The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

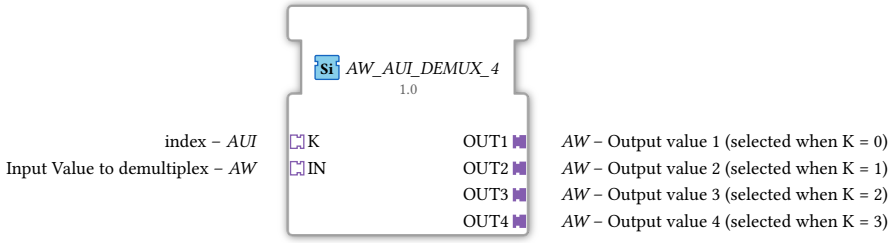
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 16-bit bit pattern to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AW_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AW_AUI_DEMUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AW_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AW_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AW_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `WORD`. Unlike `AW_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit bit pattern to forward, routed to exactly one of the outputs (AW adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AW adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AW adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AW adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_DEMUX`) – shared across all port counts of this block family (AW_AUI_DEMUX_2 … AW_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

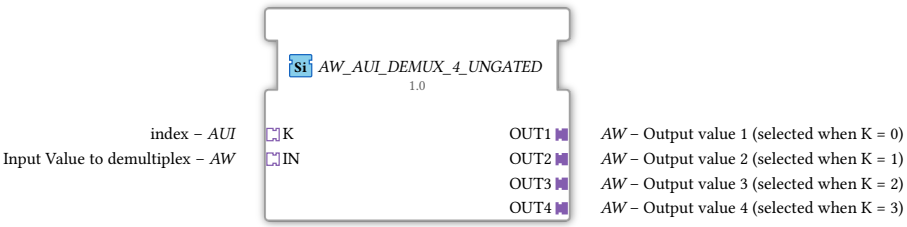
Application Scenarios

- Distributing a 16-bit bit pattern to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with AW_DEMUX_4 (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **AW_AUI_DEMUX_4_UNGATED**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

AW_AUI_DEMUX_4 carries the demultiplexer logic of the AW_DEMUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AW_AUI_DEMUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AW_AUI_DEMUX_4_UNGATED is the adapter-based variant of the generic demultiplexer for data type WORD. Unlike AW_DEMUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AW_AUI_DEMUX_4_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.

- **IN** (Socket): input adapter carrying the 16-bit bit pattern to forward, routed to exactly one of the outputs (AW adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AW adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AW adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AW adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_DEMUX`) – shared across all port counts of this block family (AW_AUI_DEMUX_2 … AW_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

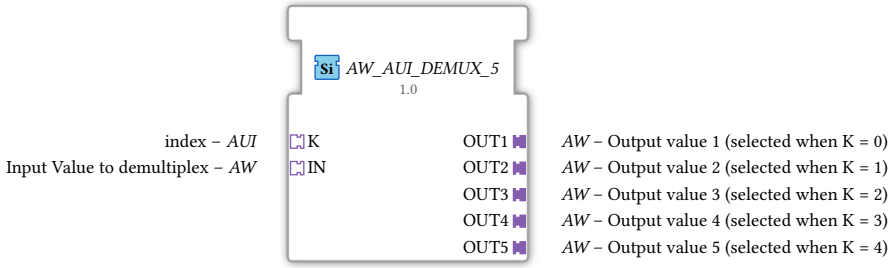
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a 16-bit bit pattern to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AW_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AW_AUI_DEMUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AW_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AW_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_DEMUX_5

• – ◦ • – ◦ • – ◦ •

Introduction

`AW_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `WORD`. Unlike `AW_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the 16-bit bit pattern to forward, routed to exactly one of the outputs (AW adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AW adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AW adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AW adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AW adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see “Change Detection” below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn’t changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_DEMUX`) – shared across all port counts of this block family (AW_AUI_DEMUX_2 … AW_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

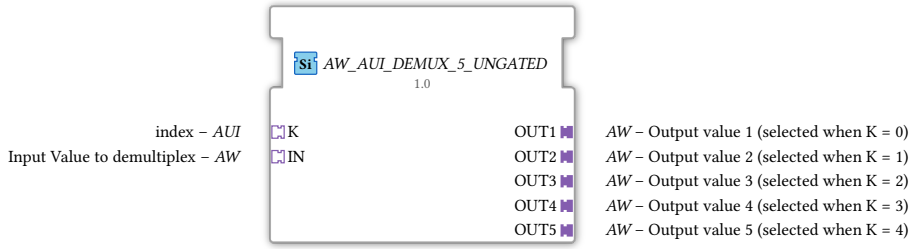
Application Scenarios

- Distributing a 16-bit bit pattern to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AW_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AW_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AW_AUI_DEMUX_5` carries the demultiplexer logic of the `AW_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_AUI_DEMUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AW_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `WORD`. Unlike `AW_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the

index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AW_AUI_DEMUX_5_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the 16-bit bit pattern to forward, routed to exactly one of the outputs (AW adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AW adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AW adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AW adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AW adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 5 output adapters (OUT1 … OUT5) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AW_AUI_DEMUX) – shared across all port counts of this block family (AW_AUI_DEMUX_2 … AW_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

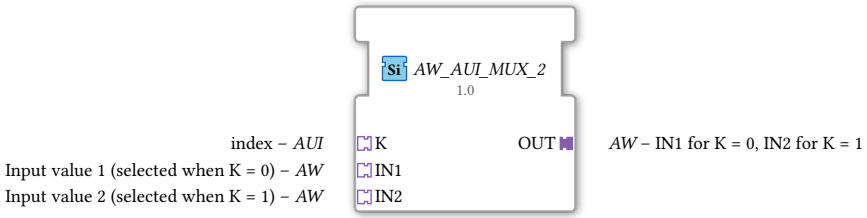
Application Scenarios

- Distributing a 16-bit bit pattern to up to 5 downstream consumers, selected via an adapter-carried index

- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AW_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AW_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AW_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AW_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_MUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AW_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `WORD`. Unlike `AW_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AW adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AW adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_MUX`) – shared across all port counts of this block family (AW_AUI_MUX_2 … AW_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

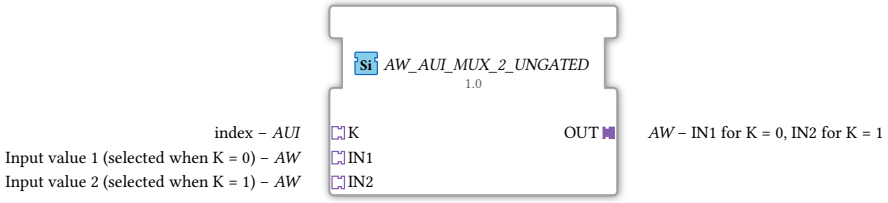
Application Scenarios

- Choosing between up to 2 16-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AW_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AW_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AW_AUI_MUX_2` carries the multiplexer logic of the `AW_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of AW_AUI_MUX_2. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AW_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `WORD`. Unlike `AW_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_MUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AW adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AW adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_MUX`) – shared across all port counts of this block family (AW_AUI_MUX_2_UNGATED … AW_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

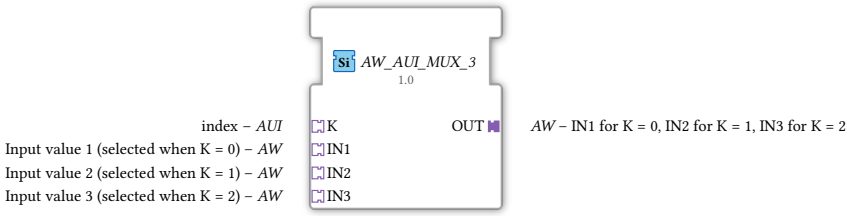
- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 16-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AW_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AW_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AW_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AW_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_MUX_3

• – ○ • – ○ • – ○ •

Introduction

`AW_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `WORD`. Unlike `AW_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AW adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AW adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AW adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_MUX`) – shared across all port counts of this block family (AW_AUI_MUX_2 … AW_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

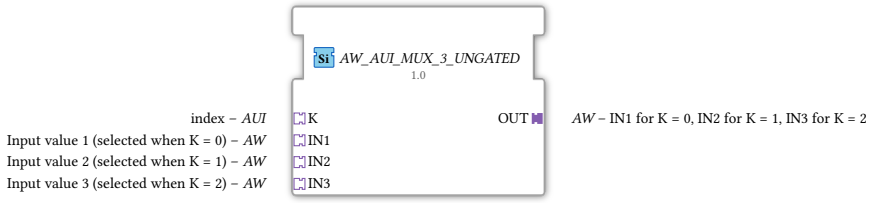
- Choosing between up to 3 16-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AW_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AW_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.



Conclusion

`AW_AUI_MUX_3` carries the multiplexer logic of the `AW_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of AW_AUI_MUX_3. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change

(e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

`AW_AUI_MUX_3_UNGATED` is the adapter-based variant of the generic multiplexer for data type `WORD`. Unlike `AW_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_MUX_3_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AW adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AW adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AW adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_MUX`) – shared across all port counts of this block family (AW_AUI_MUX_2 … AW_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 16-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AW_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AW_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AW_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AW_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AW_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `WORD`. Unlike `AW_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AW adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AW adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AW adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AW adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_MUX`) – shared across all port counts of this block family (AW_AUI_MUX_2 … AW_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

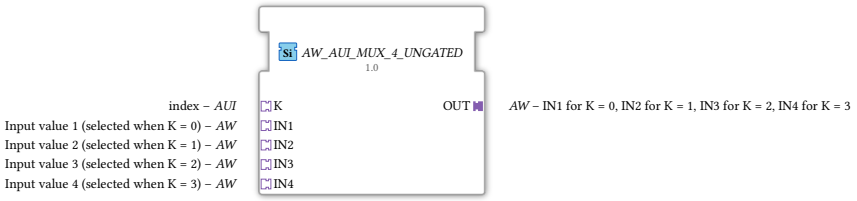
Application Scenarios

- Choosing between up to 4 16-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AW_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AW_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AW_AUI_MUX_4` carries the multiplexer logic of the `AW_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of AW_AUI_MUX_4. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AW_AUI_MUX_4_UNGATED is the adapter-based variant of the generic multiplexer for data type WORD. Unlike AW_MUX_4, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AW_AUI_MUX_4_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 4, passed through to OUT when the index is K = 0 (AW adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to OUT when the index is K = 1 (AW adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to OUT when the index is K = 2 (AW adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to OUT when the index is K = 3 (AW adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN4:

1. The current value of K.D1 determines which of the 4 input adapters (IN1 … IN4) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AW_AUI_MUX) – shared across all port counts of this block family (AW_AUI_MUX_2 … AW_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

- **Any event** (selector adapter K or IN1…IN4) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 16-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with AW_MUX_4 (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **AW_AUI_MUX_4**: The gated variant – updates the output only on an actual value change.

Conclusion

AW_AUI_MUX_4_UNGATED carries the multiplexer logic of the AW_MUX_4 family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an AUI adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

AW_AUI_MUX_5 is the adapter-based variant of the generic multiplexer for data type WORD. Unlike AW_MUX_5, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AW adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AW adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AW adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AW adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AW adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_MUX`) – shared across all port counts of this block family (AW_AUI_MUX_2 … AW_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

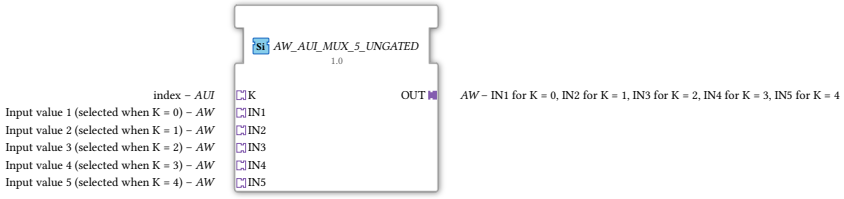
Application Scenarios

- Choosing between up to 5 16-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AW_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AW_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AW_AUI_MUX_5` carries the multiplexer logic of the `AW_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AW_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AW_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AW_AUI_MUX_5_UNGATED` is the adapter-based variant of the generic multiplexer for data type `WORD`. Unlike `AW_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AW_AUI_MUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AW adapter type).

- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AW adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AW adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AW adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AW adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AW adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AW_AUI_MUX`) – shared across all port counts of this block family (AW_AUI_MUX_2 … AW_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

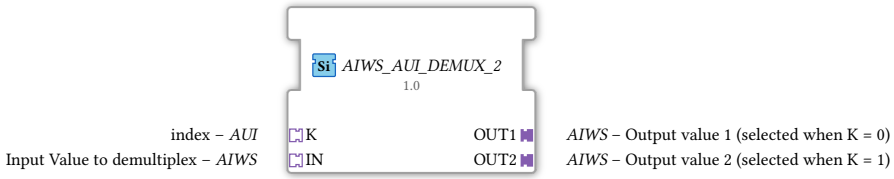
- Choosing between up to 5 16-bit bit pattern sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AW_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AW_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.



Conclusion

`AW_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AW_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

Numeric Index (unidirectional)

Here you will find all exercises from the `unidirectional` workspace, listed in ascending order. …

AIWS_AUI_DEMUX_2

• – ◦ • – ◦ • – ◦ •

Introduction

`AIWS_AUI_DEMUX_2` is the adapter-based variant of the generic demultiplexer for data type `WSTRING`. Unlike `AIWS_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_DEMUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the character string (16-bit wide characters) to forward, routed to exactly one of the outputs (AIWS adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AIWS adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_DEMUX`) – shared across all port counts of this block family (AIWS_AUI_DEMUX_2 … AIWS_AUI_DEMUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

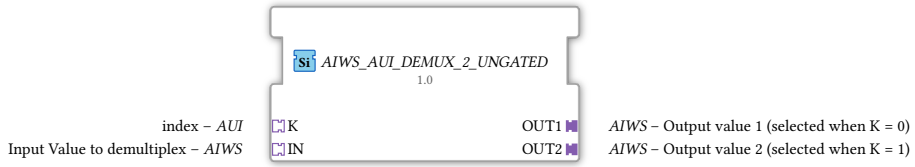
Application Scenarios

- Distributing a character string (16-bit wide characters) to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIWS_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AIWS_AUI_DEMUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIWS_AUI_DEMUX_2` carries the demultiplexer logic of the `AIWS_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_DEMUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_AUI_DEMUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AIWS_AUI_DEMUX_2_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `WSTRING`. Unlike `AIWS_DEMUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_DEMUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the character string (16-bit wide characters) to forward, routed to exactly one of the outputs (AIWS adapter type).
- **OUT1** (Plug): output adapter 1 of 2 (AIWS adapter type).
- **OUT2** (Plug): output adapter 2 of 2 (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 2 output adapters (`OUT1` … `OUT2`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_DEMUX`) – shared across all port counts of this block family (AIWS_AUI_DEMUX_2_UNGATED … AIWS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

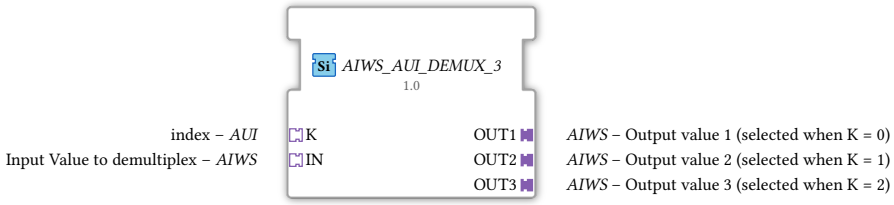
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a character string (16-bit wide characters) to up to 2 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIWS_DEMUX_2` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AIWS_AUI_DEMUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIWS_AUI_DEMUX_2_UNGATED` carries the demultiplexer logic of the `AIWS_DEMUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_DEMUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AIWS_AUI_DEMUX_3` is the adapter-based variant of the generic demultiplexer for data type `WSTRING`. Unlike `AIWS_DEMUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_DEMUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the character string (16-bit wide characters) to forward, routed to exactly one of the outputs (AIWS adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AIWS adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AIWS adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 3 output adapters (`OUT1` … `OUT3`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_DEMUX`) – shared across all port counts of this block family (AIWS_AUI_DEMUX_2 … AIWS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

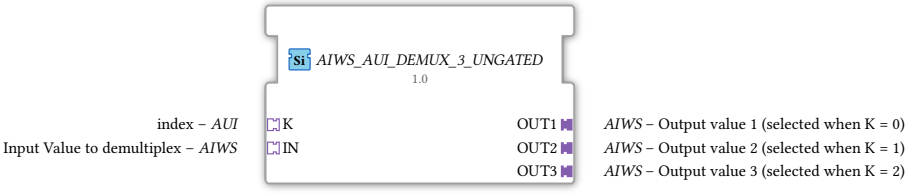
Application Scenarios

- Distributing a character string (16-bit wide characters) to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIWS_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AIWS_AUI_DEMUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIWS_AUI_DEMUX_3` carries the demultiplexer logic of the `AIWS_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_DEMUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_AUI_DEMUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ◦ • – ◦ • – ◦ •

Introduction

AIWS_AUI_DEMUX_3_UNGATED is the adapter-based variant of the generic demultiplexer for data type WSTRING. Unlike AIWS_DEMUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AIWS_AUI_DEMUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN** (Socket): input adapter carrying the character string (16-bit wide characters) to forward, routed to exactly one of the outputs (AIWS adapter type).
- **OUT1** (Plug): output adapter 1 of 3 (AIWS adapter type).
- **OUT2** (Plug): output adapter 2 of 3 (AIWS adapter type).
- **OUT3** (Plug): output adapter 3 of 3 (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from the input adapter IN:

1. The current value of K.D1 determines which of the 3 output adapters (OUT1 … OUT3) is currently selected.
2. The data value of IN is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates the current value of IN to the newly selected output immediately, even if IN hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AIWS_AUI_DEMUX) – shared across all port counts of this block family (AIWS_AUI_DEMUX_2 … AIWS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

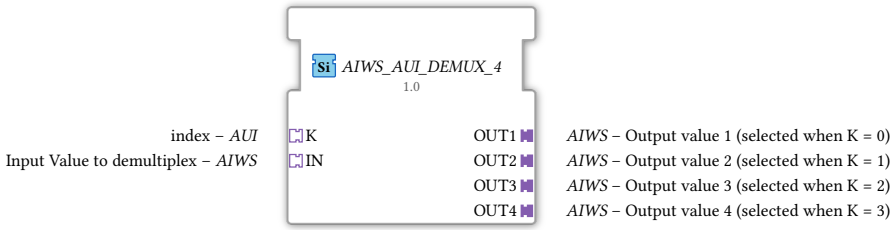
- **Any event** (selector adapter K or IN) → determine the currently selected output, update it with the current IN value on a change and send its adapter event.

Application Scenarios

- Distributing a character string (16-bit wide characters) to up to 3 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIWS_DEMUX_3` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AIWS_AUI_DEMUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIWS_AUI_DEMUX_3_UNGATED` carries the demultiplexer logic of the `AIWS_DEMUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_DEMUX_4

• – ◦ • – ◦ • – ◦ •

Introduction

`AIWS_AUI_DEMUX_4` is the adapter-based variant of the generic demultiplexer for data type `WSTRING`. Unlike `AIWS_DEMUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_DEMUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter’s own `E1`/`D1` event.

- **IN** (Socket): input adapter carrying the character string (16-bit wide characters) to forward, routed to exactly one of the outputs (AIWS adapter type).
- **OUT1** (Plug): output adapter 1 of 4 (AIWS adapter type).
- **OUT2** (Plug): output adapter 2 of 4 (AIWS adapter type).
- **OUT3** (Plug): output adapter 3 of 4 (AIWS adapter type).
- **OUT4** (Plug): output adapter 4 of 4 (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 4 output adapters (`OUT1` … `OUT4`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_DEMUX`) – shared across all port counts of this block family (AIWS_AUI_DEMUX_2 … AIWS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

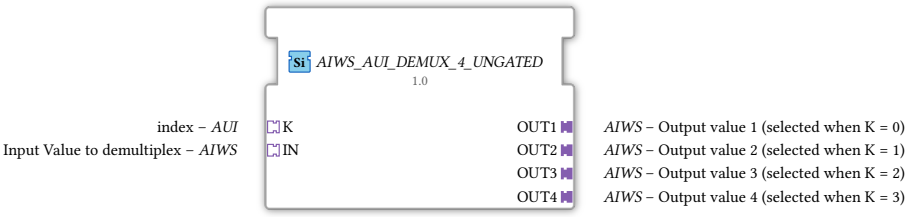
- Distributing a character string (16-bit wide characters) to up to 4 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIWS_DEMUX_4` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AIWS_AUI_DEMUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.



Conclusion

`AIWS_AUI_DEMUX_4` carries the demultiplexer logic of the `AIWS_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_DEMUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_AUI_DEMUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change

(e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

`AIWS_AUI_DEMUX_4_UNGATED` carries the demultiplexer logic of the `AIWS_DEMUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_DEMUX_5

• – ○ • – ○ • – ○ •

Introduction

`AIWS_AUI_DEMUX_5` is the adapter-based variant of the generic demultiplexer for data type `WSTRING`. Unlike `AIWS_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_DEMUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN** (Socket): input adapter carrying the character string (16-bit wide characters) to forward, routed to exactly one of the outputs (AIWS adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AIWS adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AIWS adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AIWS adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AIWS adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_DEMUX`) – shared across all port counts of this block family (AIWS_AUI_DEMUX_2 … AIWS_AUI_DEMUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN`) → determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

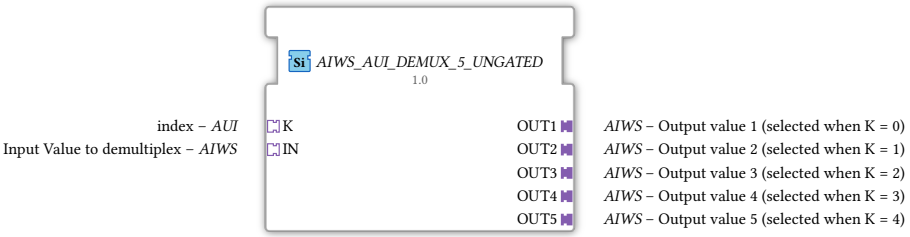
- Distributing a character string (16-bit wide characters) to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)

- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIWS_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.



- **`AIWS_AUI_DEMUX_5_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIWS_AUI_DEMUX_5` carries the demultiplexer logic of the `AIWS_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_DEMUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_AUI_DEMUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AIWS_AUI_DEMUX_5_UNGATED` is the adapter-based variant of the generic demultiplexer for data type `WSTRING`. Unlike `AIWS_DEMUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_DEMUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1/D1` event.
- **IN** (Socket): input adapter carrying the character string (16-bit wide characters) to forward, routed to exactly one of the outputs (AIWS adapter type).
- **OUT1** (Plug): output adapter 1 of 5 (AIWS adapter type).
- **OUT2** (Plug): output adapter 2 of 5 (AIWS adapter type).
- **OUT3** (Plug): output adapter 3 of 5 (AIWS adapter type).
- **OUT4** (Plug): output adapter 4 of 5 (AIWS adapter type).
- **OUT5** (Plug): output adapter 5 of 5 (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from the input adapter `IN`:

1. The current value of `K.D1` determines which of the 5 output adapters (`OUT1` … `OUT5`) is currently selected.
2. The data value of `IN` is compared against the value currently held on the selected output. Only on an actual change is that output rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates the current value of `IN` to the newly selected output immediately, even if `IN` hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_DEMUX`) – shared across all port counts of this block family (AIWS_AUI_DEMUX_2 … AIWS_AUI_DEMUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

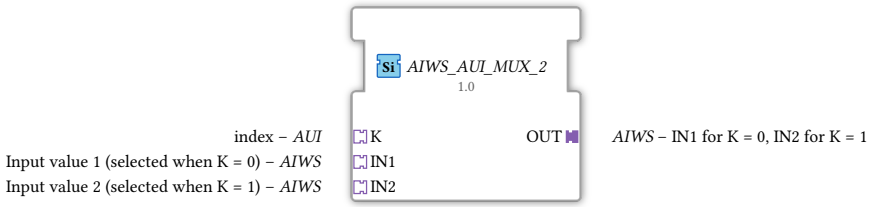
- **Any event** (selector adapter `K` or `IN`) ⟶ determine the currently selected output, update it with the current `IN` value on a change and send its adapter event.

Application Scenarios

- Distributing a character string (16-bit wide characters) to up to 5 downstream consumers, selected via an adapter-carried index
- Routing in modules that already receive the selection index as an AUI adapter link from an upstream block (no separate REQ/K pair needed)
- Building cascadable distributor networks where the index itself originates from another AUI-based block

⚖️ Comparison with Similar Blocks

Compare with `AIWS_DEMUX_5` (same distribution logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with E_DEMUX, which demultiplexes purely on events without any adapter concept.

- **`AIWS_AUI_DEMUX_5`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIWS_AUI_DEMUX_5_UNGATED` carries the demultiplexer logic of the `AIWS_DEMUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_MUX_2

• – ○ • – ○ • – ○ •

Introduction

`AIWS_AUI_MUX_2` is the adapter-based variant of the generic multiplexer for data type `WSTRING`. Unlike `AIWS_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_MUX_2` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AIWS adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AIWS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_MUX`) – shared across all port counts of this block family (AIWS_AUI_MUX_2 … AIWS_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

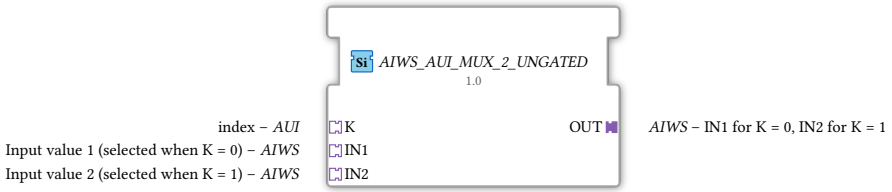
Application Scenarios

- Choosing between up to 2 character string (16-bit wide characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIWS_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.



- **`AIWS_AUI_MUX_2_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIWS_AUI_MUX_2` carries the multiplexer logic of the `AIWS_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_MUX_2_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_AUI_MUX_2`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AIWS_AUI_MUX_2_UNGATED` is the adapter-based variant of the generic multiplexer for data type `WSTRING`. Unlike `AIWS_MUX_2`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` (“Adapter Unidirectional Interface”). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_MUX_2_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 2, passed through to `OUT` when the index is `K = 0` (AIWS adapter type).
- **IN2** (Socket): input adapter 2 of 2, passed through to `OUT` when the index is `K = 1` (AIWS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN2`:

1. The current value of `K.D1` determines which of the 2 input adapters (`IN1` … `IN2`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_MUX`) – shared across all port counts of this block family (AIWS_AUI_MUX_2_UNGATED … AIWS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

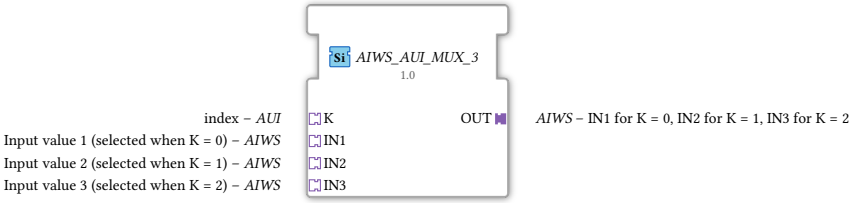
- **Any event** (selector adapter `K` or `IN1`…`IN2`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 2 character string (16-bit wide characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIWS_MUX_2` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_2, which performs the same 2:1 selection purely on data, without any adapter/event concept.

- **`AIWS_AUI_MUX_2`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIWS_AUI_MUX_2_UNGATED` carries the multiplexer logic of the `AIWS_MUX_2` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_MUX_3

• – ◦ • – ◦ • – ◦ •

Introduction

`AIWS_AUI_MUX_3` is the adapter-based variant of the generic multiplexer for data type `WSTRING`. Unlike `AIWS_MUX_3`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_MUX_3` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 3, passed through to `OUT` when the index is `K = 0` (AIWS adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to `OUT` when the index is `K = 1` (AIWS adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to `OUT` when the index is `K = 2` (AIWS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`...`IN3`:

1. The current value of `K.D1` determines which of the 3 input adapters (`IN1` … `IN3`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_MUX`) – shared across all port counts of this block family (AIWS_AUI_MUX_2 … AIWS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN3`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

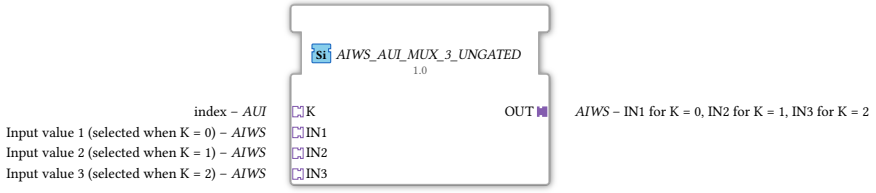
Application Scenarios

- Choosing between up to 3 character string (16-bit wide characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖ Comparison with Similar Blocks

Compare with `AIWS_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.



- **`AIWS_AUI_MUX_3_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIWS_AUI_MUX_3` carries the multiplexer logic of the `AIWS_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_MUX_3_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_AUI_MUX_3`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

AIWS_AUI_MUX_3_UNGATED is the adapter-based variant of the generic multiplexer for data type WSTRING. Unlike AIWS_MUX_3, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type AUI ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching AUI plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the AUI plug connected there fires its internal event E1 carrying the data value D1, AIWS_AUI_MUX_3_UNGATED evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (UINT, 0-based) arrives exclusively as the D1 value of the AUI adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type AUI): index input – selects the active input/output through the adapter's own E1/D1 event.
- **IN1** (Socket): input adapter 1 of 3, passed through to OUT when the index is K = 0 (AIWS adapter type).
- **IN2** (Socket): input adapter 2 of 3, passed through to OUT when the index is K = 1 (AIWS adapter type).
- **IN3** (Socket): input adapter 3 of 3, passed through to OUT when the index is K = 2 (AIWS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter K (type AUI) and on an event from one of the input adapters IN1…IN3:

1. The current value of K.D1 determines which of the 3 input adapters (IN1 … IN3) is currently selected.
2. The data value of that selected input is compared against the value currently held on OUT. Only on an actual change is OUT rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of K alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an AUI adapter.
- Generic implementation (GEN_AIWS_AUI_MUX) – shared across all port counts of this block family (AIWS_AUI_MUX_2 … AIWS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of K.D1 on every incoming event:

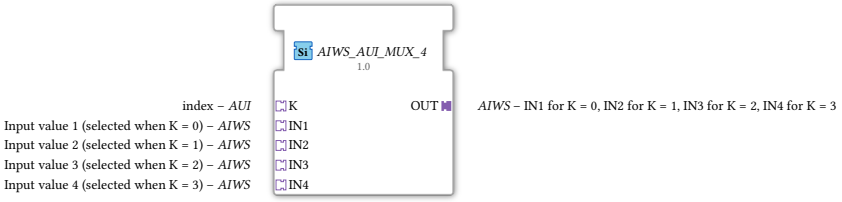
- **Any event** (selector adapter K or IN1…IN3) ⟶ read the currently selected input, update OUT on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 3 character string (16-bit wide characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIWS_MUX_3` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_3, which performs the same 3:1 selection purely on data, without any adapter/event concept.

- **`AIWS_AUI_MUX_3`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIWS_AUI_MUX_3_UNGATED` carries the multiplexer logic of the `AIWS_MUX_3` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_MUX_4

• – ○ • – ○ • – ○ •

Introduction

`AIWS_AUI_MUX_4` is the adapter-based variant of the generic multiplexer for data type `WSTRING`. Unlike `AIWS_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_MUX_4` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AIWS adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AIWS adapter type).

- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AIWS adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AIWS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_MUX`) – shared across all port counts of this block family (AIWS_AUI_MUX_2 … AIWS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

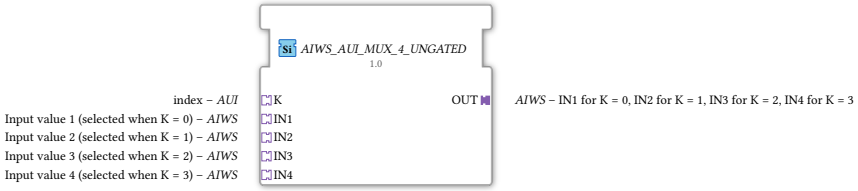
Application Scenarios

- Choosing between up to 4 character string (16-bit wide characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIWS_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.



- **`AIWS_AUI_MUX_4_UNGATED`**: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIWS_AUI_MUX_4` carries the multiplexer logic of the `AIWS_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_MUX_4_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_AUI_MUX_4`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• — ○ • — ○ • — ○ •

Introduction

`AIWS_AUI_MUX_4_UNGATED` is the adapter-based variant of the generic multiplexer for data type `WSTRING`. Unlike `AIWS_MUX_4`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_MUX_4_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 4, passed through to `OUT` when the index is `K = 0` (AIWS adapter type).
- **IN2** (Socket): input adapter 2 of 4, passed through to `OUT` when the index is `K = 1` (AIWS adapter type).
- **IN3** (Socket): input adapter 3 of 4, passed through to `OUT` when the index is `K = 2` (AIWS adapter type).
- **IN4** (Socket): input adapter 4 of 4, passed through to `OUT` when the index is `K = 3` (AIWS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN4`:

1. The current value of `K.D1` determines which of the 4 input adapters (`IN1` … `IN4`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_MUX`) – shared across all port counts of this block family (AIWS_AUI_MUX_2 … AIWS_AUI_MUX_5).

- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`...`IN4`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 4 character string (16-bit wide characters) sources through a centrally managed adapter index

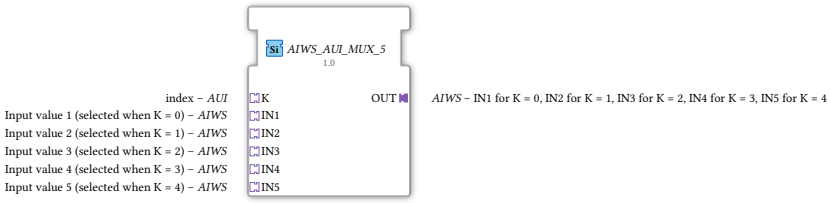
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIWS_MUX_4` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).



Compare with F_MUX_4, which performs the same 4:1 selection purely on data, without any adapter/event concept.

- **`AIWS_AUI_MUX_4`**: The gated variant – updates the output only on an actual value change.

Conclusion

`AIWS_AUI_MUX_4_UNGATED` carries the multiplexer logic of the `AIWS_MUX_4` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_MUX_5

• – ○ • – ○ • – ○ •

Introduction

`AIWS_AUI_MUX_5` is the adapter-based variant of the generic multiplexer for data type `WSTRING`. Unlike `AIWS_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_MUX_5` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AIWS adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AIWS adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AIWS adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AIWS adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AIWS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_MUX`) – shared across all port counts of this block family (AIWS_AUI_MUX_2 … AIWS_AUI_MUX_5).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

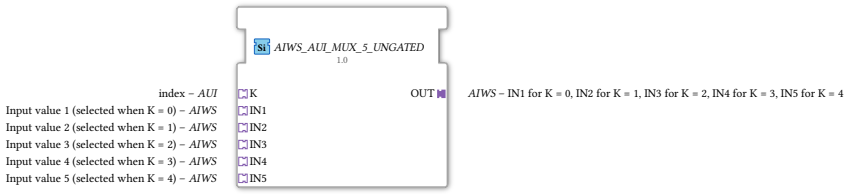
- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

- Choosing between up to 5 character string (16-bit wide characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

Compare with `AIWS_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).
No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.



- `AIWS_AUI_MUX_5_UNGATED`: Ungated variant – updates the output on every run, even without a value change.

Conclusion

`AIWS_AUI_MUX_5` carries the multiplexer logic of the `AIWS_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

AIWS_AUI_MUX_5_UNGATED

> **i UNGATED variant:** This block is the ungated version of `AIWS_AUI_MUX_5`. It suppresses **no** unchanged repeats – every newly computed result is forwarded unconditionally, even without a value change. This matters for consumers that need a periodic cadence regardless of value change (e.g. derivative/frequency calculations that would otherwise fail to decay toward zero). Any change-detection/gating statements further down this page do **not** apply to this block.

• – ○ • – ○ • – ○ •

Introduction

`AIWS_AUI_MUX_5_UNGATED` is the adapter-based variant of the generic multiplexer for data type `WSTRING`. Unlike `AIWS_MUX_5`, it does not receive the selection index through a REQ event with an associated K data input, but through its own adapter socket **K** of type `AUI` ("Adapter Unidirectional Interface"). This lets the index be fed directly from another block with a matching `AUI` plug, without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- No explicit event inputs on the block itself. The index is received exclusively through the adapter socket **K**: as soon as the `AUI` plug connected there fires its internal event `E1` carrying the data value `D1`, `AIWS_AUI_MUX_5_UNGATED` evaluates the index internally and triggers processing.

Event Outputs

- No event outputs.

Data Inputs

- No direct data inputs. The index (`UINT`, 0-based) arrives exclusively as the `D1` value of the `AUI` adapter connected to socket **K**.

Data Outputs

- No direct data outputs.

Adapters

- **K** (Socket, type `AUI`): index input – selects the active input/output through the adapter's own `E1`/`D1` event.
- **IN1** (Socket): input adapter 1 of 5, passed through to `OUT` when the index is `K = 0` (AIWS adapter type).
- **IN2** (Socket): input adapter 2 of 5, passed through to `OUT` when the index is `K = 1` (AIWS adapter type).
- **IN3** (Socket): input adapter 3 of 5, passed through to `OUT` when the index is `K = 2` (AIWS adapter type).
- **IN4** (Socket): input adapter 4 of 5, passed through to `OUT` when the index is `K = 3` (AIWS adapter type).
- **IN5** (Socket): input adapter 5 of 5, passed through to `OUT` when the index is `K = 4` (AIWS adapter type).
- **OUT** (Plug): output adapter, forwards whichever input the index selected (AIWS adapter type).

Functionality

The function block re-evaluates the current value of **K** on every incoming event – both on an event from the selector adapter `K` (type `AUI`) and on an event from one of the input adapters `IN1`…`IN5`:

1. The current value of `K.D1` determines which of the 5 input adapters (`IN1` … `IN5`) is currently selected.
2. The data value of that selected input is compared against the value currently held on `OUT`. Only on an actual change is `OUT` rewritten and its adapter event sent (see "Change Detection" below).

As a result, a pure change of `K` alone also propagates to the output immediately, even if the data value of the newly selected input hasn't changed since its own last event.

Technical Details

- Adapter-based index input instead of the classic REQ/K input pair – reduces wiring when the index is already available as an `AUI` adapter.
- Generic implementation (`GEN_AIWS_AUI_MUX`) – shared across all port counts of this block family (AIWS_AUI_MUX_2 … AIWS_AUI_MUX_5_UNGATED).
- **Change detection**: the written output plug is only updated – and its adapter event only sent – when the new value differs from the value currently held on that plug. If the value is unchanged, no adapter event is sent, avoiding redundant updates for downstream peers.

State Overview

The function block has no explicit state machine; instead it re-evaluates the current value of `K.D1` on every incoming event:

- **Any event** (selector adapter `K` or `IN1`…`IN5`) ⟶ read the currently selected input, update `OUT` on a value change and send its adapter event.

Application Scenarios

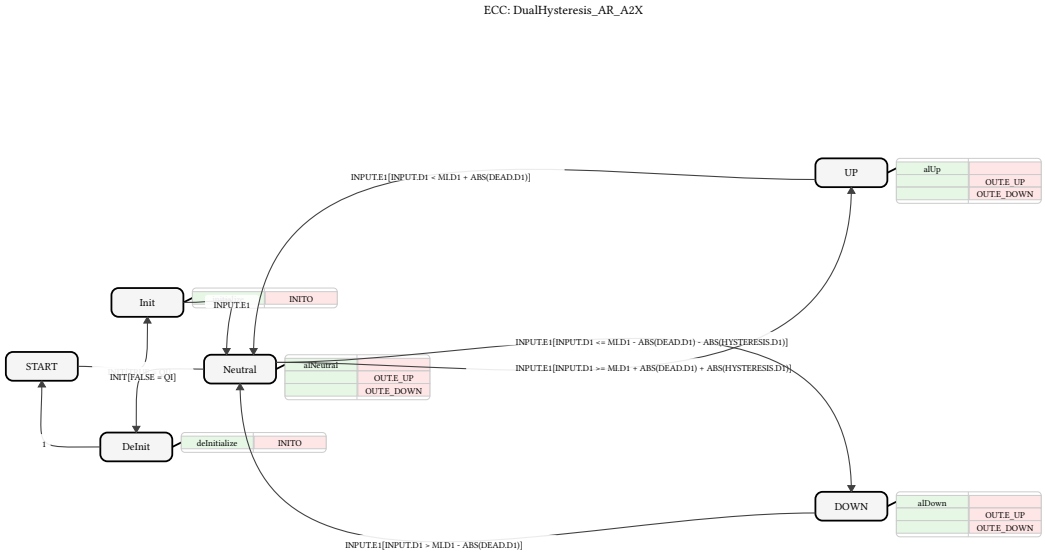
- Choosing between up to 5 character string (16-bit wide characters) sources through a centrally managed adapter index
- Replacing a REQ/K input pair with a single AUI adapter link when the index is already provided as an adapter by another block
- Building selection networks in which several MUX blocks share the same index adapter

⚖️ Comparison with Similar Blocks

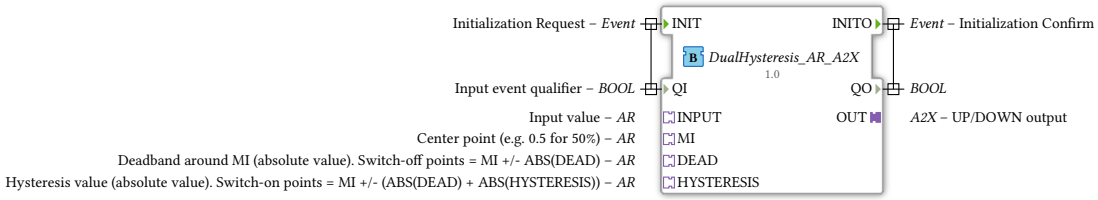
Compare with `AIWS_MUX_5` (same selection logic, but the index arrives through a classic **REQ** event plus **K** data input instead of an adapter).

No purely data-based `F_MUX` counterpart exists for this input count in the `iec61131-3` library.

- **`AIWS_AUI_MUX_5`**: The gated variant – updates the output only on an actual value change.



Conclusion



`AIWS_AUI_MUX_5_UNGATED` carries the multiplexer logic of the `AIWS_MUX_5` family over to a purely adapter-based index supply. This makes it the right choice whenever the selection index is already available as an `AUI` adapter from another block and no additional event/data wiring for the index is wanted.

2.8.0.4 Signalprocessing

Hysteresis

DualHysteresis_AR_A2X

• — ○ • — ○ • — ○ •

Introduction

The **DualHysteresis_AR_A2X** function block implements a two-way analog-to-digital conversion with configurable hysteresis and deadband. It monitors an analog input value and generates discrete UP/DOWN signals based on the relationship between the input and a configurable center point (MI). The block distinguishes between a switch-on threshold (wider due to hysteresis) and a switch-off threshold (narrower due to deadband only), providing clean and stable digital output transitions without chatter around the switching points. The outputs are provided via a single unidirectional A2X adapter interface, combining both event and data signals for UP and DOWN states.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Initialization Request.

Event Outputs

Event	Type	Comment
INIT.O	EInit	Initialization Confirm.

Data Inputs

Data	Type	Comment
QI	BOOL	Input event qualifier. When QI = TRUE, normal processing is enabled. When FALSE, the block operates in safe state.

Data Outputs

Data	Type	Comment
QO	BOOL	Output qualifier reflecting the last accepted QI value during operation.

Adapters

Direction	Name	Type	Comment
Plug	OUT	adapter::types::unidirectional::A2X	UP/DOWN output providing E_UP, E_DOWN events and UP, DOWN boolean data.
Socket	INPUT	adapter::types::unidirectional::AR	Analog input value (event E1, data D1).
Socket	MI	adapter::types::unidirectional::AR	Center point (e.g., 0.5 for 50%).
Socket	DEAD	adapter::types::unidirectional::AR	Deadband around MI (absolute value). Switch-off points = MI ± ABS(DEAD).
Socket	HYSTERESIS	adapter::types::unidirectional::AR	Hysteresis value (absolute value). Switch-on points = MI ± (ABS(DEAD) + ABS(HYSTERESIS)).

Functionality

The block converts a continuous analog input (via the INPUT adapter) into discrete two-state output signals. The conversion depends on the analog input value INPUT.D1, the center point MI.D1, the deadband DEAD.D1, and the hysteresis HYSTERESIS.D1.

The switching behavior is as follows:

- **Switch-on UP** (inclusive): When the input rises to or above MI.D1 + ABS(DEAD.D1) + ABS(HYSTERESIS.D1), the output transitions to the UP state.
- **Switch-off UP** (strict): When the input falls strictly below MI.D1 + ABS(DEAD.D1), the block leaves the UP state and returns to Neutral.
- **Switch-on DOWN** (inclusive): When the input falls to or below MI.D1 - ABS(DEAD.D1) - ABS(HYSTERESIS.D1), the output transitions to the DOWN state.
- **Switch-off DOWN** (strict): When the input rises strictly above MI.D1 - ABS(DEAD.D1), the block leaves the DOWN state and returns to Neutral.

All transitions are triggered by the INPUT.E1 event, which indicates that a new analog value is available on INPUT.D1.

The algorithms executed in each state set the UP and DOWN data outputs on the OUT adapter accordingly. The corresponding events OUT.E_UP and OUT.E_DOWN are emitted on each state change.

If QI = FALSE, the block remains in a safe state and sets both UP and DOWN outputs to FALSE, suppressing any digital output signals.

Technical Features

- **Deadband & Hysteresis Separation**: The switch-off threshold is determined only by the deadband, while the switch-on threshold adds the hysteresis value. This creates a well-defined gap between on and off points, preventing oscillation due to noise.
- **Absolute Value Handling**: The DEAD and HYSTERESIS values are taken as absolute values internally, simplifying configuration even when negative values are provided.

- **Event-Driven Processing**: All evaluations occur on the `INPUT.E1` event, ensuring deterministic behavior aligned with incoming analog updates.
- **Parameterizable Center Point**: The `MI` adapter allows setting an arbitrary center point (e.g., 50%), making the block suitable for a wide range of scaling applications.
- **Unidirectional Adapter Output**: The output is bundled in a single A2X adapter containing both events (`E_UP`, `E_DOWN`) and data (`UP`, `DOWN`), simplifying wiring in 4diac applications.
- **Initialization and De-initialization**: The block supports explicit initialization via `INIT` and safe shutdown via de-initialization, with `QO` reflecting the qualifier state.

State Overview

The internal state machine consists of six states:

State	Description
`START`	Initial power-up state.
`Init`	Performs initialization; sets `QO := QI` and clears UP/DOWN outputs; emits `INITO`.
`Neutral`	Idle state with no UP/DOWN activity; both outputs are `FALSE`.
`UP`	Active UP state; sets `OUT.UP := TRUE`, `OUT.DOWN := FALSE`; emits `E_UP`.
`DOWN`	Active DOWN state; sets `OUT.UP := FALSE`, `OUT.DOWN := TRUE`; emits `E_DOWN`.
`DeInit`	De-initialization state; clears outputs and sets `QO := FALSE`; emits `INITO`.

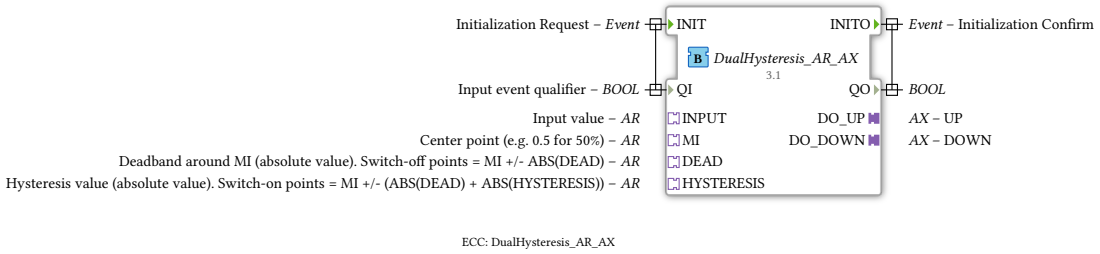
Transitions:

- `START` → `Init` on `INIT` with `QI = TRUE`.
- `Init` → `Neutral` on first `INPUT.E1` event.
- `Neutral` → `UP` when `INPUT.D1 >= MI.D1 + ABS(DEAD.D1) + ABS(HYSTERESIS.D1)`.
- `Neutral` → `DOWN` when `INPUT.D1 <= MI.D1 - ABS(DEAD.D1) - ABS(HYSTERESIS.D1)`.
- `UP` → `Neutral` when `INPUT.D1 < MI.D1 + ABS(DEAD.D1)`.
- `DOWN` → `Neutral` when `INPUT.D1 > MI.D1 - ABS(DEAD.D1)`.
- `Neutral` → `DeInit` on `INIT` with `QI = FALSE`.
- `DeInit` → `START` unconditionally.

Application Scenarios

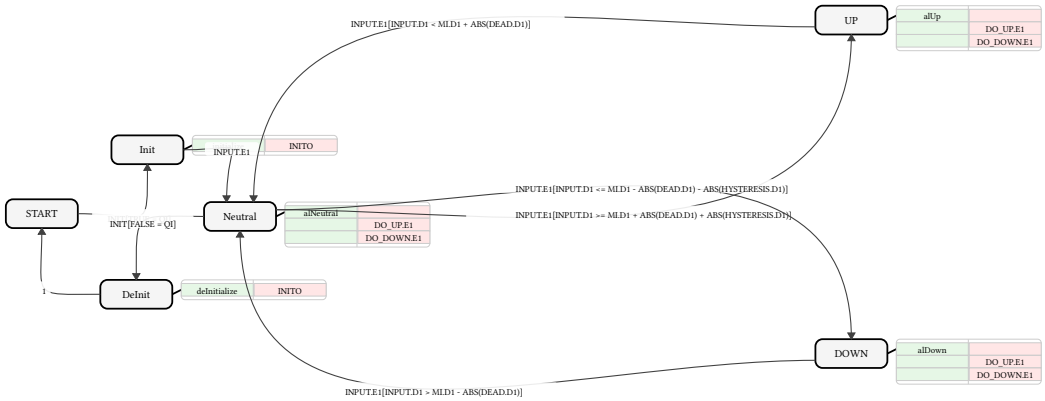
- **Level Monitoring**: Monitoring tank or silo fill levels, where a sensor provides a continuous analog signal and discrete high/low alarms are required with hysteresis to avoid relay chattering.
- **Temperature Control**: Switching heating or cooling elements based on temperature thresholds with a deadband/hysteresis configuration to prevent rapid cycling.
- **Limit Switch Replacement**: Replacing mechanical limit switches with non-contact analog sensors, using the block to derive clean digital position signals.
- **Motor Control**: Generating direction commands (UP/DOWN) for actuators (e.g., valves, drives) based on a setpoint and allowable deadband.
- **Industrial Automation**: In PLC and distributed control systems, where reliable two-state signals must be derived from analog process variables.

Comparison with Similar Blocks



Compared to a simple comparator or single-threshold hysteresis block, **DualHysteresis_AR_A2X** offers:

- **Two-way (bidirectional) evaluation**: Both rising and falling input signals are processed symmetrically, with separate switch-on and switch-off thresholds.
- **Independent deadband and hysteresis parameters**: The user can define the deadband (non-switching zone) and hysteresis (influence on switch-on point) separately, providing greater flexibility than blocks with a single parameter.
- **Unified output adapter**: All output signals (UP/DOWN events and data) are packaged in one adapter, reducing wiring complexity in comparison to blocks with multiple separate output ports.
- **Safe-state behavior**: When `QI` is false, the block guarantees both outputs are reset to `FALSE`, which is not always the case in simpler hysteresis implementations.



Conclusion

The **DualHysteresis_AR_A2X** function block provides a robust and flexible solution for converting analog signals into discrete UP/DOWN control outputs. By separating deadband and hysteresis, it offers precise control over switching behavior, preventing oscillation and ensuring reliable operation in industrial automation environments. Its event-driven design, adapter-based interfaces, and clear state machine make it well-suited for integration into 4diac-based control applications.

DualHysteresis_AR_AX

ECC: DualHysteresis_AR_AX

(No image available)

• – ○ • – ○ • – ○ •

Introduction

The function block `DualHysteresis_AR_AX` performs dual analog-to-digital conversion with hysteresis. It compares an analog input signal with a defined midpoint (`MI`) to output control commands via two separate digital outputs (UP and DOWN). This corresponds to the operation of a classic three-position controller with deadband and hysteresis thresholds. The block is designed for signal processing in control and regulation applications and uses adapters for structured signal coupling.

Interface Structure

Event Inputs

- `INIT` (Type: `EInit`): Initialization request. Starts or stops the function block depending on the data input `QI`.

Event Outputs

- `INITO` (Type: `EInit`): Initialization confirmation. Signals the successful transition to the initialized or deinitialized state.

Data Inputs

- `QI` (Type: `BOOL`): Input event qualifier. Determines whether the function block should operate actively (`TRUE`) or be placed in the safe deinitialization state (`FALSE`).

Data Outputs

- `QO` (Type: `BOOL`): Output event qualifier. Reflects the current status and operational readiness of the function block.

Adapters

- **Plugs:**
- `DO_UP` (Type: `adapter::types::unidirectional::AX`): Output adapter for the upward movement/ upper threshold (UP).
- `DO_DOWN` (Type: `adapter::types::unidirectional::AX`): Output adapter for downward movement/ lower threshold (DOWN).
- **Sockets:**
- `INPUT` (Type: `adapter::types::unidirectional::AR`): The current analog measurement or input value.
- `MI` (Type: `adapter::types::unidirectional::AR`): The center point or setpoint of the control (e.g., `0.5` for 50%).
- `DEAD` (Type: `adapter::types::unidirectional::AR`): The deadband around the center point (absolute value). Defines the cutoff points.
- `DEAD` (Type: `adapter::types::unidirectional::AR`): The deadband around the center point (absolute value). Defines the cutoff points. * `HYSTERESIS` (Type: `adapter::types::unidirectional::AR`): The hysteresis (absolute value). Together with the deadband, it defines the switch-on points.

Functionality

The state switching is event-driven via the input `INPUT.E1`. The mathematical evaluation ensures that negative parameter inputs for the deadband (`DEAD`) and the hysteresis (`HYSTERESIS`) are handled by using absolute values (`ABS`).

The logical thresholds behave as follows:

- **Switch to UP (switch to UP):**

$$INPUT \geq MI + |DEAD| + |HYSTERESIS| \tag{2.124}$$

(Outputs: `DO_UP.D1 = TRUE`, `DO_DOWN.D1 = FALSE`)

- **Switch UP (Return to Neutral):**

$$INPUT < MI + |DEAD| \tag{2.125}$$

(Ausgänge: `DO_UP.D1 = FALSE`, `DO_DOWN.D1 = FALSE`)

- **Einschalten DOWN (Wechsel nach DOWN):**

$$INPUT \leq MI - |DEAD| - |HYSTERESIS| \tag{2.126}$$

(Ausgänge: `DO_UP.D1 = FALSE`, `DO_DOWN.D1 = TRUE`)

- **Ausschalten DOWN (Wechsel zurück nach Neutral):**

$$INPUT > MI - |DEAD| \tag{2.127}$$

(Outputs: `DO_UP.D1 = FALSE`, `DO_DOWN.D1 = FALSE`)

Technical Features

- **Error Safety through Absolute Values:** The threshold calculations explicitly use the `ABS` function for the Parameters `DEAD` and `HYSTERESIS` prevent malfunctions caused by accidentally set negative values.

Safe State: In the deinitialized state (`QI` = `FALSE`) or in the state `Neutral`, both digital outputs (`DO_UP.D1` and `DO_DOWN.D1`) are forcibly set to `FALSE`.

Safe State: In the deinitialized state (`QI` = `FALSE`) or in the state `Neutral`, both digital outputs (`DO_UP.D1` and `DO_DOWN.D1`) are forcibly set to `FALSE`. * **Adapter Connection:** The use of `AR` (Analog Receiver) and

AX (Digital Actuator) adapters ensures standardized, clean encapsulation of the signal paths within the 4diac IDE.

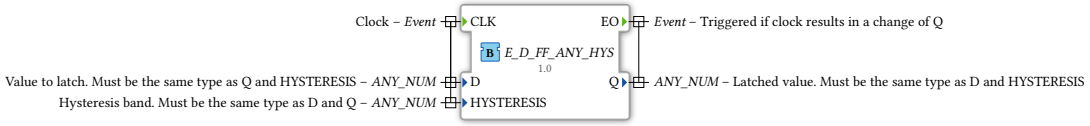
State Overview

The module is based on a state machine (ECC) with the following states:

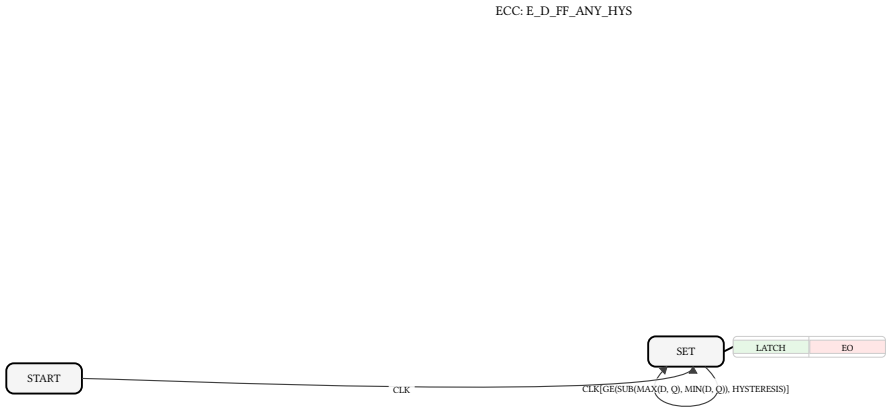
1. START: Idle state before initialization.
2. Init: Initialization phase. Sets the outputs to a safe state.
3. Neutral: The input value is within the permissible range. Both outputs are inactive.
4. UP: The upper turn-on point has been exceeded. Output DO_UP is active.
5. DOWN: The lower activation point has been reached. Output DO_DOWN is active.
6. DeInit: Transition state for deactivating the function block.

Application Scenarios

- **Three-point controller:** Temperature control (e.g., heating / neutral / cooling) or level control (e.g., open inlet valve / neutral / open outlet valve).
- **Track Guidance and Steering Systems:** Automatic steering systems in agricultural or logistics where deviations from the track center (MI) to the left (DOWN) or right (UP) need to be corrected.
- **Setpoint Band Monitoring:** Monitoring of physical quantities where an actuator should only be activated when there are significant deviations (deadband + hysteresis) to prevent constant actuator "flutter."



Comparison with Similar Components



Classic hysteresis components (e.g., two-point controllers) only control a single digital output. The DualHysteresis_AR_AX combines two opposing hysteresis loops in a single component (three-point behavior). Furthermore, compared to standard function blocks with elementary data types, it is distinguished by the use of unidirectional adapters (AR and AX), which simplifies wiring in complex applications.

Conclusion

The DualHysteresis_AR_AX is a robust and flexible function block for implementing three-point control. Thanks to the mathematical validation of the limit values and the clearly defined state behavior, it is ideally suited for demanding control tasks where actuators must be controlled gently and without chatter.

E_D_FF_ANY_HYS

• – ○ • – ○ • – ○ •

Introduction

The function block `E_D_FF_ANY_HYS` is an edge-triggered D flip-flop (data latch) for numeric data types with integrated hysteresis. It serves to store (latch) an input value and make it available at the output. However, an output update and the triggering of the output event only occur with a clock signal if the change in the input value compared to the current output value reaches or exceeds the defined hysteresis threshold.

Interface Structure

Event Inputs

- **CLK**: Clock Input. Upon the occurrence of this event, the system checks whether the input value `D` has changed by at least the value of `Q` compared to the current output value `HYSTERESIS`.

Event Outputs

- **EO**: Event Output. Triggered when a clock event (`CLK`) results in an actual value change and update of the output `Q`.

Data Inputs

- **D** (`ANY_NUM`): The current data value to be read.
- **HYSTERESIS** (`ANY_NUM`): The hysteresis band. Specifies the minimum difference that must exist between `D` and `Q` for the output to be updated.

Data Outputs

- **Q** (`ANY_NUM`): The stored (latched) value.

Adapters

- *No adapters available.*

Functionality

The function block operates internally using an Execution Control Chart (ECC) and a simple assignment algorithm:

1. **Initialization**: On first startup, the block is in state `START`. The first `CLK` event leads directly to state `SET`. The algorithm `LATCH` is executed, which writes the current value of `D` to the output `Q`. Simultaneously, the output event `EO` is sent.

The process executes the algorithm `LATCH`, which writes the current value of `D` to the output `Q`.
... 2. **Hysteresis Check for Subsequent Events**: If the function block is in state `SET`, each subsequent `CLK` event will only lead to a re-execution of `SET` (and thus to an update of `Q` and the firing of `EO`) if the following condition is met:

$$| D - Q | \geq \text{HYSTERESIS} \tag{2.128}$$

In the ECC condition, this is mathematically implemented using the formula `GE(SUB(MAX(D, Q), MIN(D, Q)), HYSTERESIS)`. This corresponds to the absolute difference between the input value `D` and the currently stored value `Q`. 3. If the difference is less than the value of `HYSTERESIS`, the event is ignored, the output `Q` remains unchanged, and no `EO` event is triggered.

Technical Features

- **Generic Data Type**: By using the data type `ANY_NUM` for the inputs and outputs, the function block is highly reusable and can be interconnected with various numeric data types (e.g., `INT`, `REAL`, `LREAL`).
- **Efficient Difference Calculation**: The difference calculation using `SUB(MAX(D, Q), MIN(D, Q))` ensures that a positive absolute value is always used for comparison with the hysteresis, regardless of whether the new value is greater or less than the old value.

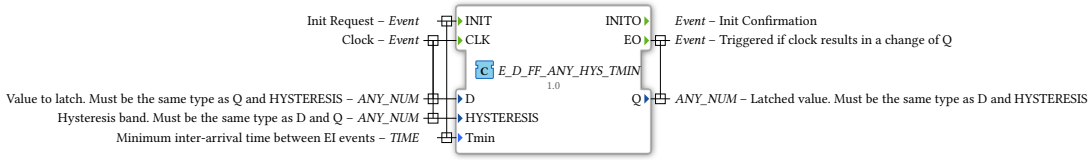
Status Overview

START –(CLK)–> [SET (Algorithmus: LATCH, Ausgang: EO)] | +–(CLK [Differenz >= HYSTERESIS])–> (erneuter Aufruf von SET)

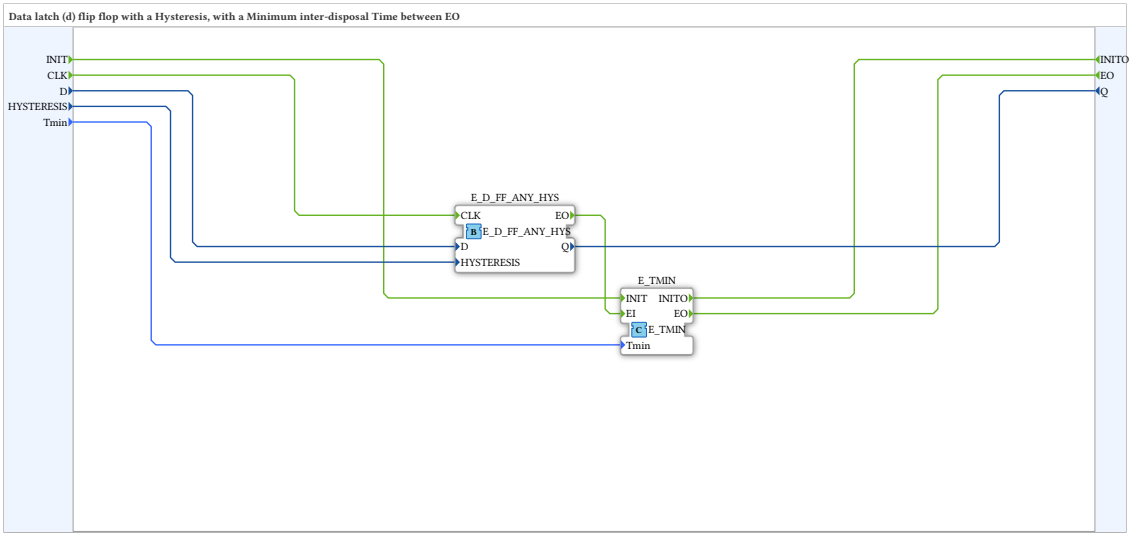
- **START**: Waiting state before the first clock cycle.
- **SET**: State in which the input value is accepted and output. This state is called cyclically at each valid clock cycle (taking hysteresis into account).

Application Scenarios

- **Noise Filtering for Analog Sensor Values**: Reduction of event floods in distributed systems. If a sensor (e.g., a temperature sensor) continuously delivers slightly fluctuating values, hysteresis prevents new control events from being constantly distributed throughout the system in response to minimal changes.
- **Limit Monitoring with Deadband**: Prevention of signal bounce when transmitting process values to visualizations (HMI) or databases.



Comparison with Similar Function Blocks



- **E_D_FF**: The standard D flip-flop typically reacts at the Boolean level or unconditionally stores values at each clock cycle. `E_D_FF_ANY_HYS` additionally filters the values using the hysteresis condition.
- **Hysteresis blocks (e.g., with Boolean output)**: Typical hysteresis blocks compare a value with fixed thresholds and output a `BOOL` signal (e.g., threshold switch). `E_D_FF_ANY_HYS`, on the other hand, outputs the numerical value itself as soon as it has changed significantly.

Conclusion

The `E_D_FF_ANY_HYS` is an extremely useful block for data- and event-driven signal processing. It combines the memory function of a D flip-flop with intelligent noise and change filtering for numerical signals, thus significantly contributing to performance optimization and reducing the event load in IEC 61499 applications.

E_D_FF_ANY_HYS_TMIN

• – ○ • – ○ • – ○ •

The function block `E_D_FF_ANY_HYS_TMIN` is a composite function block for IEC 61499-based systems. It implements an edge-triggered D flip-flop (data latch) with integrated threshold hysteresis and a minimum time interval limit (`Tmin`) for outgoing events.

This block is used to filter continuous or high-frequency changes in a numerical input signal. A new output event is only generated if the signal change exceeds the defined hysteresis and a defined minimum time interval has elapsed since the last output event. This effectively prevents so-called “event flooding” in distributed control systems.

Event	Type	Description	Associated Data
INIT	EInit	Initializes the function block and sets the minimum time limit.	`Tmin`
CLK	Event	Clock signal. When this event occurs, the value at input `D` is evaluated.	`D`, `HYSTERESIS`
Event	Type	Description	Associated Data
:—	:—	:—	:—
INITO	EInit	Confirmation of successful initialization.	None
EO	Event	Triggered when a CLK event has caused a valid change to the output value `Q` and the minimum time `Tmin` has elapsed.	`Q`
Variable	Type	Description	
:—	:—	:—	
D	ANY_NUM	The input value (Data) to be stored.	
HYSTERESIS	ANY_NUM	The hysteresis band. Determines how much `D` must differ from the current output value `Q` to trigger a change.	
Tmin	TIME	The minimum time interval that must elapse between two consecutive `EO` events.	
Variable	Type	Description	
:—	:—	:—	
Q	ANY_NUM	The stored and filtered output value (latched value).	

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters
This function block does not use any adapters.

Functionality
The module internally combines two specialized function blocks:

1. A hysteresis memory module (`E_D_FF_ANY_HYS`)
2. A time-limited event timer (`E_TMIN`)

As soon as an event arrives at input `CLK`, the internal module `E_D_FF_ANY_HYS` reads the current value from `D`.

- If the difference between the new value `D` and the currently stored value `Q` lies outside the range defined by `HYSTERESIS`, `Q` is updated with the new value and an internal event is forwarded to the limiter `E_TMIN`.
- If the change lies within the hysteresis band, the value remains unchanged and no event is forwarded.

The function block `E_TMIN` monitors the forwarding of this event to the output `EO`. It ensures that at least the time interval `Tmin` elapses between two `EO` events. Rapidly successive events are delayed or filtered accordingly to protect the subsequent logic from excessive event load.

- **Generic Data Types (`ANY_NUM`):** By using the generic data type `ANY_NUM` for `D`, `HYSTERESIS`, and `Q`, the function block is highly reusable and can be used for various numeric types (e.g., `INT`, `REAL`, `LREAL`).
- **Combined Filtering:** The function block combines amplitude filtering (hysteresis) and time filtering (Tmin) in a single component.

1. **Uninitialized:** The function block is waiting for the event `INIT`.
2. **Initialized / Ready:** The function block has configured `Tmin` and is waiting for events at input `CLK`.
3. **Value Change Blocked (Hysteresis):** A `CLK` event arrives, but the change in `D` is too small. `Q` remains unchanged; there is no `EO`.
4. **Value Change Active (Time Delay/Filtering):** A `CLK` event arrives, and the change is large enough. When `Tmin` expires, `Q` is updated and `EO` is immediately output. If `Tmin` is still active, the timer's protection function is activated.

- **Analog Sensor Value Processing:** Attenuation and noise reduction for noisy analog measurements (e.g., temperature, pressure, or fill level).
- **Network-Friendly Data Transmission:** Reduction of publish events in IoT or SCADA systems (e.g., MQTT). Data is only sent when a value has changed significantly, but at most every "X" seconds.
- **Resource Efficiency in PLC Controllers:** Relieving the CPU of cyclic calculations that would be triggered by high-frequency signal changes.

2.9 Comparison with Similar Components

- **`E_D_FF`:** Stores values directly at each clock cycle without hysteresis or time limiting. This results in extremely high event density with turbulent signals.
- **`E_D_FF_ANY_HYS`:** While it does have hysteresis, it offers no protection against rapid, continuous signal changes (e.g., during fast ramps), which would still generate too many events. `E_D_FF_ANY_HYS_TMIN` solves this problem with the integrated `Tmin` component.

The `E_D_FF_ANY_HYS_TMIN` is an extremely useful component for signal conditioning in industrial environments. It combines value-based filtering with time-based rate limiting. This makes it ideal for stable control architectures where sensor values need to be precisely acquired, but downstream systems must be protected from overload.

Technical Features

Comparison with Similar Function Blocks

Conclusion

Hysteresis

ECC: Hysteresis

• — ○ • — ○ • — ○ •

Introduction

The function block `Hysteresis` serves as an analog-to-digital converter with an integrated hysteresis curve. It converts an analog input signal (`INPUT`) into a binary output signal (`OUTPUT`). By defining a threshold (`THRESHOLD`) and a hysteresis width (`HYSTERESIS`), unwanted bounce or rapid oscillation of the output with noisy input signals is effectively prevented.

• — ○ • — ○ • — ○ •

Interface Structure

Event Inputs

- **INIT**: Initializes the function block. Updates the output qualifier `QO` based on `QI`.
- **REQ**: Triggers a calculation of the hysteresis state based on the current input values.

Event Outputs

- **INITO**: Confirms completion of initialization or deinitialization.
- **CNF**: Confirms execution of the calculation and signals that an updated output value is available.

Data Inputs

- **QI** (BOOL): Input event qualifier. Controls the validity of the input data and the activation of the function block.
- **INPUT** (REAL): The analog input signal to be monitored.
- **THRESHOLD** (REAL, default value: `0.0`): The midpoint of the hysteresis band (setpoint).
- **HYSTERESIS** (REAL, default value: `0.1`): The total width of the hysteresis band.

Data Outputs

- **QO** (BOOL): Output event qualifier (indicates whether the function block is active and ready for operation).
- **OUTPUT** (BOOL): The digital output signal of the hysteresis element.

Adapters

This function block does not use adapters.

• – ◦ • – ◦ • – ◦ •

Operation

The function block operates with a symmetrical hysteresis band around the defined midpoint (`THRESHOLD`). To ensure consistent behavior even with negative hysteresis values, the absolute value (`ABS`) of the hysteresis is used internally.

The switching thresholds are calculated as follows:

- **Switch-on point:** $THRESHOLD + \frac{|HYSTERESIS|}{2.0}$
- **Switch-off point:** $THRESHOLD - \frac{|HYSTERESIS|}{2.0}$

Switching logic

1. If the function block is in the **sOFF** state (output is `FALSE`), the output switches to `TRUE` (**sON**) as soon as the input signal reaches or exceeds the upper threshold:

$$\text{INPUT} \geq \text{THRESHOLD} + \frac{|\text{HYSTERESIS}|}{2.0} \tag{2.129}$$

1. If the function block is in the **sON** state (output is The output (`TRUE`) only switches back to `FALSE` (**sOFF**) when the input signal falls well below the lower limit:

$$\text{INPUT} < \text{THRESHOLD} - \frac{|\text{HYSTERESIS}|}{2.0} \tag{2.130}$$

• – ◦ • – ◦ • – ◦ •

Technische Besonderheiten

- **Schwingungsschutz:** Die Ausschaltbedingung verwendet eine strikte Ungleichung ($<$), während die Einschaltbedingung inklusiv ist ($\geq$). Dies verhindert Oszillationen exakt an den Grenzen des Hysteresebands.
- **Sicherheitsverriegelung über QI:** Der Ausgang `OUTPUT` kann nur dann den Zustand `TRUE` annehmen, wenn der Eingangs-Qualifier `QI` auf `TRUE` gesetzt ist. Ist `QI` im Zustand `FALSE`, bleibt der Ausgang gesperrt (`FALSE`).
- **Robustheit:** Durch die Verwendung von `ABS(HYSTERESIS)` im Algorithmus führt die Eingabe einer negativen Hysterese nicht zu einem Fehlverhalten des Bausteins.

• – ◦ • – ◦ • – ◦ •

Zustandsübersicht

Der Funktionsbaustein ist als Basic-FB mit einer Execution Control Chart (ECC) realisiert:

1. **START**: Der Standard-Ruhezustand nach dem Systemstart.
2. **Init**: Wird durch das Ereignis `INIT` bei gesetztem `QI = TRUE` aufgerufen. Initialisiert den Baustein und setzt den Ausgang `OUTPUT` auf `FALSE`.
3. **sOFF**: Der Zustand, in dem die Ausschaltbedingung erfüllt ist (`OUTPUT = FALSE`).
4. **sON**: Der Zustand, in dem die Einschaltbedingung erfüllt ist (`OUTPUT = TRUE` sofern `QI = TRUE`).

5. **DeInit**: Wird durch `INIT` bei `QI = FALSE` aufgerufen. Setzt `QO` und `OUTPUT` zurück auf `FALSE`.

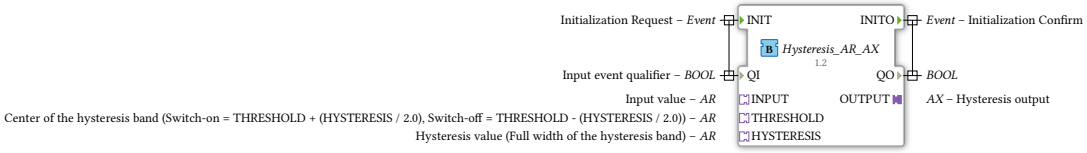
• – ○ • – ○ • – ○ •

Anwendungsszenarien

- **Zweipunktregler:** Temperaturregelung (z. B. Heizung ein bei $< 19^\circ$ C, aus bei $> 21^\circ$ C with a threshold of 20° C and a hysteresis of 2° C).
- **Level Monitoring:** Activates a pump when a maximum level is reached and deactivates it when the minimum level is reached.
- **Noise Reduction:** Digitizes noisy analog sensor signals (e.g., pressure or brightness sensors) to eliminate fluctuating signal levels at the output.

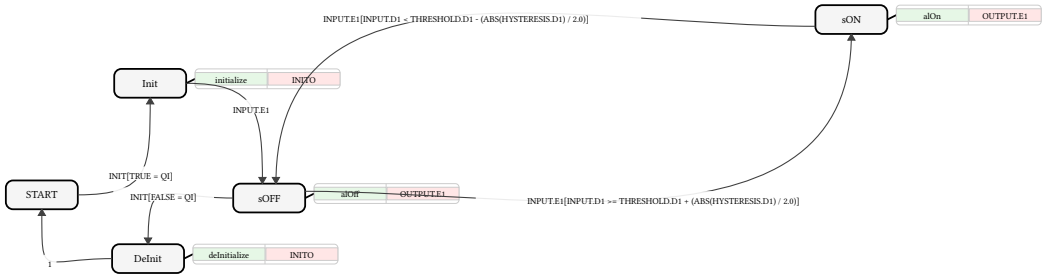
• – ○ • – ○ • – ○ • –

Comparison with Similar Components



Compared to a simple comparator (e.g., `GT` or `GE`), which switches immediately upon any minimal exceedance or fall below a specified value, the `Hysteresis` component offers inherent signal stabilization through its two switching thresholds. It combines the logic of two comparators and an RS flip-flop into a single, easily accessible component.

• – ○ • – ○ • – ○ •



Conclusion

The `Hysteresis` component is an essential tool in signal processing and control engineering within the IEC 61499 standard. It provides a robust, easy-to-configure solution for generating stable binary control signals from continuous analog input values.

Hysteresis_AR_AX

ECC: Hysteresis_AR_AX

• – ○ • – ○ • – ○ •

Introduction

The function block `Hysteresis_AR_AX` is a basic function block (BFB) for event-driven signal processing according to IEC 61499. It performs analog-to-digital conversion of an analog input signal, taking into account an adjustable hysteresis. This prevents small signal fluctuations or noise around a threshold value from causing rapid, unwanted switching back and forth of the digital output (oscillation).

Interface Structure

Event Inputs

- **INIT**: Initialization request (`EInit`). Enables or disables the block in conjunction with the input `QI`.

Event Outputs

- **INITO**: Initialization Confirmation (`EInit`). Signals the completion of initialization or deinitialization in conjunction with `QO`.

Data Inputs

- **QI** (BOOL): Input Event Qualifier. Determines whether the function block should be active (`TRUE`) or deinitialized (`FALSE`).

Data Outputs

- **QO** (BOOL): Output Event Qualifier. Displays the current status of the function block activation.

Adapters

The function block uses standardized, unidirectional adapters for clean, modular coupling of data and events.

- **Sockets (Input Adapters):**
- **INPUT** (`adapter::types::unidirectional::AR`): The analog input value to be monitored. The value is present at `INPUT.D1`; the evaluation is triggered by the event `INPUT.E1`.
- **THRESHOLD** (`adapter::types::unidirectional::AR`): The midpoint of the hysteresis band (`THRESHOLD.D1`).
- **HYSTERESIS** (`adapter::types::unidirectional::AR`): The total width of the hysteresis band (`HYSTERESIS.D1`).
- **Plugs (Output Adapters):**
- **OUTPUT** (`adapter::types::unidirectional::AX`): The digital output signal. Outputs the switching result at data point `OUTPUT.D1` (BOOL) and triggers the output via the event `OUTPUT.E1`.

Functionality

The hysteresis is defined symmetrically around the threshold value (`THRESHOLD`). The total width of the hysteresis band is specified by the parameter `HYSTERESIS`.

Calculation Formulas

To avoid misconfigurations, the absolute value of the hysteresis width (`ABS(HYSTERESIS.D1)`) is always used internally.

1. **Switch-on Condition:**

The output switches on (`OUTPUT.D1 := TRUE`) when the input value reaches or exceeds the upper limit of the hysteresis band:

$$\text{INPUT.D1} \geq \text{THRESHOLD.D1} + \frac{|\text{HYSTERESIS.D1}|}{2.0} \tag{2.131}$$

1. **Switch-off Condition:**

The output switches off (`OUTPUT.D1 := FALSE`) when the input value falls well below the lower limit of the hysteresis band:

$$\text{INPUT.D1} < \text{THRESHOLD.D1} - \frac{|\text{HYSTERESIS.D1}|}{2.0} \tag{2.132}$$

Technical Features

- **Oscillation Prevention:** By using a A strict inequality ($<$) when switching off and a soft inequality ($\geq$) when switching on guarantees stable behavior at the exact limits of the hysteresis band.
- **Absolute Hysteresis:** By using the `ABS` function in the Execution Control Chart (ECC), the function block also functions correctly if a negative value is incorrectly passed for the hysteresis width.
- **Adapter-Based Architecture:** The use of unidirectional adapters (`AR` / `AX`) consolidates data and event lines. This significantly improves clarity in the application diagram.

State Overview

The behavior is controlled via the following states in the Execution Control Chart (ECC):

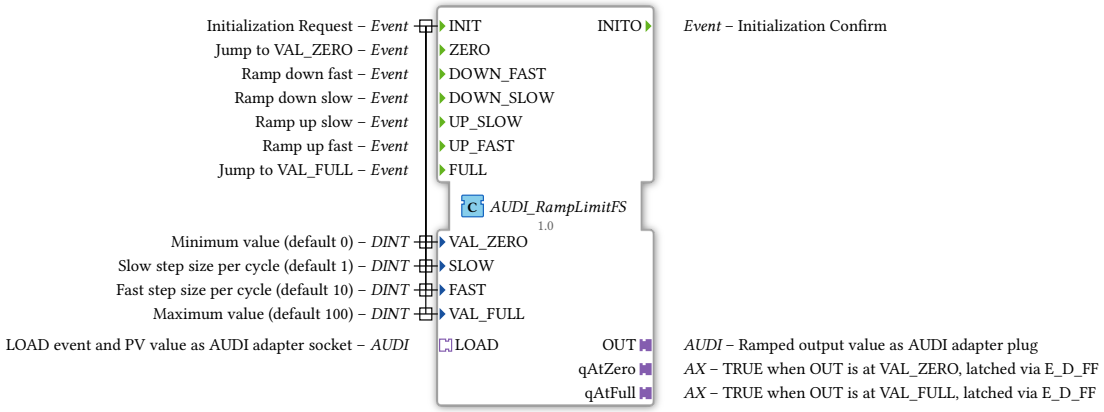
1. **START**: Idle state before initialization.
2. **Init**: Resets output `OUTPUT.D1` and sets `QO := QI`.
3. **sOFF**: State of the off output. The algorithm `alOff` ensures that `OUTPUT.D1` is set to `FALSE`. A transition to `sON` occurs as soon as the on condition is met.
4. **sON**: State of the on output. The algorithm `alOn` sets `OUTPUT.D1` to `TRUE` (if `QI` is active). A transition back to `sOFF` occurs as soon as the shutdown condition is met.
5. **DeInit**: Deinitialization state. Resets the outputs in a controlled manner.

Application Scenarios

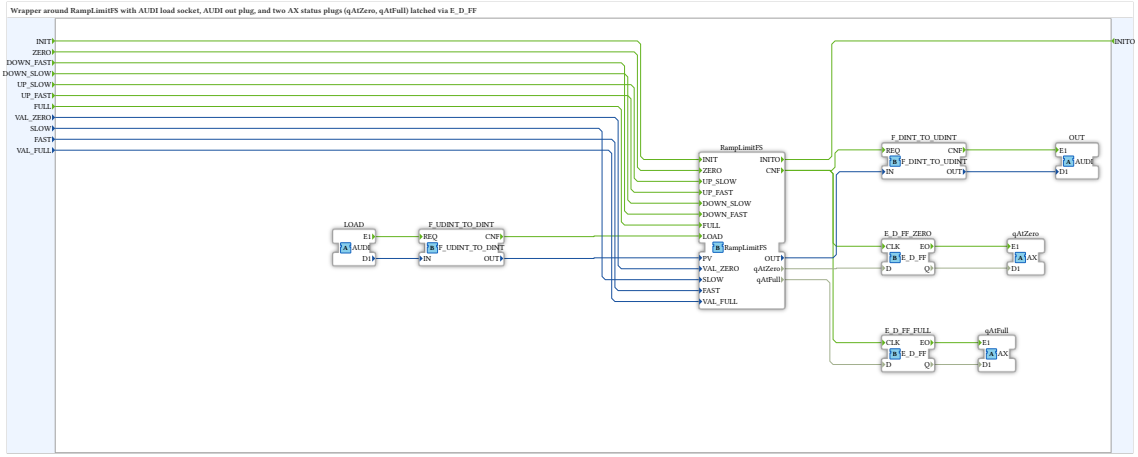
- **Two-Point Temperature Control:** Controls a heating system. The heating system switches on when the temperature falls below the setpoint minus half the hysteresis and switches off again only when the temperature exceeds the setpoint plus half the hysteresis.
- **Level Control:** Switches pumps in tanks on and off. Prevents the pumps from switching continuously due to turbulent liquid surfaces (wave motion).
- **Limit Monitoring in Process Areas:** Converts noisy analog sensor values (e.g., pressure, flow rate) into stable digital alarm signals.

2.10 · Comparison with Similar Components

Unlike classic comparator components (such as `GT` or `LT`), which react immediately to even the slightest threshold violation, the `Hysteresis_AR_AX` buffers the signal through the defined band.



Compared to standard hysteresis circuits, which often use separate pins for data and trigger events, this component significantly simplifies signal routing in more complex 4diac applications thanks to its standardized adapter concept (`AR`/`AX`).



Conclusion

The `Hysteresis_AR_AX` is a highly efficient and robust component for signal preprocessing. Thanks to its integrated absolute hysteresis calculation and asymmetric switching conditions, it offers high reliability in practical operation. The consistent use of adapters allows it to integrate seamlessly into modern, service-oriented control architectures.

Ramp

AUDI_RampLimitFS

• – ○ • – ○ • – ○ •

Introduction

The **AUDI_RampLimitFS** function block is a composite wrapper designed to integrate the ramp functionality of the `RampLimitFS` FB with an AUDI adapter interface. It provides a seamless connection between unidirectional AUDI sockets/plugs and the internal ramp generator, while also exposing latched status flags (`qAtZero` and `qAtFull`) through AX adapters. The FB accepts a setpoint via a `LOAD` socket, applies ramp-up/down or jump commands, and outputs the ramped value via the `OUT` plug. The two status plugs indicate whether the current output has reached the defined minimum or maximum value, with the latched behavior ensuring the flags persist until the next corresponding event.

Interface Structure

Event Inputs

Event	Type	Comment
`INIT`	EInit	Initialization request, sets internal parameters and initializes the ramp generator.
`ZERO`	Event	Jump to `VAL_ZERO` (minimum value).
`DOWN_FAST`	Event	Ramp down at fast speed.
`DOWN_SLOW`	Event	Ramp down at slow speed.
`UP_SLOW`	Event	Ramp up at slow speed.
`UP_FAST`	Event	Ramp up at fast speed.
`FULL`	Event	Jump to `VAL_FULL` (maximum value).

Event Outputs

Event	Type	Comment
`INITO`	EInit	Initialization confirm signal.

Data Inputs

Name	Type	Initial Value	Comment
`VAL_ZERO`	DINT	0	Minimum value of the ramp range.
`SLOW`	DINT	1	Step size for slow ramp operations.
`FAST`	DINT	10	Step size for fast ramp operations.

VAL_FULL	DINT	100	Maximum value of the ramp range.

Data Outputs

There are no direct data outputs; all data is communicated through adapters.

Adapters

Name	Type	Direction	Comment
LOAD	adapter::types::unidirectional::AUDI	Socket	Receives a load request (E1) and a process value (D1, type UDINT) to be used as the ramp setpoint.
OUT	adapter::types::unidirectional::AUDI	Plug	Delivers the ramped output value (D1, type UDINT) and an output event (E1).
qAtZero	adapter::types::unidirectional::AX	Plug	Status flag: TRUE when the output equals VAL_ZERO; latched via an internal E_D_FF.
qAtFull	adapter::types::unidirectional::AX	Plug	Status flag: TRUE when the output equals VAL_FULL; latched via an internal E_D_FF.

Functionality

The AUDI_RampLimitFS block encapsulates a RampLimitFS FB and provides a convenient adapter-based interface. Internally, the following data flow is implemented:

1. **Load Request**: An event on the LOAD socket (E1) triggers a conversion of the incoming UDINT value (D1) to DINT using F_UDINT_TO_DINT. The converted value is passed as the setpoint (PV) to the RampLimitFS FB.
2. **Ramp Control**: The events ZERO, DOWN_FAST, DOWN_SLOW, UP_SLOW, UP_FAST, and FULL are directly forwarded to the corresponding event inputs of the RampLimitFS FB. These events control how the output moves towards the setpoint:
   - ZERO causes an immediate jump to VAL_ZERO.
   - FULL causes an immediate jump to VAL_FULL.
   - The ramp events (DOWN_*, UP_*) cause the output to move stepwise in the specified direction and speed.
3. **Output Generation**: When the RampLimitFS completes a step or a jump (indicated by its CNF event), the current DINT output is converted back to UDINT via F_DINT_TO_UDINT and delivered on the OUT plug along with an E1 event.
4. **Status Latching**: The RampLimitFS provides boolean flags qAtZero and qAtFull indicating whether the current output is exactly at VAL_ZERO or VAL_FULL. These flags are latched using two E_D_FF (D-type flip-flop) FBs, one per status. On each CNF event, the current flag value is sampled and stored; the latched value is then propagated to the corresponding AX plug (qAtZero.D1 or qAtFull.D1) along with an event E1.
5. **Initialization**: The INIT event transfers the parameters (VAL_ZERO, SLOW, FAST, VAL_FULL) to the internal RampLimitFS and initiates its own initialization. Upon completion, INITO is emitted.

Technical Features

- **Adapter Integration**: Combines AUDI and AX adapter types for a clean, IEC 61499-compliant interface.
- **Type Conversion**: Automatically converts between UDINT (adapter data) and DINT (internal ramp calculations) using standard conversion FBs.
- **Latched Status**: The qAtZero and qAtFull flags are latched via edge-triggered D flip-flops, ensuring that the status remains stable until the next output change.

- **Configurable Ramp Limits**: The minimum (`VAL_ZERO`) and maximum (`VAL_FULL`) values are user-definable, as are the step sizes for slow and fast ramping.
- **Composite Architecture**: Built entirely from standard FBs (`RampLimitFS`, conversion FBs, and E_D_FF), making it easy to inspect and modify.

State Overview

The behavior of the internal `RampLimitFS` can be described in terms of operational states, which are reflected in the events and the status flags:

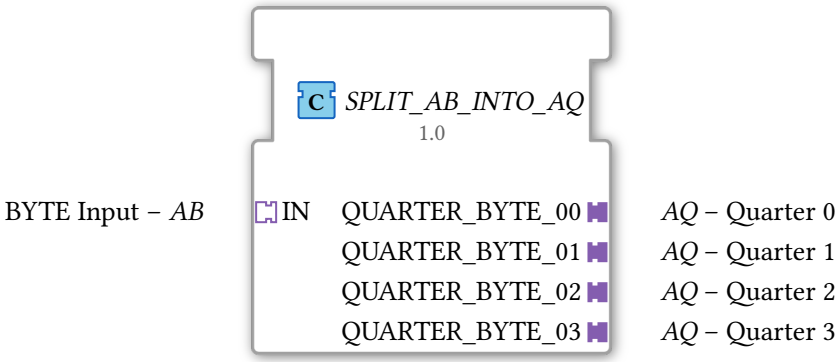
- **Idle / Initialized**: After `INIT`, the output is typically set to `VAL_ZERO` (or the last value). No ramp operations are active.
- **Jump to Zero / Full**: When `ZERO` or `FULL` is issued, the output directly moves to the respective limit. The corresponding status flag (`qAtZero` or `qAtFull`) is set and latched.
- **Ramping**: During `UP_*` or `DOWN_*` operations, the output changes stepwise by `SLOW` or `FAST` increments/decrements per cycle. The process continues until the setpoint is reached or a different command is issued.
- **Limit Reached**: When the output reaches either limit, the associated status flag becomes active and remains latched until a new command moves the output away.

Application Scenarios

- **Motion Control**: Adjusting a motor speed or position with configurable acceleration/deceleration rates, using fast/slow ramps to avoid mechanical stress.
- **Process Automation**: Smoothly transitioning a process variable (e.g., temperature, flow) between setpoints, with automatic clamping to safety minimum/maximum values.
- **HMI Integration**: The AUDI adapter format is ideal for connecting to visualization or supervisory systems that exchange UDINT data, while the AX status plugs provide simple boolean indication for limit states.

Comparison with Similar Blocks

- **vs. Standard `RampLimitFS`**: The `AUDI_RampLimitFS` adds an adapter layer and latched status outputs. It simplifies integration by hiding the conversion steps and provides a more standardized interface for industrial applications.
- **vs. Simple Ramp FBs without status**: Many basic ramp blocks only output the ramped value; this FB additionally provides explicit, latched limit indicators, which can be used for alarm or interlock logic.
- **vs. PID or other closed-loop controllers**: Unlike controllers, this block does not perform feedback regulation; it only generates a time-based ramp signal towards a given setpoint.



Conclusion

AUDI_RampLimitFS is a robust, adaptable function block that encapsulates a proven ramp generator with a modern adapter-based interface. Its use of AUDI and AX adapters promotes interoperability, while the internal type conversions and latched status flags reduce the effort required for integration and monitoring. The block is suitable for a wide range of applications where controlled, limit-bounded transitions of a numeric output are needed.

2.10.0.1 Numeric Index (adapter)

Here you will find all exercises from the `adapter` workspace, listed in ascending order. …

SPLIT_AB_INTO_AQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_AB_INTO_AQ` is used to split a data byte received via a `AB` adapter (byte) into four individual 2-bit quartets and output each of these via a `AQ` adapter (quarter). It encapsulates the decomposition of a byte into manageable partial values and makes them available for further processing via standardized unidirectional adapter interfaces.

Interface Structure

Event Inputs

Name	Description
`IN.E1`	An event at the socket triggers the decomposition and output of the quartets.

Event Outputs

No direct event outputs; output is provided via the events of the connected adapters (`QUARTER_BYTE_xx.E1`).

Data Inputs

Name	Description
`IN.D1`	The incoming data byte (type: BYTE) that is split into four quartets.

Data Outputs

No direct data outputs; the quartets are provided via the data interfaces of the output adapters (`QUARTER_BYTE_xx.D1`).

Adapters

Name	Type	Direction	Description
`IN`	`adapter::types::unidirectional::AB`	Socket (Input)	Receives the byte to be parsed, including the event.
`QUARTER_BYTE_00`	`adapter::types::unidirectional::AQ`	Plug (Output)	Outputs the quartet 0 (least significant 2 bits).
`QUARTER_BYTE_01`	`adapter::types::unidirectional::AQ`	Plug (Output)	Outputs the quartet 1.
`QUARTER_BYTE_02`	`adapter::types::unidirectional::AQ`	Plug (Output)	Outputs quartet 2.
`QUARTER_BYTE_03`	`adapter::types::unidirectional::AQ`	Plug (Output)	Outputs quartet 3 (most significant 2 bits).

Functionality

1. An event at socket `IN.E1` activates processing.
2. The byte present at the socket (`IN.D1`) is forwarded to the internal component `SPLIT_BYTE_INTO_QUARTERS`. This component splits the byte into four 2-bit parts (quartets).
3. The four quartets are fed in parallel to the data inputs of `E_D_FF_ANY` flip-flops.
4. Simultaneously, the splitter's acknowledgment event (`CNF`) is distributed to the clock inputs (`CLK`) of all four flip-flops.
5. On the rising edge of this event, the flip-flops take over the quartets and pass them on to their respective outputs (`Q`).
6. The flip-flop outputs are directly connected to the data inputs of the output adapters `QUARTER_BYTE_00` … `QUARTER_BYTE_03`. Simultaneously, the flip-flop output event (`EO`) is sent to the event input (`E1`) of the respective adapter, so that the data is output on the adapter interface.

Thus, with each activation of the socket, an entire byte is split into four quartets and transmitted synchronously to all four output adapters.

Technical Features

- **Internal Flip-Flops:** The use of `E_D_FF_ANY` ensures that the splitting occurs only once per event and that the values are buffered until a new event arrives.
- **Adapter Coupling:** Instead of direct inputs/outputs, only unidirectional adapters are used, enabling loose coupling and reusability in complex adapter networks.
- **Synchronization:** The flip-flops are clocked via the shared `CNF` event, ensuring all quartets are present simultaneously.
- **No State Machine:** The function block operates purely event-driven without its own sequential state – the logic is entirely implemented through the interconnected internal components.

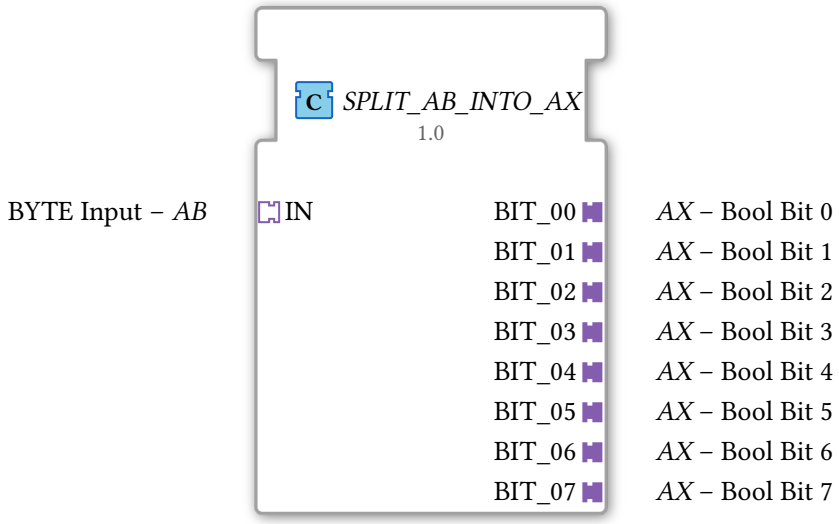
State Overview

Since `SPLIT_AB_INTO_AQ` is a composite function block without its own state machine, its behavior is determined by the internal components. Essentially, there are two phases:

1. **Idle:** No event is present at the socket; the output adapters hold the last received values.
2. **Processing:** An event at the socket triggers the decomposition and updating of all outputs. Upon completion, the function block returns to its idle state.

Application Scenarios

- **Control of Four Actuators:** A byte (e.g., from a master control bus) is split into four 2-bit values to provide separate control signals for independent actuators.
- **Data Reduction:** Splitting a byte into four individual signals for transmission to parallel, simpler processing units.
- **Adapter-Based Architectures:** Used in systems that consistently operate with unidirectional adapters to increase modularity.



Comparison with Similar Components

- **`SPLIT_BYTE_INTO_QUARTERS`:** Performs the simple splitting of a byte into four quartets, but via direct data and event inputs/outputs. `SPLIT_AB_INTO_AQ` encapsulates this logic in an adapter interface and adds flip-flops for stable output.
- **`SPLIT_WORD_INTO_BYTES`:** Splits a 16-bit word into two bytes – analogous principle, but for different data widths and adapter types.
- **Simple Multiplexers/Demultiplexers:** While these signals switch, `SPLIT_AB_INTO_AQ` focuses on the fixed, parallel division of a composite data type.

Conclusion

SPLIT_AB_INTO_AQ` is a specialized composite function block for splitting a byte adapter input into four separate quarter adapter outputs. It simplifies the design of adapter networks by hiding the complex bit manipulation and ensuring reliable, event-driven output of the quartets. The use of flip-flops ensures stable data storage between events. This component is particularly suitable for modular automation solutions that work with unidirectional adapters.

SPLIT_AB_INTO_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SPLIT_AB_INTO_AX** splits a byte received via a unidirectional AB adapter into its eight individual bits and provides these via separate AX adapters. The bits are transferred using clock-controlled D flip-flops, ensuring that the output values remain stable until a new byte is processed.

Interface Structure

Event Inputs

The function block does not have explicit top-level event inputs. Processing is triggered by an event arriving via the socket adapter **IN** (type AB). The **IN** adapter provides one event input (`E1`) and one data input (`D1`).

Event Outputs

This function block does not have explicit event outputs at the top level. Results are output via the plug adapters **BIT_00** to **BIT_07** (type AX), which also contain an event output (`E1`).

Data Inputs

- **IN.D1** – The byte to be processed is received via the socket adapter **IN** (type AB).

Data Outputs

- **BIT_00.D1 ... BIT_07.D1** – The individual Boolean values of the bits (bit 0 to bit 7) are output via the plug adapters **BIT_00** to **BIT_07** (type AX).

Adapters

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AB	Socket (Input)	BYTE value, decomposed into individual bits
BIT_00	adapter::types::unidirectional::AX	Plug (Output)	Boolean value of bit 0 (LSB)
BIT_01	adapter::types::unidirectional::AX	Plug (Output)	Boolean value of bit 1
BIT_02	adapter::types::unidirectional::AX	Plug (Output)	Boolean value of bit 2
BIT_03	adapter::types::unidirectional::AX	Plug (Output)	Boolean value of bit 3
BIT_04	adapter::types::unidirectional::AX	Plug (Output)	Boolean value of bit 4

BIT_05	adapter::types::unidirectional::AX	Plug (Output)	Boolean value of bit 5
BIT_06	adapter::types::unidirectional::AX	Plug (Output)	Boolean value of bit 6
BIT_07	adapter::types::unidirectional::AX	Plug (Output)	Boolean value of bit 7 (MSB)

Functionality

1. An incoming byte is received via the socket adapter **IN**. The event `E1` triggers the processing.
2. The internal function block `SPLIT_BYTE_INTO_BOOLS` splits the byte into eight Boolean signals (`BIT_00` ... `BIT_07`). Simultaneously, the event `CNF` is generated.
3. This event is distributed to the clock inputs (`CLK`) of eight **E_D_FF** flip-flops. Each flip-flop receives the corresponding Boolean value at its data input `D` at the clock signal.
4. The outputs `Q` of the flip-flops provide the stabilized bits. These are passed via the data connections to the plug adapters **BIT_00** ... **BIT_07**.
5. The event `EO` of each flip-flop is placed on the event output of the respective plug adapter, so that downstream components are notified of the new bit information.

Technical Features

- **State Storage**: The use of D flip-flops (E_D_FF) ensures that the output values are retained even after the processing event until a new byte is processed.
- **Parallel Output**: All eight bits are updated simultaneously as soon as the jointly clocked event `CNF` of `SPLIT_BYTE_INTO_BOOLS` occurs.
- **Unidirectional Adapters**: Both the input and output adapters are unidirectional (from the application to the resource), therefore the component is suitable for transmission directions in which only one side controls the data flow.

State Overview

The component itself does not have an explicit state machine. Its behavior results from the internal combination of:

- **SPLIT_BYTE_INTO_BOOLS**: Single-step – generates eight BOOL values and an acknowledgment event from one byte.
- **E_D_FF**: Each flip-flop stores a Boolean value on the rising clock edge and holds it until the next clock cycle.

Thus, the component can be described as a **pure combinational splitter with downstream hold elements**.

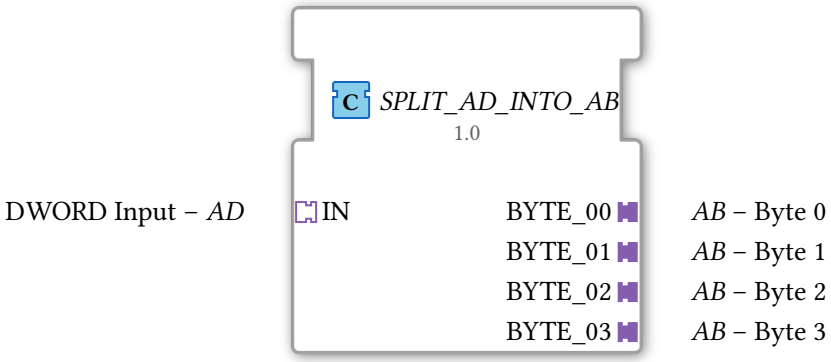
Application Scenarios

- **Digital Output Control**: A byte (e.g., from a communication adapter) is split into individual digital outputs, each connected to actuators via AX getter adapters.
- **State Monitoring**: A byte signal (e.g., from a fieldbus) is decomposed into individual status bits, which can be processed or visualized separately.
- **Bit-level data preparation**: Before passing the data to internal processing that expects individual Boolean signals.

