These typically split simple data types (BOOL, INT, REAL). The AIS_SPLIT_7 is specifically designed for adapter interfaces and utilizes the adapter concept defined in IEC 61499 for complex, structured data streams.
- **Adapter Multiplexers (e.g., AIS_MERGE)** – While a splitter distributes one input to multiple outputs, a merger combines multiple inputs into one output. The AIS_SPLIT_7 is the counterpart to this.
- **Event Splitters** – These differ in their event processing capabilities; the AIS_SPLIT_7, however, operates purely on an adapter basis without separate event channels.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AIS_SPLIT_7** is a simple yet effective functional block for distributing a unidirectional AIS data stream to seven parallel outputs. Its generic design and exclusive use of adapters make it a flexible tool in automation application development according to IEC 61499. The absence of state logic and event control makes it lightweight and ideally suited for pure distribution tasks.

AIS_SPLIT_7_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_SPLIT_7`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Its generic design and exclusive use of adapters make it a flexible tool in automation application development according to IEC 61499. The absence of state logic and event control makes it lightweight and ideally suited for pure distribution tasks.

AIS_SPLIT_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AIS_SPLIT_8** distributes an incoming AIS (Application Interface Socket) signal to eight identical output adapters. It is designed as a generic block and allows the simultaneous transmission of an AIS signal to multiple subsequent function blocks without data loss or delay.

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Data Outputs

None available.

Adapters

Direction	Name	Type	Description
Input	IN	`adapter::types::unidirectional::AIS`	Incoming AIS signal to be distributed.
Output	OUT1	`adapter::types::unidirectional::AIS`	First output channel (identical to IN).
Output	OUT2	`adapter::types::unidirectional::AIS`	Second output channel (identical to IN).
Output	OUT3	`adapter::types::unidirectional::AIS`	Third output channel (identical to IN).
Output	OUT4	`adapter::types::unidirectional::AIS`	Fourth output channel (identical to IN).
Output	OUT5	`adapter::types::unidirectional::AIS`	Fifth output channel (identical to IN).
Output	OUT6	`adapter::types::unidirectional::AIS`	Sixth output channel (identical to IN).
Output	OUT7	`adapter::types::unidirectional::AIS`	Seventh output channel (identical to IN).
Output	OUT8	`adapter::types::unidirectional::AIS`	Eighth output channel (identical to IN).

Functionality

The module forwards the AIS signal present at adapter input `IN` unchanged and without delay to all eight output adapters `OUT1` to `OUT8`. No transformation, filtering, or buffering takes place. This behavior corresponds to a passive distribution (broadcast) of an AIS interface.

Technical Features

- **Generic Type** – The function block is declared as `GEN_AIS_SPLIT` and can be adapted to specific AIS implementations via type parameterization (e.g., for different data types or event structures).
- **No Runtime Logic** – All functionality is implemented solely through the interconnection of the adapters; there are no internal algorithms or state machines.
- **Minimal Resource Requirements** – Since no active processing takes place, the function block incurs neither CPU load nor memory consumption during execution.

State Overview

The function block has no internal states. The output signal is always a direct mapping of the input signal.

Application Scenarios

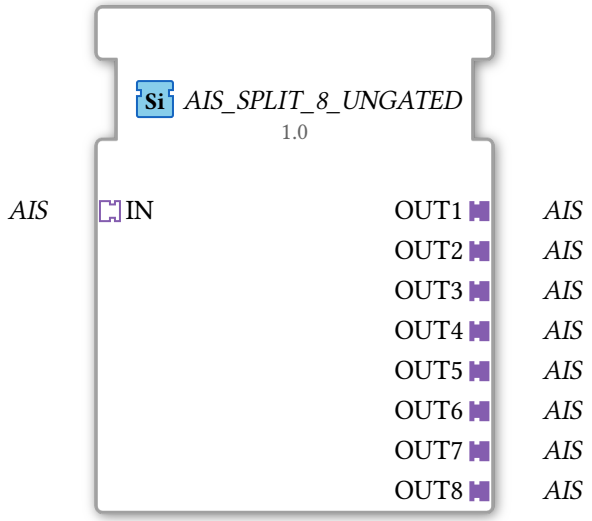
- **Parallel Processing** – Splitting a sensor signal across multiple independent evaluation blocks.

- **Redundancy** – Distributing a control signal to multiple actuators in safety-critical systems.
- **Test and Simulation Environments** – Providing an identical signal for different observers or loggers.

Comparison with Similar Modules

Unlike modules such as `AIS_MERGE_2` or `AIS_SELECT`, `AIS_SPLIT_8` does not have any selection or prioritization logic. Related variants differ only in the number of outputs (e.g., `AIS_SPLIT_2` or `AIS_SPLIT_4`). `AIS_SPLIT_8` is the maximum standard version for eight channels.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

AIS_SPLIT_8` is a simple and efficient module for replicating an AIS interface. Due to its generic nature and purely adapter-based implementation, it is ideally suited for building modular automation architectures that require distributed signal forwarding.

AIS_SPLIT_8_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIS_SPLIT_8`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

Introduction

The function block **AIS_SPLIT_8_UNGATED** distributes an incoming AIS (Application Interface Socket) signal to eight identical output adapters. It is designed as a generic block and allows the simultaneous transmission of an AIS signal to multiple subsequent function blocks without data loss or delay.

Interface Structure

Event Inputs

None available.

Event Outputs

None available.

Data Inputs

None available.

Data Outputs

None available.

Adapters

Direction	Name	Type	Description
Input	IN	`adapter::types::unidirectional::AIS`	Incoming AIS signal to be distributed.
Output	OUT1	`adapter::types::unidirectional::AIS`	First output channel (identical to IN).
Output	OUT2	`adapter::types::unidirectional::AIS`	Second output channel (identical to IN).
Output	OUT3	`adapter::types::unidirectional::AIS`	Third output channel (identical to IN).
Output	OUT4	`adapter::types::unidirectional::AIS`	Fourth output channel (identical to IN).
Output	OUT5	`adapter::types::unidirectional::AIS`	Fifth output channel (identical to IN).
Output	OUT6	`adapter::types::unidirectional::AIS`	Sixth output channel (identical to IN).
Output	OUT7	`adapter::types::unidirectional::AIS`	Seventh output channel (identical to IN).
Output	OUT8	`adapter::types::unidirectional::AIS`	Eighth output channel (identical to IN).

Functionality

The module forwards the AIS signal present at adapter input `IN` unchanged and without delay to all eight output adapters `OUT1` to `OUT8`. No transformation, filtering, or buffering takes place. This behavior corresponds to a passive distribution (broadcast) of an AIS interface.

Technical Features

- **Generic Type** – The function block is declared as `GEN_AIS_SPLIT` and can be adapted to specific AIS implementations via type parameterization (e.g., for different data types or event structures).
- **No Runtime Logic** – All functionality is implemented solely through the interconnection of the adapters; there are no internal algorithms or state machines.
- **Minimal Resource Requirements** – Since no active processing takes place, the function block incurs neither CPU load nor memory consumption during execution.

State Overview

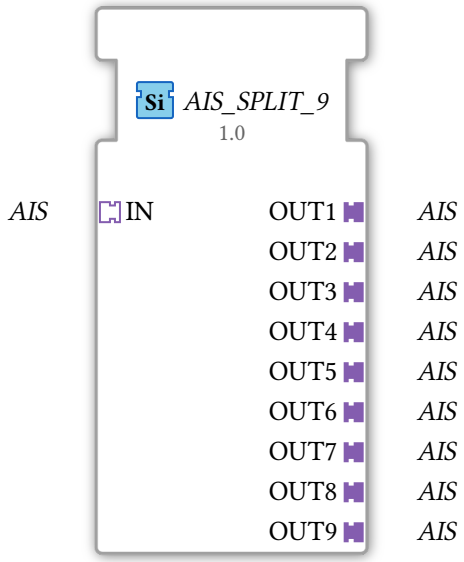
The function block has no internal states. The output signal is always a direct mapping of the input signal.

Application Scenarios

- **Parallel Processing** – Splitting a sensor signal across multiple independent evaluation blocks.
- **Redundancy** – Distributing a control signal to multiple actuators in safety-critical systems.
- **Test and Simulation Environments** – Providing an identical signal for different observers or loggers.

Comparison with Similar Modules

Unlike modules such as `AIS_MERGE_2` or `AIS_SELECT`, `AIS_SPLIT_8_UNGATED` does not have any selection or prioritization logic. Related variants differ only in the number of outputs (e.g., `AIS_SPLIT_2` or `AIS_SPLIT_4`). `AIS_SPLIT_8_UNGATED` is the maximum standard version for eight channels.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

AIS_SPLIT_8_UNGATED` is a simple and efficient module for replicating an AIS interface. Due to its generic nature and purely adapter-based implementation, it is ideally suited for building modular automation architectures that require distributed signal forwarding.

AIS_SPLIT_9

• – ◦ • – ◦ • – ◦ •

Introduction

The **AIS_SPLIT_9** function block is used to distribute an incoming unidirectional **AIS** adapter (Application Interface Socket) to nine identical outgoing **AIS** adapters (plugs). It is designed as a generic building block and enables the simple duplication of an AIS signal for up to nine downstream function blocks.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

Name	Type	Direction	Description
IN	AIS (unidirectional)	Socket	Input adapter – the AIS signal to be distributed.
OUT1	AIS (unidirectional)	Plug	First output – identical copy of the input signal.
OUT2	AIS (unidirectional)	Plug	Second output – identical copy of the input signal.
OUT3	AIS (unidirectional)	Plug	Third output – identical copy of the input signal.
OUT4	AIS (unidirectional)	Plug	Fourth output – identical copy of the input signal.
OUT5	AIS (unidirectional)	Plug	Fifth output – identical copy of the input signal.

OUT6	AIS (unidirectional)	Plug	Sixth output – identical copy of the input signal.
OUT7	AIS (unidirectional)	Plug	Seventh output – identical copy of the input signal.
OUT8	AIS (unidirectional)	Plug	Eighth output – identical copy of the input signal.
OUT9	AIS (unidirectional)	Plug	Ninth output – identical copy of the input signal.

Functionality

The **AIS_SPLIT_9** is a purely combinational function block without its own state logic or event control. It receives an AIS signal at the **Socket IN** and forwards it unchanged to all nine **Plugs OUT1** to **OUT9**. Any change at the input is immediately transmitted to all outputs. The function block thus acts as a passive signal distributor ("broadcast") on the AIS interface.

Technical Features

- **Generic Function Block**: The function block is defined as a generic type (`GenericClassName = GEN_AIS_SPLIT`). This allows for flexible reuse in different AIS contexts without having to recreate the function block for each application.
- **Unidirectional Transmission**: Both inputs and outputs use the unidirectional **AIS** adapter type, meaning data flows in only one direction (from the input to the outputs).
- **No Data Buffering or Delay**: Due to the lack of event and data handling, the function block operates without buffering or clocking – it is strictly signal-passing.
- **Simple Interface**: The function block has neither events nor data inputs/outputs, but only adapters. This makes it particularly lightweight and suitable for pure signal coupling.

State Overview

The **AIS_SPLIT_9** has no internal states or sequence controls. Its behavior is deterministic and always determined by the input signal. There are no initializing or fault states.

Application Scenarios

- **Signal Multiplication**: An AIS-based control signal is to be passed on in parallel to several independent actuators, controllers, or displays.
- **Broadcast in Modular Systems**: In a distributed automation environment, a central measured value (e.g., temperature, pressure) is provided via AIS and must be consumed simultaneously by several function blocks.
- **Prototyping and Testing**: A test signal is to be distributed to multiple instances of the same function block type without requiring the source function block to be instantiated multiple times.

Comparison with Similar Components

- **AIS_SPLIT_2 / AIS_SPLIT_4 / AIS_SPLIT_8** etc.: These components distribute the input signal to 2, 4, or 8 outputs. The **AIS_SPLIT_9** is specifically designed for applications requiring exactly nine parallel connections. The functionality is identical – the only difference lies in the number of outputs.
- **AIS_MERGE**: Unlike the Split component, a Merge component combines multiple inputs into a single output. **AIS_SPLIT_9** implements the reverse data flow.
- **Direct Coupling**: Instead of a Split component, manual wiring (multiple OUT adapters) could also be performed in the 4diac IDE. However, the **AIS_SPLIT_9** simplifies the graphical representation and reduces the complexity of the network.

AIS_MERGE

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AIS_SPLIT_9** is a simple yet extremely useful function block for duplicating a unidirectional AIS signal to nine outputs. Its generic design, the absence of event or data logic, and its clear interface make it a reliable tool for modular automation solutions. It is particularly suitable for applications where a signal needs to be distributed to multiple receivers without delay or modification.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

ATM_D_FF

• – ○ • – ○ • – ○ •

Introduction

The function block `ATM_D_FF` implements a data latch (D flip-flop) for storing a single data value. Communication occurs exclusively via adapters of type `adapter::types::unidirectional::ATM`, so events and data are transmitted as a bundled interface. The function block is implemented according to IEC 61499-1 Annex A and is licensed under the Eclipse Public License 2.0.

Interface Structure

Event Inputs

The function block does not have direct event inputs. An event is received at the adapter interface *E1* via the socket adapter **I** (type: `adapter::types::unidirectional::ATM`).

Event Outputs

The FB has no direct event outputs. An event is output via the plug adapter **Q** (type: `adapter::types::unidirectional::ATM`) at the adapter interface *E1*.

Data Inputs

The FB has no direct data inputs. A data value is provided via the socket adapter **I** at the adapter interface *D1*.

Data Outputs

The FB has no direct data outputs. A data value is output via the plug adapter **Q** at the adapter interface *D1*.

Adapters

Adapter	Type	Direction	Comment
I	`adapter::types::unidirectional::ATM`	Socket (incoming)	Latch value
Q	`adapter::types::unidirectional::ATM`	Plug (outgoing)	Stored value

Functionality

The function block internally uses the standard block `iec61499::events::E_D_FF_ANY`. Upon an event at the input adapter **I.E1** (clock), the current data value is taken from **I.D1** and temporarily stored. Immediately afterward, an event is triggered at the output adapter **Q.E1**, and the stored value is output to **Q.D1**. This behavior corresponds to an edge-triggered D flip-flop.

Technical Features

- No direct event or data ports – all communication takes place via adapters, which enables flexible coupling in IEC 61499 systems.
- The function block is fully implemented by the internal `E_D_FF_ANY`; the state logic is handled by this block.
- Licensed under the Eclipse Public License 2.0; source code and metadata are stored in the function block type.

State Overview

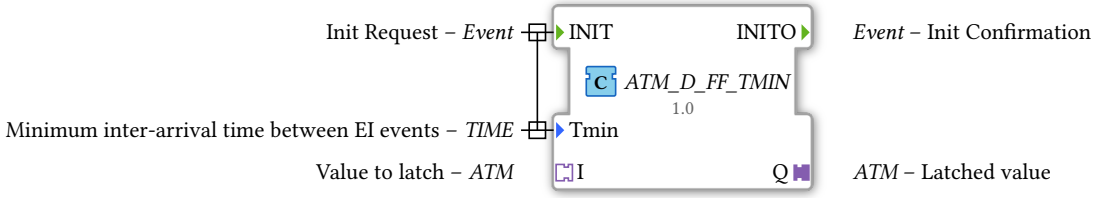
The `ATM_D_FF` does not have its own state engine. Its behavior is purely data flow-driven:

- **Waiting for Event** – the last stored value is retained.
- **On Event at I.E1** – the value from I.D1 is taken and immediately output to Q.

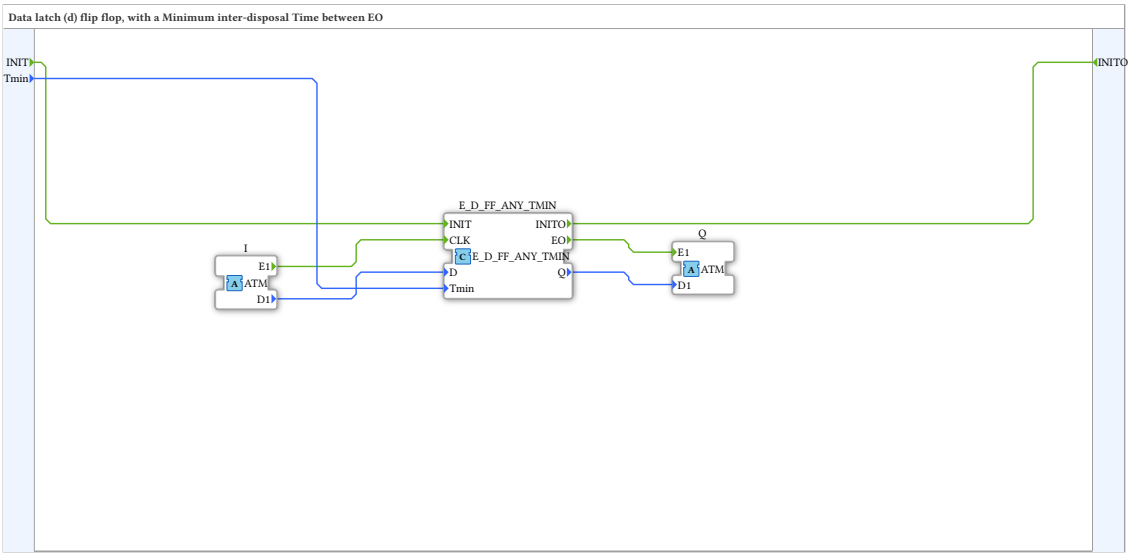
Internally, edge-triggered takeover is implemented by `E_D_FF_ANY` (rising edge of the event).

Application Scenarios

- **Cache** for data that should be updated synchronously with an event.
- **State indicator** in automation processes (e.g., marker for "Value valid").
- **Data transfer** between asynchronous process steps when a simple latch is sufficient.
- **Adapter-based communication** in distributed systems where flat interfaces are preferred.



Comparison with similar components



- **SR flip-flop** (`ATM_SR_FF`): Sets/resets state via two events, no clock-driven data input.
- **T flip-flop** (`ATM_T_FF`): Toggles the state on each event.
- **Direct `E_D_FF_ANY`**: Offers the same logic, but with explicit input/output ports instead of adapters. The `ATM_D_FF` encapsulates this logic and standardizes the interface to the unidirectional ATM adapter, facilitating reuse in adapter-based frameworks.