Comparison with similar function blocks

- **SPLIT_BYTE_INTO_BOOLS**: Also splits a byte into Boolean values, but outputs them directly as data outputs and generates a single event.

SPLIT_AB_INTO_AX extends this with clock-controlled buffering and output via AX adapters, allowing for clean event synchronization with subsequent function blocks.



- **Simple data array splitters**: Some libraries offer function blocks that split arrays into individual elements, but without the additional storage and adapter interface.

Conclusion

SPLIT_AB_INTO_AX is a specialized function block for splitting a byte value into eight stable Boolean outputs via AX adapters. The combination of splitter and flip-flops makes it particularly suitable for scenarios where individual bits need to be accessed asynchronously or with a time delay, without the

value changing during processing. Its clear, adapter-based interface facilitates integration into modular IEC 61499 applications.

SPLIT_AD_INTO_AB

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SPLIT_AD_INTO_AB** is used to split a 32-bit data word (AD adapter) into four individual bytes. The four bytes are output via separate unidirectional AB adapters. The block is implemented as a composite function block and uses a SPLIT_DWORD_INTO_BYTES and several edge-triggered D flip-flops (E_D_FF_ANY).

Interface Structure

The function block does not have any traditional event or data interfaces. All communication takes place via adapters:

Adapters (Sockets)

Adapter	Type	Comment
IN	`adapter::types::unidirectional::AD`	DWORD Input (32-bit)

Adapter (Plugs)

Adapter	Type	Comment
BYTE_00	`adapter::types::unidirectional::AB`	Byte 0 (least significant byte)
BYTE_01	`adapter::types::unidirectional::AB`	Byte 1
BYTE_02	`adapter::types::unidirectional::AB`	Byte 2
BYTE_03	`adapter::types::unidirectional::AB`	Byte 3 (most significant byte)

Each AB adapter has at least one event output (E1) and one data output (D1) connected to the internal flip-flops.

Functionality

1. An event at the **IN** adapter (E1) triggers the internal component `SPLIT_DWORD_INTO_BYTES`.
2. `SPLIT_DWORD_INTO_BYTES` parses the DWORD input at **IN.D1** into four individual bytes (BYTE_00 to BYTE_03) and outputs them as data.
3. Simultaneously, `SPLIT_DWORD_INTO_BYTES` generates an acknowledgment event (CNF), which is forwarded to the clock inputs (CLK) of all four `E_D_FF_ANY` flip-flops.
4. Each flip-flop stores its assigned byte (D input) on the rising edge of the clock and outputs it at its output (Q).
5. The flip-flop outputs are connected to the data outputs of the AB adapters (D1). Simultaneously, the event (EO) of each flip-flop is sent to the event input (E1) of the corresponding adapter, so that the connected consumer is informed of the new data.

Technical Features

- **Synchronous Output**: All four bytes are output simultaneously with the same event (CNF of `SPLIT_DWORD_INTO_BYTES`). This ensures that the consumers of the individual bytes remain synchronized.
- **Use of E_D_FF_ANY**: These edge-triggered flip-flops ensure that the data is only transferred upon a new event and remains stable at the output until then.
- **Adapter-Based Interface**: The function block operates entirely via adapters, allowing it to integrate seamlessly into an adapter-oriented architecture (e.g., when using `adapter::types::unidirectional::AB` and `AD`).

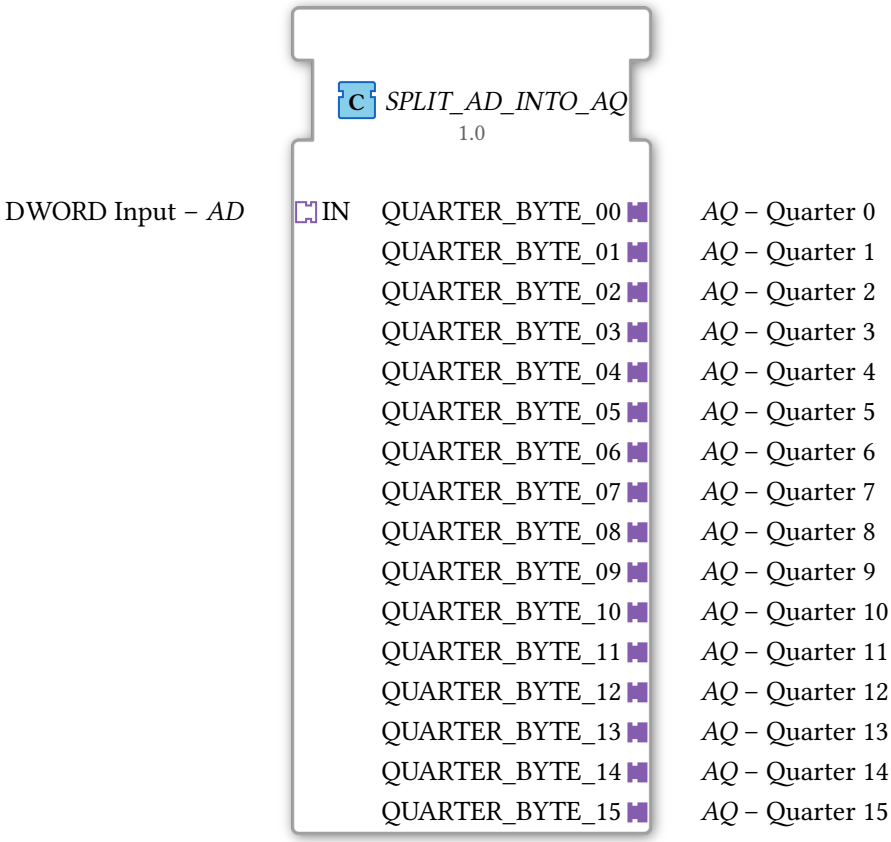
State Overview

The function block itself does not have an explicit state machine – it is a composite of standard function blocks. Internal flow control is managed through event and data flows:

- **Wait**: No input event ⟶ output remains unchanged.
- **Split**: Upon an event at the input adapter, the DWORD is split once, and all four bytes are output.

Application Scenarios

- **Decomposition of 32-bit sensor data** (e.g., encoder values, A/D converters) into individual bytes for transmission via byte-oriented protocols.
- **Control of peripherals** that expect individual bytes as address or data words (e.g., register accesses).
- **Data collection in distributed systems** where a 32-bit value must be distributed among multiple independent processors.



Comparison with similar components

- **SPLIT_DWORD_INTO_BYTES**: Also splits a DWORD into bytes, but outputs them directly as data outputs (BYTE_00..BYTE_03) without routing the data through adapters.
- **SPLIT_AD_INTO_AB**: Offers the same functionality, but encapsulates the output in unidirectional AB adapters. This allows for a clean separation of interfaces and facilitates reuse in different contexts.
- **AT** (Adapter-Type-Based Function Blocks): Other adapter splitters might, for example, split WORDs into nibbles, while this function block is specifically designed for DWORD ⟶ 4×BYTE.

Conclusion

The **SPLIT_AD_INTO_AB** is a useful composite function block that synchronously splits a 32-bit data value into four individual bytes using an adapter. Edge-triggered flip-flops ensure stable outputs until the next input event arrives. The adapter interfaces integrate seamlessly into modular real-time systems according to IEC 61499 and facilitate structured data transfer.

SPLIT_AD_INTO_AQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_AD_INTO_AQ` splits an incoming AD adapter (DWORD) into 16 individual AQ adapters (QUARTER). It serves as an interface to divide a wide data value (32 bits) into its 2-bit quarter components and forward these to separate output adapters. The block is implemented as a composite function block and internally uses a `SPLIT_DWORD_INTO_QUARTERS` block and 16 flip-flops (`E_D_FF_ANY`) for synchronous transmission.

Interface Structure

Event Inputs

The function block does not have its own independent event inputs. The event is received via the adapter interface `IN.E1` and processed internally.

Event Outputs

The function block (FB) does not have its own event outputs. Event output is provided via the AQ adapter plugs (each via `QUARTER_BYTE_xx.E1`).

Data Inputs

The FB does not have its own data inputs. Data is provided via the adapter interface `IN.D1`.

Data Outputs

The FB does not have its own data outputs. The distributed data is output via the AQ adapter plugs (each via `QUARTER_BYTE_xx.D1`).

Adapters

Name	Type	Direction	Description

IN	adapter::types::unidirectional::AD	Socket (Input)	DWORD input adapter (32 bits). Events and data are received via E1 and D1.
QUARTER_BYTE_00 ... QUARTER_BYTE_15	adapter::types::unidirectional::AQ	Plug (Output)	16 output adapters, each providing one quarter (2 bits) of the original DWORD. Each adapter has an event output E1 and a data output D1.

Functionality

The module operates entirely internally using a composite network. As soon as an event (E1) arrives via the IN adapter, it is forwarded to the internal module SPLIT_DWORD_INTO_QUARTERS. This module then parses the stored DWORD value (IN.D1) into 16 separate quarter bytes (each 2 bits).

After the division is complete, SPLIT_DWORD_INTO_QUARTERS.CNF signals a clock pulse, which is simultaneously sent to all 16 flip-flops (E_D_FF_ANY_00 to E_D_FF_ANY_15). The flip-flops then receive the respective quarter data at their data input (from SPLIT_DWORD_INTO_QUARTERS.QUARTER_BYTE_xx) and output it at their output Q. Simultaneously, they fire an event at their output EO, which is forwarded to the corresponding AQ adapter plug (QUARTER_BYTE_xx.E1). This transfers the output data value (Q) to the target device via the adapter data path (D1).

The flip-flops then receive the respective quarter data at their data input (SPLIT_DWORD_INTO_QUARTERS.QUARTER_BYTE_xx) and output it at their output Q. Processing is strictly synchronous: all 16 quarter values are updated at the same clock cycle.

Technical Features

- **Composite Architecture**: The function block (FB) uses other components (SPLIT_DWORD_INTO_QUARTERS and E_D_FF_ANY) to implement the decomposition and synchronization.
- **No Dedicated Inputs/Outputs**: All communication occurs exclusively via adapters. This enables clean encapsulation and reuse in adapter-based architectures.
- **Synchronization**: All 16 AQ outputs are updated simultaneously by a common clock (from SPLIT_DWORD_INTO_QUARTERS.CNF). This ensures that the split data is consistently available at the same time.
- **Scalability**: The FB is designed for 16 quarter values (corresponding to 32 bits). Adaptation to other bit widths would be possible by modifying the internal structure.

No Dedicated Inputs/Outputs:

State Overview

As a composite function block (FB), SPLIT_AD_INTO_AQ does not have its own state machine. Internal data processing is determined by:

- **Waiting for Event**: No internal event is generated during idle time.
- **Processing**: Upon arrival of IN.E1, the flip-flops are split and updated.
- **Output**: All AQ outputs are available immediately after the clock signal.

Application Scenarios

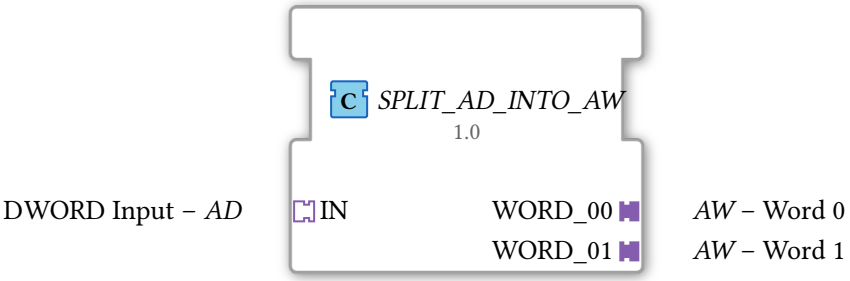
- **Data Splitting in Control Systems**: When a sensor or communication module provides a 32-bit data word (e.g., encoder position, measured value) that needs to be split into 16 separate 2-bit signals (e.g., brightness sensors, switching states).
- **Adapter-Based Communication**: Used in the 4diac IDE when adapters according to IEC 61499 are used to distribute data between different components.
- **Parallel processing of partial information**: Decomposition of a DWORD for subsequent components, each requiring only 2 bits of the original.

Comparison with similar components

Component	Description	Difference to SPLIT_AD_INTO_AQ

`SPLIT_DWORD_INTO_QUARTERS`	Decomposes a DWORD into 16 quarter values and outputs them as direct data outputs.	`SPLIT_AD_INTO_AQ` additionally encapsulates this decomposition in adapter interfaces and adds flip-flop synchronization.
`SPLIT_INT_INTO_BITS`	Splits an integer into individual bits.	Operates at the bit level and not on 2-bit quarters; Output is typically in Boolean form.
Manual partitioning with `MUX` or `DEMUX`	Could be used to implement data partitioning without adapters.	`SPLIT_AD_INTO_AQ` is specifically optimized for adapter communication and offers a bundled, synchronized solution.

Conclusion



SPLIT_AD_INTO_AQ` is a useful building block for partitioning a DWORD (AD adapter) into 16 2-bit quarter-intercept adapters (AQ). Its composite architecture with internal synchronization ensures consistent data transmission and facilitates modular, adapter-based programming in the 4diac IDE. It is particularly suitable for applications that require parallel processing of partial information without the partitioning details needing to be visible in the higher-level network.

SPLIT_AD_INTO_AW

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SPLIT_AD_INTO_AW** is used to split a 32-bit DWORD value, received via a **AD** adapter (unidirectional), into two 16-bit WORD values and output them via two separate **AW** adapters (unidirectional). The splitting is event-driven, and the output data is stabilized by flip-flops until a new trigger arrives. The function block is implemented as a composite function block and internally uses the **SPLIT_DWORD_INTO_WORDS** function block as well as two **E_D_FF_ANY** flip-flops.

Interface Structure

Event Inputs

Name	Adapter	Event	Description
IN	AD (Socket)	E1	Starts the partitioning of the incoming DWORD value.

Event Outputs

Name	Adapter	Event	Description
WORD_00	AW (Plug)	E1	Signals that the lower-order WORD (low word) is valid.

WORD_01	AW (Plug)	E1	Indicates that the higher-order WORD (High Word) is valid.

Data Inputs

Name	Adapter	Data Type	Description
IN	AD (Socket)	D1 (DWORD)	32-bit input value that is split.

Data Outputs

Name	Adapter	Data Type	Description
WORD_00	AW (Plug)	D1 (WORD)	Low-order 16-bit word of the input DWORD.
WORD_01	AW (Plug)	D1 (WORD)	High-order 16-bit word of the input DWORD.

Adapters

The adapters are designed as **unidirectional**:

- **AD** (Input): Provided via a socket, containing one event (E1) and one data (D1) channel.
- **AW** (Output): Provided via two plugs, each with one event (E1) and one data (D1) channel.

Functionality

1. An event at input **IN.E1** triggers processing.
2. The current DWORD value of **IN.D1** is read and passed to the internal function block **SPLIT_DWORD_INTO_WORDS**.
3. This block splits the 32-bit value into two 16-bit words: **WORD_00** (lower order) and **WORD_01** (higher order).
4. The two results are transferred in parallel to the flip-flops **E_D_FF_ANY_00** and **E_D_FF_ANY_01** and held there until the next event.
5. Simultaneously, the output events **WORD_00.E1** and **WORD_01.E1** are triggered, indicating that the corresponding data (**WORD_00.D1** and **WORD_01.D1**) are valid.

...

Technical Features

- **Data Synchronization:** The flip-flops ensure that the output data remains stable, even if the input value changes between two events. Only a new event at the input updates both outputs.
- **Simultaneous Output:** Both WORD outputs are updated by the same input event – there is no staggered timing.
- **Adapter Compatibility:** The function block is specifically designed for use with **AD-** and **AW-**adapters and allows seamless integration into adapter-based data flows.

State Overview

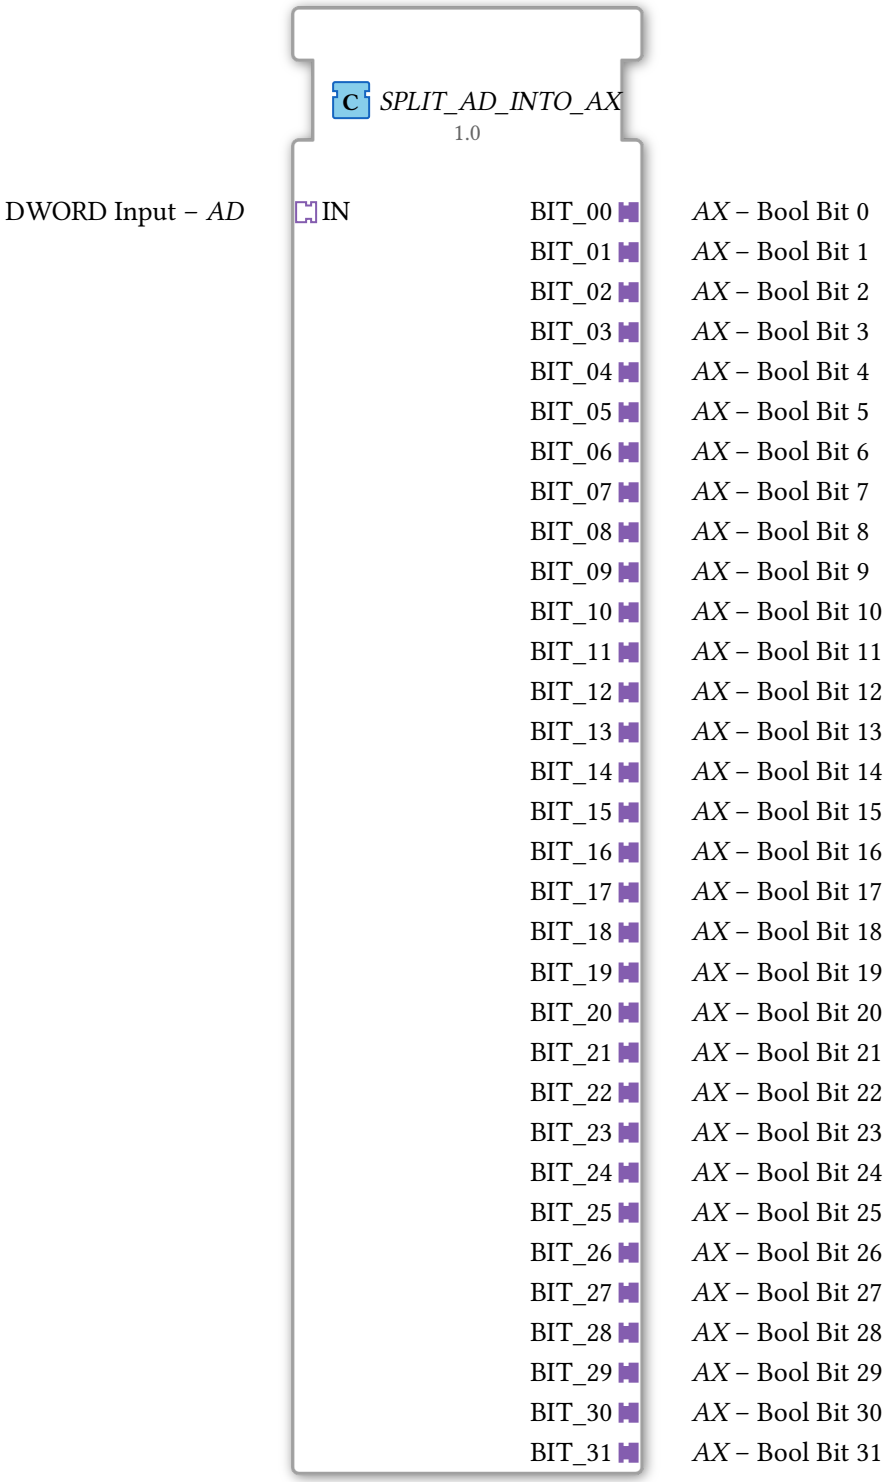
The function block does not have an explicit state machine. Its behavior is purely event-driven:

- **Idle:** Waiting for an event at **IN.E1**.
- **Processing:** Upon receipt of **IN.E1**, the data is split and the flip-flops are set.
- **Output:** The events at the outputs are triggered exactly once after processing.

Application Scenarios

- **Adapter-Based Decomposition:** Splitting a 32-bit value (e.g., from a sensor data word) into two 16-bit parts for separate processing chains.
- **Communication Protocols:** Preparing data for interfaces that transmit WORD-wise (e.g., Modbus registers or CAN messages).
- **Bit Manipulation:** Preprocessing for subsequent components that only expect WORD adapters.

Comparison with Similar Components



Component	Description	Difference

SPLIT_DWORD_INTO_WORDS	Pure data splitting without event output or adapters.	Provides only data outputs, no events, and no adapter connectivity.
SPLIT_AD_INTO_AW	Adapter-based variant with stabilized outputs.	Integrates flip-flops and event output, specifically for AD/AW adapters.

Conclusion

SPLIT_AD_INTO_AW is a practical, combined function block that simplifies the splitting of a DWORD adapter signal into two WORD adapter signals. Thanks to its built-in flip-flops and synchronized event output, it is particularly well-suited for time-critical and adapter-oriented applications in industrial control systems.

SPLIT_AD_INTO_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The SPLIT_AD_INTO_AX function block splits a 32-bit data word received via an AD adapter (DWORD) into 32 separate AX adapters (BOOL). Each AX adapter represents a single bit of the original DWORD value. The block encapsulates the necessary event control and data storage in a modular, easy-to-use function block.

Interface Structure

Event Inputs

None. Event control is handled indirectly via the adapter socket.

Event Outputs

None. Output is provided via the adapter plugs, whose internal event behavior is defined by the types used (AX).

Data Inputs

Label	Type	Comment
IN	AD	DWORD Input (32-bit)

Data is received via the IN adapter socket. The AD adapter provides a DWORD value and an associated event (E1).

Data Outputs

Label	Type	Comment
BIT_00	AX	Bool Bit 0
BIT_01	AX	Bool Bit 1
...	...	...
BIT_31	AX	Bool Bit 31

All 32 output adapters are of type AX (unidirectional BOOL adapter). Each output returns the state of the corresponding bit of the incoming DWORD.

Adapters

- **Socket**: `IN` (type `adapter::types::unidirectional::AD`) – receives the DWORD value and its associated event.
- **Plugs**: 32 adapters `BIT_00` ... `BIT_31` (type `adapter::types::unidirectional::AX`) – provide the individual bits as Boolean signals to the connected logic.

Functionality

The internal process of the function block (FB) is divided into two steps:

1. **Division of the DWORD into Boolean Values**

An internal FB `SPLIT_DWORD_INTO_BOOLS` receives the DWORD via the data connection `IN.D1`. It divides the 32 bits into individual Boolean signals (`BIT_00` ... `BIT_31`).

1. **Synchronization and Storage**

The event `IN.E1` triggers the input `REQ` of the splitter. After complete processing, the splitter sends the acknowledgment event `CNF`. This event is forwarded to the clock inputs (CLK) of 32 flip-flops (type `E_D_FF`). Simultaneously, the flip-flops receive the Boolean values provided by `SPLIT_DWORD_INTO_BOOLS` on their data inputs `D`.

The outputs `Q` of the flip-flops are permanently connected to the data inputs `D1` of the corresponding AX adapters, so the stored bit values are immediately passed on to the output adapters.

Thus, after each event at the input adapter, the entire 32-bit value is transferred in parallel to the 32 output adapters and held there until the next event.

Technical Features

- **Parallel Processing**: All 32 bits are processed simultaneously by the flip-flops, ensuring a consistent snapshot of the DWORD.
- **Modular Design**: The function block (FB) utilizes existing standard components (`SPLIT_DWORD_INTO_BOOLS` and `E_D_FF`), facilitating maintainability and reuse.
- **Adapter-Based Communication**: All input and output is handled via adapters, allowing the FB to be seamlessly integrated into adapter-based applications.

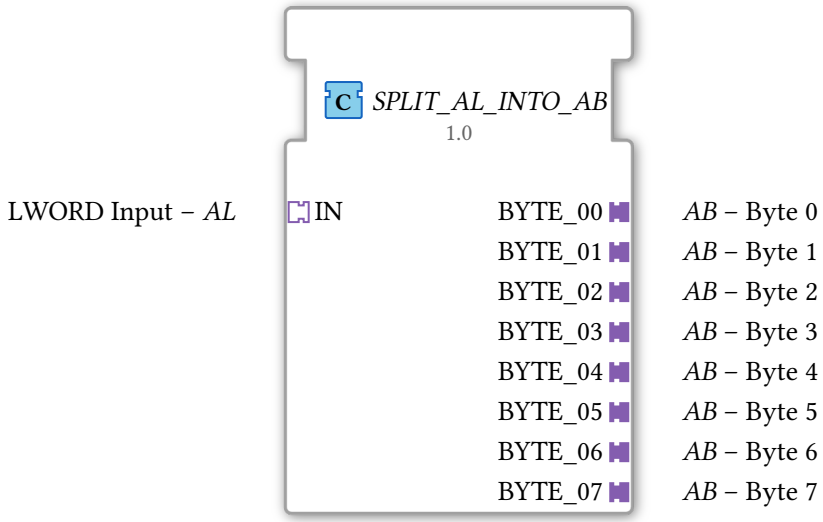
- **No External Events**: The FB has no dedicated event inputs/outputs, as event control is handled entirely by the adapters.

State Overview

The FB itself is stateless – its functionality is implemented by the internal flip-flops. Each `E_D_FF` has an internal memory state (0 or 1) that is updated by the clock event. After startup, all flip-flops are in their initial state (0) until the first event arrives at the input.

Application Scenarios

- **Digital Signal Processing**: Decomposition of a 32-bit data word into individual Boolean control signals, e.g., for status or enable bits.
- **Interface Adaptation**: Connecting a DWORD source (e.g., bus system, register) to discrete digital inputs/outputs.
- **Testing and Simulation**: Targeted analysis of individual bits of a data word without complex bit manipulation in the application code.



Comparison with Similar Components

- **SPLIT_WORD_INTO_BOOLS / SPLIT_BYTE_INTO_BOOLS**: These components operate at the 16-bit or 8-bit level and are optimized for smaller data word widths. SPLIT_AD_INTO_AX is specifically designed for 32-bit words and uses adapters instead of direct data ports.
- **Direct Bit Extraction with Adapters**: Alternatively, the `SPLIT_DWORD_INTO_BOOLS` could be used directly in an application, and the outputs connected via connectors. However, this function block encapsulates the entire synchronization process and provides a uniform, adapter-based interface, which simplifies reuse.

Conclusion

SPLIT_AD_INTO_AX is a practical function block for splitting a 32-bit data word into 32 individual Boolean adapter signals. Its modular design, parallel processing, and adapter-based communication make it ideally suited for use in complex automation solutions where bit information from a compact data word needs to be resolved into separate logical paths.

SPLIT_AL_INTO_AB

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SPLIT_AL_INTO_AB** is used to split a 64-bit value (LWORD) received via an **AL adapter** (Long Word) into its eight individual bytes and to provide these bytes via eight separate **AB adapters** (Bytes). The splitting occurs synchronously with an event at the input adapter, and each byte is temporarily stored in its own flip-flop (E_D_FF_ANY) before being delivered to the corresponding output adapter. The block is designed as an **adapter splitting component** and is particularly suitable for structured data decomposition in IEC 61499 systems.

Interface Structure

Event Inputs

- **IN** (Socket, Type: `adapter::types::unidirectional::AL`):

The integrated event output **E1** of the AL adapter triggers processing. An incoming event at the IN adapter starts the decomposition of the simultaneously present data value.

Event Outputs

The output adapters **BYTE_00** to **BYTE_07** (Plugs, Type: `adapter::types::unidirectional::AB`) each have an event input **E1**, which is triggered after successful data transfer. These events are generated by the internal network and signal that the corresponding byte is validly present at the adapter's data output.

Event Outputs ### Data Inputs

- **IN** (Socket, Type: `adapter::types::unidirectional::AL`):

Supplies the 64-bit data value to be parsed via the **D1** data input of the adapter (Type LWORD).

Data Outputs

- **BYTE_00** to **BYTE_07** (Plugs, Type: `adapter::types::unidirectional::AB`):

Each of these adapters provides a single byte (BYTE) via its **D1** data output. The mapping is as follows:

- BYTE_00: least significant byte (bits 0…7)
- BYTE_01: next byte (bits 8…15)
- …
- BYTE_07: most significant byte (bits 56…63)

Adapter

- **IN**: Socket (AL – Adapter Long Word) – receiving adapter
- **BYTE_00 … BYTE_07**: Plugs (AB – Adapter Byte) – sending adapters

Functionality

1. An event at the input adapter **IN** (E1) triggers the internal function block **SPLIT_LWORD_INTO_BYTES** (type: `eclipse4diac::utils::splitting::SPLIT_LWORD_INTO_BYTES`).
2. Simultaneously, the LWORD value (D1) provided by the IN adapter is forwarded to the input **IN** of this internal block.
3. The internal splitter divides the LWORD into eight separate bytes (**BYTE_00** … **BYTE_07**) and places them at its data outputs.
4. The splitter's completion event **CNF** is sent in parallel to eight **E_D_FF_ANY** flip-flops. Each flip-flop receives its assigned byte at this clock signal and outputs it at its **Q** output.
5. The flip-flops, in turn, generate an output event **EO**, which is directly connected to the event input **E1** of the corresponding **BYTE_XX** adapter.
6. This causes the individual bytes to be simultaneously output via the eight AB adapters – both as a data value (Q ⟶ D1) and as an acknowledgment event (EO ⟶ E1).

Technical Features

- **Adapter-based interface**: The component uses only adapters (AL and AB) and no conventional event/data ports. This enables modular encapsulation and reuse in adapter-based architectures.
- **Simultaneous Output**: The eight bytes are output simultaneously through the parallel clocking of all flip-flops, which is advantageous for time-critical applications.
- **Cacheloading**: Each byte is cached in its own flip-flop (E_D_FF_ANY), so the output value is retained even if the input value changes or a new decomposition cycle begins.
- **Unidirectional Data Flow**: The adapters are designed as unidirectional (IN: AL, OUT: AB) – data flows only from the input to the outputs.
- **No State Machines in the Function Block itself**: The function block delegates state management to the internal flip-flops; it is purely combinatorial with clocked takeover.

State Overview

The function block itself does not have its own visible state machine. The internal flip-flops **E_D_FF_ANY** have a dual state (Q = 0 or 1). The entire process follows a fixed pattern:

- **Idle**: No event at the input – outputs retain their last values.
- **Processing**: An event at the IN adapter is processed.
- **Output**: After the flip-flops have been clocked, all eight bytes are simultaneously available at the output adapters and are acknowledged by the respective events.

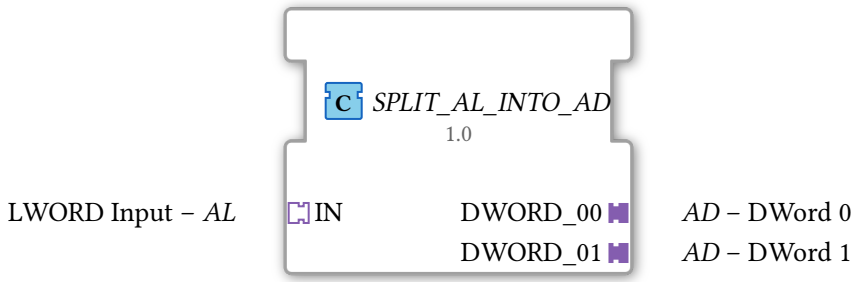
Application Scenarios

- **Decomposition of Communication Data**: Splitting a received LWORD packet (e.g., from a fieldbus or serial interface) into individual byte signals for further processing in the controller.
- **Parallel Output of Diagnostic/Status Bytes**: Splitting a composite 64-bit status word into eight separate byte outputs for display or forwarding.
- **Adapter-oriented data processing**: Integration into architectures based on adapters to ensure a strict separation of data and event interfaces.
- **Interface to sub-function blocks**: Supplies data to multiple function blocks, each requiring one byte (e.g., for seven segment displays, stepper motor control, or D/A converters).

Comparison with similar function blocks

- **SPLIT_LWORD_INTO_BYTES**: This internal function block performs the splitting without an adapter and outputs simple data outputs (BYTE) as well as an event (CNF). In contrast, **SPLIT_AL_INTO_AB** offers complete adapter encapsulation, including buffering and synchronized event output.
- **SPLIT_DWORD_INTO_BYTES** (analog, if available): Splits a 32-bit value into four bytes. SPLIT_AL_INTO_AB is designed for 64 bits and delivers eight bytes.
- **Simple MOVE Function Blocks**: Multiple MOVE blocks with bitmasks would need to be configured individually, whereas this block offers a ready-made, integrated solution.
- **Adapter-Based Alternatives**: Other splitting adapters might use symmetrical or different adapter types; this function block is specialized for AL⟶AB.

Conclusion



SPLIT_AL_INTO_AB is a useful and efficient function block for splitting a 64-bit data word into eight individual bytes, specifically designed for use with IEC 61499 adapters (AL/AB). The combination of an internal splitter and flip-flops ensures simultaneous, buffer-based output of all bytes. Thanks to its adapter-based interface, the block can be seamlessly integrated into modular control architectures where a clean separation of event and data channels is desired. It is particularly suitable for applications requiring parallel, structured data transfer.

SPLIT_AL_INTO_AD

• – ◦ • – ◦ • – ◦ •

Introduction

The function block SPLIT_AL_INTO_AD splits an incoming **AL (LWORD)** adapter into two separate **AD (DWORD)** adapters. It thus implements the necessary interface conversion for applications where a large data word (LWORD) needs to be split into two smaller DWORDs and made available via unidirectional adapters.

Interface Structure

Event Inputs

- **not directly available**

Events are received via the SOCKET adapter IN (signals IN.E1). Internally, this triggers processing.

Event Outputs

- **Not directly available**

Output events occur via the PLUG adapters DWORD_00.E1 and DWORD_01.E1 as soon as a new value is available.

Data Inputs

- **IN.D1** – Input data (LWORD) from the SOCKET adapter IN.

Data Outputs

- **DWORD_00.D1** – First split DWORD (low part) on the PLUG adapter DWORD_00.
- **DWORD_01.D1** – Second split DWORD (high part) on the PLUG adapter DWORD_01.

Adapter

Type	Name	Direction	Comment
SOCKET	IN	Input	AL (LWORD) – Source Adapter
PLUG	DWORD_00	Output	AD (DWORD) – First Destination Adapter
PLUG	DWORD_01	Output	AD (DWORD) – Second Destination Adapter

Functionality

This function block operates purely event-driven. As soon as an event arrives at SOCKET IN (IN.E1), the corresponding data word (IN.D1, type LWORD) is internally forwarded to the sub-block SPLIT_LWORD_INTO_DWORDS. This sub-block splits the 64-bit word into two 32-bit DWORDs.

The two results are then passed in parallel to the inputs of the flip-flop blocks E_D_FF_ANY_00 and E_D_FF_ANY_01. Simultaneously, the splitter block triggers a common acknowledgment event (CNF) that clocks both flip-flops. This allows the new DWORD values to be adopted and output as valid output data to the respective PLUG adapters (DWORD_00.D1 and DWORD_01.D1). Simultaneously, an event is sent to the corresponding output adapter (DWORD_00.E1 and DWORD_01.E1, respectively).

The flip-flops ensure that the output data remains stable until the next valid input event and is only updated during new processing.

Technical Features

- **Full Adapter Encapsulation** – The module has no direct events or data ports, but communicates exclusively via standardized unidirectional adapters (AL/AD).
- **Internal Use of SPLIT_LWORD_INTO_DWORDS** – This separate, typed splitter module handles the data splitting; The flip-flops decouple data and event passing.
- **Zero latency for simultaneous events** – Since both flip-flops are clocked by the same CNF, both outputs are always updated synchronously.
- **No independent state behavior** – The function block is purely combinatorial with event-driven storage; there is no internal state machine.

State Overview

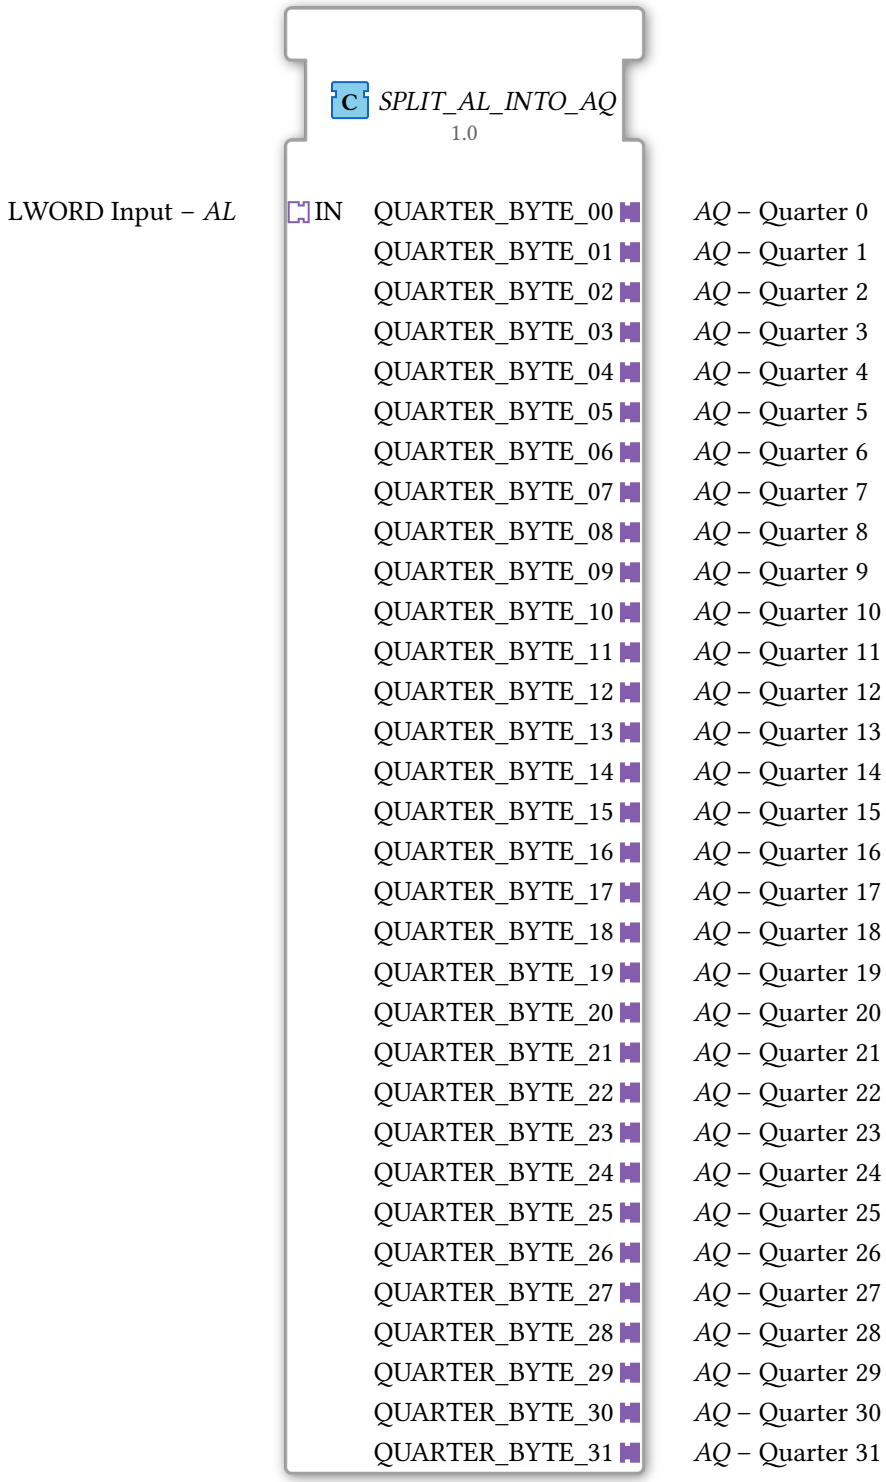
The function block does not have an explicit state machine. Its behavior is purely data- and event-driven:

- **Idle** – No input event; output data remains unchanged.

- **Processing** – After the arrival of `IN.E1`, the data is split and passed to the outputs.
- **Stable** – The flip-flops hold the values until the next event.

Application Scenarios

- **Industrial Automation** – When a sensor/actuator delivers an LWORD data word (e.g., a 64-bit counter or combined status/control words) via an AL adapter, but subsequent modules operate with two separate DWORD adapters.
- **Protocol Translation** – Decomposing large data packets into manageable subwords for adapter-based communication protocols.
- **Data Validation and Forwarding** – Splitting an LWORD into two DWORDs to serve different processing paths (e.g., visualization and control) in parallel.



Comparison with Similar Components

- **`SPLIT_LWORD_INTO_DWORDS`** – Pure data splitter without adapter connectivity and without event synchronization. `SPLIT_AL_INTO_AD` extends this with the necessary adapter interfaces and flip-flops for correct event handling.
- **Manual Splitting** – Alternatively, the splitting could be programmed directly in the logic of the higher-level system; however, this module reduces the effort and improves reusability.

Conclusion

SPLIT_AL_INTO_AD` is a specialized yet elegant adapter module that enables seamless connectivity between an LWORD source and two DWORD sinks. Due to the clean separation of data splitting and event synchronization, it is particularly well-suited for modular, adapter-based control architectures.

SPLIT_AL_INTO_AQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SPLIT_AL_INTO_AQ** is a composite function block (FB) that splits an incoming LWORD value (via a `AL` adapter) into 32 separate 2-bit values and outputs each of these via its own `AQ` adapter (quarter byte). The splitting occurs synchronously with an event provided by the input adapter. The function block serves as an interface between a wide data word and several narrow, event-driven sub-segments.

Interface Structure

Event Inputs

No direct event inputs. The triggering event is provided via the incoming adapter `IN.E1`.

Event Outputs

No direct event outputs. Output events are passed on via the outgoing adapter `QUARTER_BYTE_xx.E1`.

Data Inputs

No direct data inputs. The LWORD data value is read via the incoming adapter `IN.D1`.

Data Outputs

No direct data outputs. The 2-bit data values are output via the outgoing adapter `QUARTER_BYTE_xx.D1`.

Adapters

Direction	Name	Type	Comment
Socket (Input)	`IN`	`adapter::types::unidirectional::AL`	LWORD Input (64-bit)
Plug (Output)	`QUARTER_BYTE_00` .. `QUARTER_BYTE_31`	`adapter::types::unidirectional::AQ`	32 outputs, each providing a 2-bit value (quarter)

Each adapter has one event channel and one data channel (`E1`, `D1`).

- The `AL` adapter provides an event (`E1`) and the LWORD data value (`D1`).
- The `AQ` adapters receive an event (`E1`) and the associated 2-bit value (`D1`).

Functionality

The module operates in the following steps:

1. **Event Reception**: An event at the input adapter `IN.E1` triggers the internal processing.
2. **Splitting**: The internal instance `SPLIT_LWORD_INTO_QUARTERS` splits the incoming LWORD (64 bits) into 32 consecutive 2-bit segments (quarter bytes 0 to 31). Each segment is forwarded to the data input of one of 32 `E_D_FF_ANY` flip-flops. Simultaneously, the event is distributed to the clock input (`CLK`) of all flip-flops.
3. **Output**: On the rising edge of the clock signal, the flip-flops receive the 2-bit values. The flip-flops then pass the data and an output event to the corresponding `AQ` adapters via their outputs (`Q` and `EO`). This means that the segmented values are available at all 32 outputs simultaneously.

The entire process is strictly event-driven – a new input event updates all outputs at once.

Technical Features

- **Use of D flip-flops**: The `E_D_FF_ANY` function blocks ensure that the output data is stable only after the clock event and is not affected by intermediate values.
- **Parallelization**: All 32 partial values are calculated and output in a single step. The function block is therefore deterministic and requires no loops or sequential processing.
- **Adapter-based interface**: The function block communicates exclusively via IEC 61499 adapter interfaces. This enables a clean separation of event and data flows and facilitates reuse in different contexts.
- **Use of 32-way chaining**: The vertical arrangement of the flip-flops and adapters in the network shows a systematic but very extensive structure – sufficient performance (e.g., propagation delay of the common clock signal) must be ensured during implementation.

State Overview

The component does not contain its own state machine. The internal functionality results from the combination of:

- **one** `SPLIT_LWORD_INTO_QUARTERS` (combinational partitioning)
- **32** `E_D_FF_ANY` (storage elements with set/reset states)

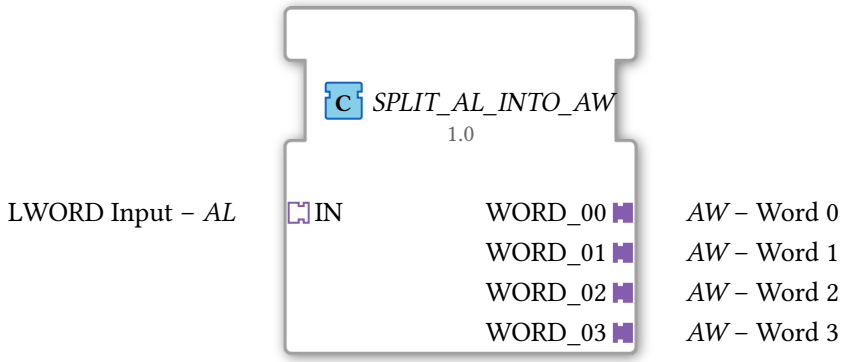
Each flip-flop stores the last loaded 2-bit value. A new input event overwrites all 32 values simultaneously.

Application Scenarios

- **Decomposition of a Fieldbus Data Telegram**: An LWORD contains multiple status or control bits that need to be distributed to separate actuators or sensors.
- **Parallelization of 2-Bit Signals**: When connecting BCD or quadrature encoders, multiple 2-bit pieces of information can be transmitted compactly and then processed separately.
- **Bridge between Wide and Narrow Data Buses**: If a system uses 64-bit words, but the target components only have 2-bit interfaces, this function block offers a simple way to split the data.

Comparison with Similar Function Blocks

Function Block	Output Format	Number of Outputs	Synchronization
`SPLIT_AL_INTO_AQ`	2-bit AQ adapter	32	Common event
`SPLIT_LWORD_INTO_BYTES` (hypothetical)	8-bit adapter	8	Event
`SPLIT_LWORD_INTO_WORDS` (hypothetical)	16-bit adapter	4	Event



This component is specifically optimized for the fine granularity of 2-bit segments and utilizes event-driven IEC 61499 adapter technology. The main difference compared to simpler split devices lies in the number of outputs (32 instead of the typical 4 or 8) and the use of flip-flops for stable output.

This component is specifically optimized for the fine granularity of 2-bit segments and utilizes event-driven IEC 61499 adapter technology.

Conclusion

The `SPLIT_AL_INTO_AQ` function block offers efficient, parallelized partitioning of a 64-bit LWORD into 32 separate 2-bit channels. Thanks to strict event control and D flip-flop storage, deterministic and time-accurate output is guaranteed. The block is particularly suitable for applications where many narrow data streams need to be derived from a compact data word. Its adapter-based interface makes it flexible and easily integrated into existing IEC 61499 systems.

SPLIT_AL_INTO_AW

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SPLIT_AL_INTO_AW** is used to split a 64-bit integer received via an AL adapter (LWORD) into four separate 16-bit values and output them via four individual AW adapters. It implements a hard-coded split that is triggered by an incoming event.

Interface Structure

Event Inputs

- **IN.E1** (Event) – Received via the **IN** socket and starts the splitting process.

Event Outputs

- **WORD_00.E1** – Output via the **WORD_00** plug.

- **WORD_01.E1** – Output via the **WORD_01** plug.
- **WORD_02.E1** – Output via the **WORD_02** plug.
- **WORD_03.E1** – Output via the **WORD_03** plug.

Each event output is activated in parallel as soon as the splitting is complete.

Data Inputs

- **IN.D1** (LWORD) – The 64-bit input size to be split. Provided via the **IN** socket.

Data Outputs

- **WORD_00.D1** (WORD) – The least significant word (bits 0–15).
- **WORD_01.D1** (WORD) – The second word (bits 16–31).
- **WORD_02.D1** (WORD) – The third word (bits 32–47).
- **WORD_03.D1** (WORD) – The most significant word (bits 48–63).

Each output is provided by an edge-triggered memory (E_D_FF_ANY) and remains stable until the next split operation.

Adapters

- **Socket IN** – Type: `adapter::types::unidirectional::AL` (LWORD)
- **Plugs WORD_00 ... WORD_03** – Type: `adapter::types::unidirectional::AW` (WORD)

Operation

1. An incoming event at **IN.E1** activates the internal function block **SPLIT_LWORD_INTO_WORDS** via its event input **REQ**.

Socket IN – Type: `adapter::types::unidirectional::AL` (LWORD)
Plugs WORD_00 ... WORD_03 – Type: `adapter::types::unidirectional::AW` (WORD)
Functionality
An incoming event at IN.E1 activates the internal function block SPLIT_LWORD_INTO_WORDS via its event input REQ.
**** 2. Simultaneously, the data **IN.D1** is transferred to the data input **IN** of the split function block.

1. **SPLIT_LWORD_INTO_WORDS** splits the LWORD into four word parts (**WORD_00**...**WORD_03**) and generates a termination event at **CNF**.
2. This termination event is forwarded to all four edge-triggered flip-flops (**E_D_FF_ANY**). Each flip-flop receives its assigned subword at its data input **D** and places it at its output **Q**.
3. Simultaneously, the event outputs **WORD_00.E1** ... **WORD_03.E1** are activated so that the downstream adapters can receive the new data together.
4. This termination event is forwarded to all four edge-triggered flip-flops (**E_D_FF_ANY**).

Technical Features

- **Use of E_D_FF_ANY**: Each partial value is temporarily stored in an edge-triggered flip-flop. This ensures that the output value is retained even if no new event is present at the input. The values are only updated during the next splitting operation.
- **Parallel Output**: All four output events are triggered simultaneously – the data is available at all plugs at the same time.
- **Adapter-Based Interface**: The function block works exclusively with adapters, enabling clean encapsulation and reusability in modular applications.

State Overview

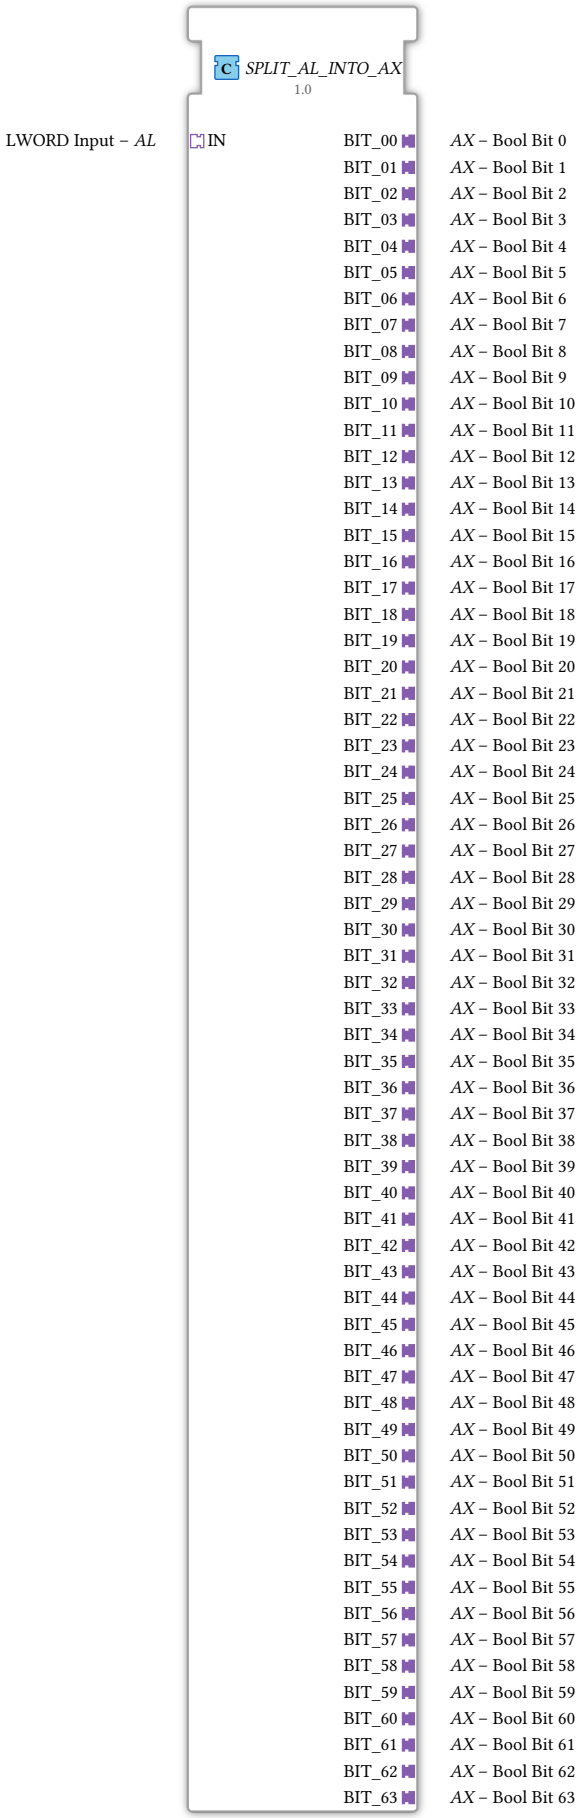
The function block itself does not have an explicit state machine. The internal flip-flops (E_D_FF_ANY) can assume the following states:

- **Idle**: No event is present – the output plugs hold the last stored value.
- **Busy**: The function block is briefly occupied during processing (between **IN.E1** and the appearance of the output events).
- **Output Active**: Upon completion, the new data is output to the plugs and the events are sent.

Application Scenarios

- **De-Seeralization**: Splitting a 64-bit telegram component into individual 16-bit register values for further processing.

- **Control Engineering**: Splitting a long bitmask into multiple submasks that are sent to different actuators or display units.
- **Data Preparation**: Decomposing an LWORD measurement value (e.g., from an encoder or an analog-to-digital converter card) into usable word channel values.



Comparison with Similar Components

- **SPLIT_LWORD_INTO_WORDS** (not adapter-based): Works with pure data and event ports. **SPLIT_AL_INTO_AW** encapsulates this function block and adds the adapter interfaces and edge-triggered storage.
- **MUX** or **DEMUX** (IEC 61499 standard): These typically split or combine data streams at the bit or bit level, while **SPLIT_AL_INTO_AW** is specifically designed for fixed 64-bit partitioning.

Conclusion

SPLIT_AL_INTO_AW offers a simple, robust solution for splitting an LWORD into four WORDS using adapters. Thanks to its integrated edge-triggered buffering, the function block is particularly well-suited for event-driven systems where data must be available in parallel and stably at different outputs. The adapter-based interface simplifies integration into existing component libraries.

SPLIT_AL_INTO_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The **SPLIT_AL_INTO_AX** function block decomposes a value encoded as an LWORD (64-bit) into 64 individual BOOL signals. The input value is provided via an **AL adapter** (analog longword), and the output is provided via 64 separate **AX adapters** (analog bits). Each output adapter provides the status of a bit along with a corresponding event. This function block is particularly suitable for processing digital signals from a compact data word, e.g., for the parallel control of 64 discrete outputs.

Interface Structure

Event Inputs

- **IN.E1** (in the IN adapter): Starts processing as soon as a new LWORD value is present at the adapter.

Event Outputs

Each AX adapter provides an event output:

- **BIT_00.E1** .. **BIT_63.E1** (in the corresponding adapters): Triggered as soon as the associated bit in the internal flip-flop is updated.

Data Inputs

- **IN.D1** (LWORD): The 64-bit data set to be parsed.

Data Outputs

- **BIT_00.D1** .. **BIT_63.D1** (BOOL): The state of the respective bit (0 or 1).

Adapters

- **IN** (Socket, Type: `adapter::types::unidirectional::AL`): Returns the LWORD value and the start event.
- **BIT_00** .. **BIT_63** (Plugs, Type: `adapter::types::unidirectional::AX`): Each outputs a BOOL signal (bit value) and an associated event.

Functionality

1. An incoming LWORD value via the AL adapter **IN** triggers processing via the **E1** event.
2. The internal component **SPLIT_LWORD_INTO_BOOLS** extracts all 64 bits from the LWORD.
3. Each bit is assigned to the **D** data input of an associated **E_D_FF** (Edge-Triggered D Flip-Flop).
4. Simultaneously, all 64 flip-flops receive the **CLK** clock pulse via the **CNF** event of the splitter. This transfers all bits to the flip-flops at once.
5. The flip-flops output the stored value at their output **Q**, which is provided via the data output **D1** of the respective AX adapter.
6. Each flip-flop generates an event at its output **EO**, which is forwarded to the event input **E1** of the corresponding AX adapter.

Technical Features

- **Synchronization**: All bits are transferred to the flip-flops simultaneously via a common event (CNF of SPLIT_LWORD_INTO_BOOLS). This ensures a consistent output state without race conditions.
- **Storage**: The use of **E_D_FF** ensures that the output state is retained until a new LWORD value is processed. The function block thus operates as a "sample and hold" for all 64 bits.
- **Large Number of Outputs**: The function block offers 64 independent BOOL outputs, which can be mapped to many device adapters in the 4diac IDE.
- **Adapter-based interface**: Inputs and outputs are implemented as unidirectional adapters, which facilitates modular encapsulation and reuse.

State overview

The function block (FB) does not have its own explicit state machine. The internal state is represented by the 64 **E_D_FF**:

- **Initial**: All flip-flops are set to FALSE (0).
- **After processing**: Each flip-flop stores the current bit value of the last received LWORD. The state changes only upon a new event on **IN.E1**.

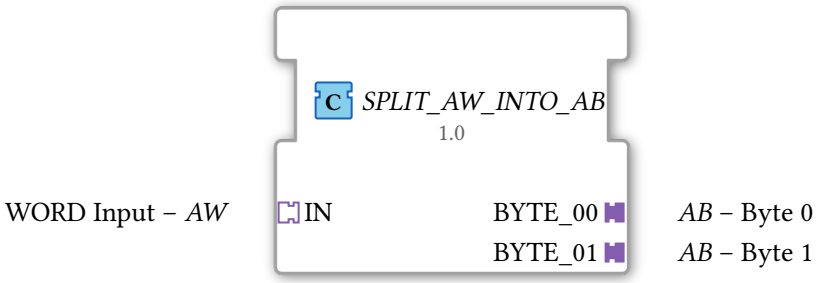
Application scenarios

- **Parallel output of digital signals** from a serial or packetized data word, e.g., from a bus system or a communication interface.
- **Masked control**: Combination with logic blocks to selectively evaluate individual bits of a status word.
- **Test and Diagnostic Interfaces**: Processes a 64-bit error word for display on separate lights or in visualizations.
- **Interface to Discrete Actuators**: Each AX adapter can be directly connected to a digital output module.

Comparison with Similar Components

- **SPLIT_LWORD_INTO_BOOLS** (purely functional splitter without memory): Provides the bits only during processing and does not retain the value. **SPLIT_AL_INTO_AX** adds the memory function and provides a stable output until the next update.
- **Type Converters like DWORD_TO_BOOL_ARRAY**: These usually operate at the array level and not at the adapter level; the present component is specifically designed for the 4diac adapter interface.
- **Flip-flop-based solutions, each with its own F_TRIG or similar:** This function block simplifies configuration because all 64 bits are combined in a single block.

Conclusion



SPLIT_AL_INTO_AX is a powerful, adapter-based function block for splitting an LWORD data set into 64 discrete BOOL signals. The integrated flip-flops maintain the output state until the next update. The large number of outputs and synchronous processing make it ideal for applications requiring parallel, time-consistent signal generation. The use of unidirectional adapters ensures clear interface definition and facilitates integration into existing 4diac projects.

]

SPLIT_AW_INTO_AB

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SPLIT_AW_INTO_AB** is used to split a word data packet (type AW, 16 bits) into two separate byte data packets (type AB, 8 bits each). The input data is received via a socket and output via two separate plugs. This function block is typically used in environments that rely on adapter-based communication, e.g., in automation technology when decomposing word-based protocols.

Interface Structure

Event Inputs

The function block does not have its own event inputs. Event control is handled indirectly via the **IN** adapter.

Event Outputs

The function block does not have its own event outputs. Events are transmitted externally via the output adapters **BYTE_00** and **BYTE_01**.

Data Inputs

The FB has no direct data inputs. Data input is indirect via the **IN** adapter.

Data Outputs

The FB has no direct data outputs. Data output is indirect via the **BYTE_00** and **BYTE_01** adapters.

Adapters

Adapter	Direction	Type	Description
IN	Socket	`adapter::types::unidirectional::AW`	Receives a 16-bit word (WORD). The adapter provides the data and an associated event.
BYTE_00	Plug	`adapter::types::unidirectional::AB`	Outputs the least significant byte (byte 0).
BYTE_01	Plug	`adapter::types::unidirectional::AB`	Outputs the most significant byte (byte 1).

Functionality

1. An incoming event on the **IN** (E1) adapter triggers the internal function block **SPLIT_WORD_INTO_BYTES**.
2. This splits the received WORD (16 bits) into two bytes: **BYTE_00** (less significant) and **BYTE_01** (most significant).
3. The completion event (CNF) of **SPLIT_WORD_INTO_BYTES** is passed to the clock inputs of two **E_D_FF_ANY** flip-flops.
4. Each flip-flop stores the corresponding byte and outputs it via its **Q** output on the next clock pulse.
5. The flip-flops each generate an event on **EO**, which is sent to the output adapters **BYTE_00** and **BYTE_01**. This makes the split bytes available externally along with an event.

Technical Features

- **Adapter-based interface:** The function block (FB) does not contain any direct event or data inputs/outputs. All communication takes place via adapters (sockets for inputs, plugs for outputs). It is therefore particularly suitable for applications that rely on the adapter-based 4diac type system.
- **Data caching:** The two **E_D_FF_ANY** flip-flops keep the split bytes stable until new data arrives. This prevents inconsistent states during the splitting process.
- **Event synchronization:** The bytes are output simultaneously because the same CNF event triggers both flip-flops.

State Overview

The function block (FB) does not have an explicit state machine. It processes pulses in an event-driven manner and outputs the split bytes on **IN** for each event. The flip-flops have the typical two states: stored value (0 or 1 per bit, depending on the byte).

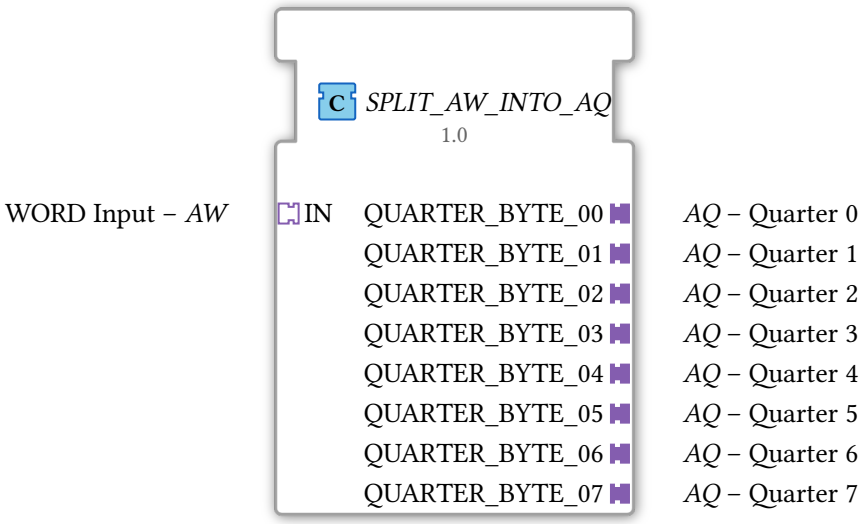
Application Scenarios

- **Byte-Oriented Communication:** When a sensor or actuator sends data in WORD format, but downstream components expect individual bytes.
- **Protocol Preparation:** Splitting telegrams consisting of a 16-bit value into separate byte adapters for further processing.
- **Modbus/IO-Link Integration:** Adapting 16-bit register values to 8-bit interfaces.

Comparison with Similar Components

- **SPLIT_WORD_INTO_BYTES:** A pure data splitter without adapter encapsulation. It operates at the data level and requires its own event and data interfaces.
- **MUX/DEMUX Components:** Multiplexers or demultiplexers for multiple values, but usually with different data types and without adapter integration.
- **Adapter Wrappers like SPLIT_AW_INTO_AB:** Specifically developed for the adapter-based 4diac architecture. They encapsulate the splitting logic behind standardized adapter interfaces.

Conclusion



SPLIT_AW_INTO_AB is a specialized adapter wrapper that cleanly splits an incoming WORD into two separate BYTE adapters. The use of flip-flops ensures a stable data flow and avoids timing inconsistencies. This component is ideal for systems that use adapter-based communication according to IEC 61499-2 and require simple transformation between 16-bit and 8-bit data.

SPLIT_AW_INTO_AQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **SPLIT_AW_INTO_AQ** divides the eight quarter adapters (AQ) of a word adapter (AW). The incoming word (16 bits) is split into eight quarter units (2 bits each) and output via the corresponding AQ plugs.

Interface Structure

Event Inputs

- `IN.E1` (via Socket IN) – Triggers the splitting of a new word value.

Event Outputs

- `QUARTER_BYTE_00.E1` to `QUARTER_BYTE_07.E1` – Signals the availability of the respective quarter result.

Data Inputs

- `IN.D1` – Receives the incoming word (16 bits, type compatible with the AW adapter).

Data Outputs

- `QUARTER_BYTE_00.D1` to `QUARTER_BYTE_07.D1` – Provide the eight divided quarter values (2 bits each).

Adapters

- **Socket:** `IN` – Adapter type `adapter::types::unidirectional::AW`
- **Plugs:** `QUARTER_BYTE_00` ... `QUARTER_BYTE_07` – Adapter type `adapter::types::unidirectional::AQ`

Functionality

1. An event at input `IN.E1` activates the internal module `SPLIT_WORD_INTO_QUARTERS`.

2. `SPLIT_WORD_INTO_QUARTERS` decomposes the 16-bit word received via `IN.D1` into eight separate 2-bit quarter values.
3. The split values are temporarily stored in parallel in eight `E_D_FF_ANY` flip-flops (`D` inputs).
4. After processing is complete (CNF event of `SPLIT_WORD_INTO_QUARTERS`), all flip-flops simultaneously receive a clock pulse (`CLK`).
5. The outputs `Q` of the flip-flops are connected to the corresponding `QUARTER_BYTE_xx.D1` outputs.
6. Simultaneously, the event `QUARTER_BYTE_xx.E1` is triggered to signal the data transfer to downstream components. ...``

Technical Features

- **Synchronization via Flip-Flops:** All eight quarter values are taken from the internal splitter in sync with the clock.
- **No Persistent State Storage:** The chip only buffers the quarter values until the next processing cycle.
- **Uniform Interfaces:** The adapters follow the unidirectional AW/AQ protocol and enable easy integration in the 4diac IDE.

State Overview

The chip does not have its own state machine. The internal `E_D_FF_ANY` flip-flops can be in two states:

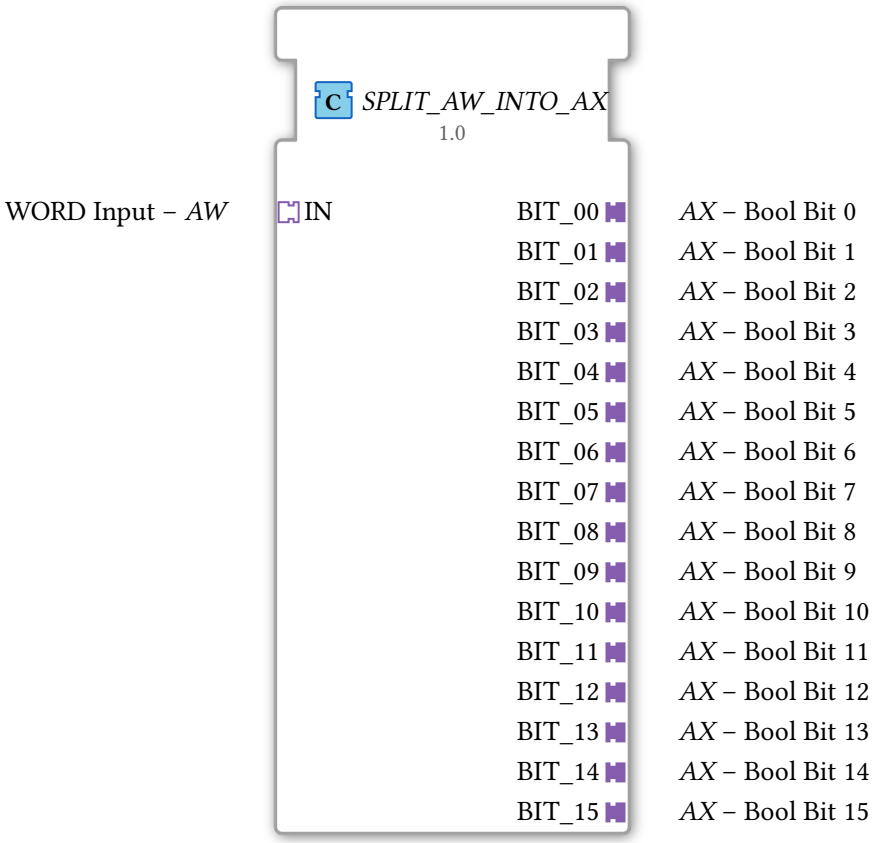
- **Stores Previous Value** – Until a new event occurs.
- **Updated Value** – After a clock pulse from the CNF event.

Application Scenarios

- **Data Preparation:** Splitting a 16-bit word from a communication adapter into eight 2-bit quarter-wave signals, e.g., for parallel processing in control logic.
- **Multiplexing/Demultiplexing:** Separating word data streams into separate quarter-wave channels.
- **Bus Structure Extension:** Easily splitting address or control words across multiple subsequent components.

Comparison with Similar Components

- **SPLIT_BYTE_INTO_NIBBLES** – Splits a byte into two 4-bit nibbles.
- **SPLIT_WORD_INTO_BYTES** – Splits a 16-bit word into two 8-bit bytes.
- **SPLIT_AW_INTO_AQ** is specifically designed for splitting one AW adapter (Word) into eight AQ adapters (Quarters). The interfaces are directly tailored to the adapter types and require no manual configuration.



Conclusion

The **SPLIT_AW_INTO_AQ** module offers a compact and reliable way to split an incoming Word signal into eight Quarter signals. Thanks to its integrated clock synchronization and standardized adapter interfaces, it is ideally suited for modular IEC 61499 applications that require simultaneous data processing for multiple participants.

SPLIT_AW_INTO_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_AW_INTO_AX` is used to split a 16-bit word (type `AW`) into 16 individual binary signals (type `AX`). Each of the 16 outputs represents one bit of the incoming word and is provided as an independent adapter with event and data lines. The splitting occurs synchronously upon the arrival of an event at the input adapter.

Interface Structure

Event Inputs

The function block does not have any independent event inputs on the interface. The initial event is received via the socket adapter `IN` (see Adapters).

Event Outputs

This module does not have any independent event outputs on the interface. Output events are provided via the plug adapters `BIT_00` ... `BIT_15` (see Adapters).

Data Inputs

This module does not have any independent data inputs on the interface. The 16-bit value to be processed is provided as a data value `D1` (type `WORD`) via the socket adapter `IN` (see Adapters).

Data Outputs

This module does not have any independent data outputs on the interface. The 16 extracted binary values are output via the plug adapters `BIT_00` ... `BIT_15` as data values `D1` (type `BOOL`).

Adapter

Direction	Name	Type	Comment

Socket (Input)	`IN`	`adapter::types::unidirectional::AW`	16-bit word as input, event input `E1`, data input `D1`
Plug (Output)	`BIT_00` … `BIT_15`	`adapter::types::unidirectional::AX`	One bit of each word, event output `E1`, data output `D1`

Functionality

1. An external event at socket `IN.E1` triggers processing.
2. The current value of `IN.D1` (type `WORD`, 16 bits) is read.
3. The internally embedded component `SPLIT_WORD_INTO_BOOLS` divides the word into 16 individual Boolean values (`BIT_00` … `BIT_15`).
4. These 16 values are passed to a `E_D_FF` (D flip-flop) at each clock cycle. The flip-flops receive the data at each clock cycle (here, the event `CNF` from `SPLIT_WORD_INTO_BOOLS`).
5. Each flip-flop outputs its stored value via the associated plug adapter `BIT_xx.D1` and an event via `BIT_xx.E1`.

… This distributes the entire word value across the 16 output adapters in a single cycle and holds it there until the next event.

Technical Features

- **Event-Synchronous Distribution:** The entire distribution occurs within a single event cycle – all 16 outputs are updated simultaneously.
- **Storage:** Each bit value is held by its own `E_D_FF`, ensuring the outputs remain stable even without constantly repeated events.
- **Adapter-Based Input/Output:** The module communicates exclusively via adapters – it can therefore be seamlessly integrated into 4diac systems that use unidirectional adapters for word or Boolean signals.
- **No Dedicated Event/Data Inputs:** The entire interface is implemented via the adapters; direct wiring on the facade is not required.

State Overview

The module does not have its own top-level state machine. The internal state is determined by the 16 D flip-flops (`E_D_FF_00` … `E_D_FF_15`):

- Each flip-flop can be in one of two states: `Q = 0` or `Q = 1`.
- The state is updated only on each clock cycle (i.e., with each new event arriving at the input).
- In the idle state between events, the last stored value is retained.

Application Scenarios

- **Control Tasks:** A higher-level controller or PLC sends a 16-bit word (e.g., as a control word) – the function block converts it into 16 individual binary control signals (e.g., for relays, valves, or indicators).
- – **Protocol Conversion:** Input signals from a bus system are stored as a word and must be distributed to discrete outputs.
- **Testing and Simulation:** Representation of a word as 16 Boolean channels for visualization or troubleshooting.

Comparison with Similar Components

- **`SPLIT_WORD_INTO_BOOLS`** – This component also divides a word into Boolean values, but without adapters and without event-driven output. It serves as an internal component of the present component.
- **`SPLIT_AW_INTO_AX`** – Extends the pure data division with adapters and event output, so that the individual bits are available as fully-fledged AX interfaces (with their own event and data). This enables direct interconnection with other 4diac components that expect AX adapters.
- **Alternative In-House Development:** Theoretically, 16 separate `SLICE` modules could be used to extract bits from a word – however, this would be more complex and would not offer synchronous event output.

Conclusion

SPLIT_AW_INTO_AX` is a compact yet powerful converter that reliably and event-synchronously divides a 16-bit word into 16 individual binary outputs. Thanks to the use of adapters and flip-flops, it is particularly well-suited for use in modular IEC 61499 applications where a clean separation of word and bit

interfaces is required. It simplifies interface adaptation and improves the readability and maintainability of the application network.

SPLIT_BYTE_INTO_QUARTERS

Image not available

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `SPLIT_BYTE_INTO_QUARTERS` is used to split an incoming byte data value into four separate quarter outputs. It implements a logical decomposition of a byte (8 bits) into four 2-bit groups, which are routed externally via unidirectional adapters. The internal implementation uses a combination of flip-flops and a recursive instance of the same function block to control the split synchronously and data-driven.

Interface Structure

Event Inputs

Not present. The function block has no independent event inputs; control is exclusively via the adapter interfaces.

Event Outputs

Not present.

Data Inputs

Not present.

Data Outputs

Not available.

Adapter

Direction	Name	Type	Description
Socket (Input)	`IN`	`adapter::types::unidirectional::AB`	Byte input that provides the data to be split.
Plug (Output)	`QUARTER_BYTE_00`	`adapter::types::unidirectional::AQ`	Output for the first quarter (least significant 2 bits).
Plug (Output)	`QUARTER_BYTE_01`	`adapter::types::unidirectional::AQ`	Output for the second quarter (bits 2-3).

Plug (Output)	QUARTER_BYTE_02	adapter::types::unidirectional::AD	Output for the third quarter (bits 4-5).
Plug (Output)	QUARTER_BYTE_03	adapter::types::unidirectional::AD	Output for the fourth quarter (most significant 2 bits).

Functionality

The function block operates as a **composite function block** with an internal network. As soon as socket `IN` receives an event (via `E1`) and the associated data, this data is forwarded to an internal instance of the same function block (`SPLIT_BYTE_INTO_QUARTERS`). Their outputs (also four quarter-wave adapters) are buffered in four parallel **E_D_FF_ANY flip-flops**. The flip-flops receive the data at the clock signal from the internal `CNF` event chain and synchronously pass it on to the outer plug-in adapters (`QUARTER_BYTE_00` ... `QUARTER_BYTE_03`). The precise mapping of the bits to the quarter-waves is implicit via the internal wiring; it is assumed that the byte is divided into four consecutive 2-bit groups (from LSB to MSB).

Technical Features

- **Recursive Type Usage**: The internal network topology includes another instance of the `SPLIT_BYTE_INTO_QUARTERS` component, enabling multi-stage or iterative decomposition. The actual depth, however, remains limited to one level due to the fixed wiring.
- **Adapter-based design**: Instead of conventional data ports, only unidirectional adapters are used, encapsulating both event and data channels. This promotes loose coupling and reusability.
- **Synchronization via flip-flops**: The four output flip-flops ensure that all quarters are updated simultaneously with a common clock signal as soon as the internal partitioning is complete.

State overview

The component has **no explicit state machine** (ECC). Its functionality is solely determined by the data and event wiring of the internal components. The system behavior is therefore purely combinatorial, triggered by a clock edge from the flip-flops.

Application scenarios

- **Parallelization of byte data**: Partitioning a received byte into four independent 2-bit channels, e.g. B. for controlling four parallel output devices or for distributed processing.
- **Serial-to-Parallel Conversion**: Conversion of a serial byte data stream into four parallel quarter signals.
- **Protocol Preparation**: Extracting partial information from a byte when each quarter has a separate meaning (e.g., status flags, configuration values).

Comparison with Similar Components

- **SPLIT_WORD_INTO_HALF_WORDS**: Analog component for splitting a 16-bit word into two 8-bit halves; usually operates with direct data ports.
- **EXTRACT_BITS_4TO1**: Standard splitting components often operate bitwise or with selectable index ranges. This module is specifically optimized for the fixed quarter-division of a byte and uses adapters instead of simple data inputs/outputs.
- **MUX/DEMUX Modules**: Multiplexers and demultiplexers offer generic division but require additional control lines. The `SPLIT_BYTE_INTO_QUARTERS` is more specialized and easier to configure.

Conclusion

The `SPLIT_BYTE_INTO_QUARTERS` function block provides a compact, adapter-based solution for decomposing a byte into four quarter-division outputs. The combination of a recursive structure and flip-flop synchronization ensures reliable, parallel data delivery. It is suitable for applications requiring a fixed division of an 8-bit value into four 2-bit units and offers good integration capabilities into modular 4diac projects thanks to its standardized adapter interface.

Introduction

The EVENT_HS adapter interface implements the **Handshake design pattern** from the IEC 61499 primer course (Module 6 – Design methods and patterns, category *Behavioural*). It bundles the four classical service primitives of a request/confirm/indication/response interaction into a single adapter connection, eliminating the need for four separate event connections between communication partners. This is the minimal, dataless variant of the pattern – no payload variables are declared.

The adapter distinguishes two roles: the **Plug** plays the *Requester/client* role, firing `REQ` and `RSP` events and reacting to `CNF` and `IND` events. The **Socket** plays the *Responder/server* role, reacting to `REQ` and `RSP` and firing `CNF` and `IND` events.

Interface Structure

Event Inputs

Name	Type	Comment
CNF	Event	Confirmation from Socket to Plug, answers a REQ
IND	Event	Indication from Socket to Plug

Event Outputs

Name	Type	Comment
REQ	Event	Request from Plug to Socket
RSP	Event	Response from Plug to Socket, answers an IND

Data Inputs

None – this adapter is dataless by design.

Data Outputs

None – this adapter is dataless by design.

Adapters

This is itself an adapter type. It exposes a **Socket** interface on the right side and a **Plug** interface on the left side, allowing it to be connected as a bidirectional handshake channel between two function blocks.

Functionality

The EVENT_HS adapter encapsulates two distinct service sequences:

1. **request_confirm** – A typical request cycle:
   - The Plug issues a `REQ` event, which is forwarded to the Socket.
   - The Socket processes the request and answers with a `CNF` event, which is forwarded back to the Plug.
2. **indication_response** – An unsolicited notification cycle:
   - The Socket emits an `IND` event, which is forwarded to the Plug.
   - The Plug acknowledges the indication with an `RSP` event, which is forwarded back to the Socket.

These two sequences can occur independently and asynchronously. The adapter itself does not enforce strict alternation between the two sequences; it merely provides the connection structure and the service protocol skeleton.

Technical Features

- **Dataless design** – No data variables are involved; the adapter is purely event-driven, making it lightweight and easy to integrate.
- **Role-based directionality** – The Plug and Socket roles are clearly defined: Plug = Requester, Socket = Responder. This yields a natural left-to-right layout in the FBNetwork editor.
- **Service sequence documentation** – The two service sequences (`request_confirm` and `indication_response`) are formally declared in the adapter's service model, enabling validation and traceability.
- **Compiler compatibility** – Confirmed to work with the 4diac ECC compiler. Note that the compiler only checks that `HS.<Name>` refers to a declared event on the adapter; it does *not* verify that the direction of the event makes sense at the given Socket/Plug side. Correct wiring must therefore be ensured by the developer.

State Overview

The EVENT_HS adapter does not maintain internal state. Its behaviour is defined entirely by the two independent service sequences. Each sequence moves through the following phases:

request_confirm sequence:

1. Idle – awaiting a `REQ` from the Plug.

2. Request sent – `REQ` has been forwarded to the Socket; awaiting `CNF`.
3. Confirmation received – `CNF` has been forwarded back to the Plug; sequence returns to Idle.

indication_response sequence:

1. Idle – awaiting an `IND` from the Socket.
2. Indication sent – `IND` has been forwarded to the Plug; awaiting `RSP`.
3. Response received – `RSP` has been forwarded back to the Socket; sequence returns to Idle.

The two sequences can overlap without interference, as they use disjoint event pairs.

Application Scenarios

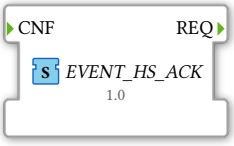
The EVENT_HS adapter is suitable for any scenario where two function blocks need a structured, handshake-based event communication, including:

- **Client/Server coordination** – A client FB requests an operation from a server FB and waits for confirmation of completion.
- **Asynchronous notifications** – A producer FB notifies a consumer FB of an event, and the consumer acknowledges receipt.
- **Resource management** – Coordinating access to shared resources between FBs, where explicit request/confirm cycles help avoid race conditions.
- **Simplified wiring** – Replacing multiple point-to-point event connections with a single adapter connection, improving diagram readability and maintainability.

Comparison with Similar Blocks

Aspect	EVENT_HS adapter	Plain event connections	Data-carrying handshake adapters
Event bundling	Yes – 4 events in one adapter	No – separate wires per event	Yes
Payload support	None (dataless)	N/A	Yes – carries data with events
Role clarity	Explicit Plug/Socket roles	No implicit roles	Depends on implementation
Wiring complexity	Low – one connection	High – multiple wires	Low – one connection but more complex interface
Suitable for	Simple synchronization, pure event protocols	Simple one-way triggers	Data exchange with handshake

The key advantage over plain event connections is the encapsulation of the complete handshake protocol into a single, well-defined interface. Compared to data-carrying handshake adapters, EVENT_HS is minimal and focused solely on event synchronization.

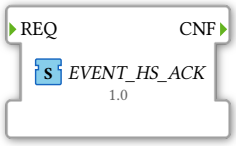


Conclusion

The EVENT_HS adapter provides a clean, dataless implementation of the IEC 61499 handshake design pattern. By defining the four core service primitives (`REQ`, `CNF`, `IND`, `RSP`) within a single adapter interface, it simplifies the wiring between communication partners and clarifies the roles of Requester and Responder. Its lightweight nature and identical behaviour to the textbook pattern make it an ideal building block for event-driven coordination in IEC 61499-based applications. Developers must, however, pay careful attention to correct Socket/Plug assignment, since the compiler does not enforce directional correctness.

EVENT_HS_ACK

Plug (adapter output)



Confirmation from Socket to Plug, answers a REQ – *Event*

Event – Request from Plug to Socket

Socket (adapter input)

Request from Plug to Socket – *Event*

Event – Confirmation from Socket to Plug, answers a REQ

• – ◦ • – ◦ • – ◦ •

Introduction

The EVENT_HS_ACK adapter is a reduced member of the EVENT_HS (Handshake) design-pattern family. It implements only the request/confirm half of the full handshake vocabulary, providing the **REQ** (request) and **CNF** (confirmation) events while omitting **IND** and **RSP**. This yields a strict, one-directional-per-transaction handshake in which every request is guaranteed to receive a confirmation.

Because the adapter is dataless, it is used purely for event synchronization and control-flow coordination between the Plug and Socket sides of a connection.

Interface Structure

The adapter exposes exactly two event interfaces and no data interfaces. It defines two roles – **PLUG** (left interface) and **SOCKET** (right interface) – which determine in which direction the events travel.

Event Inputs

Event	Description
CNF	Confirmation received from the Socket, answering a previously issued REQ.

Event Outputs

Event	Description
REQ	Request issued by the Plug towards the Socket.

Data Inputs

None – the adapter carries no data.

Data Outputs

None – the adapter carries no data.

Adapters

Role	Direction	Behaviour
PLUG	Left interface	Plays the Requester/client role. It fires **REQ** and reacts to **CNF**.
SOCKET	Right interface	Plays the Responder/server role. It reacts to **REQ** and fires **CNF**.

Functionality

EVENT_HS_ACK implements a strict request/confirm handshake sequence:

1. The **Plug** issues a **REQ** event.
2. The **Socket** receives the **REQ**, performs whatever processing is required, and responds with a **CNF** event.
3. The **Plug** receives the **CNF**, which completes the transaction.

The Socket side can never push an unsolicited indication back to the Plug. Every **REQ** must be answered by exactly one **CNF**, making the pattern a reliable request/acknowledgment protocol.

Technical Features

- **Dataless** – carries no data payload; it only synchronizes events.
- **Reduced vocabulary** – only REQ and CNF; no IND or RSP.

- **Guaranteed confirmation** – every REQ is answered by a CNF, unlike unidirectional handshake variants.
- **Standard IEC 61499 compliant** – adheres to the 61499-1 identification and uses the standard service-sequence model.
- **Simple service model** – a single `request_confirm` service sequence with two transactions fully specifies the behaviour.

State Overview

The adapter defines one service sequence, `request_confirm`, consisting of two transactions:

Transaction	Input Primitive	Output Primitive	Description
1	PLUG **REQ**	SOCKET **REQ**	Plug sends a request to the Socket.
2	SOCKET **CNF**	PLUG **CNF**	Socket confirms the request back to the Plug.

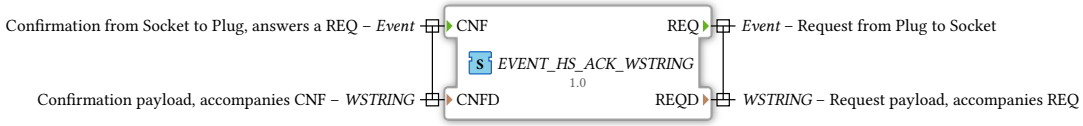
The handshake is strictly alternating: the Plug initiates, the Socket confirms, and the transaction is then complete.

Application Scenarios

- **Command/acknowledgment patterns** – when a client needs to issue commands and wait for explicit confirmation that the command was executed.
- **Simple server interactions** – when the Socket side never needs to send unsolicited indications back to the Plug.
- **Control-system coordination** – useful in distributed automation where asynchronous requests must be reliably acknowledged.
- **Reduced communication overhead** – when only two event types are needed and carrying data is unnecessary.

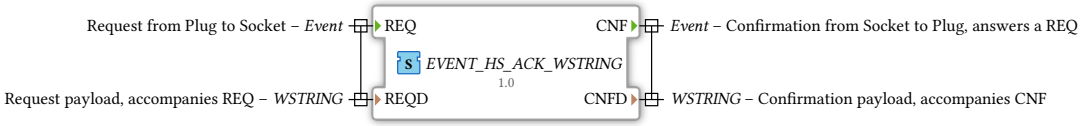
Comparison with Similar Blocks

Block	REQ	CNF	IND	RSP	Data	Description
EVENT_HS	✓	✓	✓	✓	–	Full handshake with all four event types.
EVENT_HS_UNI	✓	–	–	–	–	One-directional handshake without any confirmation.
EVENT_HS_ACK	✓	✓	–	–	–	Request/confirm only, no unsolicited indications.
EVENT_HS_ACK_WSTRING	✓	✓	–	–	✓	Same as EVENT_HS_ACK but carries a string payload.



EVENT_HS_ACK differs from **EVENT_HS_UNI** in that it guarantees a confirmation for every request. It differs from the full **EVENT_HS** by removing the IND/RSP pair, which enforces a clean server/responder model where the Socket can only answer requests.

Conclusion



EVENT_HS_ACK is a focused, dataless handshake adapter that provides a reliable request/confirm interaction pattern. By eliminating IND and RSP, it enforces a disciplined client/server relationship where every request is answered by a confirmation. It is an excellent choice for simple command/acknowledgment flows in IEC 61499 distributed control applications, offering a reduced interface footprint while preserving the essential guarantees of a handshake.

EVENT_HS_ACK_WSTRING

Plug (adapter output)

Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

`EVENT_HS_ACK_WSTRING` is a data-carrying adapter type belonging to the Handshake (`EVENT_HS`) family defined in the IEC 61499 primer course (Module 6, Valeriy Vyatkin). It implements the request/confirm half of the full REQ/CNF/IND/RSP handshake vocabulary, augmented with `WSTRING` payloads on both events.

This adapter provides a simple **Plug → Socket request → confirmation** pattern, where the Plug (client/requester) initiates a request with an attached payload, and the Socket (server/responder) answers with a confirmation carrying its own payload. Notably, the Socket cannot initiate unsolicited traffic; no `IND`/`RSP` events exist, making this a strictly client-driven, two-message exchange.

Interface Structure

The adapter exposes two complementary roles — **Plug** (left interface, `Name>>`) and **Socket** (right interface, `>>Name`) — which must be paired by connecting a Plug of one instance to a Socket of another.

Event Inputs

Event	With	Comment
`CNF`	`CNFD`	Confirmation from Socket to Plug, answers a `REQ`

Event Outputs

Event	With	Comment
`REQ`	`REQD`	Request from Plug to Socket

Data Inputs

Data	Type	Comment
`CNFD`	`WSTRING`	Confirmation payload, accompanies `CNF`

Data Outputs

Data	Type	Comment
`REQD`	`WSTRING`	Request payload, accompanies `REQ`

Adapters

The adapter defines two interface halves that act as the connection endpoints:

- **PLUG** (`Name>>`) — the request-initiating side. It fires `REQ`/`REQD` and receives `CNF`/`CNFD`.
- **SOCKET** (`>>Name`) — the request-responding side. It receives `REQ`/`REQD` and fires `CNF`/`CNFD`.

Functionality

The adapter implements a synchronous-style request/confirm handshake:

1. The **Plug** issues a request by firing the `REQ` event, simultaneously placing a value on `REQD` (e.g., `"push,100"`).
2. The **Socket** receives the `REQ` event with `REQD` and processes the request.
3. Upon completion, the **Socket** responds by firing `CNF`, placing its own payload on `CNFD`.
4. The **Plug** receives the `CNF` event with `CNFD` and can react to the confirmation.

The entire exchange is captured in the service sequence `request_confirm`, which defines two mandatory transactions: one for the REQ/REQD transfer from Plug to Socket, and one for the CNF/CNFD transfer from Socket back to Plug.

Technical Features

- **WSTRING payloads** on both `REQ` and `CNF` events, allowing arbitrary textual data (e.g., `"name,value"` messages) to travel with each handshake step.
- **Reduced vocabulary** — only `REQ`/`CNF`; no `IND`/`RSP` events are present, preventing unsolicited Socket-initiated messages.
- **Direction-preserving roles** — the Plug always acts as requester, the Socket always as responder.
- **IEC 61499-1 compliant** — defined as an adapter type with standard event/data `With` associations.
- **Single service sequence** — the `request_confirm` sequence strictly defines the allowed interaction order.

State Overview

The adapter does not maintain an explicit internal state machine in the FB sense; the interaction is governed by the service sequence `request_confirm`. Conceptually, the exchange progresses through two states:

State	Description
Idle	No pending request. The Plug may initiate a `REQ`/`REQD`.
Waiting for Confirmation	`REQ`/`REQD` has been sent; the adapter waits for the Socket's `CNF`/`CNFD`.

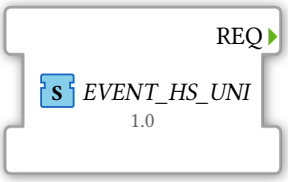
After the `CNF`/`CNFD` is received, the adapter returns to Idle and is ready for the next request. The Socket side mirrors this: it waits in Idle for an incoming `REQ`, processes it, and returns to Idle after firing `CNF`.

Application Scenarios

- **Client–Server command/acknowledge** patterns, where a controller (Plug) sends a command string and expects a textual acknowledgment (e.g., `"push,100"` → `"push,100"`).
- **Configuration or parameter update** workflows requiring a paired request/confirmation with meaningful data on both sides.
- **Reduced handshake requirements** in embedded or automation systems where only a two-message exchange is needed and the server must never push unsolicited data.
- **Inter-module communication** in distributed IEC 61499 applications where a simple data-carrying request–response interaction must be explicitly typed and verified at design time.

Comparison with Similar Blocks

Adapter	Events	Payload	Notes
`EVENT_HS`	REQ, CNF, IND, RSP	None	Full four-event handshake
`EVENT_HS_ACK`	REQ, CNF	None	Reduced two-event handshake
`EVENT_HS_UNI`	REQ, CNF	None	Unidirectional variant
`EVENT_HS_UNI_WSTRING`	REQ, CNF	WSTRING on one direction	Data-carrying unidirectional variant
`EVENT_HS_ACK_WSTRING`	REQ, CNF	WSTRING on both REQ and CNF	Data-carrying reduced handshake

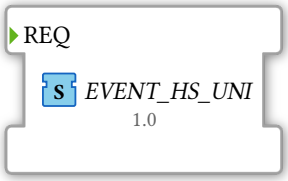


Compared to `EVENT_HS_ACK`, this adapter adds `WSTRING` payloads to both the request and the confirmation, making it suitable for message-based protocols. Compared to the full `EVENT_HS`, it drops the `IND`/`RSP` pair entirely, which simplifies the contract and eliminates the possibility of server-initiated traffic.

Conclusion

`EVENT_HS_ACK_WSTRING` is a well-defined, minimal handshake adapter for request/confirm interactions with textual payloads. Its clean separation of Plug (requester) and Socket (responder) roles, combined with its reduced event vocabulary and explicit `WSTRING` data carriage, makes it a practical building block for IEC 61499 applications that need a simple, typed, two-message client–server exchange without the overhead or ambiguity of a full four-event handshake.

EVENT_HS_UNI



Plug (adapter output)

Event – Request/notification from Plug to Socket, no reply expected

Socket (adapter input)

Request/notification from Plug to Socket, no reply expected – *Event*

• – ◦ • – ◦ • – ◦ •

Introduction

`EVENT_HS_UNI` is a unidirectional, dataless member of the `EVENT_HS` handshake family (IEC 61499 design pattern). It declares only a single **REQ** event that travels from the Plug side to the Socket side. In contrast to the full `EVENT_HS` adapter, it omits **CNF**, **IND**, and **RSP** entirely, reducing the interaction to a pure fire-and-forget notification.

This adapter is deliberately **not a real handshake**: the Socket side has no mechanism to acknowledge or refuse the request, and the Plug side has no way to determine whether the Socket actually received or acted upon it. It should only be used in scenarios where one-way, best-effort semantics are acceptable.

Interface Structure

The adapter follows the standard Plug/Socket role split: the **Plug** side (`Name>>`) keeps the declared direction and fires **REQ** the **Socket** side (`>>Name`) mirrors it and reacts to the incoming **REQ**.

Event Inputs

None. The adapter declares no event inputs; all interaction is driven by the single output event.

Event Outputs

Name	Type	Comment
REQ	Event	Request/notification from Plug to Socket, no reply expected

Data Inputs

None. The adapter is dataless; the **REQ** event carries no associated data.

Data Outputs

None. No data is returned from the Socket side.

Adapters

The adapter provides the standard two connector roles:

- **PLUG** (left interface): initiates the interaction by emitting **REQ**.
- **SOCKET** (right interface): receives and reacts to **REQ**.

The service sequence `notify` describes a single transaction: an input primitive on the PLUG interface with event **REQ** produces an output primitive on the SOCKET interface with the same event, forwarding the notification one way.

Functionality

`EVENT_HS_UNI` implements a one-way, dataless notification channel. When the connected function block on the Plug side raises the **REQ** event, it is forwarded directly to the Socket side, where the corresponding function block reacts to it.

Because no acknowledgment path exists, the semantics are purely best-effort:

- The Plug side cannot know whether the Socket side received the event.
- The Socket side cannot confirm processing or reject the request.
- No retry, timeout, or handshake state tracking is possible at the adapter level.

The adapter is a reduction of the full `EVENT_HS` pattern, keeping only the request direction and dropping all reply mechanisms.

Technical Features

- **Unidirectional event flow**: Only **REQ** is defined; no response events exist.
- **Dataless**: The event carries no payload, making it suitable for pure control signals or notifications.
- **Best-effort semantics**: No acknowledgment, no back-pressure, no delivery guarantee.
- **Standard Plug/Socket pattern**: Compatible with the IEC 61499 connector model and standard 4diac wiring practices.
- **Typed adapter family**: Part of the `adapter::types::bidirectional::Handshake` package, alongside other reduced variants.
- **Optional service documentation**: The embedded `<Service>` block is purely informational; it does not affect event forwarding at runtime.

State Overview

The adapter has no internal state machine. It is a passive connector that forwards the **REQ** event from the Plug interface to the Socket interface. Any state handling must be implemented in the connected function blocks.

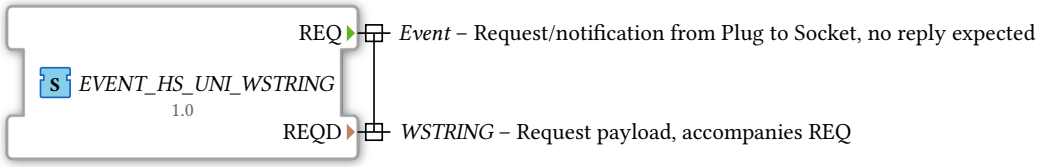
Application Scenarios

- **Fire-and-forget notifications**: Signaling a peer component that an event occurred, where no confirmation is required.
- **One-directional control pulses**: Triggering a one-shot action on the Socket side (e.g., reset, start, stop command) where the sender does not need feedback.
- **Event broadcasting / logging**: Propagating an occurrence to a downstream component without expecting a reply.
- **Reduced-resource designs**: Where the full handshake overhead of `EVENT_HS` is unnecessary and every extra event line complicates the application.

Typical use cases include simple alarm signals, watch-dog pulses, or inter-module triggers where the communication channel is inherently reliable and loss is acceptable.

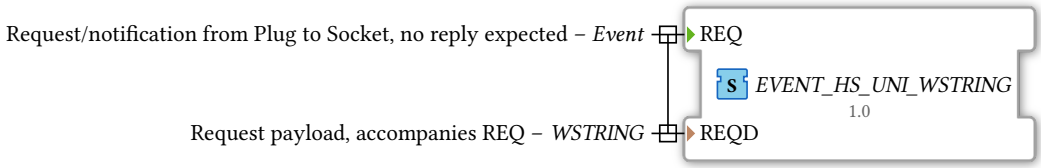
Comparison with Similar Blocks

Adapter	REQ	CNF	IND	RSP	Data	Semantics
`EVENT_HS`	Yes	Yes	Yes	Yes	No	Full handshake, acknowledged request/response
`EVENT_HS_UNI`	Yes	No	No	No	No	Unidirectional fire-and-forget, no acknowledgment
`EVENT_HS_UNI_WSTRING`	Yes	No	No	No	Yes	Unidirectional with string payload, no acknowledgment
`EVENT_HS_ACK`	Yes	Yes	No	No	No	Request with acknowledgment, no independent indication
`EVENT_HS_ACK_WSTRING`	Yes	Yes	No	No	Yes	Request with acknowledgment and string payload



Compared to the full `EVENT_HS`, `EVENT_HS_UNI` reduces the interface to a single event and drops all handshake semantics. It is therefore not a drop-in replacement where reliable delivery or confirmation is required.

Conclusion



`EVENT_HS_UNI` provides a minimal, unidirectional, dataless communication channel in the `EVENT_HS` family. Its single **REQ** event enables fire-and-forget notifications between Plug and Socket with the least possible interface overhead. However, because it offers no acknowledgment or delivery guarantee, it must only be used where best-effort semantics are acceptable. For applications requiring reliable, confirmed handshakes, the full `EVENT_HS` or one of its acknowledged variants (`EVENT_HS_ACK`, `EVENT_HS_ACK_WSTRING`) is the appropriate choice.

EVENT_HS_UNI_WSTRING

Plug (adapter output)

Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

The **EVENT_HS_UNI_WSTRING** adapter is a data-carrying, reduced member of the `EVENT_HS` (Handshake) adapter family, implementing a unidirectional, fire-and-forget communication pattern. It declares a single **REQ** event paired with a **REQD** WSTRING payload that flows exclusively from the Plug to the Socket side. Unlike a true handshake, this adapter provides no acknowledgment, no indication, and no response channel whatsoever — the Socket side cannot confirm receipt or reject the request, and the Plug side has no way of verifying that the message was ever delivered or processed.

This adapter is designed for genuine one-way, best-effort notifications where the simplicity of a single event+payload pair outweighs the need for end-to-end reliability. It follows the "name,value" message style (e.g., `push,100`) commonly used in lightweight messaging systems.

Interface Structure

The adapter exposes a minimal interface with only one event and one data output on the Plug side, mirrored to the Socket side. There are no inputs on either role.

Event Inputs

None. The adapter declares no event inputs on either the Plug or Socket interface.

Event Outputs

Name	Type	With	Comment
REQ	Event	REQD	Request/notification from Plug to Socket, no reply expected

The **REQ** event is the sole trigger of the adapter. When fired on the Plug side, it is forwarded to the Socket side, carrying the current value of **REQD** as its payload.

Data Inputs

None. The adapter declares no data inputs on either role.

Data Outputs

Name	Type	Comment

REQD	WSTRING	Request payload, accompanies REQ

The **REQD** output holds the payload that is transmitted together with the **REQ** event. It is a wide string (WSTRING) that can carry arbitrary textual content, typically structured in a `name,value` format. The value is sampled at the moment the **REQ** event fires and is delivered to the Socket side.

Adapters

The adapter defines the standard Plug/Socket role split:

- **PLUG** (interface name: `Name>>`): The initiating side. It owns the declared direction and fires **REQ** carrying **REQD**.
- **SOCKET** (interface name: `>>Name`): The receiving side. It mirrors the **REQ** event and receives the **REQD** payload for reaction.

The service sequence `notify` documents the single transaction: a Plug-side `REQ` input primitive with parameter `REQD` is propagated as a Socket-side `REQ` output primitive with the same parameter.

Functionality

The adapter implements a single, atomic, unidirectional transaction:

1. The application connected to the **Plug** side sets the **REQD** data output to the desired payload value.
2. The **REQ** event is fired on the Plug side.
3. The adapter forwards the **REQ** event to the **Socket** side, passing along the current value of **REQD**.
4. The application connected to the **Socket** side receives the **REQ** event and reads the **REQD** payload.