Conclusion

ATM_D_FF` is a compact, reliable functional block for implementing a D flip-flop in IEC 61499 environments. The use of adapters ensures a clean separation of event and data paths, which is particularly advantageous in modular, reusable automation solutions. The component is easy to integrate and fulfills the basic requirement for an edge-triggered data storage device.

ATM_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block `ATM_D_FF_TMIN` implements a clock-controlled D flip-flop (data latch) that takes the incoming data value at a clock event and outputs it as a stored value. A special feature is the adjustable minimum time (`Tmin`) between two consecutive output events, which guarantees a defined dead time.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request (with `Tmin`)

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirmation

Data Inputs

Name	Type	Comment
Tmin	TIME	Minimum time interval between two EO events

Data Outputs

The function block has no direct data outputs. The stored value is provided via the adapter output `Q.D1`.

Adapter

Direction	Name	Type	Comment
Input (Socket)	I	`adapter::types::unidirectional::ATM`	Value to be adopted
Output (Plug)	Q	`adapter::types::unidirectional::ATM`	Stored value

The adapter `ATM` provides one event channel and one data channel (`E1`, `D1` for input; `E1`, `D1` for output).

Functionality

1. **Initialization**: An event at `INIT` initializes the function block and adopts the parameter `Tmin`.
2. **Clocking**: An event at the adapter input `I.E1` (clock) causes the function block to take the current data value from `I.D1`. If the takeover is successful, the value is output at the adapter output `Q.D1`, and an event is simultaneously sent to `Q.E1`.
3. **Minimum Output Delay**: After each output event (`Q.E1`), an internal lock is activated. Only after the time specified in `Tmin` has elapsed can another clock event trigger a new output. If a new clock signal arrives within the lock time, it is ignored, or the output is delayed until `Tmin` expires (depending on the implementation of the internal function block `E_D_FF_ANY_TMIN`).

Technical Features

- **Dead Time Control**: The parameter `Tmin` forces a minimum pause between two output events – useful for protecting downstream components or debouncing signal edges.
- **Internal Implementation**: The function block internally uses the function block `iec61499::events::E_D_FF_ANY_TMIN`, which provides the actual flip-flop logic with timing. `ATM_D_FF_TMIN` acts as an interface adapter for the adapter `ATM`.
- **Internal Implementation**: The function block internally uses the function block `iec61499::events::E_D_FF_ANY_TMIN`, which provides the actual flip-flop logic with timing control. `ATM_D_FF_TMIN` acts as an interface adapter for the adapter `ATM`.

Default Time Control: - **Adapter Interface**: Both input and output data are exchanged via unidirectional adapters, enabling loose coupling in the application.

State Overview

Although no explicit state diagram is available, the following logical states can be derived:

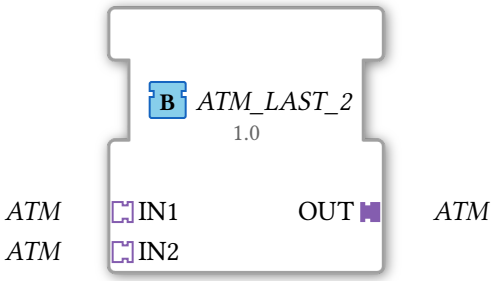
1. **Ready**: Waiting for a clock event, no lock active.
2. **Set**: Value has been accepted and output; the lock `Tmin` is active.
3. **Locked**: During `Tmin`, incoming clock events are ignored or held back.

After the lock expires, the function block returns to the **Ready** state.

Application Scenarios

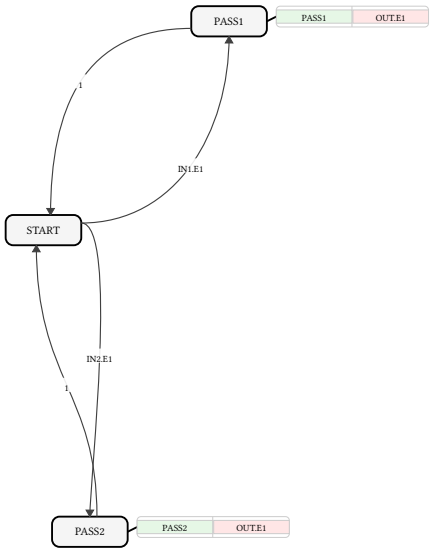
- **Signal conditioning** in automation technology, where a switching signal needs to be re-evaluated after a defined minimum pause (e.g., dead time during valve switching).
- **Debouncing** of binary sensors where a downstream output may only be generated after a stable time of `Tmin`.
- **Synchronization** of data streams where a minimum packet gap must be maintained.

Comparison with similar components



- **Standard D flip-flop** (e.g., `E_D_FF`): Provides an output immediately after each clock cycle – without any time constraint. The `ATM_D_FF_TMIN` extends this with the dead time `Tmin`.
- **Monostable flip-flops** (timers): Generate a pulse of defined length. The `ATM_D_FF_TMIN`, however, only disables the output without resetting the output level.

This component combines the properties of a flip-flop with an adjustable minimum delay time and is therefore particularly suitable for time-critical control tasks.



Conclusion

ATM_D_FF_TMIN` is a specialized D-type flip-flop component that guarantees the minimum dwell time between two output events. The use of adapters simplifies integration into modular control applications, while the adjustable delay time offers high flexibility for different physical constraints. It is a valuable addition to the IEC 61499 library for discrete-time signal processing.

ATM_LAST_2

ECC: ATM_LAST_2

Introduction

The ATM_LAST_2 function block merges two same-type TIME adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: TIME adapter (unidirectional) - first signal source
- **IN2**: TIME adapter (unidirectional) - second signal source

Output adapter (Plug):

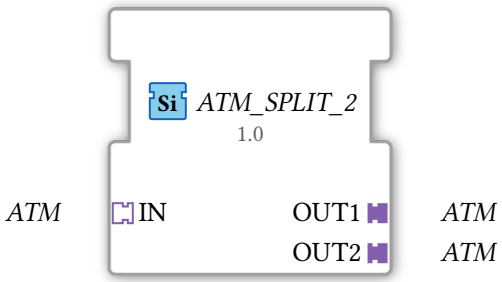
- **OUT**: TIME adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid TIME signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same TIME value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

ATM_LAST_2 is the inverse of `ATM_SPLIT_2`: ATM_SPLIT_2 distributes 1 input to 2 outputs, ATM_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

ATM_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The **ATM_SPLIT_2** is a generic function block that splits an incoming adapter of type `adapter::types::unidirectional::ATM` into 2 separate outputs (OUT1, OUT2). It serves to forward a time signal to 2 subsequent function blocks without modifying the data. The function block is implemented as a generic type (`GEN_ATM_SPLIT`) and is parameterized at runtime.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::ATM`	IN	Socket	Input signal (ATM)
`adapter::types::unidirectional::ATM`	OUT1	Plug	Output 1 (identical to IN)
`adapter::types::unidirectional::ATM`	OUT2	Plug	Output 2 (identical to IN)

Functionality

This block forwards the ATM signal present at socket **IN** unchanged to all 2 plugs (OUT1, OUT2). No data manipulation, filtering, or delay occurs. The distribution is purely structural: each output receives its own copy of the reference to the underlying time value.

Technical Features

- **Generic Implementation**: The function block uses the generic class name attribute (`eclipse4diac::core::GenericClassName`) with the value `'GEN_ATM_SPLIT'`, so the same class covers the arities `ATM_SPLIT_2`, `ATM_SPLIT_3`, and `ATM_SPLIT_4` via the GenericClassName mechanism.
- **Unidirectional Adapters**: All adapters are of type `adapter::types::unidirectional::ATM` (forward direction only).
- **No State Automation**: The function block does not have an explicit ECC (Execution Control Chart); signal routing is direct and event-independent.

State Overview

The function block does not implement state automation. Its functionality is limited to passively routing the input signal to all 2 outputs. Therefore, state visualization is not required.

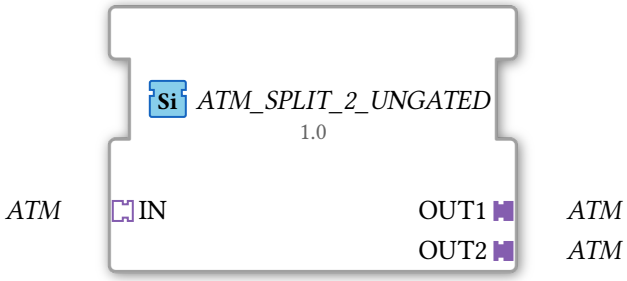
Application Scenarios

- **Signal Distribution**: Splitting an ATM-based time signal (e.g., a delay duration) to multiple parallel-operating control components.
- **Redundancy**: Providing the same time value for a primary and a redundant system.
- **Debugging**: Connecting an analysis or logging module in parallel to the existing path without interrupting the original signal chain.

Comparison with Similar Function Blocks

Similar functionality is offered by the other arities `ATM_SPLIT_2`/`ATM_SPLIT_3`/`ATM_SPLIT_4`, as well as the structurally identical `AR_SPLIT_2` for the `REAL` data type. The choice of arity depends on the required number of outputs.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ATM_SPLIT_2** is a simple yet essential module for multiplying a time signal in IEC 61499-based control systems. Its generic design and clear interface make it the first choice when a time value needs to be passed to multiple independent target components.

ATM_SPLIT_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ATM_SPLIT_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

- **Debugging**: Connecting an analysis or logging module in parallel to the existing path without interrupting the original signal chain.

Comparison with Similar Function Blocks

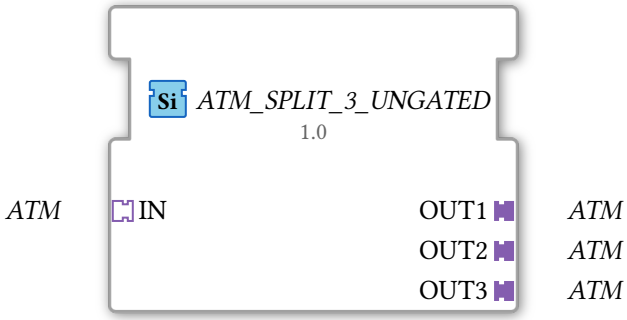
Similar functionality is offered by the other arities `ATM_SPLIT_2`/`ATM_SPLIT_3`/`ATM_SPLIT_4`, as well as the structurally identical `AR_SPLIT_3` for the `REAL` data type. The choice of arity depends on the required number of outputs.

Change Detection



Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **ATM_SPLIT_3** is a simple yet essential module for multiplying a time signal in IEC 61499-based control systems. Its generic design and clear interface make it the first choice when a time value needs to be passed to multiple independent target components.

ATM_SPLIT_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `ATM_SPLIT_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

The **ATM_SPLIT_3_UNGATED** is a generic function block that splits an incoming adapter of type `adapter::types::unidirectional::ATM` into 3 separate outputs (OUT1, OUT2, OUT3). It serves to forward a time signal to 3 subsequent function blocks without modifying the data. The function block is implemented as a generic type (`GEN_ATM_SPLIT`) and is parameterized at runtime.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapter

Type	Name	Direction	Description
`adapter::types::unidirectional::ATM`	IN	Socket	Input signal (ATM)
`adapter::types::unidirectional::ATM`	OUT1	Plug	Output 1 (identical to IN)
`adapter::types::unidirectional::ATM`	OUT2	Plug	Output 2 (identical to IN)
`adapter::types::unidirectional::ATM`	OUT3	Plug	Output 3 (identical to IN)

Functionality

This block forwards the ATM signal present at socket **IN** unchanged to all 3 plugs (OUT1, OUT2, OUT3). No data manipulation, filtering, or delay occurs. The distribution is purely structural: each output receives its own copy of the reference to the underlying time value.

Technical Features

- **Generic Implementation**: The function block uses the generic class name attribute (`eclipse4diac::core::GenericClassName`) with the value `'GEN_ATM_SPLIT'`, so the same class covers the arities `ATM_SPLIT_2`, `ATM_SPLIT_3_UNGATED`, and `ATM_SPLIT_4` via the GenericClassName mechanism.
- **Unidirectional Adapters**: All adapters are of type `adapter::types::unidirectional::ATM` (forward direction only).
- **No State Automation**: The function block does not have an explicit ECC (Execution Control Chart); signal routing is direct and event-independent.

State Overview

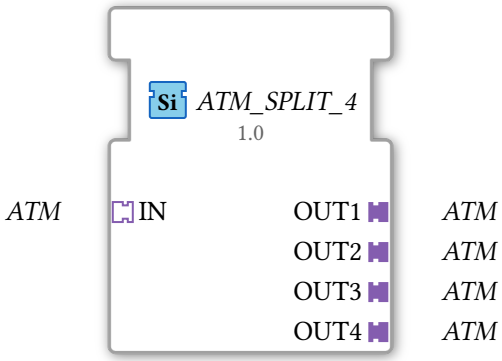
The function block does not implement state automation. Its functionality is limited to passively routing the input signal to all 3 outputs. Therefore, state visualization is not required.

Application Scenarios

- **Signal Distribution**: Splitting an ATM-based time signal (e.g., a delay duration) to multiple parallel-operating control components.
- **Redundancy**: Providing the same time value for a primary and a redundant system.
- **Debugging**: Connecting an analysis or logging module in parallel to the existing path without interrupting the original signal chain.

Comparison with Similar Function Blocks

Similar functionality is offered by the other arities `ATM_SPLIT_2`/`ATM_SPLIT_3_UNGATED`/`ATM_SPLIT_4`, as well as the structurally identical `AR_SPLIT_3` for the `REAL` data type. The choice of arity depends on the required number of outputs.



Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **ATM_SPLIT_3_UNGATED** is a simple yet essential module for multiplying a time signal in IEC 61499-based control systems. Its generic design and clear interface make it the first choice when a time value needs to be passed to multiple independent target components.

ATM_SPLIT_4

• – ◦ • – ◦ • – ◦ •

Introduction

The **ATM_SPLIT_4** is a generic function block that splits an incoming adapter of type `adapter::types::unidirectional::ATM` into 4 separate outputs (OUT1, OUT2, OUT3, OUT4). It serves to forward a time signal to 4 subsequent function blocks without modifying the data. The function block is implemented as a generic type (`GEN_ATM_SPLIT`) and is parameterized at runtime.

Interface Structure

AUDI_CTUD_UDINT (Adapter-Based Up/Down Counter)

Introduction

The `AUDI_CTUD_UDINT` is an event-driven up/down counter for unsigned 32-bit integers (UDINT), specifically designed for integration into adapter-based systems. It utilizes the `AUDI` adapter for passing the counter value and the default value, enabling a clean separation of event and data flow.

Interface Structure

Event Inputs

- **CU**: `Event` - Increments the value by one (`Count Up`; only if `CV.D1` < 4294967295).
- **CD**: `Event` - Decrements the value by one (`Count Down`; only if `CV.D1` > 0).
- **R**: `Event` - Resets the counter to zero (`Reset`).
- **LD**: `Event` - Loads the counter value `CV.D1` with the preset value `PV.D1` (`Load CV with PV`).

Event Outputs

- **CUO**: `Event` - Confirmation of `CU` (`Count Up Output`).
- **CDO**: `Event` - Confirmation of `CD` (`Count Down Output`).
- **RO**: `Event` - Confirmation of `R` (`Reset Output`).
- **LDO**: `Event` - Confirmation of `LD` (`Load Output`).

Output Variables

No classic data outputs; the status signals `QU` and `QD` are provided as AX adapters (plugs), see the Adapter section.

Adapter

- **QU** (Plug): `AX - TRUE` when the counter value (`CV.D1`) is greater than or equal to the preset value (`PV.D1`). The event `QU.E1` is only fired when `QU` changes.
- **QD** (Plug): `AX - TRUE` if the counter value (`CV.D1`) is less than or equal to zero. The event `QD.E1` is only fired when `QD` changes.
- **CV** (Plug): `AUDI` - The current counter value (`Counter Value`).
- **PV** (Socket): `AUDI` - The default value (`Preset Value`) against which the counter is checked (for `QU`).

Functionality

The counter reacts to the event inputs `CU`, `CD`, `R` and `LD`. A `CU` event increments `CV.D1` by 1, a `CD` event decrements `CV.D1` by 1. A `R` event resets `CV.D1` to 0, a `LD` event sets `CV.D1` to `PV.D1`.

When an event (`PV.E1`) arrives at the `PV` adapter, only the status signals `QU`/`QD` are re-evaluated; the counter value `CV.D1` is left unchanged.

The counter value is output via the `CV` adapter as the `AUDI` signal. After each counting action, `CUO`, `CDO`, `RO` or `LDO` confirms the operation and `CV.E1` signals the value change; `QU.E1`/`QD.E1` are only fired when the respective status changes (on-change triggering).

Technical Features

✓ **Adapter-based**: Seamless integration into AX systems.
✓ **Event-driven**: No cyclic calls required.
✓ **UDINT-based**: Supports the full range of unsigned 32-bit integers.
✓ **On-change triggering**: `QU.E1` and `QD.E1` only fire when `QU` or `QD` changes; `PV.E1` re-evaluates both statuses.

Application Scenarios

- **Piece Counting**: Counting objects in production lines.
- **Operating Hour Counter**: Recording operating times (in combination with timers).
- **Position Monitoring**: Simple position counters in handling systems.

AUDI_D_FF

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_D_FF** implements a clock-controlled D flip-flop (data latch) based on IEC 61499 adapters. Upon an event at the input adapter, it receives the incoming data value, stores it, and outputs it via the output adapter. The block encapsulates all control logic in a compact, adapter-based interface, thus allowing for a clean separation of event and data communication.

Interface Structure

Event Inputs

None – event control is handled exclusively via the socket adapter.

Event Outputs

None – event output is handled exclusively via the plug adapter.

Data Inputs

None – data acquisition is handled exclusively via the socket adapter.

Data Outputs

None – data output is exclusively via the plug adapter.

Adapters

Name	Type	Direction	Description
I	`adapter::types::unidirectional::AUDI`	Socket (Input)	Provides the clock event (E1) and the data value to be received (D1).
Q	`adapter::types::unidirectional::AUDI`	Plug (Output)	Outputs the output event (E1) and the stored data value (D1).

Both adapters are of the same unidirectional type **AUDI**, which transports an event and a data value together. The socket **I** serves as the source, the plug **Q** as the sink.

Functionality

The function block operates according to the classic D flip-flop function:

1. **Waiting for Clock**: As long as no event is present at input **I.E1**, the internal memory retains its last value.
2. **Takeover on Clock Edge**: An event at **I.E1** (interpreted as a rising edge) causes the function block to take the current data value from **I.D1** and store it in the internal memory.