There is no second transaction step. No `CNF` (confirmation), `IND` (indication), or `RSP` (response) events exist — neither with nor without payload. The communication is strictly one-way and fire-and-forget.

The `<Service>` block included in the adapter definition is purely documentation. Per the XSD's `minOccurs="0"`, a service sequence diagram is optional and not required for the adapter connection to forward events at runtime. It is included to make the single REQ transaction explicit and to aid designers reading the adapter documentation.

Technical Features

- **Single event/payload pair**: Exactly one event (`REQ`) and one data output (`REQD`) constitute the entire interface, minimizing connection overhead.
- **WSTRING payload**: The payload type is `WSTRING`, supporting Unicode text and arbitrary-length string data, suitable for name/value pairs, JSON snippets, or command strings.
- **Unidirectional flow**: Data and events travel exclusively from Plug to Socket. There is no reverse channel.
- **No handshake semantics**: Deliberately omits confirmation, indication, and response events. The Socket side cannot acknowledge or refuse, and the Plug side cannot detect delivery failure.
- **Zero state complexity**: With only a single transaction and no reply path, the adapter requires no internal state machine beyond event forwarding.
- **Standard Plug/Socket roles**: Consistent with the wider `EVENT_HS` family, preserving the conventional interface naming and direction conventions of IEC 61499 adapter types.

State Overview

The adapter does not maintain any internal state beyond the propagation of a single event. Its behavior can be modeled with a trivial two-state view:

- **Idle**: No transaction in progress. The adapter is ready to accept a `REQ` on the Plug side.
- **Transmitting**: The `REQ` event with the `REQD` payload is being forwarded from Plug to Socket. This state is instantaneous — the forwarding is atomic and completes within the same execution cycle.

There is no waiting, retry, or timeout state because the adapter does not expect a reply. Once the event is forwarded, the adapter returns to the Idle state. The absence of `CNF` or `RSP` events means there is no suspension of the execution resource waiting for a counterpart response.

Application Scenarios

The **EVENT_HS_UNI_WSTRING** adapter is suitable for scenarios where one-way notification with a small payload is acceptable and no acknowledgment is required:

- **Telemetry and status push**: Sensors or devices pushing measurement values (e.g., `temperature,23.5`) to a monitoring unit that does not need to confirm receipt.
- **Logging and audit trails**: Sending log entries or audit messages to a central collector where occasional loss is tolerable.
- **Command dispatch (fire-and-forget)**: Sending non-critical commands (e.g., `push,100`) where the receiving side is expected to act on them without the sender waiting for confirmation.
- **Event broadcasting**: Propagating system events (e.g., `mode,automatic`) to interested consumers in a one-to-many or one-to-one topology where reliability is not critical.
- **Integration with message-style protocols**: Matching the "name,value" textual message pattern documented in the Handshake design pattern, useful for bridging IEC 61499 applications to lightweight messaging middleware.

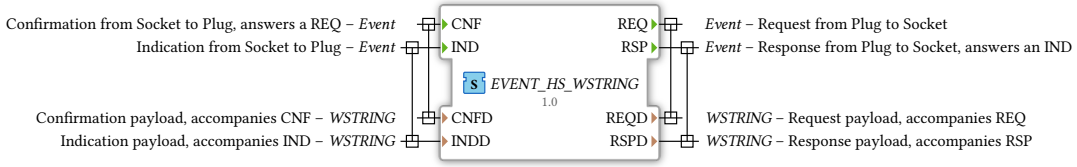
It should **not** be used when the sender needs to know whether the request was received or processed, when a reply is required, or when guaranteed delivery is a system requirement.

Comparison with Similar Blocks

The **EVENT_HS** family contains multiple variants tailored to different handshake depths. The following comparison highlights the key differences:

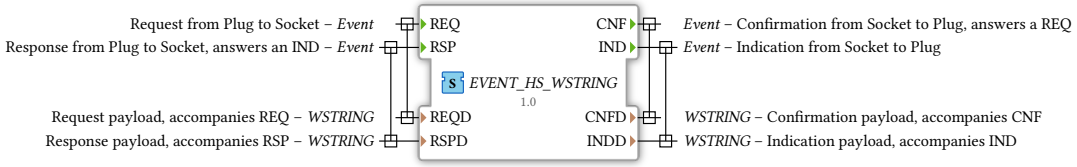
Adapter	REQ/REQD	CNF/CNFD	IND/INDD	RSP/RSPD	Payload	Use Case
EVENT_HS_UNI_WSTRING	Yes	No	No	No	WSTRING	One-way fire-and-forget with payload
EVENT_HS_UNI	Yes	No	No	No	None	One-way fire-and-forget, no payload
EVENT_HS_ACK	Yes	Yes	No	No	None	One-way with acknowledgement
EVENT_HS_ACK_WSTRING	Yes	Yes	No	No	WSTRING	One-way with acknowledgement and payload
EVENT_HS (full)	Yes	Yes	Yes	Yes	Mixed	Complete bidirectional handshake

Compared to the full `EVENT_HS`, this adapter sacrifices all reply capability for interface simplicity. Compared to `EVENT_HS_UNI`, it adds a WSTRING payload at the cost of slightly more connection wiring. Compared to the `_ACK` variants, it omits confirmation, trading reliability for minimalism.



Conclusion

The **EVENT_HS_UNI_WSTRING** adapter provides a lean, purpose-built solution for unidirectional, payload-carrying notifications within the IEC 61499 adapter framework. Its single `REQ`/`REQD` event-payload pair offers a clear and maintainable interface for fire-and-forget communication, while its deliberate exclusion of handshake mechanisms keeps the design simple and avoids the complexity of error handling and timeouts.



As a reduced member of the `EVENT_HS` family, it is best employed where best-effort semantics are acceptable and where the "name,value" message style aligns with the surrounding system design. For scenarios demanding acknowledgment or bidirectional interaction, the companion adapters (`EVENT_HS_ACK_WSTRING`, full `EVENT_HS`) provide richer handshake capabilities.

EVENT_HS_WSTRING

Plug (adapter output)

Socket (adapter input)

• – ○ • – ○ • – ○ •

Introduction

The **EVENT_HS_WSTRING** adapter is a data-carrying variant of the classic **Handshake design pattern** (IEC 61499 primer course, Module 6 – Design methods and patterns). It maintains the same REQ/CNF/IND/RSP event vocabulary as the dataless `EVENT_HS` adapter, but each event is accompanied by a `WSTRING` payload. This matches Vyatkin's generic *service* adapter (slide 48) used in service-oriented architectures, where messages such as `"push,100"` are exchanged.

The adapter implements a **plug/socket** role split:

- **Plug** (client/requester side) fires REQ and RSP events and reacts to CNF and IND events.
- **Socket** (server/responder side) fires CNF and IND events and reacts to REQ and RSP events.

Interface Structure

Event Inputs

Event	With Variable	Description
`CNF`	`CNFD`	Confirmation from Socket to Plug, answers a REQ. Carries a payload via `CNFD`.
`IND`	`INDD`	Unsolicited indication from Socket to Plug. Carries a payload via `INDD`.

Event Outputs

Event	With Variable	Description
`REQ`	`REQD`	Request from Plug to Socket. Carries a payload via `REQD`.
`RSP`	`RSPD`	Response from Plug to Socket, answers an IND. Carries a payload via `RSPD`.

Data Inputs

Variable	Type	Description
`CNFD`	`WSTRING`	Confirmation payload, accompanies `CNF`.
`INDD`	`WSTRING`	Indication payload, accompanies `IND`.

Data Outputs

Variable	Type	Description
`REQD`	`WSTRING`	Request payload, accompanies `REQ`.
`RSPD`	`WSTRING`	Response payload, accompanies `RSP`.

Adapters

The adapter itself acts as an interface between a Plug and a Socket. It does not contain any sub-adapters; instead, it defines the contract for bidirectional communication with WSTRING payloads.

Functionality

The adapter follows two primary interaction patterns:

1. **Request–Confirm** (`request_confirm`):
   - The Plug issues a `REQ` event with a payload (`REQD`).
   - The Socket receives the `REQ` and later responds with a `CNF` event carrying `CNFD`.
2. **Indication–Response** (`indication_response`):
   - The Socket sends an unsolicited `IND` event with payload (`INDD`).
   - The Plug acknowledges with an `RSP` event carrying `RSPD`.

Each transaction is atomic and unidirectional from the initiating side. The WSTRING payloads allow arbitrary textual data to be exchanged, making the adapter suitable for command/status or simple data transfer scenarios.

Technical Features

- **Standard compliance**: Implements the IEC 61499 service interface pattern.
- **Data type**: All payload variables are of type `WSTRING`, allowing Unicode string data.
- **Explicit event–data association**: Each event has a corresponding data variable, ensuring payload consistency.
- **Socket/Plug semantics**: Clearly defined roles for client and server sides.
- **Reusability**: Can be used as a template for typed payload adapters by replacing `WSTRING` with other types.
- **Documentation**: Detailed usage notes are embedded in the type's documentation attribute, referencing typical message formats like `"push,100"`.

State Overview

The adapter does not maintain an internal state machine; it defines a stateless protocol with two independent service sequences. However, each sequence can be considered a two-step exchange:

- **Idle** ⟶ `REQ` sent ⟶ waiting for `CNF` ⟶ `CNF` received ⟶ back to idle.
- **Idle** ⟶ `IND` received ⟶ `RSP` sent ⟶ back to idle.

These sequences can overlap or be interleaved, as the adapter does not enforce mutual exclusion.

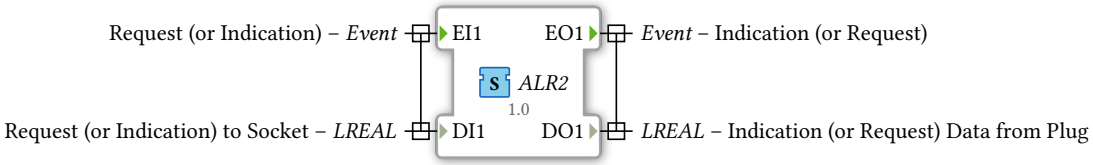
Application Scenarios

- **Service-oriented architectures** in distributed control systems, where a client requests an operation and receives confirmation.
- **Plant/process data interfaces** where a server sends unsolicited indications (e.g., alarms) and the client acknowledges.
- **Command/response patterns**: e.g., sending `"push,100"` to a machine and receiving `"ok"` as confirmation.
- **Replacement for dataless handshake** when payload transmission is required without redesigning the event structure.

Comparison with Similar Blocks

Adapter	Payload	Use Case
`EVENT_HS`	None	Pure handshake pattern, no data transfer.
`EVENT_HS_WSTRING`	`WSTRING`	Handshake with textual payload, generic and human-readable.
Typed adapters (e.g., with `INT`/`REAL`)	specific types	When strict typing and performance are critical; require custom design.

Compared to `EVENT_HS`, this adapter adds data transfer capability while preserving the same event flow. Compared to fully typed adapters, it offers flexibility and simplicity for heterogeneous string-based data.



Conclusion

The `EVENT_HS_WSTRING` adapter extends the proven handshake pattern with WSTRING payloads, enabling clear, bidirectional, and data-bearing communication between plug and socket components. It is particularly useful in service-oriented industrial applications where requests, confirmations, indications, and responses need to carry textual information. Its clear separation of events and data, combined with the standard plug/socket roles, makes it a versatile building block for IEC 61499-based systems.

AR2

Plug (adapter output)

Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

The **AR2** adapter type provides a bidirectional interface between two function blocks. It transmits exactly one event along with a REAL value in both directions. The designation “AR2” stands for “Adapter Real 2-Way”. The component is designed as a generic connector (plug/socket) within the 4diac IDE and enables clean, type-safe coupling of components.

Interface Structure

Event Inputs

Name	Type	Comment	with data
EI1	Event	Request (or Indication)	DI1

Event Outputs

Name	Type	Comment	with data
EO1	Event	Indication (or Request)	DO1

Data Inputs

Name	Data Type	Comment
DI1	REAL	Request (or Indication) to Socket

Data Outputs

Name	Data Type	Comment
DO1	REAL	Indication (or Request) Data from Plug

Adapter

None defined.

Functionality

The AR2 adapter operates in an event-driven and bidirectional manner:

- When the event input **EI1** is triggered, the current REAL value at **DI1** is transmitted to the opposite end of the adapter. There, the event **EO1** appears along with the value at **DO1**.
- The same applies in the opposite direction: If the connected counterpart adapter triggers its event, this AR2 receives the event at **EI1** and makes the received value available at **DI1**.

The comments “Request (or Indication)” and “Indication (or Request)” clarify that, depending on the installation situation (plug or socket), the adapter can assume the role of a requesting or indicating channel. Therefore, AR2 is suitable for both master/slave and peer-to-peer communication.

Technical Features

- **Typed Data Transmission:** Only the **REAL** data type is supported, which provides clear semantics for physical measured values or control variables.
- **Bidirectionality:** A single adapter enables data exchange in both directions, reducing the number of required interfaces.
- **Versioning:** The module is in version 1.0, developed by HR Agrartechnik GmbH (Copyright 2026, EPL 2.0).
- **Compiler Information:** The package is located at `adapter::types::bidirectional` and uses a type hash (`eclipse4diac::core::TypeHash`) for integrity checks.
- **No State Machine:** The adapter itself does not have its own state logic; it functions purely as a connection between two event/data pairs.

State Overview

The AR2 adapter does not implement an explicit state machine. Data flows without delay or intermediate storage when events occur – the signals are passed directly from input to output.

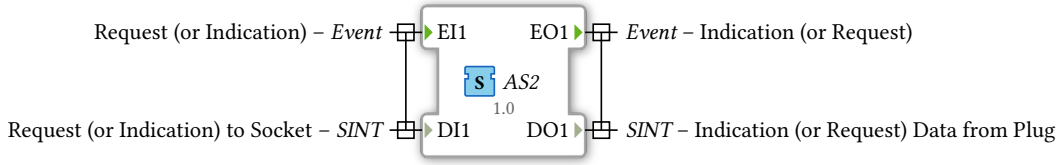
Application Scenarios

- **Sensor Value Transmission:** A function block acquires an analog sensor value (e.g., temperature, pressure) and sends it to an evaluation block via AR2. Simultaneously, the evaluation block can return a setpoint in the opposite direction.
- **Control Coupling:** In a modular control system, AR2 connects a PID controller to an actuator. The controller sends the manipulated value (REAL) and simultaneously receives the current control deviation.
- **Parameterization:** Configuration parameters (e.g., limit values) can be exchanged between an operator panel and the control logic via AR2.

Comparison with Similar Modules

- **AR1 (Unidirectional):** An adapter that transmits data in only one direction. AR2, on the other hand, enables bidirectional exchange, which reduces cabling requirements.
- **AE2 (Adapter Event 2-Way):** Transmits two events, but no data. AR2 combines an event with a REAL value – ideal for value-based communication.
- **AR4 (Adapter Real 4-Way):** Offers four independent REAL channels. AR2 is more compact when only one value is needed.

Conclusion



The AR2 adapter is an elegant component for the bidirectional transmission of a REAL value with its associated event. Its clear interface and ease of use make it particularly suitable for modular automation solutions where measurement data or control variables need to be exchanged between function blocks. By complying with the 61499 standard and being licensed under EPL 2.0, AR2 is open and extensible.

TokenRing

TokenRing
Plug (adapter output)

Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

The **TokenRing** adapter type implements the **TokenRing / Mutual Exclusion design pattern** (IEC 61499 primer course, Module 6, V. Vyatkin, slide 15). It provides a dataless, event-based interface used to pass a mutual-exclusion "token" around a ring of controllers that share a common resource. Only the controller currently holding the token may enter its critical section; when its work is complete, it passes the token to its downstream neighbour.

The adapter defines exactly two events: **GIVE** (handing the token to the neighbour) and **RCV** (acknowledging receipt of the token). The adapter itself carries no data—the token is purely logical and conveyed by the event exchange.

Interface Structure

The TokenRing adapter exposes two event endpoints, one on each side of the adapter connection:

- **Plug** side (left, named `MTXOUT` in the reference design) plays the **giver** role: it fires `GIVE` and reacts to `RCV`.
- **Socket** side (right, named `MTXIN` in the reference design) plays the **receiver** role: it reacts to `GIVE` and fires `RCV`.

Event Inputs

Event	Type	Description
`RCV`	Event	Acknowledgement from the Socket that it received the token, sent back to the Plug.

Event Outputs

Event	Type	Description
`GIVE`	Event	The Plug hands the token to the Socket.

Data Inputs

None. The adapter is **dataless** by design—the token is represented solely by the event exchange.

Data Outputs

None. No data is carried across the adapter.

Adapters

This type is itself an adapter and does not contain nested adapters. It is instantiated as an adapter connection point inside function blocks or other adapters.

Functionality

The adapter implements a strict two-step handshake per token pass, captured in the service sequence `token_pass`:

1. **Token handover**: The Plug fires `GIVE`; the event is forwarded to the Socket, signalling that the token is being passed to the downstream neighbour.
2. **Acknowledgement**: The Socket fires `RCV`; the event is forwarded back to the Plug, confirming that the token has been received.

This handshake ensures a deterministic, lossless token transfer. A controller that participates in the ring must instantiate **two** TokenRing adapters:

- One **Plug** (`MTXOUT`) connected towards its *downstream* neighbour (the controller it passes the token to).
- One **Socket** (`MTXIN`) connected towards its *upstream* neighbour (the controller it receives the token from).

The ring is formed by wiring `MTXOUT` of each controller to `MTXIN` of the next controller in the ring, creating a closed loop.

Technical Features

- **Dataless design**: No data inputs or outputs; the token is purely logical, reducing interface complexity and eliminating data consistency issues.
- **Bidirectional event flow**: The adapter defines events travelling in both directions (Plug→Socket for `GIVE`, Socket→Plug for `RCV`), making it a true bidirectional adapter.
- **Plug/Socket role separation**: The roles are explicit and asymmetric, clearly identifying which side initiates the token pass and which side acknowledges it.
- **Standard-compliant**: Conforms to IEC 61499-1 adapter type definitions, with a formally declared service sequence (`token_pass`) that defines the valid event ordering.
- **Compact footprint**: Only two events, no data, no nested adapters—minimal resource usage in embedded controllers.

State Overview

Since the adapter is dataless, its state is expressed through the progress of the handshake:

State	Description
Idle (Token Held)	No event pending. The token is held by the local controller (or the controller is waiting for the token from upstream).
Token Being Passed	The Plug has fired `GIVE`; the token is in transit to the downstream neighbour. The adapter waits for the `RCV` acknowledgement.
Token Acknowledged	The Socket has fired `RCV`; the handshake is complete. The adapter returns to the Idle state, ready for the next token pass.

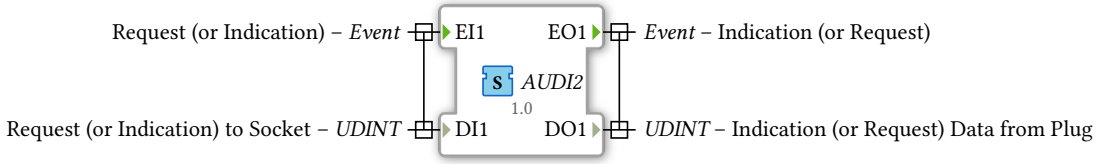
The service sequence enforces that `GIVE` must precede `RCV` in each token-pass cycle; no other event order is permitted.

Application Scenarios

- **Mutually exclusive access to a shared resource**: Multiple controllers sharing a common device (e.g., a memory bank, an I/O module, or a communication link) coordinate via the token so that only the token holder accesses the resource at any time.
- **Distributed control loops**: In agricultural machinery, industrial automation, or process control, where several PLCs or embedded controllers must serialize access to a physical actuator or sensor.
- **Ring topologies**: Closed-loop networks of controllers where deterministic, fair token rotation is required—each controller gets the token in turn, guaranteeing bounded latency for resource access.
- **Safety-critical coordination**: Where a simple, verifiable protocol is needed to prevent simultaneous access to a critical resource, the dataless handshake minimizes failure modes.

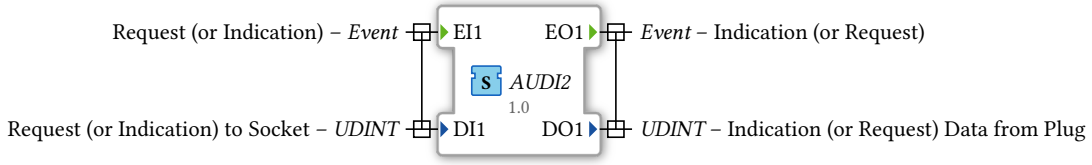
Comparison with Similar Blocks

Feature	TokenRing Adapter	Conventional Binary Semaphore / Mutex FB	Simple Event Connection
Data payload	None (pure event)	Often carries ownership/ID data	None
Acknowledgment	Explicit `RCV` handshake	Implicit release	None
Directionality	Bidirectional (Plug→Socket and Socket→Plug)	Usually unidirectional request/grant	Unidirectional
Ring topology support	Native (two instances per node)	Requires additional logic for ring wiring	Not designed for this
Failure detection	Handshake ensures delivery; no ack means no token loss	Depends on FB implementation	No delivery guarantee



Compared to a unidirectional event connection (which merely forwards a trigger), the TokenRing adapter provides a **confirmed handshake** that guarantees the token transfer is completed only when the receiver acknowledges it. Compared to a full semaphore FB, it avoids all data overhead and protocol complexity while still providing deterministic mutual exclusion.

Conclusion



The TokenRing adapter is a minimal, robust, and standard-compliant solution for implementing mutual exclusion in ring-shaped distributed control systems. Its dataless design and strict two-event handshake make it easy to use, easy to verify, and well suited for embedded controllers where determinism and low overhead are critical. By instantiating one Plug and one Socket per controller, developers can build a closed token-passing ring that provides fair, bounded-latency access to shared resources across the entire network.

constants

const_AX_FALSE

• – ○ • – ○ • – ○ •

Introduction

`const_AX_FALSE` is the counterpart to const_AX_TRUE: a simple constant block that writes the fixed value `FALSE` to an AX adapter plug on initialization. It is used to feed statically wired Boolean constants into an AX adapter network without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- **INIT**: initialization request. Triggers the constant value being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- None. The value `FALSE` is hard-wired into the block (`Parameter Name="D1" Value="FALSE"` on plug `OUT`).

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AX`): on `INIT`, outputs the fixed value `FALSE` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives, `const_AX_FALSE` triggers two internal connections: `INIT` is forwarded directly to `OUT.E1`, so the `OUT` plug fires its adapter event carrying the hard-parameterized data value `D1 = FALSE`. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

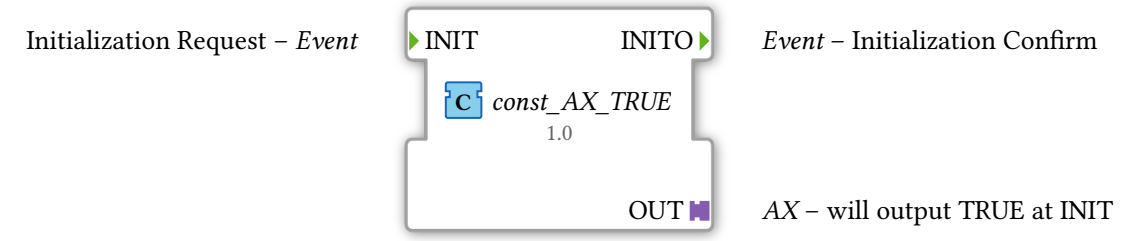
- The value `FALSE` is stored as a `Parameter` attribute directly on `OUT`'s `AdapterDeclaration` element, not as runtime data – the block has no way to output a different value at runtime. If a runtime-configurable start value is needed, use initval_AX instead.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances).

State Overview

The block is stateless: every `INIT` event immediately results in `FALSE` being output on `OUT` and confirmed via `INITO`.

Application Scenarios

- Initializing AX adapter connections with a fixed `FALSE` start value, e.g. as a disable constant
- Test setups where an AX input needs a fixed value without a real sensor or upstream block
- Replacing a manually wired constant connection in generic, AX-adapter-based networks



⚖️ Comparison with Similar Blocks

Compare with const_AX_TRUE, which uses the same mechanism for the value `TRUE`, and with initval_AX, which serves the same purpose but with a value configurable at runtime via `INIT_VAL` instead of a hard-wired one.

Conclusion

`const_AX_FALSE` is the simplest way to initialize an AX adapter plug with a fixed `FALSE` constant, and fits anywhere the value is known at design time and no runtime configuration is required.

const_AX_TRUE

• – ◦ • – ◦ • – ◦ •

Introduction

`const_AX_TRUE` is a simple constant block that writes the fixed value `TRUE` to an AX adapter plug on initialization. It is used to feed statically wired Boolean constants into an AX adapter network without wiring a separate event and data line for it.

Interface Structure

Event Inputs

- **INIT**: initialization request. Triggers the constant value being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- None. The value `TRUE` is hard-wired into the block (`Parameter Name="D1" Value="TRUE"` on plug `OUT`).

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AX`): on `INIT`, outputs the fixed value `TRUE` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives, `const_AX_TRUE` triggers two internal connections: `INIT` is forwarded directly to `OUT.E1`, so the `OUT` plug fires its adapter event carrying the hard-parameterized data value `D1 = TRUE`. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The value `TRUE` is stored as a `Parameter` attribute directly on `OUT`'s `AdapterDeclaration` element, not as runtime data – the block has no way to output a different value at runtime. If a runtime-configurable start value is needed, use initval_AX instead.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances).

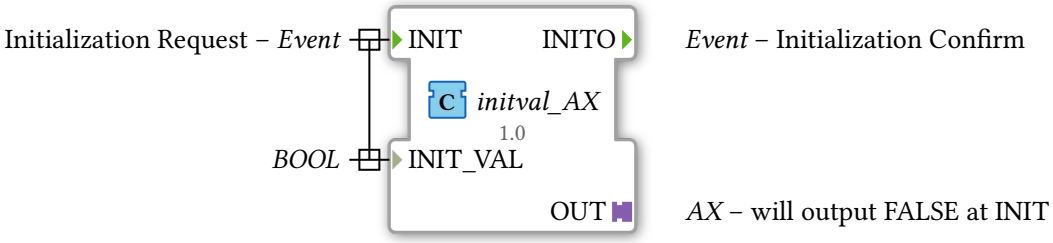
State Overview

The block is stateless: every `INIT` event immediately results in `TRUE` being output on `OUT` and confirmed via `INITO`.

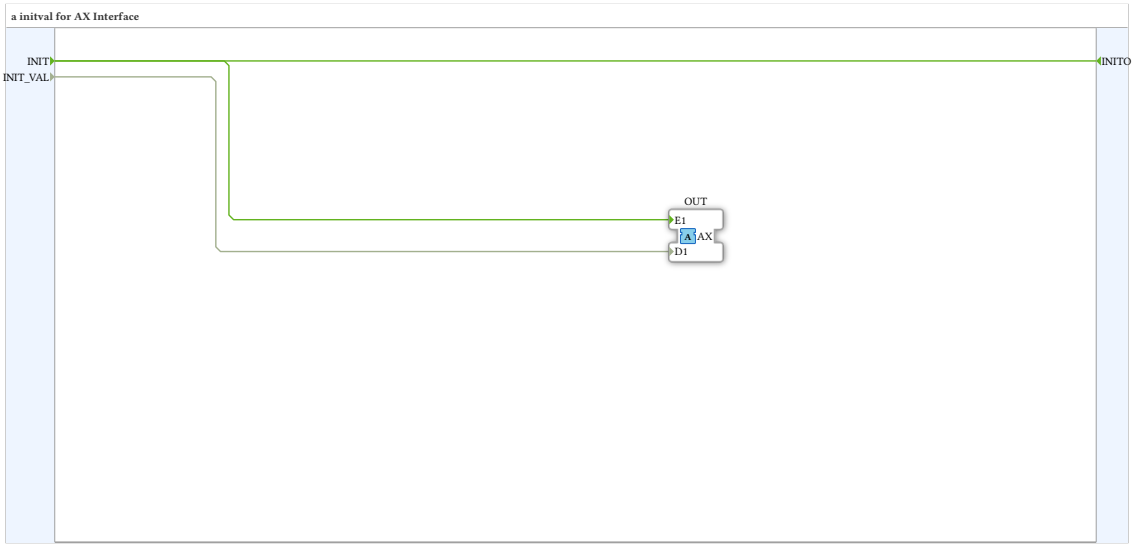
Application Scenarios

- Initializing AX adapter connections with a fixed `TRUE` start value, e.g. as an enable constant
- Test setups where an AX input needs a fixed value without a real sensor or upstream block
- Replacing a manually wired constant connection in generic, AX-adapter-based networks

⚖️ Comparison with Similar Blocks



Compare with const_AX_FALSE, which uses the same mechanism for the value `FALSE`, and with initval_AX, which serves the same purpose but with a value configurable at runtime via `INIT_VAL` instead of a hard-wired one.



Conclusion

`const_AX_TRUE` is the simplest way to initialize an AX adapter plug with a fixed `TRUE` constant, and fits anywhere the value is known at design time and no runtime configuration is required.

initval

initval_AX

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AX` is the configurable counterpart to the const_AX_TRUE/const_AX_FALSE blocks: instead of a hard-wired value, it accepts a Boolean start value as a data input at initialization time and writes it to an AX adapter plug.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (BOOL): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AX`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AX` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- Unlike `const_AX_TRUE`/`const_AX_FALSE`, the output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set an AX value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

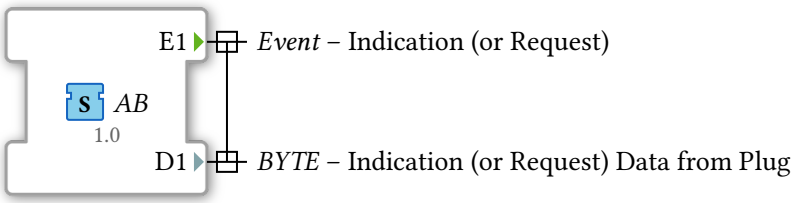
Application Scenarios

- Initializing AX adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Dynamically setting an AX value at runtime when `const_AX_TRUE`/`const_AX_FALSE`'s hard-wired value is not sufficient
- A reusable block template for test setups where different AX start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with const_AX_TRUE and const_AX_FALSE, which use the same wiring mechanism but parameterize the output value in the block itself instead of taking it from a data input.

Conclusion



`initval_AX` provides the same simple initialization logic as `const_AX_TRUE`/`const_AX_FALSE`, but makes the output value freely configurable via `INIT_VAL`, making it the right fit wherever the start value isn't already fixed at design time.

####### Initval

initval_AB

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AB` is the configurable initialization block for the AB adapter (data type `BYTE`, 8-bit bit pattern): it accepts a start value as a data input at initialization time and writes it to a `AB` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (BYTE): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AB`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1/D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AB` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AB` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

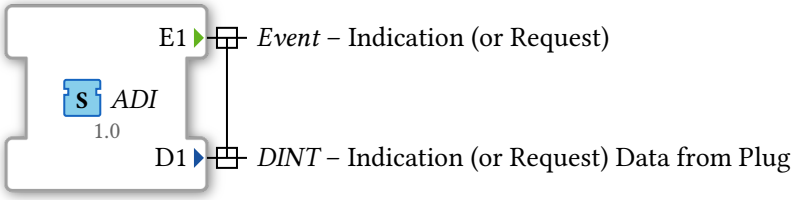
Application Scenarios

- Initializing `AB` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `BYTE` value is fed onto a `AB` adapter via `initval_AB` and can then be used together with the pure adapter-based `AB` comparison blocks.
- A reusable block template for test setups where different `AB` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE/const_AX_FALSE` (which only exist for `AX`), `initval_AB` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AB` provides simple, reusable initialization logic for the `AB` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `BYTE` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_ADI

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_ADI` is the configurable initialization block for the ADI adapter (data type `DINT`, 32-bit signed integer): it accepts a start value as a data input at initialization time and writes it to a `ADI` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (DINT): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `ADI`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_ADI` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `ADI` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

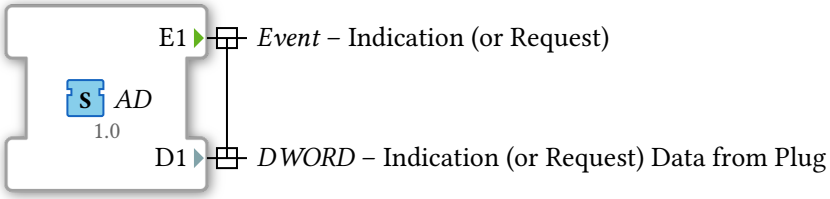
Application Scenarios

- Initializing `ADI` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `DINT` value is fed onto a `ADI` adapter via `initval_ADI` and can then be used together with the pure adapter-based `ADI` comparison blocks.
- A reusable block template for test setups where different `ADI` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_ADI` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_ADI` provides simple, reusable initialization logic for the `ADI` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `DINT` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_AD

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AD` is the configurable initialization block for the AD adapter (data type `DWORD`, 32-bit bit pattern): it accepts a start value as a data input at initialization time and writes it to a `AD` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (DWORD): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AD`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1/D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AD` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AD` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

Application Scenarios

- Initializing `AD` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `DWORD` value is fed onto a `AD` adapter via `initval_AD` and can then be used together with the pure adapter-based `AD` comparison blocks.
- A reusable block template for test setups where different `AD` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE/const_AX_FALSE` (which only exist for `AX`), `initval_AD` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion

`initval_AD` provides simple, reusable initialization logic for the `AD` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `DWORD` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_AI

• – ○ • – ○ • – ○ •

Introduction

`initval_AI` is the configurable initialization block for the AI adapter (data type `INT`, 16-bit signed integer): it accepts a start value as a data input at initialization time and writes it to a `AI` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (INT): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AI`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AI` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AI` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

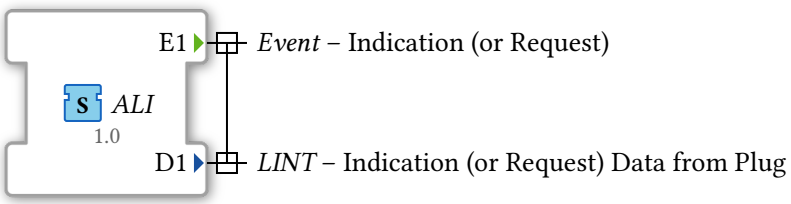
Application Scenarios

- Initializing `AI` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `INT` value is fed onto a `AI` adapter via `initval_AI` and can then be used together with the pure adapter-based `AI` comparison blocks.
- A reusable block template for test setups where different `AI` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AI` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AI` provides simple, reusable initialization logic for the `AI` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `INT` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_ALI

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_ALI` is the configurable initialization block for the ALI adapter (data type `LINT`, 64-bit signed integer): it accepts a start value as a data input at initialization time and writes it to a `ALI` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (LINT): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `ALI`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_ALI` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `ALI` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

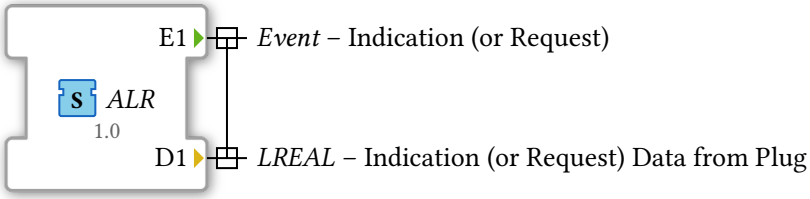
Application Scenarios

- Initializing `ALI` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `LINT` value is fed onto a `ALI` adapter via `initval_ALI` and can then be used together with the pure adapter-based `ALI` comparison blocks.
- A reusable block template for test setups where different `ALI` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_ALI` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_ALI` provides simple, reusable initialization logic for the `ALI` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `LINT` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_ALR

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_ALR` is the configurable initialization block for the ALR adapter (data type `LREAL`, 64-bit floating-point number): it accepts a start value as a data input at initialization time and writes it to a `ALR` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (LREAL): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `ALR`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_ALR` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `ALR` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

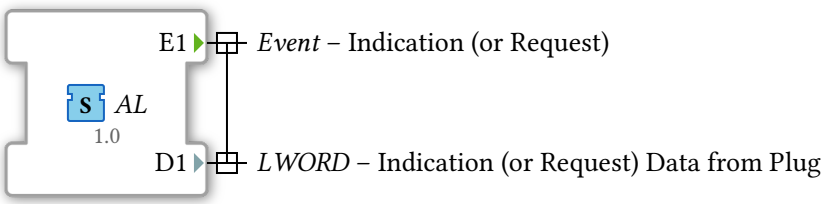
Application Scenarios

- Initializing `ALR` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `LREAL` value is fed onto a `ALR` adapter via `initval_ALR` and can then be used together with the pure adapter-based `ALR` comparison blocks.
- A reusable block template for test setups where different `ALR` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_ALR` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_ALR` provides simple, reusable initialization logic for the `ALR` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `LREAL` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

Unidirectional LWORD adapter

####### Initval

initval_AL

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AL` is the configurable initialization block for the AL adapter (data type `LWORD`, 64-bit bit pattern): it accepts a start value as a data input at initialization time and writes it to a `AL` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (LWORD): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AL`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AL` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AL` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

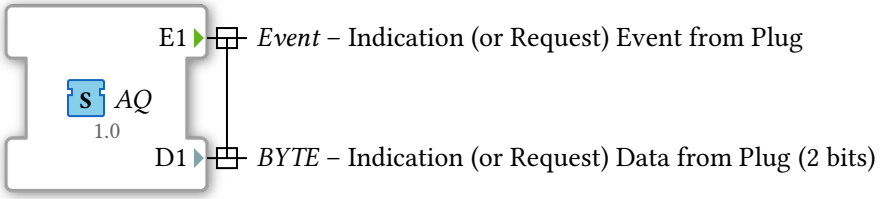
Application Scenarios

- Initializing `AL` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `LWORD` value is fed onto a `AL` adapter via `initval_AL` and can then be used together with the pure adapter-based `AL` comparison blocks.
- A reusable block template for test setups where different `AL` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AL` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AL` provides simple, reusable initialization logic for the `AL` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `LWORD` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

AQ

Plug (adapter output)

Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

The `AQ` adapter provides a unidirectional interface (plug side) for transmitting an event and a byte value (used for 2 bits). It serves as a standard definition for communication between function blocks according to IEC 61499-1 and enables simple, directed data transfer.

Interface Structure

Event Inputs

None.

Event Outputs

Name	Type	Comment

E1	Event	Indication (or Request) Event from Plug (triggered together with D1)

Data Inputs

None.

Data Outputs

Name	Type	Comment
D1	BYTE	Indication (or Request) Data from Plug (2 bits used)

Adapter

None.

Functionality

The `AQ` adapter defines a unidirectional connection. A connected function block can signal via the `E1` event that the byte value at the `D1` data output is valid. The data value is a byte, of which the lower 2 bits carry the actual information. The remaining 6 bits are not defined for the application. The adapter itself contains no processing logic – it solely represents the interface specification.

Technical Features

- **Unidirectional**: Only event and data outputs are present; no inputs. Suitable for plug pages in adapter pairings.
- **Data Usage**: Of the 8 bits of the byte value, only the lower 2 bits are considered significant. The remaining bits should be set to `0` or ignored by the sending function block.
- **Event + Data**: The event `E1` is linked to the data output `D1` (`With` relation). Both are sent together.
- **Compact**: Minimal interface with one event and one byte.

State Overview

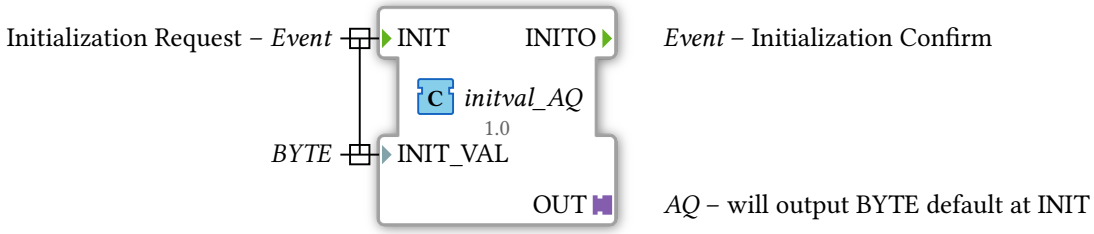
The adapter itself has no internal state. The sending function block controls the outputs based on its own state machine. The adapter simply defines the protocol: Events and data are transmitted together.

Application Scenarios

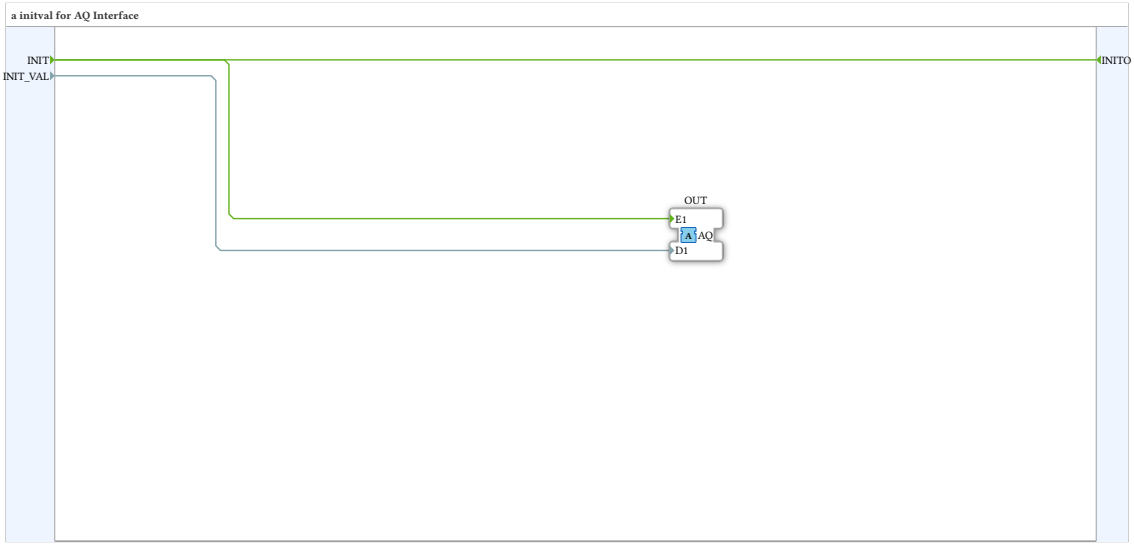
- Transmission of 2-bit status information (e.g., operating state “On/Off/Fault” or two separate flags).
- Simple command transmission with encoded bytes (e.g., 2-bit control words in automation systems).
- As part of a higher-level adapter pairing for minimal, directed communication between function blocks.

Comparison with Similar Function Blocks

Feature	AQ (this adapter)	Other adapters (e.g., with multiple events)
Events	1 output	Often multiple inputs/outputs
Data	1 byte (2 bits used)	Frequently multiple variables or complex types
Alignment	Unidirectional (Plug-side)	Bidirectional or pure socket-side
Complexity	Very low	Medium to high



The `AQ` adapter is specifically optimized for the minimal case of “one event + one byte”.



Conclusion

The `AQ` adapter offers a streamlined and standardized interface for the unidirectional transmission of an event and a 2-bit signal. Its simplicity makes it ideal for applications requiring reduced communication while maintaining IEC 61499 compatibility. The adapter is defined as a plug-side and expects a corresponding socket counterpart.

####### Initval

initval_AQ

• – ○ • – ○ • – ○ •

Introduction

`initval_AQ` is the configurable initialization block for the AQ adapter (data type `BYTE`, 2-bit value (transmitted as a byte)): it accepts a start value as a data input at initialization time and writes it to a `AQ` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (BYTE): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AQ`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1/D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AQ` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AQ` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

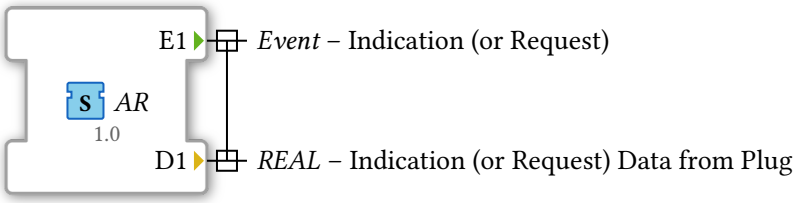
Application Scenarios

- Initializing `AQ` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `BYTE` value is fed onto a `AQ` adapter via `initval_AQ` and can then be used together with the pure adapter-based `AQ` comparison blocks.
- A reusable block template for test setups where different `AQ` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AQ` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AQ` provides simple, reusable initialization logic for the `AQ` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `BYTE` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_AR

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AR` is the configurable initialization block for the AR adapter (data type `REAL`, 32-bit floating-point number): it accepts a start value as a data input at initialization time and writes it to a `AR` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (REAL): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AR`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AR` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AR` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

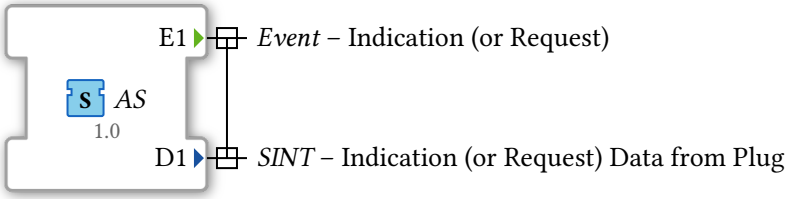
Application Scenarios

- Initializing `AR` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `REAL` value is fed onto a `AR` adapter via `initval_AR` and can then be used together with the pure adapter-based `AR` comparison blocks.
- A reusable block template for test setups where different `AR` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AR` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AR` provides simple, reusable initialization logic for the `AR` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `REAL` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_AS

• – ○ • – ○ • – ○ •

Introduction

`initval_AS` is the configurable initialization block for the AS adapter (data type `SINT`, 8-bit signed integer): it accepts a start value as a data input at initialization time and writes it to a `AS` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (SINT): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AS`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1/D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AS` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AS` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

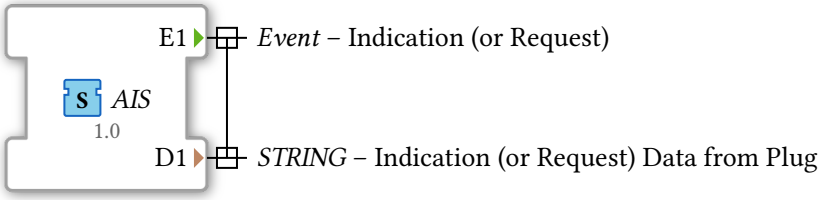
Application Scenarios

- Initializing `AS` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `SINT` value is fed onto a `AS` adapter via `initval_AS` and can then be used together with the pure adapter-based `AS` comparison blocks.
- A reusable block template for test setups where different `AS` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE/const_AX_FALSE` (which only exist for `AX`), `initval_AS` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AS` provides simple, reusable initialization logic for the `AS` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `SINT` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

AIS

Plug (adapter output)

Socket (adapter input)

Unidirectional Adapter for 1 Event and 1 String

• – ◦ • – ◦ • – ◦ •

Introduction

The **AIS** (Adapter Interface String) adapter provides a unidirectional interface through which exactly one event (E1) along with its associated string (D1) can be transmitted from a plug instance to a socket instance. It is used to implement simple, directed data flows where no feedback or additional control is required.

Interface Structure

Event Inputs

None.

Event Outputs

Name	Type	Comment
E1	Event	Indication (or Request) – the event is triggered when the data is sent.

Data Inputs

None.

Data Outputs

Name	Type	Comment
D1	STRING	The data (string) associated with the event.

Adapter

This component is itself an adapter. It has no other internal adapters.

Functionality

The adapter operates on the principle of a unidirectional “plug-socket” connection.

- The **plug** instance sends an event to E1 and simultaneously stores the data on D1.
- The **socket** instance receives this event and can read the value from D1.

Communication in the opposite direction is not supported.

Technical Features

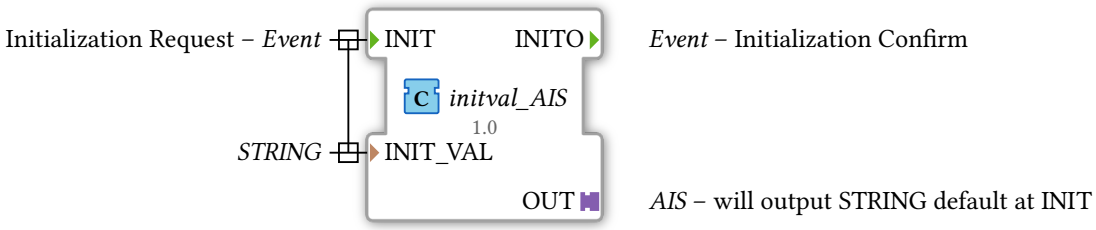
- **Minimal Resource Consumption**: The adapter requires only one event and one string – ideal for resource-constrained controllers.
- **Type Safety**: The data type is fixed to STRING; the adapter can be used directly in applications that require precisely this signature.
- **Easy Reuse**: The strict separation between plug and socket allows for easy encapsulation and replacement of modules.

State Overview

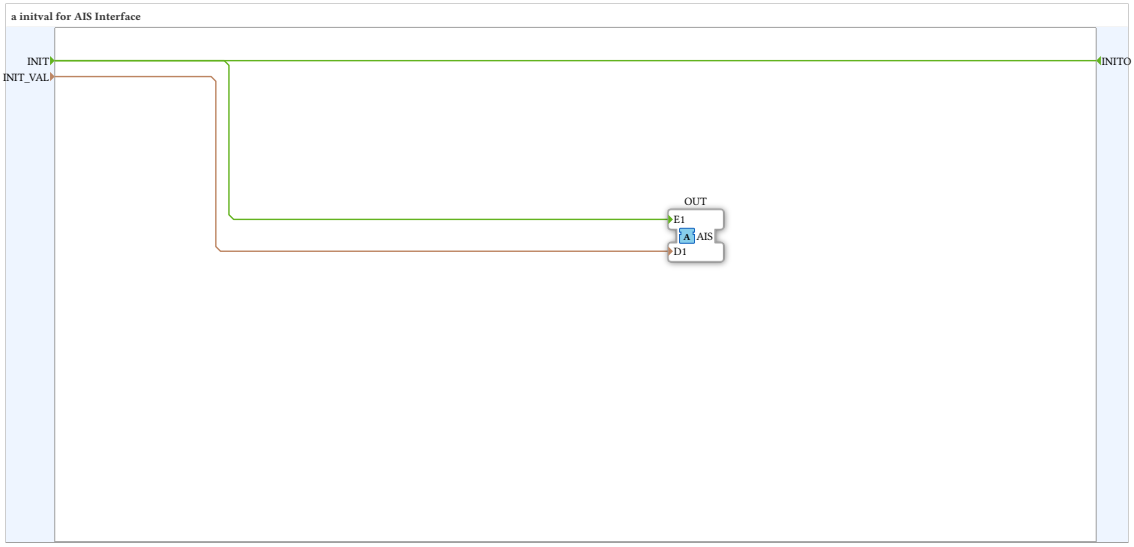
The adapter does not have an internal state machine. It behaves **stateless**: Every incoming event on the plug side is immediately forwarded as an output event on the socket side. The data value D1 is transferred at the time of the event.

Application Scenarios

- **Sensor Connection**: Transfer of a single measured value (e.g., scrolling text from an RFID reader) to a processing unit.
- **Monitor Interface**: Output of a status string from a controller to a display element.
- **Debugging**: Easy extraction of diagnostic information from a function block.



Comparison with Similar Blocks



- **More complex adapters**, such as adapters with multiple events and mixed data types, offer greater flexibility but also require more configuration effort.
- **Bidirectional adapters** (e.g., with one event in each direction) allow feedback; the AIS adapter deliberately omits this to keep the interface as simple as possible.
- The AIS is specifically optimized for **exactly one event + one string** – other adapters with the same signature but a different name could be functionally identical.

Conclusion

The **AIS** adapter is a lean, stateless block for the unidirectional transmission of an event along with a string. It is ideally suited for all cases where simple, clear signal transmission without additional logic or a feedback channel is required. The minimal interface keeps the application clear and easy to understand.
####### Initval

initval_AIS

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AIS` is the configurable initialization block for the AIS adapter (data type `STRING`, character string): it accepts a start value as a data input at initialization time and writes it to a `AIS` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (STRING): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AIS`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AIS` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AIS` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

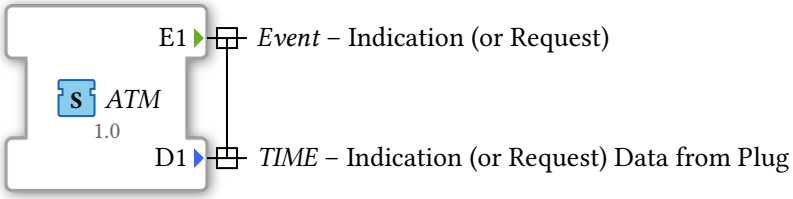
Application Scenarios

- Initializing `AIS` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `STRING` value is fed onto a `AIS` adapter via `initval_AIS` and can then be used together with the pure adapter-based `AIS` comparison blocks.
- A reusable block template for test setups where different `AIS` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AIS` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AIS` provides simple, reusable initialization logic for the `AIS` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `STRING` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

ATM

Plug (adapter output)

Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

The **ATM adapter** (short for "Adapter Time Message") is a unidirectional type according to IEC 61499-1 that provides an event-driven interface for transmitting a time value. It is used as an adapter to enable standardized, loosely coupled communication between function blocks (FBs). This adapter was developed by HR Agrartechnik GmbH and is available under the Eclipse Public License 2.0 (EPL-2.0).

Interface Structure

Event Inputs

The adapter has no event inputs.

Event Outputs

Name	Type	Comment
E1	Event	Indication (or request) – sent along with the data value D1

Data Inputs

The adapter has no data inputs.

Data Outputs

Name	Type	Comment
D1	TIME	Indication/Request Data from the Plug

Adapter

The module itself is of type `AdapterType`. No other adapter interfaces are included.

Functionality

The ATM adapter operates exclusively as a unidirectional interface. It is integrated into a function block as a **plug** (or as a **socket**) and, upon occurrence of the event **E1**, transmits the corresponding time value **D1** (type `TIME`) to the connected counterpart. The transmission is unidirectional: from the sending to the receiving block. The connection is automatically resolved by the 4diac IDE environment.

Technical Features

- **Unidirectional Adapter**: Only one data and event direction (plug → socket).
- **Simplest Implementation**: Exactly one event and one variable – minimal overhead.
- **Typing**: The transmitted variable is of the elementary type `TIME`, suitable for timestamps, delays, or time measurements.
- **License**: Released under EPL-2.0, therefore freely usable and extensible.
- No state machine or internal logic – pure interface.

State Overview

Since the ATM adapter has no internal state machine (stateless adapter), a state overview is not required. Its functionality is limited to the pure transmission of event data.

Application Scenarios

- **Transmission of timestamps** between different function blocks (e.g., logging, time-based control).
- **Signal for time-controlled actions**: A function block sends time information via the adapter, which is evaluated by another function block.
- **Test environments**: Simple, clearly defined interface for unit tests of function blocks that process time values.

Comparison with similar function blocks

Feature	ATM (this adapter)	Other unidirectional adapters (e.g., with multiple events/ data)
Events	1 (E1)	Usually multiple (e.g., INIT, REQ, IND, RSP)
Data	1 (TIME)	Often multiple data or different types
Complexity	Low	Medium to high
Application	Simple time transmission	Complex process scripts

Compared to more general adapters, ATM is limited to the essentials – ideal when only one event with a single time value needs to be exchanged.

Conclusion

The ATM adapter is a minimal yet practically relevant component for the unidirectional transmission of time values in IEC 61499 systems. Its clear interface and ease of use make it particularly suitable for

applications that focus on time-related communication. Thanks to its open licensing, the adapter can be integrated into or extended in your own projects without restrictions.

####### Initval

initval_ATM

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_ATM` is the configurable initialization block for the ATM adapter (data type `TIME`, duration): it accepts a start value as a data input at initialization time and writes it to a `ATM` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (TIME): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type ATM): on INIT, outputs the value passed via INIT_VAL through its E1/D1 adapter event.

Functionality

When the event INIT arrives (carrying With Var="INIT_VAL"), initval_ATM links two internal data paths: INIT_VAL is copied to OUT.D1 via a data connection, and INIT is forwarded to OUT.E1 via an event connection – so the OUT plug fires its adapter event carrying the value just supplied. INIT is also forwarded to INITO, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via INIT_VAL on every INIT call – so the block can also be used outside a pure initialization phase to dynamically set a ATM value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection INIT_VAL → OUT.D1 must be evaluated before the event connection so that OUT.E1 carries the current value – this is guaranteed by IEC 61499's FBNetwork connection execution order and needs no separate wiring.

State Overview

The block is stateless: every INIT event immediately results in INIT_VAL being written to OUT and confirmed via INITO.

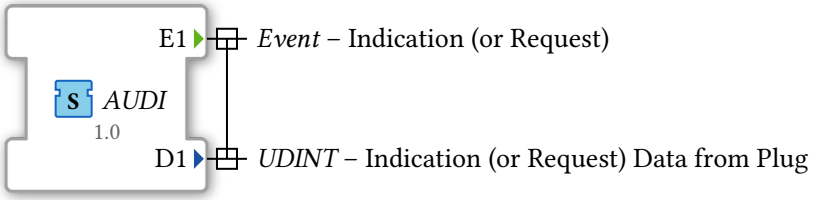
Application Scenarios

- Initializing ATM adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant TIME value is fed onto a ATM adapter via initval_ATM and can then be used together with the pure adapter-based ATM comparison blocks.
- A reusable block template for test setups where different ATM start values need to be tried out

⚖ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the BOOL data type. Unlike const_AX_TRUE/const_AX_FALSE (which only exist for AX), initval_ATM does not parameterize the output value in the block itself, but takes it from the data input INIT_VAL.

Conclusion



initval_ATM provides simple, reusable initialization logic for the ATM adapter and makes the output value freely configurable via INIT_VAL. It is the right fit wherever a TIME start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_AUDI

• – ○ • – ○ • – ○ •

Introduction

`initval_AUDI` is the configurable initialization block for the AUDI adapter (data type `UDINT`, 32-bit unsigned integer): it accepts a start value as a data input at initialization time and writes it to a `AUDI` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (UDINT): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AUDI`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1/D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AUDI` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AUDI` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

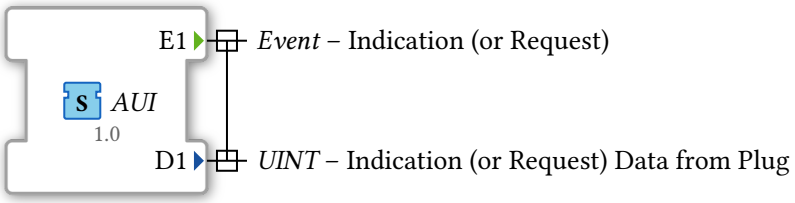
Application Scenarios

- Initializing `AUDI` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `UDINT` value is fed onto a `AUDI` adapter via `initval_AUDI` and can then be used together with the pure adapter-based `AUDI` comparison blocks.
- A reusable block template for test setups where different `AUDI` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AUDI` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AUDI` provides simple, reusable initialization logic for the `AUDI` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `UDINT` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_AUI

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AUI` is the configurable initialization block for the AUI adapter (data type `UINT`, 16-bit unsigned integer): it accepts a start value as a data input at initialization time and writes it to a `AUI` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (UINT): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AUI`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AUI` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AUI` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

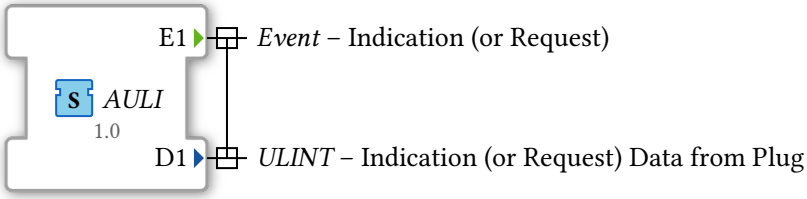
Application Scenarios

- Initializing `AUI` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `UINT` value is fed onto a `AUI` adapter via `initval_AUI` and can then be used together with the pure adapter-based `AUI` comparison blocks.
- A reusable block template for test setups where different `AUI` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AUI` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AUI` provides simple, reusable initialization logic for the `AUI` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `UINT` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

Unidirectional ULINT adapter

####### Initval

initval_AULI

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AULI` is the configurable initialization block for the AULI adapter (data type `ULINT`, 64-bit unsigned integer): it accepts a start value as a data input at initialization time and writes it to a `AULI` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (ULINT): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AULI`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AULI` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AULI` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

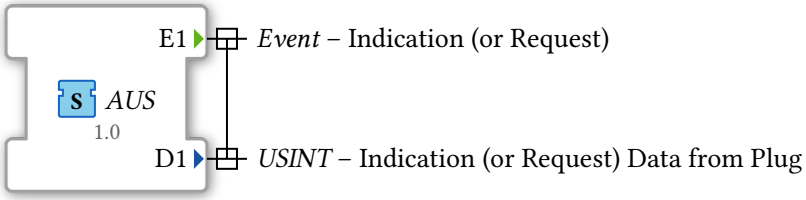
Application Scenarios

- Initializing `AULI` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `ULINT` value is fed onto a `AULI` adapter via `initval_AULI` and can then be used together with the pure adapter-based `AULI` comparison blocks.
- A reusable block template for test setups where different `AULI` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AULI` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AULI` provides simple, reusable initialization logic for the `AULI` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `ULINT` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

####### Initval

initval_AUS

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AUS` is the configurable initialization block for the AUS adapter (data type `USINT`, 8-bit unsigned integer): it accepts a start value as a data input at initialization time and writes it to a `AUS` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (USINT): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AUS`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AUS` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AUS` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

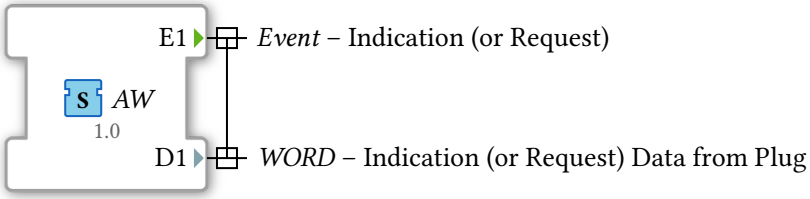
Application Scenarios

- Initializing `AUS` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `USINT` value is fed onto a `AUS` adapter via `initval_AUS` and can then be used together with the pure adapter-based `AUS` comparison blocks.
- A reusable block template for test setups where different `AUS` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AUS` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AUS` provides simple, reusable initialization logic for the `AUS` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `USINT` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

Unidirectional WORD adapter

####### Initval

initval_AW

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AW` is the configurable initialization block for the AW adapter (data type `WORD`, 16-bit bit pattern): it accepts a start value as a data input at initialization time and writes it to a `AW` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (WORD): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AW`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1`/`D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AW` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AW` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

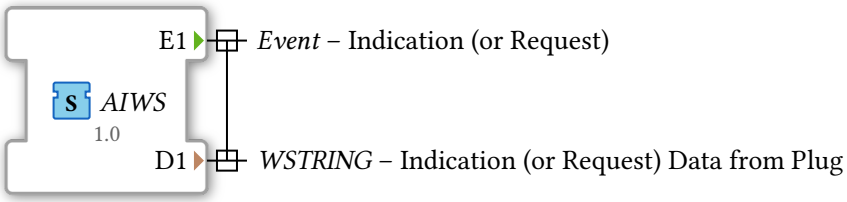
Application Scenarios

- Initializing `AW` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `WORD` value is fed onto a `AW` adapter via `initval_AW` and can then be used together with the pure adapter-based `AW` comparison blocks.
- A reusable block template for test setups where different `AW` start values need to be tried out

⚖️ Comparison with Similar Blocks

Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE`/`const_AX_FALSE` (which only exist for `AX`), `initval_AW` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.

Conclusion



`initval_AW` provides simple, reusable initialization logic for the `AW` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `WORD` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

AIWS

Plug (adapter output)

Socket (adapter input)

• – ◦ • – ◦ • – ◦ •

Introduction

The **AIWS** adapter provides a unidirectional interface for transmitting exactly one event and its associated WSTRING data. It defines the communication direction from a source to a destination, with the event always accompanied by the data. The adapter serves as a basic building block for loosely coupled, event-driven data flows in IEC 61499 applications.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

Name	Type	Comment
E1	Event	Indication (or Request)

Data Inputs

No data inputs available.

Data Outputs

Name	Type	Comment
D1	WSTRING	Indication (or Request) Data from Plug

Adapter

The adapter itself is to be understood as an interface definition. It has no further internal adapters.

Functionality

The **AIWS** adapter transmits an event **E1** along with a WSTRING value **D1** in a fixed coupling. As soon as the sending component triggers the event, the current value of **D1** is passed to the receiving side. The direction is strictly from the plug side to the socket side (or vice versa, depending on the use case) – no feedback or acknowledgment takes place. The adapter thus defines a simple, unidirectional data channel.

Technical Features

- **Unidirectionality**: There is only one event output side, no inputs. This enforces a clear flow direction.
- **Compactness**: Exactly one event with a simple data type (WSTRING) minimizes interface complexity.
- **No Error Handling**: The adapter does not provide mechanisms for timeouts, retries, or error detection. Data integrity must be ensured by the connected function blocks.
- **Standard Compliant**: Complies with the IEC 61499-1 specification for adapter types.

State Overview

The adapter itself has no internal state. It serves solely as an interface definition and does not implement its own sequence control. The state logic resides with the connected function blocks.

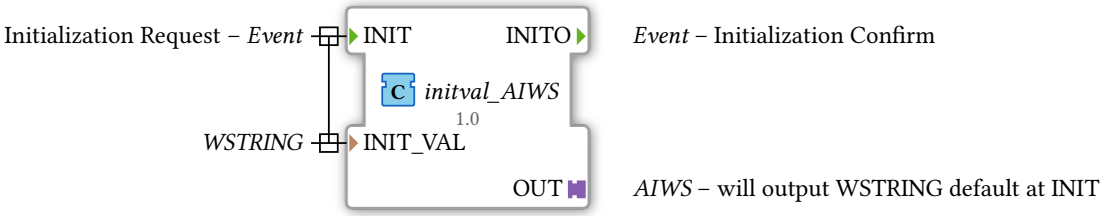
Application Scenarios

- **Integration of Sensor Data**: Transmission of an event with a measured value (e.g., status message or identification) as a WSTRING to a higher-level controller.
- **Text-Based Commands**: Sending commands (e.g., “START”, “STOP”) as events with parameters.
- **Logging and Diagnostics**: Output of descriptive events with plain text information to a log component.

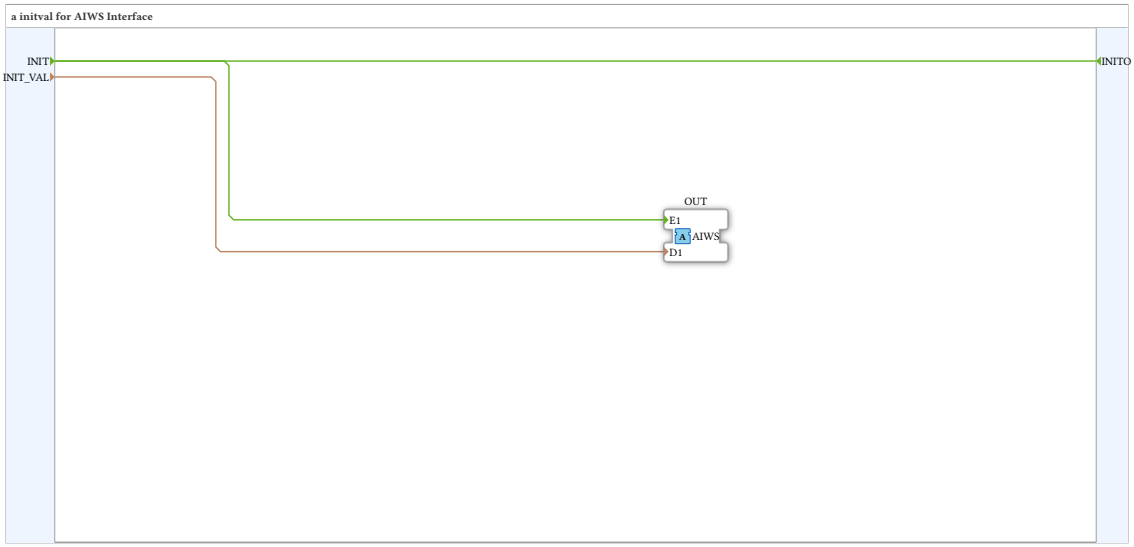
Comparison with Similar Components

Component	Events	Data	Direction	Special Feature
AIWS	1 Output	1 WSTRING	Unidirectional	Simplest adapter for WSTRING

AI (hypothetical)	1 Output	1 ANY (generic)	Unidirectional	Flexible data type, but more complex
BIWS (bidirectional)	2 Events (in/out)	2 WSTRING in both directions	Bidirectional	Requires handshake



The **AIWS** stands out due to its minimal interface and is particularly suitable for simple, clearly defined point-to-point connections where no return channel is required.



Conclusion

The **AIWS** adapter is a fundamental and efficient building block for the unidirectional transmission of an event with a WSTRING data. Its simplicity reduces coupling between components and facilitates the modular design of automation solutions according to IEC 61499. It is ideally suited for tasks requiring fast and straightforward event-driven communication.

####### Initval

initval_AIWS

• – ◦ • – ◦ • – ◦ •

Introduction

`initval_AIWS` is the configurable initialization block for the AIWS adapter (data type `WSTRING`, wide (Unicode) character string): it accepts a start value as a data input at initialization time and writes it to a `AIWS` adapter plug. This replaces the formerly common practice of feeding a constant comparison value in via a mixed adapter/elementary block.

Interface Structure

Event Inputs

- **INIT**: initialization request, carries `INIT_VAL`. Triggers `INIT_VAL` being written to plug `OUT`.

Event Outputs

- **INITO**: confirms completion of the initialization.

Data Inputs

- **INIT_VAL** (WSTRING): the start value written to adapter `OUT` when `INIT` arrives.

Data Outputs

- None directly; the value is only made available through adapter `OUT`.

Adapters

- **OUT** (Plug, type `AIWS`): on `INIT`, outputs the value passed via `INIT_VAL` through its `E1/D1` adapter event.

Functionality

When the event `INIT` arrives (carrying `With Var="INIT_VAL"`), `initval_AIWS` links two internal data paths: `INIT_VAL` is copied to `OUT.D1` via a data connection, and `INIT` is forwarded to `OUT.E1` via an event connection – so the `OUT` plug fires its adapter event carrying the value just supplied. `INIT` is also forwarded to `INITO`, letting the caller know that initialization has completed.

Technical Details

- The output value is not parameterized in the block itself but supplied fresh via `INIT_VAL` on every `INIT` call – so the block can also be used outside a pure initialization phase to dynamically set a `AIWS` value.
- Pure wiring logic with no ECC/state machine of its own (a composite FB with no internal function block instances); the data connection `INIT_VAL → OUT.D1` must be evaluated before the event connection so that `OUT.E1` carries the current value – this is guaranteed by IEC 61499's `FBNetwork` connection execution order and needs no separate wiring.

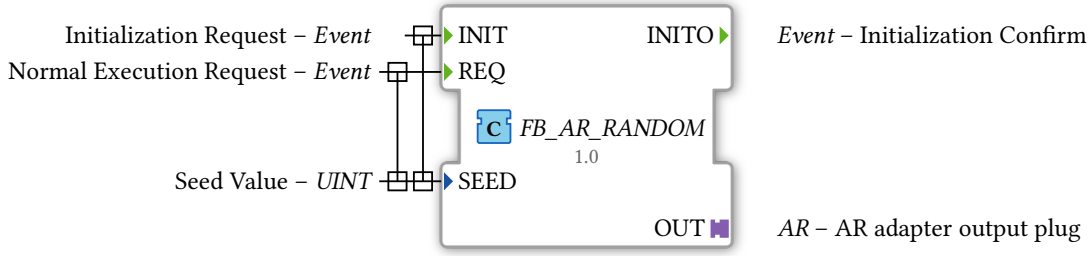
State Overview

The block is stateless: every `INIT` event immediately results in `INIT_VAL` being written to `OUT` and confirmed via `INITO`.

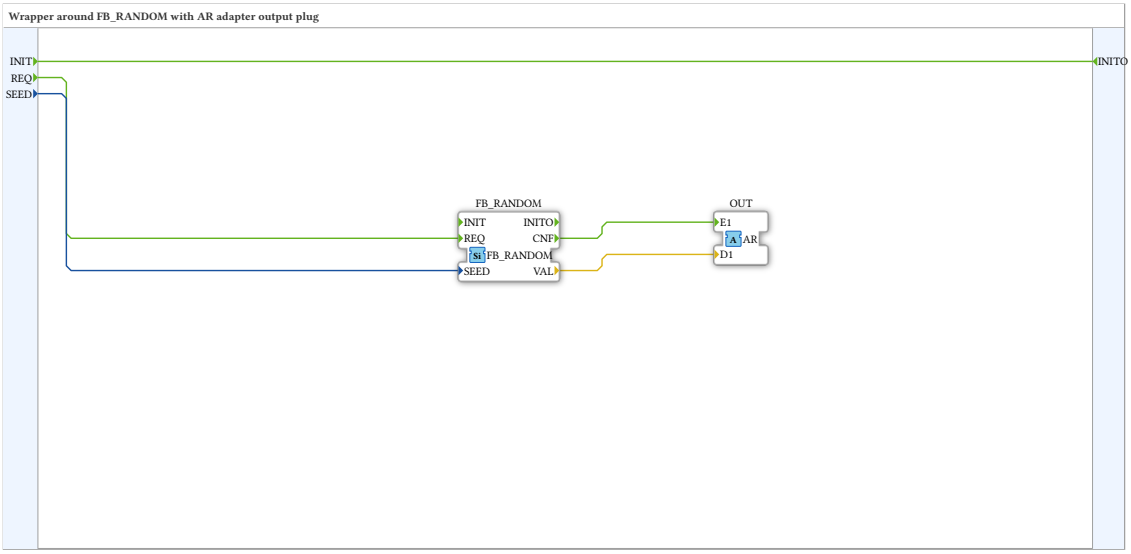
Application Scenarios

- Initializing `AIWS` adapter connections with a project- or parameter-dependent start value (e.g. from a configuration variable)
- Replacement for the removed "mixed" adapter/elementary comparison blocks: a constant `WSTRING` value is fed onto a `AIWS` adapter via `initval_AIWS` and can then be used together with the pure adapter-based `AIWS` comparison blocks.
- A reusable block template for test setups where different `AIWS` start values need to be tried out

⚖ Comparison with Similar Blocks



Compare with initval_AX, which uses the same wiring mechanism for the `BOOL` data type. Unlike `const_AX_TRUE/const_AX_FALSE` (which only exist for `AX`), `initval_AIWS` does not parameterize the output value in the block itself, but takes it from the data input `INIT_VAL`.



Conclusion

`initval_AIWS` provides simple, reusable initialization logic for the `AIWS` adapter and makes the output value freely configurable via `INIT_VAL`. It is the right fit wherever a `WSTRING` start value isn't already fixed at design time, or as a replacement for a removed mixed comparison block.

2.10.0.3 Utils

FB_AR_RANDOM

• – ◦ • – ◦ • – ◦ •

Introduction

FB_AR_RANDOM is a composite function block wrapper around `eclipse4diac::utils::FB_RANDOM`. It exposes a random value through a unidirectional AR adapter output, while keeping the external interface minimal. The block provides an initialization handshake via `INIT`/`INITO` and uses the `REQ` event to trigger the underlying random number generator.

Interface Structure

Event Inputs

- `INIT` (EInit): Initialization request. This event is associated with the `SEED` input and is directly confirmed by `INITO`.
- `REQ` (Event): Normal execution request. This event triggers the internal random number generation and causes the result to be sent through the adapter output. It is also associated with the `SEED` input.

Event Outputs

- `INITO` (EInit): Initialization confirm. This event acknowledges the `INIT` request.

Data Inputs

- `SEED` (UINT): Seed value used by the underlying random number generator. The default value is `0`.

Data Outputs

- None. The generated random value is not provided as a direct data output. It is transmitted through the adapter output instead.

Adapters

- `OUT` (plug, `adapter::types::unidirectional::AR`): Unidirectional AR adapter output. The generated value is sent via the adapter event `E1` with the corresponding data on `D1`.

Functionality

When an `INIT` event is received, the FB passes this request through and immediately acknowledges it with `INITO`. No random generation is performed during initialization.

When a `REQ` event is received, the `SEED` value is forwarded to the internal `FB_RANDOM` block. The internal block generates a random value and, upon completion, triggers the adapter event `E1` on the `OUT` plug. The generated value is made available on the adapter data port `D1`.

Technical Features

- Composite FB containing one instance of `eclipse4diac::utils::FB_RANDOM`.
- Unidirectional AR adapter output for decoupled, adapter-based communication.

- `UINT` seed input with a default value of `0`.
- Simple initialization handshake through `INIT` and `INITO`.
- No direct output variables; results are delivered exclusively through the adapter.
- No internal ECC; behavior is defined by the contained FBNetwork.

State Overview

The FB itself does not define an explicit state machine. Its behavior is event-driven and is determined by the internal FBNetwork. The initialization event is forwarded directly to the initialization confirm output without affecting the random generator. The `REQ` event can be used whenever a new random value is required.

Application Scenarios

- Integration of a random number generator into IEC 61499 applications through a standard AR adapter interface.
- Use in testbeds, simulations, or control applications that require pseudo-random values.
- Modular system designs where data exchange should be encapsulated in adapters instead of direct data connections.
- Supplying random setpoints, seeds, or scheduling parameters to other function blocks in a decoupled manner.

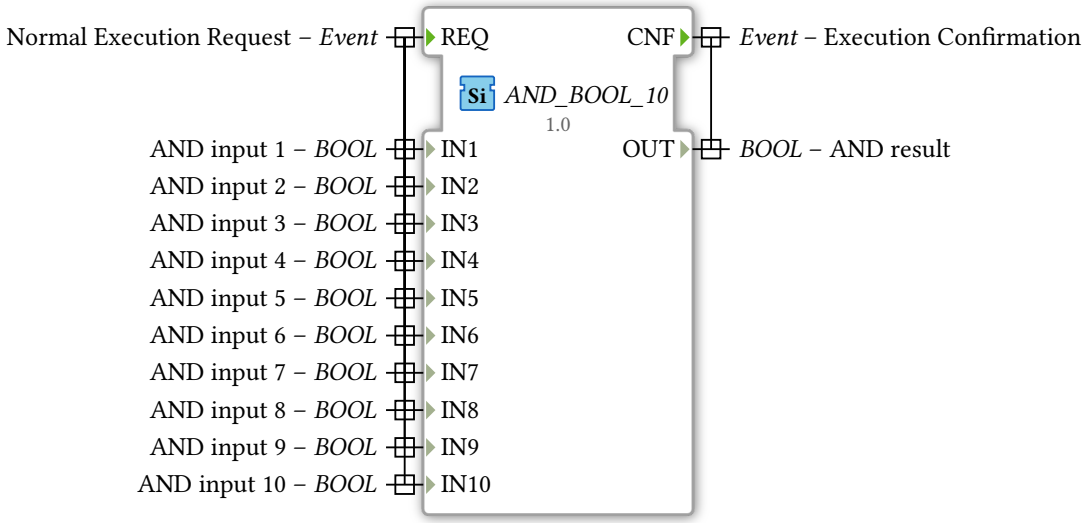
Comparison with Similar Blocks

Compared to a plain `FB_RANDOM`, this wrapper hides the `CNF` event and the `VAL` data output and instead provides them through a unidirectional AR adapter. This makes the block more suitable for adapter-based architectures and plug-and-socket connections. It also adds a distinct initialization handshake that a direct random generator does not provide. Unlike blocks with ordinary output variables, `FB_AR_RANDOM` allows the random source to be easily replaced or reused in different contexts.

Conclusion

`FB_AR_RANDOM` is a compact and reusable wrapper that makes a pseudo-random number generator available through a unidirectional AR adapter. It simplifies integration, introduces a clear initialization flow, and fits well into adapter-oriented IEC 61499 system designs.

2.10.1 iec61131-3-bool



2.10.1.1 booleanOperators

AND_BOOL_10

• − ◦ • − ◦ • − ◦ •

Introduction

The function block `AND_BOOL_10` is a generic block for calculating the logical AND operation. It performs a bitwise AND operation on up to ten separate BOOL inputs. The block is classified according to the IEC 61131-3 standard and belongs to the category of standard Boolean functions. It is typically used in control logic to link conditions where all input signals must be true (TRUE) to activate an output signal.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** This event triggers the execution of the function block. Upon its arrival, the values of all ten data inputs (`IN1` to `IN10`) are read, and the AND operation is performed.

Event Outputs

- **CNF (Execution Confirmation):** This event signals the completion of the calculation. It is output along with the calculated result at data output `OUT`.

Data Inputs

- **IN1 (AND input 1):** Boolean input 1.
- **IN2 (AND input 2):** Boolean input 2.
- **IN3 (AND input 3):** Boolean input 3.
- **IN4 (AND input 4):** Boolean input 4.
- **IN5 (AND input 5):** Boolean input 5.
- **IN6 (AND input 6):** Boolean input 6.
- **IN7 (AND input 7):** Boolean input 7.
- **IN8 (AND input 8):** Boolean input 8.
- **IN9 (AND input 9):** Boolean input 9.
- **IN10 (AND input 10):** Boolean input 10.

Data Outputs

- **OUT (AND result):** The result of the AND operation of all ten inputs. The output is only TRUE if **all** inputs `IN1` to `IN10` have the value TRUE. In all other cases, the output is FALSE.

Adapter

This function block has no adapter interfaces.

Operation

The operation is deterministic and event-driven. Upon each occurrence of the event `REQ`, the following logical operation is performed:

OUT = IN1 AND IN2 AND IN3 AND IN4 AND IN5 AND IN6 AND IN7 AND IN8 AND IN9 AND IN10`

The result is then made available at the data output `OUT`, and the acknowledgment event `CNF` is triggered to inform subsequent blocks of the availability of the new result.

Technical Features

- **Generic Block:** The block is implemented as a generic block (attribute `GenericClassName = 'GEN_AND'`). This means that its functionality can potentially be parameterized for a different number of inputs, although this specific instance is fixed to ten inputs.

- **Package:** The block is included in the package `iec61131::bitwiseOperators`.
- **Full Evaluation:** All ten inputs are evaluated on each execution.

State Overview

The `AND_BOOL_10` block has no internal state (memoryless). Its output depends solely on the current values of the inputs at the time of triggering by `REQ`. There are no delays, filters, or hysteresis.

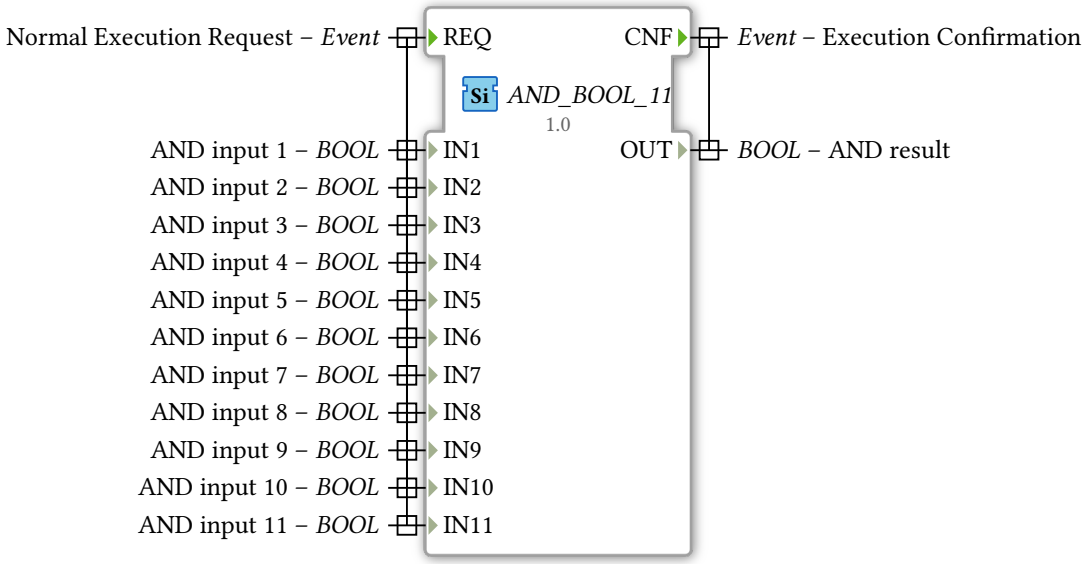
Application Scenarios

- **Safety Interconnects:** In machine safety circuits, where multiple safety switches (emergency stop, light barriers, door contacts) must all be closed before a hazardous process can begin.
- **Multiple Conditions:** In process control systems, to check whether multiple conditions (e.g., fill level, temperature, pressure) are simultaneously within their target ranges.
- **Enable Logic:** As part of an enable chain where multiple stations or operators must give their approval (TRUE signal).

⚖️ Comparison with Similar Function Blocks

- **`AND` (with 2 inputs):** The standard AND block according to IEC 61131-3 typically has only two inputs. `AND_BOOL_10` extends this functionality to ten inputs without the need to connect multiple two-input AND blocks. See: AND_10
- **`OR_BOOL_10`:** Performs a logical OR operation. The result is TRUE if at least one input is TRUE, while `AND_BOOL_10` requires all inputs to be TRUE.
- **`XOR` / `XNOR`:** Compute the exclusive OR and equivalent operations, respectively, which are based on the parity of the TRUE signals, not an all-or-none condition like AND.
- **Generic Blocks (`GEN_AND`):** `AND_BOOL_10` is a specific instance of a generic AND block. In other environments, a configurable `GEN_AND` block could be used, to which the desired number of inputs are parameterized.

Conclusion



The `AND_BOOL_10` is a specialized, reliable, and easy-to-use function block for applications that require a logical AND operation across a large, fixed number of conditions. Its event-driven, stateless nature makes it predictable and easy to integrate into existing control flows. For scenarios with a variable number of conditions, flexible, parameterizable blocks should be considered.

AND_BOOL_11

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_11` is a generic block for calculating the logical AND operation (classification `standard boolean function`, IEC 61131-3). It combines 11 separate BOOL inputs (`IN1` to `IN11`) and provides the result at the output `OUT`. It extends the standard AND_BOOL family (previously up to `AND_BOOL_10`) with the variant that has 11 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 11 data inputs (`IN1` to `IN11`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (AND input 1):** Boolean input 1.
- **IN2 (AND input 2):** Boolean input 2.
- **IN3 (AND input 3):** Boolean input 3.
- **IN4 (AND input 4):** Boolean input 4.
- **IN5 (AND input 5):** Boolean input 5.
- **IN6 (AND input 6):** Boolean input 6.
- **IN7 (AND input 7):** Boolean input 7.
- **IN8 (AND input 8):** Boolean input 8.
- **IN9 (AND input 9):** Boolean input 9.
- **IN10 (AND input 10):** Boolean input 10.
- **IN11 (AND input 11):** Boolean input 11.

Data Outputs

- **OUT (AND result):** The result of the AND operation of all 11 inputs. The output is TRUE only if **all** inputs `IN1` to `IN11` are TRUE, otherwise FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 11 inputs are read and the operation `OUT = IN1 AND IN2 AND ... AND IN11` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_AND_BOOL'`; this instance is fixed to 11 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Enable and safety interlocks:** All conditions (e.g. door contacts, emergency stop, operational readiness) must be met before an action may start.
- **Multiple conditions:** Check whether many prerequisites are fulfilled at the same time without having to cascade several smaller AND blocks.

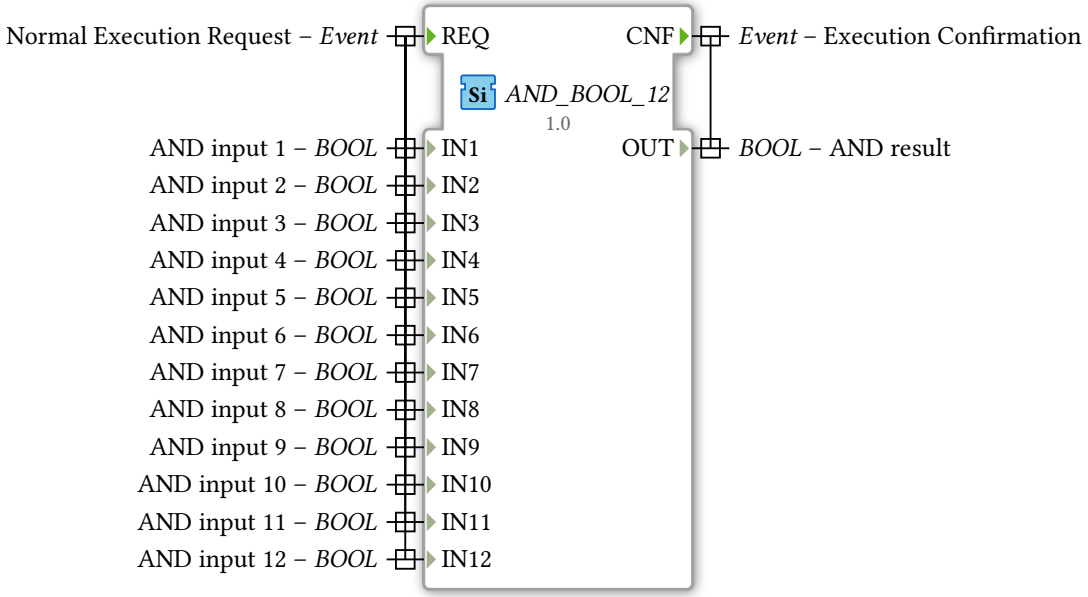
⚖️ Comparison with Similar Function Blocks

- `OR_BOOL_11`: Performs the OR operation: the result is TRUE as soon as at least one input is TRUE, while `AND_BOOL_11` requires all inputs to be TRUE.
- `AND_BOOL_10`: Sibling block of the family with 10 inputs.

Conclusion

`AND_BOOL_11` is a simple, event-driven block for the AND combination of 11 Boolean signals with a fixed interface.

🌐 Related topic subpages on ms-muc-docs.de



- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

AND_BOOL_12

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_12` is a generic block for calculating the logical AND operation (classification `standard boolean function`, IEC 61131-3). It combines 12 separate BOOL inputs (`IN1` to `IN12`) and provides the result at the output `OUT`. It extends the standard AND_BOOL family (previously up to `AND_BOOL_10`) with the variant that has 12 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 12 data inputs (`IN1` to `IN12`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (AND input 1):** Boolean input 1.
- **IN2 (AND input 2):** Boolean input 2.
- **IN3 (AND input 3):** Boolean input 3.
- **IN4 (AND input 4):** Boolean input 4.
- **IN5 (AND input 5):** Boolean input 5.
- **IN6 (AND input 6):** Boolean input 6.
- **IN7 (AND input 7):** Boolean input 7.
- **IN8 (AND input 8):** Boolean input 8.
- **IN9 (AND input 9):** Boolean input 9.
- **IN10 (AND input 10):** Boolean input 10.
- **IN11 (AND input 11):** Boolean input 11.
- **IN12 (AND input 12):** Boolean input 12.

Data Outputs

- **OUT (AND result):** The result of the AND operation of all 12 inputs. The output is TRUE only if **all** inputs `IN1` to `IN12` are TRUE, otherwise FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 12 inputs are read and the operation `OUT = IN1 AND IN2 AND ... AND IN12` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_AND_BOOL'`; this instance is fixed to 12 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Enable and safety interlocks:** All conditions (e.g. door contacts, emergency stop, operational readiness) must be met before an action may start.
- **Multiple conditions:** Check whether many prerequisites are fulfilled at the same time without having to cascade several smaller AND blocks.

⚖️ Comparison with Similar Function Blocks

- `OR_BOOL_12`: Performs the OR operation: the result is TRUE as soon as at least one input is TRUE, while `AND_BOOL_12` requires all inputs to be TRUE.
- `AND_BOOL_10`: Sibling block of the family with 10 inputs.

Conclusion

`AND_BOOL_12` is a simple, event-driven block for the AND combination of 12 Boolean signals with a fixed interface.

AND_BOOL_13

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_13` is a generic block for calculating the logical AND operation (classification `standard boolean function`, IEC 61131-3). It combines 13 separate BOOL inputs (`IN1` to `IN13`) and provides the result at the output `OUT`. It extends the standard AND_BOOL family (previously up to `AND_BOOL_10`) with the variant that has 13 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 13 data inputs (`IN1` to `IN13`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (AND input 1):** Boolean input 1.
- **IN2 (AND input 2):** Boolean input 2.
- **IN3 (AND input 3):** Boolean input 3.
- **IN4 (AND input 4):** Boolean input 4.
- **IN5 (AND input 5):** Boolean input 5.
- **IN6 (AND input 6):** Boolean input 6.
- **IN7 (AND input 7):** Boolean input 7.
- **IN8 (AND input 8):** Boolean input 8.
- **IN9 (AND input 9):** Boolean input 9.
- **IN10 (AND input 10):** Boolean input 10.
- **IN11 (AND input 11):** Boolean input 11.
- **IN12 (AND input 12):** Boolean input 12.
- **IN13 (AND input 13):** Boolean input 13.

Data Outputs

- **OUT (AND result):** The result of the AND operation of all 13 inputs. The output is TRUE only if **all** inputs `IN1` to `IN13` are TRUE, otherwise FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 13 inputs are read and the operation `OUT = IN1 AND IN2 AND ... AND IN13` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_AND_BOOL'`; this instance is fixed to 13 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Enable and safety interlocks:** All conditions (e.g. door contacts, emergency stop, operational readiness) must be met before an action may start.
- **Multiple conditions:** Check whether many prerequisites are fulfilled at the same time without having to cascade several smaller AND blocks.

⚖️ Comparison with Similar Function Blocks

- `OR_BOOL_13`: Performs the OR operation: the result is TRUE as soon as at least one input is TRUE, while `AND_BOOL_13` requires all inputs to be TRUE.
- `AND_BOOL_10`: Sibling block of the family with 10 inputs.

Conclusion

`AND_BOOL_13` is a simple, event-driven block for the AND combination of 13 Boolean signals with a fixed interface.

AND_BOOL_14

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_14` is a generic block for calculating the logical AND operation (classification `standard boolean function`, IEC 61131-3). It combines 14 separate BOOL inputs (`IN1` to `IN14`) and provides the result at the output `OUT`. It extends the standard AND_BOOL family (previously up to `AND_BOOL_10`) with the variant that has 14 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 14 data inputs (`IN1` to `IN14`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (AND input 1):** Boolean input 1.
- **IN2 (AND input 2):** Boolean input 2.
- **IN3 (AND input 3):** Boolean input 3.
- **IN4 (AND input 4):** Boolean input 4.
- **IN5 (AND input 5):** Boolean input 5.
- **IN6 (AND input 6):** Boolean input 6.
- **IN7 (AND input 7):** Boolean input 7.
- **IN8 (AND input 8):** Boolean input 8.
- **IN9 (AND input 9):** Boolean input 9.
- **IN10 (AND input 10):** Boolean input 10.
- **IN11 (AND input 11):** Boolean input 11.
- **IN12 (AND input 12):** Boolean input 12.
- **IN13 (AND input 13):** Boolean input 13.
- **IN14 (AND input 14):** Boolean input 14.

Data Outputs

- **OUT (AND result):** The result of the AND operation of all 14 inputs. The output is TRUE only if **all** inputs `IN1` to `IN14` are TRUE, otherwise FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 14 inputs are read and the operation `OUT = IN1 AND IN2 AND ... AND IN14` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_AND_BOOL'`; this instance is fixed to 14 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Enable and safety interlocks:** All conditions (e.g. door contacts, emergency stop, operational readiness) must be met before an action may start.
- **Multiple conditions:** Check whether many prerequisites are fulfilled at the same time without having to cascade several smaller AND blocks.

⚖️ Comparison with Similar Function Blocks

- `OR_BOOL_14`: Performs the OR operation: the result is TRUE as soon as at least one input is TRUE, while `AND_BOOL_14` requires all inputs to be TRUE.
- `AND_BOOL_10`: Sibling block of the family with 10 inputs.

Conclusion

`AND_BOOL_14` is a simple, event-driven block for the AND combination of 14 Boolean signals with a fixed interface.

AND_BOOL_19

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_19` is a generic block for calculating the logical AND operation (classification `standard boolean function`, IEC 61131-3). It combines 19 separate BOOL inputs (`IN1` to `IN19`) and provides the result at the output `OUT`. It extends the standard AND_BOOL family (previously up to `AND_BOOL_10`) with the variant that has 19 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 19 data inputs (`IN1` to `IN19`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (AND input 1):** Boolean input 1.
- **IN2 (AND input 2):** Boolean input 2.
- **IN3 (AND input 3):** Boolean input 3.
- **IN4 (AND input 4):** Boolean input 4.
- **IN5 (AND input 5):** Boolean input 5.
- **IN6 (AND input 6):** Boolean input 6.
- **IN7 (AND input 7):** Boolean input 7.
- **IN8 (AND input 8):** Boolean input 8.
- **IN9 (AND input 9):** Boolean input 9.
- **IN10 (AND input 10):** Boolean input 10.
- **IN11 (AND input 11):** Boolean input 11.
- **IN12 (AND input 12):** Boolean input 12.
- **IN13 (AND input 13):** Boolean input 13.
- **IN14 (AND input 14):** Boolean input 14.
- **IN15 (AND input 15):** Boolean input 15.
- **IN16 (AND input 16):** Boolean input 16.
- **IN17 (AND input 17):** Boolean input 17.
- **IN18 (AND input 18):** Boolean input 18.

- **IN19 (AND input 19):** Boolean input 19.

Data Outputs

- **OUT (AND result):** The result of the AND operation of all 19 inputs. The output is TRUE only if **all** inputs `IN1` to `IN19` are TRUE, otherwise FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 19 inputs are read and the operation `OUT = IN1 AND IN2 AND ... AND IN19` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_AND_BOOL'`; this instance is fixed to 19 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Enable and safety interlocks:** All conditions (e.g. door contacts, emergency stop, operational readiness) must be met before an action may start.
- **Multiple conditions:** Check whether many prerequisites are fulfilled at the same time without having to cascade several smaller AND blocks.

⚖️ Comparison with Similar Function Blocks

- `OR_BOOL_19`: Performs the OR operation: the result is TRUE as soon as at least one input is TRUE, while `AND_BOOL_19` requires all inputs to be TRUE.
- `AND_BOOL_10`: Sibling block of the family with 10 inputs.

Conclusion

`AND_BOOL_19` is a simple, event-driven block for the AND combination of 19 Boolean signals with a fixed interface.

AND_BOOL_2

• – ◦ • – ◦ • – ◦ •

The function block `AND_BOOL_2` is a standard function block for calculating the logical AND operation (conjunction) of two Boolean input values. It complies with the IEC 61131-3 standard for basic Boolean functions and is designed for use in the 4diac IDE. The function block waits for a trigger event, executes the operation, and signals the completion of the calculation with an acknowledgment event.

The interface of the `AND_BOOL_2` function block is simple and clearly structured, consisting of an event input, an event output, and the associated data connections.

- **REQ (Normal Execution Request):** This event triggers the execution of the function block. Upon its arrival, the current values at data inputs `IN1` and `IN2` are read, and the AND operation is calculated.
- **CNF (Execution Confirmation):** This event is generated after the calculation is complete. It signals that the result has been output to data output `OUT` and is now valid.

- **IN1 (AND input 1):** First Boolean operand (Type: `BOOL`).
- **OUT (AND result):** Result of the logical AND operation of `IN1` and `IN2` (Type: `BOOL`). The output value is `TRUE` (1) if both `IN1` and `IN2` have the value `TRUE`. In all other cases, the output is `FALSE` (0).

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block has no adapter interfaces.

The `AND_BOOL_2` block functions deterministically and follows classic Boolean logic:

1. **Trigger:** The occurrence of the event `REQ` starts the execution.
2. **Read Input:** The current values of the data inputs `IN1` and `IN2` are retrieved.
3. **Calculation:** The logical AND operation `OUT := IN1 AND IN2` is performed.
4. **Output:** The calculated result is written to the data output `OUT`.
5. **Confirmation:** Immediately after output, the confirmation event `CNF` is generated to inform downstream blocks about the availability of the new result.

The operation can be described by the following truth table:

IN1	IN2	OUT (IN1 AND IN2)
0	0	0
0	1	0
1	0	0
1	1	1

- **Generic Block:** The block is implemented as an instance of a generic AND block (`GEN_AND`), which can be specialized for different data types. In this specific instance, it is defined for the data type `BOOL`.

| IN1 | IN2 | OUT (IN1 AND IN2) | | 0 | 0 | 0 | | 1 | 1 | 1 |

Generic Block: The block is implemented as an instance of a generic AND block (`GEN_AND`), which can be specialized for different data types. In this specific instance, it is defined for the data type `BOOL`.

| IN1 | IN2 | OUT (IN1 AND IN2) ... * **Event-driven:** As is typical for 4diac function blocks, execution is strictly event-driven. A change in the input values alone does not trigger a calculation; this only occurs upon the arrival of the `REQ` event.

- **Low latency:** The execution time is negligible, so the `CNF` event follows the `REQ` event practically immediately.

The function block has no internal state in the sense of a memory for previous values. It is a purely combinational block whose output depends solely on the current input values at the time of triggering. Its "state" is therefore always "waiting for REQ" or "executing," with the execution phase being very short.

The `AND_BOOL_2` block is a fundamental building block in control and automation technology. Typical applications include:

- **Safety Conditions:** Linking multiple safety signals (e.g., "Safety door closed" AND "Emergency stop not pressed") to generate a machine enable signal.
- **Two-Hand Operation:** Ensuring that two buttons must be pressed simultaneously to initiate a hazardous operation.
- **Chaining of Switching Conditions:** Combining multiple sensor or switch states to control an actuator signal (e.g., "Material present" AND "Position reached" -> gripper close).
- **Signal Masking:** Selectively switching a signal (`DATA`) through or blocking it with an enable signal (`ENABLE`) using `OUT := DATA AND ENABLE`.

- **`AND_n` (generic):** The generic `GEN_AND` building block can be configured for more than two inputs and other data types (e.g., `WORD`, `DWORD`). `AND_BOOL_2` is a specific instance of this, fixed to two Boolean inputs, which can be used more easily and directly in Boolean logic circuits. See: AND_2
- **`OR_BOOL_2` / `XOR_BOOL_2`:** These blocks implement other basic Boolean operations (OR and exclusive OR, respectively). They have the same event-driven interface (`REQ`/`CNF`), but perform a different logical operation on the inputs `IN1` and `IN2`.
- **Combinatorial Logic in SFC/ST:** The AND function could also be directly encoded in Structured Text (ST) using the `&` or `AND` operator. The advantage of the `AND_BOOL_2` function block lies in its standardized, reusable, and graphically linkable form within the 4diac function block network (FBN).
- **Combinatorial Logic in SFC/ST:** The AND function could also be directly encoded in Structured Text (ST) using the `&` or `AND` operator.
- Exercise_002a4
- Exercise_002b3
- Exercise_006a3

The `AND_BOOL_2` function block is an essential, reliable, and easy-to-use building block for implementing Boolean logic in 4diac-based control applications. Its clear, event-driven interface and deterministic functionality make it the ideal building block for safety operations, control conditions, and general logical operations. It is the first choice for pure Boolean binary operations.