3. **Output**: After the takeover, an event is output at **Q.E1**, and the stored data value appears at **Q.D1**. This value remains stable until the next clock event arrives.

The internal implementation uses the IEC 61499 standard function block `E_D_FF_ANY`, which provides a type-independent D flip-flop function. Adapters **I** and **Q** are directly connected to its event and data ports.

Technical Features

- **Adapter-based interface**: The function block (FB) does not use individual event or data inputs/outputs, but communicates exclusively via unidirectional adapters. This simplifies connections in complex networks and supports modular type checking.
- **Type independence**: The internal block `E_D_FF_ANY` works with any data type (ANY). The actual data type is defined by the adapter definition of type `AUDI`.
- **Unidirectional communication**: The adapter type `adapter::types::unidirectional::AUDI` transmits events and data only in one direction – from the socket to the plug. Feedback is not provided.
- **No additional initialization state**: The FB starts without a defined data value; The internal state corresponds to the initial state of the `E_D_FF_ANY` function block used.

State Overview

Since this is a purely combinational, event-driven memory, its behavior can be described by two stable states:

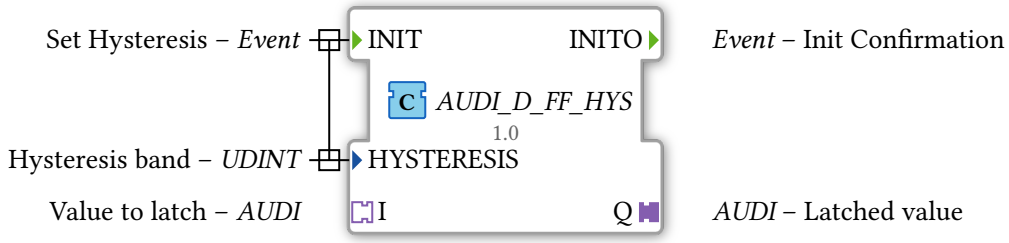
- **State A (Waiting)**: No clock event is received – output **Q.D1** holds the last acquired value.
- **State B (Accepting)**: A clock event at **I.E1** triggers the acquisition of **I.D1**. After processing, the function block immediately returns to the waiting state (not a multi-stage state machine).

A graphical representation as a state machine is not required, as the logic is delegated to the internal `E_D_FF_ANY`, whose state diagram is defined in the IEC 61499 specification.

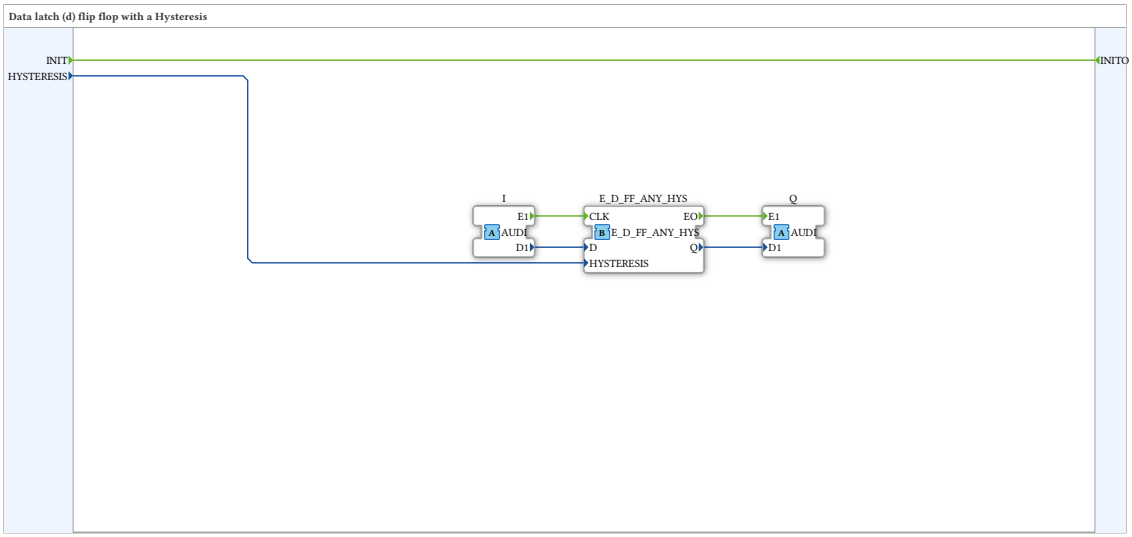
Application Scenarios

- **Data Buffer**: Acquires a sensor signal at a defined measurement time and forwards it to a controller.
- **Synchronization**: Simultaneous reading of multiple data sources via a common clock event.
- **Register Implementation**: Multiple `AUDI_D_FF` modules can be connected in parallel to create an n-bit register.
- **Interface to Event-Driven Communication Protocols**: The adapter is particularly suitable for systems that use standardized data-event pairs (e.g., OPC UA or MQTT connections).

Comparison with Similar Modules



- **`E_D_FF_ANY`** (IEC 61499 standard module): Has separate event and data inputs/outputs, no adapter interface. The `AUDI_D_FF` encapsulates these interfaces in an adapter, thus simplifying their use in adapter-based networks.
- **SR Flip-Flop (Set-Reset)**: Has two data inputs (Set/Reset) and does not allow pure clock operation. The `AUDI_D_FF` is tailored to the simple D flip-flop application.
- **AUDI Adapter-Based Function Blocks (e.g., `AUDI_D_FF_2`)**: Other implementations might include additional logic such as asynchronous reset. This function block implements the minimal D flip-flop without additional control functions.



SR Flip-Flop (Set-Reset)

Conclusion

The **AUDI_D_FF** represents a cleanly encapsulated, adapter-based implementation of a D flip-flop. By using the unidirectional `AUDI` adapter type, the interface is reduced to the essentials – one event and one data value per side. The internal use of the proven `E_D_FF_ANY` function block ensures robust, standards-compliant functionality. The function block is particularly suitable for modular architectures that rely on adapter connectivity and facilitates reuse in various control projects.

AUDI_D_FF_HYS

• – ○ • – ○ • – ○ •

Introduction

The function block `AUDI_D_FF_HYS` implements a data-triggered flip-flop (D-latch) with a hysteresis function. It serves to accept an incoming data value upon an event, with the hysteresis enabling switching behavior with a defined deadband. The block encapsulates the logic of the internal block `E_D_FF_ANY_HYS` and provides the interfaces via two unidirectional adapters of type `AUDI`.

Interface Structure

Event Inputs

Event	Type	Comment	With Variable
`INIT`	EInit	Set Hysteresis	`HYSTERESIS`

Event Outputs

Event	Type	Comment
`INITO`	EInit	Init Confirmation

Data Inputs

Variable	Type	Comment
`HYSTERESIS`	UDINT	Hysteresis band

Data Outputs

No direct data outputs – output data is provided via the `Q` adapter.

Adapters

Role	Name	Type (Adapter)	Comment
Plug	Q	adapter::types::unidirectional::AUDI	Latched value
Socket	I	adapter::types::unidirectional::AUDI	Value to latch

The adapter AUDI contains one event channel and one data channel:

- I.E1 – Event that triggers the latch operation
- I.D1 – Data value to be latched
- Q.E1 – Confirmation event after successful latch
- Q.D1 – The latched (and hysteresis-affected) data value

Functionality

The module operates as a wrapper around the internal module E_D_FF_ANY_HYS. During the initialization event INIT, the hysteresis value (passed to HYSTERESIS) is transferred; The INITO event confirms initialization.

During operation, the current data value from I.D1 is taken at each event on the adapter input I.E1 and processed with the configured hysteresis. The result is output via the adapter output Q.D1, accompanied by an event Q.E1.

The hysteresis prevents constant switching with small signal changes: The output only changes its state when the input value leaves the hysteresis range.

Technical Features

- The function block uses the generic implementation E_D_FF_ANY_HYS (from the library logiBUS::signalprocessing::hysteresis).
- The hysteresis is specified as UDINT (unsigned double integer) – the value range is therefore 0… 4294967295.
- All input/output is handled exclusively via unidirectional adapters (AUDI), which promotes clear separation and reusability in complex networks.
- The INIT event is passed directly to INITO without intermediate processing – however, the hysteresis setting is configured before INITO (according to the data connection).