AND_BOOL_20

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_20` is a generic block for calculating the logical AND operation (classification `standard boolean function`, IEC 61131-3). It combines 20 separate BOOL inputs (`IN1` to `IN20`) and provides the result at the output `OUT`. It extends the standard AND_BOOL family (previously up to `AND_BOOL_10`) with the variant that has 20 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 20 data inputs (`IN1` to `IN20`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (AND input 1):** Boolean input 1.
- **IN2 (AND input 2):** Boolean input 2.
- **IN3 (AND input 3):** Boolean input 3.
- **IN4 (AND input 4):** Boolean input 4.
- **IN5 (AND input 5):** Boolean input 5.
- **IN6 (AND input 6):** Boolean input 6.
- **IN7 (AND input 7):** Boolean input 7.
- **IN8 (AND input 8):** Boolean input 8.
- **IN9 (AND input 9):** Boolean input 9.
- **IN10 (AND input 10):** Boolean input 10.
- **IN11 (AND input 11):** Boolean input 11.
- **IN12 (AND input 12):** Boolean input 12.
- **IN13 (AND input 13):** Boolean input 13.
- **IN14 (AND input 14):** Boolean input 14.
- **IN15 (AND input 15):** Boolean input 15.
- **IN16 (AND input 16):** Boolean input 16.
- **IN17 (AND input 17):** Boolean input 17.

- **IN18 (AND input 18):** Boolean input 18.
- **IN19 (AND input 19):** Boolean input 19.
- **IN20 (AND input 20):** Boolean input 20.

Data Outputs

- **OUT (AND result):** The result of the AND operation of all 20 inputs. The output is TRUE only if **all** inputs `IN1` to `IN20` are TRUE, otherwise FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 20 inputs are read and the operation `OUT = IN1 AND IN2 AND ... AND IN20` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_AND_BOOL'`; this instance is fixed to 20 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Enable and safety interlocks:** All conditions (e.g. door contacts, emergency stop, operational readiness) must be met before an action may start.
- **Multiple conditions:** Check whether many prerequisites are fulfilled at the same time without having to cascade several smaller AND blocks.

⚖️ Comparison with Similar Function Blocks

- `OR_BOOL_20`: Performs the OR operation: the result is TRUE as soon as at least one input is TRUE, while `AND_BOOL_20` requires all inputs to be TRUE.
- `AND_BOOL_10`: Sibling block of the family with 10 inputs.

Conclusion

`AND_BOOL_20` is a simple, event-driven block for the AND combination of 20 Boolean signals with a fixed interface.

AND_BOOL_21

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_21` is a generic block for calculating the logical AND operation (classification `standard boolean function`, IEC 61131-3). It combines 21 separate BOOL inputs (`IN1` to `IN21`) and provides the result at the output `OUT`. It extends the standard AND_BOOL family (previously up to `AND_BOOL_10`) with the variant that has 21 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 21 data inputs (`IN1` to `IN21`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (AND input 1):** Boolean input 1.
- **IN2 (AND input 2):** Boolean input 2.
- **IN3 (AND input 3):** Boolean input 3.
- **IN4 (AND input 4):** Boolean input 4.
- **IN5 (AND input 5):** Boolean input 5.
- **IN6 (AND input 6):** Boolean input 6.
- **IN7 (AND input 7):** Boolean input 7.
- **IN8 (AND input 8):** Boolean input 8.
- **IN9 (AND input 9):** Boolean input 9.
- **IN10 (AND input 10):** Boolean input 10.
- **IN11 (AND input 11):** Boolean input 11.
- **IN12 (AND input 12):** Boolean input 12.
- **IN13 (AND input 13):** Boolean input 13.
- **IN14 (AND input 14):** Boolean input 14.
- **IN15 (AND input 15):** Boolean input 15.
- **IN16 (AND input 16):** Boolean input 16.

- **IN17 (AND input 17):** Boolean input 17.
- **IN18 (AND input 18):** Boolean input 18.
- **IN19 (AND input 19):** Boolean input 19.
- **IN20 (AND input 20):** Boolean input 20.
- **IN21 (AND input 21):** Boolean input 21.

Data Outputs

- **OUT (AND result):** The result of the AND operation of all 21 inputs. The output is TRUE only if **all** inputs `IN1` to `IN21` are TRUE, otherwise FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 21 inputs are read and the operation `OUT = IN1 AND IN2 AND ... AND IN21` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_AND_BOOL'`; this instance is fixed to 21 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Enable and safety interlocks:** All conditions (e.g. door contacts, emergency stop, operational readiness) must be met before an action may start.
- **Multiple conditions:** Check whether many prerequisites are fulfilled at the same time without having to cascade several smaller AND blocks.

⚖️ Comparison with Similar Function Blocks

- `OR_BOOL_21`: Performs the OR operation: the result is TRUE as soon as at least one input is TRUE, while `AND_BOOL_21` requires all inputs to be TRUE.
- `AND_BOOL_10`: Sibling block of the family with 10 inputs.

Conclusion

`AND_BOOL_21` is a simple, event-driven block for the AND combination of 21 Boolean signals with a fixed interface.

AND_BOOL_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_3` is a standardized building block for calculating the logical AND operation for three Boolean input signals. It complies with the IEC 61131-3 standard for basic Boolean functions and operates according to the 4diac real-time execution control model, where the calculation is triggered by an incoming event.

Interface Structure

The interface of the `AND_BOOL_3` block is clear and simple, consisting of one event input, one event output, three data inputs, and one data output.

Event Inputs

- **REQ (Normal Execution Request):** This incoming event triggers the execution of the function block. Upon the arrival of `REQ`, the current values at data inputs `IN1`, `IN2`, and `IN3` are read, and the logical AND operation is performed.

Event Outputs

- **CNF (Execution Confirmation):** This event is generated after the calculation is complete. It signals that the result has been output to data output `OUT` and is now valid.

Data Inputs

- **IN1 (BOOL):** First Boolean input signal for the AND operation.
- **IN2 (BOOL):** Second Boolean input signal for the AND operation.
- **IN3 (BOOL):** Third Boolean input signal for the AND operation.

Data Outputs

- **OUT (BOOL):** The result of the logical AND operation of all three inputs. `OUT` is only `TRUE` (1) if **all** inputs `IN1`, `IN2`, and `IN3` are simultaneously `TRUE`. In all other cases, `OUT` is `FALSE` (0).

Adapters

This function block has no adapter interfaces.

Functionality

The functionality is deterministic and follows a simple sequence:

1. **Trigger:** The incoming event `REQ` activates the block.
2. **Reading the Inputs:** The current values of the three Boolean data inputs (`IN1`, `IN2`, `IN3`) are read.
3. **Calculation:** The logical AND operation is performed: `OUT := IN1 AND IN2 AND IN3`.
4. **Output:** The calculated result is written to the data output `OUT`.
5. **Acknowledgement:** The output event `CNF` is generated to signal the successful completion of the operation to subsequent blocks.

Technical Features

- **Generic Function Block:** This block is marked as a generic function block (`GEN_AND`), meaning it can serve as a basis for creating similar AND blocks with a different number of inputs.
- **Real-Time Capable:** Due to its execution control model (event-driven control), this block is suitable for deterministic real-time applications.
- **Simple Logic:** Contains no internal states or memory. The output is a pure combinatorial function of the current inputs.

State Overview

The `AND_BOOL_3` block is a **combinatorial** function block without internal state (stateless). Its behavior on each call (`REQ`) depends solely on the current values at the data inputs. There are no prior calculations or states that influence the result.

Application Scenarios

Typical applications include control logics where an action may only be executed if several safety or enabling conditions are met simultaneously:

- **Two-Hand Operation:** A machine only starts when three separate buttons are pressed simultaneously (`IN1`, `IN2`, `IN3`).
- **Safety Circuit:** A process is only activated if the safety door is protected (`IN1`), the emergency stop bypass is activated (`IN2`), and material is present (`IN3`).
- **Condition Chaining:** As part of a more complex logical equation within an algorithm.

⚖️ Comparison with similar building blocks

- **`AND_BOOL_2`:** Performs the AND operation for only two inputs. `AND_BOOL_3` is a direct extension for three inputs.
- **`AND_n_BOOL` (theoretical):** A generic block for a variable number of inputs. `n` is a specific, hard-wired instance of `AND_BOOL_3`. See: AND_3
- **`OR_BOOL_3`:** Calculates the logical OR operation (output is `TRUE` if at least one input is `TRUE`). This is the complementary function.
- **Combinatorial Logic in SFC/ST:** The same function could also be implemented in Structured Text (ST) as `OUT := IN1 & IN2 & IN3;` or in an SFC action. The advantage of the function block is its reusability, clear encapsulation, and easy integration into the 4diac event system.

Conclusion

The `AND_BOOL_3` is a fundamental, reliable, and easy-to-use building block for Boolean logic in 4diac-based control applications. Its strict event-driven control ensures deterministic behavior, and its clear interface allows for intuitive integration into function block networks. For all control tasks requiring a triple AND operation, this block is the standard solution.

]

AND_BOOL_4

• – ◦ • – ◦ • – ◦ •

The function block `AND_BOOL_4` is a standard function block for calculating the logical AND operation. It performs a bitwise AND operation on four Boolean input values. The block is implemented as a generic function block and complies with the IEC 61131-3 standard for basic Boolean functions.

- **REQ** (Normal Execution Request): This event triggers the execution of the function block. It is associated with all four data inputs (`IN1` to `IN4`).
- **CNF** (Execution Confirmation): This event signals the completion of the calculation. It is output along with the result at data output `OUT`.
- **IN1** (BOOL): First operand for the AND operation.
- **IN2** (BOOL): Second operand for the AND operation.
- **IN3** (BOOL): Third operand for the AND operation.
- **IN4** (BOOL): Fourth operand for the AND operation.
- **OUT** (BOOL): Result of the logical AND operation of all four inputs. The output is only `TRUE` if **all** inputs `IN1`, `IN2`, `IN3`, and `IN4` have the value `TRUE`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use any adapters.

Whenever a `REQ` event occurs, the function block reads the current values at the four Boolean data inputs. It then calculates the logical AND of these four values according to the following truth table:

IN1	IN2	IN3	IN4	OUT
0	0	0	0	0
0	0	0	1	0
…	…	…	…	…
1	1	1	1	1

The result is set at the data output `OUT`, and simultaneously the `CNF` event is triggered to signal the completion of the operation.

- **Generic Implementation:** The function block is marked as a generic function block (`GEN_AND`), which means it can serve as the basis for similar function blocks with a different number of inputs.
- **Event-driven execution:** The operation is triggered exclusively by an incoming event (`REQ`), which is typical for the function block (FB) style in IEC 61499.
- **Standard compliance:** The block is classified as a standard Boolean function according to IEC 61131-3.

The function block does not have an internal state in the sense of a memory. Its behavior is purely combinatorial and depends only on the current input values at the time of triggering. The only "state" is the idle state, in which it waits for the next `REQ` event.

- **Safety chain:** Linking several safety switches (e.g., emergency stop, guardrail, two-hand control), all of which must be closed to start a machine.
- **Masking:** Selectively activates a function only if multiple enable signals are present.
- **AND (2 Inputs):** A basic AND block with only two inputs. `AND_BOOL_4` consolidates four such operations into a single block, improving diagram readability and maintainability. See: AND_4
- **OR_BOOL_4:** Performs a logical OR operation where the result is `TRUE` if at least one input is `TRUE`. This is the logical counterpart to AND.
- **GEN_AND:** The generic base class on which `AND_BOOL_4` is built. It can be configured to create AND blocks with any number of inputs.

The `AND_BOOL_4` function block is a simple, robust, and standards-compliant block for processing logic signals. Its clear, event-driven interface and fixed number of four inputs make it particularly suitable for control tasks where multiple conditions must be met simultaneously. As part of the `iec61131::bitwiseOperators` library, it is a fundamental component for designing control logic in 4diac.

AND_BOOL_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_5` is a standard function block for calculating the logical AND operation. It performs a bitwise AND operation on five separate Boolean input values. The block follows the real-time and event-driven processing model of IEC 61499, where the calculation is triggered by an incoming event and confirmed by an outgoing event.

Interface Structure

Event Inputs

- **REQ**: Triggers the execution of the function block. Upon arrival of this event, all five inputs (`IN1` to `IN5`) are read and the AND operation is calculated.

Event Outputs

- **CNF**: Confirms completion of the operation. This event is output after the result is calculated and includes the calculated value `OUT`.

Data Inputs

- **IN1**: Boolean input 1 for the AND operation.
- **IN2**: Boolean input 2 for the AND operation.
- **IN3**: Boolean input 3 for the AND operation.
- **IN4**: Boolean input 4 for the AND operation.
- **IN5**: Boolean input 5 for the AND operation.

Data Outputs

- **OUT**: The Boolean result of the AND operation of all five inputs. The output is only `TRUE` if **all** inputs `IN1` to `IN5` have the value `TRUE`.

Adapters

This function block does not use any adapters.

Operation

The operation is deterministic and event-driven:

1. The incoming event `REQ` activates the block.
2. The current values of all five Boolean data inputs (`IN1` to `IN5`) are read.
3. The logical AND operation is calculated: `OUT = IN1 AND IN2 AND IN3 AND IN4 AND IN5`.
4. The result is provided at data output `OUT`.
5. The output event `CNF` is triggered along with the new value of `OUT` to signal the completion of the operation.

Technical Features

- **Generic Block**: The block is implemented as an instance of a generic AND block (`GEN_AND`), which can be parameterized for a variable number of inputs. This specific instance is defined for exactly five inputs.
- **Event Chain**: The execution strictly follows the REQ/CNF pattern, which allows for easy integration into event-driven control sequences.
- **No Internal State**: The block is memory-free (combinatory). The output signal depends solely on the current input values at the time of the `REQ` request.

State Overview

The function block has no persistent internal state. Its behavior is purely combinatorial and is fully described by the interface events and data. The "state" is the transition from waiting (`REQ` wait) to active (perform calculation and trigger `CNF`).

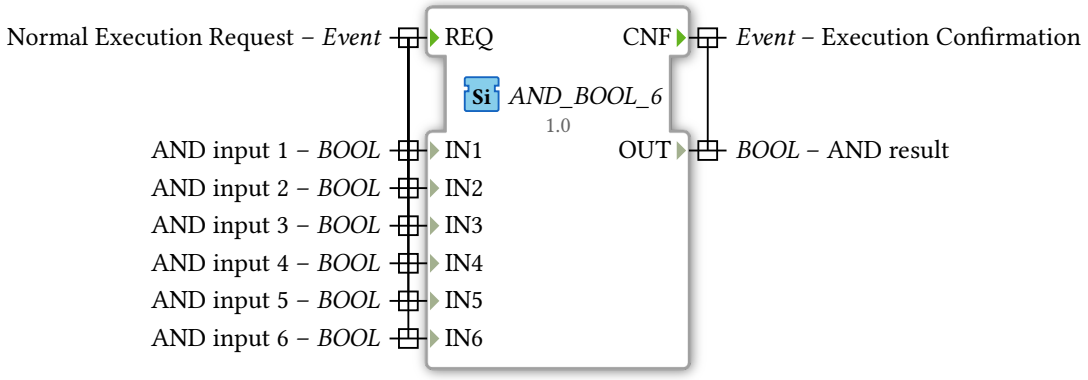
Application Scenarios

Typical applications include safety and enable chains in automation technology, where multiple conditions must be met simultaneously:

- Monitoring whether all safety guards of a machine are closed.
- Checking whether all required media (pressure, vacuum, cooling) are available before a process is started.
- Linking multiple sensor or switch states to a common enable logic.

⚖️ Comparison with similar building blocks

- **`AND_BOOL_2` / `AND_BOOL_3` etc.**: Basic AND blocks with two, three, or four inputs. `AND_BOOL_5` extends this logic to five inputs without the need to chain multiple blocks. See: AND_5
- **`GEN_AND`**: The underlying generic block. `AND_BOOL_5` is a pre-configured, unchangeable instance of it with a fixed number of inputs.
- **OR blocks**: Perform a logical OR operation. While `AND_BOOL_5` outputs `TRUE` only if all `TRUE` inputs are present, OR gates output `TRUE` even if only one `TRUE` input is present.



Conclusion

The `AND_BOOL_5` is a robust and easy-to-use standard function block for five-input logic gates. Its event-driven, stateless architecture makes it highly predictable and easy to integrate into more complex IEC 61499 applications. It offers an optimal and readable solution for applications that need to link exactly five conditions.

AND_BOOL_6

• − ◦ • − ◦ • − ◦ •

The function block `AND_BOOL_6` is a standard function block for calculating the logical AND operation. It performs a bitwise AND operation using six separate Boolean inputs. This block belongs to the category of standard Boolean functions and is designed for use in control applications according to IEC 61131-3.

- **REQ** (Normal Execution Request): This event triggers the calculation of the AND operation. Upon receiving `REQ`, the values of all six data inputs (IN1 to `IN6`) are read and processed.
- **CNF** (Execution Confirmation): This event signals the completion of the calculation. It is output along with the calculated result at data output `OUT`.
- **IN1** (BOOL): AND input 1.
- **IN2** (BOOL): AND input 2.
- **IN3** (BOOL): AND input 3.
- **IN4** (BOOL): AND input 4.
- **IN5** (BOOL): AND input 5.
- **IN6** (BOOL): AND input 6.
- **OUT** (BOOL): Result of the AND operation. The output is only `TRUE` if **all** six inputs (`IN1` to `IN6`) have the value `TRUE`. In all other cases, the output is `FALSE`.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

This function block has no adapter interfaces.

Functionality

The functionality is deterministic and simple: Upon each occurrence of the event `REQ`, the logical state of all six inputs is evaluated. The result of the AND operation is provided at the data output `OUT`, and simultaneously, the acknowledgment event `CNF` is triggered. The logical operation corresponds to the formula: OUT = IN1 AND IN2 AND IN3 AND IN4 AND IN5 AND IN6`

- **Generic Block:** The block is implemented as a generic block (`GEN_AND`), meaning it is a specific instance of a more general AND function block family.
- **Fixed Number of Inputs:** Unlike blocks with a variable number of inputs, this block has exactly six fixed inputs.
- **Event-driven:** The operation is executed exclusively by an incoming event (`REQ`), which is typical for the function block (FB) architecture in 4diac.

The block has no internal state or memory. Its behavior is purely combinatorial and depends solely on the current values of the inputs at the time of triggering by `REQ`.

Typical applications include safety and enable chains in control logic, where multiple conditions must be met simultaneously before an action is executed.

- **Machine Start:** A machine will only start if all safety doors are closed (`TRUE`) and all emergency stop buttons are not pressed (`TRUE`).

- **Multiple Sensor Polling:** Evaluates multiple sensors, all of which must provide a signal to confirm a position or state.
- **AND (with 2 inputs):** The standard `AND` block typically has only two inputs. `AND_BOOL_6` offers a specialized, more compact representation for applications with exactly six inputs, without the need to chain multiple blocks together. See: AND_6
- **GEN_AND (Generic AND Block):** `AND_BOOL_6` is a concrete instance of this generic type. Other instances could have a different number of inputs (e.g., `AND_BOOL_4`).
- **OR_BOOL_6:** A similar block, but it performs a logical OR operation where the result is `TRUE` if at least one input is `TRUE`.

The `AND_BOOL_6` function block is a reliable and easy-to-use block for six-input logical AND operations. Its event-driven, stateless nature makes it predictable and easily integrated into the 4diac architecture. It is the optimal choice when a fixed set of six conditions must be met simultaneously to trigger a subsequent action.

AND_BOOL_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_7` is a generic function block for calculating the logical AND operation. It performs a bitwise AND operation across seven separate BOOL inputs and outputs the result on a single BOOL output. The block follows the ECC execution model, where a calculation is triggered by an incoming event and confirmed by an outgoing event.

Interface Structure

Event Inputs

- **REQ**: Triggers the calculation of the AND operation. Upon arrival of this event, all data inputs (`IN1` to `IN7`) are read and processed.

Event Outputs

- **CNF**: Confirms completion of the calculation. This event is generated after the calculation and returns the result `OUT`.

Data Inputs

- **IN1**: AND input 1 (BOOL)
- **IN2**: AND input 2 (BOOL)
- **IN3**: AND input 3 (BOOL)
- **IN4**: AND input 4 (BOOL)
- **IN5**: AND input 5 (BOOL)
- **IN6**: AND input 6 (BOOL)
- **IN7**: AND input 7 (BOOL)

Data Outputs

- **OUT**: Result of the AND operation (BOOL). The output is only `TRUE` if **all** seven inputs (`IN1` to `IN7`) have the value `TRUE`. In all other cases, the output is `FALSE`.

Adapters

This function block has no adapter interfaces.

Operation

The operation is deterministic and follows Boolean algebra. Upon each occurrence of the event `REQ`, the following operation is performed:

OUT := IN1 AND IN2 AND IN3 AND IN4 AND IN5 AND IN6 AND IN7`

Immediately after the result is calculated, the confirmation event `CNF` is output along with the current value of `OUT`.

- **Generic Block**: This block is marked as a generic block (`GEN_AND`). This means it can serve as a template for the automatic generation of similar blocks with a different number of inputs.
- **Event-driven**: The operation is only executed when required by an event, which conserves resources and allows for clear control of the flow.
- **Fixed Number of Inputs**: This specific block has a fixed number of seven inputs. For a different number of operands, a corresponding block (e.g., `AND_BOOL_2`, `AND_BOOL_4`) must be used, or a generic block must be instantiated.

State Overview

The block does not have an internal state in the sense of a memory. Its behavior is purely combinatorial and event-driven:

1. **Idle State**: Waits for the event `REQ`.
2. **Execution State**: Upon `REQ`, all inputs are read, the AND operation is calculated, and the result `OUT` is set.
3. **Acknowledgement State**: The event `CNF` is sent immediately, after which the block returns to the idle state.

Application Scenarios

- **Safety Chain**: Linking multiple safety switches (e.g., emergency stop, safety guard, light barrier), where a machine may only start if all switches are closed (TRUE).
- **Multiple Condition**: Checking whether multiple parallel process steps have been successfully completed before a subsequent process is started.
- **Control Logic**: Implementation of complex AND conditions in sequential or logic controls.

⚖️ Comparison with similar blocks

- **`AND_n_BOOL` family**: Blocks with identical functionality but different numbers of inputs exist (e.g., `AND_BOOL_2`, `AND_BOOL_8`). `AND_BOOL_7` fills the gap for applications requiring exactly seven conditions. See: AND_7
- **`&` (Bit-AND) Operator**: While `AND_BOOL_7` only works with BOOL data types and is event-driven, the `&` operator in Structured Text (ST) can also be applied to byte, word, or DWORD data types and is evaluated cyclically or statement-wise.

- **Serial AND Interlock**: The same result could be achieved by serially concatenating multiple `AND_BOOL_2` blocks. `AND_BOOL_7` offers a more compact and concise solution.

Conclusion

The `AND_BOOL_7` is a specialized, reliable, and easy-to-use function block for the logical AND operation of seven Boolean signals. Its event-driven architecture makes it ideal for integration into control-type flowcharts within the 4diac IDE. For applications with a different number of inputs, the corresponding variant from the `AND_n_BOOL` family should be used.

AND_BOOL_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_8` is a standard function block for calculating the logical AND operation. It performs a bitwise AND operation on eight Boolean input values and outputs the result to a single Boolean output. The function block follows the event-driven execution model of IEC 61499.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the execution of the function block. Upon receipt of this event, all eight data inputs are read, the AND operation is calculated, and the result is provided at output `OUT`. The acknowledgment event `CNF` is then generated.

Event Outputs

- **CNF (Execution Confirmation):** This event is output after the successful calculation and update of output `OUT`. It indicates that a new result is available.

Data Inputs

- **IN1 (BOOL):** AND input 1.
- **IN2 (BOOL):** AND input 2.
- **IN3 (BOOL):** AND input 3.
- **IN4 (BOOL):** AND input 4.
- **IN5 (BOOL):** AND input 5.
- **IN6 (BOOL):** AND input 6.
- **IN7 (BOOL):** AND input 7.
- **IN8 (BOOL):** AND input 8.

Data Outputs

- **OUT (BOOL):** Result of the AND operation of all eight inputs. The output is `TRUE` (1) only if **all** inputs `IN1` to `IN8` have the value `TRUE`. In all other cases, the output is `FALSE` (0).

Adapter

This function block has no adapter interfaces.

Operation

The operation is deterministic and follows classical Boolean logic. When triggered by the event `REQ`, the block evaluates the states of all eight inputs (`IN1` to `IN8`). The logical operation is performed according to the following truth table:

IN1	IN2	IN3	IN4	IN5	IN6	IN7	IN8	OUT
0	X	X	X	X	X	X	X	0
1	0	X	X	X	X	X	X	0
1	1	0	X	X	X	X	X	0
...	...	...	...	...	...	...	...	...
1	1	1	1	1	1	1	1	1

(X = Don't-Care / Any Value)

The result `OUT = IN1 AND IN2 AND IN3 AND IN4 AND IN5 AND IN6 AND IN7 AND IN8` is set immediately after the calculation. Execution is completed by triggering the confirmation event `CNF`, which accompanies the new result at the data output `OUT`.

Technical Features

- **Generic Block:** The block is implemented as an instance of a generic AND template (`GEN_AND`), ensuring a consistent architecture within the library.
- **Fixed Input Count:** Unlike variable or configurable blocks, `AND_BOOL_8` has exactly eight fixed inputs. For a different number of operands, a corresponding block (e.g., `AND_BOOL_2`, `AND_BOOL_16`) must be used.
- **Event-driven execution:** The calculation only takes place upon the arrival of a `REQ` event. Continuous sampling of the inputs without an event does not result in an output update.

State overview

The function block has no internal state (memory-free / combinatorial). Its behavior depends solely on the current values at the data inputs at the time of the `REQ` event. Previous calculations have no influence on the current result.

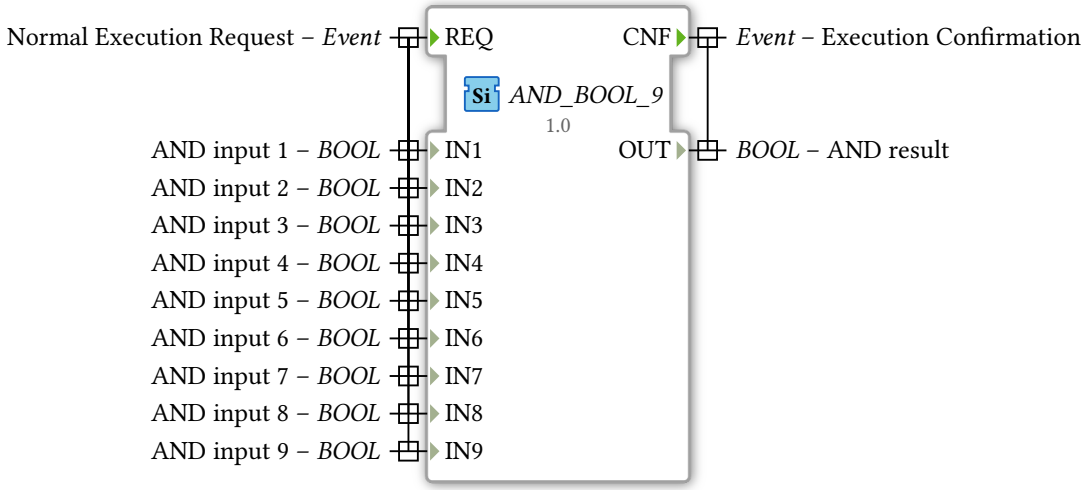
Application scenarios

- **Safety-critical connections:** Monitoring of multiple safety switches (e.g., emergency stop, safety gates, light barriers) where all conditions must be met to signal a safe state (`OUT=TRUE`).
- **Multiple Conditions in Process Sequences:** Checks whether all prerequisites for starting a machine cycle are met (e.g., "Workpiece inserted," "Pressure reached," "Temperature reached," "Protective cover closed").
- **Status Message Combination:** Combines multiple error or status bits into a single, summarized signal.

⚖️ Comparison with Similar Blocks

- **`AND_BOOL_2`, `AND_BOOL_16`, etc.:** These blocks offer the same logical function, but for a different number of inputs (2, 16, etc.). The choice of block depends on the required number of operands. See: AND_8
- **`OR_n_BOOL`:** Performs a logical OR operation. The result is `TRUE` if at least one input is `TRUE`.
- **`XOR_n_BOOL`:** Performs an exclusive OR (XOR) operation.
- **Continuous Function Blocks (IEC 61131-3):** In IEC 61131-3, AND operations are typically implemented as continuous contacts or operations in languages such as FBD or LD. The `AND_BOOL_8` function block, however, is event-driven and explicitly requires a trigger event.

Conclusion



The `AND_BOOL_8` is a fundamental, reliable, and easy-to-use logic block for IEC 61499 systems. Its strength lies in its clear, event-driven semantics and the explicit handling of eight Boolean input signals. It is ideally suited for control logic where multiple conditions must be met simultaneously before an action is executed. For applications with a different number of inputs than eight, the corresponding variant of the `AND_n_BOOL` family should be used.

AND_BOOL_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AND_BOOL_9` is a standard building block for calculating the logical AND operation. It performs a bitwise AND operation across nine separate Boolean inputs. The block complies with the IEC 61131-3 standard and is designed for use in the 4diac IDE.

Interface Structure

The block has an event-driven input/output model.

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation of the AND operation. This event reads all data inputs (`IN1` to `IN9`) and calculates the result.

Event Outputs

- **CNF (Execution Confirmation):** Triggered after the calculation is complete, this indicates that the result is available at data output `OUT`.

Data Inputs

- **IN1 (BOOL):** AND Input 1.
- **IN2 (BOOL):** AND Input 2.
- **IN3 (BOOL):** AND Input 3.
- **IN4 (BOOL):** AND Input 4.
- **IN5 (BOOL):** AND Input 5.
- **IN6 (BOOL):** AND Input 6.
- **IN7 (BOOL):** AND Input 7.
- **IN8 (BOOL):** AND Input 8.
- **IN9 (BOOL):** AND Input 9.

Data Outputs

- **OUT (BOOL):** Result of the AND operation. The output is only `TRUE` if **all** nine inputs (`IN1` to `IN9`) have the value `TRUE`. In all other cases, the output is `FALSE`.

Adapters

This function block does not use any adapters.

Operation

When an event occurs at input `REQ`, the block reads the current values of all nine Boolean inputs (`IN1` to `IN9`). Then, a logical AND operation is performed on all nine values. The result of this operation is immediately output at data output `OUT`. Simultaneously, an acknowledgment event is generated at output `CNF` to signal the successful completion of the operation.

The logical function can be described as follows:

OUT = IN1 AND IN2 AND IN3 AND IN4 AND IN5 AND IN6 AND IN7 AND IN8 AND IN9`

Technical Features

- **Generic Block:** The block is implemented as an instance of a generic AND block (`GEN_AND`) that has been specialized for a fixed number of inputs (here, 9).
- **Event-driven:** The operation is only executed upon an incoming `REQ` event, enabling resource-efficient and deterministic processing.
- **Fixed Number of Inputs:** Unlike variable functions, this block operates with exactly nine inputs.

State Overview

The block does not have an internal state in the sense of a memory. Its behavior is combinatorial and depends solely on the current values of the inputs at the time of the `REQ` event. The output `OUT` retains its value until the next execution cycle.

Application Scenarios

- **Safety Chain:** Linking multiple safety switches (e.g., emergency stop, safety guard, two-hand control) that must all be closed to start a machine.
- **Multiple Conditions:** Checking whether multiple conditions are met simultaneously in a process step.
- **Logic Chaining:** As part of a larger logic circuit where the results from nine sources must be evaluated together.

⚖️ Comparison with Similar Function Blocks

- **`AND` (2 inputs):** The standard AND block with only two inputs. `AND_BOOL_9` is a special, extended version for exactly nine inputs. See: AND_9
- **`GEN_AND`:** The underlying generic function block that can be instantiated with a configurable number of inputs. `AND_BOOL_9` is a predefined instance of it.
- **`OR_*` / `XOR_*` function blocks:** Perform other basic logic operations (OR, exclusive OR) with a fixed number of inputs.

Conclusion

The `AND_BOOL_9` is a robust and easy-to-use standard function block for applications requiring a logical AND operation across exactly nine Boolean signals. Its event-driven nature and clear interface make it easily integrated into 4diac-based control applications. For a different number of inputs, the corresponding specialized blocks (`AND_BOOL_2`, `AND_BOOL_3`, etc.) or the generic `GEN_AND` should be used.

F_NOT_BOOL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `F_NOT_BOOL` implements the logical NOT function (negation) for the data type `BOOL`. It inverts the logical state of a binary input signal. This block belongs to the standard bit operators according to IEC 61131-3 and is designed for use in control applications where logical operations are required.

Interface Structure

Event Inputs

- **REQ (Service Request)**: This event triggers the execution of the logical negation. Upon its arrival, the current value at data input `IN` is processed, and the result is output to `OUT`.

Event Outputs

- **CNF (Confirmation of Requested Service)**: This event signals the completion of the operation. It is generated simultaneously with the output of the calculated value at data output `OUT`.

Data Inputs

- **IN (Input)**: Data type `BOOL`. This is the binary input value to be negated. Valid values are `TRUE` (1) or `FALSE` (0).

Data Outputs

- **OUT (Output)**: Data type `BOOL`. This is the result of the logical negation. The output value is the logical opposite of the input value `IN`.

Adapters

This function block does not use any adapter interfaces.

Operation

The operation is deterministic and simple: Upon each occurrence of a `REQ` event, the function block reads the current value at the data input `IN`. It then calculates the logical negation and writes the result to the data output `OUT`. Simultaneously, a `CNF` event is generated to signal the completion of the operation.

The logical operation can be described by the following table:

Input (IN)	Output (OUT)
FALSE (0)	TRUE (1)
TRUE (1)	FALSE (0)

Technical Features

- **Standard Compliance**: The function block is classified as a standard function according to IEC 61131-3.
- **I/O Delay**: The processing of `REQ` up to the output of `CNF` and `OUT` takes place within one cycle of the executing resource. There are no inherent delays.
- **Initialization**: The output variables are set to their default values (`FALSE` for `BOOL`) during the initialization of the function block.

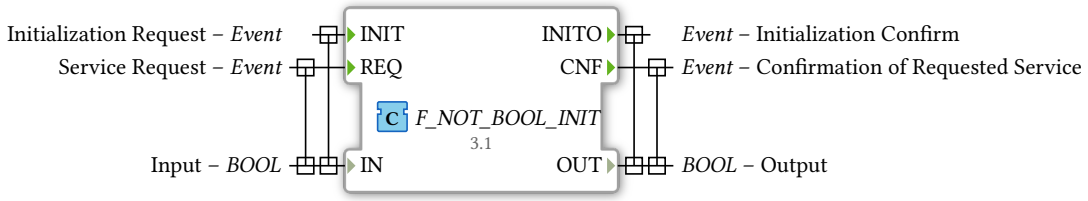
State Overview

The function block does not have an internal state in the sense of a state machine. Its behavior is purely combinatorial and depends solely on the current input values when triggered by a `REQ` event. No previous values are stored.

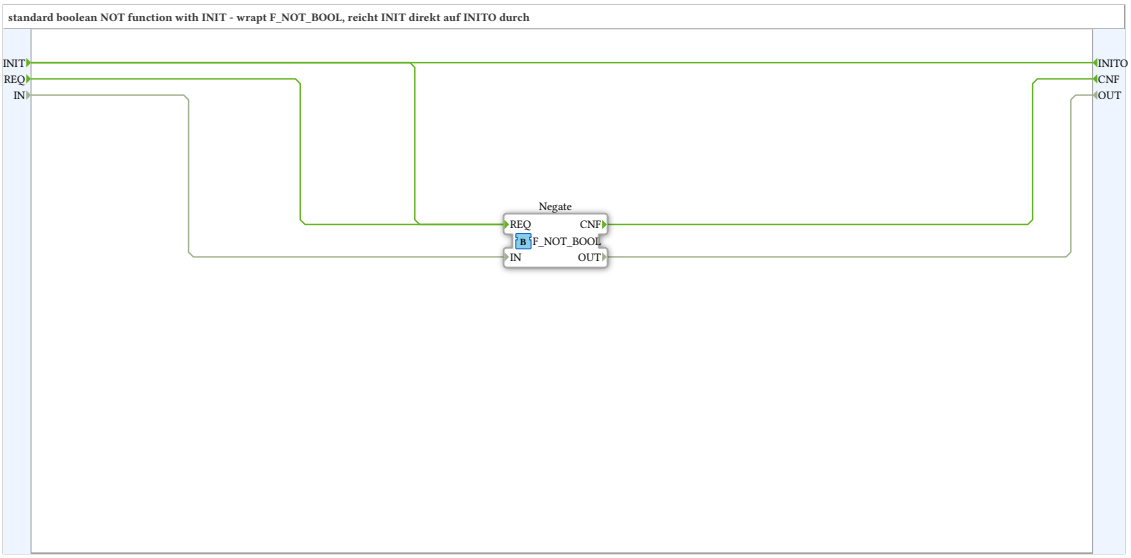
Application Scenarios

- **Sensor Signal Inversion**: Conversion of an active low sensor signal (e.g., “Button pressed” = FALSE) into an active high signal for further logic.
- **Safety Logic**: Generation of a block signal from an enable signal or vice versa.
- **Control Logic**: As a fundamental building block in more complex logical expressions and conditions within sequential control systems.

- **Status Display**: Inversion of an internal status for controlling a lamp (e.g., “Machine Ready” = TRUE, but “Fault Lamp Lights Up” if FALSE).



⚖️ Comparison with Similar Function Blocks



Within the `iec61131::bitwiseOperators` library, other basic logical operators exist, such as `F_AND`, `F_OR`, and `F_XOR`. Unlike these function blocks, which combine two or more inputs, `F_NOT_BOOL` has only a single data input. Its function is essential for completing logical expressions and performing direct inversions. Implementing it as a standalone function block (rather than as an integrated operator within an expression) improves clarity in graphical programming environments like FBD. See: F_NOT

Conclusion

The `F_NOT_BOOL` function block is an essential, robust, and easy-to-use basic building block for binary logic in IEC 61131-3-based control programs. Its clear interface and deterministic operation make it the first choice for inverting Boolean signals in automation technology.

F_NOT_BOOL_INIT

• – ○ • – ○ • – ○ •

The function block `F_NOT_BOOL_INIT` implements the logical negation (NOT) of a Boolean input signal and extends the basic NOT function with an initialization mechanism. It is designed as a standardized block according to IEC 61131-3 for use in programmable logic controllers (PLCs). During initialization, the function block allows a first negation to be triggered and the resulting value to be provided at the output before normal cyclic operation begins.

Event	Type	With Variables	Description
`INIT`	EInit	`IN`	Initialization request – the function block is initialized once and the input is negated.
`REQ`	Event	`IN`	Normal processing request – the logical negation is applied to the current input value.
Event	Type	With Variables	Description

| ----- | --- | ------ | ------- |
INITO	EInit	OUT	Initialization confirmation – output after successful initialization.
CNF	Event	OUT	Confirmation of normal processing – sent to REQ after each execution.
Variable	Type	Description	
-----	----	-------	
IN	BOOL	Input value to be negated.	
Variable	Type	Description	
-----	----	-------	
OUT	BOOL	Negated value of the input (NOT IN).	

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapter

None.

Functionality

The function block delegates the actual negation function to the internal function block F_NOT (from the library iec61131::bitwiseOperators). Processing is event-driven:

- **For INIT:** The input value IN is immediately transferred via the data connection to the internal function block F_NOT. Simultaneously, the event REQ is sent to the internal function block, which calculates the negation and passes the result to the output OUT. After this operation is completed, the event INITO is output at the main function block. This sets the output OUT with the negated initial value.
- **For REQ (during operation):** The current value of IN is passed to the internal F_NOT and negated. The result is written to OUT, and then the event CNF is triggered.

Thus, both INIT and REQ result in the same core functionality (negation), but differ in the triggered event: INIT generates INITO, and REQ generates CNF.

- The function block does not contain its own algorithmic logic, but uses an internal sub-function (F_NOT). This promotes reuse and consistency.
- The initialization mechanism allows the output to be assigned the negated input even before the first "normal" call – useful in PLC programs where start values need to be defined.
- The function block does not contain its own algorithmic logic, but uses an internal sub-function (F_NOT). This promotes reuse and consistency.
- The initialization mechanism allows the output to be set to the negated input even before the first "normal" call – useful in PLC programs where start values need to be defined.
- The simultaneous use of INIT and REQ enables a clear separation between startup behavior and cyclic operation.
- By including the input variables in the events (WITH), it is ensured that the data is always up-to-date.

The function block (FB) does not have an explicit state machine, as all logic is implemented in the internal network. The following behavior is implicit:

1. **Initial State:** After the PLC starts, outputs and internal values are undefined.
2. **After `INIT`:** The output `OUT` is set to the negated value of `IN`; the FB is ready for operation.
3. **After `REQ`:** For each `REQ` pulse, the negation is performed again, and `OUT` is updated.

A repeated triggering of `INIT` (e.g., after a reset) leads to re-initialization and sets `OUT` to the negated current input value.

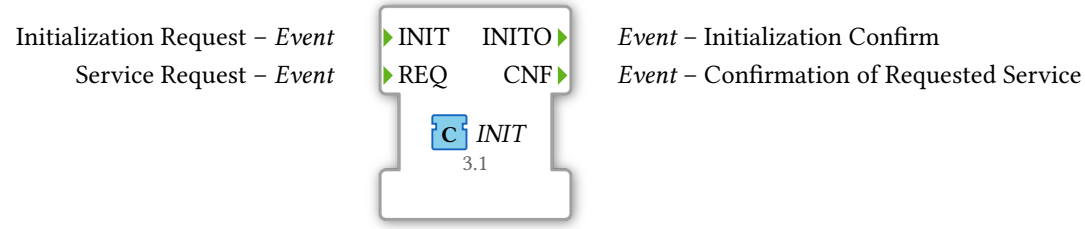
- **Initializing a Control Output:** An output should assume the negated value of a sensor signal during the startup phase before the cyclic program starts.
- **Error Monitoring:** During a startup sequence, it is checked whether an input signal has the negated state of an enable signal.
- **Safety Logic:** Used in safety functions where an initial negation step is mandatory (e.g., NOT operation after system startup).

Function Block	Description	Difference to `F_NOT_BOOL_INIT`
`F_NOT` (Standard)	Pure negation without an initialization event.	The `INIT`/`INITO` pair is missing; the output is undefined after system startup.
`F_NOT_BOOL_INIT`	Like `F_NOT`, but with an explicit initialization event.	Offers defined start behavior and outputs a separate acknowledgment event upon initialization.

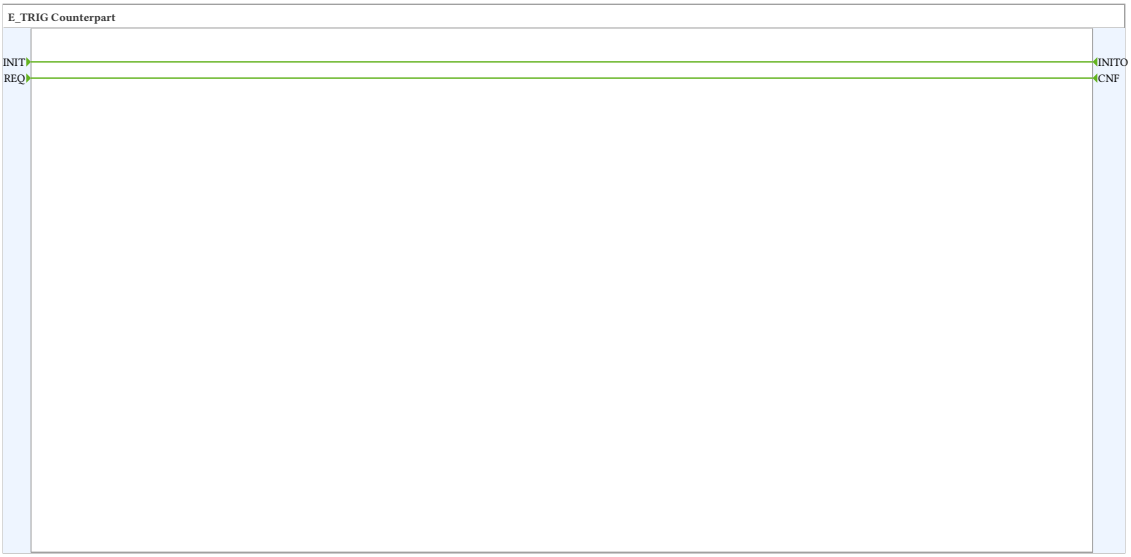
The standard `F_NOT` is sufficient if the start behavior is controlled by the higher-level control sequence. The initializable function block is advantageous when the function block itself should have control over its first execution.

F_NOT_BOOL_INIT`is a useful function block that extends the simple NOT operation with an initialization facility. It is particularly suitable for PLC applications where a defined start value for the negated output is required. Thanks to the clear event control and the internal use of the provenF_NOT` function block, the implementation remains robust and well-organized. The function block represents a useful extension of the IEC 61131 bit operators.

Technical Features



State Overview



Application Scenarios

Comparison with Similar Function Blocks

Conclusion

INIT

• – ○ • – ○ • – ○ •

Introduction

The **INIT** function block serves as a direct event pass-through. It is designed as the counterpart to a `E_TRIG` function block and is typically used in the initialization phase of a system. The function block has two event inputs and two corresponding event outputs; no data is processed.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request
REQ	Event	Service Request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement
CNF	Event	Request Acknowledgement

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The function block operates in an event-driven manner and does not perform any logic or state changes of its own. Every incoming event is forwarded to the corresponding output without delay or processing:

- An event at input `INIT` immediately generates an event at output `INITO`.
- An event at input `REQ` immediately generates an event at output `CNF`.

This behavior is achieved through a simple connection of the event paths within the internal function block network. No value changes or state storage occur.

Technical Features

- **Direct Pass-Through**: The function block is extremely lightweight and requires no internal variables or time delays.
- **Event Types**: The input and output events `INIT`/`INITO` are typed as `EInit`, while `REQ`/`CNF` are declared as the default `Event`. This allows for a clear semantic separation between initialization and operational events.
- **License**: The function block is licensed under the Eclipse Public License 2.0 (EPL-2.0).

State Overview

The function block has **no internal states**. It is a pure pass-through block that reacts to incoming events at any time without changing state. Therefore, a state machine is not required.

Application Scenarios

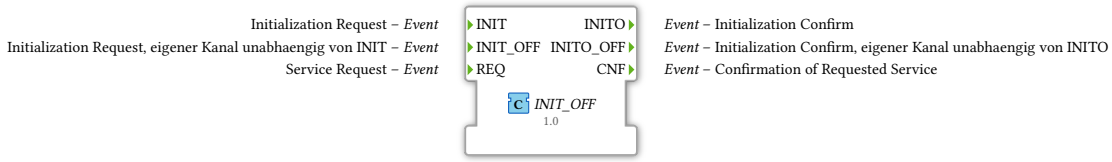
- **Placeholder in Design Phases**: If a `E_TRIG` block is later to be replaced by more complex logic, `INIT` can temporarily serve as a simple pass-through block.
- **Initialization Cascades**: In architectures that perform multiple initialization steps, `INIT` blocks can be used to pass events to subsequent blocks without processing them.
- **Prototyping and Testing**: For bridging unused initialization logic or for debugging event flows.

Comparison with Similar Function Blocks

- **E_TRIG (Input Trigger)**: `E_TRIG` generates an output event only on a rising or falling edge of a connected Boolean input. `INIT`, on the other hand, reacts directly to an event and does not require a data value.
- **E_PERMIT (Enable)**: `E_PERMIT` allows events to pass only if a Boolean enable input is set. `INIT` has no such condition.
- **E_DELAY (Delay)**: `E_DELAY` delays events for a specific period of time. `INIT` operates without delay.

Conclusion

The `INIT` function block is a minimalist yet useful building block for direct event forwarding. Due to its simplicity, it is particularly suitable for design phases, initialization processes, and as a temporary placeholder. It fulfills the basic requirement of passing on initialization and service events unchanged and can be replaced by more functionally richer building blocks if needed.



INIT_OFF

• – ○ • – ○ • – ○ •

Introduction

`INIT_OFF` is the counterpart of `E_TRIG`, extended by an independent `INIT_OFF`/`INITO_OFF` pass-through (event type `EInitOff`). The block contains no logic; every input event is forwarded directly to the corresponding output.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization request
INIT_OFF	EInitOff	Initialization request, own channel independent of `INIT`
REQ	Event	Service request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization confirm
INITO_OFF	EInitOff	Initialization confirm, own channel independent of `INITO`
CNF	Event	Confirmation of requested service

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The block consists of event connections only:

- `INIT` ⟶ `INITO`
- `REQ` ⟶ `CNF`
- `INIT_OFF` ⟶ `INITO_OFF`

Technical Details

- Pure pass-through without logic and without data
- The `INIT_OFF` channel is independent of the `INIT` channel

Application Scenarios

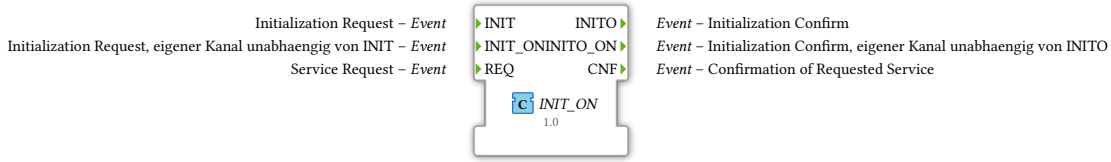
- Forwarding initialisation and shutdown events (`EInitOff`) in a chain of blocks

⚖️ Comparison with Similar Building Blocks

- INIT only contains `INIT`/`REQ` without the `INIT_OFF` channel
- INIT_ON_OFF additionally offers an `INIT_ON`/`INITO_ON` channel

Conclusion

`INIT_OFF` forwards `INIT`, `INIT_OFF` and `REQ` unchanged as `INITO`, `INITO_OFF` and `CNF`.



INIT_ON

• – ○ • – ○ • – ○ •

Introduction

`INIT_ON` is the counterpart of `E_TRIG`, extended by an independent `INIT_ON`/`INITO_ON` pass-through (event type `EInitOn`). The block contains no logic; every input event is forwarded directly to the corresponding output.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization request
INIT_ON	EInitOn	Initialization request, own channel independent of `INIT`
REQ	Event	Service request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization confirm
INITO_ON	EInitOn	Initialization confirm, own channel independent of `INITO`
CNF	Event	Confirmation of requested service

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The block consists of event connections only:

- `INIT` ⟶ `INITO`
- `REQ` ⟶ `CNF`
- `INIT_ON` ⟶ `INITO_ON`

Technical Details

- Pure pass-through without logic and without data
- The `INIT_ON` channel is independent of the `INIT` channel

Application Scenarios

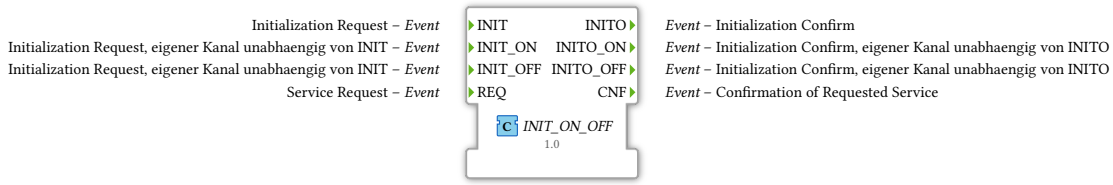
- Forwarding initialisation events of a dedicated channel (`EInitOn`) in a chain of blocks

⚖️ Comparison with Similar Building Blocks

- INIT only contains `INIT`/`REQ` without the `INIT_ON` channel
- INIT_OFF offers an `INIT_OFF`/`INITO_OFF` channel (`EInitOff`) instead, INIT_ON_OFF offers both channels

Conclusion

`INIT_ON` forwards `INIT`, `INIT_ON` and `REQ` unchanged as `INITO`, `INITO_ON` and `CNF`.



INIT_ON_OFF

• – ○ • – ○ • – ○ •

Introduction

`INIT_ON_OFF` is the counterpart of `E_TRIG`, extended by two independent pass-throughs: `INIT_ON`/`INITO_ON` (event type `EInitOn`) and `INIT_OFF`/`INITO_OFF` (event type `EInitOff`). The block contains no logic; every input event is passed directly to the associated output.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Initialization request
- **INIT_ON** (`EInitOn`): Initialization request, own channel independent of `INIT`
- **INIT_OFF** (`EInitOff`): Initialization request, own channel independent of `INIT`
- **REQ**: Service request

Event Outputs

- **INITO** (`EInit`): Initialization confirmation
- **INITO_ON** (`EInitOn`): Initialization confirmation, own channel independent of `INITO`
- **INITO_OFF** (`EInitOff`): Initialization confirmation, own channel independent of `INITO`
- **CNF**: Confirmation of the requested service

Data Inputs

No data inputs

Data Outputs

No data outputs

Adapters

This function block uses no adapters.

How it works

Pure event connections:

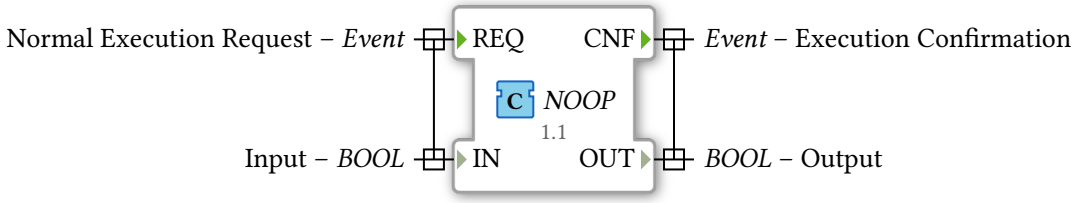
- `INIT` ⟶ `INITO`
- `REQ` ⟶ `CNF`
- `INIT_ON` ⟶ `INITO_ON`
- `INIT_OFF` ⟶ `INITO_OFF`

Technical Details

- Composite function block (`FBNetwork`) without data and without internal state
- The three initialization channels are independent of each other, so that on- and off-related initializations can be wired separately.
- See also `INIT`.

Application Scenarios

- Separate initialization events for the on and off path in a network



🛠️ Related Exercises

- Uebung_006g_AX

Summary

`INIT_ON_OFF` provides three independent initialization pass-throughs and one `REQ`/`CNF` pass-through.

NOOP

• — ○ • — ○ • — ○ •

Introduction

The NOOP function block (“No Operation”) serves as a simple pass-through block. It copies the BOOL value present at data input `IN` to data output `OUT` as soon as an event occurs at input `REQ`. The output `CNF` is then triggered. The function block does not perform any logical or arithmetic operation; it simply passes the signal on unchanged.

Interface Structure

Event Inputs

Event	Type	Comment
`REQ`	Event	Normal Execution Pulse

Event Outputs

Event	Type	Comment
`CNF`	Event	Execution Acknowledgement

Data Inputs

Name	Type	Comment
`IN`	BOOL	Input Signal

Data Outputs

Name	Type	Comment
`OUT`	BOOL	Output signal (identical to `IN`)

Adapter

None.

Functionality

Internally, the function block consists of an instance of `F_MOVE` (from the library `iec61131::selection::F_MOVE`), configured with the data type `BOOL`.

- Upon an event on `REQ`, the value of `IN` is passed to `F_MOVE.IN`, triggering execution.

- After successful processing, `F_MOVE.OUT` outputs the value, which is then set to `OUT`. Simultaneously, `F_MOVE.CNF` is triggered, which activates the event output `CNF`.

Thus, the behavior corresponds exactly to a passthrough: `OUT := IN`.

Technical Features

- The function block uses a pre-built MOVE block internally, so no custom state logic is required.
- The data paths are explicitly designed for `BOOL`. Extending it to other data types would be possible by modifying the `F_MOVE` attribute, but this is not included in the current design.
- No side effects such as delays or state changes beyond pure signal transmission are implemented. ...

State Overview

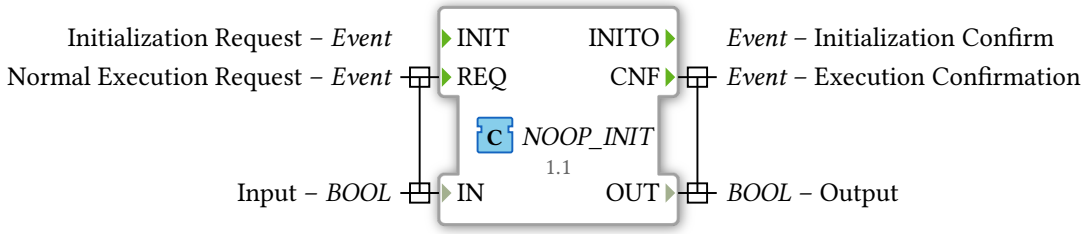
Since the function block does not have its own state machine, the process can be viewed as a simple two-step operation:

1. **Wait** – for an event `REQ`.
2. **Forward** – immediate transfer of `IN` to `OUT` and output of `CNF`.

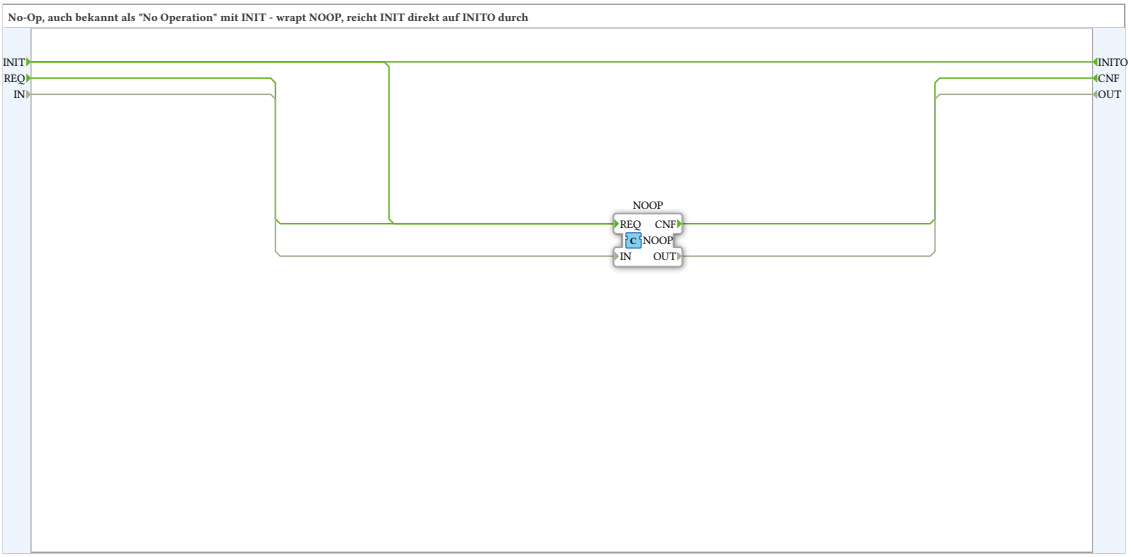
There are no internal memory states or branches.

Application Scenarios

- **Debugging and Testing**: Used as a placeholder to test signal paths in a complex network without affecting functionality.
- **Signal Forwarding**: When an event signal needs to be passed through unchanged, e.g., for synchronizing multiple branches.
- **Placeholder for Future Extensions**: In an early development phase, NOOP can be placed at locations that will later require specific processing.
- **Cascading of Events**: Event coupling allows multiple receivers to be served sequentially.



Comparison with Similar Function Blocks



- **MOVE**: A MOVE function block (like the one used internally) also performs a value assignment. NOOP differs only in name and its explicit documentation as "no operation." Both are functionally almost identical, with the difference that MOVE is often typed for arbitrary data types, while NOOP is statically set to BOOL.
- **BISTABLE (RS / SR)**: These function blocks change their state based on inputs. NOOP does not store a state but only outputs the current input value.
- **CONSTANT**: A constant function block always returns a fixed value. NOOP, on the other hand, reacts to changing inputs and events.

Conclusion

The NOOP function block is a simple yet useful function block that requires no internal logic. It copies the incoming BOOL value to the output upon each event and confirms execution. Due to its pass-through characteristics, it is ideally suited for testing purposes, as a placeholder or for event-driven signal transmission in IEC 61499 networks.

NOOP_INIT

• – ○ • – ○ • – ○ •

Introduction

The function block **NOOP_INIT** (No Operation with INIT) serves as a simple pass-through or placeholder block. It enables the initialization and normal data transmission of a Boolean signal from an input to an output. Its special feature lies in the additional handling of the INIT event, which triggers both an acknowledgment (INITO) and data transmission.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization Request
REQ	Event	Normal Execution Request (connected to IN)

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement
CNF	Event	Execution Acknowledgement (connected to OUT)

Data Inputs

Name	Type	Comment
IN	BOOL	Input Signal

Data Outputs

Name	Type	Comment
OUT	BOOL	Output Signal (corresponds to IN after one iteration)

Adapters

No adapters available.

Functionality

The function block processes incoming events as follows:

1. **INIT Event**:

- An **INITO** event is immediately triggered.
- Simultaneously, the `F_MOVE` function block is triggered internally, which copies the value from `IN` to `OUT`. Upon completion of this copy operation, the **CNF** event is triggered.

1. **REQ Event**:

- The same `F_MOVE` function block is activated, which transfers `IN` to `OUT`. Upon completion, **CNF** is triggered.

As a result, data is transferred during both INIT and REQ, and an acknowledgment event is generated in each case. The data output `OUT` always corresponds to the last received value of the input `IN`.

Technical Features

- The function block internally uses an instance of the standard FB `iec61131::selection::F_MOVE` for data copying.
- The INIT process is twofold: It immediately acknowledges with `INITO` and simultaneously executes the data transfer. This can be useful for initialization sequences where the system should start working after the first input of a start value.
- There are no internal states or timings; the response is event-driven.

State Overview

The FB does not have an explicit state machine; its behavior is purely event-driven:

- In the idle state (no event), the inputs wait.
- Data copying is started on **INIT** or **REQ** Upon completion, `CNF` is sent. Upon INIT, `INITO` is also immediately emitted.

Application Scenarios

- **Placeholder** in the development phase: Instead of a complex function block, NOOP_INIT is inserted to test data flows.
- **Debugging**: The explicit INIT event can be used to set an initial value and simultaneously receive confirmation.
- **Signal coupling**: When a signal needs to be passed on unchanged, but the INIT interface of a subsequent function block needs to be accessed.
- **Testing initialization sequences**: Simulation of a start routine that sets a value and acknowledges it.

Comparison with similar function blocks

- **NOOP (without INIT)**: Simple pass-through function block without an initialization event. NOOP_INIT extends this with the INIT/INITO pairing.

NOOP (without INIT): Simple pass-through function block without an initialization event. - **MOVE (direct)**: A pure data copier without event handling; NOOP_INIT offers an event-driven version with acknowledgments.

- **E_CYCLE or E_PERMIT**: These blocks control events but do not transfer data. NOOP_INIT combines data transfer with event forwarding.

Conclusion

The **NOOP_INIT** function block is a simple yet flexible utility block for event-driven data transfer. Its combination of INIT and REQ events makes it particularly suitable for initialization processes and test environments. Its internal structure makes it easy to understand and integrates well into existing 4diac networks.

OR_BOOL_10

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_10` is a generic block for calculating the logical OR operation. It performs the OR operation on up to ten separate Boolean input values and outputs the result on a single output. This block is classified according to the IEC 61131-3 standard and serves as a standard function for bitwise operations in control applications.

Interface Structure

The function block follows the standard I/O and event model of the 4diac IDE.

Event Inputs

- **REQ (Normal Execution Request):** This event triggers the execution of the function block. Upon its arrival, all ten data inputs (`IN1` to `IN10`) are read and the OR operation is calculated.

Event Outputs

- **CNF (Execution Confirmation):** This event signals the completion of the calculation. It is output along with the calculated result at data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.

Data Outputs

- **OUT (OR result):** Boolean result of the OR operation of all ten inputs. The output is `TRUE` (1) if at least one of the inputs is `TRUE`. It is only `FALSE` (0) if all ten inputs are `FALSE`.

Adapter

This function block has no adapter interfaces.

Operation

The operation is deterministic and event-driven:

1. The arrival of the event REQ starts the execution.
2. The current values of all ten Boolean inputs (IN1 to IN10) are read.
3. The logical OR operation OUT = IN1 OR IN2 OR IN3 OR ... OR IN10 is calculated.
4. The result is made available at data output OUT.
5. The event CNF is triggered to signal the successful completion of the operation to subsequent blocks.

Technical Features

- **Generic Block:** The block is implemented as a generic function block (GEN_OR), which allows for flexible reuse in different contexts.
- **Fixed Number of Inputs:** Unlike blocks with a variable number of inputs, OR_BOOL_10 has exactly ten fixed inputs. Unused inputs should be set to FALSE.
- **Event-driven:** The calculation only occurs when a REQ event occurs, enabling energy- and computationally efficient processing in the control system.

State Overview

The function block has no internal state (memoryless). The output signal OUT is a pure function of the current input values at the time of the REQ request. There is no delay, hysteresis, or storage of previous states.

Application Scenarios

- **Monitoring Logic:** Combining multiple error or warning signals (e.g., from different sensors) into a single alarm signal.
- **Enable Logic:** Generating an enable signal for a process step when at least one of several prerequisites is met.
- **Button Group Linking:** In an operator station where a process can be initiated by pressing at least one of several "Start" buttons.
- **Redundant Sensor Evaluation:** Evaluates multiple redundant sensors, where the signal from any one sensor is considered valid.

⚖️ Comparison with Similar Blocks

- **OR_BOOL_2 / OR_BOOL_4:** These blocks offer the same OR functionality, but for a smaller number of inputs (2 and 4, respectively). OR_BOOL_10 is intended for applications with a higher number of signals to be linked. See: OR_10
- **AND_BOOL_10:** Performs the logical AND operation. The result is only TRUE if *all* inputs are TRUE, whereas for OR_BOOL_10, it is sufficient if *at least one* input is TRUE.
- **XOR_BOOL_10:** Performs the exclusive OR operation. The result is TRUE if an odd number of inputs are TRUE, which is fundamentally different from inclusive OR logic.
- **Blocks with variable input count:** Some libraries offer OR blocks where the number of inputs is configurable. OR_BOOL_10, however, offers a fixed, explicit interface.

OR_BOOL_10:

Conclusion

The OR_BOOL_10 is a robust and easy-to-use basic building block for logical signal processing in IEC 61131-3-based control applications. Its strength lies in its clear interface with ten inputs and the reliable, event-driven calculation of the inclusive OR function. It represents an optimal solution for applications that require combining multiple Boolean sources into a single signal.

OR_BOOL_11

• – ◦ • – ◦ • – ◦ •

Introduction

The function block OR_BOOL_11 is a generic block for calculating the logical OR operation (classification standard boolean function, IEC 61131-3). It combines 11 separate BOOL inputs (IN1 to IN11) and pro-

vides the result at the output OUT. It extends the standard OR_BOOL family (previously up to OR_BOOL_16) with the variant that has 11 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 11 data inputs (IN1 to IN11).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output OUT.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 11 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs IN1 to IN11 are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event REQ, all 11 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN11` is calculated. The result is then made available at OUT and CNF is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 11 inputs.

- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_11`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_11` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_11` is a simple, event-driven block for the OR combination of 11 Boolean signals with a fixed interface.

OR_BOOL_12

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_12` is a generic block for calculating the logical OR operation (classification `standard boolean function`, IEC 61131-3). It combines 12 separate BOOL inputs (`IN1` to `IN12`) and provides the result at the output `OUT`. It extends the standard OR_BOOL family (previously up to `OR_BOOL_16`) with the variant that has 12 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 12 data inputs (`IN1` to `IN12`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.
- **IN12 (OR input 12):** Boolean input 12.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 12 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs `IN1` to `IN12` are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 12 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN12` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 12 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_12`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_12` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_12` is a simple, event-driven block for the OR combination of 12 Boolean signals with a fixed interface.

OR_BOOL_13

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_13` is a generic block for calculating the logical OR operation (classification `standard boolean function`, IEC 61131-3). It combines 13 separate BOOL inputs (`IN1` to `IN13`) and provides the result at the output `OUT`. It extends the standard OR_BOOL family (previously up to `OR_BOOL_16`) with the variant that has 13 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 13 data inputs (`IN1` to `IN13`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.
- **IN12 (OR input 12):** Boolean input 12.
- **IN13 (OR input 13):** Boolean input 13.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 13 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs `IN1` to `IN13` are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 13 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN13` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 13 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_13`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_13` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_13` is a simple, event-driven block for the OR combination of 13 Boolean signals with a fixed interface.

OR_BOOL_14

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_14` is a generic block for calculating the logical OR operation (classification `standard boolean function`, IEC 61131-3). It combines 14 separate BOOL inputs (`IN1` to `IN14`) and provides the result at the output `OUT`. It extends the standard OR_BOOL family (previously up to `OR_BOOL_16`) with the variant that has 14 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 14 data inputs (`IN1` to `IN14`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.
- **IN12 (OR input 12):** Boolean input 12.
- **IN13 (OR input 13):** Boolean input 13.
- **IN14 (OR input 14):** Boolean input 14.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 14 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs `IN1` to `IN14` are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 14 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN14` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 14 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_14`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_14` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_14` is a simple, event-driven block for the OR combination of 14 Boolean signals with a fixed interface.

OR_BOOL_15

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_15` is a generic block for calculating the logical OR operation (classification `standard boolean function`, IEC 61131-3). It combines 15 separate BOOL inputs (`IN1` to `IN15`) and provides the result at the output `OUT`. It extends the standard OR_BOOL family (previously up to `OR_BOOL_16`) with the variant that has 15 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 15 data inputs (`IN1` to `IN15`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.
- **IN12 (OR input 12):** Boolean input 12.
- **IN13 (OR input 13):** Boolean input 13.
- **IN14 (OR input 14):** Boolean input 14.
- **IN15 (OR input 15):** Boolean input 15.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 15 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs `IN1` to `IN15` are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 15 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN15` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 15 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_15`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_15` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_15` is a simple, event-driven block for the OR combination of 15 Boolean signals with a fixed interface.

🌐 Related topic subpages on ms-muc-docs.de

OR_BOOL_16

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_16` is a standard function block for calculating the logical OR operation. It performs the OR operation via 16 separate Boolean inputs and provides the result at a single output. This function block is part of the IEC 61131-3 compliant library for bitwise operations and is suitable for applications where a logical combination of multiple signals is required.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** This event triggers the calculation of the OR function. It is linked to all 16 data inputs (`IN1` to `IN16`).

Event Outputs

- **CNF (Execution Confirmation):** This event signals the completion of the calculation. It is output along with the updated data output `OUT`.

Data Inputs

The function block has 16 identical Boolean data inputs:

- **IN1** to **IN16 (BOOL):** The input signals to be combined. Each input represents an operand for the OR operation.

Data Outputs

- **OUT (BOOL):** The result of the logical OR operation on all 16 inputs. The output is `TRUE` (1) if at least one of the inputs is `TRUE`. It is only `FALSE` (0) if all 16 inputs are `FALSE`.

Adapter

This function block does not use any adapter interfaces.

Operation

The operation is deterministic and event-driven:

1. The block is activated when an event occurs at input `REQ`.
2. The block reads the current values of all 16 inputs `IN1` to `IN16`.
3. The logical OR operation is calculated on all read values: `OUT = IN1 OR IN2 OR ... OR IN16`. 4. The result is set at the data output `OUT`.
4. Immediately after the calculation, the confirmation event `CNF` is output along with the new value of `OUT`.

Technical Features

- **Generic Block:** The block is marked as a generic block (`GEN_OR`), indicating that the underlying logic can be reused for other OR blocks with different numbers of inputs.
- **Fixed Number of Inputs:** Unlike blocks with a variable number of inputs, `OR_BOOL_16` has exactly 16 inputs. This provides a clear and fixed interface.
- **Event-driven execution:** The calculation only occurs upon receipt of an incoming `REQ` event, enabling energy-efficient and demand-based processing in the real-time system.

State overview

The function block does not have an internal state in the sense of a memory. It behaves purely combinatorially with respect to the input data. Its "state" is defined solely by the presence or absence of a pending calculation job (`REQ`). After processing and sending `CNF`, it returns to a passive waiting state.

Application scenarios

- **Monitoring logic:** Combining multiple error or warning signals into a single fault signal. (e.g., "Stop the machine if sensor A OR sensor B OR ... OR sensor P reports a fault").
- **Enable Logic:** Checks whether at least one of several conditions for starting a process is met.
- **Button Group Linking:** In an operator station where an action can be triggered by pressing at least one of several (up to 16) buttons.

⚖️ Comparison with Similar Function Blocks

- **`OR_BOOL_2`, `OR_BOOL_8`:** These are identical OR function blocks with a smaller number of inputs (2 and 8, respectively). `OR_BOOL_16` extends this series for applications with a higher number of inputs. See: OR_16
- **`AND_BOOL_16`:** Performs the logical AND operation. The result is only `TRUE` if *all* inputs are `TRUE`, whereas for `OR_BOOL_16`, it is sufficient if *at least one* input is `TRUE`.
- **Blocks with variable input count:** Some libraries offer OR blocks where the number of inputs is configurable. `OR_BOOL_16`, on the other hand, offers a fixed, optimized interface for exactly 16 signals.

Conclusion

The `OR_BOOL_16` is a robust and easy-to-use standard block for the logical OR operation of a large group of Boolean signals. Its fixed structure with 16 inputs makes it predictable and easy to use, especially when the required number of signals is known and constant. Event-driven execution seamlessly integrates it into 4diac's dataflow-oriented architecture. It's the ideal choice when up to 16 digital signals need to be reduced to a common OR result.

OR_BOOL_17

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_17` is a generic block for calculating the logical OR operation (classification `standard boolean function`, IEC 61131-3). It combines 17 separate BOOL inputs (`IN1` to `IN17`) and provides the result at the output `OUT`. It extends the standard OR_BOOL family (previously up to `OR_BOOL_16`) with the variant that has 17 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 17 data inputs (`IN1` to `IN17`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.
- **IN12 (OR input 12):** Boolean input 12.
- **IN13 (OR input 13):** Boolean input 13.
- **IN14 (OR input 14):** Boolean input 14.
- **IN15 (OR input 15):** Boolean input 15.
- **IN16 (OR input 16):** Boolean input 16.
- **IN17 (OR input 17):** Boolean input 17.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 17 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs `IN1` to `IN17` are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 17 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN17` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 17 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_17`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_17` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_17` is a simple, event-driven block for the OR combination of 17 Boolean signals with a fixed interface.

OR_BOOL_18

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_18` is a generic block for calculating the logical OR operation (classification `standard boolean function`, IEC 61131-3). It combines 18 separate BOOL inputs (`IN1` to `IN18`) and provides the result at the output `OUT`. It extends the standard OR_BOOL family (previously up to `OR_BOOL_16`) with the variant that has 18 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 18 data inputs (`IN1` to `IN18`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.
- **IN12 (OR input 12):** Boolean input 12.
- **IN13 (OR input 13):** Boolean input 13.
- **IN14 (OR input 14):** Boolean input 14.
- **IN15 (OR input 15):** Boolean input 15.
- **IN16 (OR input 16):** Boolean input 16.
- **IN17 (OR input 17):** Boolean input 17.
- **IN18 (OR input 18):** Boolean input 18.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 18 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs `IN1` to `IN18` are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 18 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN18` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 18 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_18`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_18` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_18` is a simple, event-driven block for the OR combination of 18 Boolean signals with a fixed interface.

OR_BOOL_19

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_19` is a generic block for calculating the logical OR operation (classification `standard boolean function`, IEC 61131-3). It combines 19 separate BOOL inputs (`IN1` to `IN19`) and provides the result at the output `OUT`. It extends the standard OR_BOOL family (previously up to `OR_BOOL_16`) with the variant that has 19 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 19 data inputs (`IN1` to `IN19`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.
- **IN12 (OR input 12):** Boolean input 12.
- **IN13 (OR input 13):** Boolean input 13.
- **IN14 (OR input 14):** Boolean input 14.
- **IN15 (OR input 15):** Boolean input 15.
- **IN16 (OR input 16):** Boolean input 16.
- **IN17 (OR input 17):** Boolean input 17.
- **IN18 (OR input 18):** Boolean input 18.

- **IN19 (OR input 19):** Boolean input 19.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 19 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs `IN1` to `IN19` are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 19 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN19` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 19 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_19`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_19` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_19` is a simple, event-driven block for the OR combination of 19 Boolean signals with a fixed interface.

OR_BOOL_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_2` performs a logical OR operation (disjunction) on two Boolean input values. It is a generic function block classified according to the IEC 61131-3 standard for standard Boolean functions. The block waits for an execution request, calculates the result, and signals its availability.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): This event triggers the execution of the function block. Upon its arrival, the values at data inputs `IN1` and `IN2` are read, and the OR operation is performed.

Event Outputs

- **CNF** (Execution Confirmation): This event is generated after the calculation is complete. It indicates that the result has been output to data output `OUT` and is valid.

Data Inputs

- **IN1** (BOOL): First operand for the OR operation.
- **IN2** (BOOL): Second operand for the OR operation.

Data Outputs

- **OUT** (BOOL): Result of the logical OR operation of `IN1` and `IN2`. The output value is `TRUE` if at least one of the two inputs is `TRUE`. Otherwise, it is `FALSE`.

Adapter

This function block has no adapter interfaces.

Operation

The operation is event-driven and follows a simple request-acknowledgment cycle:

1. The arrival of the event `REQ` starts the execution.
2. The current values of the data inputs `IN1` and `IN2` are retrieved.
3. The logical OR operation `OUT := IN1 OR IN2` is calculated.
4. The result is placed at the data output `OUT`.
5. The event `CNF` is generated to indicate the completion of the operation.

The truth table of the operation is:

IN1	IN2	OUT (IN1 OR IN2)
0	0	0
0	1	1
1	0	1
1	1	1

Technical Features

- **Generic Block:** The block is marked as a generic block (`GEN_OR`), which means it can serve as a basis for deriving similar blocks with other data types.
- **Simple Runtime:** The execution time is constant and very short, as it involves a simple logical operation.
- **No Internal State:** The block is stateless (combinatorial). The result depends solely on the current input values at the time of the `REQ` request.

State Overview

The function block has no persistent internal state. Its behavior is purely combinatorial and is fully described by the interface events and data.

Application Scenarios

- **Logical Connections in Control Logic:** Combination of two conditions where an action is to be executed if at least one of the conditions is met (e.g., "Start motor if button is pressed OR remote control signal is received").
- **Error Aggregation:** Summarizing multiple error signals into a single error status. If at least one error is present (`TRUE`), the combined error status is activated.
- **Lever Logic:** Creates a allow when one of several possible sources is active.
- **Basic Building Block in More Complex Logic Circuits:** As part of AND-OR logic gates (SOPs - Sum of Products) to implement switching functions.

⚖️ Comparison with Similar Building Blocks

- **AND_BOOL_2:** Performs a logical AND operation. The result is `TRUE` only if **both** inputs are `TRUE`.

- **XOR_BOOL_2:** Performs an exclusive OR operation (antivalence). The result is `TRUE` if exactly **one** input is `TRUE`.
- **NOT_BOOL:** Performs a logical NOT operation (negation) on a single input.
- **OR_n_BOOL:** A generic OR gate that can combine a variable number of inputs (n), whereas `OR_BOOL_2` has exactly two fixed inputs. See: OR_2

- Exercise_002b3
- Exercise_160
- Exercise_160b
- Exercise_160b2

Conclusion

The `OR_BOOL_2` is a fundamental, reliable, and easy-to-use function block for implementing the basic logical OR function in 4diac IDE applications. Its event-driven, stateless architecture makes it predictable and easily integrated into the data flow of IEC 61499 systems. It is an indispensable component for implementing control logic and conditional evaluation.

OR_BOOL_20

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_20` is a generic block for calculating the logical OR operation (classification `standard boolean function`, IEC 61131-3). It combines 20 separate BOOL inputs (`IN1` to `IN20`) and provides the result at the output `OUT`. It extends the standard OR_BOOL family (previously up to `OR_BOOL_16`) with the variant that has 20 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 20 data inputs (`IN1` to `IN20`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.
- **IN12 (OR input 12):** Boolean input 12.
- **IN13 (OR input 13):** Boolean input 13.
- **IN14 (OR input 14):** Boolean input 14.
- **IN15 (OR input 15):** Boolean input 15.
- **IN16 (OR input 16):** Boolean input 16.
- **IN17 (OR input 17):** Boolean input 17.

- **IN18 (OR input 18):** Boolean input 18.
- **IN19 (OR input 19):** Boolean input 19.
- **IN20 (OR input 20):** Boolean input 20.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 20 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs `IN1` to `IN20` are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 20 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN20` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 20 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_20`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_20` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_20` is a simple, event-driven block for the OR combination of 20 Boolean signals with a fixed interface.

OR_BOOL_21

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_21` is a generic block for calculating the logical OR operation (classification `standard boolean function`, IEC 61131-3). It combines 21 separate BOOL inputs (`IN1` to `IN21`) and provides the result at the output `OUT`. It extends the standard OR_BOOL family (previously up to `OR_BOOL_16`) with the variant that has 21 inputs.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation. The event is associated with all 21 data inputs (`IN1` to `IN21`).

Event Outputs

- **CNF (Execution Confirmation):** Signals completion of the calculation. The event is associated with the data output `OUT`.

Data Inputs

- **IN1 (OR input 1):** Boolean input 1.
- **IN2 (OR input 2):** Boolean input 2.
- **IN3 (OR input 3):** Boolean input 3.
- **IN4 (OR input 4):** Boolean input 4.
- **IN5 (OR input 5):** Boolean input 5.
- **IN6 (OR input 6):** Boolean input 6.
- **IN7 (OR input 7):** Boolean input 7.
- **IN8 (OR input 8):** Boolean input 8.
- **IN9 (OR input 9):** Boolean input 9.
- **IN10 (OR input 10):** Boolean input 10.
- **IN11 (OR input 11):** Boolean input 11.
- **IN12 (OR input 12):** Boolean input 12.
- **IN13 (OR input 13):** Boolean input 13.
- **IN14 (OR input 14):** Boolean input 14.
- **IN15 (OR input 15):** Boolean input 15.

- **IN16 (OR input 16):** Boolean input 16.
- **IN17 (OR input 17):** Boolean input 17.
- **IN18 (OR input 18):** Boolean input 18.
- **IN19 (OR input 19):** Boolean input 19.
- **IN20 (OR input 20):** Boolean input 20.
- **IN21 (OR input 21):** Boolean input 21.

Data Outputs

- **OUT (OR result):** The result of the OR operation of all 21 inputs. The output is TRUE if at least one input is TRUE and FALSE only if all inputs `IN1` to `IN21` are FALSE.

Adapter

This function block has no adapter interfaces.

Operation

Upon each occurrence of the event `REQ`, all 21 inputs are read and the operation `OUT = IN1 OR IN2 OR ... OR IN21` is calculated. The result is then made available at `OUT` and `CNF` is triggered.

Technical Features

- **Generic block:** The type carries the attribute `GenericClassName = 'GEN_OR_BOOL'`; this instance is fixed to 21 inputs.
- **Package:** `iec61131::booleanOperators`.
- **Stateless:** The block is memoryless: `OUT` depends solely on the input values at the time of `REQ`.

Application Scenarios

- **Collective fault:** Combine several fault or warning signals into one common signal.
- **Multiple triggers:** An action is to start as soon as at least one of many conditions or buttons is active.

⚖️ Comparison with Similar Function Blocks

- `AND_BOOL_21`: Performs the AND operation: the result is TRUE only if all inputs are TRUE, while `OR_BOOL_21` needs just one TRUE input.
- `OR_BOOL_16`: Sibling block of the family with 16 inputs.

Conclusion

`OR_BOOL_21` is a simple, event-driven block for the OR combination of 21 Boolean signals with a fixed interface.

OR_BOOL_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_3` is a standardized block according to IEC 61131-3 for performing a logical OR operation. It calculates the logical OR (disjunction) of three Boolean input signals. The block is implemented as a generic function and is executed on every trigger event.

Interface Structure

The function block has one event input, one event output, three data inputs, and one data output. No adapter interfaces are available.

Event Inputs

- **REQ** (Normal Execution Request): This event triggers the calculation of the OR function. Upon receiving `REQ`, the current values at inputs `IN1`, `IN2`, and `IN3` are read, and the result is calculated.

Event Outputs

- **CNF** (Execution Confirmation): This event signals the completion of the calculation. It is output along with the calculated result at output `OUT`.

Data Inputs

- **IN1** (BOOL): First OR input signal.
- **IN2** (BOOL): Second OR input signal.
- **IN3** (BOOL): Third OR input signal.

Data Outputs

- **OUT** (BOOL): Result of the OR operation (`IN1` OR `IN2` OR `IN3`).

Adapters

No adapter interfaces are available.

Functionality

Whenever the event `REQ` occurs, the function block performs a logical OR operation on the three Boolean inputs `IN1`, `IN2`, and `IN3`. The result of this operation is output to data output `OUT`. Immediately after the calculation, the confirmation event `CNF` is triggered to signal the successful completion of the operation.

The logical function can be described by the following truth table:

IN1	IN2	IN3	OUT (IN1 OR IN2 OR IN3)		
0	0	0	0		
0	0	1	1		
0	1	0	1		
0	1	1	1		
1	0	0	1		
1	0	1	1		
1	1	1	1		
0 …	0	1	1	1	1
0	0	1	1	1	1
The output `OUT` is `TRUE` (1) if and only if at least one of the three inputs is `TRUE`.					

Technical Features

- **Generic Block:** The block is implemented as an instance of a generic OR block (`GEN_OR`), enabling consistent integration into libraries.
- **Event-Driven Execution:** Function execution is strictly linked to the occurrence of the `REQ` event, ensuring deterministic control in real-time systems.
- **Standard Compliance:** Conforms to the “standard boolean function” classification according to IEC 61131-3.

State Overview

The function block has no internal state (memory-free, combinatorial). Its output depends solely on the current values of the inputs at the time of the trigger event `REQ`.

Application Scenarios

- **Safety and Monitoring Logic:** Combination of multiple fault sensors (e.g., temperature too high, pressure too low, level critical), where each sensor can trigger an alarm.
- **Control Logic:** Activation of an actuator (e.g., a pump or motor) when at least one of several conditions is met (e.g., manual start command OR automatic setpoint reached OR emergency start active).
- **Chaining of Logic Operations:** As part of more complex logical expressions in conjunction with AND and NOT blocks.

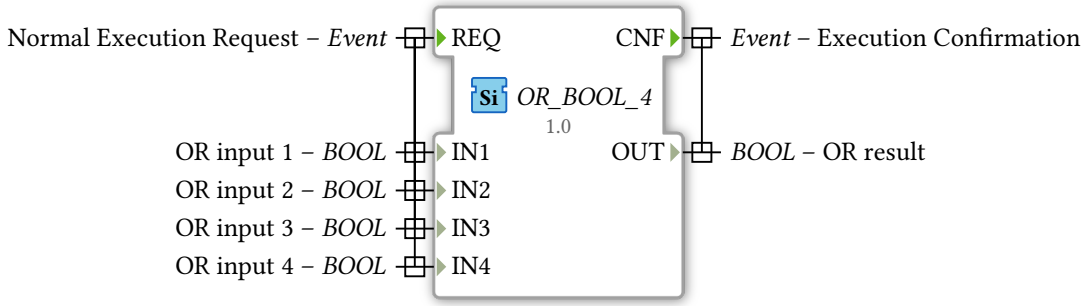
⚖️ Comparison with Similar Blocks

- **OR_BOOL_2:** Combines only two inputs. `OR_BOOL_3` extends this functionality to include a third input. See also: OR_3
- **GEN_OR:** The underlying generic function block, which can be configured for a variable number of inputs. `OR_BOOL_3` is a specific instance of this, fixed to three inputs.
- **AND_n_BOOL:** Performs a logical AND operation. The result is `TRUE` only if **all** inputs are `TRUE`, whereas for the OR operation, **just one** `TRUE` input is sufficient.

🛠️ Related Exercises

- Exercise_002a5b

Conclusion



The `OR_BOOL_3` is a fundamental, reliable, and standards-compliant function block for the logical OR operation of three signals. Its event-driven, stateless operation makes it ideal for use in clearly structured control sequences in automation technology. It represents an essential component for implementing monitoring, safety, and control logic.

OR_BOOL_4

• – ○ • – ○ • – ○ •

Introduction

The function block `OR_BOOL_4` is a standard function block for calculating the logical OR operation. It performs an OR operation with up to four Boolean input values and outputs the result as a single Boolean value. The function block follows the IPO (Event-driven Processing) principle and is designed for use in control applications according to IEC 61131-3.

Interface Structure

Event Inputs

- **REQ**: Starts the execution of the function block. Upon this event, the values at the data inputs `IN1` to `IN4` are read, and the OR operation is calculated.

Event Outputs

- **CNF**: Confirms completion of the operation. This event is triggered after the result is calculated and outputs the value to the data output `OUT`.

Data Inputs

- **IN1**: Boolean OR input 1.
- **IN2**: Boolean OR input 2.

- **IN3**: Boolean OR input 3.
- **IN4**: Boolean OR input 4.

Data Outputs

- **OUT**: Boolean result of the OR operation of all active inputs.

Adapters

This function block does not have any adapter interfaces.

Functionality

When the event `REQ` occurs, the current values at the four Boolean inputs `IN1`, `IN2`, `IN3`, and `IN4` are read. The function block calculates the logical OR of these four values according to the following rule:

The result `OUT` is `TRUE` (1) if at least one of the four inputs is `TRUE`. The result is `FALSE` (0) only if all four inputs are `FALSE`.

The result `FALSE` (0) is `FALSE`. After the calculation, the confirmation event `CNF` is triggered, and the calculated value is carried over to the output `OUT`.

Technical Features

- **Generic Block**: The block is marked as a generic block (`GEN_OR`). This allows it to be used as a basis for creating OR blocks with a different number of inputs.
- **Event-driven**: The operation is only executed upon an incoming `REQ` event, ensuring resource-efficient and deterministic processing in the control system.
- **Standard-compliant**: Conforms to the IEC 61131-3 classification for standard Boolean functions.

State Overview

The function block has no internal state (memory-free). Its behavior is combinatorial and depends solely on the current values at the inputs at the time of the `REQ` event.

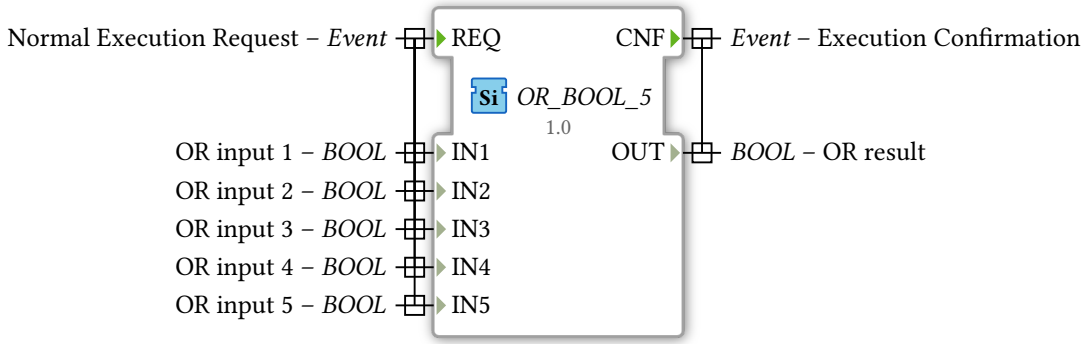
Application Scenarios

- **Linking of Alarm Signals**: Combining multiple status or fault alarms where a single signal should trigger an action (e.g., “Stop machine if sensor A OR sensor B OR emergency stop is activated”).
- **Logic in Safety Controllers**: Implementing OR gates in safety circuits.
- **Simplifying Control Logic**: As a clearly defined building block for structuring programs in function block diagrams (FBDs) or sequenced function charts (SFCs).
-

⚖️ Comparison with similar function blocks

- **`OR_BOOL_2` / `OR_BOOL_8`**: These blocks perform the identical logical OR operation, but with a different number of inputs (2 and 8, respectively). The choice of function block depends on the required number of signals to be combined. See: OR_4
- **`AND_BOOL_4`**: Performs a logical AND operation. The result is only `TRUE` if *all* inputs are `TRUE`.
- **`XOR_BOOL_4`**: Performs an exclusive OR (XOR) operation. The result is `TRUE` if there is an odd number of inputs, and `TRUE` if there is an odd number of inputs.

Conclusion



The `OR_BOOL_4` is a basic, reliable, and standards-compliant function block for implementing four-input OR logic. Its event-driven, stateless operation makes it ideal for integration into larger, event-driven control applications according to IEC 61131-3. Its generic nature also makes it a suitable basis for library extensions.

OR_BOOL_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_5` is a standard function block for calculating the logical OR operation. It performs an OR operation on five separate Boolean input signals. The function block belongs to the category of standard Boolean functions according to IEC 61131-3 and is implemented as a generic function block.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** This event triggers the execution of the function block. Upon receiving `REQ`, the values of all five inputs (IN1 to `IN5`) are read, and the OR operation is calculated.

Event Outputs

- **CNF (Execution Confirmation):** This event signals the completion of the calculation. It is output along with the calculated result `OUT`.

Data Inputs

- **IN1 (BOOL):** OR Input 1.
- **IN2 (BOOL):** OR Input 2.
- **IN3 (BOOL):** OR Input 3.
- **IN4 (BOOL):** OR Input 4.
- **IN5 (BOOL):** OR Input 5.

Data Outputs

- **OUT (BOOL):** The result of the OR operation on all five inputs. The output is `TRUE` if at least one of the inputs `IN1` to `IN5` has the value `TRUE`.

Adapters

This function block does not have any adapter interfaces.

Functionality

The functionality is deterministic and event-driven:

1. The arrival of the event `REQ` starts the execution.
2. The block reads the current values of the five Boolean inputs `IN1` to `IN5`.
3. The logical OR operation `OUT = IN1 OR IN2 OR IN3 OR IN4 OR IN5` is calculated.
4. The result is provided at the data output `OUT`, and simultaneously the confirmation event `CNF` is triggered to signal the successful completion of the operation to subsequent blocks.

Technical Features

- **Generic Block:** The block is marked with the attribute `eclipse4diac::core::GenericClassName` as `'GEN_OR'`. This indicates that it is part of a family of generic OR gates with varying numbers of inputs.
- **Package:** The gate is included in package `iec61131::bitwiseOperators`.
- **Event-driven execution:** Computation only occurs when requested by a `REQ` event, enabling energy-efficient and deterministic execution.

State overview

The function block has no internal state in the sense of a memory. Its behavior is purely combinatorial and depends solely on the current input values at the time of the `REQ` event. The block returns to a passive wait state after the `CNF` event is triggered.

Application Scenarios

Typical applications can be found in control logic, where a condition is considered fulfilled if one of several possible subconditions is met:

- Monitoring: Alarm triggering when at least one of several monitoring sensors exceeds a threshold.
- Enabling logic: Starting a machine when at least one of several safety devices is activated.
- Selection or prioritization logic in interconnected control systems.

⚖️ Comparison with Similar Function Blocks

In contrast to this function block with five fixed inputs, 4diac often also includes:

- **OR_BOOL_2, OR_BOOL_3, etc.:** Same functionality, but with a smaller, fixed number of inputs (e.g., 2, 3, 4). See: OR_5
- **GEN_OR (Generic OR):** A higher-level, configurable function block that can have a variable number of inputs depending on its instantiation. `OR_BOOL_5` is a specific instantiation of this principle.
- **AND_BOOL_5:** Performs a logical AND operation across all five inputs (the result is only `TRUE` if *all* inputs are `TRUE`).

Conclusion

The `OR_BOOL_5` is a simple, robust, and standards-compliant function block for implementing an OR operation with five inputs. Its event-driven architecture integrates seamlessly with 4diac's function block networks and is ideally suited for clear and concise logic connections in automation applications.

]

OR_BOOL_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_6` is a generic block for calculating the logical OR operation. It performs an OR operation on six separate BOOL inputs and outputs the result on a single output. The block complies with the IEC 61131-3 standard and is designed for use in control applications where multiple conditions must be combined to trigger an action.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** This event triggers the calculation of the OR function. It is linked to all six data inputs (`IN1` to `IN6`).

Event Outputs

- **CNF (Execution Confirmation):** This event signals the completion of the calculation. It is output along with the calculated result at data output `OUT`.

Data Inputs

- **IN1 (BOOL):** OR input 1.
- **IN2 (BOOL):** OR input 2.
- **IN3 (BOOL):** OR input 3.
- **IN4 (BOOL):** OR input 4.
- **IN5 (BOOL):** OR input 5.
- **IN6 (BOOL):** OR input 6.

Data Outputs

- **OUT (BOOL):** Result of the OR operation on all six inputs. The output is `TRUE` if at least one of the inputs is `TRUE`.

Adapter

This function block has no adapter interfaces.

Operation

The operation is deterministic and event-driven. Upon each occurrence of the input event `REQ`, the current values of all six BOOL inputs (`IN1` to `IN6`) are read. The logical OR operation of these values is then calculated. The result of this operation is immediately set at the data output `OUT`, and simultaneously, the acknowledgment event `CNF` is triggered to signal the completion of the operation to subsequent blocks.

The logical operation corresponds to the formula: `OUT = IN1 OR IN2 OR IN3 OR IN4 OR IN5 OR IN6`

Technical Features

- **Generic Block:** The block is marked as a generic block (`GEN_OR`). This means it can serve as the basis for creating similar blocks with a different number of inputs.
- **Event-Driven Execution:** The calculation only occurs when requested by an event, enabling efficient and demand-driven processing in the control system.
- **Fixed Number of Inputs:** This specific instance is defined for exactly six inputs.

State Overview

The function block has no internal state or memory. Its behavior is purely combinatorial and depends solely on the current values of the inputs at the time of the `REQ` event. After outputting `CNF`, the block remains in a waiting state until the next `REQ`.

Application Scenarios

Typical applications include monitoring and safety logic where an action should be triggered when one of several possible conditions is met.

- **Emergency Stop Logic:** The block can be used to monitor multiple emergency stop buttons. If any of the buttons is pressed (`TRUE`), a shutdown signal (`OUT = TRUE`) is generated.
- **Alarm Aggregation:** Multiple sensors, each capable of detecting a fault condition, are interconnected. A general alarm is triggered as soon as at least one sensor reports a fault.
- **Multiple Operator Control:** In a machine, multiple operator stations can start a process. The block combines all start commands into a single start signal.
-

⚖️ Comparison with similar function blocks

- **AND_BOOL_6:** Performs a logical AND operation. The result is only `TRUE` if **all** inputs are `TRUE`. In contrast, `OR_BOOL_6` requires only **one** true input.
- **XOR_BOOL:** Performs an exclusive OR (XOR) operation. The result is `TRUE` if there is an odd number of inputs, `TRUE`. `OR_BOOL_6` does not distinguish between one or more true conditions. See: OR_6
- **Blocks with Variable Number of Inputs:** OR blocks with two (`OR`) or other numbers of inputs exist. `OR_BOOL_6` offers a fixed interface with six inputs, optimized for specific applications.

Conclusion

The `OR_BOOL_6` function block is a simple, robust, and standards-compliant building block for logical signal combination. Its strength lies in its clear, event-driven interface and the fixed number of six inputs, making it ideal for applications that require precisely this number of conditions to be combined. As a generic building block, it also supports reuse and customization within the 4diac IDE.

OR_BOOL_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_7` is a standard function block for calculating the logical OR operation. It performs an OR operation on seven separate Boolean inputs and provides the result at a single output. This function block is part of the IEC 61131-3 compliant library for bitwise operations.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): This event triggers the calculation of the OR function. It is associated with all seven data inputs (`IN1` to `IN7`).

Event Outputs

- **CNF** (Execution Confirmation): This event signals the completion of the calculation. It is output along with the calculated result at data output `OUT`.

Data Inputs

- **IN1** (BOOL): OR input 1.
- **IN2** (BOOL): OR input 2.
- **IN3** (BOOL): OR input 3.
- **IN4** (BOOL): OR input 4.
- **IN5** (BOOL): OR input 5.
- **IN6** (BOOL): OR input 6.
- **IN7** (BOOL): OR input 7.

Data Outputs

- **OUT** (BOOL): Result of the OR operation of all seven inputs.

Adapters

This function block does not have any adapter interfaces.

Functionality

Upon receiving the event `REQ`, the function block reads the values of all seven Boolean inputs (`IN1` to `IN7`). A logical OR operation is then applied to these values. The result of this operation is set at the data output `OUT`, and simultaneously, the confirmation event `CNF` is triggered.

The logical function can be described as follows:
OUT = IN1 OR IN2 OR IN3 OR IN4 OR IN5 OR IN6 OR IN7`

This means that the output OUT is TRUE (1) if at least one of the seven inputs is TRUE. The output is FALSE (0) only if all seven inputs are FALSE.

Technical Features

- **Generic Block:** The function block is marked as a generic implementation (GEN_OR), indicating that the core can be reused for similar blocks.
- **Hard-wired Logic:** The OR operation is hard-coded for exactly seven inputs. For a different number of inputs, a corresponding block (e.g., OR_BOOL_2, OR_BOOL_4) must be used.
- **Event-driven Execution:** The calculation is performed only when the input event REQ occurs, enabling resource-efficient and deterministic processing in the real-time system.

State Overview

The function block has no internal state or memory. Its behavior is purely combinatorial and event-driven:

1. **Idle State:** Waits for the event REQ.
2. **Calculation State:** Upon REQ, the inputs are read and the OR operation is performed.
3. **Output State:** The result is output to OUT, and the event CNF is generated. The block then returns to the idle state.

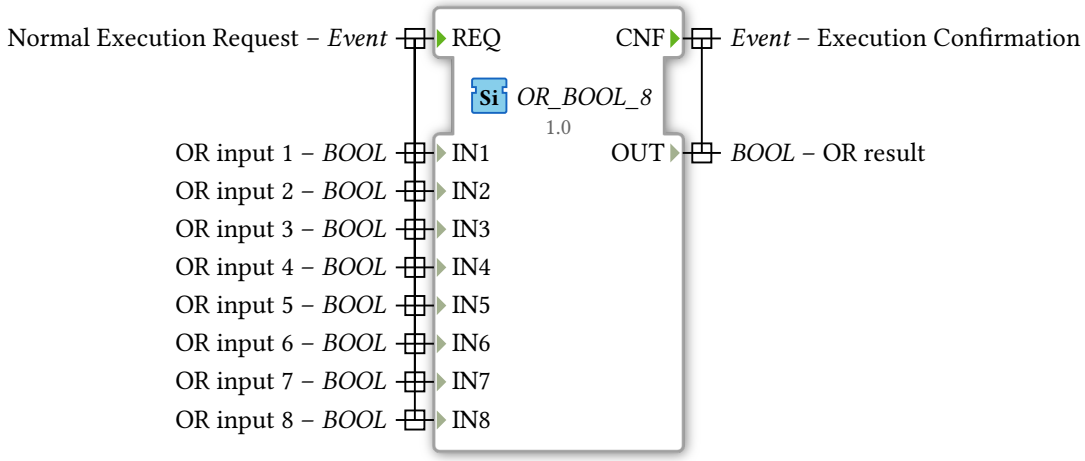
Application Scenarios

- **Monitoring Logic:** Combines multiple error or warning signals into a common alarm output. If one of seven possible sources of interference is activated, a common warning light illuminates.
- **Leverage Logic:** Combines multiple enable signals (e.g., from different safety systems) for a process step. The process starts when at least one condition is met.
- **Sensor Linking:** Evaluates multiple limit detectors to check if at least one sensor has exceeded a threshold.

⚖️ Comparison with Similar Function Blocks

- **AND_BOOL_7:** Performs a logical AND operation. The output is only TRUE if *all* inputs are TRUE.
- **XOR_BOOL_7:** Performs an exclusive OR (XOR) operation. The output is TRUE if an odd number of inputs are TRUE.
- **OR_n_BOOL (n=2,4,...):** Function blocks of the same family that provide the OR function for a different, fixed number of inputs. The choice of block depends on the required number of signals. See: OR_7
- **Generic FB (GEN_OR):** The underlying generic implementation used to create the specific OR_n_BOOL variants.

Conclusion



The OR_BOOL_7 is a simple, robust, and standardized function block for the logical OR operation of seven Boolean signals. Its event-driven architecture makes it ideal for integration into control engineering applications according to IEC 61131-3, where it operates reliably and deterministically. It is the right choice when exactly seven binary states need to be combined to produce a common result.

OR_BOOL_8

• – ◦ • – ◦ • – ◦ •

Introduction

The function block OR_BOOL_8 is a standardized block for calculating the logical OR operation. It performs the OR operation on eight separate Boolean input values and outputs the result on a single Boolean output. This block is part of the IEC 61131-3 compliant library for bitwise operations and is used for simple and structured logic processing in control applications.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): This event triggers the execution of the function block. Upon its arrival, all eight data inputs (`IN1` to `IN8`) are read and the OR operation is calculated.

Event Outputs

- **CNF** (Execution Confirmation): This event signals the completion of the calculation. It is output along with the calculated result at data output `OUT`.

Data Inputs

- **IN1** (BOOL): OR input 1.
- **IN2** (BOOL): OR input 2.
- **IN3** (BOOL): OR input 3.
- **IN4** (BOOL): OR input 4.
- **IN5** (BOOL): OR input 5.
- **IN6** (BOOL): OR input 6.
- **IN7** (BOOL): OR input 7.
- **IN8** (BOOL): OR input 8.

Data Outputs

- **OUT** (BOOL): Result of the OR operation of all eight inputs. The output is `TRUE` (1) if at least one of the inputs `IN1` to `IN8` has the value `TRUE`. Otherwise, the output is `FALSE` (0).

Adapter

This function block does not use any adapter interfaces.

Operation

The operation is event-driven and follows a simple request-confirm cycle:

1. The arrival of the event `REQ` starts execution.
2. The block reads the current values of all eight Boolean inputs (`IN1` to `IN8`).
3. The logical OR operation is calculated across all eight inputs: `OUT = IN1 OR IN2 OR IN3 OR IN4 OR IN5 OR IN6 OR IN7 OR IN8`.
4. The result is output at `OUT`, and simultaneously, the confirmation event `CNF` is triggered to signal the successful completion of the operation.

Technical Features

- **Generic Block:** This block is marked as a generic block (`GEN_OR`), meaning it can serve as a basis for creating similar OR blocks with a different number of inputs.
- **Standard Compliant:** It is classified according to the IEC 61131-3 standard and implements a standardized Boolean function.

- **Deterministic Behavior:** Execution is deterministic and does not result in any internal state storage between calls.

State Overview

The function block `OR_BOOL_8` is stateless (combinatorial logic). It has no internal memory. The output `OUT` is, at any given time, solely a direct function of the current input values read in by the last `REQ` event.

Application Scenarios

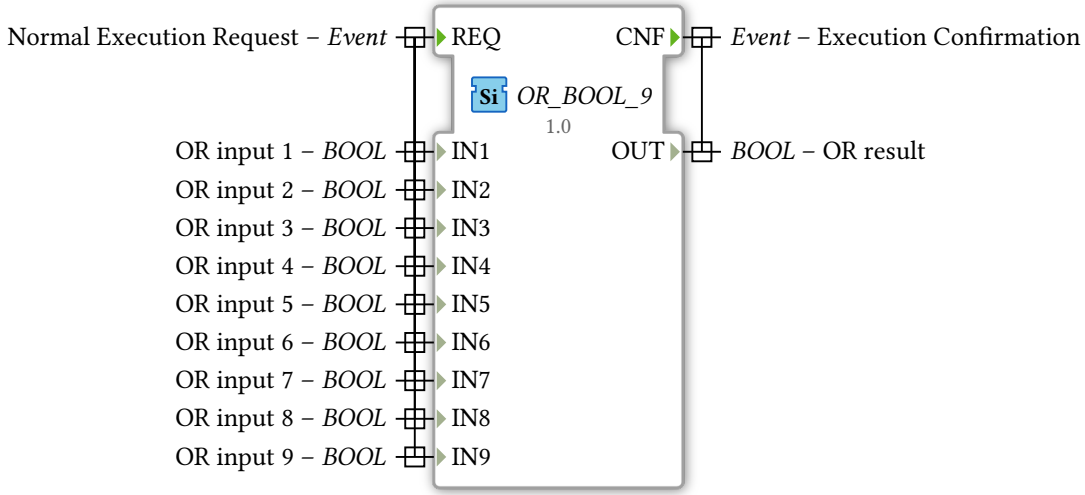
Typical applications include:

- **Monitoring Logic:** Combining multiple error or warning signals (e.g., from different sensors or subsystems) into a single alarm output.
- **Enable Logic:** Checking whether at least one of several possible enable conditions (e.g., "Manually enabled" OR "Automatically enabled") is met.
- **Linking Button Inputs:** In control panels to trigger an action when one of several buttons is pressed.

⚖️ Comparison with similar function blocks

- **`OR_BOOL_2`, `OR_BOOL_4`:** These are structurally identical function blocks, but they only connect two or four inputs, respectively. `OR_BOOL_8` offers a higher number of inputs without having to cascade multiple instances of blocks with fewer inputs. See: OR_8
- **`AND_n_BOOL`:** Performs the logical AND operation. The result is only `TRUE` if *all* inputs are `TRUE`, whereas for the OR operation, a single `TRUE` input is sufficient.
- **`XOR_n_BOOL`:** Performs an exclusive OR (XOR) operation. The result is `TRUE` if there is an odd number of inputs; it is `TRUE`, which differs from inclusive OR logic.

Conclusion



The `OR_BOOL_8` function block is a fundamental, reliable, and easy-to-use building block for Boolean logic processing. Its strength lies in its clear, standards-compliant interface and efficient processing of up to eight signals into a single statement. It is the first choice for applications requiring an inclusive OR operation across multiple signals.

OR_BOOL_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `OR_BOOL_9` is a standardized building block according to IEC 61131-3 for calculating the logical OR operation. It performs the OR operation via nine separate Boolean inputs. The block follows the event-driven execution model of the 4diac IDE: The calculation is triggered by an incoming event, and the result is output along with an acknowledgment event.

Interface Structure

Event Inputs

- **REQ**: Triggers the execution of the function block. Upon arrival of this event, all nine input values (`IN1` to `IN9`) are read, and the OR operation is calculated.

Event Outputs

- **CNF**: This event is generated after the calculation is complete. It signals that the result is valid and available at the data output `OUT`.

Data Inputs

- **IN1** (BOOL): OR input 1.
- **IN2** (BOOL): OR input 2.
- **IN3** (BOOL): OR input 3.
- **IN4** (BOOL): OR input 4.
- **IN5** (BOOL): OR input 5.
- **IN6** (BOOL): OR input 6.
- **IN7** (BOOL): OR input 7.
- **IN8** (BOOL): OR input 8.
- **IN9** (BOOL): OR input 9.

Data Outputs

- **OUT** (BOOL): Result of the logical OR operation of all nine inputs. The output is `TRUE` (1) if at least one of the inputs is `TRUE`. It is only `FALSE` (0) if all nine inputs are `FALSE`.

Adapter

This function block has no adapter interfaces.

Operation

The `OR_BOOL_9` block operates according to the following algorithm:

1. **Trigger**: The incoming event `REQ` activates the block.
2. **Input Collection**: The current values of all nine Boolean inputs (`IN1` to `IN9`) are read.
3. **Calculation**: The logical OR function is applied to the input values. The operation can be described as `OUT = IN1 OR IN2 OR IN3 OR IN4 OR IN5 OR IN6 OR IN7 OR IN8 OR IN9`.
4. **Output**: The calculated result is set to the data output `OUT`.
5. **Acknowledgement**: Immediately after the output is set, the acknowledgement event `CNF` is generated to inform downstream blocks about the availability of the new result.

Technical Features

- **Generic Function Block**: The block is implemented as a generic function block (attribute `eclipse4diac::core::GenericClassName` is set to `'GEN_OR'`). This means it can serve as the basis for deriving similar OR blocks with a different number of inputs.
- **Standard Compliance**: It is explicitly classified as a standardized Boolean function according to IEC 61131-3.
- **Deterministic Behavior**: The execution time is constant and predictable, as it is a simple logical operation.

State Overview

The block has no internal state or memory. Its behavior is purely combinatorial and depends solely on the current input values at the time of the `REQ` event. Previous calculations have no influence on the current result.

Application Scenarios

- **Monitoring Logic**: Combination of multiple error or status messages (e.g., from nine sensors), where even a single message (`TRUE`) triggers a collective alarm message (`OUT = TRUE`).
- **Enable Logic**: In safety circuits, where one of several possible enable conditions is sufficient to start a process step.
- **Simplification of Logic Networks**: Replaces multiple cascaded two-input OR gates, improving clarity in a function block diagram (FBD).

•

⚖️ Comparison with similar building blocks

- **`OR_BOOL_2`, `OR_BOOL_4` etc.**: These blocks offer the same OR functionality, but for a smaller number of inputs (2, 4, ...). `OR_BOOL_9` is optimized for applications with nine signals to be combined. See: OR_9
- **`AND_BOOL_9`**: Performs the logical AND operation. The result is only `TRUE` if *all* inputs are `TRUE`, unlike OR, where *at least one* input must be `TRUE`.
- **`XOR_BOOL_9`**: Calculates the exclusive OR (antivalence). The result is `TRUE` if there is an odd number of inputs, resulting in `TRUE`.

Conclusion

The `OR_BOOL_9` is a robust and easy-to-use standard block for the logical OR operation of nine Boolean signals. Its event-driven, stateless architecture makes it a reliable and efficient component for control and monitoring logic in 4diac-based automation systems. Using this specialized block instead of a cascade of basic gates improves the readability and maintainability of the application code.

XOR_BOOL_10

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_BOOL_10` is a generic function block for calculating the logical exclusive OR (XOR) operation on up to ten Boolean input signals. It complies with the IEC 61131-3 standard and is designed for use in the 4diac IDE. The function block evaluates all connected inputs for each request and returns the corresponding result.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** This event triggers the calculation of the XOR function. It is linked to all ten data inputs (`IN1` to `IN10`).

Event Outputs

- **CNF (Execution Confirmation):** This event signals the completion of the calculation. It is output along with the calculated result at the data output `OUT`.

Data Inputs

- **IN1 (XOR input 1):** Boolean input 1.

- **IN2 (XOR input 2):** Boolean input 2.
- **IN3 (XOR input 3):** Boolean input 3.
- **IN4 (XOR input 4):** Boolean input 4.
- **IN5 (XOR input 5):** Boolean input 5.
- **IN6 (XOR input 6):** Boolean input 6.
- **IN7 (XOR input 7):** Boolean input 7.
- **IN8 (XOR input 8):** Boolean input 8.
- **IN9 (XOR input 9):** Boolean input 9.
- **IN10 (XOR input 10):** Boolean input 10.

Data Outputs

- **OUT (XOR result):** Boolean result of the XOR operation of all active inputs Inputs.

Adapter

This function block has no adapter interfaces.

Functionality

Upon receiving the `REQ` event, the block reads the values of all ten Boolean data inputs (`IN1`...`IN10`). It then performs the logical XOR operation on all these inputs. The XOR function outputs a `TRUE` signal (1) at the output `OUT` if and only if there is an odd number of inputs (`TRUE`). If there are zero, two, four, six, eight, or ten inputs (`TRUE`), the result is `FALSE`. After the calculation, the `CNF` event is triggered along with the current result value.

Technical Features

- **Generic Block:** The block is marked as a generic block (`GEN_XOR`). This allows for flexible reuse and potential specialization.
- **Fixed Number of Inputs:** Unlike blocks with a variable number of inputs, this block offers exactly ten fixed inputs. Unused inputs should be set to a defined logic level (e.g., `FALSE`).
- **Event-Driven Execution:** The calculation is performed exclusively event-driven by the `REQ` input. There is no cyclic execution.

State Overview

The function block does not have an internal state in the sense of a memory. Its behavior is purely combinatorial and depends on the current input values. The only "state" is waiting for a `REQ` event. Upon receiving this event, the system immediately calculates and sends the `CNF` event.

Application Scenarios

- **Parity Check:** Detects whether an odd number of signals (e.g., error messages, switch positions) are active.
- **Control Logic:** Implements special logic logic in sequence controls where a state change should only occur with an odd activation pattern.
- **Encoding/Decoding:** Simple cryptographic or coding tasks based on the XOR operation.
-

⚖️ Comparison with Similar Blocks

- **Standard XOR Blocks (e.g., 2-Input XOR):** This block extends the classic 2-input XOR function to up to ten inputs in a single block, improving clarity when dealing with many signals. See: XOR_10
- **Blocks with Variable Input Count:** Some libraries offer XOR blocks to which inputs can be dynamically added. `XOR_BOOL_10` has a fixed, explicitly declared interface, which can simplify code analysis.
- **Combinatorial Logic in SFC/ST:** The same functionality could also be implemented in Structured Text (ST) using an expression like `OUT := IN1 XOR IN2 XOR ... XOR IN10;`. The advantage of the FB lies in its clear encapsulation and event-driven interface, which integrates better into FB networks.

Conclusion

The `XOR_BOOL_10` is a specialized and useful function block for applications requiring XOR operations across more than two signals. Its robust, well-documented ten-input interface and event-driven IEC 61499 model make it a reliable building block for implementing parity checks and specialized control logic. However, for simpler operations with fewer inputs or for maximum flexibility, alternative implementations should be considered.

XOR_BOOL_2

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_BOOL_2` is a standard function block for calculating the logical exclusive OR (XOR) operation of two Boolean input signals. It belongs to the category of bitwise operators and is implemented as a generic function block used in control applications according to IEC 61131-3. The block waits for an execution request, calculates the result, and returns it along with an acknowledgment.

Interface Structure

Event Inputs

- **REQ**: Normal execution request. Triggers the calculation of the XOR operation. The data associated with this event (`IN1`, `IN2`) are read during processing.

Event Outputs

- **CNF**: Execution Confirmation. This event is generated after the calculation and signals the availability of the result. It is associated with the data output `OUT`.

Data Inputs

- **IN1**: Boolean input 1 for the XOR operation.
- **IN2**: Boolean input 2 for the XOR operation.

Data Outputs

- **OUT**: Boolean result of the XOR operation of `IN1` and `IN2`.

Adapters

This function block does not have any adapter interfaces.

Functionality

The `XOR_BOOL_2` block operates in an event-driven manner. Upon the arrival of the event `REQ`, the current values at the data inputs `IN1` and `IN2` are read. The logical XOR operation (`OUT = (IN1 AND NOT IN2) OR (NOT IN1 AND IN2)`) is then performed. The calculated result is output at the data output `OUT`, and simultaneously, the confirmation event `CNF` is activated to signal the completion of the operation to subsequent blocks.

The truth table of the operation is:

IN1	IN2	OUT
0	0	0
0	1	1
1	0	1

1	1	0

Technical Features

- **Generic Block**: The block is identified with the generic class name `'GEN_XOR'`, which facilitates its reusability and potential integration into higher-level structures.
- **Event-Driven Execution**: The functionality is strictly linked to the input events, enabling deterministic and energy-efficient processing in real-time systems.
- **Simple Interface**: The block has a minimal and intuitive interface that corresponds to the classic XOR function commonly used in digital technology.

State Overview

The function block does not have an internal state in the sense of a memory. Its behavior is combinatorial and depends solely on the current input values when the `REQ` event occurs. After outputting `CNF`, the block remains in a waiting state until the next `REQ` event arrives.

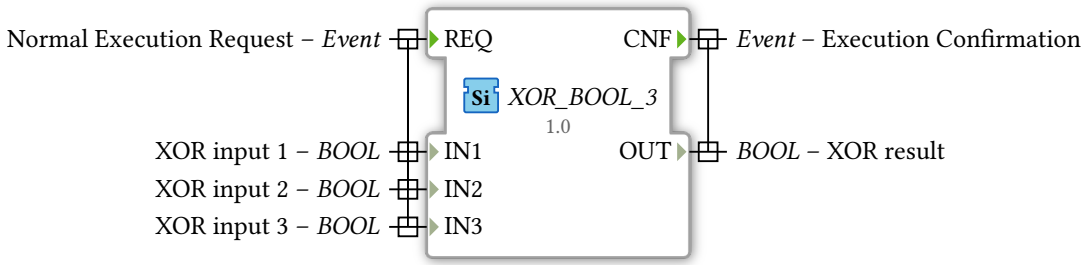
Application Scenarios

- **Comparison and Change Detection**: Detects when exactly one of two states (e.g., two limit switches) has changed.
- **Parity Check**: Simple check for an odd number of `TRUE` signals with two inputs.
- **Control Logic**: Implementation of special branches in sequential control systems where a decision must be made when the inputs are different.
- **Safety-Critical Circuits**: Generates signals that are only active when two monitored variables contradict each other (e.g., in emergency stop circuits).
-

⚖️ Comparison with similar building blocks

Compared to other basic logic function blocks like `AND_BOOL_2` or `OR_BOOL_2`, `XOR_BOOL_2` is the only one that returns a `TRUE` result when the inputs are *different*. Blocks like `NOT` only invert a single input. `XOR_BOOL_2` can be considered a special case of an inequality comparison (`NE_BOOL`) for two Boolean values. See: XOR_2

Conclusion



The `XOR_BOOL_2` is a fundamental, reliable, and easy-to-use building block for logical operation in IEC 61131-3-based control applications. Its event-driven, stateless architecture makes it particularly suitable for integration into complex, deterministic control networks. Its clear functionality and minimal interface make it an indispensable tool for every control system developer.

XOR_BOOL_3

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_BOOL_3` is a standardized function block for calculating the logical exclusive OR (XOR) operation for three Boolean input values. It is implemented as a generic function block and performs its operation on every incoming execution event.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): Triggers the calculation of the XOR function. The data associated with this event (`IN1`, `IN2`, `IN3`) are read and processed.

Event Outputs

- **CNF** (Execution Confirmation): Triggered after the calculation is complete. This event returns the calculated result via the corresponding data output `OUT`.

Data Inputs

- **IN1** (BOOL): First Boolean operand for the XOR operation.
- **IN2** (BOOL): Second Boolean operand for the XOR operation.
- **IN3** (BOOL): Third Boolean operand for the XOR operation.

Data Outputs

- **OUT** (BOOL): The result of the triple XOR operation of the inputs `IN1`, `IN2`, and `IN3`.

Adapter

This function block has no adapter interfaces.

Operation

The block operates in an event-driven manner. Upon each occurrence of the event `REQ`, the current values of the three Boolean inputs `IN1`, `IN2`, and `IN3` are read. The logical XOR operation is then calculated for all three inputs. The result is output at the data output `OUT`, and simultaneously, the confirmation event `CNF` is triggered to signal the completion of the operation.

The corresponding logical function is: `OUT = (IN1 XOR IN2) XOR IN3`. For three inputs, the result is `TRUE` (1) if and only if there is an odd number of inputs (`TRUE`) (i.e., 1 or 3 inputs).

Technical Features

- **Generic Block:** The block is marked as a generic block (`'GEN_XOR'`) with the attribute `eclipse4diac::core::GenericClassName`. This allows for potential reuse of the logic for other data types that support the XOR operation.
- **Standard Compliance:** The block is classified as a "standard boolean function" according to the IEC 61131-3 standard.
- **Package Assignment:** The block is assigned to the package `iec61131::bitwiseOperators`.

State Overview

The function block does not have an internal state in the sense of a memory. Its behavior is purely combinatorial and depends solely on the current input values when the `REQ` event arrives. The only "state" is the idle state, in which the block waits for the next `REQ` event.

Application Scenarios

- **Parity Check:** Detects whether an odd number of three Boolean signals are active.
- **Control Logic:** In specialized control algorithms that require "either-or" logic with more than two conditions.
- **Encryption and Coding:** As a fundamental component in simple cryptographic or error-detecting circuits (e.g., for parity bits).
- **Signal Comparison:** Determines whether a third signal differs from the combination of two other signals.
-

⚖️ Comparison with Similar Blocks

- **XOR (2 Inputs):** The standard XOR block with only two inputs. `XOR_BOOL_3` extends this function to three operands. See: XOR_3
- **OR / AND (3 Inputs):** These blocks calculate the logical OR or AND operation of all inputs. The XOR logic is more specialized and differs, in particular, when all three inputs are `TRUE` (OR=TRUE, AND=TRUE, XOR=TRUE).

- **GEN_XOR:** This is the generic basis from which `XOR_BOOL_3` is derived as a specific instance for the data type `BOOL`.
-

Conclusion

The `XOR_BOOL_3` function block is a specialized, standards-compliant building block for reliably calculating triple exclusive OR operations. Its clear, event-driven interface and deterministic functionality make it ideal for use in control applications that require this specific Boolean logic. As an instance of a generic building block, it also benefits from the maintenance and consistency advantages of a generic design.

XOR_BOOL_4

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_BOOL_4` is a standard block for calculating the logical exclusive OR (XOR) operation for up to four Boolean input values. It complies with the IEC 61131-3 standard and is implemented as a generic block used in control applications for combinational logic processing.

Interface Structure

Event Inputs

- **REQ** (Normal Execution Request): This event triggers the calculation of the XOR operation. It is linked to all four data inputs (`IN1` to `IN4`).

Event Outputs

- **CNF** (Execution Confirmation): This event signals the completion of the calculation. It is output along with the calculated result at data output `OUT`.

Data Inputs

- **IN1** (BOOL): XOR input 1.
- **IN2** (BOOL): XOR input 2.
- **IN3** (BOOL): XOR input 3.
- **IN4** (BOOL): XOR input 4.

Data Outputs

- **OUT** (BOOL): Result of the XOR operation of all active inputs.

Adapters

This function block does not have any adapter interfaces.

Functionality

When the event `REQ` occurs, the function block reads the values of all four Boolean inputs (`IN1`, `IN2`, `IN3`, `IN4`). It then calculates the logical exclusive OR over these values. The result `OUT` is `TRUE` (1) if and only

if an odd number of the inputs have the value `TRUE`. If the number of `TRUE` inputs is even (0, 2, or 4), the result is `FALSE` (0). After the calculation, the confirmation event `CNF` is output along with the result value.

Technical Features

- **Generic Block:** The block is marked with the attribute `eclipse4diac::core::GenericClassName` as `'GEN_XOR'`. This allows for flexible instantiation and reuse within the 4diac IDE.
- **Event-Driven Execution:** The functionality is strictly event-driven. A calculation only takes place upon an incoming `REQ` event.
- **Four Inputs:** Unlike a simple 2-input XOR, this block offers direct processing of up to four signals without additional nesting.

State Overview

The function block has no internal state (memory-free, combinatorial). Its behavior depends solely on the current values at the data inputs during each call.

Application Scenarios

- **Parity Check:** Detects whether an odd number of conditions (e.g., error messages, limit exceedances) are active in a group of four signals.
- **Control Logic:** Implements safety circuits where exactly one of several possible input combinations is allowed to trigger an action.
- **Nested Logic Simplification:** Replaces multiple cascaded 2-input XOR blocks with a single `XOR_BOOL_4` block for improved clarity in the function block diagram (FBD).

⚖️ **Comparison with Similar Blocks**

- **Standard XOR (2 Inputs):** A classic XOR block with only two inputs. The `XOR_BOOL_4` consolidates the functionality of several such blocks. See: XOR_4
- **OR_BOOL_4 / AND_BOOL_4:** These blocks calculate the logical OR or AND operation across four inputs. The XOR operation differs fundamentally, as it evaluates the case where all inputs are `TRUE` as `FALSE`.
- **Parity Check Blocks:** Specialized blocks for parity calculation often exist for data words (BYTE, WORD). `XOR_BOOL_4` provides this function for individual bits/Bool values.

Conclusion

The `XOR_BOOL_4` is a useful and efficient standard block for implementing exclusive OR logic with up to four inputs in 4diac-based control applications. Its event-driven, stateless architecture and direct support for multiple inputs make it a practical choice for parity checks and specialized combinatorial control tasks.

]

XOR_BOOL_5

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_BOOL_5` is a standard function block for calculating the logical exclusive OR (XOR) operation for five Boolean input values. It complies with the IEC 61131-3 standard and is implemented as a generic function block. The operation is performed on each incoming execution event, and the result is output via an acknowledgment event.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** Triggers the calculation of the XOR operation. This event is associated with all five data inputs (`IN1` to `IN5`).

Event Outputs

- **CNF (Execution Confirmation):** Signals the completion of the calculation. This event is linked to the data output `OUT` and returns the result.

Data Inputs

- **IN1 (XOR input 1):** First Boolean operand (BOOL).
- **IN2 (XOR input 2):** Second Boolean operand (BOOL).
- **IN3 (XOR input 3):** Third Boolean operand (BOOL).
- **IN4 (XOR input 4):** Fourth Boolean operand (BOOL).
- **IN5 (XOR input 5):** Fifth Boolean operand (BOOL).

Data Outputs

- **OUT (XOR result):** The Boolean result of the XOR operation of all five inputs (BOOL).

Adapter

This function block has no adapter interfaces.

Functionality

Whenever the event `REQ` occurs, the function block performs the logical XOR operation on its five Boolean inputs `IN1` to `IN5`. The result is output `OUT`, and the acknowledgment event `CNF` is triggered simultaneously.

The logical function is defined as: `OUT = IN1 XOR IN2 XOR IN3 XOR IN4 XOR IN5`.

The result is `TRUE` (1) if and only if an odd number of the inputs have the value `TRUE` (1). With an even number of `TRUE` inputs, the result is `FALSE` (0).

Technical Features

- **Generic Block:** The block is marked as a generic implementation (`'GEN_XOR'`) by the attribute `eclipse4diac::core::GenericClassName`. This allows for flexible reuse of the core logic.
- **Event-driven:** The calculation is performed exclusively event-driven by `REQ` and is non-cyclic.
- **Five Inputs:** Unlike standard XOR blocks with typically two inputs, this block offers five hard-wired inputs, eliminating the need to chain multiple blocks for a higher number of operands.

State Overview

The block has no internal state (memory-free). Its output depends solely on the current values of the inputs at the time of the `REQ` event.

Application Scenarios

- **Parity Check:** Checks whether an odd number of conditions (e.g., error signals, limit exceedances) are active in a group of five signals.
- **Control Logic:** Implements special logic logic in PLC programs where exactly one, three, or five of five possible individual conditions must be met.

- **Signal Comparison:** Detects inequality in a group of five binary signals.

⚖️ Comparison with Similar Blocks

- **Standard XOR (2 Inputs):** Library blocks often only offer the XOR operation for two operands. For five operands, several of these blocks would have to be chained together (e.g., `((IN1 XOR IN2) XOR (IN3 XOR IN4)) XOR IN5`). `XOR_BOOL_5` summarizes this logic in a single, concise block. See: XOR_5
- **OR / AND Blocks:** While OR (`OR`) returns `TRUE` with at least one `TRUE` input, and AND (`AND`) only with all `TRUE` inputs, XOR specifically responds to an odd number of `TRUE` values.
- **Generic XOR Blocks:** Generic blocks could exist that handle a variable number of inputs via arrays or repeated inputs. `XOR_BOOL_5` is a fixed, specific instance for exactly five inputs.

Conclusion

The `XOR_BOOL_5` function block is a specialized and efficient building block for calculating the exclusive OR operation across exactly five Boolean signals. Its event-driven, stateless operation and clear interface make it a reliable tool for control applications that require this specific logic function, especially in the areas of parity checking and complex conditional logic.

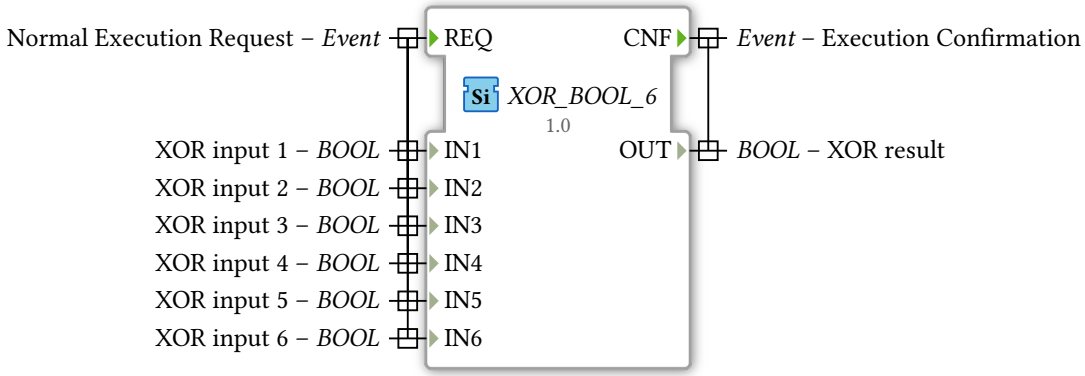
- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de



]

XOR_BOOL_6

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_BOOL_6` is a generic block for calculating the logical exclusive OR (XOR) operation for up to six Boolean input values. It complies with the IEC 61131-3 standard and is designed for use in control and automation applications. The block waits for a trigger event, calculates the result of the XOR operation across all active inputs, and outputs it along with an acknowledgment event.

Interface Structure

The function block has an event-driven input/output mechanism with six Boolean data inputs and one Boolean data output.

Event Inputs

REQ (Normal Execution Request): This event triggers the calculation. Upon arrival of `REQ`, the values at inputs `IN1` to `IN6` are read, and the XOR operation is performed.

Event Outputs

- **CNF** (Execution Confirmation): This event is triggered after the calculation is complete and signals that the result is available at output `OUT`.

Data Inputs

- **IN1** (BOOL): XOR input 1.

- **IN2** (BOOL): XOR input 2.
- **IN3** (BOOL): XOR input 3.
- **IN4** (BOOL): XOR input 4.
- **IN5** (BOOL): XOR input 5.
- **IN6** (BOOL): XOR input 6.

Data Outputs

- **OUT** (BOOL): The result of the XOR operation of all six inputs.

Adapters

This function block does not have any adapter interfaces.

Functionality

When triggered by the `REQ` event, the function block calculates the logical XOR value across all six inputs `IN1` to `IN6`. The XOR operation yields `TRUE` (1) if and only if an odd number of inputs have the value `TRUE`. If there are zero, two, four, or six inputs `TRUE`, the result is `FALSE` (0). Formally, this corresponds to the calculation: `OUT = IN1 XOR IN2 XOR IN3 XOR IN4 XOR IN5 XOR IN6`. After the calculation, the result is output at data output `OUT`, and the confirmation event `CNF` is simultaneously activated.

Technical Features

- **Generic Block:** The function block is marked as a generic block (`GEN_XOR`). This allows it to be reused in different contexts or used as a basis for specialized versions.
- **Fixed Number of Inputs:** Unlike blocks with a variable number of inputs, `XOR_BOOL_6` has exactly six fixed inputs. Unused inputs should be set to a defined logic level (e.g., `FALSE`).
- **Package Assignment:** The block is assigned to the package `iec61131::bitwiseOperators`, which underlines its classification as a bitwise/logical operation.
- **Fixed Number of Inputs:**

State Overview

The function block is stateless (combinatory). It has no internal memory. The output `OUT` is a pure function of the current input values at the time of the `REQ` event. There is no dependency on previous calculations or states.

Application Scenarios

- **Parity Check:** Detects whether an odd number of conditions are active in a group of six signals.
- **Safety-Critical Logic:** In circuits where a state may only be active if exclusive conditions are met (e.g., selection between different, mutually exclusive operating modes).
- **Status Bit Combination:** Combines multiple status or error flags into a single "odd parity" signal.

⚖️ Comparison with Similar Blocks

- **`XOR` (2 inputs):** The standard XOR block with only two inputs. `XOR_BOOL_6` extends this functionality to six inputs without the need to connect multiple 2-input XOR blocks. See: XOR_6
- **`AND_BOOL_6` / `OR_BOOL_6`:** Similar blocks for the logical AND and OR operations with six inputs. While these blocks test for "All" or "At least one," `XOR_BOOL_6` tests for "Odd number."
- **Blocks with Variable Number of Inputs:** Some implementations may offer a `XOR` block to which any number of inputs can be assigned. In contrast, `XOR_BOOL_6` offers an explicit and fixed interface.

Conclusion

The `XOR_BOOL_6` is a specialized and easy-to-use function block for exclusive OR operation on up to six Boolean signals. Its fixed interface and event-driven execution make it easily integrated into 4diac IDE-based applications. It is particularly useful in scenarios requiring parity checking or the evaluation of exclusive conditions across a small, fixed number of signals. For applications with a variable or significantly larger number of inputs, alternative solutions should be considered.

The `XOR_BOOL_6` is a specialized and easy-to-use function block for exclusive OR operation on up to six Boolean signals. —

XOR_BOOL_7

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_BOOL_7` is a generic block for calculating the logical exclusive OR (XOR) operation. It processes seven Boolean input signals and returns the result of the XOR operation as a Boolean output signal. The block complies with the IEC 61131-3 standard and is designed for use in control applications where odd parity checking or logical antivalence across multiple signals is required.

Interface Structure

Event Inputs

- **REQ (Normal Execution Request):** This event triggers the execution of the function block. Upon its arrival, all seven data inputs (`IN1` to `IN7`) are read and the XOR calculation is performed.

Event Outputs

- **CNF (Execution Confirmation):** This event signals the completion of the calculation. It is output along with the calculated data output `OUT`.

Data Inputs

- **IN1 (XOR input 1):** Boolean input 1.
- **IN2 (XOR input 2):** Boolean input 2.
- **IN3 (XOR input 3):** Boolean input 3.
- **IN4 (XOR input 4):** Boolean input 4.
- **IN5 (XOR input 5):** Boolean input 5.
- **IN6 (XOR input 6):** Boolean input 6.
- **IN7 (XOR input 7):** Boolean input 7.

Data Outputs

- **OUT (XOR result):** Boolean result of the XOR operation of all seven inputs.

Adapters

This function block does not have any adapter interfaces.

Functionality

When the event `REQ` occurs, the block performs the logical XOR operation on all seven Boolean inputs `IN1` to `IN7`. The result `OUT` is `TRUE` (1) if and only if an odd number of the inputs have the value `TRUE`. If the number of `TRUE` inputs is even (0, 2, 4, 6), the result is `FALSE` (0).

Mathematically expressed: `OUT = IN1 XOR IN2 XOR IN3 XOR IN4 XOR IN5 XOR IN6 XOR IN7`

Immediately after the calculation, the completion event `CNF` is triggered along with the valid result `OUT`.

Technical Features

- **Generic Block:** The block is implemented as a generic function block (`GEN_XOR`), which allows for flexible reuse in different contexts.

- **Fixed Number of Inputs:** Unlike blocks with a variable number of inputs, this block has exactly seven fixed inputs.
- **Event-Driven Execution:** The operation is triggered exclusively by an incoming event (`REQ`), which enables deterministic and energy-efficient processing in the real-time system.

State Overview

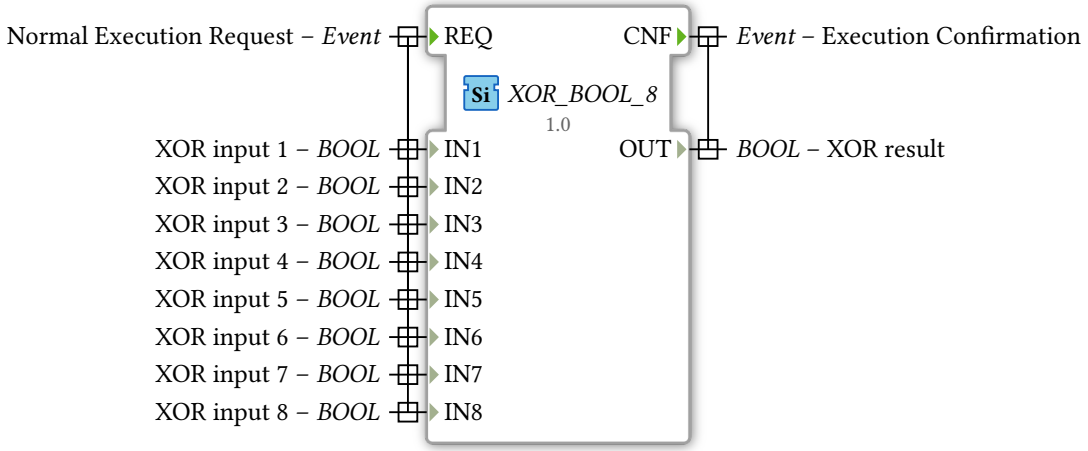
The function block does not have an internal state in the sense of a memory. Its behavior is purely combinatorial and depends solely on the current values at the inputs at the time of the `REQ` event. After the output of `CNF`, the block remains in a waiting state until the next `REQ` event.

Application Scenarios

- **Parity Check:** Monitoring whether an odd number of sensors (e.g., limit switches, light barriers) are in a specific state (`TRUE`).
- **Safety-Critical Logic:** In safety circuits where an antivalence condition across multiple safety devices is required.
- **Control Logic:** Implementation of special logic operations in sequence controls or logic controllers that require an XOR function with exactly seven operands.

⚖️ Comparison with similar building blocks

- **`XOR` (2 inputs):** The standard XOR block only combines two inputs. To combine seven signals, this block would have to be nested multiple times, which reduces program readability. `XOR_BOOL_7` offers a direct and clear solution. See: XOR_7
- **`GEN_XOR` (Generic, n inputs):** The underlying generic block `GEN_XOR` can be instantiated with a variable number of inputs. `XOR_BOOL_7` is a specific, pre-configured instance with seven inputs that can be used directly without having to parameterize the number of inputs.
- **`PARITY_CHECK`:** A pure parity check block could deliver similar results, but is often conceptually designed for error detection in data streams, whereas `XOR_BOOL_7` serves as a general-purpose logical operator in control logic.



Conclusion

The `XOR_BOOL_7` function block is a specialized and efficient building block for the logical anti-valence operation of seven Boolean signals. Its event-driven, stateless operation and clear interface make it ideal for use in structured IEC 61131-3-based control programs where such a fixed operation is required. It simplifies programming compared to nesting multiple two-input XOR blocks and provides a ready-to-use, reliable component.

XOR_BOOL_8

• – ◦ • – ◦ • – ◦ •

The function block `XOR_BOOL_8` is a generic block for calculating the logical exclusive OR (XOR) operation on up to eight Boolean input values. It complies with the IEC 61131-3 standard and is designed for use in the 4diac IDE. The block executes its operation in an event-driven manner and returns the result via a single Boolean output.

- **REQ** (Normal Execution Request): This event triggers the calculation. It is associated with all eight data inputs (`IN1` to `IN8`).
- **CNF** (Execution Confirmation): This event signals the completion of the calculation. It is linked to the data output `OUT`.
- **IN1** (BOOL): XOR input 1.
- **IN2** (BOOL): XOR input 2.
- **IN3** (BOOL): XOR input 3.
- **IN4** (BOOL): XOR input 4.
- **IN5** (BOOL): XOR input 5.
- **IN6** (BOOL): XOR input 6.
- **IN7** (BOOL): XOR input 7.
- **IN8** (BOOL): XOR input 8.
- **OUT** (BOOL): The result of the XOR operation of all active inputs.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use adapters.

Functionality

Upon the occurrence of the event `REQ`, the function block reads the values of all eight Boolean inputs (`IN1` to `IN8`). It then calculates the logical exclusive OR operation on all these input values. The result of this calculation is output at the data output `OUT`, and simultaneously, the confirmation event `CNF` is set to signal the completion of the operation.

The logical function can be described as follows:

OUT = IN1 XOR IN2 XOR IN3 XOR IN4 XOR IN5 XOR IN6 XOR IN7 XOR IN8`

An XOR (exclusive OR) operation returns `TRUE` (1) as the result if and only if there is an odd number of inputs connected, and `TRUE` (1) is the result. If there is an even number of inputs, the result is `FALSE` (0).

- **Generic Block:** The block is marked as a generic block (`GEN_XOR`), indicating its reusability and possible parameterization for other data types. In this specific instance, however, it is fixed to the data type `BOOL`.
- **Generic Block:** The block is marked as a generic block (`GEN_XOR`), which indicates its reusability and possible parameterization for other data types. In this specific instance, however, it is fixed to the data type `BOOL`.
- **Event-driven execution:** The operation is only performed upon an incoming `REQ` event, enabling efficient and deterministic control.
- **Fixed number of inputs:** The block provides exactly eight inputs. Unused inputs should be set to a defined logical value (e.g., `FALSE`).

The function block does not have an internal state in the sense of a memory. Its behavior is purely combinatorial and event-driven:

1. **Idle state:** Waits for the arrival of the `REQ` event.
2. **Computation state:** Upon `REQ`, all inputs are read and the XOR operation is performed.
3. **Output State:** The result is output to `OUT`, and the `CNF` event is generated. The block then returns to its idle state.

- **Parity Check:** Detects whether an odd number of signals (e.g., error messages, limit exceedances) are active in a group.
- **Toggle Logic:** Control where an action is only executed if exactly one of several possible control signals is active (e.g., selection between manual and automatic mode).

- **Basic Encryption and Coding Functions:** As a basic building block for simple cryptographic operations or error detection codes.
- **Comparison of Two or More States:** Determines whether at least one signal in a group differs from its expected state.
- **`OR_BOOL_8` / `AND_BOOL_8`:** These blocks calculate the logical OR and AND operations, respectively. Unlike XOR, OR (`TRUE`) returns true if *at least* one input is true, and AND (`TRUE`) returns true only if *all* inputs are true. XOR is more specific and responds to the *parity* (even/odd) of the true inputs.
- **`XOR` (with 2 inputs):** A standard XOR block with only two inputs. `XOR_BOOL_8` extends this functionality to up to eight inputs without the need to chain multiple blocks together. See: XOR_8
- **Combinatorial Logic in SFC/ST:** The function could also be programmed directly in Structured Text (ST) (e.g., `OUT := IN1 XOR IN2 XOR ...;`). The advantage of this function block lies in its standardized, reusable, and graphically representable interface within FBD networks.

The `XOR_BOOL_8` is a specialized, reliable, and easy-to-use function block for logical XOR operations with up to eight inputs. Its event-driven architecture makes it ideal for integration into control-typical flowcharts in the 4diac IDE. It is particularly suitable for applications where the parity of signal groups is important and offers a clearly defined alternative to basic OR and AND operations.

[Following the previous sentence about the function block, the `XOR_BOOL_8` is not relevant to the context and should be omitted.] —

XOR_BOOL_9

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `XOR_BOOL_9` is a generic block for calculating the logical exclusive OR (XOR) operation for up to nine Boolean input signals. It implements an n-ary XOR function where the output is `TRUE` if and only if there is an odd number of active inputs, such as `TRUE`. The block complies with the IEC 61131-3 standard and is designed for use in control applications that require checking for odd parity or specific selection or monitoring logic.

Interface Structure

The function block has a simple event-driven interface with a request event and an acknowledge event.

Event Inputs

- **REQ (Normal Execution Request):** This event triggers the calculation of the XOR function. It is associated with all nine data inputs (`IN1` to `IN9`).

Event Outputs

- **CNF (Execution Confirmation):** This event signals the completion of the calculation. It is output along with the calculated result at data output `OUT`.

Data Inputs

- **IN1 (XOR input 1):** Boolean input 1.
- **IN2 (XOR input 2):** Boolean input 2.
- **IN3 (XOR input 3):** Boolean input 3.
- **IN4 (XOR input 4):** Boolean input 4.
- **IN5 (XOR input 5):** Boolean input 5.
- **IN6 (XOR input 6):** Boolean input 6.
- **IN7 (XOR input 7):** Boolean input 7.
- **IN8 (XOR input 8):** Boolean input 8.
- **IN9 (XOR input 9):** Boolean input 9.

Data Outputs

- **OUT (XOR result):** Boolean result of the n-way XOR operation of all active inputs.

Adapters

This function block does not use adapters.

Functionality

When the event `REQ` arrives, the logical operation is executed. The output `OUT` is set to `TRUE` if the number of inputs with the value `TRUE` is odd. If the number of `TRUE` inputs is even (or zero), `OUT` is set to `FALSE`. Immediately after the calculation, the acknowledgment event `CNF` is output along with the current value of `OUT`.

The mathematical description is: `OUT = IN1 XOR IN2 XOR IN3 XOR IN4 XOR IN5 XOR IN6 XOR IN7 XOR IN8 XOR IN9`.

Technical Features

- **Generic Function Block:** The function block is designated as a generic function (`GEN_XOR`), which means it can serve as the basis for deriving specific XOR function blocks with a fixed number of inputs.
- **Hard-wired Logic:** The operation is performed across all nine inputs. For applications with fewer inputs, the unused inputs must be set to a defined value (typically `FALSE`).
- **Event-driven Execution:** The calculation only occurs when the `REQ` event occurs, enabling resource-efficient and deterministic processing.

State Overview

The function block does not have an internal state in the sense of a memory. Its behavior is purely combinatorial and depends solely on the current values at the data inputs at the time of the `REQ` event. The "calculation in progress" state is transient and ends immediately with the output of `CNF`.

Application Scenarios

- **Parity Check:** Monitoring whether an odd number of sensors (e.g., limit monitors, safety switches) report an alarm condition.
- **Selection or Toggle Logic:** Control where an action is executed only when the state of an odd number of conditions has changed.
- **Error Detection in Redundant Systems:** Simple plausibility check in systems with multiple redundant channels.
- **Encryption and Coding Methods:** As a fundamental component in simple cryptographic or error-correcting codes.
-

⚖️ Comparison with Similar Blocks

- **Standard XOR blocks (e.g., XOR, E_XOR):** These typically have only two inputs. `XOR_BOOL_9` extends this functionality to up to nine inputs in a single block.
- **OR blocks (OR) / AND blocks (AND):** Return a `TRUE` if at least one or all inputs are `TRUE`. The XOR logic is more specific (odd number).
- **Parity blocks:** Specialized blocks for parity calculation, often working directly with data words (BYTE, WORD). `XOR_BOOL_9` works with individual Boolean bits and is more flexible in terms of the number of inputs.
- – **Combinatorial Logic Blocks (GEN_AND, GEN_OR):** Similar generic blocks for other basic logical operations.

Conclusion

The `XOR_BOOL_9` is a specialized, generic function block that provides the logical XOR operation for up to nine signals in a single, event-driven component. Its strength lies in its clear interface and direct implementation of the n-ary XOR function, making it ideal for parity checks and specialized control logic. For applications with a variable or very large number of inputs, the logic may need to be built from multiple basic components.

Here you will find all exercises for the `iec61131-3-bool` workspace in ascending order.

F_MUX_32

• – ○ • – ○ • – ○ •

Introduction

The function block **F_MUX_32** is a generic multiplexer (selection function) according to IEC 61131-3. It allows the selection of one of 32 input values (IN1 ... IN32) and outputs it at output OUT. The selection is made using the integer selector K. The block is event-driven: When an event occurs at the REQ input, the current value of K is evaluated and the corresponding input value is applied.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Service Request – triggers the selection

Event Outputs

Name	Type	Comment
CNF	Event	Confirmation – confirms the selection has been made

Data Inputs

Name	Type	Comment
K	ANY_INT	Selection value (0 ... 31), selects one of the 32 inputs

IN1	ANY	Input value 1
IN2	ANY	Input value 2
…	…	…
IN32	ANY	Input value 32

Data Outputs

Name	Type	Comment
OUT	ANY	Output value: IN1 if K=0; IN2 if K=1; …; IN32 if K=31

Adapter

No adapters available.

Functionality

The FB `F_MUX_32` operates in an event-driven manner:

1. An event at the **REQ** input triggers processing.
2. The selector **K** (integer value) is evaluated.
3. Depending on the value of K, the corresponding data input is selected:

- K = 0 ⟶ **IN1**
- K = 1 ⟶ **IN2**
- …
- K = 31 ⟶ **IN32**

1. The selected value is passed to the **OUT** output.
2. An event at the **CNF** output signals the completion of the operation.

Values outside the valid range (0 … 31) result in undefined behavior; the function block does not offer range checking.

Technical Features

- **Generic Data Type (ANY):** All data inputs and the output are declared with `ANY`. The function block can therefore be used with various data types (BOOL, INT, REAL, etc.). However, all inputs and the output must have the same specific type.
- **Event Association:** The **REQ** event is associated with all data inputs (IN1 … IN32 and K). When a REQ event occurs, all these inputs are read simultaneously.
- **Lack of Range Check:** The function block does not check whether K is in the range 0 … 31. An invalid value can lead to unexpected results (e.g., selecting a non-existent channel). This must be addressed in the application.
- **Standard Compliance:** The function block implements the `SELECT` functionality from IEC 61131-3 and is classified as a “standard selection function”.

State Overview

The function block does not have an explicit state machine in its XML definition. It behaves like an event-driven function: After the **REQ** event, the output is immediately updated and **CNF** is triggered. There are no internal states.

Application Scenarios

- **Switching between multiple sensor values** in a controller (e.g., temperature, pressure, or level sensors).
- **Configurable Configuration:** Selection of different operating modes or setpoints via an index.
- **Test and diagnostic functions** where different signal sources are connected to an analysis point.
- **Extension of existing multiplexer solutions** with fewer channels to 32 inputs.

Comparison with Similar Function Blocks

- **F_MUX_2, F_MUX_3, ... F_MUX_n:** These function blocks have a smaller number of inputs (2, 3, ...). `F_MUX_32` covers the maximum requirement of 32 channels. If only a smaller number is needed, smaller variants are more space-saving and easier to understand.
- **CASE Statement (ST):** A `CASE` structure in Structured Text can represent the same behavior but is not encapsulated as a reusable function block. The function block offers event-driven encapsulation for graphical and textual programming.
- **MUX Function in IEC 61131-3:** The integrated `MUX` function is typically limited to smaller numbers (e.g., 8). The function block extends this to 32 channels.

Conclusion

The **F_MUX_32** is a powerful and flexible multiplexer IC for use in automation technology. Its generic type and large number of 32 inputs make it suitable for a wide variety of selection tasks. The simple event control and the clean separation of event and data paths make it easily integrated into IEC 61131-3 environments. However, users should ensure the valid selection range is used to avoid errors.

TC_ID

• – ◦ • – ◦ • – ◦ •

Introduction

The TC_ID function block is an input service interface module for double-word input data. It serves as an interface for communication with tractor control (TC) input devices and enables access to specific input data via defined data words.

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- Linked to: QI, PARAMS, wDevElementNumb, wDDI
- **REQ**: Service Request
- Linked to: QI

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service Request
- Linked to: QO, STATUS, IN
- **IND**: Resource Indication
- Linked to: QO, STATUS, IN

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **wDevElementNumb** (UINT): Requested Element Number TC Input
- **wDDI** (UINT): Data Dictionary Identifier of the input

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status
- **IN** (DWORD): Input data from the resource

Adapter

No adapter interfaces are available.

Functionality

The TC_ID block enables access to TC input data via standardized service interfaces. During initialization (INIT), the device parameters are configured. Service requests (REQ) trigger data acquisition, with the results being returned via CNF or IND events. The block supports both requested and spontaneous data deliveries from the connected resource.

Technical Features

- Processes double-word data (DWORD, 32-bit)
- Supports Data Dictionary Identifiers (DDI) for standardized data access
- Provides both requested (CNF) and spontaneous (IND) data deliveries
- Includes comprehensive status feedback via STRING parameters

State Overview

The block goes through typical service interface states:

1. **Not Initialized**: Before an INIT event
2. **Initialized**: After successful INITO feedback
3. **Ready**: For REQ requests
4. **Active**: During data querying and processing

Application Scenarios

- Agricultural control systems (ISOBUS environment)
- Tractor control and monitoring
- Data acquisition from TC input devices
- Automated agricultural systems with standardized data formats

⚖️ Comparison with Similar Blocks

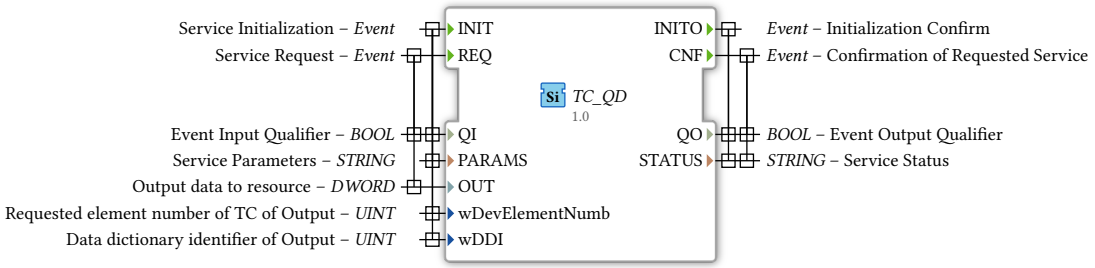
Compared to simple input blocks, TC_ID offers:

- Standardized ISOBUS Interface
- DDI-based data identification
- Comprehensive status and error management
- Both requested and spontaneous data transmission

🛠️ Related Exercises

- Exercise_060

Conclusion



The TC_ID function block provides a robust and standardized interface for TC input data in ISOBUS environments. Its flexible architecture, with both requested and spontaneous data transmission mechanisms, makes it ideal for complex agricultural applications that require reliable access to specific input data.

TC_QD

• – ○ • – ○ • – ○ •

Introduction

The TC_QD function block is an output service interface function block for double-word output data. It serves as an interface for communication with external resources and enables the output of 32-bit data values via specified device elements.

Interface Structure

Event Inputs
- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs
- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs
- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **OUT** (DWORD): Output Data for the Resource
- **wDevElementNumb** (UINT): Requested TC Element Number for Output
- **wDDI** (UINT): Output Data Dictionary Identifier

Data Outputs
- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status

Adapter
No adapter interfaces are available.

Functionality
The TC_QD function block initializes and manages communication with external output devices. Upon activating the INIT event, the service is initialized, configuring the parameters PARAMS, wDevElement-Numb, and wDDI. The REQ event triggers the actual data output, sending the double-word value provided in the OUT input to the specified resource.

Technical Features
- Processes 32-bit data values (DWORD)
- Supports Data Dictionary Identifiers (DDI) for standardized data referencing
- Provides device element number specification for precise device control
- Delivers detailed status information via the STRING output STATUS

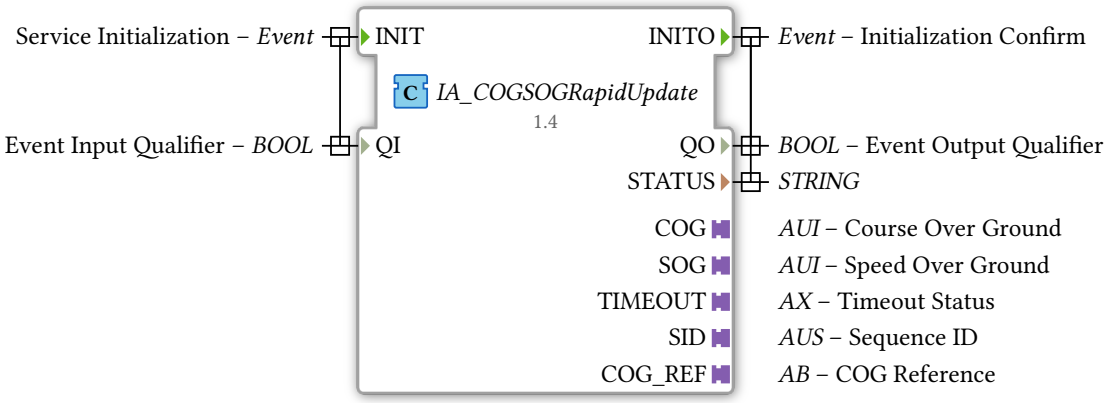
State Overview
The function block has two main operating states:

1. **Initialization State**: Activated by the INIT event and confirmed by INITO
2. **Service Operating State**: Activated by the REQ event and completed by CNF

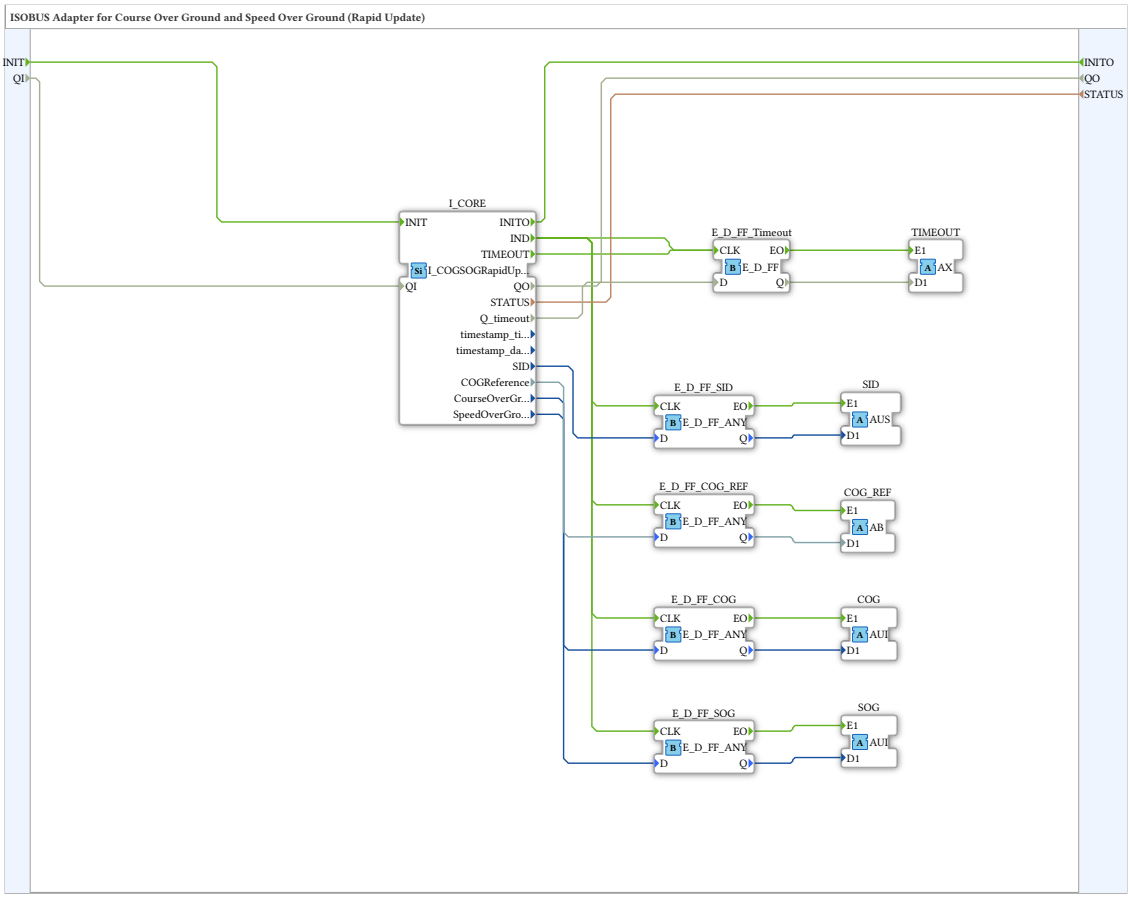
Application Scenarios
- Control of ISOBUS-compatible agricultural machinery
- Output of control commands to industrial actuators
- Communication with TC (Tractor Controller) output devices
- Applications in agricultural technology and mobile machinery

⚖️ Comparison with Similar Function Blocks
Compared to simpler output blocks, TC_QD offers enhanced functionality through:

- DDI-based data identification
- Configurable device element numbers
- ISOBUS specification compatibility
- Comprehensive status feedback



🛠️ Related exercises
- Exercise_060



Conclusion

The TC_QD function block represents a powerful and flexible solution for outputting double-word data in ISOBUS environments. Its structured interface and extensive parameterization options make it particularly suitable for demanding control applications in mobile automation.

2.10.2.3 TECU

IA_COGSOGRapidUpdate

• – ○ • – ○ • – ○ •

Introduction

The function block **IA_COGSOGRapidUpdate** serves as an ISOBUS adapter for the NMEA 2000 PGN 129026 messages “Course Over Ground (COG)” and “Speed Over Ground (SOG)” with support for rapid updates. It decouples the ISOBUS communication and provides the received navigation data and a timeout

status via standardized adapter interfaces. The block was developed under the Eclipse Public License 2.0 and is optimized for use in agricultural control systems (TECU).

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Service initialization, triggered by input QI

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization acknowledgment, returns QO and STATUS

Data Inputs

Variable	Type	Comment
QI	BOOL	Input qualifier for initialization

Data Outputs

Variable	Type	Comment
QO	BOOL	Output qualifier (initialization status)
STATUS	STRING	Status message (e.g., error text or “OK”)

Adapter

Adapter Name	Type	Comment
COG	adapter::types::unidirectional::AUI	Course Over Ground
SOG	adapter::types::unidirectional::AUI	Speed Over Ground
TIMEOUT	adapter::types::unidirectional::AX	Timeout status (active when no update occurs)
SID	adapter::types::unidirectional::AUS	Sequence ID (sequential number of the data record)
COG_REF	adapter::types::unidirectional::AB	Course reference (e.g., True/Magnetic)

Functionality

1. **Initialization**

An event at **INIT** activates the function block. The **QI** input controls the start. After successful initialization, **INITO** is triggered, and the **QO** (TRUE on success) and **STATUS** outputs are set.

1. **ISOBUS Message Processing**

The internal core (FB `I_CORE` of type `isobus::tecu::I_COGSOGRapidUpdate`) continuously receives NMEA 2000 PGN 129026 messages. As soon as new data is available, the following values are output via the corresponding adapters:

- **COG**: Course over ground (e.g., in 0.01° increments)
- **SOG**: Speed over ground (e.g., in 0.01 km/h)
- **SID**: Sequence ID for synchronization
- **COG_REF**: Reference (True or Magnetic)

1. **Timeout Monitoring**

If no valid message is received within a configured time period, the function block activates the **TIMEOUT** adapter. This event can be used by the application to trigger error conditions or plausibility checks.

1. **Output Cycles**

The **COG**, **SOG**, **SID**, and **COG_REF** adapters are triggered together with each valid data reception (event connection `IND`). The **TIMEOUT** adapter is triggered independently upon timeout.

Technical Features

- **NMEA 2000 PGN 129026** – This module is specifically designed to interpret this PGN, enabling rapid updates of COG and SOG.
- **Adapters instead of direct inputs/outputs** – All navigation data is provided via unidirectional adapters (type `unidirectional::AUI`, `AX`, etc.), allowing for flexible further processing and encapsulation in higher-level networks.
- **License and Origin** – This module is available under the Eclipse Public License 2.0 and was developed by **HR Agrartechnik GmbH** (Version 1.0, April 19, 2026, Author: Franz Höpfinger).

Adapters instead of direct inputs/outputs – - **Integration in isobus::tecu** – The function block is part of the `isobus::tecu` library and is based on a low-level ISOBUS implementation.

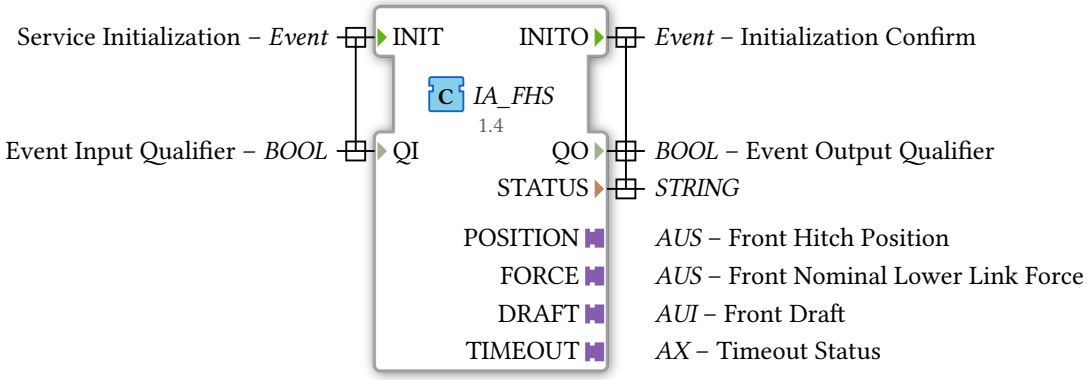
State Overview

The function block does not have explicitly modeled states; however, the following operating phases can be derived:

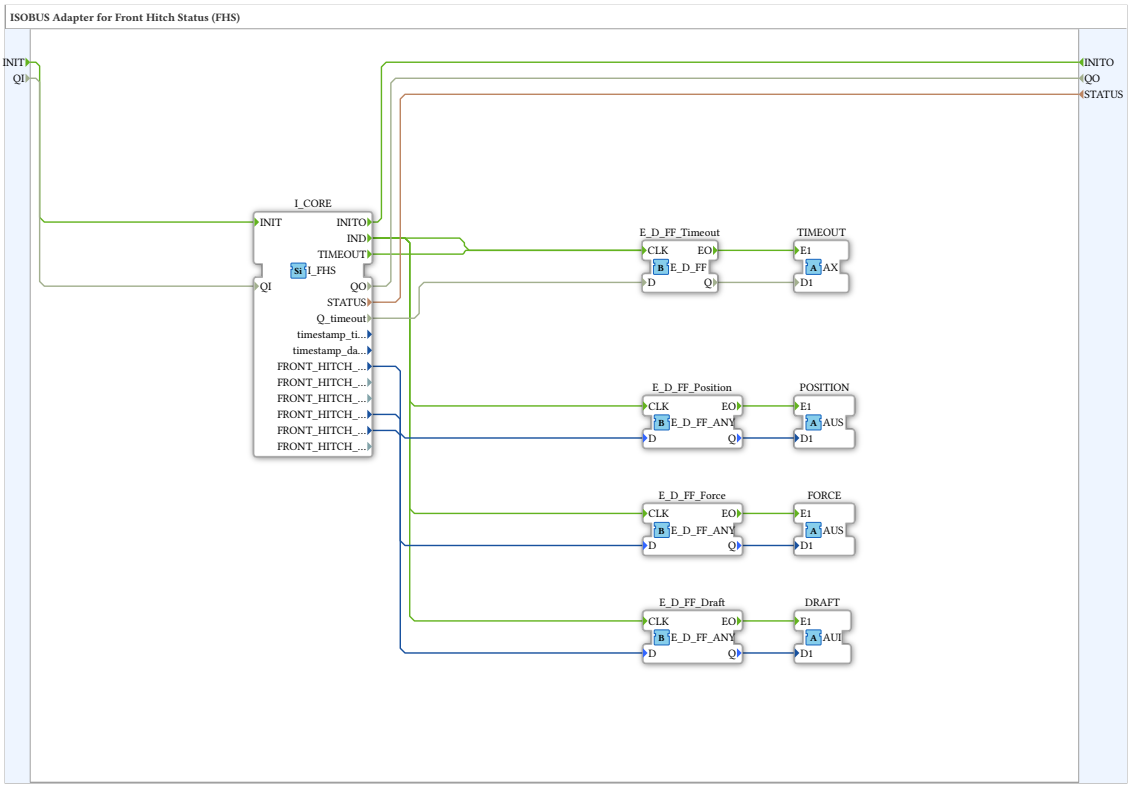
State	Description
Inactive	INIT not yet triggered or QI = FALSE
Initializing	After INIT, until INITO is reported with QO
Active (Data Received)	Regular reception of PGN 129026, adapter updates
Timeout	No valid message within the timeout threshold – TIMEOUT adapter active
Error	Initialization failed (STATUS = error text)

Application Scenarios

- **Agricultural Tractors** – Providing course and speed data for automatic steering systems or application maps.
- **ISOBUS-based ECUs** – Integration into a TECU network for evaluating GPS/GNSS data.
- **Fast Control Loops** – Utilizing the rapid update function for dynamic control variables (e.g., for site-specific treatment).
- **Fault Monitoring** – Using the TIMEOUT adapter to detect data failures and activate redundancy mechanisms.



Comparison with Similar Modules



There are general ISOBUS adapters for COG/SOG (e.g., `I_COGSOG`), but these do not offer rapid update support. The **IA_COGSOGRapidUpdate** is specifically designed for PGN 129026 and additionally provides the sequence ID and timeout status. Similar modules like `I_COGSOGStd` may use a slower update rate or lack timeout detection. Using adapter interfaces (instead of a fixed data port) increases flexibility but requires corresponding adapter configuration in the parent project.

Conclusion

The **IA_COGSOGRapidUpdate** is a specialized, license-free ISOBUS adapter for high-frequency navigation data. It encapsulates the complex NMEA 2000 communication and offers standardized adapter outputs for heading, speed, sequence ID, and timeout. Its clear initialization logic and error monitoring capabilities make it ideal for real-time applications in agricultural technology. The use of adapter technology enables clean modularization and reusability in a wide variety of control architectures.

IA_FHS

• – ○ • – ○ • – ○ •

Introduction

The function block **IA_FHS** serves as an ISOBUS adapter for the Front Hitch Status (FHS) according to ISO 11783-7 (PGN 65094). It encapsulates the internal processing of the function block `I_FHS` and provides the acquired measurement and status values via standardized unidirectional adapter outputs. Initialization occurs via the event `INIT`; after successful completion, the data is provided via the adapter interfaces.

Interface Structure

Event Inputs

Event	Type	with variables	Description
`INIT`	EInit	`QI`	Service Initialization

Event Outputs

Event	Type	with Variables	Description

INITO	EInit	QO, STATUS	Initialization Acknowledgement

Data Inputs

Variable	Type	Description
QI	BOOL	Event Input Qualifier

Data Outputs

Variable	Type	Description
QO	BOOL	Output Qualifier
STATUS	STRING	Status Message (e.g., “OK”)

Adapters

Adapter	Type	Description
POSITION	adapter::types::unidirectional::AUS	Front Hitch Position (analog, unsigned)
FORCE	adapter::types::unidirectional::AUS	Front Nominal Lower Link Force (analog)
DRAFT	adapter::types::unidirectional::AUI	Front Draft (analog, integer, unsigned)
TIMEOUT	adapter::types::unidirectional::AX	ISOBUS Reception Timeout Status

Functionality

The function block internally contains an instance I_CORE of type isobus::tecu::I_FHS. Upon arrival of the initialization event INIT, the kernel is activated with the qualifier QI. After successful initialization, it triggers the event INITO, sets QO = TRUE, and outputs the status as STATUS. Simultaneously, the kernel generates the event IND, which is forwarded via internal event connections to the adapters POSITION, FORCE, and DRAFT. The corresponding data values (FRONT_HITCH_POSITION, FRONT_HITCH_NOMINAL_LOWER_LINK_FORCE, FRONT_HITCH_DRAFT) are transmitted to the adapter outputs via the appropriate data connections. Any ISOBUS reception timeout is reported via the adapter event TIMEOUT.E1 and the data value Q_timeout.

Technical Features

- **Standard Compliance**: The module meets the requirements of ISO 11783-7 for **PGN 65094** (Front Hitch Status).
- **Adapter Interfaces**: All sensor values are output via unidirectional adapters, enabling flexible and decoupled further processing in the 4diac IDE.
- **Initialization Sequence**: Initialization must be explicitly triggered via the event INIT; the function block will only function correctly after successful completion.
- **Timeout Monitoring**: The adapter TIMEOUT signals whether ISOBUS data reception occurs within the expected time. This serves to detect errors in fieldbus communication.

State Overview

The function block does not have its own visible state machine. Internal sequence control is handled by the core function block I_FHS. Broadly speaking, two phases can be distinguished:

- **Before Initialization**: The function block is inactive. The event outputs and adapters do not provide any data.
- **After Initialization (INIT successful)**:
- INITO is triggered, QO = TRUE.
- The adapters POSITION, FORCE, and DRAFT are supplied with current measured values cyclically or event-driven.
- The adapter TIMEOUT reports the current timeout status.

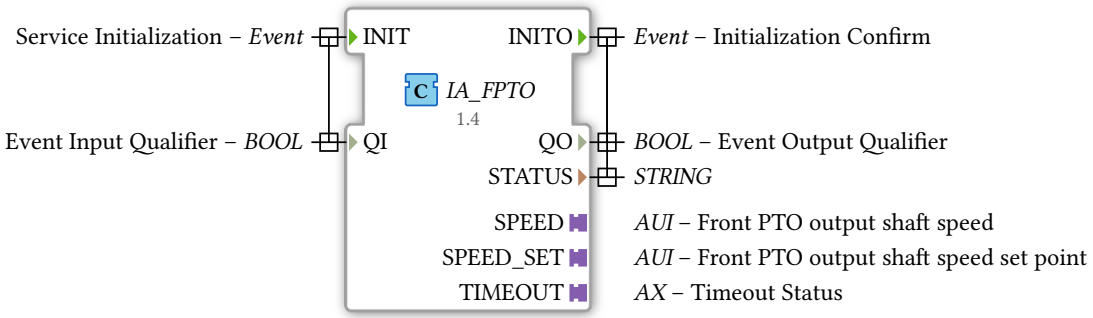
If an error occurs during operation (e.g., connection loss), this is signaled via the timeout adapter or the status output.

Application Scenarios

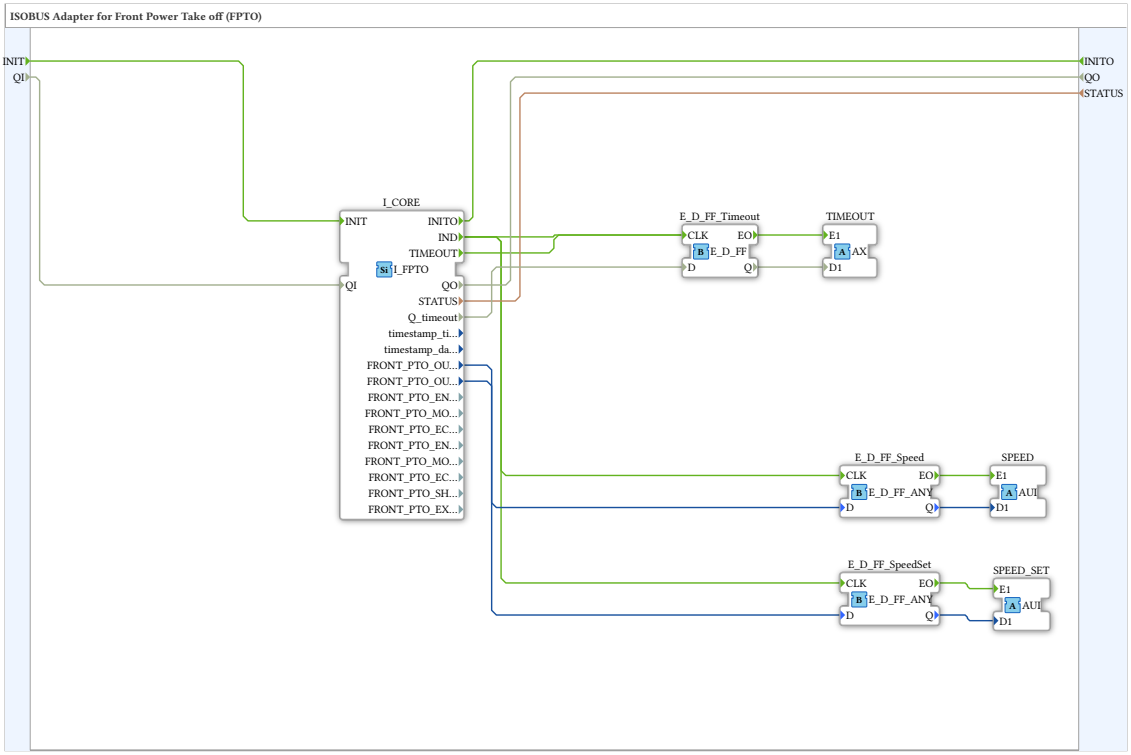
- **Tractor Control**: Acquisition of the front linkage position and the load on the lower links for controlling implements (e.g., front loader, front linkage).
- **ISOBUS Diagnostics**: Monitoring of the ISOBUS data stream for timeouts and plausibility of the force and position values.
- **Data Recording**: Provides position, force, and tractive force data for telemetry or logging applications.

Comparison with Similar Modules

- **IA_RHS** (Rear Hitch Status): Analog adapter for the rear hitch. The addressing and PGN number differ (e.g., PGN 65096). While `IA_FHS` provides front hitch data, `IA_RHS` focuses on the rear hitch.
- **Direct I_FHS Module**: Without an adapter wrapper, the user would have to integrate the core module `I_FHS` themselves and manually configure the necessary data and event connections. The adapter module simplifies handling through standardized, pre-configured interfaces.



Conclusion



The **IA_FHS** function block offers a ready-to-use ISOBUS adapter for front hitch status. Thanks to the internal encapsulation of the `I_FHS` core and the output via unidirectional adapters, users can quickly and reliably integrate the values for position, force, and tensile force into their own control or monitoring applications. The integrated timeout monitoring increases the operational reliability of the ISOBUS communication.

IA_FPTO

[Image of the function block, if available]

• – ○ • – ○ • – ○ •

Introduction

The **IA_FPTO** function block serves as an ISOBUS adapter for the front power take-off (FPTO) according to ISO 11783-7 (PGN 65092). It encapsulates the internal logic of the **I_FPTO** block and provides the relevant signals via standardized adapter interfaces. This enables seamless integration into ISOBUS-based control systems.

Interface Structure

Event Inputs

Event	Type	Description	With Variables
INIT	EInit	Service Initialization	QI

Event Outputs

Event	Type	Description	With Variables
INITO	EInit	Initialization Confirmation	QO, STATUS

Data Inputs

Variable	Type	Description
QI	BOOL	Qualifier for the INIT input

Data Outputs

Variable	Type	Description
QO	BOOL	Qualifier for the INITO output
STATUS	STRING	Status message after initialization

Adapter

Adapter	Type	Description
SPEED	adapter::types::unidirectional::AUI	Front PTO output speed (actual value)
SPEED_SET	adapter::types::unidirectional::AUI	Front PTO setpoint speed
TIMEOUT	adapter::types::unidirectional::AX	Communication timeout status

All adapters are unidirectional: Values are sent by the function block (FB), but not received.

Functionality

The FB is activated via the **INIT** event. If the input qualifier **QI** is set, the internal logic initializes the connection to the ISOBUS communication layer. After successful initialization, the **INITO** event is triggered, and the output variables **QO** and **STATUS** return the initialization status.

After initialization, the function block operates autonomously: It cyclically provides the current speed of the front PTO via the **SPEED** adapter and the corresponding setpoint via **SPEED_SET**. The **TIMEOUT** adapter indicates whether a communication timing error has occurred (e.g., if the control unit is not sending current data). These outputs are continuously updated as long as the initialization remains valid.

Technical Features

- The function block is based on the internal function block **I_FPTO** from the library `isobus::tecu`. The adapter interfaces decouple the application from the specific signal encoding of the ISOBUS.
- The adapters **SPEED** and **SPEED_SET** use the unidirectional type **AUI** (address unknown, integer), which is suitable for analog values such as rotational speeds.
- The adapter **TIMEOUT** uses the type **AX** (address unknown, Boolean value) to represent the timeout state in binary.
- The function block (FB) does not contain its own behavior for events outside of initialization; data updates are implicitly handled via the network connections of the block **I_FPTO**.

State Overview

The FB does not have an explicit state machine. Its behavior can be described as follows:

1. **Initialization Phase**: After the **INIT** event, the internal FB **I_FPTO** is initialized. During this phase, the adapter outputs are invalid or set to a defined initial value (0/FALSE).

The FB does not have an explicit state machine. 2. **Active Phase**: After confirmation of the initialization (**INITO**), the current values are stably available at the **SPEED**, **SPEED_SET**, and **TIMEOUT** adapters.

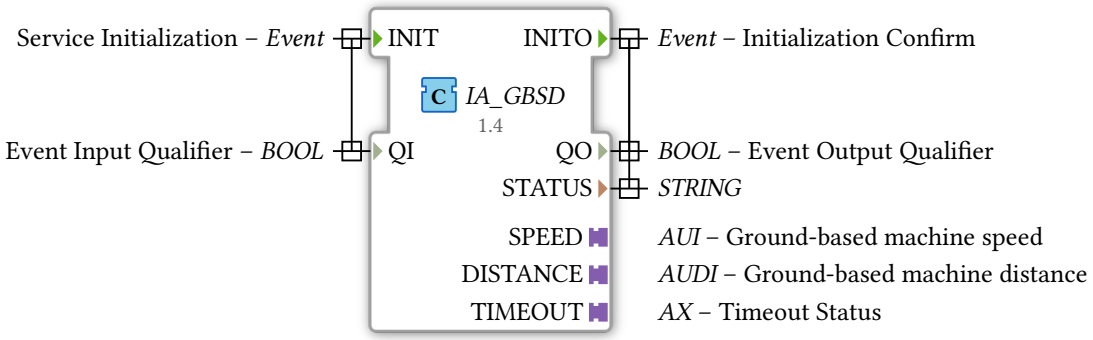
1. **Error State**: If a timeout occurs, the **TIMEOUT** adapter is set to TRUE. The speed values may remain at the last valid value until communication is restored.

Reinitialization (another INIT pulse) can reset and restart the FB.

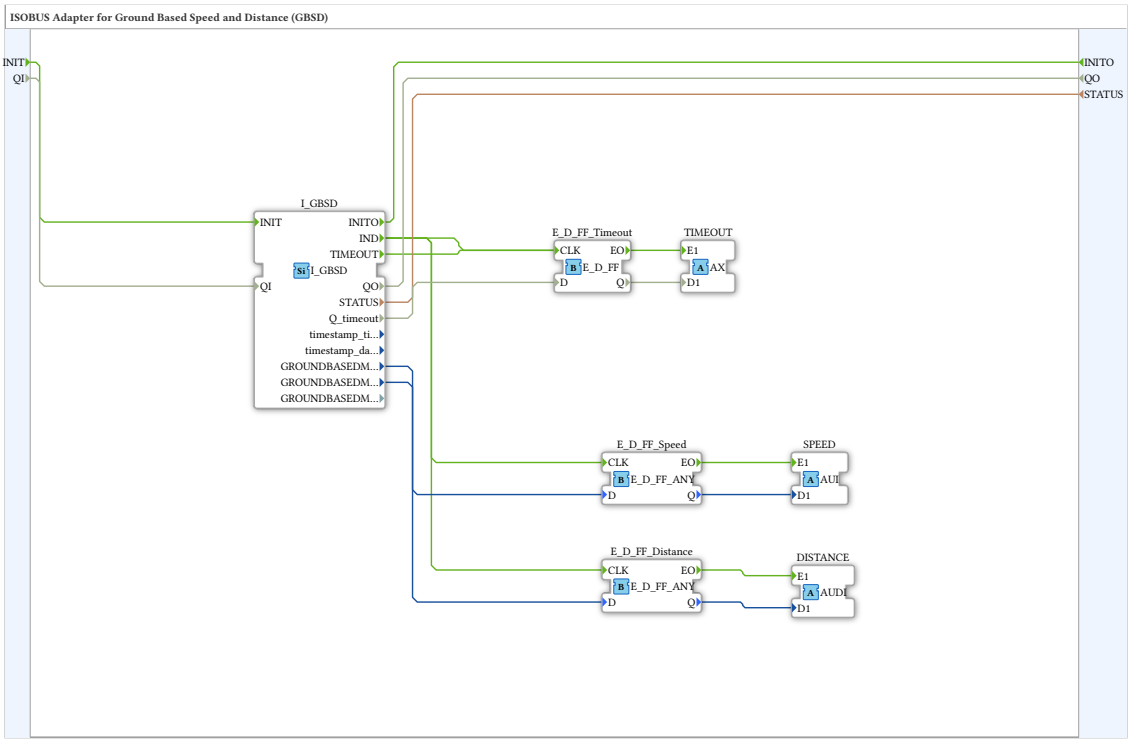
Application Scenarios

- **Front PTO Control in Agricultural Tractors**: The FB receives the target and actual speeds of the front PTO via ISOBUS and forwards them to higher-level controllers or displays.
- **Integration into ISOBUS-Compliant Implements**: Implements such as front mowers or front loaders can use the speed and timeout information to adjust their functions accordingly.
- **Remote Diagnostics and Monitoring**: The timeout signal enables monitoring of the communication link to the PTO control unit, which is important for fault detection and safety functions.

Comparison with Similar Modules



In the ISOBUS environment, there are other adapters for different PTOs (e.g., **IA_RPTO** for the rear PTO) or for general control units. **IA_FPTO** is specifically tailored to the front PTO and contains only the signals relevant to this application (actual/target speed and timeout). Compared to a generic ISOBUS adapter, it therefore offers a higher level of abstraction and easier handling for the application developer.



Conclusion

The **IA_FPTO** function block provides a streamlined and specific interface for ISOBUS-compliant use of the front PTO. The encapsulation of the internal communication logic and its provision via unidirectional adapters significantly simplifies integration into control applications. The module is particularly

suitable for tractors and agricultural machinery where reliable speed monitoring and timeout detection are required.

IA_GBSD

• – ○ • – ○ • – ○ •

Introduction

The function block **IA_GBSD** serves as an adapter wrapper for the ISOBUS-compatible module **I_GBSD** (“Ground Based Speed and Distance”). It encapsulates the initialization and data communication of a ground-based speed and distance sensor according to ISO 11783-7 (PGN 65097) and provides the values via unidirectional adapter interfaces.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Service Initialization

Event Outputs

Name	Type	Comment

INITO	EInit	Initialization Confirm

Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Status Information

Adapters

Name	Type	Comment
SPEED	adapter::types::unidirectional::AUI	Ground-based machine speed
DISTANCE	adapter::types::unidirectional::AUDI	Ground-based machine distance
TIMEOUT	adapter::types::unidirectional::AX	Timeout status

Functionality

The function block is implemented as a pure adapter wrapper:

- An INIT event at the input is directly forwarded to the internal block **I_GBSD**.
- The data input **QI** activates or deactivates processing.
- After initialization, the **INITO** event is output with the qualifier **QO** and a **STATUS**.
- The calculated values (speed and distance) are output via the adapters **SPEED** and **DISTANCE**. If a timeout occurs, the **TIMEOUT** adapter is activated.
- All data connections are established within the FB network between the inputs/outputs and the internal module.

Technical Features

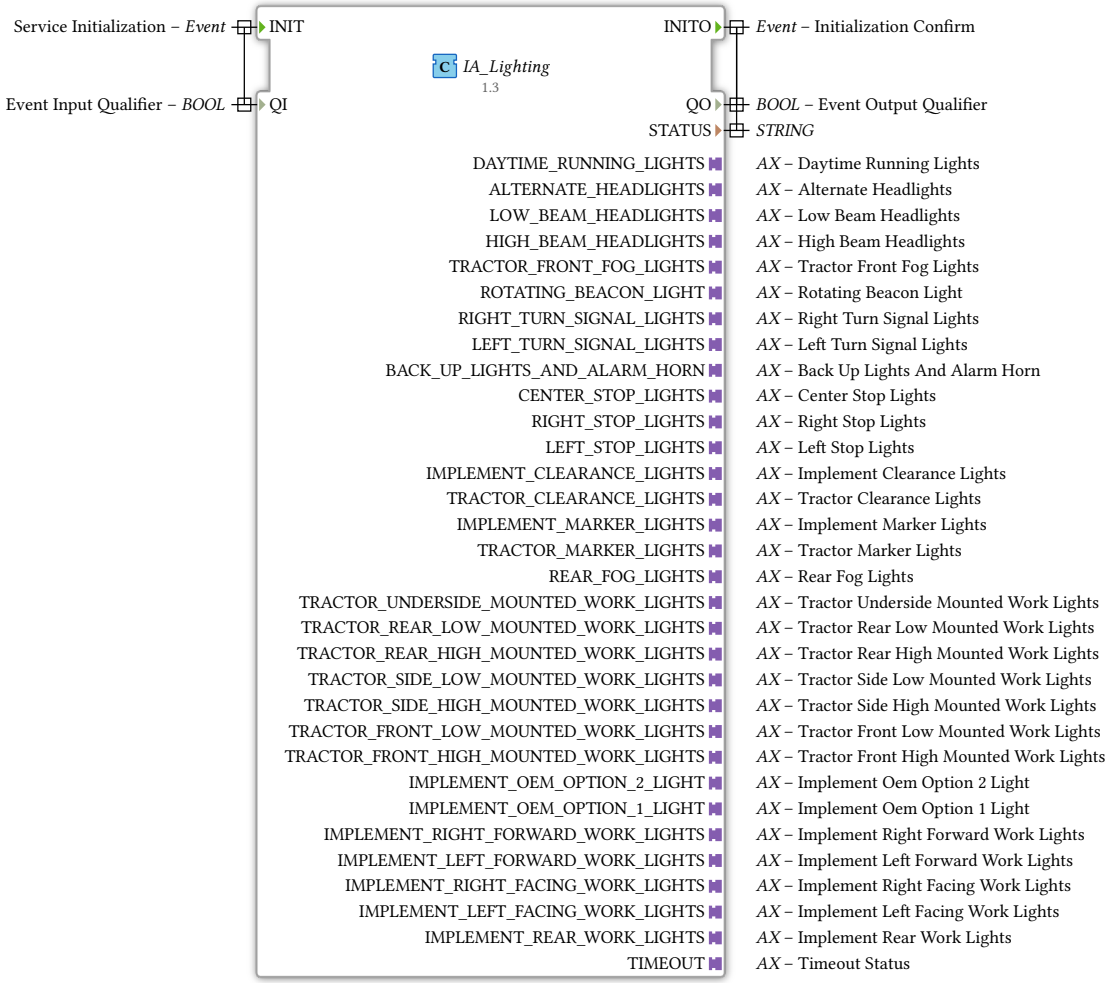
- **Adapter-based interface**: The output data is not provided as fixed variables, but via unidirectional adapters (AUI, AUDI, AX), allowing for flexible integration with other components.
- **ISOBUS compliance**: The FB implements PGN 65097 according to ISO 11783-7 – the standard for ground-based speed and distance in agricultural technology.
- **Timeout monitoring**: The separate timeout adapter signals whether the sensor values have been updated within an expected time period.
- **Compact design**: There is no separate state machine; all control logic resides in the internal module **I_GBSD**.

State Overview

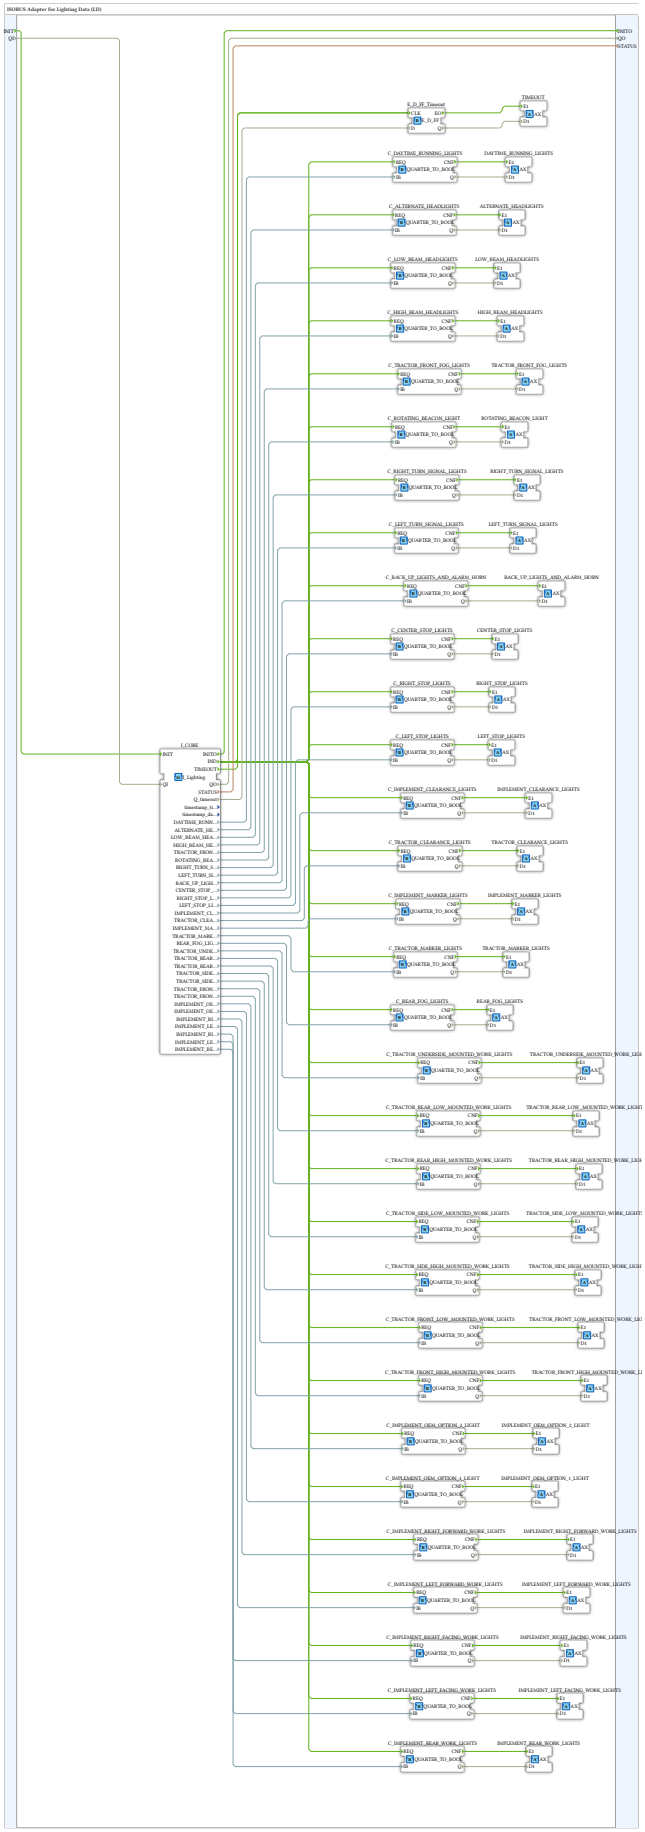
The function block itself does not have an explicit finite state machine. The internal block goes through an initialization state (triggered by INIT) and an operating state in which speed, distance, and timeout status are continuously updated.

Application Scenarios

- **ISOBUS Control Units (TECUs)**: Integration of a radar sensor or other ground-based speed/distance sensor into an ISOBUS-compatible system.
- **Agricultural Vehicles**: Provision of driving speed and distance traveled for downstream functions (e.g., metered applications, section control).
- **Test and Simulation Environments**: Use of the adapter wrapper to replace the real sensor with a simulated data source.



Comparison with Similar Modules



- **IA_GBSD** vs. **I_GBSD**: I_GBSD is the natively programmed ISOBUS module, while IA_GBSD makes its functionality accessible exclusively via adapters. The wrapper simplifies wiring in graphical editors and separates the actual logic from the interface connection.
- **Alternative Adapter Wrappers**: Similar wrappers exist for other ISOBUS PGNs (e.g., for navigation data or hydraulic systems), which also provide adapters for their output values.

Conclusion

IA_GBSD is an efficient adapter wrapper that encapsulates ground-based speed and distance measurement according to ISO 11783-7. The adapter interfaces enable clean, modular integration into higher-level control logic, while the actual ISOBUS implementation remains intact. This makes the component usable for both direct applications and for simulation and testing purposes.

IA_Lighting

• – ◦ • – ◦ • – ◦ •

Introduction

The **IA_Lighting** function block serves as an ISOBUS adapter for lighting data (LD) according to ISO 11783-7 (PGN 65088). It encapsulates an internal `I_Lighting` core and converts its 32-bit integer outputs for each lighting function into individual Boolean signals. A variety of adapter plugs transmit the individual lighting functions, such as daytime running lights, low beams, turn signals, work lights, etc., as separate logical signals to the application.

• – ◦ • – ◦ • – ◦ •

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initialization of the function block. Triggered by `QI`.

Event Outputs

Event	Type	Description
INITO	EInit	Confirmation of successful initialization. Output along with `QO` and `STATUS`.

Data Inputs

Name	Type	Description
QI	BOOL	Qualifier for initialization (enabling).

Data Outputs

Name	Type	Description
QO	BOOL	Output qualifier – indicates whether the block is ready for operation.
STATUS	STRING	Status message (e.g., error text or success message).

Adapters

The block has **32 unidirectional adapter plugs** (type `adapter::types::unidirectional::AX`). Each adapter represents a specific lighting function according to ISO 11783-7 and provides an event output (`E1`) and a data output (`D1`) of type `BOOL`:

Adapter Name	Description
DAYTIME_RUNNING_LIGHTS	Daytime Running Lights
ALTERNATE_HEADLIGHTS	Alternative High Beam (e.g., High Beam Assist)
LOW_BEAM_HEADLIGHTS	Low Beam
HIGH_BEAM_HEADLIGHTS	High Beam
TRACTOR_FRONT_FOG_LIGHTS	Front Fog Lights for Tractor
ROTATING_BEACON_LIGHT	Rotating Beacon
RIGHT_TURN_SIGNAL_LIGHTS	Right Turn Signal
LEFT_TURN_SIGNAL_LIGHTS	Left Turn Signal
BACK_UP_LIGHTS_AND_ALARM_HORN	Reversing Light and Alarm Horn
CENTER_STOP_LIGHTS	Center Brake Light
RIGHT_STOP_LIGHTS	Right Brake Light
LEFT_STOP_LIGHTS	Left Brake Light

IMPLEMENT_CLEARANCE_LIGHTS	Implement Marker Lights
TRACTOR_CLEARANCE_LIGHTS	Tractor Marker Lights
IMPLEMENT_MARKER_LIGHTS	Implement Marker Lights
TRACTOR_MARKER_LIGHTS	Tractor Marker Lights
REAR_FOG_LIGHTS	Rear Fog Lights
TRACTOR_UNDERSIDE_MOUNTED_WORK_LIGHTS	Tractor Work Lights (Underside Mounted)
TRACTOR_REAR_LOW_MOUNTED_WORK_LIGHTS	Tractor Work Lights (Rear, Low Mounted)
TRACTOR_REAR_HIGH_MOUNTED_WORK_LIGHTS	Tractor Work Lights (Rear, High Mounted)
TRACTOR_SIDE_LOW_MOUNTED_WORK_LIGHTS	Tractor work lights (side, low)
TRACTOR_SIDE_HIGH_MOUNTED_WORK_LIGHTS	Tractor work lights (side, high)
TRACTOR_FRONT_LOW_MOUNTED_WORK_LIGHTS	Tractor work lights (front, low)
TRACTOR_FRONT_HIGH_MOUNTED_WORK_LIGHTS	Tractor work lights (front, high)
IMPLEMENT_OEM_OPTION_2_LIGHT	Attachment OEM Option 2 Light
IMPLEMENT_OEM_OPTION_1_LIGHT	Attachment OEM Option 1 Light
IMPLEMENT_RIGHT_FORWARD_WORK_LIGHTS	Attachment work lights (front right)
IMPLEMENT_LEFT_FORWARD_WORK_LIGHTS	Attachment work light (front left)
IMPLEMENT_RIGHT_FACING_WORK_LIGHTS	Attachment work light (side right)
IMPLEMENT_LEFT_FACING_WORK_LIGHTS	Attachment work light (side left)
IMPLEMENT_REAR_WORK_LIGHTS	Attachment work light (rear)
TIMEOUT	Timeout status of the internal core (Boolean signal).

• – ◦ • – ◦ • – ◦ •

Functionality

The function block is initialized via the event input `INIT` with the data value `QI`. Upon successful initialization, the event `INITO` is output, and the data `QO = TRUE` and `STATUS` are set with a success message.

Internally, the module contains a core of type `isobus::tecu::I_Lighting`, which handles the ISOBUS communication for the lighting PGN (Parameter Group Number 65088). The core provides the 32 lighting functions as 32-bit integer values. These integer values are then divided into individual Boolean signals by instances of the module `logiBUS::utils::quarter::QUARTER_TO_BOOL`. Each `QUARTER_TO_BOOL` instance presumably extracts 4 bits from the input value and outputs the corresponding four Boolean outputs – however, the exact structure is application-specific.

The resulting Boolean signals are then provided via the adapter plugs simultaneously with an event (`E1`) on the associated data outputs (`D1`). Thus, when the ISOBUS data is updated, the module provides a synchronous event stream for each individual lighting function.

• – ◦ • – ◦ • – ◦ •

Technical Features

- **ISOBUS Compliance**: The module implements the standardized PGN 65088 (Lighting Data) according to ISO 11783-7 and can be directly connected to an ISOBUS bus.
- **Bit Division**: The internal 32-bit values from the ISOBUS telegram are divided into individual Boolean signals using `QUARTER_TO_BOOL` modules. The term “quarter” indicates a division into groups of 4 bits each.

- **Unidirectional Adapters**: Each adapter plug is unidirectional (output only) and provides both an event (`E1`) and a Boolean value (`D1`). This allows for easy further processing in IEC 61499 applications, e.g., for controlling actuators.
- **Status Output**: In addition to the actual light status, there is a special adapter, `TIMEOUT`, which signals the timeout status of the ISOBUS core.

• – ◦ • – ◦ • – ◦ •

State Overview

The module itself does not have an explicit state machine, as it is essentially a data converter. Its behavior is controlled by the internal kernel `I_Lighting`:

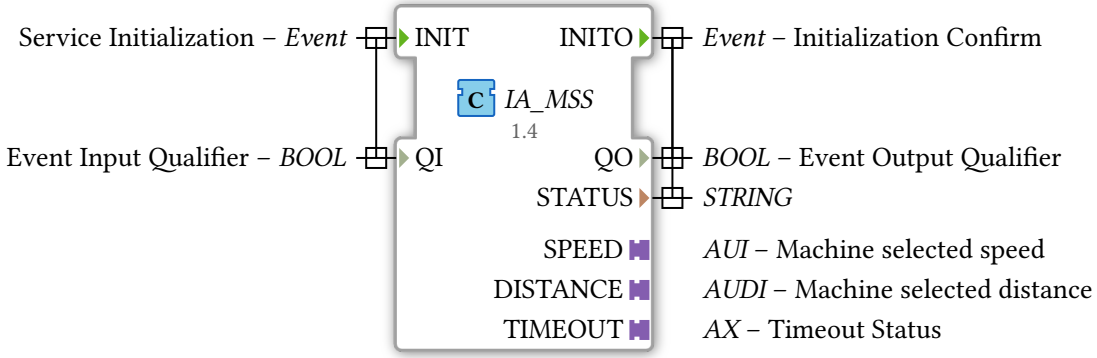
- **Initialization**: After a `INIT` event, the kernel switches to the operational state (provided `QI = TRUE` is present). The process is completed with `INITO`.Acknowledged.
- **Data Provisioning**: As long as the core is active, it updates the output data with each incoming ISOBUS telegram and generates an event on the corresponding adapter for each lighting function.
- **Timeout**: The timeout adapter is set if no ISOBUS messages are received.