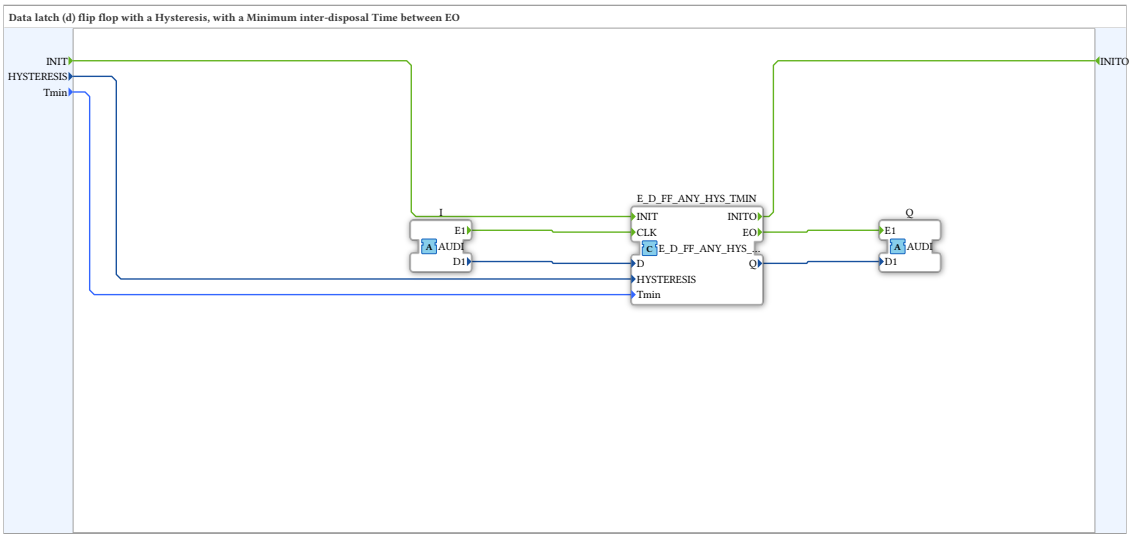
State Overview

Since the FB is a pure function block network (no dedicated ECC), the state is determined by the internal block E_D_FF_ANY_HYS. Simplified:

- **Reset**: Output Q.D1 is 0 or a defined initial value.
- **Set**: The output is set to 1 when the upper hysteresis threshold is exceeded.
- **Hold**: The output remains unchanged for values within the hysteresis range.
- **Reset**: The output is reset when the lower hysteresis threshold is undershot.

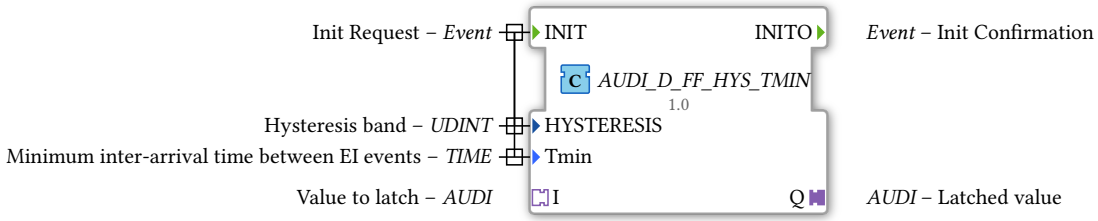
Application Scenarios

- **Sensor Signal Debouncing**: Prevents chatter in mechanical switches or proximity sensors.
- **Threshold Switch with Feedback Suppression**: E.g., temperature control with adjustable deadband.
- **Digital Input Buffering**: Adopts a stable value upon a defined event (e.g., clock edge).



Comparison with Similar Components

- **Standard D Flip-Flop (without hysteresis)**: Responds instantly to any change – no noise or bounce suppression.
- **RS Flip-Flop with hysteresis (e.g., RS_FF_HYS)**: Controls via separate set/reset events, while AUDI_D_FF_HYS uses a single data/event input.
- **Schmitt Trigger Component**: Functionally similar, but usually without latch/store behavior – here, the value is latched at an event and held until the next event.



Conclusion

AUDI_D_FF_HYS` combines the properties of a data-triggered flip-flop with adjustable hysteresis. By being encapsulated as an adapter module, it can be easily integrated into modular automation networks and offers a robust solution for signal processing with debouncing or threshold logic.

AUDI_D_FF_HYS_TMIN

No image available

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_D_FF_HYS_TMIN** implements a clock-edge-triggered data latch (D flip-flop) with a hysteresis function and a minimum dwell time between output events (EO). It serves to reliably and cleanly acquire a data value while simultaneously suppressing noise and undesirably fast switching operations. The function block encapsulates the logic of an internal component `E_D_FF_ANY_HYS_TMIN` and provides the inputs/outputs via standardized adapters.

Interface Structure

Event Inputs

| Event | Type | Comment | | INIT | EInit | Initialization request, sets hysteresis and minimum time |

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization confirmation

Data Inputs

Variable	Type	Comment
HYSTERESIS	UDINT	Hysteresis band (width of the dead zone for noise suppression)
Tmin	TIME	Minimum time between two consecutive output events

Data Outputs

No direct data outputs – the output data is provided via the **Q** adapter.

Adapter

Name	Type	Direction	Comment
I	`adapter::types::unidirectional::AUDI`	Input	Data value to be received
Q	`adapter::types::unidirectional::AUDI`	Output	Latched value

Functionality

1. **Initialization** – The parameters `HYSTERESIS` and `Tmin` are set via the event input `INIT`. After successful initialization, `INITO` is output.
2. **Data Latch** – Each event at the adapter input `I.E1` is interpreted as a clock signal (CLK). The current data value from `I.D1` is adopted.
3. **Hysteresis** – The output value only changes if the difference between the new and old values exceeds the hysteresis band (`HYSTERESIS`). This suppresses small fluctuations (e.g., noise).
4. **Minimum Time** – After an output event (`Q.E1`), no further output event is generated for the duration `Tmin`, even if new clock signals are present at the input. This prevents an excessively high output event rate.

The function block (FB) internally uses the block `logiBUS::signalprocessing::hysteresis::E_D_FF_ANY_HYS_TMIN`, which implements the described logic.

Technical Features

- **Adapter-Based Input/Output** – The FB communicates via standardized unidirectional adapters of type `AUDI`. This enables type-safe and modular integration with other function blocks.
- **Configurable Hysteresis** – The hysteresis width can be adjusted at runtime using `HYSTERESIS`.
- **Minimum Time Between Events** – The minimum time `Tmin` between two output events protects downstream components from overload and defines a maximum update rate.
- **Initialization Required** – Before initial operation, the FB must be configured using `INIT`; otherwise, the internal parameters are undefined.

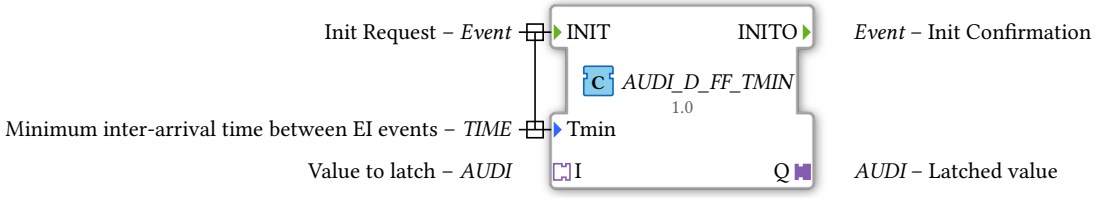
State Overview

The function block (FB) does not have an explicit state machine in the XML. Its behavior is entirely determined by the internal block `E_D_FF_ANY_HYS_TMIN`. The following states can be logically derived:

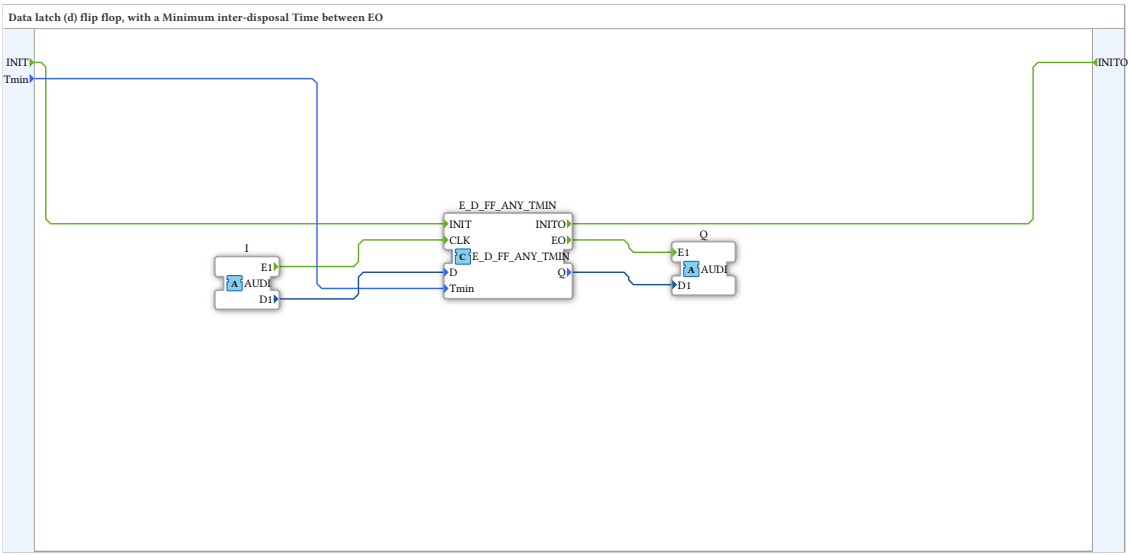
- **Initial** – After a reset, waits for `INIT`.
- **Ready** – After `INIT` and `INITO`, ready to receive data.
- **Waiting for Clock** – Awaits an event at `I.E1`.
- **Processing** – Data is being evaluated, hysteresis is being checked.
- **Output Locked** – After an output event, the `Tmin` timer starts running, during which no further output is possible.

Application Scenarios

- **Sensor Value Wiring** – Stabilization of analog or digital sensor signals with hysteresis (e.g., level, temperature, pressure) and update rate limitation.
- **Clock Edge-Triggered Data Acquisition** – Reliable reading of values from noisy environments when a minimum time between value changes is required.
- **Actuator Control** – Protection of actuators from excessively rapid switching by limiting the output event frequency.