• – ◦ • – ◦ • – ◦ •

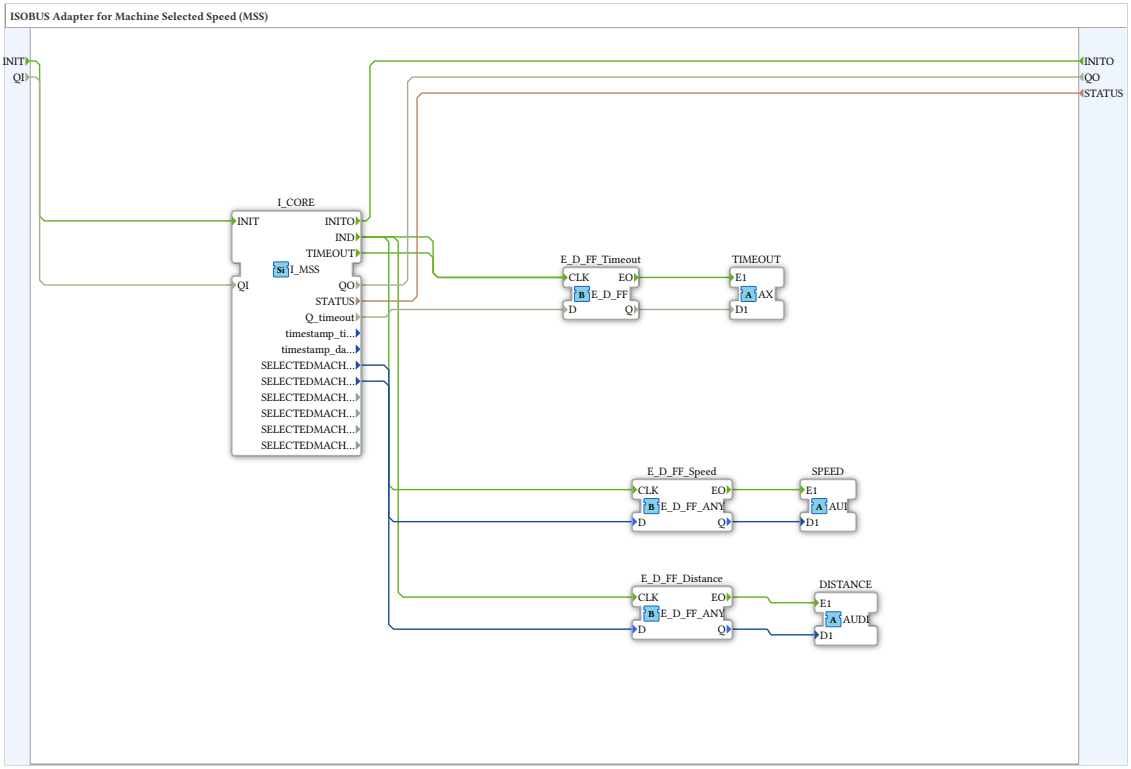
Application Scenarios

- **Agricultural Control Systems**: Integration of all vehicle lighting (tractor and implement) into an IEC 61499-based control system, e.g., for automatic lighting control according to ISO 11783.
- **ISOBUS Gateway Modules**: This module is suitable as an intermediary layer to convert ISOBUS lighting data into a simpler binary signal format and thus transmit it to programmable logic controllers (PLCs) or visualization systems.
- **Retrofit**: Older tractors without a CAN bus can be equipped with modern ISOBUS lighting control using this adapter.

• – ◦ • – ◦ • – ◦ •



Comparison with similar modules



Other ISOBUS adapter wrappers exist for other PGNs (e.g., for work hydraulics, seat control, or PTO control). These modules follow the same principle: An internal, specialized core is connected to the application code via an adapter. The main difference lies in the number and type of output signals – `IA_Lighting` offers a particularly high number of lighting functions with 32 adapters. Other adapters (e.g., `IA_ImplementSteer`) have fewer outputs because they report only a few states.

Conclusion

The function block `IA_Lighting` enables convenient and standardized integration of ISOBUS lighting data into IEC 61499 applications. By splitting the telegram content into individual Boolean signals via adapters, simple further processing in the application logic is achieved. This module is particularly suitable for agricultural control systems that require a complete representation of all common lighting functions according to ISO 11783-7.

IA_MSS

• — ○ • — ○ • — ○ •

Introduction

The **IA_MSS** function block represents an ISOBUS adapter for machine-selected speed (MSS). It encapsulates the communication with the underlying ISOBUS protocol (PGN 61474) and provides the determined values for speed, distance traveled, and timeout status via standardized adapter interfaces. The block is typically embedded in an ISOBUS-compatible control unit (TECU) and enables easy integration into IEC 61499-based automation systems.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Service Initialization; is triggered by the data input `QI`.

Event Outputs

Event	Type	Description
INITO	EInit	Initialization confirmation; outputs the data `QO` and `STATUS`.

Data Inputs

Variable	Type	Description
QI	BOOL	Qualifier for the initialization input.

Data Outputs

Variable	Type	Description
QO	BOOL	Qualifier for the initialization output.

STATUS	STRING	Initialization status message.

Adapter

Adapter	Type	Description
SPEED	adapter::types::unidirectional::AUI	Output for the machine-selected speed (value of type `AUI`).
DISTANCE	adapter::types::unidirectional::AUDI	Output for the machine-selected distance (value of type `AUDI`).
TIMEOUT	adapter::types::unidirectional::AX	Output for the timeout status (value of type `AX`).

Functionality

The **IA_MSS** block is implemented as a pure adapter wrapper. Internally, it contains an instance of the function block `isobus::tecu::I_MSS` (*I_CORE*), which implements the actual ISOBUS logic. The external interfaces of the adapter are mapped to the internal component via event and data connections:

1. **Initialization** – An event on `INIT` (with `QI` set) activates `I_CORE.INIT`. After successful initialization, `INITO` is triggered, which forwards the qualifiers `QO` and `STATUS` to the adapter's outputs.
2. **Data Provision** – The internal module provides the selected speed (`SELECTEDMACHINESPEED`), the distance (`SELECTEDMACHINEDISTANCE`), and the timeout status (`Q_timeout`). These values are output via the adapters `SPEED`, `DISTANCE`, and `TIMEOUT` as soon as the corresponding events (`IND` and `TIMEOUT`, respectively) occur.

The adapter thus provides a clean separation between ISOBUS communication and the application level.

Technical Features

- **Standard Compliance** – The module is based on the ISOBUS standard ISO 11783-7 (PGN 61474) for machine-selected speed.
- **Unidirectional Adapters** – The outputs `SPEED`, `DISTANCE`, and `TIMEOUT` are defined as unidirectional adapters (types `AUI`, `AUDI`, `AX`). They only transmit data from the module to the calling application; feedback is not provided.
- **Adapter Wrapper** – The internal logic is fully encapsulated in component `I_CORE`. `IA_MSS` is used exclusively for interface adaptation and event forwarding.
- **Error Handling** – The initialization status is signaled via `STATUS` (STRING) and `QO` (BOOL). Any timeout is reported via the `TIMEOUT` adapter.

State Overview

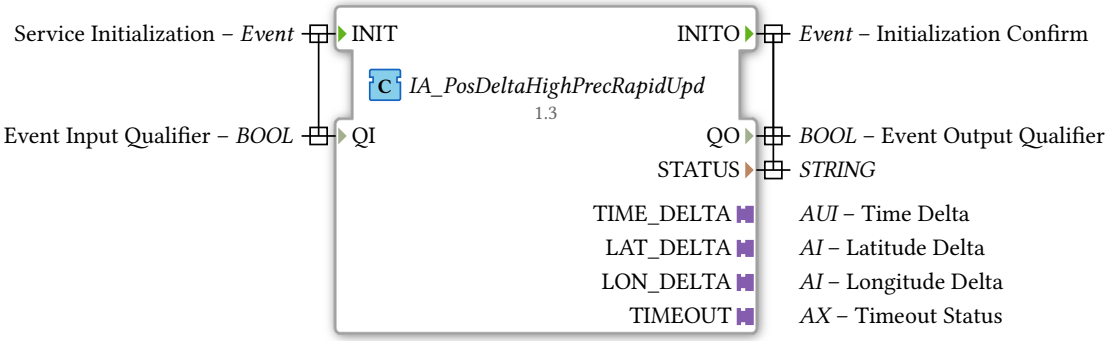
Since the function block does not have its own execution state (ECC), the state results from the interaction of input and output events:

State	Description
Not Initialized	After system startup or after a failed initialization. `INIT` can be triggered.
Initialized	After successful execution of `INIT` ⟶ `INITO` with `QO` set. The adapters deliver valid values.
Error/Timeout	If the internal initialization fails or a timeout is detected, this is signaled via `STATUS` and the `TIMEOUT` adapter.

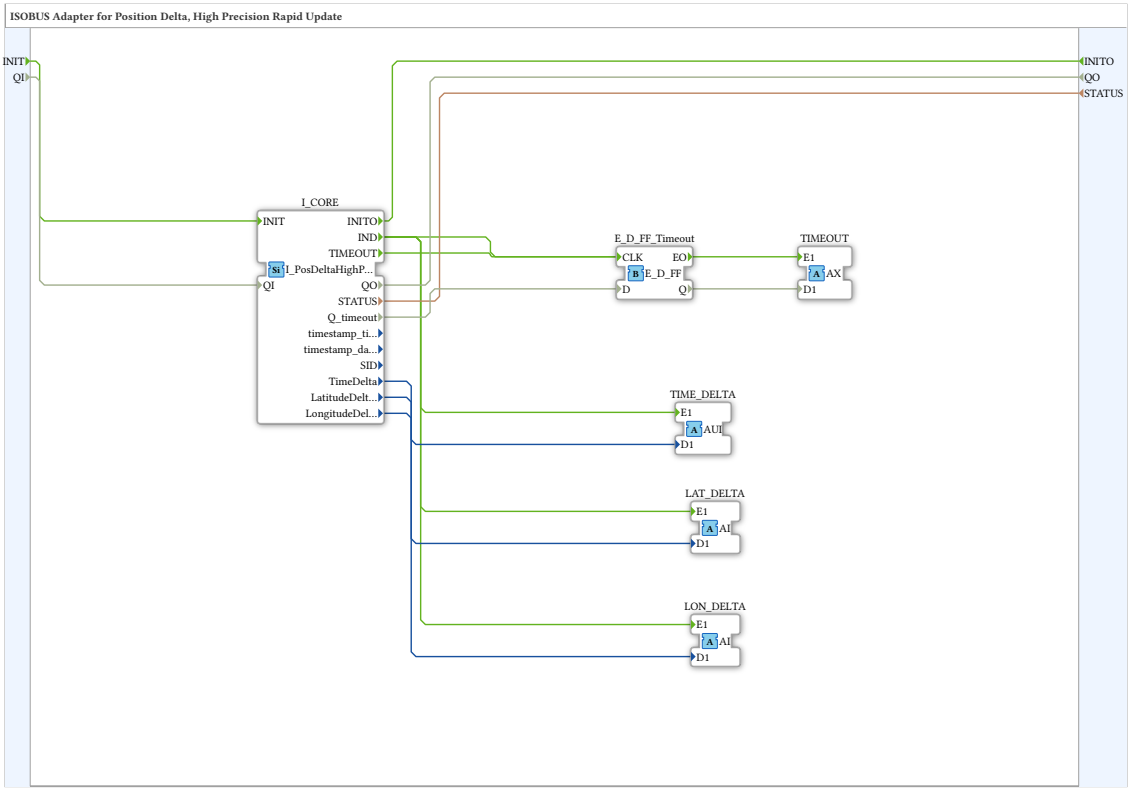
Application Scenarios

- **ISOBUS Control Units (TECU)** – Integration into agricultural machinery to read the speed provided by the tractor or implement.
- **Traction Control** – Use of the selected speed for site-specific applications (e.g., fertilization, crop protection).
- **Distance and Path Measurement** – Evaluation of the distance traveled for controlling working widths or for documentation purposes.

- **Communication Monitoring** – Detection of timeout situations in the ISOBUS network via the `TIMEOUT` adapter.



Comparison with Similar Modules



- **I_MSS (Direct)** – The internal module `I_CORE` of type `isobus::tecu::I_MSS` offers the same functionality, but without adapter interfaces. `IA_MSS` facilitates integration into systems based on standardized adapters (AUI, AUDI, AX).
- **Other ISOBUS Adapters** – Numerous adapters exist for other PGNs (e.g., for GPS, working width, engine speed). `IA_MSS` is specifically designed for machine-selected speed.

Conclusion

The **IA_MSS** block is a practical adapter wrapper for the ISOBUS "Machine Selected Speed" data set. It abstracts the communication with the ISOBUS protocol and provides the relevant parameters (speed, distance, timeout) via standardized unidirectional adapters. This enables simple and reusable integration into IEC 61499 applications for agricultural machinery. The block is standards-compliant, robust thanks to timeout monitoring, and particularly suitable for use in TECU-based controllers.

IA_PosDeltaHighPrecRapidUpd

• – ○ • – ○ • – ○ •

Introduction

The function block `IA_PosDeltaHighPrecRapidUpd` is an ISOBUS adapter module for high-precision, rapidly updated position deltas according to the NMEA 2000 standard (PGN 129027). It encapsulates the internal core module `I_PosDeltaHighPrecRapidUpd` and makes its output data available via adapter interfaces. This allows position changes (time, latitude, and longitude deltas) as well as a timeout status to be seamlessly integrated into automation systems.

Interface Structure

Event Inputs

Event	Type	Description
`INIT`	EInit	Initialize the function block; used with `QI`.

Event Outputs

Event	Type	Description
`INITO`	EInit	Initialization confirmation; returns `QO` and `STATUS`.

Data Inputs

Name	Type	Description
`QI`	`BOOL`	Qualifier for INIT event.

Data Outputs

Name	Type	Description
`QO`	`BOOL`	Output qualifier (Initialization successful?).
`STATUS`	`STRING`	Initialization status message.

Adapters

Adapter name	Type (Adapter)	Description
`TIME_DELTA`	`adapter::types::unidirectional::AUI`	Returns the time delta (unsigned integer).
LAT_DELTA`	`adapter::types::unidirectional::AI`	Returns the latitude delta (signed integer).
LON_DELTA`	`adapter::types::unidirectional::AI`	Returns the longitude delta (signed integer).
TIMEOUT`	`adapter::types::unidirectional::AX`	Indicates whether a timeout occurred (Bool).

Functionality

This function block acts as a wrapper around the internal function block `I_PosDeltaHighPrecRapidUpd`. The kernel is initialized when a `INIT` event occurs with a set `QI`. After successful initialization, the kernel reports back with `INITO` and delivers `QO = TRUE` along with a corresponding status. As soon as new position data arrives, the kernel generates the event `IND` (internal, not directly visible), which forwards the data to the three delta adapters. Simultaneously, if a timeout occurs, the event `TIMEOUT` is triggered, and the corresponding adapter is updated.

... The internal data connections ensure that the values from `TimeDelta`, `LatitudeDelta`, `LongitudeDelta`, and `Q_timeout` are transferred to the corresponding adapter data port `D1`.

Technical Features

- **Standard Compliance**: The module implements NMEA 2000 PGN 129027 – "Position Delta, High Precision Rapid Update".
- **Adapter-Based**: The output data is provided via flexible, unidirectional adapters, allowing direct connection to other modules in a 4diac system.
- **High Precision & Update Rate**: Optimized for applications requiring accurate and rapid position changes (e.g., in agriculture or vehicle navigation).
- **Initialization with Status**: The function block provides an explicit initialization confirmation (QO, STATUS) and can therefore be integrated into safety-critical processes.

State Overview

The function block does not have an explicit finite state machine (ECC) in its XML definition. Its behavior is entirely controlled by the internal core function block `I_PosDeltaHighPrecRapidUpd`:

1. **Wait for Initialization**: After system startup, `QI = FALSE` is present; `INIT` is not triggered.
2. **Start Initialization**: Upon the `INIT` event with `QI = TRUE`, the core is activated.
3. **Initialization Confirmed**: The core reports `INITO` with `QO = TRUE` and a positive status; data provisioning then begins.
4. **Data Update**: With each new position delta, the adapters are automatically updated with the current values.
5. **Timeout**: If no more valid data is received, the core sets `Q_timeout = TRUE` and triggers the `TIMEOUT` event.

Application Scenarios

- **Precision Agriculture**: Monitoring of position changes of a tractor or agricultural machine in real time (e.g., for steering systems or application maps).
- **Vehicle Navigation**: Processing of high-precision GNSS deltas in autonomous vehicles.
- **ISOBUS Integration**: Connection to existing ISOBUS control units based on PGN 129027.
- **Safety Monitoring**: Detection of data failures via the timeout adapter.

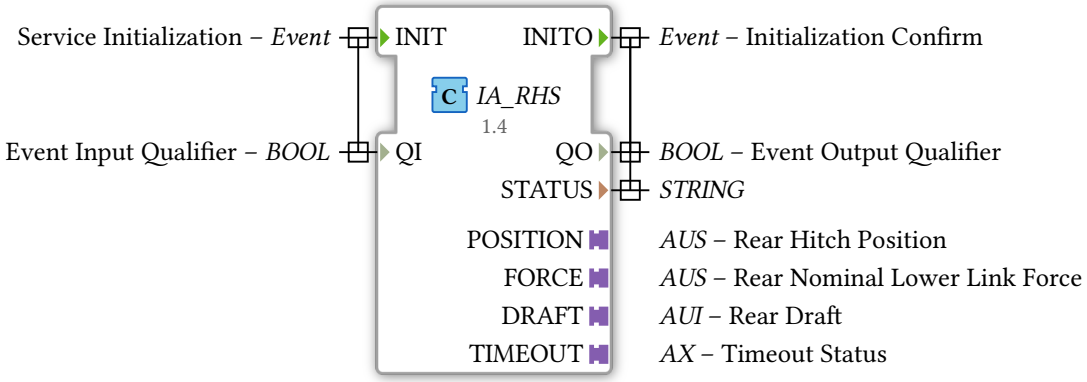
Comparison with Similar Modules

Similar ISOBUS adapter modules (e.g., `IA_PosSpeed` or `IA_TimeDate`) also encapsulate specific PGNs and provide their data via adapters. The `IA_PosDeltaHighPrecRapidUpd` differs in that:

- Specialization in **position deltas** (not absolute positions)
- Support for **time, latitude, and longitude deltas** as well as a separate **timeout** signal
- Focus on high **precision** and fast **update rates**

Other modules often only provide a single measurement or lack timeout monitoring.

Conclusion



The `IA_PosDeltaHighPrecRapidUpd` is a specialized ISOBUS adapter for high-precision position changes according to NMEA 2000 PGN 129027. It offers a standards-compliant, adapter-based interface that integrates seamlessly into 4diac systems. Thanks to its integrated timeout detection and explicit initialization confirmation, it is particularly suitable for safety-critical automation solutions in agriculture and automotive engineering.

IA_RHS

• – ○ • – ○ • – ○ •

Introduction

The function block **IA_RHS** (ISOBUS Adapter for Rear Hitch Status) serves as an interface between the ISOBUS system (according to ISO 11783-7, PGN 65093) and an application network. It encapsulates the communication with the internal module I_RHS and provides the measured rear hitch data (position, force, tractive force) as well as the timeout status via standardized, unidirectional adapters. This module is primarily used in tractor and agricultural machinery control systems.

Interface Structure

Event Inputs

Name	Type	Comment	With Data
INIT	EInit	Service Initialization	QI

Event Outputs

Name	Type	Comment	With Data
INITO	EInit	Initialization Confirm	QO, STATUS

Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Status Message

Adapters

Name	Type	Comment
POSITION	OFF	Rear Hitch Position
FORCE	OFF	Rear Nominal Lower Link Force
DRAFT	AUI	Rear Draft
TIMEOUT	AX	Timeout Status

Functionality

The function block is activated by the **INIT** event. The qualifier signal **QI** is then forwarded to the internal function block **I_RHS**. After successful initialization (or an error), the function block reports back via the **INITO** event and outputs the **QO** and **STATUS** signals. Simultaneously, the data supplied by I_RHS (position, lower link force, draft force) is applied to the corresponding adapters **POSITION**, **FORCE**, and **DRAFT**. The timeout status of I_RHS is output via the **TIMEOUT** adapter. The adapters each use a unidirectional data format (e.g., OFF for analog, unscaled values). Output to the adapters occurs via a separate event (through internal connections of I_CORE.IND). This allows a receiving module to react to the arrival of new data.

Technical Features

- The module is based on the ISOBUS standard ISO 11783-7 and uses PGN 65093.
- The internal calculations and ISOBUS communication are performed entirely by the **I_RHS** module. IA_RHS serves solely as an adapter wrapper for providing data to the 4diac network.
- All four adapters are unidirectional (output), meaning data is only sent but not received by the connected module.
- Data output to the adapters occurs simultaneously with the **IND** event (internal), which originates from I_RHS.
- Timeout information is provided separately from the main data path.

State Overview

This function block does not have explicitly modeled states. Its behavior is determined by the internal function block I_RHS:

- **Initialization (INIT)**: The qualifier QI controls activation.
- **Operation**: After successful initialization, I_RHS cyclically or event-driven delivers new data to the adapters.
- **Error/Timeout**: A timeout is signaled via the TIMEOUT adapter, and the status is output as text via the **STATUS** output.

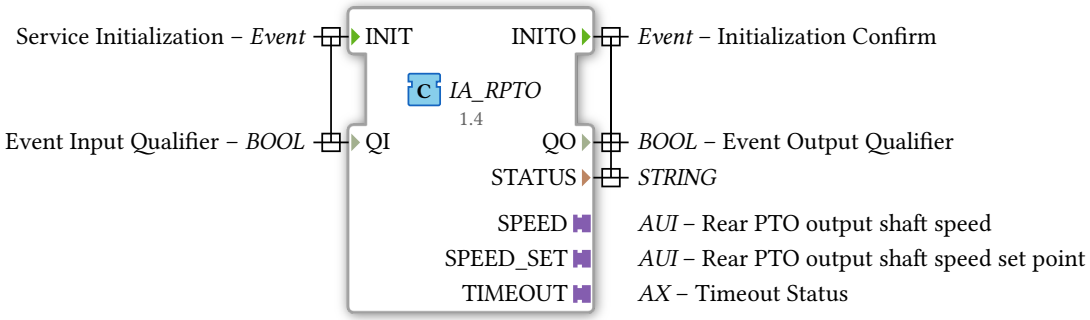
Application Scenarios

- **Tractor Control with ISOBUS Connection**: Reading the rear linkage data (hitch status) from an ISOBUS-compatible terminal or control unit and forwarding it to a higher-level controller.
- **Agricultural Implements**: Connecting implements that require the rear linkage position or force (e.g., plow depth control).
- **Diagnostics and Monitoring**: Recording timeout status and system status for maintenance and fault analysis.

Comparison with Similar Modules

Unlike a general ISOBUS receiver (e.g., a raw PGN parser), **IA_RHS** abstracts the ISOBUS-specific message processing and provides the data in standardized adapter formats. Compared to a direct I_RHS module, IA_RHS offers the advantage that data output is via separate adapters, enabling loose coupling in the network and easier reuse. Modules such as **IA_RHC** (Rear Hitch Control) or **IA_PTO** follow a similar adapter concept but are designed for other ISOBUS functions.

Conclusion



The IA_RHS module is a practical, standards-compliant encapsulation of the rear hitch status according to ISO 11783-7. It simplifies the integration of ISOBUS data into a 4diac-based control system by hiding the complex bus interface behind easy-to-use adapters. The division into multiple data adapters and the provision of a timeout status make it flexibly applicable to various agricultural technology applications.

]

IA_RPTO

Introduction

The IA_RPTO function block is an ISOBUS adapter for the rear power take-off (RPTO) according to ISO 11783-7 (PGN 65091). It provides an encapsulated interface to an internal I_RPTO function block and outputs the most important parameters (speed, setpoint, timeout status) via adapter ports.

Interface Structure

Event Inputs

Name	Type	Comment	With Data
INIT	EInit	Service Initialization	QI

Event Outputs

Name	Type	Comment	With Data
INITO	EInit	Initialization Confirm	QO, STATUS

Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Status Message

Adapter

Name	Type	Comment
SPEED	adapter::types::unidirectional::AUI	Rear PTO output shaft speed

SPEED_SET	adapter::types::unidirectional::AUI	Rear PTO output shaft speed set point
TIMEOUT	adapter::types::unidirectional::AX	Timeout Status

Functionality

This function block internally instantiates a `I_RPTO` block, which handles the actual ISOBUS communication for the rear PTO shaft. Initialization is triggered via an INIT event; upon successful execution, INITO acknowledges with QO = TRUE and a corresponding STATUS. The values `REAR_PTO_OUTP_SHAFT_SPEED`, `REAR_PTO_OUTP_SH_SPEED_SET`, and `Q_timeout` of the inner block are forwarded directly to the corresponding adapter ports SPEED, SPEED_SET, and TIMEOUT.

Technical Specifications

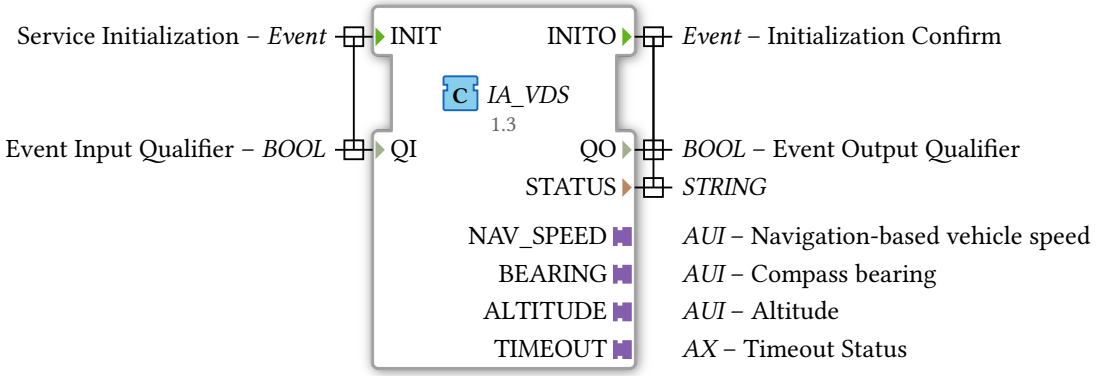
– The block operates according to ISO 11783-7 (PGN 65091) and is intended for use in agricultural control units (tractor ECUs).
  – All adapters are unidirectional (AUI, AX), meaning they only transmit data in one direction.
  – The inner block is from the package `isobus::tecu`.
  – License: Eclipse Public License 2.0.

State Overview

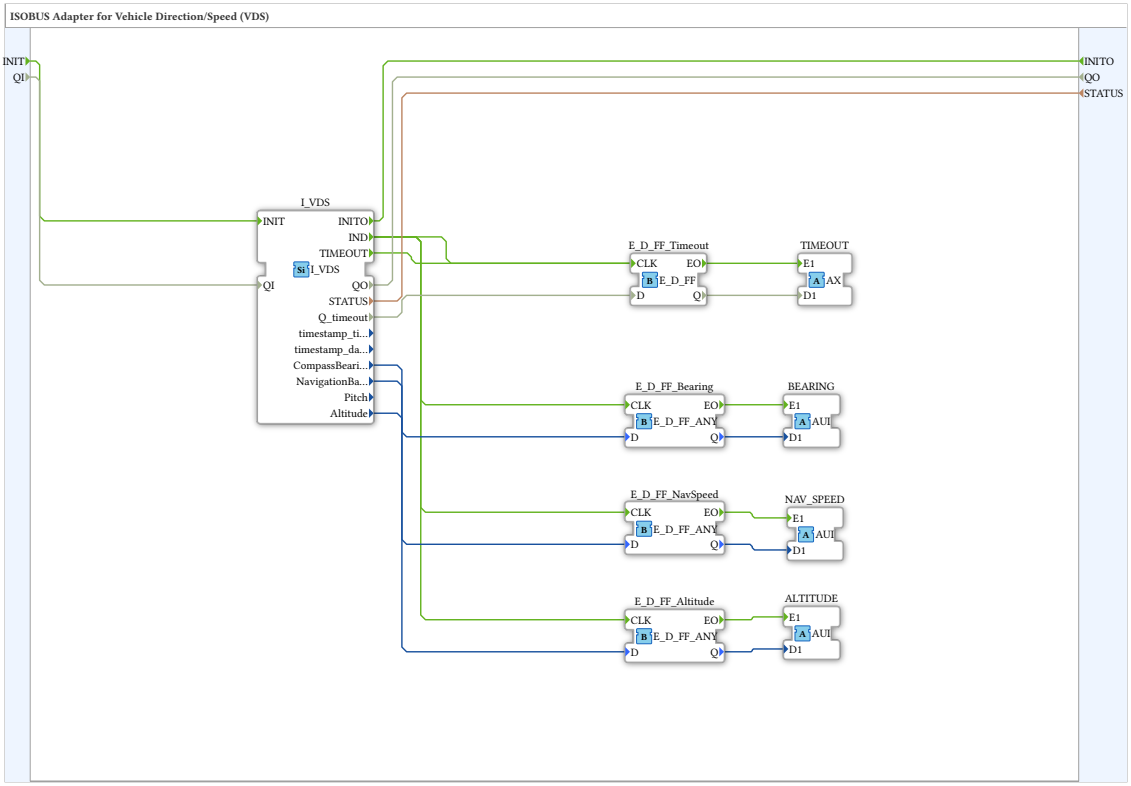
The function block has two main states: **not initialized** and **initialized**. Upon receiving INIT, the inner block performs the initialization. Upon success, QO = TRUE is set and the STATUS displays a positive value. If an error or timeout occurs, this is signaled via the TIMEOUT adapter and the STATUS. A detailed state diagram is not included as part of the outer description, as all logic is implemented within the inner block.

Application Scenarios

– Integration of an ISOBUS-compatible rear PTO into a tractor control unit.
  – Monitoring and control of the PTO speed via the ISOBUS network.
  – Time monitoring of data communication to detect connection interruptions.



Comparison with Similar Blocks



Related adapter blocks exist for other ISOBUS functions, e.g., IA_FPTO (front PTO), IA_HITCH (lift mechanism), or IA_TSC (tractor control). The main difference lies in the PGN (65091) used and the specific data points (speed, setpoint, timeout). IA_RPTO thus offers an interface specifically tailored to the rear PTO.

Conclusion

IA_RPTO encapsulates the ISOBUS communication for the rear PTO and provides the relevant information via clearly defined adapter ports. The module simplifies integration into IEC 61499 applications and ensures standards-compliant connection according to ISO 11783-7.

IA_VDS

• — ○ • — ○ • — ○ •

Introduction

The **IA_VDS** function block is an ISOBUS adapter for vehicle direction and speed according to ISO 11783-7 (PGN 65256). It encapsulates access to the corresponding CAN bus data and provides it as modern 4diac adapter interfaces. The block is initialized via an INIT event and subsequently provides continuous navigation speed, compass direction, altitude, and a timeout status.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initializes the block. Expects the qualifier QI.

Event Outputs

Event	Type	Description
INITO	EInit	Confirms successful initialization. Returns QO and STATUS.

Data Inputs

Name	Type	Description
QI	BOOL	Event Input Qualifier (TRUE = Initialization active).

Data Outputs

Name	Type	Description
QO	BOOL	Event Output Qualifier (TRUE = Initialization OK).
STATUS	STRING	Message text (e.g., error description or “Ready”).

Adapter

Adapter	Type	Description
NAV_SPEED	AUI	Navigation-based vehicle speed (unidirectional, receiver).
BEARING	AUI	Compass direction (unidirectional, receiver).
ALTITUDE	AUI	Altitude above sea level (unidirectional, receiver).
TIMEOUT	AX	Timeout status (unidirectional, receiver).

All adapters are implemented as plugs (outgoing) – the IA_VDS sends the data to the connected sinks.

Functionality

The module internally contains another function block, **I_VDS** (from the library `isobus::tecu`), which handles the actual ISOBUS communication. Upon arrival of the INIT event, the initialization of I_VDS is triggered. After successful initialization, I_VDS reports this via its INITO event, which is forwarded to the INITO output of IA_VDS. Simultaneously, I_VDS begins cyclically updating the values for NavigationBasedVehicleSpeed, CompassBearing, and Altitude. These values are output via the corresponding adapters (NAV_SPEED, BEARING, ALTITUDE) as soon as the IND event from I_VDS arrives. If a timeout occurs (e.g., a CAN bus error), this is reported via the TIMEOUT adapter.

Technical Features

- The module is based on the **Eclipse Public License 2.0 (EPL-2.0)** and is designed as an ISOBUS adapter for PGN 65256.
- Data is distributed asynchronously to the adapter outputs via dedicated events (IND), enabling decoupled processing in the 4diac environment.
- The internal block I_VDS is implemented in the `isobus::tecu` library and optimized for direct bus access.
- The timeout status is provided by a dedicated adapter (type AX) to clearly separate error handling from the normal data stream.

State Overview

The IA_VDS does not have an explicit state machine; its behavior is determined by the internal I_VDS:

1. **Initial** – No INIT signal has been received yet.
2. **Initialization in progress** – After INIT, as long as I_VDS is not yet ready.
3. **Active** – After successful initialization (INITO = TRUE). Values are updated regularly.
4. **Error** – In case of timeout or invalid bus data (STATUS contains an error message, QO = FALSE).

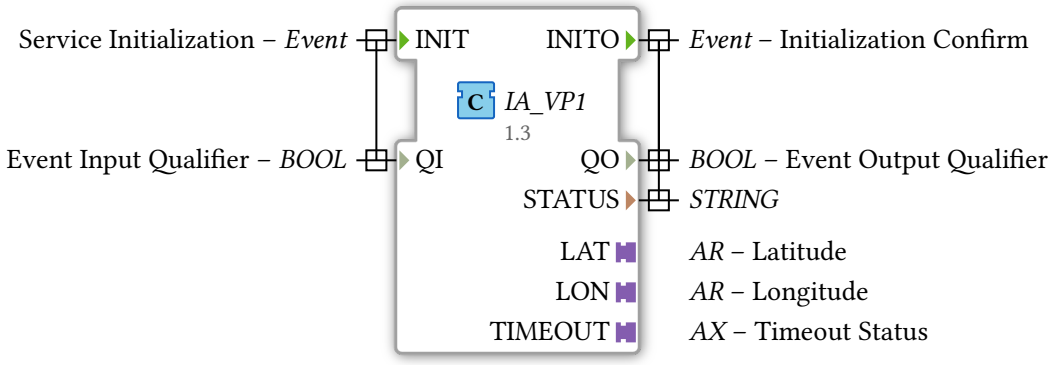
Application Scenarios

- **Agricultural Machinery Control** – Integration of driving speed, direction, and height into control logic (e.g., for site-specific applications).
- **ISOBUS Network Connection** – As an adapter in 4diac applications that use ISOBUS data from a tractor or harvester.
- **Telemetry Systems** – Forwarding of VDS data to higher-level systems (cloud, display).

Comparison with Similar Modules

- **I_TC** (ISOBUS Tractor Control) – Provides general tractor data (speed, PTO speed, linkage) via similar adapters, but not specifically the VDS-PGN.
- **I_GNSS** (ISOBUS GNSS Adapter) – Provides GPS-based position data, but without a focus on direction/speed via CAN.
- **IA_VDS** is specialized for pure vehicle direction/speed information (PGN 65256) and has a particularly streamlined interface.

Conclusion



The **IA_VDS** is a practical module for easily integrating ISO-11783-7-specific vehicle data (direction/speed) into a 4diac application. The adapter-based output keeps the architecture modular and extensible. The division into data and timeout adapters facilitates robust error handling. Ideal for all applications requiring precise, bus-based vehicle dynamics.

]

IA_VP1

• – ○ • – ○ • – ○ •

Introduction

The function block **IA_VP1** is an ISOBUS adapter for Vehicle Position 1 (VP1) according to ISO 11783-7 (PGN 65267). It encapsulates the communication for the vehicle position and provides the received data via unidirectional adapter interfaces for further processing in the 4diac IDE.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Service Initialization

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization Confirm

Data Inputs

Variable	Type	Comment
QI	BOOL	Event Input Qualifier

Data Outputs

Variable	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Status Information

Adapters

Adapter	Type	Comment
LAT	adapter::types::unidirectional::AR	Latitude
LON	adapter::types::unidirectional::AR	Longitude
TIMEOUT	adapter::types::unidirectional::AX	Timeout Status

Functionality

The function block internally contains an instance of the function block `I_VP1` from the library `isobus::tecu`. Upon arrival of the INIT event, initialization is triggered – the qualifier `QI` determines whether initialization is active. After successful initialization, the INITO event is triggered, accompanied by the output data `QO` and `STATUS`.

The actual position data (latitude and longitude) and the timeout status are output via the unidirectional adapters. Each adapter is triggered by an event (e.g., `IND` from the core module) and provides the corresponding data value (`D1`) at the adapter interface.

Technical Features

- **Unidirectional Adapters:** The LAT and LON interfaces use the type `AR`, which provides only one output data value. The TIMEOUT adapter uses the type `AX` for a Boolean timeout status.
- **ISOBUS Compliance:** The module implements the Vehicle Position 1 (VP1) message format according to ISO 11783-7.
- **Latitude/Longitude Provisioning:** The values are passed directly from the internal core block and are available as floating-point numbers in the adapter.
- **Timeout Monitoring:** The TIME OUT adapter signals whether the position data has arrived within the expected time.

State Overview

The block does not have an explicitly displayed state machine. Its behavior is event-driven:

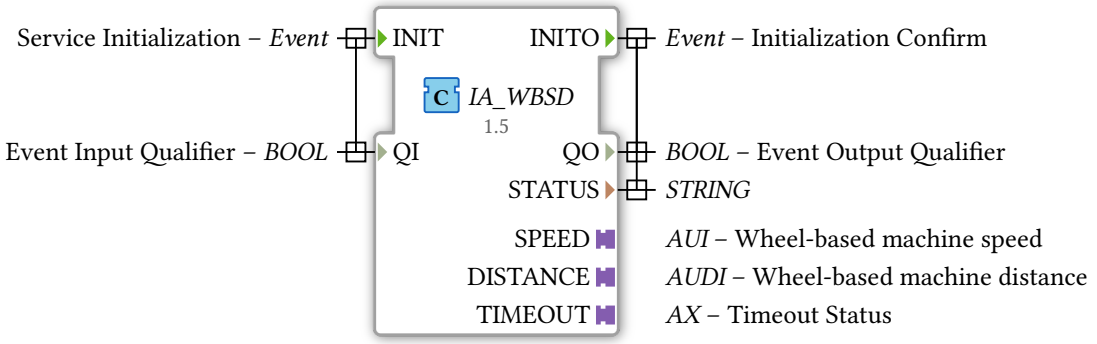
- **Inactive:** No initialization occurs before the INIT event.
- **Initialization:** As soon as INIT arrives with `QI=TRUE`, the initialization sequence is started.
- **Active:** After successful INITO, the position and timeout data are available at the adapters. The data is updated with each new internal event (triggered by the core).
- **Error Case:** The status string and `QO` provide information about errors or timeouts.

Application Scenarios

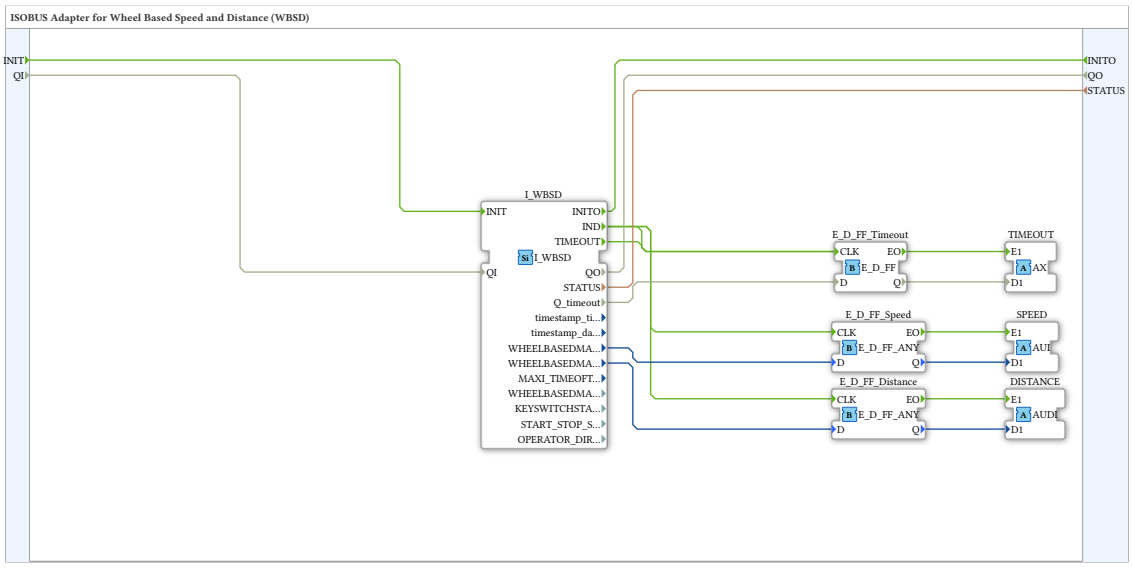
- **Agricultural Vehicles:** Reading the current GPS position (latitude/longitude) via the ISOBUS on-board computer.
- **Precision Agriculture:** Using the position data to control section control, variable application rates, or guidance systems.
- **Documentation and Telemetry:** Recording vehicle movements and position data for fleet management.

Comparison with Similar Modules

- **IA_VP0, IA_GP, IA_PD:** Other ISOBUS position and data adapters (e.g., for speed, machine position). In contrast, IA_VP1 focuses solely on the vehicle position (latitude, longitude) and the timeout status. The data is provided here as unidirectional adapters and not as simple data outputs.
- **I_VP1 (Core Block):** The internal core block offers the same functionality, but without the adapter encapsulation. IA_VP1 makes the interfaces more accessible for the modular 4diac environment.



Conclusion



The **IA_VP1** function block is a practical and standards-compliant block for integrating vehicle position data from ISOBUS into the 4diac world. The use of unidirectional adapters enables clean separation and easy integration into larger automation networks. Thanks to its standards compliance and simple initialization, it is ideally suited for agricultural control systems and IoT applications.

- Eclipse 4diac IDE & Color Reference on ms-muc-docs.de

IA_WBSD

• – ○ • – ○ • – ○ •

Introduction

The function block **IA_WBSD** (ISOBUS Adapter for Wheel Based Speed and Distance) serves as an interface wrapper for ISOBUS communication of wheel-based speed and distance values according to ISO 11783-7. It encapsulates the internal module `I_WBSD` and provides its functionality via standardized adapter connections.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Service Initialization

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization Confirm

Data Inputs

Name	Type	Comment
QI	BOOL	Event Input Qualifier (Initialization Confirmation)

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier (Initialization Result)
STATUS	STRING	Status Message (e.g., Error or Success)

Adapters

Adapter	Type	Comment
SPEED	adapter::types::unidirectional::AUI	Wheel-based machine speed (unidirectional, analog value)
DISTANCE	adapter::types::unidirectional::AUDI	Wheel-based machine distance (unidirectional)
TIMEOUT	adapter::types::unidirectional::AX	Timeout status (unidirectional)

Functionality

The **IA_WBSD** function block is a pure adapter wrapper. It connects the external event and data interfaces as well as the three adapters directly to the internal function block `I_WBSD` (of type `isobus::tecu::I_WBSD`).

- The initialization of the ISOBUS service is triggered via the **INIT** input and the qualifier signal **QI**.
- After successful initialization, **INITO** is triggered and **QO** is set to `TRUE`. **STATUS** contains textual feedback.
- The **SPEED** and **DISTANCE** adapters provide the current measured values for wheel-based speed and distance, respectively.
- The **TIMEOUT** adapter signals whether a timeout has occurred in the ISOBUS communication.

The internal logic (calculation, timeout monitoring, ISOBUS frame handling) is handled entirely by the internal function block `I_WBSD`; **IA_WBSD** makes this available externally as an IEC 61499-compliant adapter interface.

Technical Features

- **Standard:** ISO 11783-7 (ISOBUS) – PGN 65096
- **Development History:**
- Version 1.0: Initial implementation as an adapter wrapper for `I_WBSD`
- Version 1.1: Bug fixes – correct connection between internal pins and adapter plugs through additional conversion blocks
- **Compiler Package:** `isobus::tecu`
- **License:** Eclipse Public License 2.0

- **Author:** - (not named)

State Overview

The block does not have its own explicit state machine. Its behavior is controlled by the internal function block `I_WBSD`:

- **Idle State:** No initialization pending.
- **Initialization Run:** After **INIT** with **QI** = **TRUE**, the internal process is started. If **QI** = **FALSE**, no action is taken.
- **Initialization Complete: INITO** is triggered, **QO** indicates success (`TRUE`) or failure (`FALSE`). Afterward, measured values and timeout status can be continuously received via the adapters.

Application Scenarios

- **Agricultural Machine Control:** Integration of wheel-based speed and distance sensors into an ISOBUS control system (e.g., for tractors, harvesters).
- **Positioning without GPS:** Use of the wheel sensors for relative position determination in field work applications.
- **Monitoring of Driving Cycles:** Acquisition of speed and distance data for diagnostics or process control.

Comparison with Similar Function Blocks

- **IA_WBSD vs. Direct I_WBSD:** The internal function block `I_WBSD` provides the pure ISOBUS implementation, while **IA_WBSD** encapsulates this in an IEC 61499 adapter interface. This facilitates reuse in various tools (e.g., 4diac IDE) and loose coupling with other function blocks.
- **IA_WBSD vs. Other ISOBUS Adapters:** Specific to the PGN 65096 (Wheel Based Speed and Distance). Adapters for other PGNs (e.g., for GPS position or motor speed) have a similar structure but differ in data types and internal interpretation.

IA_WBSD vs. Other ISOBUS Adapters:

Conclusion

The **IA_WBSD** is a practical adapter wrapper for the ISOBUS module `I_WBSD`. It reduces the complexity of integrating wheel-based speed and distance data into IEC 61499 projects and provides the functionality via standardized unidirectional adapters. Thanks to its EPL 2.0 license, it can be freely used and adapted in your own projects. Version 1.1 ensures that all internal connections are correctly routed to the adapter plugs.

I_COGSOGRapidUpdate

• — ○ • — ○ • — ○ •

Introduction

The function block `I_COGSOGRapidUpdate` implements the processing of the NMEA 2000 Parameter Group Number (PGN) 129026 “COG & SOG, Rapid Update”. This block is used to receive and provide navigation data, specifically the current course over ground (COG) and speed over ground (SOG) at a high update rate. It is designed for use in maritime or mobile machinery control systems based on the ISOBUS standard.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block. Triggered together with the qualifier `QI`.

Event Outputs

- **INITO**: Confirms successful initialization. Triggers the outputs `QO` and `STATUS`.
- **IND**: Indicates successful reception and processing of new COG/SOG data. Triggers the corresponding data outputs.
- **TIMEOUT**: Triggered if a timeout occurs during data reception.

Data Inputs

- **QI** (BOOL): Qualifier for the INIT event input. Controls the initialization (`TRUE` = start).

Data Outputs

- **QO** (BOOL): Qualifier for the INITO and IND event outputs. Indicates the general operating status.
- **STATUS** (STRING): Status message providing additional information (e.g., error descriptions).
- **Q_timeout** (BOOL): Indicates whether the last received event was a timeout (`TRUE`) or valid data (`FALSE`).
- **timestamp_timeout** (DINT): Timestamp associated with the TIMEOUT event.
- **timestamp_data** (DINT): Timestamp of the last received valid COG/SOG data.
- **SID** (USINT): Sequence identifier. Enables synchronization of this data with other PGNs sent by the vessel in the same cycle.
- **COGReference** (BYTE): Reference direction for the course over ground. The value `0` represents the "True North" reference. * **CourseOverGround** (UINT): Course over ground (COG). The unit is 1x10 radians.
- **SpeedOverGround** (UINT): Speed over ground (SOG). The unit is 1x10 meters per second.

Adapter

This function block has no adapter interfaces.

Functionality

The block acts as a passive receiver for the NMEA 2000 PGN 129026. After initialization via `INIT` with `QI=TRUE`, it waits for incoming data frames. Upon receiving a valid frame, the contained data (COG, SOG, reference, SID) is decoded and made available via the `IND` output along with the associated data values. Simultaneously, `Q_timeout` is set to `FALSE`. If no new data frame occurs within a configured time window, a `TIMEOUT` event is generated, and `Q_timeout` is set to `TRUE`. The `STATUS` output can be used for diagnostic purposes.
STATUS`

Technical Features

- **NMEA 2000 Compliance**: Implements the specification for PGN 129026 exactly.
- **Resolution**: The physical values for heading and speed are encoded in the fixed resolutions defined in the NMEA standard (COG: 0.0001 rad/LSB, SOG: 0.01 m/s/LSB). Conversion to more common units (degrees, knots) must be performed in subsequent blocks, if necessary.
- **Sequencing**: The `SID` supports the correlation of data sent simultaneously in different PGNs.

Status Overview

1. **Inactive**: Before initialization.
2. **Initialized/Pending**: After successful `INIT`. The module listens on the CAN bus or the corresponding interface on PGN 129026.
3. **Data Reception**: Upon arrival of a frame, the data is processed and a `IND` event is generated.
4. **Timeout**: Activates if expected data does not arrive within the specified time. Triggers a `TIMEOUT` event.

Application Scenarios

- **Maritime Navigation**: Displays current heading and speed on a multifunction display (MFD).
- **Autonomous Control**: Provides basic navigation data for autopilots or routing algorithms of construction machinery.

- **Data Logging**: Logs vehicle movement data with high temporal resolution.
- – **Sensor Fusion**: Combining COG/SOG data with other position and motion sensors (e.g., GNSS, gyroscope) to improve overall accuracy.

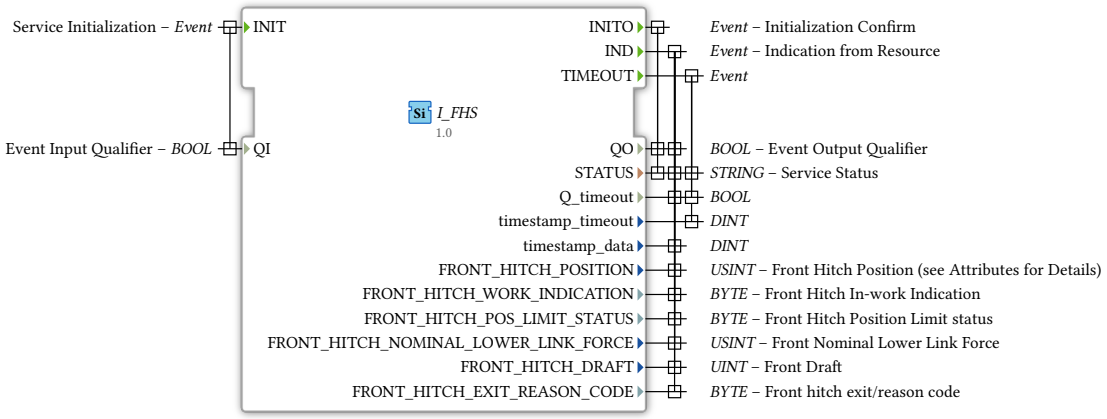
⚖️ Comparison with Similar Components

- **Compared to Generic CAN Receiver Blocks**: `I_COGSOGRapidUpdate` is specialized for PGN 129026. It handles the complete decoding of the raw data according to the NMEA specification and provides the physical values directly. A generic receiver would only deliver the raw bytes.
- **Compared to PGN 129025 (COG/SOG)**: PGN 129026 is the "Rapid Update" variant, optimized for a higher update rate and lower latency, while PGN 129025 can contain additional fields such as timestamps. The choice of function block depends on the application's requirements for data timeliness and scope.

🛠️ Related Exercises

- Exercise_079

Conclusion



The `I_COGSOGRapidUpdate` function block is an essential component for any ISOBUS- or NMEA 2000-based system that relies on precise and rapidly updated course and speed information over ground. Its standards-compliant implementation ensures reliable data exchange and easy integration into higher-level control and display systems.

I_FHS

• – ◦ • – ◦ • – ◦ •

Introduction

The **I_FHS** is a standards-compliant function block for front-mounted implement status information according to ISO 11783-7 (PGN 65094). Developed under the EPL-2.0 license, it enables the monitoring and control of front-mounted implements in modern agricultural systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request

Event Outputs

- `INITO`: Initialization Acknowledgement
- `IND`: Status Indication
- `TIMEOUT`: Timeout Event

Data Inputs

- `QI` (BOOL): Initialization Qualifier

Data Outputs

- `QO` (BOOL): Status Qualifier
- `STATUS` (STRING): Operational Status
- `timestamp_data` (DINT): Timestamp of the data (with `IND`)
- `timestamp_timeout` (DINT): Timestamp of the timeout (with `TIMEOUT`)
- `Q_timeout` (BOOL): Timeout Indicator

Parameters (SPN Details)

Parameter	SPN	Type	Length	Scale	Value Range	Description
FRONT_HITCH_POSITION	1872	USINT	8 bits	0.4%/bit	0-100%	Current Position of Front Attachment
FRONT_HITCH_WORK_INDICATION	1876	BYTE	2 bits	4 States	0-3	Working Status Indicator
FRONT_HITCH_POS_LIMIT_STATUS	5158	BYTE	3 bits	8 states	0-7	Position limit status
FRONT_HITCH_NOMINAL_LOWER_LINK_FORCE	1873	USINT	8 bits	0.8%/bit	−100% to +100%	Normal lower link force
FRONT_HITCH_DRAFT	1878	UINT	16 bits	10 N/bit	−320 kN to +320 kN	Pulling force at front implement
FRONT_HITCH_EXIT_REASON_CODE	5016	BYTE	6 bits	64 states	0-63	Basic code for system shutdown

Functionality

1. **Initialization**:

- Activation via `INIT` event
- Confirmation via `INITO` with status information

1. **Data Update**:

- Automatic status messages via `IND` event
- Contains all relevant front-mounted implement parameters

1. **Error Handling**:

- Timeout detection via `TIMEOUT` event
- Detailed status codes in the `STATUS` field

Technical Features

✓ **ISO 11783-7 compliant** (PGN 65094)
✓ **Real-time** status monitoring ✓ **Comprehensive parameters** for front-mounted implements ✓ **Integrated fault diagnostics**

Application Scenarios

- **Front Loader Control**: Precise Position Control
- **Force Measurement**: Real-time Monitoring of Traction Forces
- **Safety Systems**: Detection of Limit Exceedances
- **Diagnostics**: Systematic Fault Analysis

⚖️ **Comparison with Similar Modules**

Feature	I_FHS	Standard Hitch Control	Advanced Hitch Manager
ISO Standard	✓	✖	✖
Front Mounting	✓	✖	✓
Force Measurement	✓	✓	✓

Diagnostic Codes	✓	✖	✓

🛠️ Related Exercises

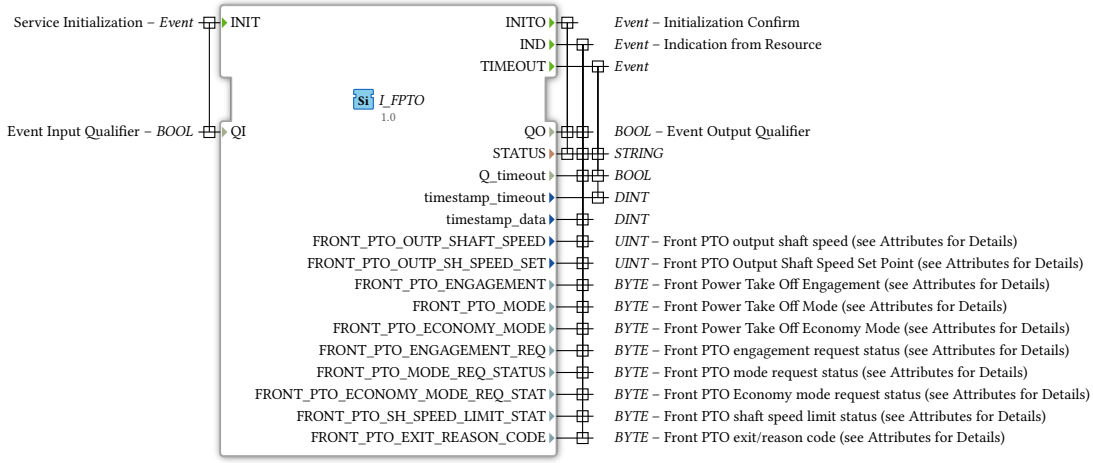
- Exercise_079

Conclusion

The I_FHS module offers comprehensive front implement control:

- **Standard-compliant**: Full ISO 11783-7 compatibility
- **Precise**: High-resolution measurement parameters
- **Reliable**: Integrated fault detection

Essential for:



- Modern front loader systems
- Precision agriculture
- Safety-critical applications

I_FPTO

• – ◦ • – ◦ • – ◦ •

Introduction

The **I_FPTO** is a standards-compliant function block for controlling and monitoring the front power take-off (FPTO) output shaft, developed under the EPL 2.0 license. Version 1.0 implements the ISO 11783-7 specification (PGN 65092) for measuring and controlling FPTO parameters.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with qualifier `QI`)

Event Outputs

- `INITO`: Initialization Confirmation (with status)
- `IND`: Indication Event with all FPTO parameters
- `TIMEOUT`: Timeout Event

Data Inputs

- `QI` (BOOL): Qualifier for Initialization

Data Outputs

- `QO` (BOOL): Qualifier for Output Events
- `STATUS` (STRING): Operating status message
- `Q_timeout` (BOOL): Timeout indicator
- `timestamp_timeout` (DINT): Timeout timestamp

- `timestamp_data` (DINT): Data timestamp

FPTO Parameters

Parameter	Type	Description	SPN	Bit length	Scaling
FRONT_PTO_OUTP_SHAFT_SPEED	UINT	Current FPTO shaft speed	1882	16	0.125 rpm/bit
FRONT_PTO_OUTP_SH_SPEED_SET	UINT	Target speed of FPTO shaft	1884	16	0.125 rpm/bit
FRONT_PTO_ENGAGEMENT	BYTE	FPTO coupling status	1888	2	4 states/2 bits
FRONT_PTO_MODE	BYTE	FPTO operating mode	1889	2	4 states/2 bits
FRONT_PTO_ECONOMY_MODE	BYTE	FPTO economy mode	1891	2	4 states/2 bits
FRONT_PTO_ENGAGEMENT_REQ	BYTE	Coupling request status	5152	2	4 states/2 bits
FRONT_PTO_MODE_REQ_STATUS	BYTE	Mode Request State	5153	2	4 states/2 bits
FRONT_PTO_ECONOMY_MODE_REQ_STAT	BYTE	Economy Mode Request State	5154	2	4 states/2 bits
FRONT_PTO_SH_SPEED_LIMIT_STAT	BYTE	Speed Limit State	5155	3	8 states/3 bits
FRONT_PTO_EXIT_REASON_CODE	BYTE	FPTO Failure Base Code	5817	6	64 states/6 bits

Functionality

1. **Initialization**:

- `INIT` with `QI`=TRUE starts initialization
- `INITO` confirms operational readiness with `QO` and `STATUS`

1. **Data Provision**:

- `IND` provides all FPTO parameters with timestamps
- Automatic updates upon state changes

1. **Error Handling**:

- `TIMEOUT` in case of communication problems
- Detailed status messages in the `STATUS` field

Technical Features

✓ **ISO 11783-7 compliant** (PGN 65092)
✓ **16-bit Speed measurement** with 0.125 rpm resolution ✓ **State control** for clutch and operating modes
✓ **Diagnostic functions** with basic codes

Application scenarios

- **Agricultural machinery**: Control of front PTOs on tractors
- **Speed control**: Precise speed control
- **Condition monitoring**: Real-time diagnostics of the FPTO system
- **Energy efficiency**: Economy mode control

⚖️ **Comparison with similar components**

Feature	I_FPTO	Standard_PTO	Advanced_PTO

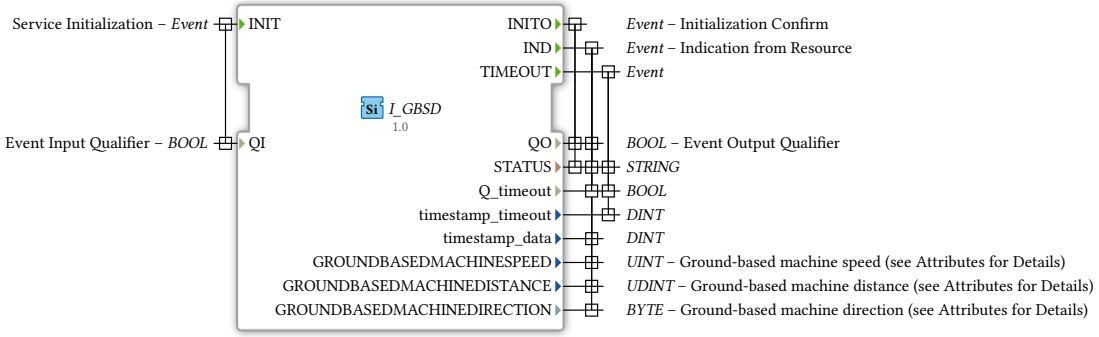
Conclusion

The I_FPTO module offers the standard implementation for front PTO systems:

- **Precise**: High-resolution speed measurement
- **Comprehensive**: Complete condition monitoring
- **Robust**: Integrated fault diagnostics

Ideal for use in:



- Front PTO systems in agricultural machinery
- Applications with high demands on speed accuracy
- Systems with advanced diagnostic requirements

I_GBSD

• – ◦ • – ◦ • – ◦ •

Introduction

The **I_GBSD** (Ground-based Speed and Distance) is a standards-compliant function block for measuring vehicle speed, distance, and direction of travel, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-7 specification (PGN 65097) for precise motion data in agricultural and construction machinery.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with qualifier `QI`)

Event Outputs

- `INITO`: Initialization Acknowledgement (with status)
- `IND`: Data Indication with Speed, Distance, and Direction
- `TIMEOUT`: Timeout Event

Data Inputs

- `QI` (BOOL): Qualifier for Initialization

Data Outputs

- `QO` (BOOL): Qualifier for Output Events
- `STATUS` (STRING): Operational status message
- `Q_timeout` (BOOL): Timeout indicator
- `timestamp_timeout` (DINT): Timeout timestamp
- `timestamp_data` (DINT): Movement data timestamp

Movement data parameters

Parameter	Type	Description	SPN	Bit length	Scale	Accuracy
GROUNDBASEDMACHINESPEED	UINT	Machine speed	1859	16	0.001 m/s per bit	±0.1% at >1 m/s
GROUNDBASEDMACHINEDISTANCE	UDINT	Distance traveled	1860	32	0.001 m per bit	±0.5% cumulative
GROUNDBASEDMACHINEDIRECTION	BYTE	Direction of travel	1861	2	4 states/2 bits	-

Direction of travel states

Value	State	Description
0	Stationary	No movement detected
1	Forward	Moving forward
2	Reverse	Moving backward
3	Undefined	Direction cannot be determined

Functionality

1. **Initialization**:

- `INIT` with `QI`=TRUE starts sensor calibration
- `INITO` confirms operational readiness with system status

1. **Data Update**:

- `IND` delivers all motion data with a 100ms update rate
- Distance measurement as a free-running counter (32-bit)

1. **Special Operating Modes**:

- Automatic accuracy adjustment at low speeds (<0.5 m/s)
- Integrierte Plausibilitätsprüfung der Sensordaten

Technische Besonderheiten

✓ **ISO 11783-7 konform** (PGN 65097) ✓ **Hochpräzise Messung** mit 1mm Auflösung ✓ **32-bit Distanzzähler** (bis zu 4,294,967km Reichweite) ✓ **Robuste Richtungserkennung** mit 4 Zuständen

Anwendungsszenarien

- **Präzisionslandwirtschaft**: Geschwindigkeitskontrolle für Saat- und Düngemittel
- **Flächenberechnung**: Automatische Arbeitsflächenmessung
- **Fahrassistenz**: Richtungserkennung bei Rückwärtsfahrt
- **Telematik**: Betriebsdatenerfassung für Maschinenmanagement

Genauigkeitsmerkmale

Geschwindigkeitsbereich	Typische Genauigkeit	Update-Rate
> 2 m/s (7.2 km/h)	±0.1%	100 ms
0.5 - 2 m/s	±1%	200 ms
< 0.5 m/s	±5%	500 ms

⚖️ **Comparison with similar systems**

Feature	I_GBSD	Wheel-based	GPS-based

Ground contact	✓ Direct	✓ Indirect	✖
Low speed	✓ Good	✖ Inaccurate	✖ Inaccurate
Direction detection	✓ Precise	✓	✖ Ambiguous
Signal loss	Robust	Susceptible	Prone to interference

🛠️ Related exercises

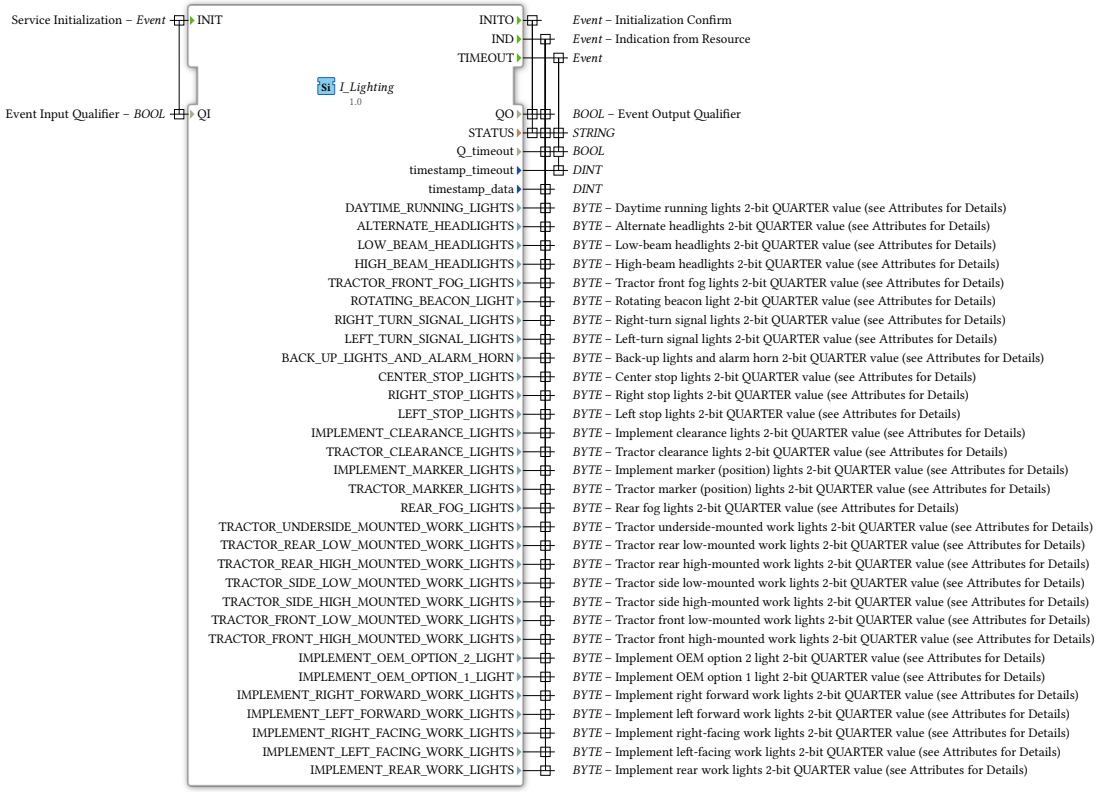
- Exercise_072b
- Exercise_072c
- Exercise_073
- Exercise_079

Conclusion



The I_GBSD module provides reliable motion data for mobile machinery:

- **Precision**: Submillimeter-accurate distance measurement
- **Reliability**: Functionality even under poor GPS conditions
- **Flexibility**: Universal application in agriculture and construction machinery

Ideal for:

- Automatic steering systems
- Working width calculations
- Machines with high accuracy requirements
- Applications with frequent changes of direction

I_Lighting

• — ○ • — ○ • — ○ •

Introduction

The **I_Lighting** function block processes the lighting data of an agricultural vehicle according to ISO 11783-7 (ISOBUS). It receives and decodes the parameter group number (PGN) 65088, which transmits the status of all lighting functions of a tractor and connected implements. The block serves as an interface between the ISOBUS network and the application logic for monitoring and controlling the lighting.

Interface Structure

Event Inputs

Event	Type	Description	Data Carried
INIT	EInit	Initializes the block and activates processing.	QI

Event Outputs

Event	Type	Description	Data Carried
INITO	EInit	Confirms successful initialization.	QO, STATUS
IND	Event	Signals new lighting data from the bus.	QO, timestamp_data, STATUS, Q_timeout, and all 32 luminaire status outputs
TIMEOUT	Event	Triggered when the expected data is not received (timeout).	timestamp_timeout, STATUS, Q_timeout

Data Inputs

Name	Data Type	Description
QI	BOOL	Activation signal for initialization; The function block is started when TRUE.

Data Outputs

Name	Data Type	Description
QO	BOOL	Acknowledgement signal after successful initialization or data processing.
STATUS	STRING	Status message (e.g., error messages or operating instructions).
Q_timeout	BOOL	Signals whether a timeout has occurred (TRUE = Timeout active).
timestamp_timeout	DINT	Timestamp of the last timeout event.
timestamp_data	DINT	Timestamp of the last received lighting data.
32 Lighting Outputs	BYTE	One 2-bit value (QUARTER) for each lighting function. Initial value: 0xFF. - DAYTIME_RUNNING_LIGHTS - ALTERNATE_HEADLIGHTS - LOW_BEAM_HEADLIGHTS - HIGH_BEAM_HEADLIGHTS – TRACTOR_FRONT_FOG_LIGHTS – ROTATING_BEACON_LIGHT – RIGHT_TURN_SIGNAL_LIGHTS – LEFT_TURN_SIGNAL_LIGHTS – BACK_UP_LIGHTS_AND_ALARM_HORN – CENTER_STOP_LIGHTS – RIGHT_STOP_LIGHTS – LEFT_STOP_LIGHTS – IMPLEMENT_CLEARANCE_LIGHTS – TRACTOR_CLEARANCE_LIGHTS – IMPLEMENT_MARKER_LIGHTS – TRACTOR_MARKER_LIGHTS – REAR_FOG_LIGHTS – TRACTOR_UNDERSIDE_MOUNTED_WORK_LIGHTS

		– TRACTOR_REAR_LOW_MOUNTED_WORK_LIGHTS – TRACTOR_REAR_HIGH_MOUNTED_WORK_LIGHTS – TRACTOR_SIDE_LOW_MOUNTED_WORK_LIGHTS – TRACTOR_SIDE_HIGH_MOUNTED_WORK_LIGHTS – TRACTOR_FRONT_LOW_MOUNTED_WORK_LIGHTS – TRACTOR_FRONT_HIGH_MOUNTED_WORK_LIGHTS – IMPLEMENT_OEM_OPTION_2_LIGHT – IMPLEMENT_OEM_OPTION_1_LIGHT – IMPLEMENT_RIGHT_FORWARD_WORK_LIGHTS – IMPLEMENT_LEFT_FORWARD_WORK_LIGHTS – IMPLEMENT_RIGHT_FACING_WORK_LIGHTS – IMPLEMENT_LEFT_FACING_WORK_LIGHTS – IMPLEMENT_REAR_WORK_LIGHTS

Adapter

None.

Functionality

The **I_Lighting** block is activated by the event `INIT`. This prepares the internal processing. After successful initialization, it acknowledges with `INITO`. The function block then waits for incoming ISOBUS messages (PGN 65088). When a valid message arrives, the event `IND` is triggered, and all lighting outputs are updated with the decoded 2-bit values (QUARTER). Simultaneously, a timestamp is stored in `timestamp_data`. If no new data arrives within a configured time period, the event `TIMEOUT` is triggered, and `Q_timeout` is set to TRUE. The function block thus ensures reliable monitoring of the lighting status.

Technical Features

- **ISO 11783-7 Compliance:** The function block implements the parameter group PGN 65088 “Lighting Data LD” according to the ISOBUS standard.
- **2-Bit QUARTER Encoding:** Each light output encodes four states in two bits – typical interpretation: 0 = off, 1 = on, 2 = error, 3 = unavailable. The initial value `16#FF` (decimal 255) corresponds to the “unavailable” state.
- **SPN Attributes:** Each output is provided with detailed metadata (SPN, position in the data telegram, scaling, link to the specification), which facilitates traceability and configuration.
- **Timeout Detection:** The module can detect and report the absence of bus messages, e.g., for error handling or redundant behavior.
- **Timestamps:** Both data arrival and timeouts are timestamped (DINT), enabling analysis over time.

State Overview

The function block does not have an explicit, published state machine. However, its logical behavior can be described as follows:

- **Initialization:** After `INIT`, the function block enters the active state, acknowledged with `INITO`.
- **Ready to Receive:** It waits for incoming messages. Upon receipt ⟶ `IND`, it updates all outputs and resets `Q_timeout`.
- **Timeout Monitoring:** If an internal timer expires without new data arriving, the function block briefly enters the timeout state and signals this via `TIMEOUT`. It then returns to the ready-to-receive state.
- **Error handling:** If an error occurs during decoding, `STATUS`Set accordingly.

Application Scenarios

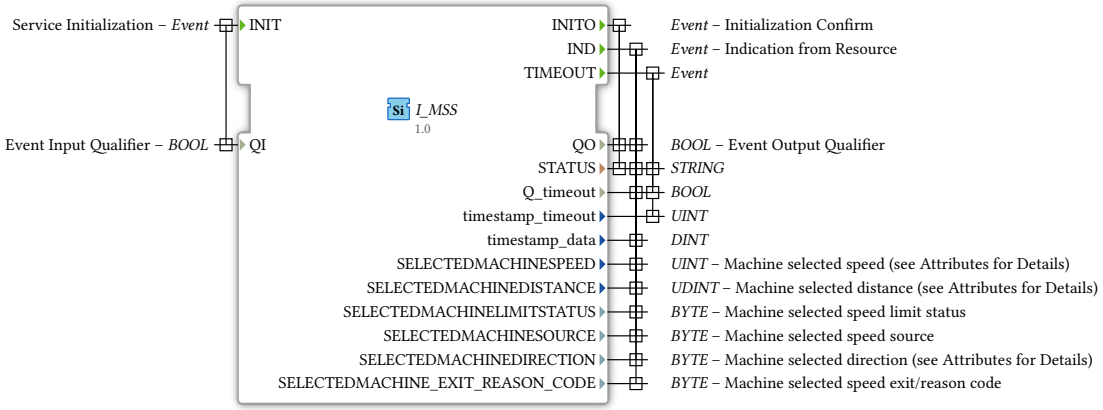
- **Tractor Lighting Control:** Integration into a vehicle control unit (ECU) for monitoring and displaying the lighting status on the terminal.
- **ISOBUS-Compliant Implements:** Use in implements that report their own lighting via the ISOBUS network (e.g., front loaders, rear-mounted implements).
- **Diagnostics and Troubleshooting:** Reading the lighting status and timeouts for fault analysis or logging in the service workshop.
- **Light Control in Automated Systems:** Combination with other modules for automatically adjusting the lighting to ambient conditions (e.g., day/night detection).

Comparison with Similar Modules

Similar ISOBUS modules exist for other parameter groups, e.g., **I_Engine** (engine data), **I_Steering** (steering), or **I_WorkState** (working state). In comparison to these:

- **Specialization: I_Lighting** is focused on lighting and offers a high number of 32 specific lighting outputs.
- **Data Width:** The outputs are BYTE (2 bits used), while other function blocks often use WORD or DWORD.
- **Timeout Handling:** Not all function blocks implement their own timeout detection – here it is explicitly provided.
- **Initial Value:** The outputs start with 0xFF ("not available"), which enables robust initialization without validity conflicts.

Conclusion



The **I_Lighting** function block is a specialized, standards-compliant function block for processing ISOBUS lighting data (PGN 65088). It decodes the status of 32 different lighting functions from the CAN bus and offers reliable timeout monitoring. Thanks to detailed SPN metadata and a simple interface, it is ideally suited for integration into agricultural control systems that require precise and standards-compliant light control.

I_MSS

• – ◦ • – ◦ • – ◦ •

Introduction

The **I_MSS** (Machine Selected Speed) is a standards-compliant function block for controlling and monitoring the machine-selected speed, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-7 specification (PGN 65097) for precise speed control in agricultural and construction machinery.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with qualifier `QI`)

Event Outputs

- `INITO`: Initialization Confirmation (with status)
- `IND`: Indication Event with all speed parameters
- `TIMEOUT`: Timeout Event

Data Inputs

- `QI` (BOOL): Qualifier for Initialization

Data Outputs

- `QO` (BOOL): Qualifier for Output Events
- `STATUS` (STRING): Operating status message
- `Q_timeout` (BOOL): Timeout indicator
- `timestamp_timeout` (UINT): Timeout timestamp

- `timestamp_data` (DINT): Speed data timestamp

Speed parameters

Parameter	Type	Description	SPN	Bit length	Scaling
SELECTEDMACHINESPEED	UINT	Machine speed	4305	16	0.001 m/s/bit (LSB), 0.256 m/s/bit (MSB)
SELECTEDMACHINEDISTANCE	UDINT	Distance Traveled	4306	32	0.001 m/bit
SELECTEDMACHINELIMITSTATUS	BYTE	Speed Limit Status	4307	3	8 states/3 bits
SELECTEDMACHINESOURCE	BYTE	Speed Source	4308	3	8 states/3 bits
SELECTEDMACHINEDIRECTION	BYTE	Direction of Travel	4309	2	4 states/2 bits
SELECTEDMACHINE_EXIT_REASON_CODE	BYTE	Speed Failure Root Code	5818	6	64 States/6 bits

Direction of Travel States

Value	State	Description
0	Stationary	No movement detected
1	Forward	Moving forward
2	Reverse	Moving backward
3	Undefined	Direction cannot be determined

Functionality

1. **Initialization**:

- `INIT` with `QI`=TRUE starts system initialization
- `INITO` confirms operational readiness with `QO` and `STATUS`

1. **Data Provision**:

- `IND` provides all speed parameters with timestamps
- Automatic updates upon state changes

1. **Error Handling**:

- `TIMEOUT` in case of communication problems
- Detailed error codes in `SELECTEDMACHINE_EXIT_REASON_CODE`

Technical Features

✓ **ISO 11783-7 compliant** (PGN 65097)
✓ **Dual Speed Scaling** for High Precision ✓ **Multi-Source Support** (8 possible speed sources) ✓ **Intelligent Limit Detection** with 3-stage status

Application Scenarios

- **Tractors**: Automatic speed adjustment for field work
- **Harvesting Machines**: Precise row length calculation
- **Construction Machinery**: Speed limitation in hazardous areas
- **Fleet Management**: Operational data collection and analysis

Speed Sources

Code	Source	Typical Application
0	Undefined	System startup
1	Wheel sensor	Standard operation

2	Soil sensor	Precision agriculture
3	GPS	Monitoring
4-7	Reserved	Manufacturer-specific

⚖️ Comparison with similar systems

Feature	I_MSS	Standard	GPS-based
Accuracy	±0.2%	±1-2%	±5-10%
Response Time	<100ms	200ms	1-2s
Source Flexibility	8	1-2	1

🛠️ Related Exercises

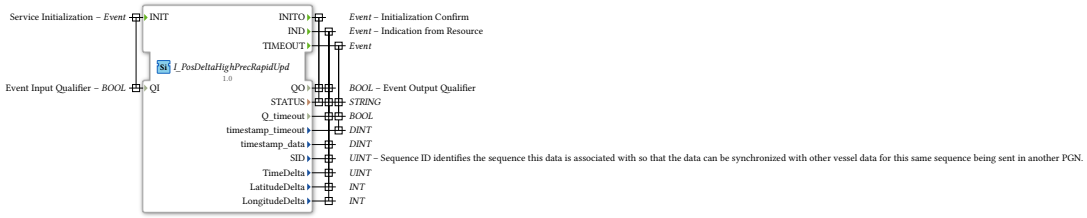
- Exercise_079

Conclusion

The I_MSS module offers precise speed control for mobile machinery:

- **Flexible**: Supports multiple speed sources
- **Precise**: Dual scaling for high accuracy
- **Robust**: Integrated fault diagnostics

Ideal for use in:



- Automatic steering systems
- Precision agriculture
- Machines with high speed requirements
- Applications with varying operating conditions

I_PosDeltaHighPrecRapidUpd

• – ○ • – ○ • – ○ •

Introduction

The function block `I_PosDeltaHighPrecRapidUpd` implements the processing of the NMEA 2000 Parameter Group Number (PGN) 129027 “Position Delta, High Precision Rapid Update”. This block is designed for applications requiring very high precision and very fast update rates for position data. It can provide position changes (delta) with a resolution of up to 1 millimeter and a delta time interval with an accuracy of 5 milliseconds.

Interface Structure

Event Inputs

- **INIT**: Service initialization. Triggered together with the qualifier `QI` to initialize or deactivate the function block.

Event Outputs

- **INITO**: Initialization confirmation. Triggered in response to the `INIT` event, it returns the current status (`STATUS`) and the qualifier `QO`.

- **IND**: Indication from the resource manager. Triggered when new position data is available. Transmits all relevant delta position data and status information.
- **TIMEOUT**: Triggered when a timeout occurs, for example, if no new data is received within an expected timeframe.

Data Inputs

- **QI** (BOOL): Event Input Qualifier. Controls the initialization. The function block is activated on `TRUE` and deactivated on `FALSE`.

Data Outputs

- **QO** (BOOL): Event Output Qualifier. Indicates the current operating state of the function block (e.g., active/inactive).
- **STATUS** (STRING): Contains status or error messages of the function block.
- **Q_timeout** (BOOL): Indicates whether the last received data is outdated due to a timeout.
- **timestamp_timeout** (DINT): Timestamp associated with the `TIMEOUT` event.
- **timestamp_data** (DINT): Timestamp of the last received valid position data.
- **SID** (UINT): Sequence ID. Identifies the sequence to which this data is assigned to enable synchronization with other vehicle data of the same sequence in another PGN.
- **TimeDelta** (UINT): The time difference in milliseconds over which the position change was measured.
- **LatitudeDelta** (INT): The change in latitude (delta) at high-precision resolution (1/1e-7 min = 1.85 mm).
- **LongitudeDelta** (INT): The change in longitude (delta) at high-precision resolution (1/1e-7 min = 1.85 mm).

Adapter

This function block does not use any adapter interfaces.

Operation

The function block is started or stopped via the `INIT` event with the corresponding `QI` value. After successful initialization, it confirms this with `INITO`. In the active state, the function block listens for incoming PGN 129027 messages from the NMEA 2000 network.

Upon receiving new, valid data, it triggers the `IND` event and makes all calculated delta values (time, latitude, longitude) available at its outputs, along with the sequence ID (`SID`) and a data timestamp. The `STATUS` output can provide additional information.

If no new message is received for a defined period, the function block can generate a `TIMEOUT` event. This indicates that the currently held data may be outdated (`Q_timeout` = TRUE).

Technical Features

- **High Precision**: Processes positional deltas with millimeter resolution (1/1e-7 arcminutes).
- **Fast Update**: Supports very short update intervals, represented by `TimeDelta` (minimum 5 ms accuracy).
- **Sequencing**: `SID` (Sequence ID) enables the correct assignment and synchronization of position deltas with other time-critical data streams in the system.
- **Timeout Detection**: Integrated monitoring of data freshness to detect communication failures or delayed messages.

State Overview

The function block essentially has two main states:

1. **Inactive / Initialized**: The block is initialized but not active (`QI` = FALSE). No data is processed.
2. **Active / Listening**: The module is activated (`QI` = TRUE) and is waiting for incoming PGN 129027 messages. Upon receipt, these are processed and output via `IND`. A missing signal can lead to a timeout state, which is indicated by the `TIMEOUT` event.

Application Scenarios

- **Precision Agriculture**: For high-precision guidance systems and automatic steering systems that require real-time position corrections.
- **Dynamic Positioning**: In maritime applications for the precise attitude control of ships or offshore platforms.
- **Autonomous Vehicles**: For high-frequency odometry and path correction in real time.

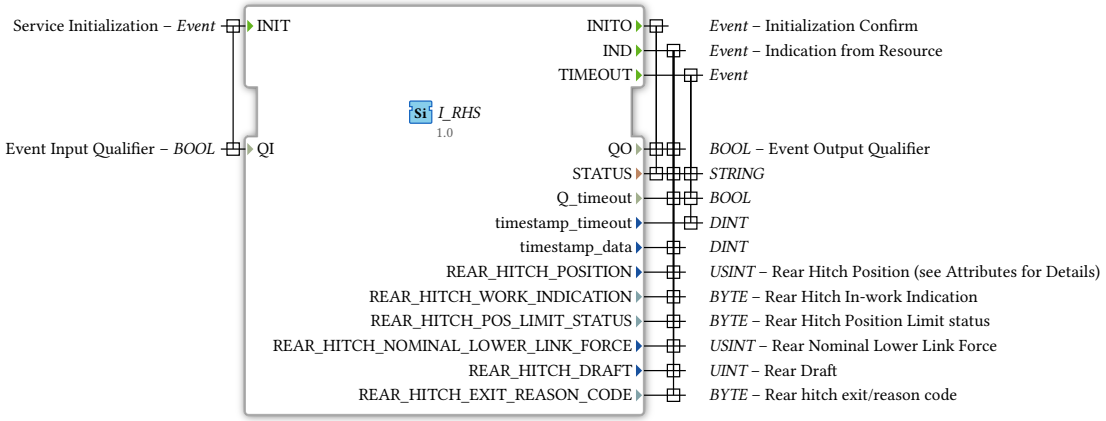
- **Surveying and Mapping**: For the acquisition of terrain data with very high spatial and temporal resolution.

⚖️ Comparison with Similar Function Blocks

Compared to standard position function blocks (e.g., those that process PGN 129029 "Position, Rapid Update"), `I_PosDeltaHighPrecRapidUpd` offers:

- **Delta-based data**: Instead of absolute positions, changes (deltas) are transmitted, which can be more bandwidth-efficient at high update rates.
- **Higher precision**: Specified for applications requiring higher accuracy than typical rapid update PGNs.
- **Explicit time difference**: The `TimeDelta` field is an integral part of the message, enabling more precise velocity and acceleration calculations.

Conclusion



The `I_PosDeltaHighPrecRapidUpd` function block is a specialized tool for demanding real-time position determination. Its ability to deliver and synchronize highly precise position changes at very high frequencies makes it ideal for precision-critical control tasks in agricultural, maritime, and autonomous systems. The integrated timeout detection further enhances the application's robustness.

I_RHS

• – ◦ • – ◦ • – ◦ •

Introduction

The **I_RHS** (Rear Hitch Status) is a standards-compliant function block for monitoring rear hitch parameters, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-7 specification (PGN 65093) for the precise acquisition of the position, force, and status of the rear hitch in agricultural machinery.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with qualifier `QI`)

Event Outputs

- `INITO`: Initialization Confirmation (with status)
- `IND`: Indication Event with all coupling parameters
- `TIMEOUT`: Timeout Event

Data Inputs

- `QI` (BOOL): Qualifier for Initialization

Data Outputs

- `QO` (BOOL): Qualifier for Output Events
- `STATUS` (STRING): Operating status message
- `Q_timeout` (BOOL): Timeout indicator

- `timestamp_timeout` (DINT): Timeout timestamp
- `timestamp_data` (DINT): Coupling data timestamp

Coupling parameters

Parameter	Type	Description	SPN	Bit length	Scaling
`REAR_HITCH_POSITION`	USINT	Coupling position	1873	8	0.4 %/bit
`REAR_HITCH_WORK_INDICATION`	BYTE	Operating State	1877	2	4 states/2 bits
`REAR_HITCH_POS_LIMIT_STATUS`	BYTE	Position Limitation	5151	3	8 states/3 bits
`REAR_HITCH_NOMINAL_LOWER_LINK_FORCE`	USINT	Lower Link Force	1881	8	0.8%/bit (-100% Offset)
`REAR_HITCH_DRAFT`	UINT	Tensile Force	1879	16	10 N/bit (-320kN Offset)
`REAR_HITCH_EXIT_REASON_CODE`	BYTE	Fault Reason Code	5819	6	64 states/6 bits

Functionality

1. **Initialization**:

- `INIT` with `QI`=TRUE starts system calibration
- `INITO` confirms operational readiness with `QO` and `STATUS`

1. **Data Provision**:

- `IND` provides all coupling parameters with timestamps
- Automatic updates upon state changes

1. **Error Handling**:

- `TIMEOUT` in case of communication problems
- Detailed error codes in `REAR_HITCH_EXIT_REASON_CODE`

Technical Features

✓ **ISO 11783-7 compliant** (PGN 65093)
✓ **Bidirectional force measurement** (+/- 100% range)
✓ **Precise position detection** with 0.4% resolution
✓ **64-level fault diagnosis** with detailed codes

Coupling characteristics

Feature	Description
Position range	0-100% (0 = fully down)
Force measurement	±100% of rated load
Tensile force range	−320kN to +350kN
Update rate	100ms in normal operation

Return codes (REAR_HITCH_EXIT_REASON_CODE)

Code range	Meaning
0-15	System error
16-31	Position Error
32-47	Force Measurement Error
48-63	Reserved

Application Scenarios

- **Plow Control**: Automatic Depth Control
- **Load Management**: Traction Force Adjustment
- **Diagnostics**: Early Detection of Hydraulic Problems
- **Safety**: Coupling Position Monitoring

⚖️ Comparison with Similar Components

Feature	I_RHS	Standard	Premium
Accuracy	±0.4%	±2%	±0.2%
Force Measurement	Bidirectional	Traction Only	Triaxial
Diagnostic Codes	64	8	128
ISO Compliance	Full	Partial	Full

🛠️ Related Exercises

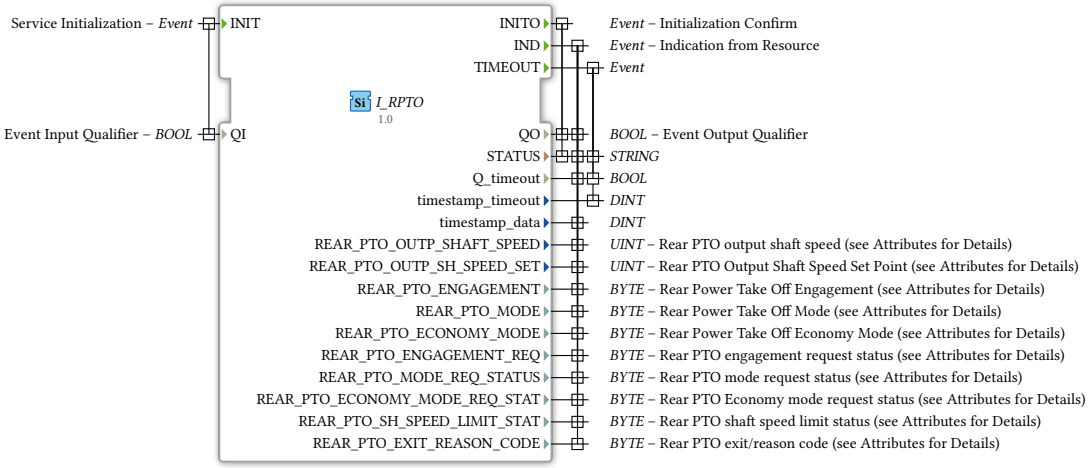
- Exercise_079

Conclusion

The I_RHS module offers comprehensive monitoring for rear hitch systems:

- **Precise**: High-resolution position and force measurement
- **Reliable**: Robust fault detection
- **Flexible**: Suitable for various implements

Ideal for use with:



- Modern tractors
- Precision agriculture
- Heavy implements
- Automatic steering systems

I_RPTO

• – ○ • – ○ • – ○ •

Introduction

The **I_RPTO** (Rear Power Take-Off) is a standards-compliant function block for controlling and monitoring the rear power take-off (PTO), developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-7 specification (PGN 65091) for the precise control of PTO parameters in agricultural machinery.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with qualifier `QI`)

Event Outputs

- `INITO`: Initialization Confirmation (with status)
- `IND`: Indication Event with all PTO Parameters
- `TIMEOUT`: Timeout Event

Data Inputs

- `QI` (BOOL): Qualifier for Initialization

Data Outputs

- `QO` (BOOL): Qualifier for Output Events
- `STATUS` (STRING): Operating status message
- `Q_timeout` (BOOL): Timeout indicator
- `timestamp_timeout` (DINT): Timeout timestamp
- `timestamp_data` (DINT): PTO data timestamp

PTO parameters

Parameter	Type	Description	SPN	Bit length	Scaling

Ideal for use in:

- Tractors with demanding implements
- Precision agriculture
- Energy-efficient drive systems
- Automated work processes

I_TD

• – ◦ • – ◦ • – ◦ •

Introduction

The **I_TD** (Time/Date) function block is a special component for ISOBUS that enables the processing of time and date information according to the ISO 11783-7 standard (PGN 65254). It receives and processes the current time and date transmitted over the ISOBUS network. The output data corresponds to the defined SPNs (Suspect Parameter Numbers) of the protocol and is provided including the associated scaling and offsets.

Interface Structure

Event Inputs

Event	With Variable	Description
`INIT`	`QI`	Initialization of the function block.

Event Outputs

Event	With variables	Description
`INITO`	`QO`, `STATUS`	Confirmation of successful initialization.
`IND`	`QO`, `timestamp_data`, `STATUS`, `Q_timeout`, `SECONDS`, `MINUTES`, `HOURS`, `MONTH`, `DAY`, `YEAR`, `LOCAL_MINUTE_OFFSET`, `LOCAL_HOUR_OFFSET`	Display of a received time/date telegram.
`TIMEOUT`	`timestamp_timeout`, `STATUS`, `Q_timeout`	Timeout event if no valid telegram arrives within an expected timeframe.

Data Inputs

Variable	Type	Description
`QI`	BOOL	Qualifier for initialization (TRUE = enable).

Data Outputs

Variable	Type	Description (with ISOBUS attributes)
`QO`	BOOL	Output qualifier (TRUE = Operational).

STATUS	STRING	Status message (e.g., error or success).
Q_timeout	BOOL	Indicates whether a timeout occurred.
timestamp_timeout	DINT	Timestamp of the timeout (if it occurred).
timestamp_data	DINT	Timestamp of the received data telegram.
SECONDS	USINT	Seconds (scale 0.25s/bit, offset 0).
MINUTES	USINT	Minutes (scale 1min/bit, offset 0).
HOURS	USINT	Hours (Scale 1h/bit, Offset 0).
MONTH	USINT	Month (Scale 1 month/bit, Offset 0).
DAY	USINT	Day (Scale 0.25d/bit, Offset 0).
YEAR	UINT	Year (Scale 1y/bit, Offset 1985, Initial value 0xFFFF = "not available").
LOCAL_MINUTE_OFFSET	SINT	Local Minute Offset (Scale 1 min/bit, Offset −125).
LOCAL_HOUR_OFFSET	SINT	Local hour offset (scaling 1h/bit, offset −125).

Adapter

None.

Functionality

The function block is initialized via the event input INIT with QI set. After successful initialization, the event INITO is triggered and the output QO is set to TRUE. The function block then waits for incoming ISOBUS telegrams (PGN 65254). When such a telegram arrives, the event IND is generated and all corresponding data outputs are updated with the decoded values. The scaling and offsets defined in the attributes are applied automatically.

If no valid telegram is received within an unspecified timeframe, the event TIMEOUT is triggered and the output Q_timeout is set to TRUE. The timeout timestamp is stored in timestamp_timeout.

Technical Features

- **ISOBUS Compliance:** The FB implements exactly PGN 65254 of the ISO 11783-7 standard, part "Time/Date TD".
- **Initial Values:** Many data outputs are initialized with predefined "not available" values (e.g., YEAR = 0xFFFF), which allows for easy error detection.
- **Scaling & Offset:** All values are scaled and offset according to the ISOBUS specification. The raw values of the SPNs are converted into physical units.
- **Local Time Offset:** The outputs LOCAL_MINUTE_OFFSET and LOCAL_HOUR_OFFSET allow the specification of the deviation from UTC time in the range of −125 min to +130 min.
- **No State Machine:** The function block (FB) is event-driven; there is no explicit state machine in the XML. The internal logic is based on the IEC 61499 execution rules.

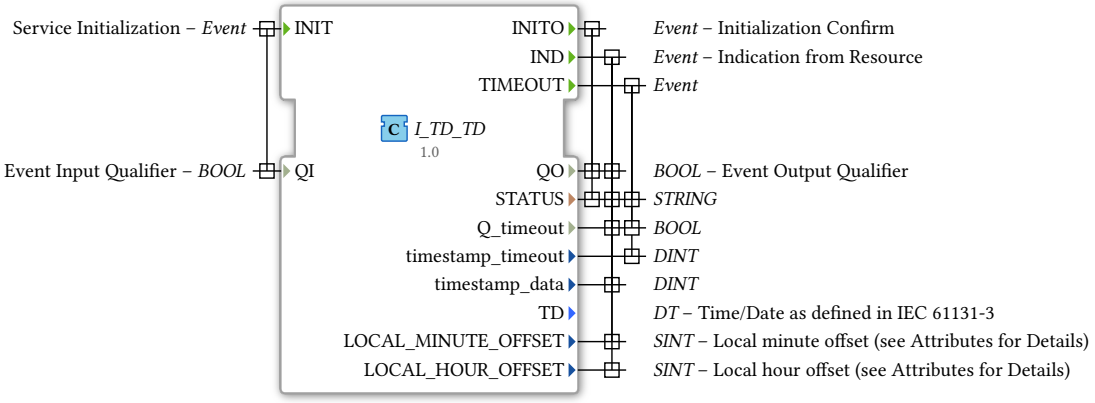
State Overview

An explicit state machine is not defined in the XML. The FB operates as a reactive block:

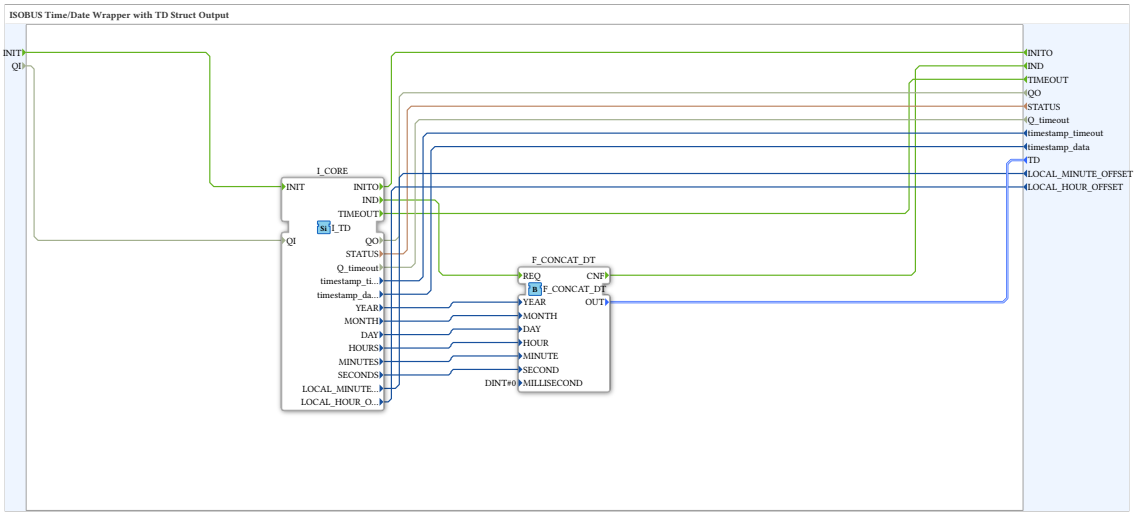
1. **Idle State** – waits for INIT.
2. **Initialization Phase** – After INIT, if TRUE QI, INITO is triggered.
3. **Operational Ready** – Receiving telegrams ⟶ IND; if no telegrams are received ⟶ TIMEOUT.

Application Scenarios

- **Agricultural Machinery:** Receiving current time and date data from the ISOBUS on-board network, e.g., for loggers, controllers, or displays.
- **Time Stamping:** Using the timestamp_data outputs to synchronize events in various control units.
- **Time Zone Adjustment:** Evaluating local offsets to display local time in user interfaces.



Comparison with Similar Function Blocks



Compared to general IEC 61499 time blocks (e.g., `E_CYCLE` or `E_TIME`), `I_TD` is specifically designed for ISOBUS communication. It does not decode an internal system time but receives external telegrams and delivers the data in ISOBUS-compliant formats. A universal function block, `I_DATE` (if available), would be suitable for proprietary systems but does not offer the ISOBUS SPN structure.

Conclusion

The `I_TD` function block is an essential component for ISOBUS applications that rely on accurate time and date information from the network. Its complete mapping of SPNs and built-in timeout handling make it robust and standards-compliant. Thanks to automatic scaling and offsets, the physical values can be processed directly without manual conversion.

I_TD_TD

• – ○ • – ○ • – ○ •

Introduction

The function block **I_TD_TD** is a wrapper around the base block `I_TD` and generates a combined IEC 61131-3 date/time struct (type `DT`) from the individual time and date components. It serves as an interface to an ISOBUS-compliant time/date service (PGN 65254) and provides the processed time information as well as local time offsets as separate outputs.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Service Initialization, controlled by qualifier `QI`

Event Outputs

Name	Type	Carrying Data
INITO	EInit	QO, STATUS
IND	Event	QO, timestamp_data, STATUS, Q_timeout, LOCAL_MINUTE_OFFSET, LOCAL_HOUR_OFFSET
TIMEOUT	Event	timestamp_timeout, STATUS, Q_timeout

Data Inputs

Name	Type	Comment
QI	BOOL	Input Qualifier (Controls the Initialization Process)

Data Outputs

Name	Type	Comment
QO	BOOL	Output Qualifier (Processing Status)
STATUS	STRING	Status Message
Q_timeout	BOOL	Timeout Flag
timestamp_timeout	DINT	Timeout Timestamp
timestamp_data	DINT	Timestamp of valid data
TD	DT	Combined time/date (IEC 61131-3 DT)
LOCAL_MINUTE_OFFSET	SINT	Local minute offset (SPN 1601, Unit: 1 min/bit, Offset −125)
LOCAL_HOUR_OFFSET	SINT	Local hour offset (SPN 1602, Unit: 1 h/bit, Offset −125)

Adapter

No adapters available.

Functionality

The function block encapsulates the following steps:

1. **Initialization**

An event at input INIT starts the internal function block I_TD (I_CORE). This block executes its own initialization sequence and confirms with INITO. The qualifiers QO and STATUS are passed to the corresponding outputs.

1. **Cyclic Time/Date Capture**

Once the internal function block is ready, it cyclically generates a IND event. This event triggers the downstream function block F_CONCAT_DT. F_CONCAT_DT combines the individual components (year, month, day, hour, minute, second) provided by I_TD into a DT struct. The millisecond component is fixed at 0. After concatenation is complete, a CNF event is generated, which activates the external IND output, along with all other data outputs (timestamps, offsets, etc.).

1. **Timeout**

If the internal service reports a timeout, the TIMEOUT event is activated at the output. The associated data (timestamp_timeout, STATUS, Q_timeout) are taken directly from the inner block.

1. **Forwarding the Raw Data**

The outputs timestamp_data, timestamp_timeout, LOCAL_MINUTE_OFFSET, and LOCAL_HOUR_OFFSET are taken unchanged from I_TD.

Technical Features

- **Wrapper Principle**

This block simplifies the handling of the ISOBUS time service by combining the individual time components into a platform-compatible `DT` struct. The user does not need to perform any custom chaining of year, month, etc.

- **ISO 11783-7 compliant**

The underlying service corresponds to PGN number 65254 and provides the SPNs (1601, 1602) required by ISO 11783-7 for local time offsets. The attribute information (scaling, offset) is stored in the output variables.

- **Timestamp handling**

Separate timestamps (`DINT`) are provided for both valid data and timeout events, allowing the sequence and recency of events to be tracked.

- **Event-driven process**

Processing is purely event-driven. Each cycle is initiated by the `IND` of the internal component and ends with the `IND` of the wrapper.

State Overview

The function block does not have an explicit internal state machine that would be visible to the user. However, the process can be divided into the following phases:

1. **Idle State** – After initialization, the function block waits for the first `IND` of `I_TD`.
2. **Active Processing** – `IND` of `I_TD` triggers `F_CONCAT_DT`; subsequently, the outer `IND` is output.
3. **Timeout State** – If `I_TD` times out, `TIMEOUT` is output.
4. **Initialization Phase** – The internal module is initialized during `INIT` and `INITO`.

Application Scenarios

- **ISOBUS Control Units**

Used in agricultural control units that regularly query the current UTC time and the local time offset from the ISOBUS bus and require this data as a uniform data type (`DT`) for display or logging.

- **Time Synchronization**

Used in systems that rely on an exact time base, e.g., recording devices (loggers), GPS-based applications, or process controls.

- **Wrapper for IEC 61131-3 Compatibility**

If subsequent function blocks do not expect access to individual time components, but only to a `DT` struct, `I_TD_TD` can serve as a link.

Comparison with Similar Function Blocks

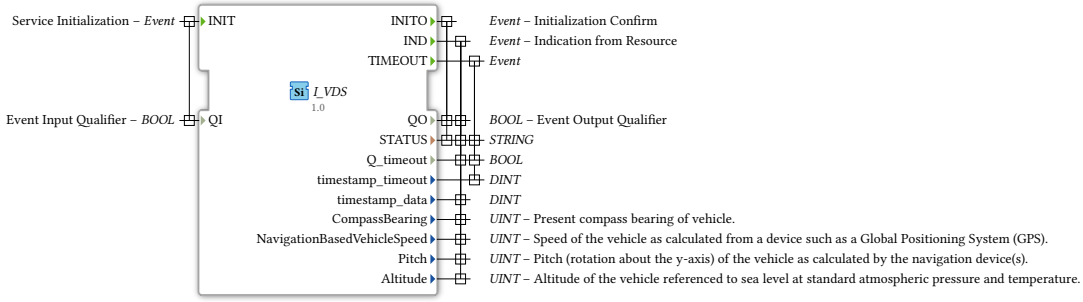
- **I_TD (Basic Function Block)**

Returns the time components as separate outputs (YEAR, MONTH, DAY, etc.). The user would have to concatenate them manually to a `DT`. `I_TD_TD` does this automatically and also adds the raw data timestamps.

- **Other Time/Date Wrappers**

Some implementations use direct system time functions. `I_TD_TD` is specifically optimized for use in an ISOBUS context and provides the required SPN attributes as well as timeout handling.

Conclusion



I_TD_TDextends the standardized ISOBUS time blockI_TDby adding a direct output of the IEC 61131-3 date-time typeDT`. This simplifies integration into control applications that do not want to perform a separate date conversion. The transparent transmission of raw data and timeout information, as well as the consistent event handling, make this block a practical and standards-compliant component for ISOBUS-based systems.

I_VDS

• – ◦ • – ◦ • – ◦ •

Introduction

The **I_VDS** function block (Vehicle Direction/Speed) is an ISO 11783-7 compliant system for the precise detection of vehicle direction, speed, and inclination, developed under the EPL-2.0 license. The block integrates navigation data for modern agricultural machinery and commercial vehicles.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with qualifier `QI`)

Event Outputs

- `INITO`: Initialization Confirmation (with status)
- `IND`: Data Indication with Navigation Parameters (with `QO`, `timestamp_data`, `CompassBearing`, `NavigationBasedVehicleSpeed`, `Pitch`, `STATUS`, `Q_timeout`, `Altitude`). Fires on every cycle without an active timeout and thereby also publishes the reset of `Q_timeout` to FALSE
- `TIMEOUT`: Timeout Event (with `timestamp_timeout`, `STATUS`, `Q_timeout`). Fires only when a timeout actually occurs; the reset of `Q_timeout` is reported via `IND`, not here

Data Inputs

- `QI` (BOOL): Qualifier for Initialization

Data Outputs

| Parameter | Type | SPN | Bit | Scale | Range | Description | | |–––––|––|––|––|–––––|–––––|–––––| | `QO` | BOOL | - | 1 | - | TRUE/FALSE | Event Qualifier | | `STATUS` | STRING | - | - | - | - | System Status Message | | `CompassBearing` | UINT | 165 | 16 | 1/128°/bit | 0-360° | Compass Direction | | `NavigationBasedVehicleSpeed` | UINT | 517 | 16 | 1/256 km/h/bit | 0-250 km/h | GPS-based speed | | `Pitch` | UINT | 583 | 16 | - | 0xFFFF | Pitch angle (reserved) | | `Altitude` | UINT | 580 | 16 | - | 0xFFFF | Altitude above sea level (reserved) | | `Q_timeout` | BOOL | - | - | - | TRUE/FALSE | Timeout flag (set with `TIMEOUT`, reset via `IND`) | | `timestamp_data` | DINT | - | - | - | - | Timestamp of the data (with `IND`) | | `timestamp_timeout` | DINT | - | - | - | - | Timestamp of the timeout (with `TIMEOUT`) |

Functionality

1. **Initialization**:

- `INIT` with `QI`=TRUE starts the GPS/navigation system
- `INITO` confirms operational readiness with `QO` and `STATUS`

1. **Data Update**:

- `IND` provides continuously updated navigation data
- Standard update rate: 100ms for real-time applications

1. **Error Handling**:

- `TIMEOUT` in case of signal loss or communication errors
- Status messages in the `STATUS` field

Technical Features

✓ **ISO 11783-7 compliant** (PGN) 65256)
✓ **High-precision direction detection** with 0.008° resolution
✓ **GPS-based speed** with 0.004 km/h accuracy

✓ **Extended sensor data** (pitch angle/altitude reserved)

Application Scenarios

- **Precision agriculture**: Automatic guidance
- **Fleet management**: Real-time tracking and speed monitoring
- **Slope detection**: Safety systems for slopes
- **Telematics**: Operational data acquisition and analysis

Data formats

Parameter	Example value	Meaning
`CompassBearing`	16384	128° (16384 × 1/128)
`NavigationBasedVehicleSpeed`	12800	50 km/h (12800 × 1/256)
`Pitch`	0xFFFF	Not used
`Altitude`	0xFFFF	Not used

⚖️ **Comparison with similar systems**

Feature	I_VDS	Standard GPS	Premium Navigation
Accuracy	±0.1° Direction	±5°	±0.05°
Speed	±0.1%	±2%	±0.05%
Update Rate	10 Hz	1 Hz	20 Hz
ISO Compliance	Full	Partial	Full

🛠️ **Related Exercises**

- Exercise_073
- Exercise_079

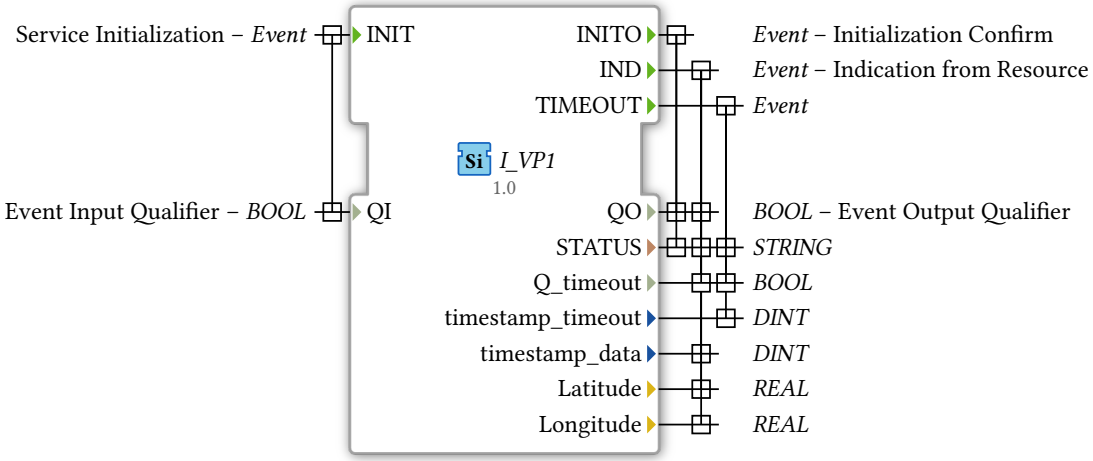
Conclusion

The I_VDS module offers precise navigation for mobile machinery:

- **Precision**: Subgrade-accurate direction detection
- **Reliability**: Robust GPS-based speed
- **Future-proof**: Reserved parameters for extensions

Ideal for use in:

- Automatic steering systems
- Precision agriculture
- Fleet management systems
- Safety-critical applications



Designed for high-precision vehicle guidance and monitoring

I_VP1

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `I_VP1` is used to process and provide vehicle position data according to the ISO 11783 standard (ISOBUS). It specifically implements the “Vehicle Position 1” function, which is defined by the parameter Group Number (PGN) 65267. The block receives position data from a resource (e.g., a GNSS receiver) and makes it available via standardized interfaces for downstream control and display functions in an agricultural or mobile machinery network.

Interface Structure

Event Inputs

- **`INIT`**: Initialization event. Triggered on `QI=TRUE` to start the function block. Deactivated on `QI=FALSE`.

Event Outputs

- **`INITO`**: Confirms completion of initialization. Sent in response to the `INIT` event.
- **`IND`**: Indication event. Signals successful reception of new, valid position data from the connected resource.
- **`TIMEOUT`**: Timeout event. Triggered if no new position data is received within a configured time frame.

Data Inputs

- **`QI` (BOOL)**: Qualifies the `INIT` event. Controls the activation state of the function block (`TRUE` = activate, `FALSE` = deactivate).

Data Outputs

- **`QO` (BOOL)**: Qualifies the event outputs `INITO` and `IND`. Reflects the current operating state of the function block (`TRUE` = active and ready for operation).
- **`STATUS` (STRING)**: Provides status or error messages of the function block in a readable format.
- **`Q_timeout` (BOOL)**: Indicates whether a timeout has occurred (`TRUE` = timeout active, `FALSE` = no timeout).
- **`timestamp_timeout` (DINT)**: Timestamp (e.g., in milliseconds) associated with the `TIMEOUT` event.
- **`timestamp_data` (DINT)**: Timestamp of the last received position data output via `IND`.
- **`Latitude` (REAL)**: The geographical latitude of the vehicle's position in degrees. The value is scaled according to PGN 65267 (SPN 584) and includes an offset of −210°.
- **`Longitude` (REAL)**: The geographical longitude of the vehicle's position in degrees. The value is scaled according to PGN 65267 (SPN 585) and includes an offset of −210°.

Adapters

This function block does not use any adapter interfaces.

Operation

1. **Initialization**: Sending a `INIT` event with `QI=TRUE` activates the function block. It reports a successful start with the `INITO` output event, accompanied by `QO=TRUE` and a `STATUS` string.
2. **Data Reception and Processing**: In the active state, the function block monitors a connected resource (e.g., an ISOBUS data stream) for the arrival of position data according to PGN
3. Upon receiving valid data, it is decoded, scaling and offset are applied, and the resulting `Latitude` and `Longitude` values are calculated.
4. **Data Output**: Upon successful processing, the function block triggers the `IND` event. Simultaneously, the calculated position data (`Latitude`, `Longitude`), a corresponding timestamp (`timestamp_data`), the active state (`QO=TRUE`), and a status are provided via the output variables. `Q_timeout` is set to `FALSE`.

5. **Timeout Monitoring**: The function block continuously monitors the data stream. If no new position data is received for a configured period, it triggers the `TIMEOUT` event. This sets `Q_timeout=TRUE`, a timestamp (`timestamp_timeout`), and a corresponding `STATUS`.
6. **Deactivation**: A `INIT` event with `QI=FALSE` resets the module to an inactive state, which is acknowledged by `INITO` with `QO=FALSE`.

Technical Features

- **ISOBUS Compliance**: The module is specifically designed for use in ISO 11783 (ISOBUS) networks and processes data according to the official specification for PGN 65267.
- **Data Encoding**: The raw data for latitude (`Latitude`, SPN 584) and longitude (`Longitude`, SPN 585) are received as 4-byte values. The function block applies the scaling defined in the attributes and an offset of −210 degrees to calculate the final `REAL` values.
- **Attribute-based metadata**: The output variables for the position data are annotated with detailed attributes (SPN, name, length, offset, reference link). This simplifies configuration, documentation, and maintenance within an IEC 61499 development environment.

State overview

The function block can transition to the following main states:

- **Inactive**: Initial state. `QO=FALSE`. No data processing.
- **Active (waiting for data)**: After successful initialization. `QO=TRUE`. The function block monitors the input data stream.
- **Data processing**: Upon receiving a new PGN 65267 data packet. Decoding, scaling, and calculation of position values.
- **Data Output**: Triggering the `IND` event and setting the output variables.
- **Timeout**: Triggering the `TIMEOUT` event if no data is received.

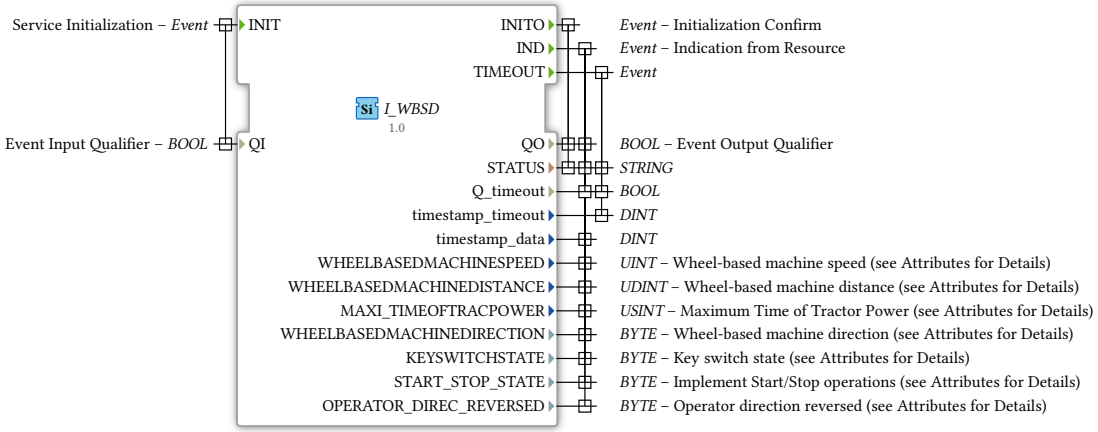
Application Scenarios

- **Precision Farming / Sub-Area Management**: Providing precise vehicle positions for application maps, guidance systems, or documentation purposes.
- **Machine and Fleet Management**: Tracking agricultural or municipal vehicles within a company's premises.
- **Assistance Systems**: Basis for collision avoidance systems or automatic steering systems that require accurate and standardized position information.

⚖️ Comparison with Similar Blocks

- **Generic Input Blocks (e.g., `E_SR`, `E_RTRIG`)**: These offer basic read or trigger functions but are not designed to process a specific ISOBUS PGN. `I_VP1`, on the other hand, contains the complete logic for decoding, scaling, and error handling for PGN 65267.
- **General ISOBUS Input Blocks**: More general blocks that read various PGNs may exist. `I_VP1` is specialized and optimized for the efficient and reliable processing of vehicle position data, which simplifies configuration and reduces the potential for errors.

Conclusion



The `I_VP1`The -Function Block is a specialized, standards-compliant tool for integrating vehicle position data into IEC 61499-based control systems for mobile machinery. Through the direct implementation of the ISOBUS specification (PGN 65267) and integrated features such as timeout monitoring, it offers a reliable and easy-to-use interface for applications in precision farming and automation. Its attribute-based documentation supports developers in correct implementation and maintenance.

I_WBSD

• − ◦ • − ◦ • − ◦ •

Introduction

The **I_WBSD** function block (Wheel-based Speed and Distance) is an ISO 11783-7 compliant system for acquiring wheel-based speed and distance data, developed under the EPL-2.0 license. The block enables the precise monitoring of vehicle movements and operating conditions for agricultural and construction machinery.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with qualifier `QI`)

Event Outputs

- `INITO`: Initialization Confirmation (with status)
- `IND`: Data Indication with Motion and State Parameters (incl. `timestamp_data`, `Q_timeout`); fires on every cycle without an active timeout and thereby also publishes the reset of `Q_timeout` to `FALSE`
- `TIMEOUT`: Timeout Event (with `timestamp_timeout`, `STATUS`, `Q_timeout`); fires only when a timeout actually occurs (entry trigger). The reset of `Q_timeout` to `FALSE` is not reported here but via `IND`

Data Inputs

- `QI` (BOOL): Qualifier for Initialization

Data Outputs

Parameter	Type	SPN	Bit	Scale	Range	Description	
`QO`	BOOL	-	1	-	TRUE/FALSE	Event Qualifier	
`STATUS`	STRING	-	-	-	-	System Status Message	
`Q_timeout`	BOOL	-	-	-	TRUE/FALSE	Timeout flag (`TRUE` while a timeout is active)	
`timestamp_timeout`	DINT	-	-	-	-	Timestamp of the timeout (with `TIMEOUT`)	
`timestamp_data`	DINT	-	-	-	-	Timestamp of the data (with `IND`)	
`WHEELBASEDMACHINESPEED`	UINT	1862	16	0.001 m/s/bit	0-65.535 m/s	Wheel-Based Speed	
`WHEELBASEDMACHINEDISTANCE`	UDINT	1863	32	0.001 m/bit	0-4,294,967 km	Distance traveled	
`MAXI_TIMEOFTRACPOWER`	USINT	1866	8	1 min/bit	0-255 min	Maximum operating time

`OPERATOR_DIREC_REVERSED`	BYTE	5244	2	4 States	0-3	Reverse

Driving Direction States

Code	State	Description
0	Stationary	No movement
1	Forward	Forward travel
2	Reverse	Reverse travel
3	Undefined	Direction not determinable

Functionality

1. **Initialization**:

- `INIT` with `QI`=TRUE starts wheel sensor calibration
- `INITO` confirms operational readiness with system status

1. **Data Provision**:

- `IND` provides continuously updated motion data
- Automatic adjustment of the update rate (100 ms at >0.5 m/s)

1. **Error Handling**:

- `TIMEOUT` in case of signal loss from the wheel speed sensors
- Status messages in the `STATUS` field

Technical Features

✓ **ISO 11783-7 compliant** (PGN 65096) ✓ **Precise speed measurement** with 1 mm/s Resolution ✓ **32-bit distance counter** for extended operating times ✓ **Integrated status monitoring** (ignition, start/stop)

Application Scenarios

- **Tractors**: Speed control for field work
- **Harvesting machines**: Working distance calculation
- **Fleet management**: Operating hour recording
- **Safety systems**: Direction detection when reversing

Status Codes

Parameter	Code	Meaning
`KEYSWITCHSTATE`	0	Off
	1	On
	2	Start
	3	Undefined
`START_STOP_STATE`	0	Stop
	1	Start
	2	Pause
	3	Reserved

⚖️ Comparison with similar systems

Feature	I_WBSD	Standard	GPS-based
Accuracy	±0.5%	±2%	±5%
Low speed	Good	Excellent	Poor
Signal stability	High	Medium	Low

I

I_GetAttribute

• – ◦ • – ◦ • – ◦ •

Introduction

`I_GetAttribute` implements the **Get Attribute Value** command (ISO 11783-6, F.58). It is available from VT version 4 and is used by a working set to query the VT for the current state of objects within the VT.

Interface Structure

Event Inputs

- **INIT** (`EInit`): Service initialization
  - Associated with: `u16ObjId`, `u8AID`
- **REQ**: Service request

Event Outputs

- **INITO** (`EInit`): Initialization confirmation
- **CNF**: Confirmation of the requested service
  - Associated with: `STATUS`, `s16result`

Data Inputs

- **u16ObjId** (`UINT`, initial value `ID_NULL`): Object ID
- **u8AID** (`USINT`): Attribute ID of the object

Data Outputs

- **STATUS** (STRING): Service status
- **s16result** (INT): Return value (see below)

Adapters

No adapter interfaces.

How it works

The Get Attribute Value command (F.58) is a fixed 8-byte message (object ID in bytes 2 and 3, attribute ID in byte 4; no Transport Protocol).

Before the command is ever sent, INIT validates both the object type (iso_has_readable_attribute_id: does this object type have any attribute ID at all, read-only or writable?) and the specific attribute ID against that type's attribute table (iso_is_readable_attribute). Unlike Change Attribute, both read-only and writable attribute IDs are accepted here. The underlying C implementation (cmd_get_attribute_value) performs no type check of its own, only ID_NULL handling; the VT additionally validates the object ID and the attribute ID on its side and returns an error response if either is invalid.

ID_NULL (65535) is not a command target but can be used in INIT to deactivate the function block.

Return values (s16result)

Value	Meaning
VT_E_NO_ERR (0)	OK
VT_E_DEACTIVATED (-40)	FB deactivated via ID_NULL on INIT
VT_E_INVALID_OBJECT_ID (-132)	The object ID's type has no readable AID at all (iso_has_readable_attribute_id)
VT_E_INVALID_ATTRIBUTE_ID (-133)	Attribute ID is not a valid/readable AID for this object type (iso_is_readable_attribute)
VT_E_NOT_READY (-131)	Buffered: INIT not yet completed / VT not yet ready
VT_E_OVERFLOW (-6)	Buffer overflow
VT_E_NOACT (-8)	Command not possible in current state
VT_E_NO_INSTANCE (-21)	No VT client available
VT_E_HANDLE_INVALID (-128)	Error cause: invalid handle
VT_E_ISO_INSTANCE_INVALID (-129)	Identifier for instance (connection) invalid
VT_E_NOT_ALIVE (-130)	Identifier for instance valid, but VT dead

Technical Details

- **Instance uniqueness**: This block requires uniqueness with respect to the pair (u16ObjId, u8AID). Only one instance of I_GetAttribute may exist in the whole program for the same object/attribute pair. u8AID is read in at INIT; a second instance for the same object ID and attribute ID is deactivated at INIT.
- The block delivers only status and return value via CNF; the read attribute value is delivered by service interface blocks such as Attribute_IDA.

Application Scenarios

- Querying the current state of an object in the VT (from VT version 4)

Summary

I_GetAttribute sends the Get Attribute Value command (F.58) for an object/attribute pair and reports status and return value.

BargraphSplitFS

• – ○ • – ○ • – ○ •

Introduction

The **BargraphSplitFS** function block visualizes a signed REAL value on a pair of adjacent Linear Bar Graphs that meet at a shared zero point. The left bar graph renders the magnitude of negative values, while the right bar graph renders the magnitude of positive values. This arrangement provides an intuitive "split" display where the user sees a single continuous bar that extends from the center to either side, depending on the sign of the input value.

The block wraps two `Q_NumericValue_PHYS` instances (ISO 11783-6, clause F.22) that command the two bar graph objects defined in Annex B.11.3. The object configuration is provided once at initialization and remains fixed for the lifetime of the block instance.

Interface Structure

Event Inputs

Event	Description	With
`INIT`	Service initialization. Snapshots the `stObj` configuration.	`stObj`
`REQ`	Displays a new signed value on the split bar graph.	`rValue`

Event Outputs

Event	Description	With
`INITO`	Initialization confirm. Emitted after both internal bar graph services are initialized.	–

CNF	Confirmation of the requested display service. Emitted after both sides have processed the value.	STATUSRight, s16resultRight, xOverRight, STATUSLeft, s16resultLeft, xOverLeft

Data Inputs

Data	Type	Description
stObj	isobus::utils::bargraph::BargraphSplit_S	Split-bargraph object pool properties (left/right bar graph references, shared magnitude bounds). Snapshotted once at INIT.
rValue	REAL	Signed physical value to display. May originate from any source, not limited to a NumericValue_PHYS.

Data Outputs

Data	Type	Description
STATUSRight	STRING	Service status – passthrough from the internal right-side Q_NumericValue_PHYS.
s16resultRight	INT	Return value – passthrough from the internal right-side Q_NumericValue_PHYS.
xOverRight	BOOL	TRUE when the positive input value exceeded stObj.r32MaxMagnitude and the right side was clamped.
STATUSLeft	STRING	Service status – passthrough from the internal left-side Q_NumericValue_PHYS.
s16resultLeft	INT	Return value – passthrough from the internal left-side Q_NumericValue_PHYS.
xOverLeft	BOOL	TRUE when the negated negative input value exceeded stObj.r32MaxMagnitude and the left side was clamped.

Adapters

None.

Functionality

The block operates in two phases: initialization and value display.

Initialization (INIT):

1. The stObj structure is snapshotted into an internal copy using an F_MOVE block (Snap).
2. From the snapshot, the right-side configuration (stRight) is forwarded to the internal right Q_NumericValue_PHYS, and the left-side configuration (stLeft) is forwarded to the internal left Q_NumericValue_PHYS.
3. Both internal instances are initialized sequentially. The INITO event confirms completion.

Value display (REQ):

The signed rValue is processed along two parallel paths:

- **Right side (positive branch):** rValue is fed directly into a clamping stage (ClampRight) that bounds the value to [stObj.r32MinMagnitude, stObj.r32MaxMagnitude]. The clamped magnitude is then written to the right bar graph via Q_NumericValue_PHYS. If rValue > r32MaxMagnitude, xOverRight is set to TRUE.
- **Left side (negative branch):** rValue is first negated by an F_MUL with -1.0, producing the magnitude of the negative input. This value is clamped with the same bounds (ClampLeft) and written to the left bar graph. If -rValue > r32MaxMagnitude, xOverLeft is set to TRUE.

Both branches are processed using a strict sequential event chain: `REQ → ClampRight → NumRight → NegateValue → ClampLeft → NumLeft → CNF`. This guarantees deterministic ordering and ensures both bar graphs are updated before the confirmation event is emitted.

The clamping stage maps `r32MinMagnitude` (typically 0) to the empty state, while `r32MaxMagnitude` corresponds to the full-scale fill of the bar graph. Values below `r32MinMagnitude` are clamped upward to the minimum, and values above `r32MaxMagnitude` are clamped to full scale.

There are deliberately no `xUnder` outputs. A magnitude falling below `r32MinMagnitude` on the currently inactive side is the normal resting state during ordinary operation and does not constitute a diagnostic condition.

Technical Features

- **Object snapshotting:** The `BargraphSplit_S` structure is captured once at `INIT` via `F_MOVE`, making the block immune to later changes of the source object references.
- **Reusable internal services:** The block leverages standard `Q_NumericValue_PHYS` (ISO 11783-6 F.22) and `F_ClampReal` building blocks, ensuring consistent behavior with other parts of the ISOBUS object pool.
- **Shared bounds:** Both bar graph sides use the same `r32MinMagnitude` and `r32MaxMagnitude` from the snapshot, guaranteeing a symmetric, coherent presentation around the zero point.
- **Deterministic event sequencing:** The internal event chain guarantees that both sides are fully processed in a fixed order before `CNF` is emitted.
- **Over-range indication:** Dedicated boolean outputs report magnitude overruns independently for each side, allowing the application to react (e.g., log a diagnostic or highlight the value).
- **No under-range diagnostic:** By design, the block omits under-range flags to avoid spurious diagnostics during normal zero-crossing operation.

State Overview

The block is stateless from the application perspective. Its internal lifecycle is:

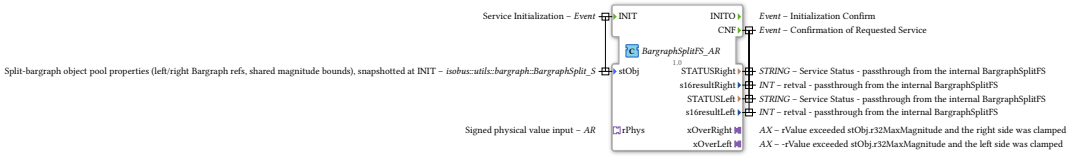
State/Phase	Trigger	Actions
Idle	–	Waiting for `INIT` or `REQ`.
Initializing	`INIT`	Snapshot `stObj`, initialize right instance, then left instance, emit `INITO`.
Processing	`REQ`	Clamp right branch, update right bar graph, negate/clamp left branch, update left bar graph, emit `CNF`.
Ready	`INITO` / `CNF`	Return to idle, awaiting next service request.

Application Scenarios

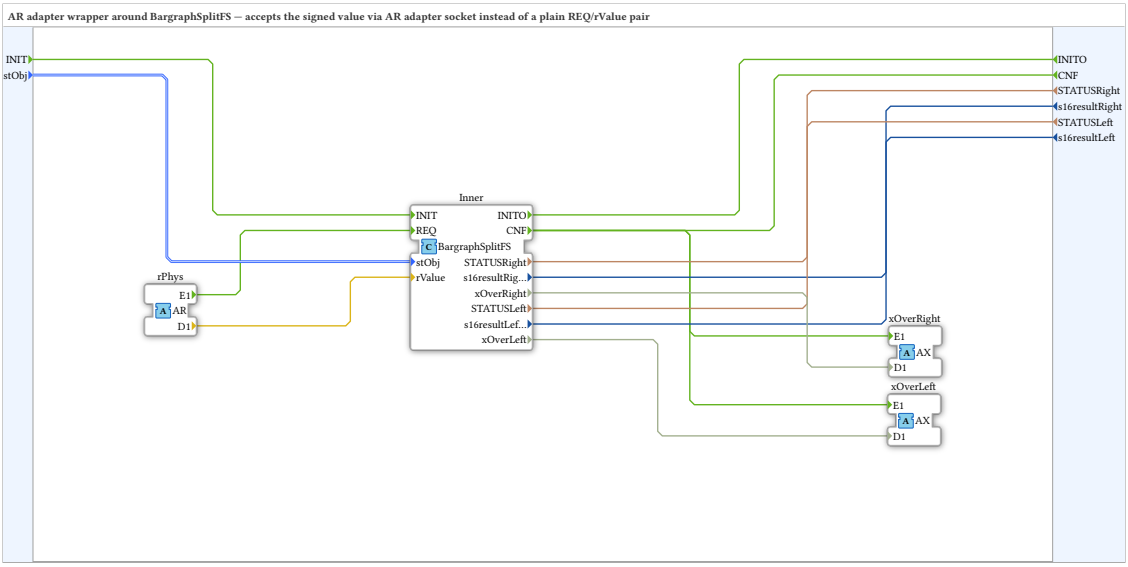
- **Tank level / fill indication with direction:** Displaying a differential value (e.g., pressure difference, flow balance) where positive values fill the right bar and negative values fill the left bar.
- **Dual-directional machine parameter display:** Showing joystick deflection, steering angle, or actuator position in both directions from a neutral center point.
- **Operator diagnostics:** In ISOBUS-based agricultural machinery, presenting signed physical quantities (speed deviation, draft force imbalance) in a compact split-bar format.
- **Generic human-machine interface:** Any HMI requiring a signed value to be rendered as two adjacent magnitude bars with a common zero, using standard ISO 11783-6 bar graph objects.

Comparison with Similar Blocks

Feature	BargraphSplitFS	Simple single bar graph FB
Display of signed values	Yes – split into two directional bars	Usually requires absolute value pre-processing
Zero point	Shared central zero between two bars	Typically at one end of the bar
Over-range reporting	Per-side via `xOverRight` / `xOverLeft`	Often single over-range flag



Under-range reporting	None (intentional)	Often present, may cause false alarms on inactive side
Configuration snapshotting	Yes, at `INIT`	Varies



Unlike a single `Q_NumericValue_PHYS` block, which can only display an unsigned magnitude, BargraphSplitFS preserves the sign information natively by assigning the value to one of two bar graph objects. This removes the need for external sign-detection and absolute-value logic in the application.

Conclusion

The BargraphSplitFS function block provides a robust and reusable solution for displaying signed REAL values on a pair of adjacent linear bar graphs. By combining ISO 11783-6 compliant `Q_NumericValue_PHYS` services with systematic clamping and deterministic event sequencing, it delivers a clean, symmetric visual representation where the zero point is always shared between the two bars. Its per-side over-range flags, configuration snapshotting, and deliberate omission of under-range diagnostics make it well suited for agricultural and industrial HMIs that require clear directional magnitude indication.

BargraphSplitFS_AR

• — ○ • — ○ • — ○ •

Introduction

`BargraphSplitFS_AR` is an adapter-based wrapper around the function block `BargraphSplitFS`. Instead of requiring an explicit `REQ` event and a plain `rValue` data input, this block accepts the value through a unidirectional `AR` (adapter-request) socket. This design simplifies integration in systems where the value is already provided via an adapter interface, such as those defined for ISO 11783-6 (ISOBUS) applications. The wrapper internally maps the adapter's event and data to the inner block's `REQ` and `rValue` pins, and passes through the results (status codes and numerical values) to the external interface. Over-range conditions on the left and right sides are re-exposed as `AX` adapter plugs, following the same pattern as `PositionMarkerFSA`.

Interface Structure

Event Inputs

Event	Type	Comment	With Var

INIT	EInit	Service Initialization	stObj

Event Outputs

Event	Type	Comment	With Var
INITO	EInit	Initialization Confirm	–
CNF	Event	Confirmation of Requested Service	STATUSRight, s16resultRight, STATUSLeft, s16resultLeft

Data Inputs

Name	Type	Comment
stObj	isobus::utils::bargraph::BargraphSplit_S	Split-bargraph object pool properties (left/right Bargraph refs, shared magnitude bounds), snapshotted at INIT

Data Outputs

Name	Type	Comment
STATUSRight	STRING	Service Status – passthrough from the internal BargraphSplitFS
s16resultRight	INT	Return value – passthrough from the internal BargraphSplitFS
STATUSLeft	STRING	Service Status – passthrough from the internal BargraphSplitFS
s16resultLeft	INT	Return value – passthrough from the internal BargraphSplitFS

Adapters

Type	Name	Direction	Comment
AX	xOverRight	Plug	rValue exceeded stObj.r32MaxMagnitude, right side clamped
AX	xOverLeft	Plug	–rValue exceeded stObj.r32MaxMagnitude, left side clamped
AR	rPhys	Socket	Signed physical value input (adapter request)

Functionality

The block is a pure wrapper that delegates all processing to an internal instance of BargraphSplitFS. Upon receiving an INIT event, the block snapshots the provided stObj structure and passes it to the inner block. When a value arrives through the rPhys adapter socket (its event E1 and data D1), the internal block's REQ and rValue inputs are activated and supplied accordingly. The inner block computes the two-sided bar graph and issues a CNF event together with the status and result values for both the right and left sides. These outputs are directly forwarded to the parent block's corresponding pins. Any over-range conditions (xOverRight, xOverLeft) are also propagated via the adapter plugs, using the same event/data connection mechanism.

The internal network connections confirm this behaviour:

- INIT ⟶ Inner.INIT
- rPhys.E1 ⟶ Inner.REQ
- rPhys.D1 ⟶ Inner.rValue
- Inner.INITO ⟶ INITO
- Inner.CNF ⟶ CNF, xOverRight.E1, xOverLeft.E1
- Data: stObj ⟶ Inner.stObj; all four status/result outputs are directly mapped from the inner block; Inner.xOverRight ⟶ xOverRight.D1 and Inner.xOverLeft ⟶ xOverLeft.D1.

Technical Features

- **Adapter-Based Input** – The signed physical value is supplied via a unidirectional `AR` socket, eliminating the need for a separate `REQ` event and `rValue` data pin.
- **Passthrough Outputs** – All status and return values of the internal block are directly forwarded without additional processing.
- **Over-Range Indication** – Over-range conditions are exposed as `AX` plugs in the same style as `PositionMarkerFSA`.
- **Single-Shot Initialization** – The `INIT` event transfers the configuration structure `stObj` to the internal block.
- **Complete Encapsulation** – The wrapper hides the internal event/data protocol, presenting a clean adapter interface to the surrounding application.

State Overview

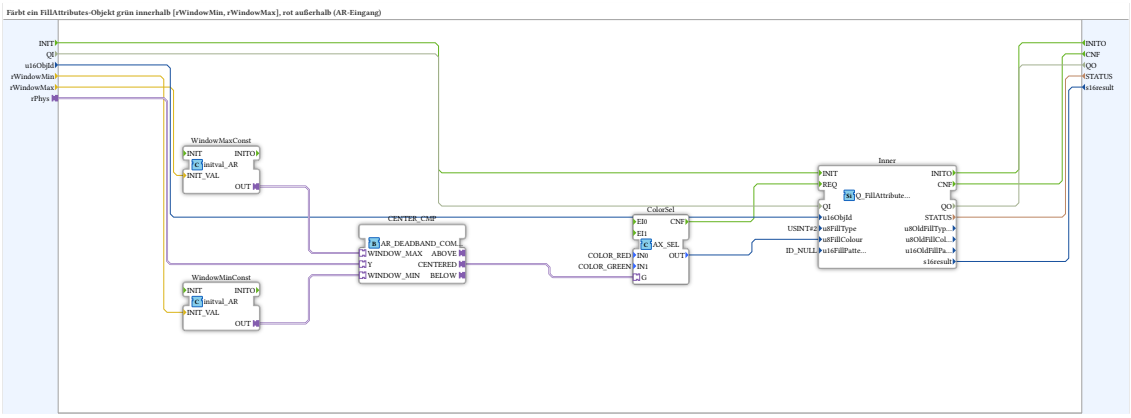
The block itself does not maintain a state machine; it acts as a transparent bridge. Its operational behaviour is fully defined by the internal `BargraphSplitFS` block, which manages the actual split-bargraph calculation. From the perspective of an external caller, the block is ready to accept a value via `rPhys` after initialization (`INITO` has been issued). The `CNF` event signals that the processing of the current request has finished and that the output data are valid.

Application Scenarios

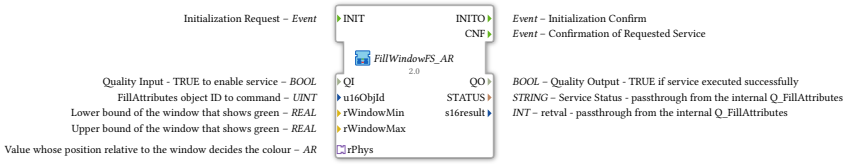
This block is suitable for ISOBUS (ISO 11783-6) applications where a split bar graph must be displayed for a signed physical value, and where the value is already delivered through an adapter interface. Typical use cases include:

- Tractor and implement displays that receive sensor data via a CAN-based adapter.
- Scenarios where the value source is reused across multiple logic parts and both left and right over-range indicators need to be forwarded to other visualisation components.
- Systems that prefer a uniform adapter-based interface for all value inputs, reducing wiring complexity and improving modularity.

Comparison with Similar Blocks



The primary difference to the base block `BargraphSplitFS` is the input mechanism. `BargraphSplitFS` requires an explicit `REQ` event and a separate `rValue` data input, while `BargraphSplitFS_AR` encapsulates these into a single `AR` adapter socket. This makes the block more convenient in adapter-centric architectures, but adds the overhead of a wrapper – the internal block still performs the same calculations.



Compared to `PositionMarkerFSA`, which wraps a position marker block in a similar fashion, this block follows the same design pattern: it uses `AR` for the value input and `AX` for the over-range indications. The naming and structure are consistent, promoting a uniform look and feel across a suite of adapter-wrapped ISOBUS widgets.

Conclusion

`BargraphSplitFS_AR` provides a clean, adapter-based interface to the `BargraphSplitFS` functionality. It simplifies integration in systems that use adapter sockets for value input, while preserving all the features and outputs of the underlying block. The block is well-suited for ISOBUS applications that require a split bar graph with over-range indication and prefer a modular, adapter-oriented design.

FillWindowFS_AR

• — ○ • — ○ • — ○ •

Introduction

The **FillWindowFS_AR** subapplication is a reusable IEC 61499 composite function block designed to colorize a FillAttributes object based on the position of a physical value relative to a configurable window. It accepts a real-valued input through an AR adapter, evaluates whether this value falls within the interval `[rWindowMin, rWindowMax]`, and then commands an internal `Q_FillAttributes` function block (window comparison by an internal `AR_DEADBAND_COMPARE`) to apply either green (inside the window) or red (outside the window) to the specified visualization object. This subapp encapsulates the complete evaluation and coloring logic into a single, network-embeddable component.

Interface Structure

The subapplication exposes the initialization events `INIT`/`INITO`, the quality signals `QI`/`QO`, one confirmation event, three further data inputs, two further data outputs and one adapter socket.

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization request - passed through to the internal `Q_FillAttributes` (`Inner.INIT`).

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization confirmation (from `Inner.INITO`).
CNF	Event	Confirmation of the requested service, passed through from the internal `Q_FillAttributes` block upon completion.

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	TRUE	Quality Input - TRUE to enable the service (to `Inner.QI`).
u16ObjId	UINT	ID_NULL	FillAttributes object ID to command. Identifies the visualization object whose color shall be set.

rWindowMin	REAL	—	Lower bound of the window that shows green. Values equal to or greater than this bound are considered inside the window.
rWindowMax	REAL	—	Upper bound of the window that shows green. Values equal to or less than this bound are considered inside the window.

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if the service was executed successfully (from `Inner.QO`).
STATUS	STRING	Service status — passthrough from the internal `Q_FillAttributes` block, providing textual feedback about the last operation.
s16result	INT	Return value — passthrough from the internal `Q_FillAttributes` block, providing a numeric result code.

Adapters

Name	Type	Direction	Comment
rPhys	adapter::types::unidirectional::AR	Socket	Physical value whose position relative to the window determines the applied color. The incoming AR adapter carries a real number that is evaluated against the configured bounds.

Functionality

The subapplication implements a window evaluation combined with a two-color selection scheme. The functional flow proceeds as follows:

1. **Window Constants** — Two `initval_AR` blocks (`WindowMinConst` and `WindowMaxConst`) convert the externally provided `rWindowMin` and `rWindowMax` values into AR adapter values.
2. **Window Comparison** — The incoming AR adapter `rPhys` is connected as measured value `Y` to an `AR_DEADBAND_COMPARE` block (named `CENTER_CMP`), together with `WINDOW_MIN` (from `WindowMinConst`) and `WINDOW_MAX` (from `WindowMaxConst`). Its AX plug `CENTERED` is `TRUE` while `WINDOW_MIN ≤ Y ≤ WINDOW_MAX` holds (the plugs `ABOVE`/`BELOW` are not used here), i.e. the closed interval `[rWindowMin, rWindowMax]`.
3. **Color Selection** — `CENTERED` drives an `AX_SEL` block (named `ColorSel`) with `IN0` fixed to `COLOR_RED` and `IN1` fixed to `COLOR_GREEN`. When `CENTERED` is `TRUE`, green is selected; otherwise, red is selected. The chosen color is passed as the `OUT` value.
4. **Fill Command** — The color output from `ColorSel` is routed to the `u8FillColour` input of the internal `Q_FillAttributes` block (named `Inner`). Simultaneously, the external `u16ObjId` is connected to the block's object ID input. The block is parameterized with `u8FillType = USINT#2` (solid fill) and `u16FillPatternId = ID_NULL`.
5. **Event Handshaking** — The `ColorSel.CNF` event triggers the `Inner.REQ` event, initiating the fill operation. Upon completion, the internal block's `CNF` event is propagated to the subapplication's external `CNF` output.
6. **Result Propagation** — Both `STATUS` and `s16result` from the internal `Q_FillAttributes` block are forwarded directly to the subapplication's corresponding output ports, providing full transparency about the operation's outcome.
7. **Initialization and Quality Signals** — These are passed straight through: `INIT` ⟶ `Inner.INIT`, `Inner.INITO` ⟶ `INITO`, `QI` ⟶ `Inner.QI` and `Inner.QO` ⟶ `QO`.

Technical Features

- **Composite SubApplication Type** — Implemented as a `SubAppType` rather than a custom FBType, allowing easy reuse and modification through standard 4diac-IDE tooling.
- **Adapter-Based Input** — The physical value is acquired via a unidirectional AR adapter, decoupling the subapp from specific sensor or data source implementations and promoting type-safe connections.
- **Constant Initialization Pattern** — Utilizes `initval_AR` blocks to convert runtime REAL variables into adapter-based constant values, leveraging the adapter framework's type system.
- **Window Comparison** — Closed interval evaluation by `AR_DEADBAND_COMPARE` (`CENTERED` output), guaranteeing that boundary values are treated as inside the window. Since version 2.0 this replaces the former own split/GE/LE/AND wiring.
- **Color Mapping** — Pre-configured `AX_SEL` parameters with `COLOR_RED` and `COLOR_GREEN` constants, drawing from the `isobus::UT::Q::const::colours` namespace.
- **Event Propagation Chain** — A clean event cascade from selection confirmation to fill request, then back to the caller via the `CNF` output. Apart from `INIT` there are no event inputs; the coloring is triggered by new data on the adapter `rPhys` (or on the window bounds).
- **Status Passthrough** — Both status string and result integer are exposed at the subapp boundary, enabling callers to monitor and log operations without inspecting internal state.
- **Quality Pattern** — `QI` (default `TRUE`) enables the service, `QO` reports the success of the internal `Q_FillAttributes`.
- **Namespace Imports** — Explicit imports of `ID_NULL` and the color constants ensure compile-time correctness in the target runtime environment.

State Overview

`FillWindowFS_AR` does not maintain an explicit internal state machine of its own (`AR_DEADBAND_COMPARE` only reports changes of its outputs, and `INIT`/`INITO` are merely passed through). The observable behavior per service cycle can be summarized as:

Condition	Evaluation Result	Selected Color	Fill Command
`rPhys < rWindowMin`	Outside (below)	RED	Solid red fill
`rWindowMin ≤ rPhys ≤ rWindowMax`	Inside window	GREEN	Solid green fill
`rPhys > rWindowMax`	Outside (above)	RED	Solid red fill

The behavior is fully deterministic for a given set of inputs.

Application Scenarios

- **Visualization of Process Variables** — In a process control HMI, the subapp can color-code a numeric indicator (e.g., temperature, pressure, level) green when it lies within an acceptable operating range and red when it deviates, providing immediate visual feedback to operators.
- **Alarm and Limit Monitoring** — When integrated with alarm handling logic, the subapp can be used to repaint warning icons or trend markers based on whether a measured value violates configured thresholds.
- **Quality Control and Sorting** — In manufacturing or inspection systems, the block can visually flag measured dimensions or test results that fall outside tolerance windows.
- **Interactive Panels and Dashboards** — The subapp can drive color changes on dashboard widgets where a physical quantity's range (e.g., speed, fuel level, temperature) determines the displayed color.
- **Educational Demonstrations** — As a clearly structured composite, it serves as a learning example for adapter-based data flow, window comparisons, and event-driven service invocation in IEC 61499 systems.

Comparison with Similar Blocks

Feature	FillWindowFS_AR	Custom FBType with ST Helper	GreenRedBackground1_AX
Implementation	SubAppType composite	Custom compiled FBType	Similar SubApp approach
Input Paradigm	AR adapter for physical value	Direct data inputs	AR adapter

Window Evaluation	Internal `AR_DEADBAND_COMPARE (CENTERED)`	Inline ST condition	Configurable via parameters
Color Constants	Fixed RED/GREEN	Depends on implementation	Fixed RED/GREEN
Event Output	Single CNF	Depends on design	Single CNF
Reconfigurability	High (network editable)	Medium (code changes)	High
Runtime Dependencies	Only standard adapter FBs	Custom compiled code	Standard adapter FBs

Compared to a hand-coded FBType with ST logic, this subapp leverages standard building blocks, making it more transparent, portable, and inspectable at the network level. Relative to similar background-coloring subapps, it adds the window-based comparison and the physical-value adapter input in an integrated form.

Conclusion

The **FillWindowFS_AR** subapplication provides a compact, well-structured, and reusable solution for range-based color visualization of physical values on FillAttributes objects. By combining the standard window comparison block `AR_DEADBAND_COMPARE`, a selection block, and a `Q_FillAttributes` service block, it implements a complete green-inside / red-outside logic with minimal external wiring. The clear interface, event passthrough (`INIT`/`INITO`, `CNF`), quality signals (`QI`/`QO`) and status propagation make it straightforward to integrate into larger IEC 61499 applications, while the adapter-based input ensures compatibility with a wide range of sensor and data sources. It is a practical building block for HMI development, alarm visualization, and quality-related color-coding tasks in industrial automation environments.

Instance Uniqueness of Q_* Function Blocks

Each `Q_*` function block maintains its own independent value/pending buffer (`var_qPending`, `var_*OldValue`, see `sendXxx()`/`resetPendingState()`). If two instances of the SAME class are connected to the same target (Object ID, Mask ID, etc.), they operate independently without mutual awareness, leading to competing VT bus commands. Therefore, each block requires an instance uniqueness criterion defining what may exist at most once.

Since commit `792e35673` (“Detect duplicate object-ID claims across instances of the same FB class”), an enforcement mechanism exists: `CQ_VTCommandBase::mTargetObjectId` (+ optional `mTargetSubId` for composite keys, see `Q_Attribute` below) + `IsObjectIdAlreadyClaimed(objId, subId = 0xFFFF)` (`CQ_VTCommandBase.h`/`.cpp`). A second instance encountering an already claimed (Object ID[, Sub-ID]) pair upon `INIT` is deactivated with `STATUS = "This objID is already in use"`.

Criterion: One Instance PER OBJECT ID (Enforced)

The target is a variable VT Object ID (`u16ObjId`, set during `INIT` via `var_u16ObjId` and validated against class-specific ID ranges). Two instances with the same Object ID would compete independently over the same object state.

Function Block	Target ID Definition
`Q_Attribute`	**Pair** (Object ID, Attribute ID) - `mTargetObjectId=u16ObjId`, `mTargetSubId=u8IdAttribute`. Two instances targeting the same object but different attributes are valid; only duplicate pairs collide.
`Q_BackgroundColour`	Object with background color attribute. May share an Object ID with ONE `Q_BackgroundColourAux` instance (different FB class), but NEVER two `Q_BackgroundColour` instances on the same Object ID.
`Q_BackgroundColourAux`	AuxFunction object (AUX VT, **enforced**). Unique per Object ID within its own FB class (`getFBTypeId()`). May share an Object ID with ONE `Q_BackgroundColour` instance, but NEVER two `Q_BackgroundColourAux` instances on the same Object ID.

Q_ChangeObjectLabel	Labelable object
Q_ChangePolygonPoint	Polygon object
Q_ChangePolygonScale	Polygon object
Q_ChildLocation	Child object (Child Location)
Q_ChildPosition	Child object (Child Position)
Q_EndPoint	Line object
Q_FillAttributes	Object with fill attributes
Q_FontAttributes	Object with font attributes
Q_GraphicsContext	Graphics Context object
Q_LineAttributes	Object with line attributes
Q_ListItem	**Pair** (List Object ID, List Index) - mTargetObjectId=u16ObjId, mTargetSubId=u8ListIndex. Read at INIT via With Var="u8ListIndex" — claimed during INIT in iso_init().
Q_NumericValue	Numeric Value object. (ObjectPointer exception allows co-existence with Q_NumericValueAux).
Q_ObjEnableDisable	Enableable/disableable object
Q_ObjHideShow	Container object (3000–3999)
Q_ObjSelectInput	Input-selectable object
Q_Size	Resizable object
Q_StringValue	String Value object

Criterion: One Instance PER OBJECT ID (Not Yet Enforced)

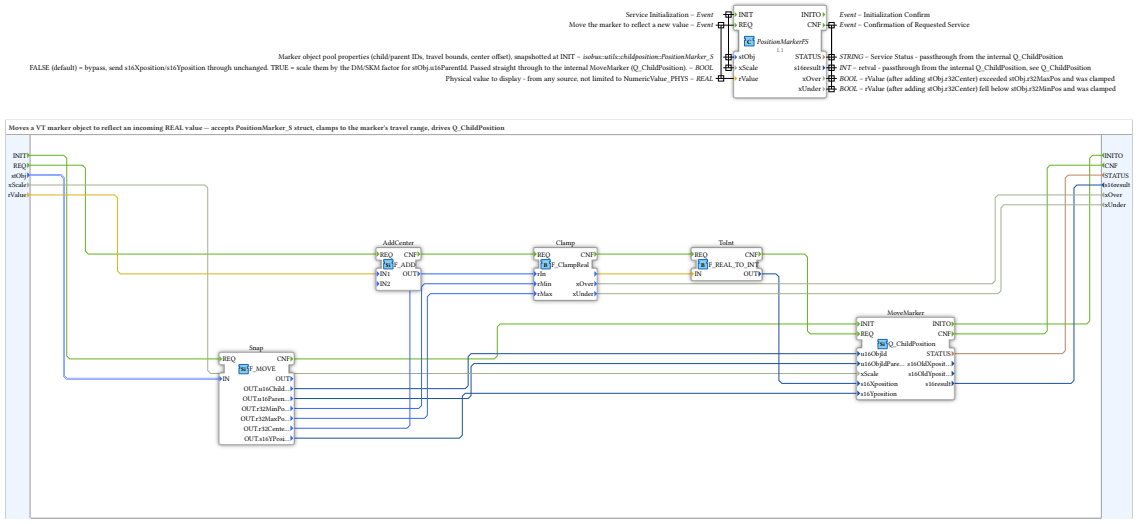
Function Block	Target ID Definition	Notes
Q_NumericValueAux	AUX VT Object	Additional gate (VtAuxAssignment)
Q_ExecuteMacro	Macro object	
Q_ExecuteExtendedMacro	Macro object	
Q_LockUnlockMask	Mask Object (u16MaskId, read at INIT)	Target is a mask (u16MaskId)
Q_Priority	Alarm Mask object	

Criterion: Exactly ONE Instance Program-Wide (Singleton)

Function Block	Real Target (Parameter at REQ)	Status
Q_ActiveMask	u16NewMaskId (Fixed target ID = 0)	**Enforced**
Q_SelectActiveWorkingSet	Working Set Name	Open gap
Q_SelectColourMap	Colour Map Object ID	Open gap
Q_SetAudioVolume	Volume setting	Open gap
Q_SoftKeyMask	Data Mask / SoftKey Mask IDs	Open gap
Q_CtrlAudioSignal	Signal parameters	Open gap

No Criterion Needed (Stateless)

Function Block	Reason
`Q_ESC`	No Object ID or old value buffering. Direct transmission upon `REQ`.



Adapter Wrappers (`_AUI`, `_AUDI`, `_AB`, `_AX`, `_AR`)

Adapter variants (e.g., `Q_NumericValue_AUDI`, `Q_ObjHideShow_AB`) are wrapper function blocks around their respective base classes (e.g., `Q_NumericValue`, `Q_ObjHideShow`). Because the adapter wrapper builds on the underlying base class, **instance uniqueness applies across the wrapper boundary**: An Object ID may be claimed program-wide by at most **one** instance (either base class or adapter wrapper). Simultaneous usage of base and wrapper instances on the same Object ID is invalid.

Separate I_* Module

`I_GetAttribute` (`isobus_UT/src/isobus/UT/I/`) requires pair uniqueness over (`u16ObjId`, `u8IdAttribute`).

PositionMarkerFS

• – ○ • – ○ • – ○ •

Introduction

PositionMarkerFS is a function block designed to move a Virtual Terminal (VT) marker object so that it reflects an arbitrary incoming REAL value. It wraps a single **Q_ChildPosition** instance (ISO 11783-6, Annex F.16) and provides a clean, high-level interface for positioning a marker (e.g., a triangle or other graphical element) within its parent container on an ISOBUS VT display.

The block accepts a structured configuration object (`PositionMarker_S`) containing the marker's object pool identifiers, travel bounds, and center offset. It snapshots this structure once at initialization, then on each request:

1. Offsets the incoming value by the configured center offset.
2. Clamps the result to the marker's minimum/maximum travel range.
3. Converts the clamped value to an integer and forwards it as the marker's X position.
4. Passes through the Y position unchanged.

Clamping events are reported via dedicated status outputs, and all results from the underlying `Q_ChildPosition` service are propagated to the caller.

Interface Structure

Event Inputs

Event	Type	With Variables	Description

`INIT`	EInit	`stObj`, `xScale`	Service initialization. Snapshots the marker configuration and initializes the internal `Q_ChildPosition` instance.
`REQ`	Event	`rValue`	Requests the marker to move to reflect the newly supplied value.

Event Outputs

Event	Type	With Variables	Description
`INITO`	EInit	—	Initialization confirm. Emitted after `INIT` has been successfully processed.
`CNF`	Event	`STATUS`, `s16result`, `xOver`, `xUnder`	Confirmation of a requested move, carrying the service status, return value, and clamp indicators.

Data Inputs

Name	Type	Initial Value	Description
`stObj`	`sitobus::utils::childposition::PositionMarker_S`	—	Marker object pool properties: child ID, parent ID, travel bounds (`r32MinPos`, `r32MaxPos`), center offset (`r32Center`), and fixed Y position (`s16YPosition`). Snapshot once at `INIT`.
`xScale`	`BOOL`	`FALSE`	When `FALSE` (default), X and Y positions are passed through unchanged. When `TRUE`, they are scaled by the DM/SKM factor for the parent object. Passed straight through to the internal `Q_ChildPosition`.
`rValue`	`REAL`	—	The physical value to display. Can originate from any source — a VT input number, a sensor reading, or any other logic.

Data Outputs

Name	Type	Description
`STATUS`	`STRING`	Service status, passed through directly from the internal `Q_ChildPosition` instance.
`s16result`	`INT`	Return value from the internal `Q_ChildPosition`, indicating the outcome of the child-position command.
`xOver`	`BOOL`	Set when the requested value (after adding `r32Center`) exceeded `r32MaxPos` and was clamped.
`xUnder`	`BOOL`	Set when the requested value (after adding `r32Center`) fell below `r32MinPos` and was clamped.

Adapters

This function block does not expose any adapters.

Functionality

The block operates in two distinct phases:

Initialization — When `INIT` is triggered, the input structure `stObj` is copied into an internal snapshot using an `F_MOVE` function block. This snapshot is then used to configure the embedded `Q_ChildPosition`

service with the correct child ID, parent ID, and scale flag. The INITO event confirms successful initialization.

Value Processing — On each REQ event, the following pipeline is executed:

1. **Offset**: The incoming rValue is added to the snapshot's r32Center value using F_ADD. This accounts for any centering offset of the marker within its travel range.
2. **Clamp**: The offset result is passed through F_ClampReal, which restricts the value to the interval [r32MinPos, r32MaxPos]. If clamping occurs, the xOver or xUnder flags are set accordingly.
3. **Conversion**: The clamped REAL value is converted to an INT using F_REAL_TO_INT (truncation).
4. **Positioning**: The converted value is written to s16Xposition of the internal Q_ChildPosition service, along with the snapshot's s16YPosition (passed through unchanged). The service is then requested to move the marker.

The CNF event propagates the STATUS, s16result, xOver and xUnder outputs from the internal service and the clamping stage, giving the caller full visibility into the operation's outcome.

Technical Features

- **ISO 11783-6 compliant** — the wrapped Q_ChildPosition service follows the ISOBUS VT child position semantics (Annex F.16).
- **Snapshot-based configuration** — the PositionMarker_S structure is captured once at INIT, preventing later modifications from corrupting the working state.
- **Integer conversion** — the REAL input is converted to an INT only once, at the point where it is needed by the VT service, minimizing unnecessary conversions.
- **Clamp reporting** — over-range and under-range conditions are explicitly reported, allowing the caller to react to out-of-bounds input values.
- **Scale pass-through** — the xScale flag is forwarded verbatim to the internal Q_ChildPosition, giving direct control over DM/SKM scaling behavior.
- **Fully event-driven** — both initialization and operation follow the strict REQ/CNF and INIT/INITO handshake patterns common to 4diac service interface function blocks.

State Overview

The block does not maintain an explicit state machine but relies on the internal Q_ChildPosition service for its lifecycle. The externally observable states are:

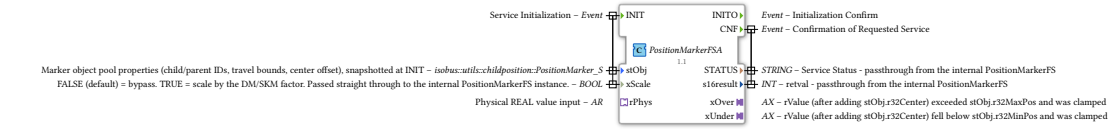
- **Uninitialized** — before INIT has been processed, or after an unsuccessful initialization. A REQ issued in this state will produce undefined behavior and should be avoided.
- **Initialized / Idle** — after INITO is emitted, the block is ready to accept REQ events. It remains idle while no request is being processed.
- **Processing** — between receiving a REQ and emitting the corresponding CNF. During this window, the internal pipeline (add → clamp → convert → move) is active.
- **Clamped** — a sub-state during processing where the value was out of range; indicated by xOver or xUnder being TRUE on the CNF output.

Application Scenarios

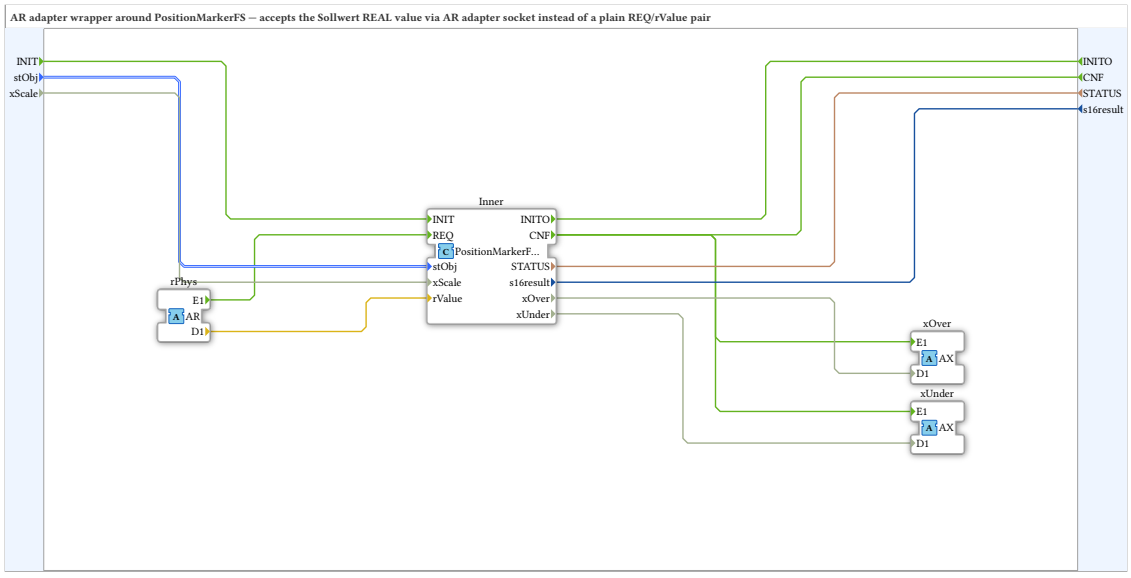
- **ISOBUS VT input displays** — Display a numeric value (e.g., from a NumericValue_PHYS object) as a moving marker on a VT screen.
- **Sensor value visualization** — Map a continuous sensor reading (temperature, pressure, position) to the position of a graphical indicator on a machine display.
- **Process control dashboards** — Drive a marker inside a tank, gauge, or scale graphic, where the marker's horizontal position encodes a real-world measurement.
- **Machine automation** — Combine with any REAL-valued process variable to provide immediate visual feedback on a VT, including automatic clamping when limits are exceeded.

Comparison with Similar Blocks

Feature	PositionMarkerFS	Typical raw Q_ChildPosition usage
Input type	Accepts a physical REAL value	Requires an already-formatted INT position
Center offset handling	Built-in via r32Center	Must be handled by the caller



Clamp protection	Automatic, with status flags	Not provided; out-of-range values would corrupt the display
Configuration	Snapshot-based, single `stObj` struct	Requires manual set-up of multiple parameters
Y-position handling	Passed through automatically	Must be managed separately
Scale handling	Optional pass-through `xScale`	Caller must know when to scale



Compared to using `Q_ChildPosition` directly, `PositionMarkerFS` abstracts away the type conversion, clamping, and center offset, resulting in fewer errors at the call site and a clearer data flow. It is more specialized than a generic clamp/scale block but significantly more convenient for VT marker positioning tasks.

Conclusion

PositionMarkerFS bridges the gap between arbitrary REAL-valued process data and precise, clamp-safe VT marker positioning in the ISOBUS environment. By encapsulating the offset, clamping, conversion, and child-position service calls into a single, well-defined interface, it simplifies application code and reduces the risk of marker positioning errors. The block is particularly suited for dashboards, gauges, and any scenario where a physical value must be rendered visually on a Virtual Terminal with predictable behavior at range limits.

PositionMarkerFSA

• — ○ • — ○ • — ○ •

Introduction

PositionMarkerFSA is an adapter wrapper around the `PositionMarkerFS` function block. It accepts a physical REAL value (Sollwert) via an AR (incoming) adapter socket and forwards it as the setpoint to an internally instantiated `PositionMarkerFS`. This design follows the same pattern as `Q_NumericValue_PHYSA` around `Q_NumericValue_PHYS`, re-exposing the over- and under-limit indications through AX (outgoing) adapter plugs instead of distinct event/data ports.

The wrapper handles all communication between the adapter-based interface and the internal FB, relieving the developer from manually connecting the `REQ`/`rValue` pair for each invocation.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Service initialization; snapshots stObj and xScale into the internal PositionMarkerFS instance.

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization confirm – emitted after the internal FB has been successfully initialized.
CNF	Event	Confirmation of a requested service – raised whenever the internal FB confirms a position-rating request. Carries STATUS and s16result as data.

Data Inputs

Data	Type	Comment
stObj	forte::isobus::utils::childposition::PositionMarkerObj	Marker object pool properties: child/parent IDs, travel bounds, and center offset. This structure is captured at INIT and passed unchanged to the internal FB.
xScale	BOOL	Scaling control: FALSE (default) bypasses the DM/SKM scaling factor; TRUE enables it. This flag is forwarded to the internal PositionMarkerFS.

Data Outputs

Data	Type	Comment
STATUS	STRING	Service status – a direct passthrough from the internal PositionMarkerFS.
s16result	INT	Return value – a direct passthrough from the internal PositionMarkerFS.

Adapters

Adapter	Direction	Type	Comment
rPhys	Socket (Input)	adapter::types::unidirectional::AR	Physical REAL value input – the Sollwert that drives the internal FB.
xOver	Plug (Output)	adapter::types::unidirectional::AX	Signals when the actual position (after adding stObj.r32Center) exceeds stObj.r32MaxPos and is clamped.
xUnder	Plug (Output)	adapter::types::unidirectional::AX	Signals when the actual position falls below stObj.r32MinPos and is clamped.

Functionality

PositionMarkerFSA encapsulates the complete data and event flow of a position marker calculation. On INIT, it passes the stObj and xScale values to the internal PositionMarkerFS instance, which initializes its internal state. Later, each incoming event from the rPhys adapter (via its internal E1 output) triggers the REQ event of the internal FB, simultaneously transferring the physical value (rPhys.D1) as the new setpoint (rValue). The internal FB performs the marker position analysis and responds with a CNF event.

The wrapper forwards the INIT0 and CNF events to its own outputs, and also re-emits the CNF event to both adapter plugs xOver and xUnder so that limit violations can be propagated asynchronously. The data outputs STATUS and s16result are copied directly from the internal FB.

Technical Features

- **Adapter-based I/O**: The input (physical value) and outputs (limit flags) are provided using unidirectional AR/AX adapter types, making the block easy to connect in CAN-based environments where such adapter patterns are common.
- **Single internal FB instance**: The block instantiates exactly one PositionMarkerFS, keeping the implementation lean and preserving all its original semantics.
- **Passthrough of status and result**: STATUS and s16result are forwarded without modification, allowing the host system to inspect detailed results.
- **Scaling control**: The xScale flag is passed straight through to the internal FB, giving developers the option to enable or disable scaling without altering the adapter interface.
- **Automatic event wiring**: The adapter's event output (E1) is directly connected to the internal REQ event; the internal CNF event is distributed to both the main CNF output and the two adapter plugs.

State Overview

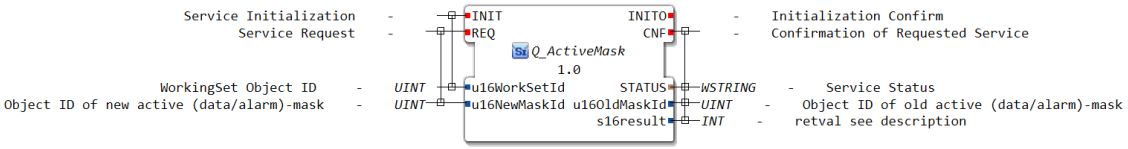
PositionMarkerFSA does not introduce its own state machine. Instead, it delegates all state handling to the internal PositionMarkerFS. Therefore, the state behaviour matches that of the underlying block:

- **Initialization phase**: After INIT, the internal FB is configured with the marker object pool and scaling flag. It then emits INIT0.
- **Request/confirmation phase**: Each request via rPhys (or the corresponding adapter event) leads to a calculation cycle. On completion, the internal FB emits CNF and updates STATUS and s16result. Additionally, if the calculated position exceeds or falls below the given limits, the corresponding adapter plug (xOver/xUnder) is activated.

Application Scenarios

PositionMarkerFSA is best suited for systems that use adapter-based communication, particularly in agricultural or mobile machinery applications following the ISO 11783 (ISOBUS) standard. Common use cases include:

- Integrating a position marker into a CAN network where the setpoint is transmitted as a physical REAL value and the limit flags are expected as separate adapter-based outputs.
- Replacing older designs that used plain REQ/rValue input pairs with a more structured adapter interface, without changing the core calculation logic.
- Using the xScale flag to conditionally apply scaling factors, making the block adaptable to different machine configurations.

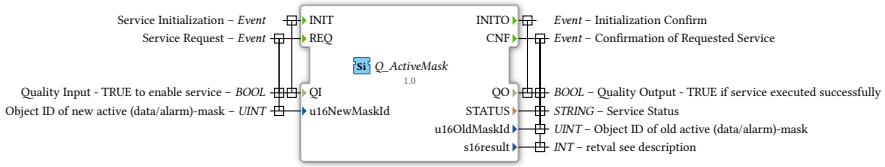


Comparison with Similar Blocks

- **PositionMarkerFS** – This is the underlying FB, which provides a plain REQ/rValue interface and separate xOver/xUnder data outputs. PositionMarkerFSA wraps it to present an adapter-based interface, simplifying integration in adapter-friendly networks.
- **Q_NumericValue_PHYSA** – A similar wrapper pattern that wraps Q_NumericValue_PHYS; PositionMarkerFSA follows the same design philosophy but is specifically tailored for the position marker logic.
- **PositionMarker_S** – This is a data structure used as input, not an FB itself. In comparison, PositionMarkerFSA is a complete function block that consumes PositionMarker_S and produces status and limit indications.

Conclusion

PositionMarkerFSA provides a clean, adapter-oriented interface for driving a position marker calculation. By wrapping the established PositionMarkerFS FB, it preserves all functional behaviour while improving integration flexibility in adapter-based systems. The clear separation of the input (physical value), outputs (status, result, and limit flags), and the optional scaling control makes it a valuable building block for ISOBUS-compliant implementations.



Q_ActiveMask

• — ○ • — ○ • — ○ •

Introduction

The **Q_ActiveMask** is a standards-compliant function block for controlling active masks in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.34) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request
- `REQ`: Screen Change Request (with parameters)

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Screen Change Confirmation (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16NewMaskId` (UINT): Object ID of the new screen

!!! Note: “WorkingSet Object ID fixed to 0”

The **WorkingSet Object ID** (`u16WorkSetId`) is **fixed to 0** by the authors of logiBUS®. The user must ensure that the WorkingSet object in the object pool always has Object ID 0. This is the default setting in most tools:

- ISO-Designer from Bucher Automation AG
- Isobus Studio from to-the-future / Tobias Tenberg

Since the working set is a single object and only exists once, this limitation is not a problem.

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operating status message
- `u16OldMaskId` (UINT): Object ID of the previous screen
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16NewMaskId` — valid mask object types (Annex F.34): Data Mask (1000–1999), Alarm Mask (2000–2999).

ID_NULL (65535) is not a valid command target for the new active mask. Any ID outside these ranges is invalid for commanding.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` event starts the function block
- `INITO` confirms successful setup

1. **Mask Change**:

- Trigger `REQ` with new mask parameters
- Return `CNF` result and previous mask ID

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.34)
✓ **Deterministic** behavior ✓ **Multi-client capable** architecture ✓ **Real-time capable** execution

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	Invalid State
−21	VT_E_NO_INSTANCE	No VT Instance

Application Scenarios

- **Tractor Controls**: Operating Mode Switching
- **Harvest Monitoring**: Data Acquisition Masks
- **Diagnostic Systems**: Fault Display Masks
- **Multi-Terminal Operation**: Synchronized Displays

⚖️ Comparison with Similar Function Blocks

Feature	Q_ActiveMask	VtMaskManager	VtDynamicDisplay

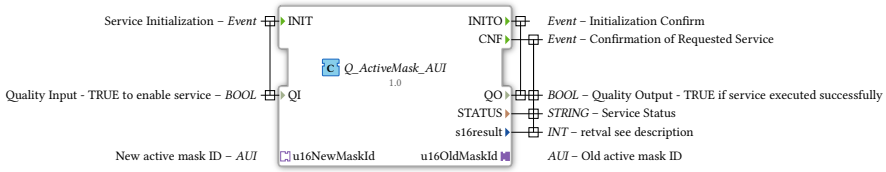
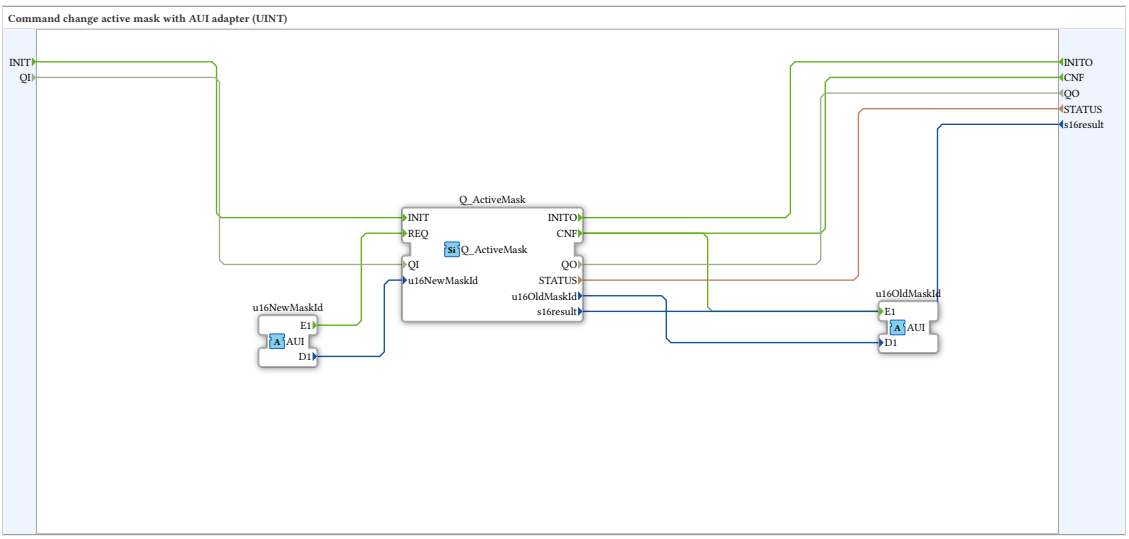
- Exercise_019a
- Exercise_019b
- Exercise_019c

Conclusion



The Q_ActiveMask block provides the reference implementation for ISOBUS mask switching:



- **Standard-compliant**: Full ISO 11783-6 compatibility
- **Robust**: Proven technology in series production
- **Flexible**: Supports complex display scenarios

Essential for:

- Manufacturers of ISOBUS terminals
- Developers of agricultural control units
- System integrators in agricultural technology

Q_ActiveMask_AUI

• – ○ • – ○ • – ○ •

Introduction

The **Q_ActiveMask_AUI** function block is an AUI (Adapter User Interface) wrapper for the core block **Q_ActiveMask**. It provides a convenient, unidirectional adapter–based interface to change the active mask on an ISO 11783-6 (ISOBUS) Virtual Terminal. The block encapsulates the functionality of the underlying service, translating adapter signals into the internal request/confirm protocol of the wrapped block.

This wrapper is designed for applications that already use the unidirectional AUI adapter type for data exchange, simplifying integration into existing adapter-based networks. It handles the complete command sequence to change the active mask, returning both the status of the operation and a result code.

Interface Structure

Event Inputs

Event	Type	Comment
`INIT`	EInit	Service Initialization (with `QI`)

Event Outputs

Event	Type	With Variables	Comment
`INITO`	EInit	`QO`	Initialization Confirm
`CNF`	Event	`QO`, `STATUS`, `s16result`	Confirmation of Requested Service

Data Inputs

Data Name	Type	Comment
`QI`	BOOL	Quality input, `TRUE` enables the service (default `TRUE`)

All other input data is exchanged via the adapters.

Data Outputs

Data Name	Type	Comment
QO	BOOL	Quality output, TRUE if the service was executed successfully
STATUS	STRING	Service Status
s16result	INT	Retval – see description in the core block

Adapters

Direction	Name	Type	Comment
Socket	u16NewMaskId	adapter::types::unidirectional::AUI	New active mask ID
Plug	u16OldMaskId	adapter::types::unidirectional::AUI	Old active mask ID

The adapter data (D1) carries a 16-bit unsigned integer (UINT) representing the mask ID. The AUI adapter provides a single event (E1) on both sides to trigger the transfer.

Functionality

The block acts as a bridge between an AUI adapter network and the internal Q_ActiveMask function block. When the **u16NewMaskId** socket receives a new value via its E1 event, the wrapper internally issues a REQ to the Q_ActiveMask block, supplying the new mask ID. After processing, the Q_ActiveMask block produces a CNF event, which is propagated to the output as CNF, together with the STATUS and s16result values. Additionally, the old mask ID is sent back through the **u16OldMaskId** plug using its E1 event, and the corresponding data value is transferred.

Initialization is handled by the INIT event, which is forwarded to the internal block, and INITO is generated once the initialization completes. QI is passed through to Q_ActiveMask.QI, and Q_ActiveMask.QO is passed through to QO.

This wrapper does not implement the service logic itself; it relies entirely on the Q_ActiveMask function block for the actual ISO 11783-6 command (Part 6, F.34). The wrapper only adapts the data flow to and from the AUI interfaces.

Technical Features

- **AUI Adapter Compatible**: Uses the standard unidirectional AUI adapter type, allowing direct connection to other adapter-based components.
- **Seamless Integration**: The internal Q_ActiveMask block is fully encapsulated; only the adapter interface is exposed.
- **Error and Status Reporting**: Provides textual status (STATUS) and a numeric result (s16result) on every confirmation.
- **Event-Driven**: All operations are triggered by incoming events (init, new mask ID), making it suitable for cyclic or event-driven control systems.
- **Platform Independent**: The block is written in standard IEC 61499 and can be used in any 4diac-compatible runtime.

State Overview

The block does not maintain an explicit state machine of its own; it inherits the behaviour of the wrapped Q_ActiveMask block. The internal block typically operates in the following states:

1. **Idle**: Waiting for a new mask ID command.
2. **Busy**: Processing a request (between REQ and CNF).
3. **Completed**: A CNF has been issued, the block returns to idle.

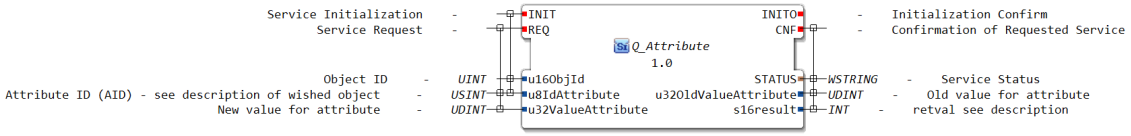
The wrapper only forwards events and data accordingly. The INIT event initialises the internal block, and INITO confirms successful initialisation.

Application Scenarios

- **ISOBUS Virtual Terminal Control**: Use this block in agricultural machinery to change the currently displayed working set or main mask on a VT.
- **Adapter-Based Architectures**: In systems where all external communication is performed via AUI adapters, this wrapper eliminates the need to expose raw event/data ports.

- **Multi-Mask Management**: Combine multiple instances to manage several mask IDs or to switch between different screens based on operational state.
- **Prototyping and Simulation**: The wrapper simplifies testing by providing a clean adapter interface that can be easily driven by simulation models or other adapters.

Comparison with Similar Blocks



- **Q_ActiveMask (core block)**: The core block provides separate event and data inputs/outputs. The AUI wrapper abstracts those into a single adapter pair, reducing wiring complexity, but adds an extra layer of indirection.
- **Q_ActiveMask_AUI vs. other adapter wrappers**: Many ISOBUS commands have similar AUI wrappers (e.g., `Q_SetBackgroundColor_AUI`). They all follow the same pattern – a socket for the "new" data, a plug for the "old" data, and common event outputs.

The main advantage of this wrapper is that it fits directly into adapter-based communication frameworks, promoting modular design and reusability. The disadvantage is a slight increase in block count and the need to manage two adapter connections.

Conclusion

The **Q_ActiveMask_AUI** function block provides a pragmatic and clean solution for changing the active mask in an ISOBUS VT using unidirectional AUI adapters. It encapsulates the underlying `Q_ActiveMask` logic, exposes a minimal and well-defined interface, and integrates smoothly into event-driven industrial control systems. Its use of standard AUI types ensures high compatibility with existing adapter-oriented designs, making it a valuable component for ISOBUS applications.

Q_Attribute

• — ○ • — ○ • — ○ •

Introduction

The **Q_Attribute** is a standards-compliant function block for modifying VT object properties, developed under the EPL 2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.38) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID and attribute ID)
- `REQ`: Attribute Change Request (with new value)

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Object Identifier
- `u8IdAttribute` (USINT): Attribute Identifier (AID)
- `u32ValueAttribute` (UDINT): New Attribute Value

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operational status message
- `u32OldValueAttribute` (UDINT): Previous attribute value
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` (the object whose attribute is changed) and `u8IdAttribute` (the Attribute ID, AID) are subject to **different** validity rules.

`u16ObjId` — valid object types (Annex F.38): Data Mask (1000–1999), Alarm Mask (2000–2999), Soft Key Mask (4000–4999), Key (5000–5999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Input List Field (10000–10999), Auxiliary Function Type 2 (31000–31999).

`u8IdAttribute` (AID): Valid attribute IDs are object-type specific and defined in Annex B, in the attribute tables of each object type. An AID with no attribute assigned is rejected by the VT ("Invalid Attribute ID", F.39).

ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with object and attribute ID
- `INITO` confirms operational readiness

1. **Attribute Change**:

- `REQ` triggers with new value
- `CNF` returns result and old value

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 Compliant** (F.38) ✓ **Deterministic** Execution ✓ **32-bit Value Support** ✓ **Real-time** Processing

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	Invalid State
−21	VT_E_NO_INSTANCE	No VT Instance

Application Scenarios

- **Display Settings**: Visibility/Position of VT Objects
- **Machine Configuration**: Adjusting Operating Parameters
- **Diagnostic Systems**: Controlling Debug Information
- **Multi-Terminal Operation**: Consistent Object Attributes

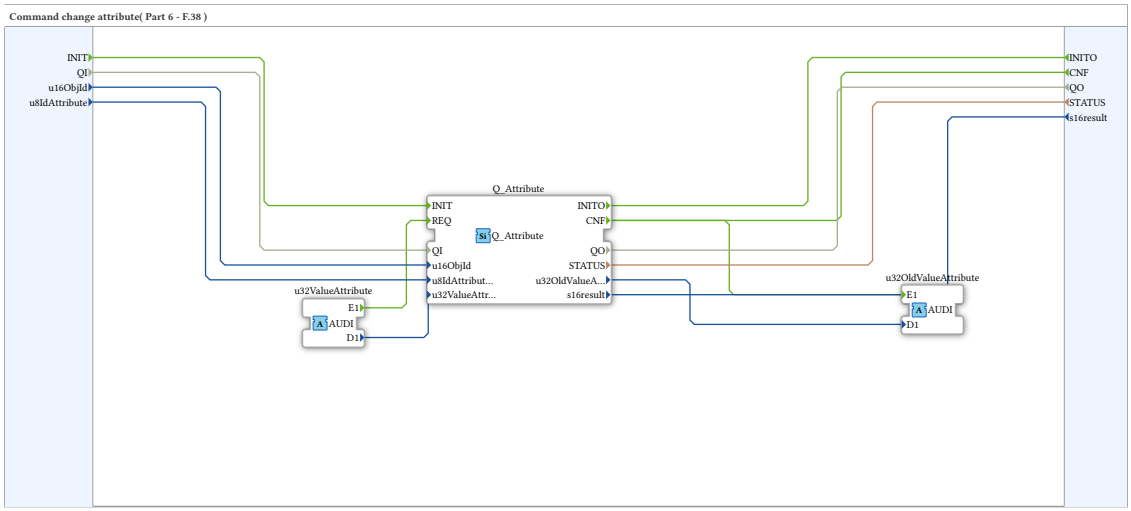
⚖️ Comparison with Similar Blocks

Feature	Q_Attribute	VtPropertySet	VtDynamicConfig
ISO Standard	✓	✖	✖

Value Range	32-bit	16-bit	32-bit
State Management	Full	Partial	Extended

Conclusion

The Q_Attribute block provides the reference implementation for ISOBUS attribute control:



- **Standard-compliant**: Full ISO 11783-6 compatibility
- **High-performance**: 32-bit value support
- **Reliable**: Proven technology in field devices

Essential for:

- VT object controllers
- Dynamic display configurations
- Machine parameter adapters

Q_Attribute_AUDI

• – ○ • – ○ • – ○ •

Introduction

The function block **Q_Attribute_AUDI** implements the “Change Attribute” command of the ISOBUS standard ISO 11783-6 (Part 6 – F.38). It allows you to change an attribute of an object that is identified by a unique attribute ID (AID). The block supports passing the new attribute value via an adapter interface and returns the old value via an adapter as well. String attributes cannot be changed with this command.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initializes the service and starts communication with the ISOBUS VT

Event Outputs

Event	Type	Description

INITO	EInit	Confirms successful completion of initialization
CNF	Event	Confirms execution of the requested attribute change command

Data Inputs

Variable	Type	Description
QI	BOOL	Quality Input - TRUE to enable service
u16ObjId	UINT	Object ID of the attribute to be changed (initial value: ID_NULL)
u8IdAttribute	USINT	Attribute ID (AID) – defines which attribute of the object is to be changed

Data Outputs

Variable	Type	Description
QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Status message of the executed service
s16result	INT	Return value of the command (error codes, see Functionality)

Adapters

Adapter	Direction	Type	Description
u32ValueAttribute	Socket	unidirectional::AUDI	New value for the attribute (32-bit, fed into the FB via the adapter)
u32OldValueAttribute	Plug	unidirectional::AUDI	Old attribute value (32-bit, output by the function block via the adapter)

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Q_Attribute`. The data output `QO` (BOOL) is taken over from `Q_Attribute.QO` and is associated with the events `INITO` and `CNF`.

Valid Object IDs

`u16ObjId` (the object whose attribute is changed) and `u8IdAttribute` (the Attribute ID, AID) are subject to **different** validity rules.

`u16ObjId` — valid object types (Annex F.38): Data Mask (1000–1999), Alarm Mask (2000–2999), Soft Key Mask (4000–4999), Key (5000–5999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Input List Field (10000–10999), Auxiliary Function Type 2 (31000–31999).

`u8IdAttribute` (AID): Valid attribute IDs are object-type specific and defined in Annex B, in the attribute tables of each object type. An AID with no attribute assigned is rejected by the VT ("Invalid Attribute ID", F.39).

ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`.

Functionality

1. **Initialization**: After a rising edge at **INIT**, the service is initialized. The required parameters (object ID and attribute ID) are read from the data inputs.
2. **Command Execution**: As soon as the event output **E1** is triggered at socket **u32ValueAttribute** (e.g., by a connected function block providing a new value), the attribute change command is started. The new attribute value is adopted by the adapter.
3. **Feedback**: After the command is completed, the output **CNF** is activated. The STATU string and the return value **s16result** contain the result. Simultaneously, the previously stored old attribute value is signaled at plug **u32OldValueAttribute** via the event output **E1** and made available via **D1**.

The function block delegates the actual ISOBUS communication to the internal function block **Q_Attribute**, which performs the necessary protocol steps.

Technical Features

- **Error Codes** (output via s16result):
- `VT_E_NO_ERR (0)` – no error
- `VT_E_OVERFLOW (-6)` – buffer overflow
- `VT_E_NOACT (-8)` – command not possible in the current state
- `VT_E_NO_INSTANCE (-21)` – no VT client instance available
- `VT_E_ISO_INSTANCE_INVALID (-129)` – invalid connection instance
- `VT_E_NOT_ALIVE (-130)` – instance valid, but VT not active
- **Adapter Interfaces**: The use of unidirectional adapters (AUDI) enables loose coupling between the encoder and the function block. The old and new values can thus be managed in separate function blocks (FBs).
- **Limitations**: The command does not support string attributes.

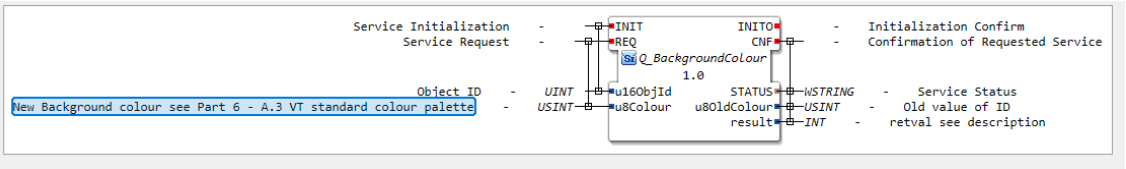
State Overview

The FB does not have an explicitly displayed state machine. The sequence control is event-driven:

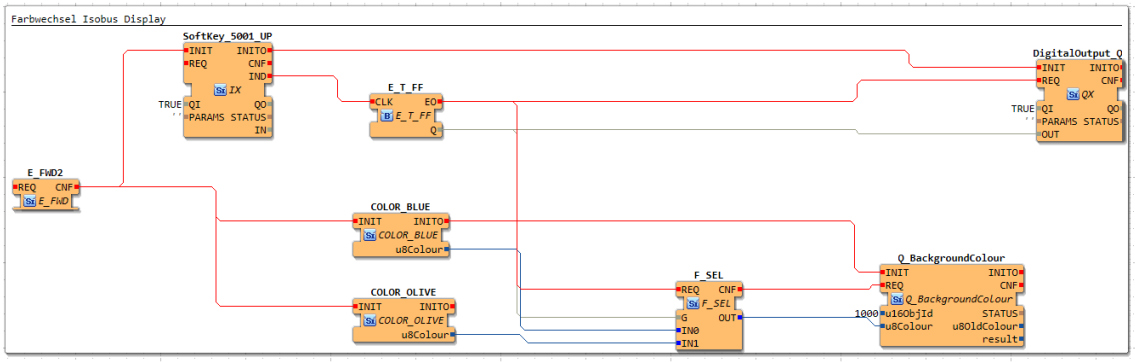
- After **INIT**, it transitions to a ready state.
- Another event is only triggered by the connected adapter socket (E1 of u32ValueAttribute). After processing, **CNF** is sent.
- The function block is **stateless** in the sense of a reusable sequence; each request is processed individually.

Application Scenarios

- **ISOBUS VT Applications**: Changing parameters of a virtual terminal (e.g., background color, label, visibility) at runtime.
- **Control of Agricultural Equipment**: Dynamically adjusting attributes such as machine settings or diagnostic data.
- **Implementation of ISO 11783-6 Workouts**: Replicating the “Change Attribute” command structure from the standard.



Comparison with Similar Function Blocks

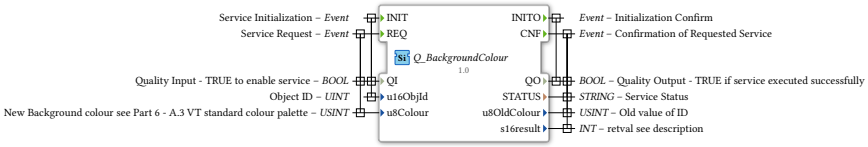


- **Q_Attribute** (without AUDI): Offers the same core functionality, but without adapter interfaces. The new value must be passed directly as a data input, and no feedback of the old value is provided. **Q_Attribute_AUDI** extends this function block with flexible, adapter-based value passing and the return of the old value, increasing reusability and encapsulation.

Conclusion

Q_Attribute_AUDI is a specialized function block for ISOBUS applications that enables the secure and standards-compliant modification of attributes. The adapter-based interface for attribute values ensures high modularity, and the output of the old value allows for easy change tracking. The function block is ideal for complex VT implementations where values originate from different sources or are managed in separate logic units.

Q_BackgroundColour



• — ○ • — ○ • — ○ •

Introduction

The **Q_BackgroundColour** is a standards-compliant function block for controlling background colors in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.20) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID)
- `REQ`: Color Change Request (with color code)

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Change Confirmation (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Object Identifier
- `u8Colour` (USINT): New Color Value (ISO 11783-6 palette)

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operating status message
- `u8OldColour` (USINT): Previous color value
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` — valid object types (Annex F.20, objects with background colour attribute): WorkingSet (0), Data Mask (1000–1999), Alarm Mask (2000–2999), Soft Key Mask (4000–4999), Key (5000–5999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Output String Field (11000–11999), Output Number Field (12000–12999), Window Mask (34000–34999), Graphics Context (36000–36999), Auxiliary Function (29000–29999), Auxiliary Function Type2 (31000–31999), Auxiliary Input Type2 (32000–32999).

ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`. Any ID outside these ranges is invalid for commanding.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with object ID
- `INITO` confirms operational readiness

1. **Color Change**:

- `REQ` triggers with new color code (0-255)
- `CNF` returns result and previous color value

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.20 + A.3 color palette) ✓ **8-bit color support** (256 values) ✓ **Real-time processing** ✓ **State preservation** (u8OldColour)

Standard color palette (excerpt)

Code	Color	RGB equivalent
0	Black	#000000
1	Red	#FF0000
2	Green	#00FF00
3	Yellow	#FFFF00
4	Blue	#0000FF

Return codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	Invalid State
−128	VT_E_HANDLE_INVALID	Invalid Object ID

Application Scenarios

- **Machine Status**: Color-coded Alarm Indication
- **Night Mode**: Dark Color Palettes
- **Markings**: Highlighting Objects

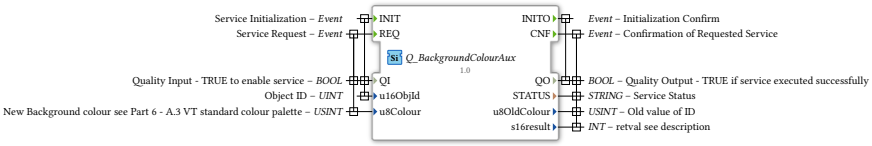
- **Easy integration**: Clear color palette definition
- **Robust**: Proven field reliability

Essential for:



- Color status indicators
- User interface design
- Dynamic visualizations

Q_BackgroundColourAux

• – ◦ • – ◦ • – ◦ •

Introduction

The **Q_BackgroundColourAux** is a standards-compliant function block for controlling secondary background colors in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.20) specification for auxiliary colors in agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID)
- `REQ`: Color Change Request (with color code)

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Change Confirmation (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Object Identifier
- `u8Colour` (USINT): New Auxiliary Color Value (ISO 11783-6 palette)

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operational status message
- `u8OldColour` (USINT): Previous auxiliary color value
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` — valid object types (Annex F.20, objects with background colour attribute): WorkingSet (0), Data Mask (1000–1999), Alarm Mask (2000–2999), Soft Key Mask (4000–4999), Key (5000–5999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Output String Field (11000–11999), Output Number Field (12000–12999), Window Mask (34000–34999), Graphics Context (36000–36999), Auxiliary Function (29000–29999), Auxiliary Function Type2 (31000–31999), Auxiliary Input Type2 (32000–32999).

ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`. Any ID outside these ranges is invalid for commanding.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with object ID for auxiliary element
- `INITO` confirms operational readiness

1. **Color Change**:

- `REQ` triggers with new auxiliary color code (0-255)
- `CNF` returns result and previous color value

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.20 (for auxiliary colors)
✓ **8-bit color support** (256 values)
✓ **Compatible with Q_BackgroundColour**
✓ **State preservation** (u8OldColour)

Standard auxiliary colors (excerpt)

Code	Scope	Typical color
16	Status bar	Blue
32	Secondary areas	Gray
48	Guidelines	Light blue

Return codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−128	VT_E_HANDLE_INVALID	Invalid object ID
−129	VT_E_ISO_INSTANCE_INVALID	Invalid instance

Application Scenarios

- **Status Indicators**: Secondary colors for bars
- **Groupings**: Color separation of areas
- **Editor Modes**: Guidelines in configurators
- **Diagnostics**: Additional information

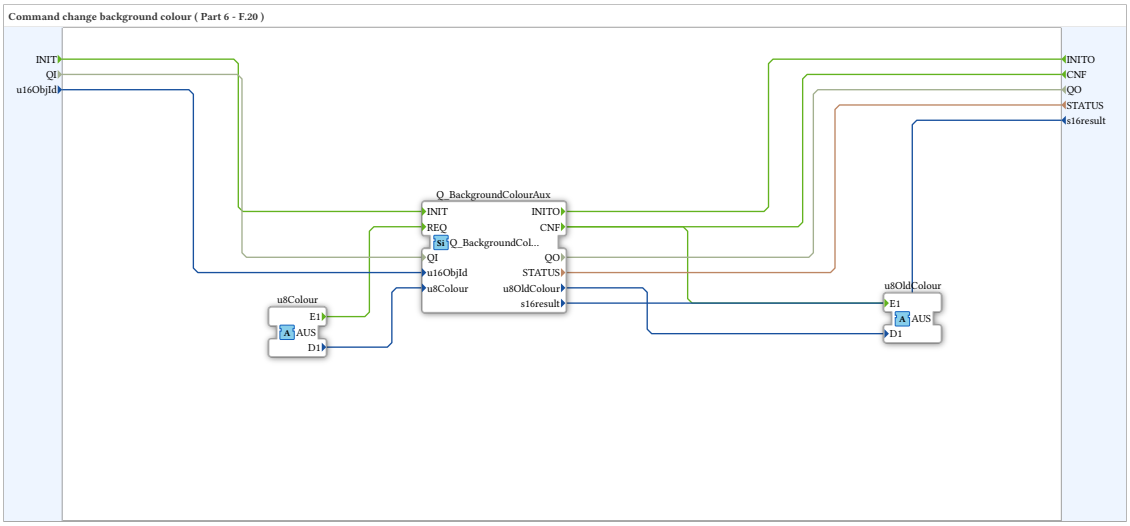
⚖️ **Comparison with similar building blocks**

Feature	Q_BackgroundColourAux	Q_BackgroundColour	VtAuxColour
ISO Standard	✓	✓	✖
Color range	Auxiliary elements	Primary elements	All
Usage	Secondary	Primary	Universal

Conclusion

The Q_BackgroundColourAux module extends ISOBUS color control for auxiliary elements:

- **Specialized**: Optimized for secondary display elements
- **Consistent**: Same API as Q_BackgroundColour
- **Proven in practice**: Used in modern tractor displays



Ideal for:

- Complex display layouts

- Multi-layered visualizations
- Systems with advanced color management

Q_BackgroundColourAux_AUS

• — ○ • — ○ • — ○ •

Introduction

This function block implements the command to change the background color of an object according to ISO 11783-6, Part F.20. It enables interaction with the Virtual Terminal (VT) and handles the transmission of the new color as well as the feedback of the result.

Interface Structure

Event Inputs

Event	Type	With Parameter	Description
INIT	EInit	QI, u16ObjId	Service Initialization

Event Outputs

Event	Type	With Parameter	Description
INITO	EInit	QO	Initialization confirmed
CNF	Event	QO, STATUS, s16result	Confirmation of requested service

Data Inputs

Name	Type	Initial Value	Description
QI	BOOL	TRUE	Quality Input - TRUE to enable service
u16ObjId	UINT	ID_NULL	Object ID of the affected object

Data Outputs

Name	Type	Description

QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service status (e.g., error message)
s16result	INT	Return value (see below)

Adapter

Direction	Name	Type	Description
Socket	u8Colour	OFF	New background color (according to ISO 11783-6 A.3)
Plug	u8OldColour	OFF	Old background color (returned by the VT)

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Q_BackgroundColourAux`. The data output `QO` (BOOL) is taken over from `Q_BackgroundColourAux.QO` and is associated with the events `INITO` and `CNF`.

Valid Object IDs

`u16ObjId` is valid for the same object types as the wrapped base block `Q_BackgroundColourAux` / `Q_BackgroundColour` (Annex F.20, objects with background colour attribute): WorkingSet (0), Data Mask (1000–1999), Alarm Mask (2000–2999), Soft Key Mask (4000–4999), Key (5000–5999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Output String Field (11000–11999), Output Number Field (12000–12999), Window Mask (34000–34999), Graphics Context (36000–36999), Auxiliary Function (29000–29999), Auxiliary Function Type2 (31000–31999), Auxiliary Input Type2 (32000–32999).

ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`.

Functionality

The module first expects initialization with the object ID (`INIT` with `u16ObjId`).

As soon as a new color value is present at the socket adapter `u8Colour` (triggered by the adapter's event `E1`), an internal event `REQ` is sent to the encapsulated function block `Q_BackgroundColourAux`.

This executes the VT command and returns the status (`STATUS`) and the result (`s16result`) via the output `CNF`.

The previous color is output via the plug adapter `u8OldColour`.

All the logic is encapsulated in a subordinate function block of the same family, so this block serves only as an outer shell for the adapter coupling.

This function block executes the VT command and returns the status (`STATUS`) and the result (`s16result`) via the output `CNF`.

Technical Features

- The initial value for `u16ObjId` is `ID_NULL`, meaning the function block must be initialized with a valid object ID before use.
- Color values are transmitted as 8-bit values via the AUS adapter. The valid colors are defined in the VT standard color palette (ISO 11783-6 Annex A.3).
- The initial value for `u16ObjId` is `ID_NULL`, meaning the function block must be initialized with a valid object ID before use.
- The color values are transmitted as 8-bit values via the AUS adapter. The valid colors are defined in the VT standard color palette (ISO 11783-6 Annex A.3). - Possible return values (`s16result`):
- `VT_E_NO_ERR` (0): Success
- `VT_E_OVERFLOW` (-6): Buffer overflow
- `VT_E_NOACT` (-8): Command not possible in the current state
- `VT_E_NO_INSTANCE` (-21): No VT client available
- `VT_E_ISO_INSTANCE_INVALID` (-129): Invalid connection identifier
- `VT_E_NOT_ALIVE` (-130): VT instance valid, but VT not reachable

State Overview

The FB does not have explicit state machines in the XML. Event control is handled solely via event connections:

1. **INIT** → Initialization of the service.

2. **External event via socket adapter** ⟶ Start of the color change request.
3. **CNF** ⟶ Completion of the operation with status and return value.

Application Scenarios

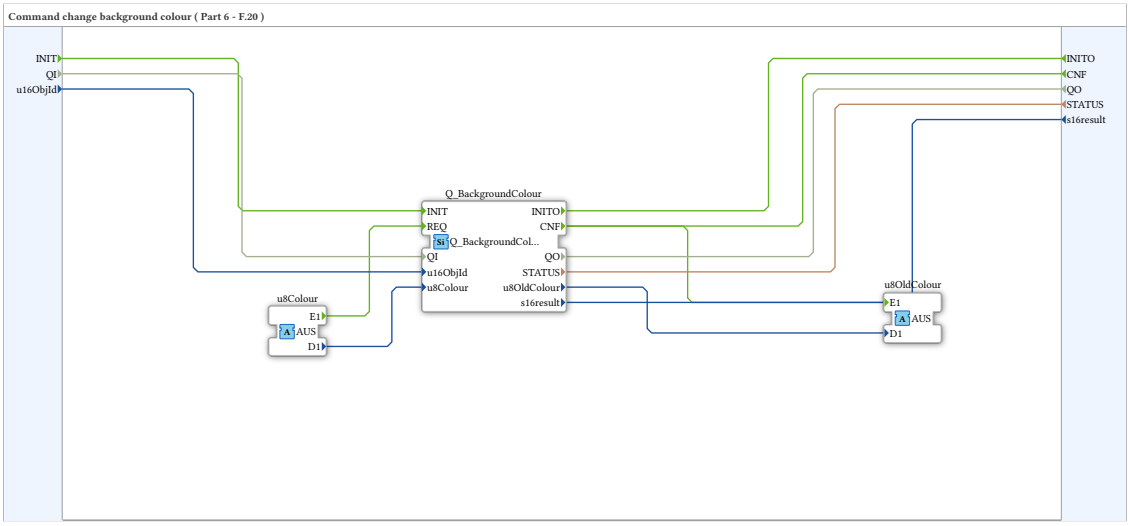
- Dynamic adjustment of the background color of an ISOBUS VT object (e.g., button, text field) depending on operating states or user input.
- Implementation of color changes in agricultural control and visualization systems.