Comparison with Similar Components



- **Standard D Flip-Flop (e.g., `E_D_FF`)** – No hysteresis and no time limit; responds to every clock edge without filtering.
- **D Flip-Flop with Hysteresis (e.g., `AUDI_D_FF_HYS`)** – Includes hysteresis, but no minimum time between output events.
- **AUDI_D_FF_HYS_TMIN** – Combines both features: hysteresis for noise suppression and `Tmin` for limiting the event rate.

Conclusion

The FB `AUDI_D_FF_HYS_TMIN` offers a robust, configurable solution for clock-driven data acquisition in industrial automation environments. By combining hysteresis and minimal inter-event time, it is particularly suitable for applications with noisy signals or limited output bandwidth. The adapter-based interface facilitates integration into existing systems and promotes reusability.

AUDI_D_FF_TMIN

• – ○ • – ○ • – ○ •

Introduction

The function block **AUDI_D_FF_TMIN** implements a D flip-flop (data latch) with a minimum lock time between successive output events. It serves to receive a value received via one adapter and output it via a second adapter, with the propagation of the output event being time-controlled.

Interface Structure

Event Inputs

Name	Type	Description
INIT	EInit	Initializes the function block; sets the minimum time between two EO events.

Event Outputs

Name	Type	Description
INITO	EInit	Confirmation of completed initialization.

Data Inputs

Name	Type	Description
Tmin	TIME	Minimum time that must elapse between two consecutive EO events.

Data Outputs

No direct data outputs; the latched value is provided via the **Q** adapter.

Adapters

Name	Type (unidirectional)	Role
I	AUDI	Input adapter: provides the value to be latched (via D1) and the latch event (via E1).
Q	AUDI	Output adapter: outputs the latched value (via D1) and an output event (via E1).

Functionality

The function block internally contains an instance of the function block `E_D_FF_ANY_TMIN`, which implements the core logic of a time-limited D flip-flop.

1. **Initialization**

An INIT event sets the minimum delay time `Tmin` (via the With association) and is passed to the internal instance. After successful initialization, INITO is output.

1. **Latch Operation**

An event at the input `I.E1` (of the adapter) is passed as a clock signal (CLK) to the internal flip-flop. Simultaneously, the value from `I.D1` (D input) is taken. The latched value appears at output `Q.D1`, and the corresponding output event appears at the adapter's event output (`Q.E1`).

1. **Minimum Wait Time**

The internal function block enforces a minimum time interval between successive `Q.E1` events. If the time defined at `Tmin` is exceeded, the next output event is only triggered after this time interval has elapsed. This prevents overloads on the output side.

Technical Features

- **Adapter-Based Communication**

The function block uses two unidirectional AUDI adapters for input and output. This achieves loose coupling between data flow and event control.

- **Interval Control**

The minimum time between two EO events is configured via the parameter `Tmin`. The internal function block `E_D_FF_ANY_TMIN` ensures that this condition is met by delaying incoming clock events as needed.

- **No Explicit Data Outputs**

The latched value is provided exclusively via the adapter `Q`. This simplifies the connection to subsequent function blocks with the same adapter type.

State Overview

The function block has no externally visible states, as the state logic is encapsulated within the internal function block. The internal logic cycles through at least the following internal states:

- **IDLE**: Waiting for INIT or a clock event (I.E1).
- **LATCH**: Value is being stored; waiting time is being checked.
- **OUTPUT**: Outputs Q.E1 and Q.D1 when the minimum time since the last output event has elapsed.

An INIT event resets all states.

Application Scenarios

- **Time-Controlled Data Buffer**

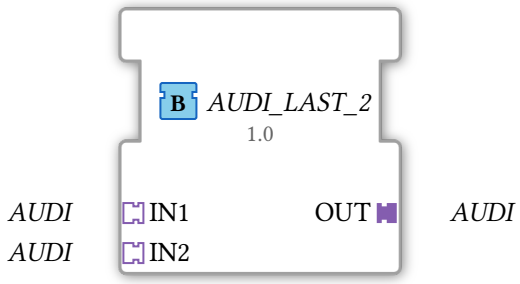
Accepts measured values or control signals at fixed time intervals, e.g., to decouple a fast sensor from a slow actuator.

- **Event Filter**

Suppresses events that follow each other too quickly (application-level debouncing).

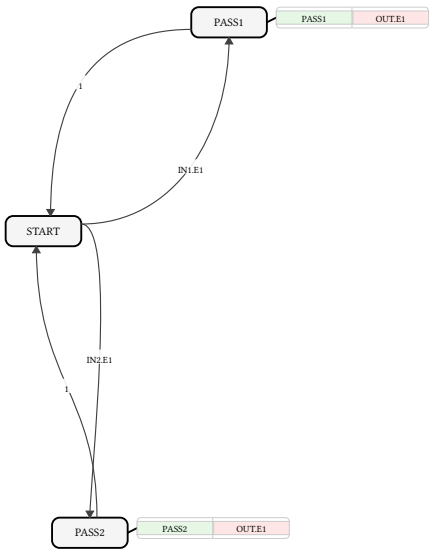
- **Synchronization**

Used as a basic building block for implementing delay elements or clock locks in IEC 61499 applications.



Comparison with Similar Building Blocks

Building Block	Special Feature
AUDI_D_FF	Pure D flip-flop without a time limit between EO events.
E_D_FF_ANY	Standard D flip-flop with universal data types, but without a minimum delay.
AUDI_D_FF_TMIN	Like AUDI_D_FF, but with the additional `Tmin` parameter to control the minimum pause between output events.



Conclusion

The **AUDI_D_FF_TMIN** is a specialized D flip-flop component that limits the output of events and values. Its adapter interface allows it to be seamlessly integrated into unidirectional communication structures. The combination of a latch function and adjustable lock time makes it a valuable tool for event-driven real-time processing in automation systems.

AUDI_LAST_2

ECC: AUDI_LAST_2

Introduction

The AUDI_LAST_2 function block merges two same-type UDINT adapter signals (**IN1**, **IN2**) into one shared output (**OUT**), using a **last-writer-wins** rule: whichever of the two sockets last wrote an event

wins, and its data value is passed through to OUT immediately and unchanged. This is explicitly not a naive merge (e.g. averaging or OR-ing) - it is pure arbitration by write order.

Interface Structure

Adapters

Input adapters (Sockets):

- **IN1**: UDINT adapter (unidirectional) - first signal source
- **IN2**: UDINT adapter (unidirectional) - second signal source

Output adapter (Plug):

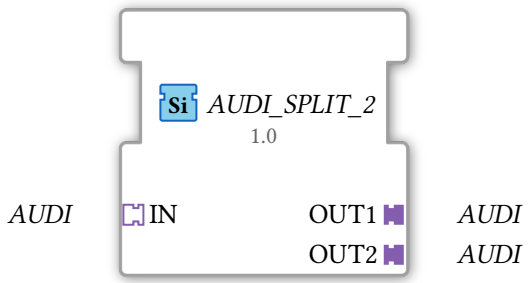
- **OUT**: UDINT adapter (unidirectional) - merged signal

How it works

The block is implemented as a simple Basic FB with a 3-state ECC (START, PASS1, PASS2). When an event arrives at IN1, the ECC moves to PASS1: IN1's current data value is copied to OUT and the adapter event is fired on OUT. When an event arrives at IN2, the same happens symmetrically via PASS2. After each pass-through the ECC immediately returns to START, ready for the next event from either input.

Technical Details

- Last-writer-wins semantics instead of a naive data combination
- Simple Basic FB (3-state ECC), no extra buffering needed
- No signal delay: the value is passed through in the same cycle the triggering event arrives
- Both inputs are equal - there is no fixed priority other than write order



Application Scenarios

- Merging two equally-valid UDINT signal sources into one downstream adapter path (e.g. two redundant sensors, or a manual and an automatic setpoint source)
- Arbitrating between two operator stations that may both write the same UDINT value
- Simplifying networks that would otherwise need an inline `F_SEL`/`E_RS` construct

⚖️ Comparison with Similar Blocks

AUDI_LAST_2 is the inverse of `AUDI_SPLIT_2`: AUDI_SPLIT_2 distributes 1 input to 2 outputs, AUDI_LAST_2 merges 2 inputs into 1 output. For mixed operation between a data adapter and a pure event adapter (e.g. AX + AE), use `AX_AE_MERGE` instead, which merges only the event without altering the data value.

AUDI_SPLIT_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_SPLIT_2** is a generic block for signal distribution. It receives a signal via a single **AUDI** adapter (unidirectional) and forwards it to two identical **AUDI** output adapters. The function block is declared as a **generic FB**, meaning the specific signal type can be defined during project configuration using the attribute `GenericClassName`. It was developed by HR Agrartechnik GmbH (Version 1.0, 2025-01-24).

Interface Structure

Event Inputs
None.

Event Outputs
None.

Data Inputs
None.

Data Outputs
None.

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AUDI`	Incoming unidirectional AUDIO adapter (signal source).
Plug	`OUT1`	`adapter::types::unidirectional::AUDI`	First output – forwards the input signal.
Plug	`OUT2`	`adapter::types::unidirectional::AUDI`	Second output – forwards the input signal.

Functionality
The module operates as a **passive splitter** without its own logic or states. The signal arriving via socket `IN` is passed through to both plugs `OUT1` and `OUT2`. The signal is forwarded unchanged and without buffering – any change at the input is immediately visible at both outputs.

Since this is a **unidirectional** adapter, data only flows from the socket to the plugs. No feedback from the outputs to the input is provided.

Technical Features
- **Generic Module**: The attribute `eclipse4diac::core::GenericClassName` allows adaptation to different AUDI types (e.g., `AUDI_Int`, `AUDI_Bool`). The actual type is only determined during instantiation.
- **No internal ECC**: The function block (FB) does not have an execution state machine because it does not process events. Data transfer is purely structural.
- **Unidirectional interface**: Both sockets and plugs are of type `adapter::types::unidirectional::AUDI`, meaning that the data flow direction is fixed.
- **Copyright**: The function block is licensed under the Eclipse Public License 2.0.

State overview
The FB does not have its own state diagrams because it does not contain any event-driven processes. Its function is limited to simple line branching.

Application scenarios
- **Signal distribution**: A central sensor or controller (e.g., a PID controller) sends a value that is to be passed on in parallel to two downstream actuators or monitoring units.
- **Redundant Monitoring**: A measured value is simultaneously sent to two independent evaluation blocks to implement comparison or safety functions.
- **Generic Adapter Architecture**: Particularly useful in systems where the specific AUDI type is only determined at runtime (e.g., in a configurable device platform).

Comparison with Similar Function Blocks
- **Non-generic Splitters** (e.g., `AUDI_SPLIT_2` with a fixed type): Do not allow type adaptation; the function block presented here is more flexible.
- **Other Splitters with More Outputs** (e.g., `AUDI_SPLIT_3`): Increase the number of branches but follow the same principle.

- **Event-based splitters** (e.g., `E_SPLIT`): These require event and data inputs/outputs and perform synchronized distribution—unlike the asynchronous data adapter split presented here.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion

The **AUDI_SPLIT_2** is a compact, generic adapter splitter for the 4diac IDE. It performs the simple task of splitting signals to two outputs without introducing additional latency or logic. Its generic design makes it suitable for a wide variety of AUDI data types and allows for flexible reuse in modular automation projects. Its simplicity and type safety make it a solid foundation for distributed control systems.

Adapters

Direction	Name	Type	Description
Socket	`IN`	`adapter::types::unidirectional::AUDI`	Incoming unidirectional AUDIO adapter (signal source).
Plug	`OUT1`	`adapter::types::unidirectional::AUDI`	First output – forwards the input signal.
Plug	`OUT2`	`adapter::types::unidirectional::AUDI`	Second output – forwards the input signal.

Functionality

The module operates as a **passive splitter** without its own logic or states. The signal arriving via socket `IN` is passed through to both plugs `OUT1` and `OUT2`. The signal is forwarded unchanged and without buffering – any change at the input is immediately visible at both outputs.

Since this is a **unidirectional** adapter, data only flows from the socket to the plugs. No feedback from the outputs to the input is provided.

Technical Features

- **Generic Module**: The attribute `eclipse4diac::core::GenericClassName` allows adaptation to different AUDI types (e.g., `AUDI_Int`, `AUDI_Bool`). The actual type is only determined during instantiation.
- **No internal ECC**: The function block (FB) does not have an execution state machine because it does not process events. Data transfer is purely structural.
- **Unidirectional interface**: Both sockets and plugs are of type `adapter::types::unidirectional::AUDI`, meaning that the data flow direction is fixed.
- **Copyright**: The function block is licensed under the Eclipse Public License 2.0.

State overview

The FB does not have its own state diagrams because it does not contain any event-driven processes. Its function is limited to simple line branching.

Application scenarios

- **Signal distribution**: A central sensor or controller (e.g., a PID controller) sends a value that is to be passed on in parallel to two downstream actuators or monitoring units.
- **Redundant Monitoring**: A measured value is simultaneously sent to two independent evaluation blocks to implement comparison or safety functions.
- **Generic Adapter Architecture**: Particularly useful in systems where the specific AUDI type is only determined at runtime (e.g., in a configurable device platform).

Comparison with Similar Function Blocks

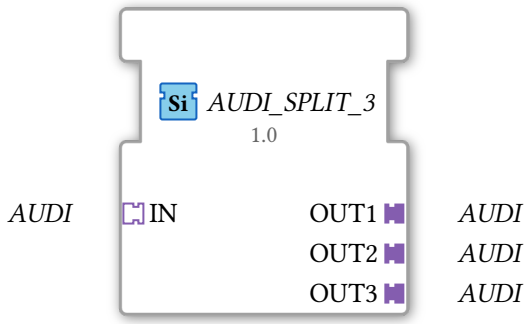
- **Non-generic Splitters** (e.g., `AUDI_SPLIT_2_UNGATED` with a fixed type): Do not allow type adaptation; the function block presented here is more flexible.
- **Other Splitters with More Outputs** (e.g., `AUDI_SPLIT_3`): Increase the number of branches but follow the same principle.
- **Event-based splitters** (e.g., `E_SPLIT`): These require event and data inputs/outputs and perform synchronized distribution—unlike the asynchronous data adapter split presented here.

Change Detection

This block performs **no** change detection. Every newly computed result is written to the output and its adapter event fired unconditionally, regardless of whether the value differs from the previous run.

Conclusion

The **AUDI_SPLIT_2_UNGATED** is a compact, generic adapter splitter for the 4diac IDE. It performs the simple task of splitting signals to two outputs without introducing additional latency or logic. Its generic design makes it suitable for a wide variety of AUDI data types and allows for flexible reuse in



modular automation projects. Its simplicity and type safety make it a solid foundation for distributed control systems.

AUDI_SPLIT_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AUDI_SPLIT_3** is used to multiply an incoming **AUDI** adapter signal to three separate outputs. It is designed as a generic function block (Generic FB) and is particularly suitable for architectures where a signal (e.g., a control or data stream) needs to be distributed to multiple downstream components.

Interface Structure

Event Inputs

- None

Event Outputs

- None

Data Inputs

- None

Data Outputs

- None

Adapter

Type	Name	Description
Socket (adapter::types::unidirectional::AUDI)	**IN**	Input adapter for receiving the AUDI signal
Plug (adapter::types::unidirectional::AUDI)	**OUT1**	First output adapter
Plug (adapter::types::unidirectional::AUDI)	**OUT2**	Second output adapter
Plug (adapter::types::unidirectional::AUDI)	**OUT3**	Third output adapter

Functionality

This module forwards the AUDI signal present at the **IN** socket unchanged to all three **OUT** plugs. No conversion, filtering, or logical processing takes place – the distribution is transparent. The use of adapters of type `unidirectional::AUDI` ensures that the signal direction (input → outputs) is clearly defined.

Technical Features

- **Generic Implementation**: The function block is implemented as a generic FB (`eclipse4diac::core::GenericClassName = 'GEN_AUDI_SPLIT'`). This allows for easy reuse in different contexts without requiring the specific AUDI type to be fully defined at development time.
- **Type Hash**: The type hash can be set at runtime if needed to enable static type checking.
- **Pure Adapter Interface**: The FB has neither event nor data inputs/outputs in the traditional sense, but communicates exclusively via adapters.

State Overview

Since the FB has no event inputs, it does not have an explicit state machine. Signal transmission occurs continuously and asynchronously as soon as the IN adapter is connected.

Application Scenarios

- **Signal Multiplication**: Distribution of a common control or measurement signal to different function blocks (e.g., parallel connection of several actuators or sensors).
- **Test and Simulation Environments**: Injecting a simulated audio signal into multiple independent analysis or monitoring paths.
- **Architecture Coupling**: Used in modular systems where a data stream needs to be passed to different subsystems without degrading the original signal.

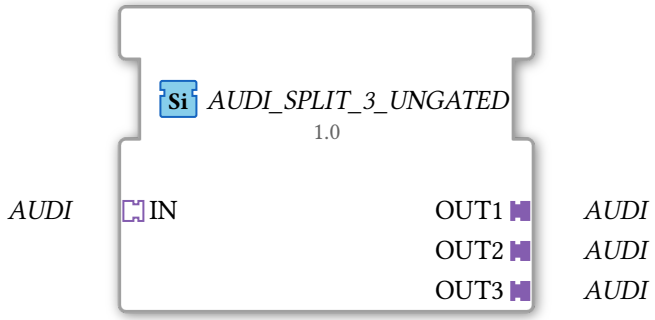
Comparison with Similar Blocks

- **AUDI_MERGE** (counterpart): A combining element that merges multiple audio inputs into one output – unlike the split block.
- **AUDI_SPLIT_2**: A splitter reduced to two outputs; this block extends this to three outputs.
- **Generic Splitters**: Many libraries contain split variants for other adapter types (e.g., `DATA_SPLIT`), but these are data-type specific.
- `AUDI_SPLIT_3_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Change Detection

Each output plug is updated independently: the incoming value is written to a given output, and its adapter event sent, only if it differs from that output's current value. Outputs that are already in sync stay quiet, while an output that was just connected (or has drifted out of sync) still receives the update it needs.

Conclusion



The **AUDI_SPLIT_3** is a simple yet useful function block for distributing a unidirectional AUDI adapter signal to three outputs. Its generic nature and pure adapter interface allow it to integrate seamlessly into event-driven and data-stream-oriented IEC 61499 applications. It provides a clean, maintainable solution for architectural signal distribution and reduces the need for manual signal routing.