Comparison with Similar Function Blocks

Analogous function blocks exist for other visual properties (e.g., `Q_TextColourAux_AUS`, `Q_VisibilityAux_AUS`).

All of them share the schema-based adapter pattern, which implements the signaling of value changes via OFF adapters.

This function block specializes in background color and uses the same error and return values.



Conclusion

The `Q_BackgroundColourAux_AUS` function block compactly encapsulates an ISOBUS-VT service for background color change and offers easy integration into higher-level controllers via its adapter interfaces.

It is reliable, standards-compliant, and allows for robust error handling through status feedback.

Q_BackgroundColour_AUS

• – ○ • – ○ • – ○ •

Introduction

The function block **Q_BackgroundColour_AUS** is used to change the background color of an object in the ISOBUS Virtual Terminal (VT). It encapsulates the corresponding command interface according to ISO 11783-6 (Part 6 – F.20). The block is supplied with the new color via a socket and returns the previous color via a plug. The actual color change is performed by the internal block `Q_BackgroundColour`.

Interface Structure

Event Inputs

Name	Type	Comment	With Variables
`INIT`	EInit	Service Initialization	`QI`, `u16ObjId`

Event Outputs

Name	Type	Comment	With Variables
INITO	EInit	Initialization Acknowledgement	QO
CNF	Event	Acknowledgement of Requested Service	QO, STATUS, s16result

Data Inputs

Name	Data Type	Initial Value	Comment
QI	BOOL	TRUE	Quality Input - TRUE to enable service
u16ObjId	UINT	ID_NULL	Object ID of the object to be modified

Data Outputs

Name	Data Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service status (e.g., error message or “OK”)
s16result	INT	Return value (see description – error codes)

Adapter

- **Socket** u8Colour

Type: adapter::types::unidirectional::AUS
Returns the new background color (according to ISO 11783-6, A.3 VT standard color palette).
The adapter provides both the event E1 (to trigger the color change) and the data value D1 (color value).

- **Plug** u8OldColour

Returns the previous background color after the change command has been executed.
The event E1 signals that the value is valid; the data value D1 contains the old color.
Quality signals QI/QO: The data input QI (BOOL, initial value TRUE) is associated with the event INIT and is passed through to QI of the internal block Q_BackgroundColour. The data output QO (BOOL) is taken over from Q_BackgroundColour.QO and is associated with the events INITO and CNF.

Valid Object IDs

u16ObjId is valid for the same object types as the wrapped base block Q_BackgroundColour (Annex F.20, objects with background colour attribute): WorkingSet (0), Data Mask (1000–1999), Alarm Mask (2000–2999), Soft Key Mask (4000–4999), Key (5000–5999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Output String Field (11000–11999), Output Number Field (12000–12999), Window Mask (34000–34999), Graphics Context (36000–36999), Auxiliary Function (29000–29999), Auxiliary Function Type2 (31000–31999), Auxiliary Input Type2 (32000–32999).
ID_NULL (65535) is not a command target but deactivates the FB when used with INIT.

Functionality

1. **Initialization**

An event INIT starts the function block. The passed object ID (u16ObjId) is forwarded to the internal function block Q_BackgroundColour and initialized there. After successful initialization, INITO is output.

1. **Triggering a Color Change**

As soon as an event arrives at socket u8Colour (via the adapter path E1), the internal function block is triggered with REQ. The color value (u8Colour.D1) is passed to Q_BackgroundColour.u8Colour.

1. **Feedback**

After the command is completed, the internal module sends a CNF event.

- The outputs STATUS and s16result are set accordingly and are valid at the event output CNF.

- Simultaneously, the previous color value (data `D1`) and an acknowledgment event (`E1`) are output via the plug `u8OldColour`.
-

Technical Features

- The module implements the “Change Background Colour” command according to ISO 11783-6, section F.20.
- The color values correspond to the VT standard color palette from Annex A.3 of the standard.
- Possible return values (`s16result`) are:
- `VT_E_NO_ERR (0)` – Success
- `VT_E_OVERFLOW (-6)` – Buffer overflow
- `VT_E_NOACT (-8)` – Command not possible in the current state
- `VT_E_NO_INSTANCE (-21)` – No VT client available
- `VT_E_ISO_INSTANCE_INVALID (-129)` – Invalid connection identifier
- `VT_E_HANDLE_INVALID (-128)` – Invalid handle
- `VT_E_NOT_ALIVE (-130)` – VT not reachable
- The function block uses a unidirectional adapter (`AUS`) that combines the event and data channels – this reduces the number of interfaces.

State Overview

The function block (FB) does not have an explicit state machine at the top level, but the interaction with `INIT`, `REQ` (via adapter), and `CNF` results in the following implicit states:

1. **IDLE** – Waiting for `INIT` or for an event on socket `u8Colour`.
2. **INIT** – After `INIT`, the internal block is initialized.
3. **READY** – After `INITO`, the FB is ready to receive color changes.
4. **BUSY** – During the execution of the color change command (after `REQ`). 5. **DONE** – After `CNF`, the next command can be processed.

Application Scenarios

- **ISOBUS Virtual Terminal**

Changing the background color of a graphical object (e.g., button, group, softkey) on the VT screen in an agricultural control system.

- **HMI Customization**

Responding to user input or system states to dynamically adjust the visual display (e.g., alarm colors, highlighting active elements).

- **Recovering the Previous Color**

The `u8OldColour` plugin allows you to save the previous color value or use it for later restoration.

-

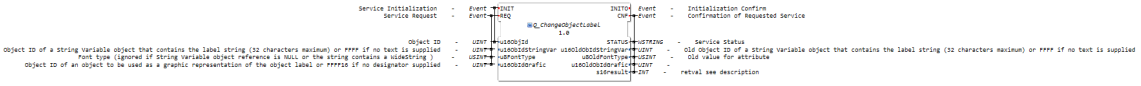
Comparison with Similar Function Blocks

- **`Q_BackgroundColour`** (without `_AUS`):

Offers the same core functionality, but usually with individual event/data ports instead of encapsulated adapters. The `_AUS` function block simplifies the connection to other function blocks that also use AUS adapters.

- **`Q_Colour`** or **`Q_ForegroundColour`**:

Modify different color properties (foreground, full color) and use similar return values and status mechanisms.



- **`Command_ChangeColour`** (more general):

Could modify multiple color parameters simultaneously, while `Q_BackgroundColour_AUS` specializes in background colors.

Conclusion

The `Q_BackgroundColour_AUS` function block offers a standards-compliant, compact interface for changing background colors in an ISOBUS VT. The use of the unidirectional adapter simplifies integration with other components and improves clarity. The documented error codes and the clear separation of initialization and service execution make it a reliable building block for dynamic HMI adjustments in agricultural control systems.

Q_ChangeObjectLabel

• — ○ • — ○ • — ○ •

Introduction

The **Q_ChangeObjectLabel** is a standards-compliant function block for changing object labels in Virtual Terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.50) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID)
- `REQ`: Label Change Request (with text/graphic parameters)

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Target Object Identifier
- `u16ObIdStringVar` (UINT): Text Variable Object ID (max. 32 characters)
- `u8FontType` (USINT): Font (for text labeling)
- `u16ObIdGrafic` (UINT): Graphic object ID (for symbol labeling)

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operating status message
- `u16OldObIdStringVar` (UINT): Previous text variable ID
- `u8OldFontType` (USINT): Previous font
- `u16OldObIdGrafic` (UINT): Previous graphic object ID
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

The F.50 command addresses, in bytes 2,3, the **Object ID of the object to label** — per Annex F.51 (error bit 0) and B.21 this object must be **listed in the Object Label Reference List** (i.e. any pool object whose ID is an entry of the reference list).

Implementation note (VTClientHelper): `iso_is_object_label_refer_list_id` accepts only the **ObjectLabelReferList** range (the Object Label Reference List object's own ID) — a known deviation from the Annex F.50 semantics:

- **ObjectLabelReferList**: 40000 – 40999

ID_NULL (65535) is not a valid command target but deactivates the FB when sent via `INIT`.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with target object ID
- `INITO` confirms operational readiness

1. **Label Change**:

- `REQ` with new label parameters
- Supports text (with font) or graphic symbols
- `CNF` returns the result and the old values

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.50) ✓ **Flexible Labeling**: Text or graphics ✓ **Font Control** (8-bit) ✓ **32-character limit** for text labels

Standard Parameters

Parameter	NULL value	Description
u16ObIdStringVar	0xFFFF	No text
u16ObIdGrafic	0xFFFF	No graphic

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−6	VT_E_OVERFLOW	Buffer overflow (text too long)
−128	VT_E_HANDLE_INVALID	Invalid object ID

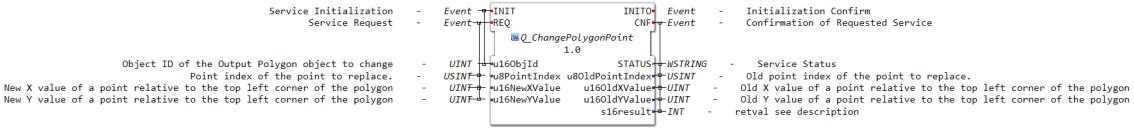
Application Scenarios

- **Machine Control**: Dynamic button labels
- **Language Switching**: Multilingual interfaces
- **Status Indicators**: Icon change on alarms
- **Personalization**: User-defined labels

⚖️ Comparison with similar building blocks

Feature	Q_ChangeObjectLabel	VtDynamicLabel	VtTextManager
ISO Standard	✓	✖	✖
Labeling	Text + Graphics	Text Only	Text Only
Font	Controllable	Fixed	Partial

Conclusion

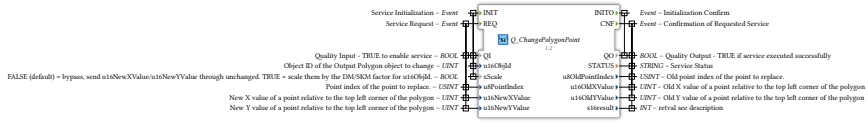


The Q_ChangeObjectLabel block provides the reference implementation for ISOBUS labeling:

- **Versatile**: Combination of text and graphics
- **Standard-compliant**: Full ISO 11783-6 compatibility
- **Proven in practice**: Used in modern agricultural machinery

Essential for:

- Adaptive user interfaces
- Multilingual systems
- Icon-driven operating concepts



Q_ChangePolygonPoint

• — ○ • — ○ • — ○ •

Introduction

The **Q_ChangePolygonPoint** is a standards-compliant function block for modifying polygon points in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.52) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with polygon object ID and xScale)
- `REQ`: Point Change Request (with index and coordinates)

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Change Confirmation (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Polygon Object ID
- `xScale` (BOOL): If TRUE, `u16NewXValue`/`u16NewYValue` are scaled by the DM/SKM factor for `u16ObjId` before sending; if FALSE (default) they are passed through unchanged.
- `u8PointIndex` (USINT): Point Index (0-based)
- `u16NewXValue` (UINT): New X-coordinate (relative)
- `u16NewYValue` (UINT): New Y-coordinate (relative)

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operational status message
- `u8OldPointIndex` (USINT): Previous point index
- `u16OldXValue` (UINT): Previous X-coordinate
- `u16OldYValue` (UINT): Previous Y-coordinate
- `s16result` (INT): ISO-compliant result code

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with polygon object ID
- `INITO` confirms operational readiness

1. **Point Change**:

- `REQ` with index and new coordinates
- Coordinates relative to the upper left corner

- `CNF` returns result and old values

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.52) ✓ **Precise coordinate control** (16-bit) ✓ **Index-based access** (0-255 points) ✓ **One point per command** (fixed 8-byte message, no Transport Protocol) ✓ **Real-time processing**

Coordinate Range

Parameter	Range	Description
X-value	0 - 65535	Horizontal position (px)
Y-value	0 - 65535	Vertical Position (px)

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−6	VT_E_OVERFLOW	Invalid Point Index
−128	VT_E_HANDLE_INVALID	Invalid Polygon ID

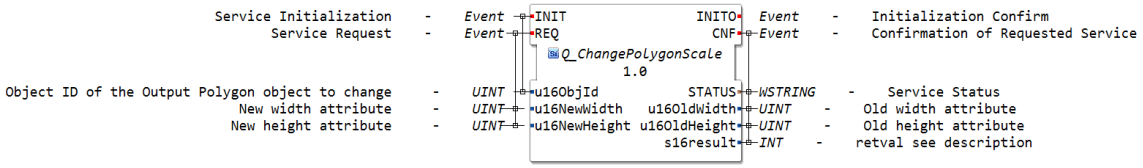
Application Scenarios

- **Machine Visualization**: Contour Adjustment
- **Map Display**: Dynamic Polygon Deformation
- **Diagnostic Displays**: Geometric Highlighting
- **Animated Elements**: Moving Polygon Shapes

⚖️ Comparison with Similar Building Blocks

Feature	Q_ChangePolygonPoint	VtGeometryEditor	VtDynamicShape
ISO Standard	✓	✖	✖
Accuracy	16-bit Coordinates	8-bit	16-bit
Point Count	Up to 255	Unlimited	Limited

Conclusion

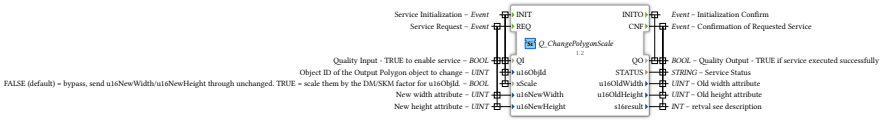


The Q_ChangePolygonPoint block provides the reference implementation for dynamic polygon changes:

- **Precise**: Millimeter-accurate position control
- **Powerful**: Real-time processing
- **Standard-compliant**: Full ISO 11783-6 compatibility

Essential for:

- Adaptive geometry representations
- Technical drawings
- Interactive mapping applications



Q_ChangePolygonScale

• — ○ • — ○ • — ○ •

Introduction

The **Q_ChangePolygonScale** is a standards-compliant function block for scaling polygon objects in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.54) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with polygon object ID and `xScale`)
- `REQ`: Scaling request (with new dimensions)

Event Outputs

- `INITO`: Initialization confirmation
- `CNF`: Scaling confirmation (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Polygon object ID
- `xScale` (BOOL, initial value `FALSE`): `FALSE` = bypass, `u16NewWidth`/`u16NewHeight` are sent unchanged; `TRUE` = both are scaled by the DM/SKM factor for `u16ObjId`
- `u16NewWidth` (UINT): New width in pixels
- `u16NewHeight` (UINT): New height in pixels

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operational status message
- `u16OldWidth` (UINT): Previous width
- `u16OldHeight` (UINT): Previous height
- `s16result` (INT): ISO-compliant result code

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with polygon object ID
- `INITO` confirms operational readiness

1. **Scaling**:

- `REQ` triggers with new dimensions
- Proportional scaling of all polygon points
- `CNF` returns result and previous values

1. **Error Handling**:

- ISO-standardized Error Codes
- Detailed Status Messages

Technical Features

✓ **ISO 11783-6 compliant** (F.54) ✓ **Proportional scaling** (width/height) ✓ **16-bit resolution** (0-65535 pixels) ✓ **Real-time processing**

Scaling Behavior

Parameter	Effect
Width	Horizontal scaling
Height	Vertical scaling

Per Annex F.54 the VT rescales all polygon points using 32-bit integer math: `new_x = [(old_x × new_width) + (old_width/2)] / old_width` and analogously for `new_y`.

Return Codes (s16result)

Code	Constant	Meaning				
0	VT_E_NO_ERR	Success		−6	VT_E_OVERFLOW	Invalid Dimensions
−128	VT_E_HANDLE_INVALID	Invalid Polygon ID				
−127	VT_E_ISO_INSTANCE_INVALID	Invalid Instance				

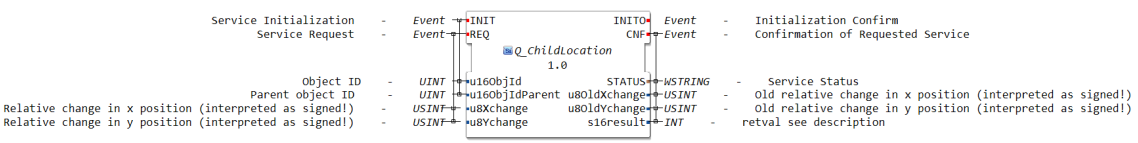
Application Scenarios

- **Machine Display**: Dynamic Resizing
- **Zoom Functions**: Detail Magnification
- **Responsive Designs**: Adapting to Display Sizes
- **Animated Transitions**: Smooth Size Changes

⚖️ Comparison with Similar Building Blocks

Feature	Q_ChangePolygonScale	VtGeometryScaler	VtDynamicResize
ISO Standard	✓	✖	✖
Scaling	Proportional	Free	Width Only
Resolution	16-bit	8-bit	16-bit

Conclusion

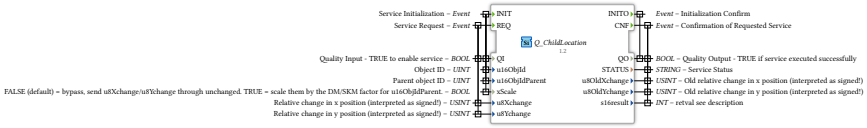


The Q_ChangePolygonScale block provides the reference implementation for polygon scaling:

- **Precise**: Pixel-accurate size control
- **Proportional**: Maintains the original shape
- **Standards-compliant**: Full ISO 11783-6 compatibility

Ideal for:

- Adaptive visualizations
- Dynamic map views
- Resizable controls



Q_ChildLocation

• — ○ • — ○ • — ○ •

Introduction

The **Q_ChildLocation** is a standards-compliant function block for changing the position of child objects in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.14) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object and parent ID as well as `xScale`)
- `REQ`: Position Change Request (with relative coordinates)

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Child Object ID
- `u16ObjIdParent` (UINT): Parent Object ID
- `xScale` (BOOL, default `FALSE`): `FALSE` = bypass, `u8Xchange`/`u8Ychange` are sent through unchanged; `TRUE` = scale them by the DM/SKM factor for `u16ObjIdParent`
- `u8Xchange` (USINT): Relative X-Position Change (-128 to +127)
- `u8Ychange` (USINT): Relative Y-position change (-128 to +127)

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operational status message
- `u8OldXchange` (USINT): Previous X-change
- `u8OldYchange` (USINT): Previous Y-change
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` (the child object to move) and `u16ObjIdParent` (the parent object) are subject to **different** validity rules. ISO 11783-6 Annex F only defines which object types are valid as the child — which object types may act as parent is defined separately in Annex B, under each object type's "Allowed commands" list.

`u16ObjId` — valid child object types (Annex F.14): Container (3000–3999), Key (5000–5999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Input List Field (10000–10999), Output String Field (11000–11999), Output Number Field (12000–12999), Output Line (13000–13999), Output Rectangle (14000–14999), Output Ellipse (15000–15999), Output Polygon (16000–16999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Picture Graphic (20000–20499), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object (48000–48999), Auxiliary Function/Type2 (29000–29999 / 31000–31999), Auxiliary Input/Type2 (30000–30999 / 32000–32999), Auxiliary Control Designator (33000–33999).

`u16ObjIdParent` — valid parent object types (Annex B, "Allowed commands"): WorkingSet (B.1), Data Mask (B.2), Alarm Mask (B.3), **Container (B.4)**, Key (B.6), Window Mask, Button, Auxiliary Function (Type 1/2), Auxiliary Input (Type 1/2).

Not valid as parent: Soft Key Mask (B.5 does not list the command as allowed) and Animation Object (its children are indexed frames, not X/Y-positioned).

ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with child and parent object IDs
- `INITO` confirms operational readiness

1. **Position Change**:

- `REQ` with relative coordinate changes
- Values are interpreted as signed 8-bit
- `CNF` returns the result and previous values

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.14) ✓ **Relative position change** (relative to the parent) ✓ **Signed 8-bit values** (-128 to +127) ✓ **Real-time processing**

Position Change Range

Parameter	Range	Description
X Change	−128 - +127	Horizontal Displacement
Y-Change	−128 - +127	Vertical Shift

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−6	VT_E_OVERFLOW	Invalid Position Values
−128	VT_E_HANDLE_INVALID	Invalid Object ID

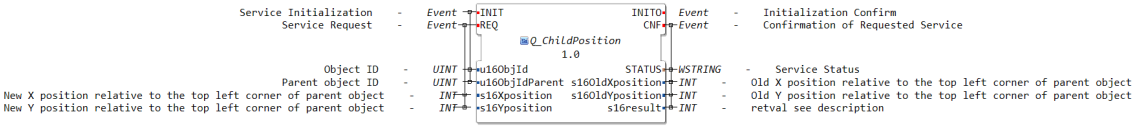
Application Scenarios

- **Dynamic Layouts**: Object Positioning
- **Animated Elements**: Smooth Movements
- **Responsive Designs**: Adaptation to Different Screen Sizes
- **Grouped Objects**: Shared Movements

⚖️ Comparison with Similar Building Blocks

Feature	Q_ChildLocation	VtAbsolutePosition	VtGroupMove
ISO Standard	✓	✖	✖
Movement	Relative	Absolute	Groups
Value Range	±127 pixels	0-65535 pixels	±127 pixels

Conclusion

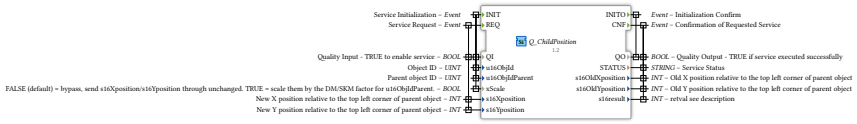


The Q_ChildLocation block provides the reference implementation for relative position changes:

- **Flexible**: Simple relative positioning
- **Precise**: Pixel-accurate control
- **Standard-compliant**: Full ISO 11783-6 compatibility

Ideal for use with:

- Dynamic surfaces
- Animated transitions
- Parent-child object relationships



Q_ChildPosition

• — ○ • — ○ • — ○ •

Introduction

The **Q_ChildPosition** is a standards-compliant function block for the absolute position change of child objects in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.16) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with object ID, parent ID and xScale)
- `REQ`: Position change request (with absolute coordinates)

Event Outputs

- `INITO`: Initialization confirmation
- `CNF`: Change confirmation (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Child object ID
- `u16ObjIdParent` (UINT): Parent object ID
- `xScale` (BOOL): If TRUE, `s16Xposition`/`s16Yposition` are scaled by the DM/SKM factor for `u16ObjIdParent` before sending; if FALSE (default) they are passed through unchanged.
- `s16Xposition` (INT): Absolute X-position relative to the parent
- `s16Yposition` (INT): Absolute Y-position relative to the parent

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operational status message
- `s16OldXposition` (INT): Previous X-position
- `s16OldYposition` (INT): Previous Y-position
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` (the child object to move) and `u16ObjIdParent` (the parent object) are subject to **different** validity rules. ISO 11783-6 Annex F only defines which object types are valid as the child — which object types may act as parent is defined separately in Annex B, under each object type's "Allowed commands" list.

`u16ObjId` — valid child object types (Annex F.16): Container (3000–3999), Key (5000–5999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Input List Field (10000–10999), Output String Field (11000–11999), Output Number Field (12000–12999), Output Line (13000–13999), Output Rectangle (14000–14999), Output Ellipse (15000–15999), Output Polygon (16000–16999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Picture Graphic (20000–20499), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object

(48000–48999), Auxiliary Function/Type2 (29000–29999 / 31000–31999), Auxiliary Input/Type2 (30000–30999 / 32000–32999), Auxiliary Control Designator (33000–33999).

`u16ObjIdParent` — valid parent object types (Annex B, "Allowed commands"): WorkingSet (B.1), Data Mask (B.2), Alarm Mask (B.3), **Container (B.4)**, Key (B.6), Window Mask, Button, Auxiliary Function (Type 1/2), Auxiliary Input (Type 1/2).

Not valid as parent: Soft Key Mask (B.5 does not list the command as allowed) and Animation Object (its children are indexed frames, not X/Y-positioned).

ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with child and parent object IDs
- `INITO` confirms operational readiness

1. **Position Change**:

- `REQ` with absolute coordinates relative to the parent
- Value range: −32768 to +32767 pixels
- `CNF` returns the result and the previous position

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.16) ✓ **Absolute position change** (relative to the parent) ✓ **16-bit value range** (±32768 pixels) ✓ **Real-time processing**

Position Range

Parameter	Range	Description
X-Position	−32768 - +32767	Horizontal Position
Y-Position	−32768 - +32767	Vertical Position

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−6	VT_E_OVERFLOW	Position outside the valid range
−128	VT_E_HANDLE_INVALID	Invalid object ID

Application Scenarios

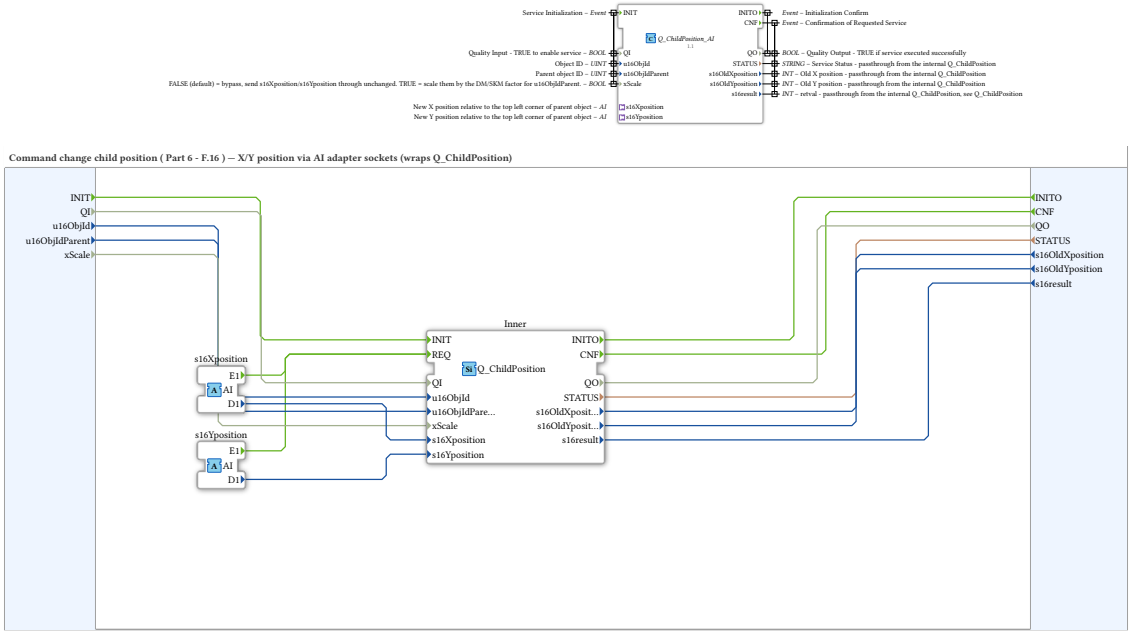
- **Precise Object Placement**: Exact positioning of UI elements
- **Dynamic Layouts**: Reorientation of controls
- **Complex Arrangements**: Multi-layered interfaces
- **Machine Visualization**: Technical drawings

⚖️ Comparison with Similar Function Blocks

Feature	Q_ChildPosition	Q_ChildLocation	VtAbsoluteMove
ISO Standard	✓	✓	✖
Position Type	Absolute	Relative	Absolute

Value Range	±32767 pixels	±127 pixels	±32767 pixels

Conclusion



The Q_ChildPosition block provides the reference implementation for absolute position changes:

- **Precise**: Pixel-accurate positioning
- **Flexible**: Large value range
- **Standard-compliant**: Full ISO 11783-6 compatibility

Ideal for use in:

- Complex user interfaces
- Technical drawings
- Precise layout requirements

Q_ChildPosition_AI

• – ○ • – ○ • – ○ •

Introduction

The **Q_ChildPosition_AI** function block implements a command to change the position of a child object (Part 6, F.16) within an ISO 11783-6 compliant automation system. It acts as a wrapper around the `Q_ChildPosition` function block, replacing the conventional REQ/data input interface with two unidirectional AI adapter sockets. This allows the X and Y position values to be delivered through adapter connections, decoupling the position source from the command logic. A scaling option (xScale) enables the position values to be adjusted by the display-master/slave (DM/SKM) factor of the parent object.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Service Initialization – triggers the initialization of the inner block.

The `INIT` event is associated with the data inputs `u16ObjId`, `u16ObjIdParent`, and `xScale`.

Event Outputs

Event	Type	Comment

INITO	EInit	Initialization Confirm – acknowledged after `INIT` completes.
CNF	Event	Confirmation of the requested position-change service.

The `CNF` event is associated with the data outputs `STATUS`, `s16OldXposition`, `s16OldYposition`, and `s16result`.

Data Inputs

Name	Type	Comment
QI	BOOL	Quality Input - TRUE to enable service
u16ObjId	UINT	Object ID of the child object whose position is to be changed. Defaults to `ID_NULL`.
u16ObjIdParent	UINT	Object ID of the parent object (reference coordinate system). Defaults to `ID_NULL`.
xScale	BOOL	If FALSE (default), the X/Y positions are passed through unchanged. If TRUE, they are scaled by the DM/SKM factor of the parent object.

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service status – passthrough from the internal `Q_ChildPosition`.
s16OldXposition	INT	Previous X position of the child object – passthrough from the inner block.
s16OldYposition	INT	Previous Y position of the child object – passthrough from the inner block.
s16result	INT	Return value – passthrough from the internal `Q_ChildPosition`.

Adapters

Adapter Name	Type	Comment
s16Xposition	adapter::types::unidirectional::AI	New X position relative to the top-left corner of the parent object.
s16Yposition	adapter::types::unidirectional::AI	New Y position relative to the top-left corner of the parent object.

Both adapters are unidirectional inputs (sockets). Each provides one event (`E1`) and one data value (`D1`). The adapter's event triggers the position update.

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Inner`. The data output `QO` (BOOL) is taken over from `Inner.QO` and is associated with the events `INITO` and `CNF`.

Functionality

The block encapsulates an internal instance of `Q_ChildPosition`, called `Inner`. Its public interface is adapted as follows:

- On the `INIT` event, the inner block is initialized with the current values of `u16ObjId`, `u16ObjIdParent`, and `xScale`. The resulting `INITO` of the inner block is forwarded to the external `INITO`.
- A position update is triggered either by the event of the `s16Xposition` adapter or by the event of the `s16Yposition` adapter. In both cases, the internal `Q_ChildPosition.REQ` is fired. The actual position values are always read from both adapters' `D1` data pins at that moment – so an update triggered by the Y adapter will also pick up the latest X value, and vice versa. This design ensures that the command always uses the most current values from both sources.

- The data values `D1` of the adapters are connected directly to the corresponding inputs `s16Xposition` and `s16Yposition` of the inner block.
- All outputs (`STATUS`, `s16OldXposition`, `s16OldYposition`, `s16result`) of the inner block are passed through unchanged to the outer interface.

The block therefore acts as a pure adapter layer that preserves the full semantics and state machine of the underlying `Q_ChildPosition`.

Technical Features

- **Adapter-based input decoupling** – X and Y positions are received via separate unidirectional AI adapter sockets rather than conventional event/data pairs. This allows a clean separation of data source and command logic in the surrounding network.
- **Independent event triggering** – Either adapter's event can initiate the position update, providing flexibility in the data flow topology.
- **Optional scaling** – The `xScale` flag enables automatic scaling of the position values using the DM/SKM factor of the specified parent object, without requiring external preprocessing.
- **Passthrough semantics** – All internal status and result data are forwarded transparently to the outer interface, so diagnostics and old-position reporting remain fully available.
- **Standard compliance** – Designed in accordance with ISO 11783-6, Part 6, command set F.16.

State Overview

The block does not maintain its own state machine; it inherits the behavior of the encapsulated `Q_ChildPosition`. In general terms:

- After initialization (`INIT`/`INITO`), the block is ready to accept position-change requests.
- Whenever an adapter event occurs, a single request transaction is started on the inner block, which performs the required validation, scaling (if enabled), and position update.
- Upon completion, the inner block issues `CNF`, carrying the new status, the old coordinates, and the result code.

Because both adapter events are connected to the same inner REQ input, simultaneous or rapid successive events are serialized by the inner block's execution model; the system behaves deterministically with respect to the inner state machine.

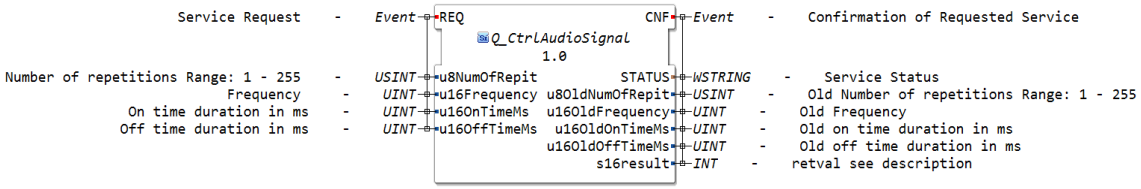
Application Scenarios

- **Decoupled HMI input handling** – When the X and Y coordinate values originate from separate UI widgets or external bus nodes, the AI adapters allow those sources to be connected directly to the position command without a central coordinator.
- **Distributed automation architectures** – In networked ISO 11783 installations, position sources can be located on different nodes, while the command logic resides in a central controller.
- **Scaled coordinate transformation** – For applications where the parent object uses a different coordinate scaling (DM/SKM factor), enabling `xScale` adapts the incoming raw values to the parent's coordinate system automatically.
- **Reusable wrapper pattern** – This block demonstrates how to adapt an existing command FB to an adapter-based interface, improving modularity and testability in larger FB networks.

Comparison with Similar Blocks

Compared to the direct `Q_ChildPosition` block, the following differences apply:

Aspect	Q_ChildPosition	Q_ChildPosition_AI
Position inputs	Plain `s16Xposition` / `s16Yposition` data inputs, triggered by a single REQ event.	Position values arrive via two AI adapter sockets; either adapter event triggers the update.
Interface style	Conventional input/output variables.	Adapter-based input sockets, clean separation of event and data for each coordinate.
Scaling control	Provided as input (xScale).	Provided as input (xScale); behavior identical.



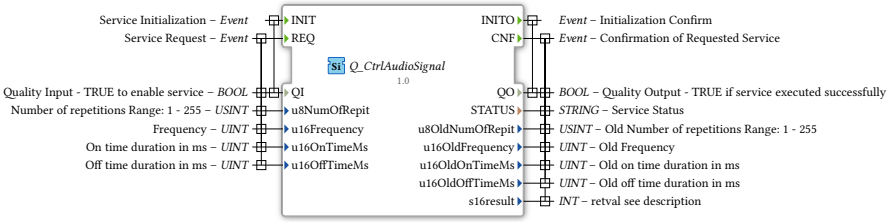
Outputs	STATUS, old positions, result.	All outputs passthrough unchanged.
Use case	Direct command invocation in a fixed network.	Flexible connection of external position sources via adapters.

The AI wrapper adds architectural flexibility but does not change the service semantics of the underlying command.

Conclusion

`Q_ChildPosition_AI` is an adapter wrapper around the ISO 11783-6 child-position command, providing a clean, event-driven interface for X and Y coordinates via unidirectional AI sockets. It preserves all functionality of the original `Q_ChildPosition` – including status reporting, old-position feedback, and optional DM/SKM scaling – while enabling a more modular and flexible network design. This makes it well-suited for distributed control systems where position data originates from multiple independent sources.

Q_CtrlAudioSignal



• — ○ • — ○ • — ○ •

Introduction

The **Q_CtrlAudioSignal** is a standards-compliant function block for controlling audio devices in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.10) specification for agricultural tax systems.

The F.10 command addresses the VT's **audio device** directly — it does **not reference any object**, so this block has no Object ID input. **Activations = 0** terminates any audio in process from the originating Working Set (frequency and duration values are ignored); 1–255 sets the number of audio activations.

Interface Structure

Event Inputs

- `INIT`: Initialization Request
- `REQ`: Audio Control Request (with signal parameters)

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Control Acknowledgement (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u8NumOfRepit` (USINT): Repetitions (1-255)
- `u16Frequency` (UINT): Frequency in Hz
- `u16OnTimeMs` (UINT): On-time in ms
- `u16OffTimeMs` (UINT): Off-time in ms

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operating status message
- `u8OldNumOfRepit` (USINT): Previous repetitions
- `u16OldFrequency` (UINT): Previous frequency
- `u16OldOnTimeMs` (UINT): Previous on-time
- `u16OldOffTimeMs` (UINT): Previous off-time
- `s16result` (INT): ISO-compliant result code

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` without parameters
- `INITO` confirmed Operational Readiness

1. **Audio Control**:

- Trigger `REQ` with signal parameters
- Generates tone with a configurable pattern
- `CNF` returns result and previous values

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.10) ✓ **Flexible Signal Control**: Frequency, Duration, Repetitions ✓ **16-bit Time Resolution** (0-65535 ms) ✓ **255 Repetitions** maximum

Standard Parameter Ranges

Parameter	Range	Typical Value
Frequency	0-65535 Hz	2000 Hz
Duty Cycle	0-65535 ms	200 ms
Shutdown time	0-65535 ms	100 ms
Repetitions	1-255	3

Return codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−6	VT_E_OVERFLOW	Invalid parameter values
−8	VT_E_NOACT	VT in incorrect state
−128	VT_E_HANDLE_INVALID	Invalid audio configuration

Application Scenarios

- **Warning Signals**: Audible alarm messages
- **Confirmation Tones**: Operator feedback
- **Voice Announcements**: Pre-recorded messages
- **Machine Status**: Audible status indicators

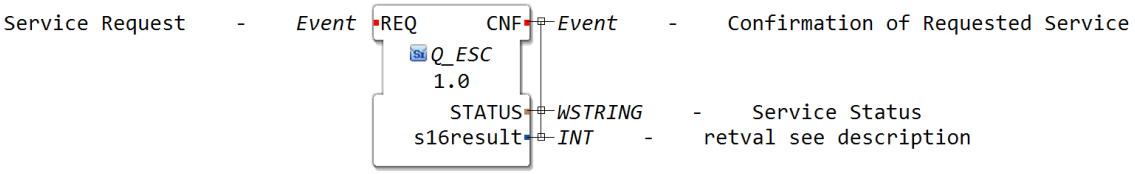
⚖️ Comparison with similar modules

Feature	Q_CtrlAudioSignal	VtSoundManager	VtAudioAlert
ISO Standard	✓	✖	✖
Parameterization	Full	Partial	Simple
Frequency Control	Yes	No	No

🛠️ Related Exercises

- Exercise_017
- Exercise_018
- Exercise_018a

Conclusion

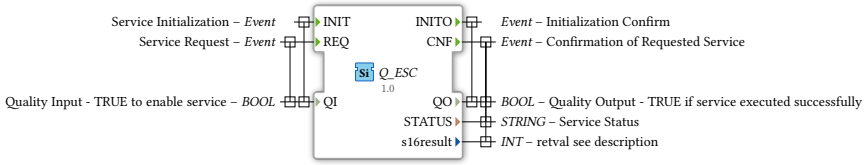


The Q_CtrlAudioSignal block provides the reference implementation for VT audio control:

- **Flexible**: Fully configurable audio signals
- **Standards compliant**: Full ISO 11783-6 compatibility
- **Robust**: Proven technology in field devices

Essential for:

- Safety-critical warning signals
- User-friendly acoustic feedback
- Machines with complex audio status messages



Q_ESC

• — ◦ • — ◦ • — ◦ •

Introduction

The **Q_ESC** is a standards-compliant function block for termination control in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.8) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request
- `REQ`: Abort Request

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Abort Confirmation (with status)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operational Status Message
- `s16result` (INT): ISO-compliant Result Code

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` without parameters
- `INITO` confirmed Operational Readiness

1. **Cancel Function**:

- `REQ` terminates the current user input
- No additional parameters required
- `CNF` returns the result status

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.8)
✓ **Universal cancel command**
✓ **No configuration required** ✓ **Immediate effect upon execution

Typical Use Cases

Scenario	Effect
Dialog cancel	Ends current input
Exit menu	Return to main screen
Alarm acknowledgement	Stops audible signals

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successfully aborted
−8	VT_E_NOACT	No active input to abort
−21	VT_E_NO_INSTANCE	No VT instance available
−130	VT_E_NOT_ALIVE	VT not reachable

Application Scenarios

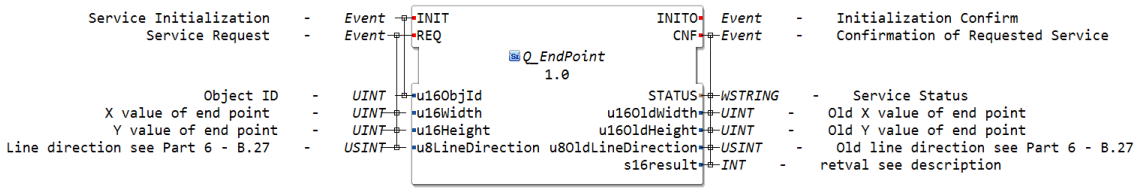
- **Emergency Abort**: Quickly terminate processes
- **Input Error**: Correction option for users
- **Menu Navigation**: Back functionality
- **System Reset**: Abort all active operations

⚖️ **Comparison with similar modules**

Feature	Q_ESC	VtAbortCmd	VtCancelOp
ISO Standard	✓	✖	✖
Effect	Global	Local	Object-Specific

Parameters	None	Configurable	Configurable

Conclusion

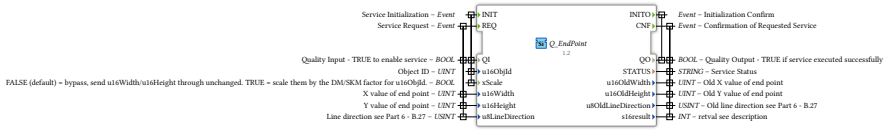


The Q_ESC block provides the standardized abort function for ISOBUS systems:

- **Universal**: Suitable for all abort scenarios
- **Simple**: No configuration required
- **Reliable**: Immediate system response

Essential for:

- Safety-critical applications
- User-friendly interfaces
- Robust error handling



Q_EndPoint

• — ○ • — ○ • — ○ •

Introduction

The **Q_EndPoint** is a standards-compliant function block for controlling line endpoints in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.26) specification for agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID and `xScale`)
- `REQ`: Endpoint Change Request (with position/direction)

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Change Confirmation (with result data)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Line Object ID
- `xScale` (BOOL, initial value `FALSE`): `FALSE` = bypass, `u16Width`/`u16Height` are sent unchanged; `TRUE` = both are scaled by the DM/SKM factor for `u16ObjId`
- `u16Width` (UINT): New X End Position (0-65535 pixels)
- `u16Height` (UINT): New Y-End Position (0-65535 pixels)
- `u8LineDirection` (USINT): Line Direction (ISO 11783-6 B.27)

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operating Status Message
- `u16OldWidth` (UINT): Previous X-End Position
- `u16OldHeight` (UINT): Previous Y-End Position
- `u8OldLineDirection` (USINT): Previous Line Direction

- `s16result` (INT): ISO-compliant Result Code

Valid Object IDs

`u16ObjId` — valid object type (Annex F.26, Output Line object): Output Line (13000–13999).
ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`. Any ID outside these ranges is invalid for commanding.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with Line Object ID
- `INITO` confirms operational readiness

1. **Endpoint Change**:

- `REQ` with new position and direction parameters
- Changes the endpoint and orientation of the line
- `CNF` returns the result and the old values

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.26 + B.27)
✓ **16-bit position resolution** (0-65535 pixels) ✓ **Full line control** (position + direction)
✓ **Real-time processing**

Line directions (B.27)

| Value | Direction | Description | |—|—————|———————| | 0 | Horizontal | From left to right | | 1 | Vertical | From top to bottom | | 2 | Diagonal right | Top left → Bottom right | | 3 | Diagonal left | Top right → Bottom left |

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Success
−6	VT_E_OVERFLOW	Invalid position values
−128	VT_E_HANDLE_INVALID	Invalid line object ID
−129	VT_E_ISO_INSTANCE_INVALID	Invalid instance

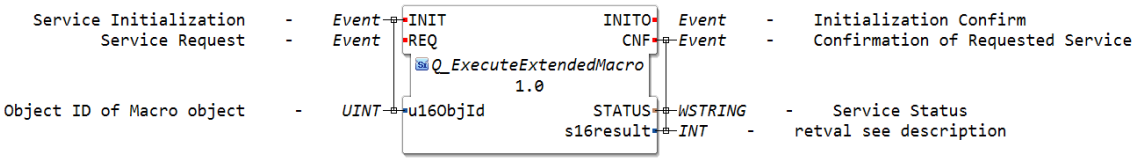
Application Scenarios

- **Machine Visualization**: Dynamic Connecting Lines
- **Diagrams**: Customizable Data Displays
- **Technical Drawings**: Configurable Guidelines
- **UI Design**: Adaptive Dividing Lines

⚖️ **Comparison with Similar Building Blocks**

Feature	Q_EndPoint	VtLineEditor	VtDynamicLine
ISO Standard	✓	✖	✖
Control	Endpoint	Full	Position Only
Directions	4 Options	8 Options	None

Conclusion



The Q_EndPoint block provides the reference implementation for line endpoint control:

- **Precise**: Pixel-accurate positioning
- **Flexible**: Combined position and direction control
- **Standard-compliant**: Full ISO 11783-6 compatibility

Ideal for use in:

- Dynamic technical drawings
- Adaptive diagram displays
- Configurable user interfaces

Q_ExecuteExtendedMacro

• — ○ • — ○ • — ○ •

Introduction

The **Q_ExecuteExtendedMacro** is a standards-compliant function block for executing extended macros in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.62) specification for VT from version 5 onwards.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with macro ID)
- `REQ`: Macro execution request

Event Outputs

- `INITO`: Initialization acknowledgment
- `CNF`: Execution acknowledgment (with status)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Macro object ID (16-bit)

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operational status message
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` addresses the Macro object (range **1–999**, 16-bit field in bytes 2,3 of command F.62). Unlike Q_ExecuteMacro (F.48, 8-bit field), all Macro IDs 1–999 can be addressed here.

ID_NULL (65535) is not a valid command target but deactivates the FB when sent via `INIT`.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with macro object ID
- `INITO` confirms operational readiness

1. **Macro Execution**:

- `REQ` without additional parameters
- Executes saved macro sequence
- `CNF` returns result status

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.62) ✓ **Exclusive to VT Version 5+** ✓ **16-bit Macro IDs** (Extended Address Space) ✓ **Atomised Execution** (Transaction-Safe)

Macro Properties

Feature	Description
Location	Permanently stored in the VT
Size	Up to 255 commands
Content	VT command sequences
ID Range	0x0001 - 0xFEFF (reserved)

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful execution
−6	VT_E_OVERFLOW	Macro too complex
−8	VT_E_NOACT	VT not ready
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance

Application Scenarios

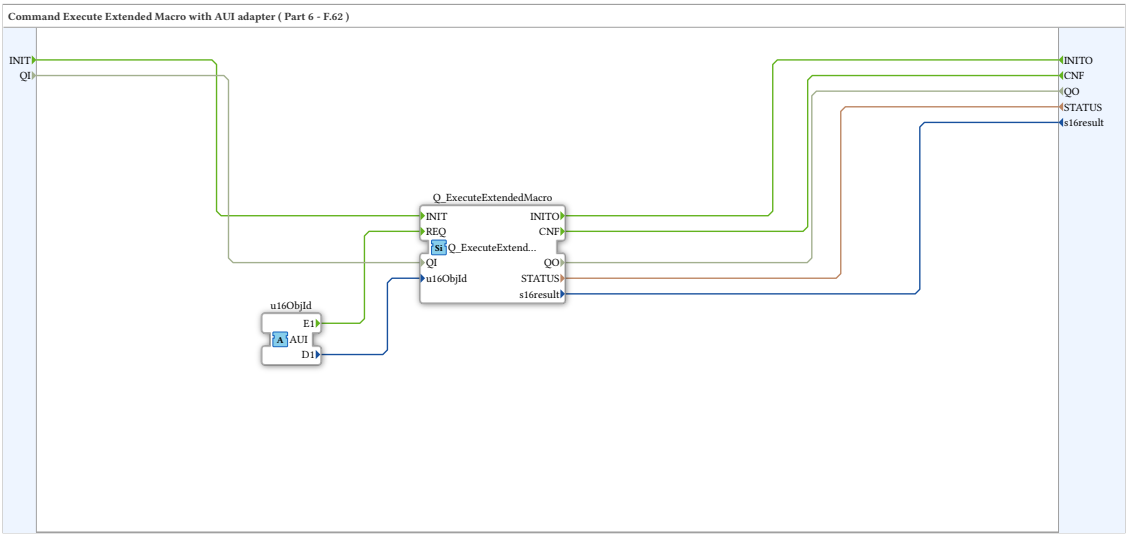
- **Automated Processes**: Complex Command Chains
- **System Initialization**: Startup Procedures
- **Diagnostic Routines**: Automated Tests
- **User Actions**: Macro Recordings

⚖️ **Comparison with Similar Components**

Feature	Q_ExecuteExtendedMacro	VtMacroPlayer	VtCommandSequence
ISO Standard	✓	✖	✖
VT Version	5+	All	All
ID Type	16-bit	8-bit	16-bit

Conclusion

The Q_ExecuteExtendedMacro block provides the standard implementation for extended macros:



- **Powerful**: Complex automations possible
- **Future-proof**: Optimized for VT Generation 5
- **Reliable**: Atomic execution guaranteed

Essential for:

- Highly automated agricultural systems
- Complex operating processes
- Systems with extended functionality

Q_ExecuteExtendedMacro_AUI

• – ○ • – ○ • – ○ •

Introduction

The **Q_ExecuteExtendedMacro_AUI** function block is an AUI adapter wrapper for **Q_ExecuteExtendedMacro** (ISO 11783-6, Part 6 – F.62). It enables executing extended macros (16-bit macro IDs 1–999) on an ISOBUS Virtual Terminal using an AUI adapter interface.

Interface Structure

Event Inputs

Name	Type	Comment
`INIT`	`EInit`	Service Initialization

Event Outputs

Name	Type	Comment
`INITO`	`EInit`	Initialization Confirm
`CNF`	`Event`	Confirmation of Requested Service

Data Inputs

Apart from `QI`, there are no direct data inputs — extended macro Object ID is received via the AUI adapter socket.

Name	Type	Initial value	Comment
`QI`	`BOOL`	`TRUE`	Quality Input - TRUE to enable service

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service Status
s16result	INT	Command return code

Adapters

Type	Name	Direction	Comment
adapter::types::unidirectional::AUI	u16ObjId	Socket (Input)	Object ID of extended macro (1–999)

Quality signals QI/QO: The data input QI (BOOL, initial value TRUE) is associated with the event INIT and is passed through to QI of the internal block Q_ExecuteExtendedMacro. The data output QO (BOOL) is taken over from Q_ExecuteExtendedMacro.QO and is associated with the events INITO and CNF.

Functionality

Connects internal Q_ExecuteExtendedMacro (*isobus::UT::Q::Q_ExecuteExtendedMacro*) to the AUI adapter interface. An event on u16ObjId.E1 triggers REQ on the inner FB, sending the 16-bit macro ID from u16ObjId.D1 to the VT.

Technical Features

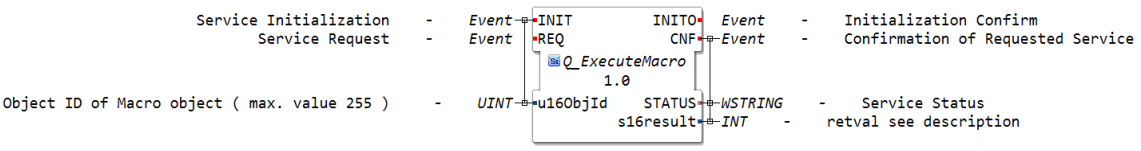
- **16-bit Extended Macro Range:** Supports macro IDs 1 to 999 (ISO 11783-6 VT version 5+).
- **Adapter Wrapper:** Unidirectional AUI connection.

State Overview

Delegates state handling to inner Q_ExecuteExtendedMacro.

Application Scenarios

- Triggering extended macros in VT version 5+ systems via AUI adapter lines.

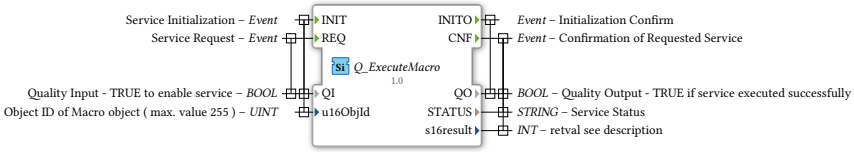


Comparison with Similar Blocks

Use **Q_ExecuteMacro_AUI** for standard 8-bit macro IDs (1–255) and **Q_ExecuteExtendedMacro_AUI** for 16-bit macro IDs (1–999).

Conclusion

Q_ExecuteExtendedMacro_AUI provides an adapter wrapper for extended macro execution in ISOBUS VT applications.



Q_ExecuteMacro

• — ○ • — ○ • — ○ •

Introduction

The **Q_ExecuteMacro** is a standards-compliant function block for executing macros in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.48) specification for VT from version 4 onwards.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with macro ID)
- `REQ`: Macro execution request

Event Outputs

- `INITO`: Initialization acknowledgment
- `CNF`: Execution acknowledgment (with status)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality Input - TRUE to enable service (associated with `INIT` and `REQ`)
- `u16ObjId` (UINT): Macro object ID (max. value 255)

Data Outputs

- `QO` (BOOL): Quality Output - TRUE if service executed successfully (associated with `INITO` and `CNF`)
- `STATUS` (STRING): Operational status message
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` addresses the Macro object. Annex A defines the range 1–999, but the F.48 command carries the Macro Object ID in only a **single byte** (Byte 2). This FB can therefore address only **IDs 1–255** (values > 255 are truncated). Use Q_ExecuteExtendedMacro (F.62) for Macro IDs 256–999.

ID_NULL (65535) is not a valid command target but deactivates the FB when sent via `INIT`.

Functionality

`QI` (default `TRUE`) is taken over with the `INIT` and `REQ` events and enables the service; `QO` is output with `INITO` and `CNF` and indicates whether the service executed successfully.

1. **Initialization**:

- `INIT` with macro object ID (8-bit compatible)
- `INITO` confirms operational readiness

1. **Macro Execution**:

- `REQ` without additional parameters
- Executes stored macro sequence
- `CNF` returns result status

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ ISO 11783-6 compliant (F.48) **✓ Compatible with VT version 4+ ✓ 8-bit Macro IDs** (0-255) **✓ Atomised Execution** (Transaction-Safe)

Macro Properties

Feature	Description
Location	Permanently stored in the VT
Size	Up to 255 commands

Content	VT command sequences
ID Range	0x01 - 0xFF (8-bit)

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful execution
−6	VT_E_OVERFLOW	Macro too complex
−8	VT_E_NOACT	VT not ready
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance

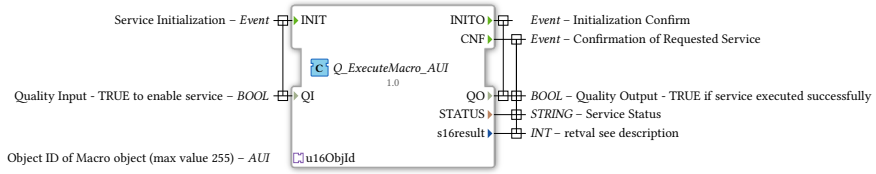
Application Scenarios

- **Standard Flows**: Frequently Used Command Chains
- **System Startup**: Basic Initializations
- **Operating Sequences**: Automated Menu Navigation
- **Diagnostics**: Predefined Test Routines

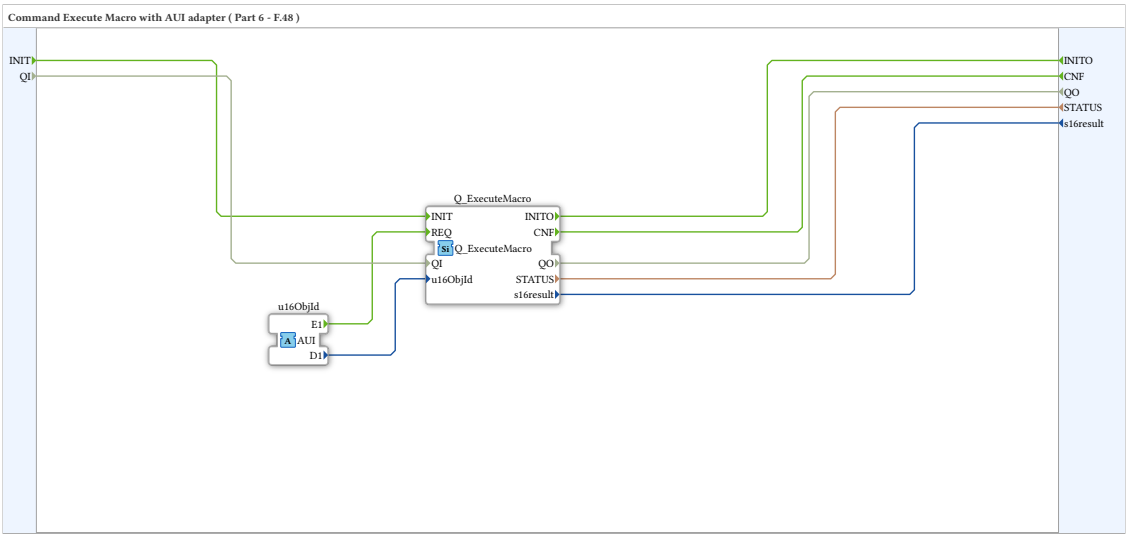
⚖️ Comparison with Similar Components

Feature	Q_ExecuteMacro	Q_ExecuteExtendedMacro	VtMacroRunner
ISO Standard	✓	✓	✖
VT Version	4+	5+	All
ID Type	8-bit	16-bit	8-bit

Conclusion



The Q_ExecuteMacro block offers the standard implementation for basic macros:



- **Simple**: Compact 8-bit addressing
- **Compatible**: Works with VT Generation 4+
- **Reliable**: Proven technology in production devices

Ideal for:

- Standard automation
- Compatibility-critical systems
- Simple macro applications

Q_ExecuteMacro_AUI

• – ○ • – ○ • – ○ •

Introduction

The **Q_ExecuteMacro_AUI** function block is an AUI adapter wrapper for **Q_ExecuteMacro** (ISO 11783-6, Part 6 – F.48). It enables executing macros on an ISOBUS Virtual Terminal using a unidirectional AUI adapter interface (UINT). The block encapsulates the internal `Q_ExecuteMacro` core and provides a clean, adapter-based interface.

Interface Structure

Event Inputs

Name	Type	Comment
`INIT`	`EInit`	Service Initialization

Event Outputs

Name	Type	Comment
`INITO`	`EInit`	Initialization Confirm
`CNF`	`Event`	Confirmation of Requested Service

Data Inputs

Apart from `QI`, there are no direct data inputs — macro Object ID is received via the AUI adapter socket.

Name	Type	Initial value	Comment
`QI`	`BOOL`	`TRUE`	Quality Input - TRUE to enable service

Data Outputs

Name	Type	Comment
`QO`	`BOOL`	Quality Output - TRUE if service executed successfully
`STATUS`	`STRING`	Service Status
`s16result`	`INT`	Command return code

Adapters

Type	Name	Direction	Comment
adapter::types::unidirectional::AUI	u16ObjId	Socket (Input)	Object ID of macro to execute (1–255)

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Q_ExecuteMacro`. The data output `QO` (BOOL) is taken over from `Q_ExecuteMacro.QO` and is associated with the events `INITO` and `CNF`.

Functionality

Internally connects `Q_ExecuteMacro` (*isobus::UT::Q::Q_ExecuteMacro*) to the AUI adapter interface. Upon receiving an event at socket `u16ObjId.E1`, the internal FB's `REQ` event is triggered with the macro ID from `u16ObjId.D1`. Following execution, the internal FB emits `CNF` and updates `STATUS` and `s16result`.

Technical Features

- **Adapter Wrapper:** Input data received via AUI socket.
- **8-bit Macro Range:** Handles macro IDs in the range 1–255.
- **ISOBUS Standard Compliance:** Complies with ISO 11783-6 Annex F.48.

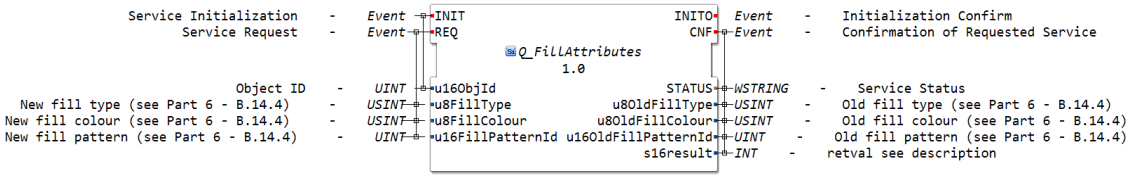
State Overview

Delegates all state handling to the inner FB `Q_ExecuteMacro`.

1. **Initialization** – `INIT` initializes the inner FB and confirms with `INITO`.
2. **Command Execution** – Event on `u16ObjId.E1` triggers macro execution.
3. **Confirmation** – `CNF` confirms completion with updated `STATUS` and `s16result`.

Application Scenarios

- Triggering VT macros via AUI adapter in ISO 11783-6 applications.
- Sequence-driven macro execution.

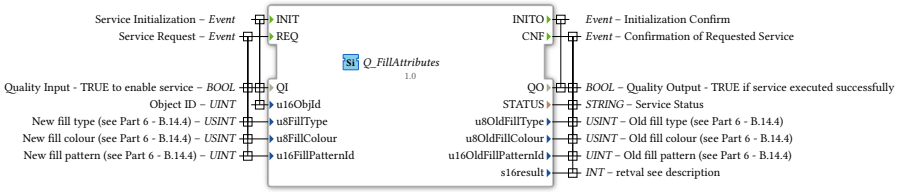


Comparison with Similar Blocks

Compared to direct `Q_ExecuteMacro`, **Q_ExecuteMacro_AUI** provides an adapter interface. For macro IDs > 255, use **Q_ExecuteExtendedMacro_AUI**.

Conclusion

Q_ExecuteMacro_AUI is a clean adapter wrapper for executing ISOBUS VT macros via AUI adapter connections.



Q_FillAttributes

• — ○ • — ○ • — ○ •

Introduction

The **Q_FillAttributes** is a standards-compliant function module for modifying fill attributes in Virtual Terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.32) specification for VT systems.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with object ID)
- `REQ`: Attribute change request (with new fill attributes)

Event Outputs

- `INITO`: Initialization confirmation
- `CNF`: Change confirmation (with status and old attributes)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Object ID (16-bit)
- `u8FillType` (USINT): New fill type
- `u8FillColour` (USINT): New fill color
- `u16FillPatternId` (UINT): New fill pattern

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `u8OldFillType` (USINT): Old fill type
- `u8OldFillColour` (USINT): Old fill color
- `u16OldFillPatternId` (UINT): Old fill pattern
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` addresses the target object of the **F.32** command (Change Fill Attributes). Valid is a **Fill Attributes object**:

FillAttributesObject: 25000–25999
ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with object ID
- `INITO` confirms operational readiness

1. **Attribute Change**:

- `REQ` with new fill attributes
- Changes Object Fill Properties
- `CNF` provides result status and previous values

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.32)
✓ **Comprehensive attribute control** (type, color, pattern)
✓ **Feedback of previous values** for reversal options ✓ **Transaction-safe** (Atomic execution)

Attribute Properties

Feature	Description
Fill types	According to ISO 11783-6 B.14.4

Color palette	8-bit color index
Patterns	16-bit pattern references
Object range	All fillable VT objects

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful change
−6	VT_E_OVERFLOW	Buffer overflow
−8	VT_E_NOACT	VT not ready
−21	VT_E_NO_INSTANCE	No VT client available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance
−130	VT_E_NOT_ALIVE	VT not active

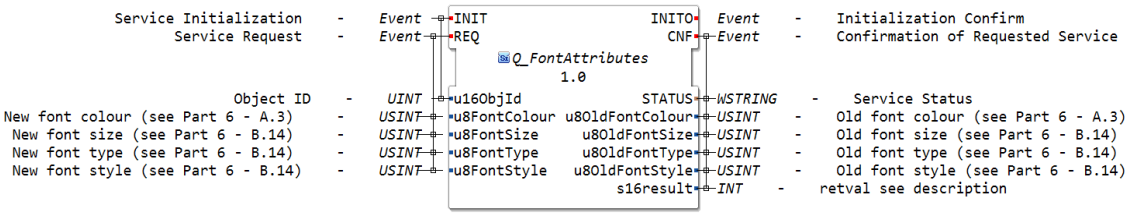
Application Scenarios

- **Design Adjustments**: Dynamic Interface Design
- **Status Visualization**: Color Highlighting
- **Pattern Change**: Context-Sensitive Displays
- **Theme Change**: Dark/Light Mode Switching

⚖️ Comparison with Similar Building Blocks

Feature	Q_FillAttributes	VtSetColor	VtPatternManager
ISO Standard	✓	✖	✖
Color Control	✓	✓	✖
Pattern Control	✓	✖	✓
Type Control	✓	✖	✖

Conclusion

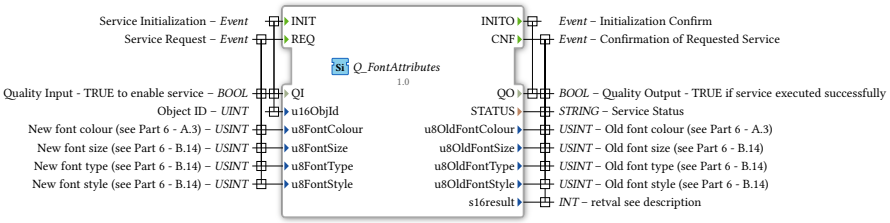


The Q_FillAttributes module provides the standard implementation for fill attribute changes:

- **Versatile**: Complete control over fill properties
- **Traceable**: Feedback of previous values
- **Robust**: ISO-compliant error handling

Essential for:

- Dynamic user interfaces
- State-dependent visualizations
- Design-flexible VT applications



Q_FontAttributes

• — ○ • — ○ • — ○ •

Introduction

The **Q_FontAttributes** is a standards-compliant function module for modifying font attributes in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.28) specification for VT systems.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with object ID)
- `REQ`: Attribute change request (with new font attributes)

Event Outputs

- `INITO`: Initialization confirmation
- `CNF`: Change confirmation (with status and old attributes)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Object ID (16-bit)
- `u8FontColour` (USINT): New font color
- `u8FontSize` (USINT): New font size
- `u8FontType` (USINT): New font
- `u8FontStyle` (USINT): New font style

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `u8OldFontColour` (USINT): Old font color
- `u8OldFontSize` (USINT): Old font size
- `u8OldFontType` (USINT): Old font
- `u8OldFontStyle` (USINT): Old font style
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` addresses the target object of the **F.28** command (Change Font Attributes). Valid is a **Font Attributes object**:

FontAttributesObject: 23000–23999
ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with object ID
- `INITO` confirms operational readiness

1. **Attribute Change**:

- `REQ` with new font attributes
- Changes the object's font properties
- `CNF` returns the result status and previous values

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.28) ✓ **Comprehensive font control** (color, size, type, style) ✓ **Feedback of previous values** for reversal options ✓ **Transaction-safe** (Atomic execution)

Attribute Properties

Feature	Description
Color Palette	8-bit Color Index (ISO 11783-6 A.3)
Sizes	Standardized Font Sizes
Fonts	Predefined Types
Styles	Bold/Italic/Underline Bit Field

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful Change
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	VT Not Ready
−21	VT_E_NO_INSTANCE	No VT Client Available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT Instance
−130	VT_E_NOT_ALIVE	VT not active

Application Scenarios

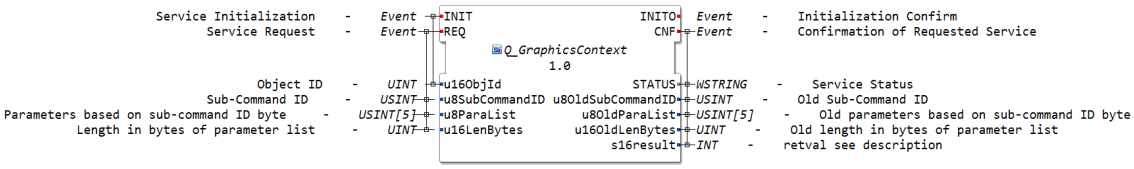
- **Text Display**: Dynamic font adjustments
- **Warnings**: Color highlighting
- **User Interfaces**: Style changes
- **Accessibility**: Font enlargements

⚖️ **Comparison with similar building blocks**

Feature	Q_FontAttributes	VtTextStyle	VtFontManager
ISO Standard	✓	✖	✖
Color Control	✓	✓	✖
Size Control	✓	✖	✓
Style Control	✓	✓	✓

Conclusion

The Q_FontAttributes module provides the standard implementation for font attribute changes:

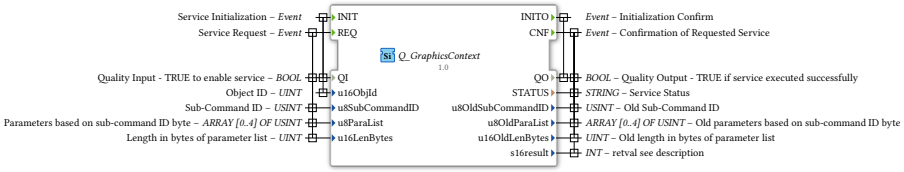


- **Versatile**: Complete control over font properties
- **Traceable**: Feedback of previous values
- **Robust**: ISO-compliant error handling

Essential for:

- Dynamic text rendering
- Accessible applications

- Design-flexible VT interfaces



Q_GraphicsContext

• — ○ • — ○ • — ○ •

Introduction

The **Q_GraphicsContext** is a standards-compliant function block for controlling graphics context objects in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.56) specification for VT systems from version 4 onwards.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with object ID)
- `REQ`: Configuration request (with sub-command and parameters)

Event Outputs

- `INITO`: Initialization acknowledgment
- `CNF`: Configuration acknowledgment (with status and previous values)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Graphics context object ID (16-bit)
- `u8SubCommandID` (USINT): Subcommand ID (8-bit)
- `u8ParaList` (USINT[5]): Parameter list (5-byte array)
- `u16LenBytes` (UINT): Parameter length in bytes

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operating status message
- `u8OldSubCommandID` (USINT): Previous subcommand ID
- `u8OldParaList` (USINT[5]): Previous parameter list
- `u16OldLenBytes` (UINT): Previous parameter length
- `s16result` (INT): ISO-compliant result code

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with graphics context object ID
- `INITO` confirms operational readiness

1. **Configuration**:

- `REQ` with sub-command ID and parameter list
- Configures graphics context properties

- `CNF` returns result status and previous configuration

1. **Error Handling**:

- ISO-standardized error codes
- Buffer overflow check

Technical Features

✓ **ISO 11783-6 compliant** (F.56) ✓ **Exclusive to VT Version 4+** ✓ **Flexible parameterization** (5-byte parameter array) ✓ **Traceability** (Previous configuration)

Sub-Command Reference

The sub-command IDs correspond to Table F.1 of ISO 11783-6 (not to be confused with earlier/derived numbering):

ID	Command	Parameter Description
0	Set Graphics Cursor	Bytes 5-6 X, 7-8 Y (signed)
1	Move Graphics Cursor	Bytes 5-6 X offset, 7-8 Y offset (signed)
2	Set Foreground Colour	Byte 5 colour index
3	Set Background Colour	Byte 5 colour index
4	Set Line Attributes Object ID	Bytes 5-6 object ID (65535 = no line)
5	Set Fill Attributes Object ID	Bytes 5-6 object ID (65535 = no fill)
6	Set Font Attributes Object ID	Bytes 5-6 object ID (65535 = no font)

⚠️ **Variable data length / Transport Protocol:** The F.56 command has a **variable data length**. Messages **larger than 8 bytes** are transmitted via the **Transport Protocol (TP)** smaller commands are padded to 8 bytes with FF16. With this FB's 5-byte parameter list (`u8ParaList`, ArraySize 5) the message becomes 9 bytes (⟶ TP). Sub-commands requiring more than 5 parameter bytes (e.g. Draw Polygon with several points, Pan & Zoom Viewport) cannot be fully expressed through this FB.

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful Execution
−6	VT_E_OVERFLOW	Parameter Buffer Too Small
−8	VT_E_NOACT	VT not ready
−21	VT_E_NO_INSTANCE	No VT client available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance
−130	VT_E_NOT_ALIVE	VT not active

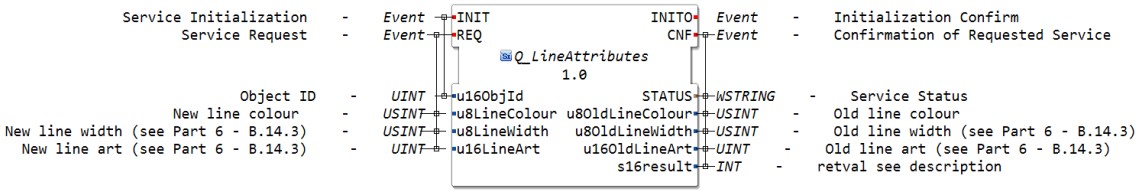
Application Scenarios

- **Graphics Rendering**: Line and Fill Styles
- **User Interfaces**: Transparency Effects
- **Charts**: Clipping Ranges for Excerpts
- **Animations**: Transformation Matrices

Safety Notes

⚠️ **Consider Buffer Size**: Parameter lists must not exceed `ISO_VTC_CMD_STR_MAX_LENGTH` ⚠️ **Sub-Command Validation**:
Unknown command IDs can lead to unexpected behavior

Conclusion

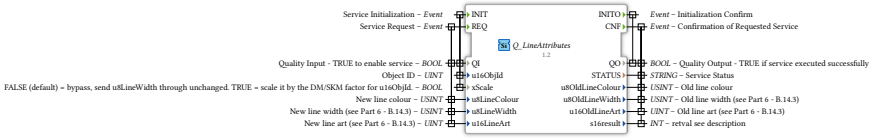


The Q_GraphicsContext block offers powerful graphics control:

- **Precise Control**: Over all graphics attributes
- **Traceable**: Previous State Backup
- **High Performance**: Optimized command load

Essential for:

- High-quality graphics rendering
- Dynamic visualizations
- Complex user interfaces



Q_LineAttributes

• — ○ • — ○ • — ○ •

Introduction

The **Q_LineAttributes** is a standards-compliant function module for modifying line attributes in Virtual Terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.30) specification for VT systems.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with object ID and `xScale`)
- `REQ`: Attribute change request (with new line attributes)

Event Outputs

- `INITO`: Initialization confirmation
- `CNF`: Change confirmation (with status and old attributes)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Object ID (16-bit)
- `xScale` (BOOL, default `FALSE`): `FALSE` = bypass, `u8LineWidth` is sent through unchanged; `TRUE` = scale it by the DM/SKM factor for `u16ObjId`
- `u8LineColour` (USINT): New line color
- `u8LineWidth` (USINT): New line width
- `u16LineArt` (UINT): New line style

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `u8OldLineColour` (USINT): Old line color
- `u8OldLineWidth` (USINT): Old line width
- `u16OldLineArt` (UINT): Old line style
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` addresses the target object of the **F.30** command (Change Line Attributes). Valid is a **Line Attributes object**:

LineAttributesObject: 24000–24999
ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with object ID
- `INITO` confirms operational readiness

1. **Attribute Change**:

- `REQ` with new line attributes
- Changes Object Line Properties
- `CNF` provides result status and previous values

1. **Error Handling**:

- ISO-standardized error codes
- Detailed status messages

Technical Features

✓ **ISO 11783-6 compliant** (F.30)
✓ **Comprehensive line control** (color, width, style)
✓ **Feedback of previous values** for reversal options ✓ **Transaction-safe** (Atomic execution)

Attribute Reference

Attribute	Value range	Description
Color	0-255 (8-bit)	Color index according to ISO 11783-6 A.3
Width	1-255 pixels	Line thickness in pixels
Style	16-bit Bitmask	Line type according to B.14.3

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful change
−6	VT_E_OVERFLOW	Buffer overflow
−8	VT_E_NOACT	VT not ready
−21	VT_E_NO_INSTANCE	No VT client available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance
−130	VT_E_NOT_ALIVE	VT not active

Application Scenarios

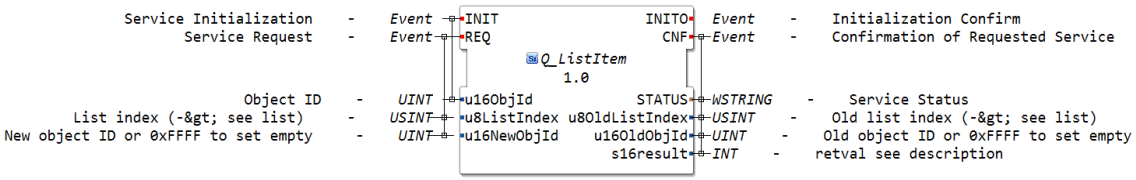
- **Graphic Design**: Dynamic Line Adjustments
- **Diagrams**: Highlighting Important Elements
- **User Guidance**: Visual Markers
- **Machine Visualization**: Status Indicators

⚖️ **Comparison with Similar Building Blocks**

Feature	Q_LineAttributes	VtLineStyle	VtGraphicAttributes
ISO Standard	✓	✖	✖

Color Control	✓	✓	✓
Width Control	✓	✓	✖
Style Control	✓	✓	✓

Conclusion

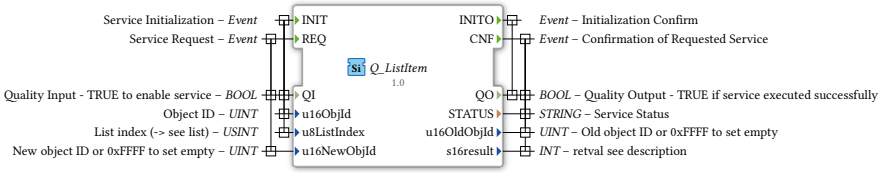


The Q_LineAttributes block offers precise control over line attributes:

- **Flexible**: Complete design freedom
- **Reliable**: ISO-compliant implementation
- **Traceable**: Previous state storage

Essential for:

- Technical drawings
- Process visualizations
- Interactive graphics applications



Q_ListItem

• — ○ • — ○ • — ○ •

Introduction

The **Q_ListItem** is a standards-compliant function module for managing list entries in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.42) specification for list input objects in VT systems.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with list object ID `u16ObjId` and list index `u8ListIndex`)
- `REQ`: Change request (with new object ID `u16NewObjId`)

Event Outputs

- `INITO`: Initialization confirmation
- `CNF`: Change confirmation (with status and previous object ID)

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): List object ID (16-bit)
- `u8ListIndex` (USINT): List index (0-based, provided at `INIT`)
- `u16NewObjId` (UINT): New object ID or 0xFFFF (empty entry)

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `u16OldObjId` (UINT): Previous object ID
- `s16result` (INT): ISO-compliant result code

Instance Uniqueness

This block requires instance uniqueness regarding the pair (**u16ObjId**, **u8ListIndex**). Only one instance of `Q_ListItem` may exist in the entire program for the same list item entry. `u8ListIndex` is read at `INIT` — a second instance with the same list object ID and list index is deactivated during `INIT` (STATUS = "This objID is already in use"). See also Instance Uniqueness.

Valid Object IDs

`u16ObjId` (the list object) and `u16NewObjId` (the new list item) are subject to **different** rules.

`u16ObjId` — valid list object types (Annex F.42): Input List Field (10000–10999), Output List Object (37000–37999, VT v4+), Animation Object (44000–44999, VT v5+), External Object Definition (41000–41999, VT v5+).

`u16NewObjId` — new list item: any object ID (the item points to that object) or 0xFFFF (ID_NULL) to set an empty item. The validity of the new object ID is verified by the VT and reported back via F.43 (bit 2 = Invalid New List Item Object ID).

ID_NULL (65535) is not a valid command target for `u16ObjId` but deactivates the FB when used with `INIT`.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:
   - `INIT` with list object ID and list index
   - `INITO` confirms operational readiness
2. **List Change**:
   - `REQ` with new object ID
   - Updates the list item
   - `CNF` provides result status and previous object ID
3. **Special Case**:
   - `u16NewObjId = 0xFFFF` creates an empty entry

Technical Features

✓ **ISO 11783-6 compliant** (F.42) ✓ **Dynamic list management** (real-time changes) ✓ **Pairwise uniqueness at INIT** (`u16ObjId` + `u8ListIndex`) ✓ **Flexible empty items** (0xFFFF special value)

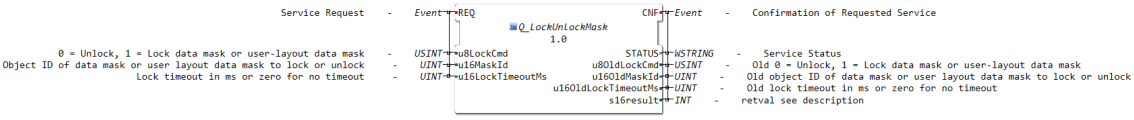
Index Reference

Index	Description
0	First list item entry
…	
255	Maximum index (uint8_t)

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful change
−6	VT_E_OVERFLOW	Buffer overflow
−8	VT_E_NOACT	VT not ready
−21	VT_E_NO_INSTANCE	No VT client available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance
−130	VT_E_NOT_ALIVE	VT not active

Application Scenarios



- **Dynamic Menus**: Context-dependent items
- **Device Selection**: Plug-and-play device lists
- **Parameter Settings**: Selection options
- **Diagnostic Lists**: Error code management

Conclusion

The Q_ListItem block provides efficient list management:

- **Reactive**: Instant GUI updates
- **Robust**: Integrated error handling
- **Compatible**: Full ISO compliance

Q_LockUnlockMask

• — ○ • — ○ • — ○ •

Introduction

The **Q_LockUnlockMask** is a standards-compliant function block for controlling the locking state of masks in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.46) specification for VT systems from version 4 onwards.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with mask object ID `u16MaskId`)
- `REQ`: Lock/Unlock Request (with lock command and timeout)

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Operation Acknowledgement

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16MaskId` (UINT): Mask Object ID (provided at `INIT`)
- `u8LockCmd` (USINT): Lock Command (0=Unlock, 1=Lock)
- `u16LockTimeoutMs` (UINT): Timeout in ms (0 = no timeout)

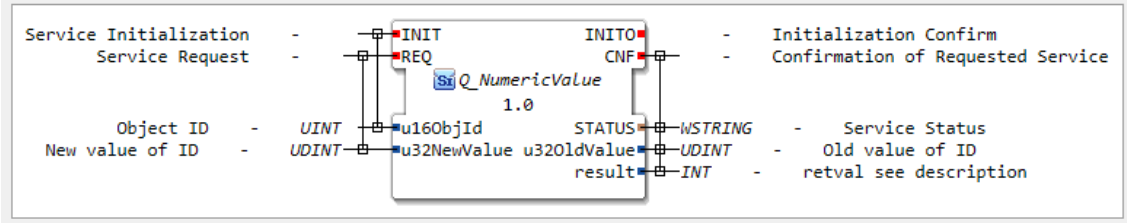
Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `u8OldLockCmd` (USINT): Previous lock state
- `u16OldLockTimeoutMs` (UINT): Previous timeout
- `s16result` (INT): ISO-compliant result code

Instance Uniqueness

This block requires instance uniqueness regarding **u16MaskId**. Only one instance of `Q_LockUnlockMask` may exist in the entire program for the same mask ID. `u16MaskId` is read at `INIT` — a second instance with the same mask ID is deactivated during `INIT` (STATUS = “This objID is already in use”). See also Instance Uniqueness.

Valid Object IDs

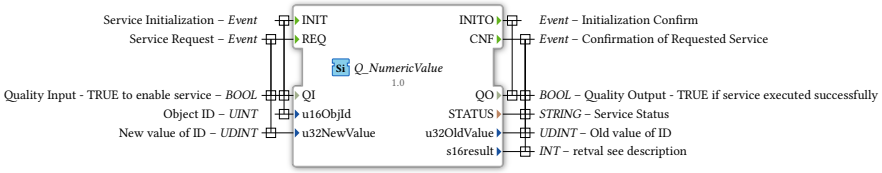


`u16MaskId` addresses the mask to lock/unlock (F.46). Valid are:
Data Mask (1000–1999) and **Window Mask / User-Layout Data Mask (34000–34999)**.
ID_NULL (65535) is not a valid command target — the command is answered by the VT with an error code (the mask must match the currently visible mask).

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:
   - `INIT` with `u16MaskId`
   - `INITO` confirms operational readiness
2. **Mask Locking**:
   - `REQ` with lock command and timeout
   - Controls the screen refresh of the mask
   - `CNF` provides operating status and previous values
3. **Timeout Behavior**:
   - Automatic unlock upon expiration



Q_NumericValue

• — ○ • — ○ • — ○ •

Introduction

The **Q_NumericValue** is a standards-compliant function block for changing numeric values in Virtual Terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.22) specification for numeric VT objects.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID)
- `REQ`: Value Change Request

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Object ID (16-bit)
- `u32NewValue` (UDINT): New Numeric Value (32-bit unsigned)

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational Status Message
- `u32OldValue` (UDINT): Previous numeric value
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` — valid object types (Annex F.22, objects with numeric value attribute): Input Boolean Field (7000–7999), Input Number Field (9000–9999), Input List Field (10000–10999), Output Number Field (12000–12999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Number Variable (21000–21999), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object (48000–48999).

ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`. Any ID outside these ranges is invalid for commanding.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with target object ID
- `INITO` confirms operational readiness

1. **Value Update**:

- `REQ` with new 32-bit value
- Updates the numeric VT object
- `CNF` returns operational status and previous value

1. **Value Range**:

- 0 to 4,294,967,295 (32-bit unsigned)

Technical Features

✓ **ISO 11783-6 compliant** (F.22)
✓ **32-bit value range** (UDINT)
✓ **Instant update**
✓ **Traceability** (Previous value)
✓ **Internal buffering**: The function block buffers the value internally. A message is only sent to the bus if `u32NewValue` differs from `u32OldValue`. This significantly reduces the bus load and tolerates frequent REQ events.

Value range

Parameter	Type	Value range
u32NewValue	UDINT	0 to 4,294,967,295

Return codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful change
−6	VT_E_OVERFLOW	Buffer overflow
−8	VT_E_NOACT	VT not ready
−21	VT_E_NO_INSTANCE	No VT client available
−128	VT_E_HANDLE_INVALID	Invalid object ID
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance

–130	VT_E_NOT_ALIVE	VT not active

Application Scenarios

- **Process Visualization**: Real-time Measurement Data
- **Control Elements**: Setpoint Specifications
- **Diagnostic Systems**: Error Code Display
- **Production Data**: Counters and Statistics

⚖️ Comparison with Similar Function Blocks

Conclusion

The Q_NumericValue block offers precise numerical control:

- **High-resolution**: 32-bit precision
- **Reliable**: Integrated error checking

- **Flexible**: For all numerical objects

Essential for:

- Precise process visualization
- Real-time data monitoring
- Industrial control systems

Example applications

Q_NumericValueAux

• – ○ • – ○ • – ○ •

Introduction

The **Q_NumericValueAux** is a standards-compliant function block for numeric value changes in Virtual Terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.22) specification for numeric VT objects.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID)
- `REQ`: Value Change Request

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Object ID (16-bit)
- `u32NewValue` (UDINT): New Numeric Value (32-bit unsigned)

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational Status Message
- `u32OldValue` (UDINT): Previous numeric value
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` — valid object types (Annex F.22, objects with numeric value attribute): Input Boolean Field (7000–7999), Input Number Field (9000–9999), Input List Field (10000–10999), Output Number Field (12000–12999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Number Variable (21000–21999), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object (48000–48999).

ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`. Any ID outside these ranges is invalid for commanding.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with target object ID
- `INITO` confirms operational readiness

1. **Value Update**:

Q_NumericValueAux_AUDI

• — ○ • — ○ • — ○ •

Introduction

This function block implements the **Change Numeric Value** command according to ISO 11783-6 (Part 6, F.22). It is used to change the numeric value of an object and is only suitable for objects that have a numeric value attribute.

Interface Structure

Event Inputs

Event	Type	Comment	Carried Variable
`INIT`	EInit	Service Initialization	`u16ObjId`

Event Outputs

Event	Type	Comment	Carried Variable
`INITO`	EInit	Initialization Acknowledgement	–
`CNF`	Event	Acknowledgement of Requested Service	`STATUS`, `s16result`

Data Inputs

Variable	Type	Comment	Initial Value
`QI`	BOOL	Quality Input - TRUE to enable service	`TRUE`

u16ObjId	UINT	Object ID	ID_NULL

Data Outputs

Variable	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service Status
s16result	INT	Return Value (see description)

Adapters

Adapter	Direction	Type	Comment
u32OldValue	Plug	adapter::types::unidirectional::AUDI	Old Value of ID
u32NewValue	Socket	adapter::types::unidirectional::AUDI	New ID Value

Quality signals QI/QO: The data input QI (BOOL, initial value TRUE) is associated with the event INIT and is passed through to QI of the internal block Q_NumericValueAux. The data output QO (BOOL) is taken over from Q_NumericValueAux.QO and is associated with the events INITO and CNF.

Valid Object IDs

u16ObjId is valid for the same object types as the wrapped base block Q_NumericValueAux / Q_NumericValue (Annex F.22, objects with numeric value attribute): Input Boolean Field (7000–7999), Input Number Field (9000–9999), Input List Field (10000–10999), Output Number Field (12000–12999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Number Variable (21000–21999), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object (48000–48999).

ID_NULL (65535) is not a command target but deactivates the FB when used with INIT.

Functionality

The function block (FB) expects a valid object ID (u16ObjId) via the INIT input. After successful initialization, a new value can be passed via the socket adapter (u32NewValue). The socket adapter event (E1) triggers internal processing, in which the old value is returned via the plug adapter (u32OldValue). The result is signaled via the CNF output with status and return code (s16result).

Possible return codes are:

- VT_E_NO_ERR (0) – Success
- VT_E_OVERFLOW (-6) – Buffer overflow
- VT_E_NOACT (-8) – Command not possible in the current state
- VT_E_NO_INSTANCE (-21) – No VT client available
- VT_E_ISO_INSTANCE_INVALID (-129) – Connection instance invalid
- VT_E_HANDLE_INVALID (-128) – Invalid handle
- VT_E_NOT_ALIVE (-130) – VT unreachable

Technical Features

- Use of unidirectional adapters for transmitting old and new values, enabling flexible, loose coupling in the application.
- Initialization with an object ID (u16ObjId) is mandatory.
- Returns ISO-11783-specific error codes, allowing for detailed error diagnosis.
- The function block internally contains a sub-FB (Q_NumericValueAux) that encapsulates the actual logic.

State Overview

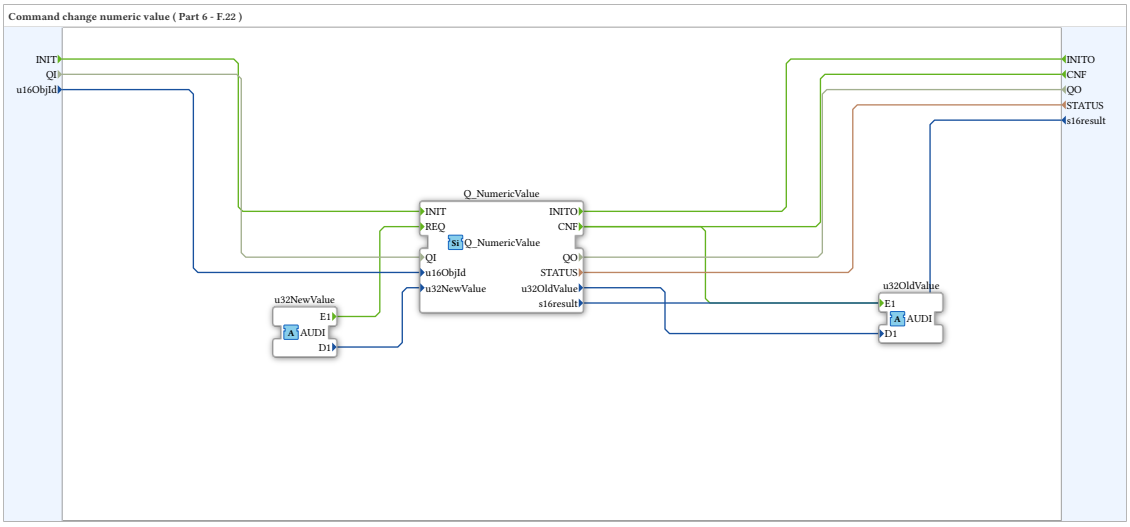
The FB does not have any explicit state machines in its XML description. Its operation is event-driven:

1. **INIT** – Sets the object ID and initializes the internal logic.
2. **Waiting for Value** – After INIT, the function waits for an event from the socket adapter (u32NewValue.E1).

3. **Processing** – Upon arrival, the value is processed, the previous value is returned via the plug adapter, and the result is reported via `CNF`.

Application Scenarios

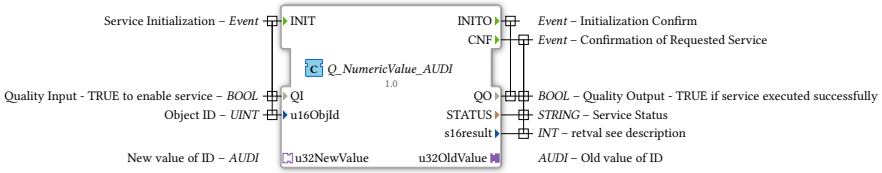
- Changing numerical attributes of objects in a Virtual Terminal (VT) according to the ISOBUS standard.
- Controlling agricultural machinery – e.g., setting target values for speeds, pressures, or positions within an ISOBUS network.



Comparison with Similar Modules

The basic module `Q_NumericValueAux` (without the suffix `_AUDI`) offers the same core functionality, but without the two unidirectional adapters. The `_AUDI` variant allows for separate and reusable connections of legacy and new values, which facilitates the development of modular and testable applications.

Conclusion



The `Q_NumericValueAux_AUDI` is a specialized function block for ISO 11783 communication. It encapsulates the "Change Numeric Value" command and provides a clean, decoupled interface for value transfer via adapters. With its detailed error feedback, it is particularly suitable for safety-critical applications in agricultural engineering.

Q_NumericValue_AUDI (ISOBUS Numeric Value Adapter)

Introduction

The `Q_NumericValue_AUDI` is a special ISOBUS function block that allows numeric values (`UDINT`) to be sent from a controller to a Universal Terminal (UT) for display or modification. It uses the `AUDI` adapter for transferring new and old values, ensuring a modern and type-safe connection.

Interface Structure

Event Inputs

- **INIT**: `EInit` - Initializes the service with `u16ObjId`. Associated with `QI`.

Event Outputs

- **INITO**: `EInit` - Confirms initialization. Associated with `QO`.
- **CNF**: `Event` - Confirms service execution. Associated with `QO`.
- Linked to variables `STATUS` and `s16result`.

Input Variables

- **QI**: `BOOL` - Quality Input - TRUE to enable service. Initial value TRUE.
- **u16ObjId**: `UINT` - The object ID of the numeric input field on the ISOBUS terminal (default: `ID_NULL`).

Output Variables

- **QO**: `BOOL` - Quality Output - TRUE if service executed successfully.
- **STATUS**: `STRING` - Service status message (e.g., "OK", "Error").
- **s16result**: `INT` - Service return value (error codes according to ISO 11783-6).

Adapter

- **u32OldValue** (Plug): `AUDI` - The old/current value of the object.
- **u32NewValue** (Socket): `AUDI` - The new value to be sent to the ISOBUS terminal.

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Q_NumericValue`. The data output `QO` (BOOL) is taken over from `Q_NumericValue.QO` and is associated with the events `INITO` and `CNF`.

Valid Object IDs

`u16ObjId` is valid for the same object types as the wrapped base block `Q_NumericValue` (Annex F.22, objects with numeric value attribute): Input Boolean Field (7000–7999), Input Number Field (9000–9999), Input List Field (10000–10999), Output Number Field (12000–12999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Number Variable (21000–21999), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object (48000–48999).

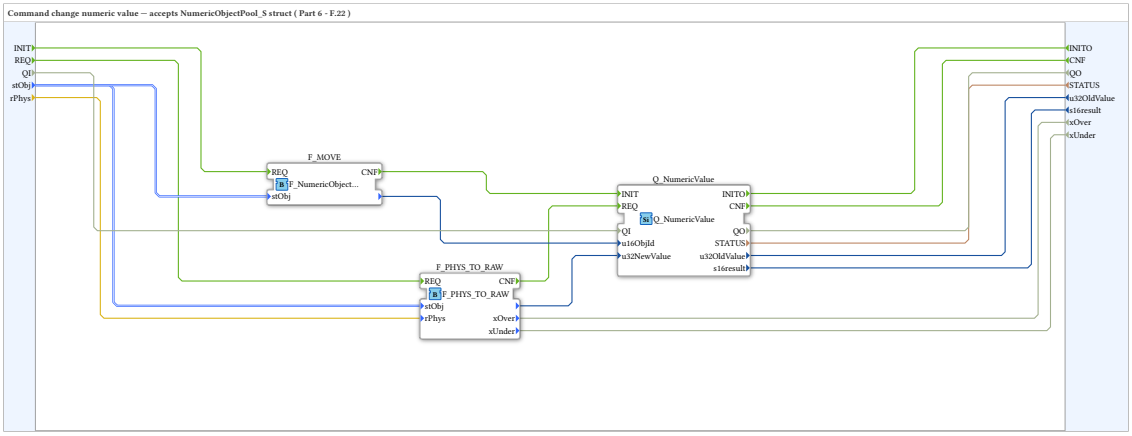
ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`.

Functionality

The function block is initialized via the `INIT` event with the object ID `u16ObjId`. As soon as an event arrives at the `u32NewValue` socket (`u32NewValue.E1`), the contained UDINT value (`u32NewValue.D1`) is sent to the ISOBUS terminal to update the displayed numeric value. After successful execution, a `CNF` event is triggered, and the object's previous value is provided via the `u32OldValue` plug.

Technical Features

✓ **ISO 11783-6 Standard**: Compliant implementation for ISOBUS Universal Terminals.
  ✓ **Adapter-based**: Uses the `AUDI` adapter for numerical values.
  ✓ **Asynchronous operation**: Event-driven communication.



Application scenarios

- **Display of counter readings**: Visualization of counter readings (e.g., operating hours, quantities) on the terminal.
- **Setpoint specification**: Transfer of target values (e.g., temperature, pressure) from the ISOBUS terminal to the controller (in combination with a NumericValue_IDA input block).
- **Feedback systems**: Display of process values in real time.

Q_NumericValue_PHYS

Introduction

The function block `Q_NumericValue_PHYS` is a composite function block according to the standard **ISO 11783-6 (ISOBUS)**. It is used to change the numeric value of an ISOBUS object by specifying a physical value. The conversion from physical to raw data values is performed automatically based on the scaling, offset, and decimal places defined in the object structure `NumericObjectPool_S`. The function block encapsulates three sub-functions:

- **`F_MOVE`** – Intermediate storage of object parameters during initialization
- **`F_PHYS_TO_RAW`** – Conversion of physical values to raw integers (UDINT)
- **`Q_NumericValue`** – Actual ISOBUS write operation to the numeric object

Interface Structure

Event Inputs

Name	Type	Comment
`INIT`	EInit	Service Initialization – Loads the object parameters (`stObj`) into the function block
`REQ`	Event	Service Request – converts `rPhys` and writes the value to the ISOBUS object

Event Outputs

Name	Type	Comment
`INITO`	EInit	Initialization Confirmation
`CNF`	Event	Confirmation of Value Change – Contains Result Data

Data Inputs

Name	Type	Comment
`QI`	BOOL	Quality input, `TRUE` enables the service (default `TRUE`)
`stObj`	`logiBUS::utils::conversion::phys::NumericObjectPool_S`	Structure with object ID, scale, offset, and decimal places (initial value: ID_NULL, 1.0, 0, 0)

rPhys	REAL	Physical value to be set (e.g., temperature, pressure)

Data Outputs

Name	Type	Comment
QO	BOOL	Quality output, TRUE if the service was executed successfully
STATUS	STRING	Service status message (e.g., error or success message)
u32OldValue	UDINT	Original raw value of the ISOBUS object before the change
s16result	INT	Return value of the write operation (see Q_NumericValue)
xOver	BOOL	True if the physical value exceeds the upper limit of the ISOBUS value range
xUnder	BOOL	True if the physical value falls below the lower limit of the ISOBUS value range

Adapters

No adapters available.

Valid Object IDs

stObj.u16ObjId is valid for the same object types as the internally used Q_NumericValue (Annex F.22, objects with numeric value attribute): Input Boolean Field (7000–7999), Input Number Field (9000–9999), Input List Field (10000–10999), Output Number Field (12000–12999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Number Variable (21000–21999), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object (48000–48999).

ID_NULL (65535) is not a command target but deactivates the FB when used with INIT.

Functionality

Quality handling (QI/QO): The input QI (BOOL, default TRUE) is associated with the events INIT and REQ; TRUE enables the service. The output QO (BOOL) is associated with INITO and CNF and indicates with TRUE that the service was executed successfully. QI is passed through to Q_NumericValue.QI, and Q_NumericValue.QO is passed through to QO.

Processing occurs in two separate steps:

1. **Initialization (event INIT):**

- The passed parameter stObj is temporarily stored via F_MOVE.
- Upon completion, Q_NumericValue.INIT is triggered, providing the object ID (u16ObjId) from F_MOVE.OUT.
- Initialization is acknowledged with INITO.

1. **Value Change (Event REQ):**

- The physical value rPhys, along with the stored structure stObj, is passed to F_PHYS_TO_RAW.
- F_PHYS_TO_RAW calculates the raw value (u32NewValue) as well as the limit flags xOver and xUnder.
- Subsequently, Q_NumericValue.REQ is triggered, which writes the calculated raw value to the ISOBUS object.
- The result data (STATUS, u32OldValue, s16result) are taken by Q_NumericValue and made available at the output.
- The event CNF signals completion.

Technical Features

- **Standard Compliance:** This module implements the ISO 11783-6 specification (Part 6, Annex F.22) – developed for agricultural ISOBUS applications.
- **Limit Violation Calculation:** The flags xOver / xUnder are determined during the conversion stage (F_PHYS_TO_RAW) and output in parallel with the actual write operation. This allows the user to identify early on whether the requested physical value is outside the permissible ISOBUS value range.

- **Typing:** The object ID is provided as `UINT` (16-bit), and the raw value as `UDINT` – this corresponds to the common ISOBUS convention for numeric attributes.
- **Reuse of Internal Components:** The division into `F_PHYS_TO_RAW` and `Q_NumericValue` allows for modular testability and reusability of the conversion logic.

State Overview

The function block does not have an explicit entry state machine, but implements its functionality as a data flow network. The process is strictly sequential:

- **Initialization Phase:**

INIT→F_MOVE.REQ→F_MOVE.CNF→Q_NumericValue.INIT→Q_NumericValue.INITO→INITO`

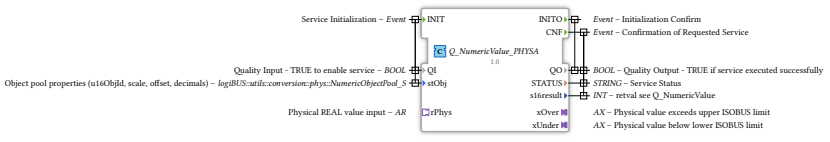
- **Operational Phase (Write):**

REQ→F_PHYS_TO_RAW.REQ→F_PHYS_TO_RAW.CNF→Q_NumericValue.REQ→Q_NumericValue.CNF→CNF`
During the execution of a run, the function block is not prepared for new events. The respective confirmation signal (`INITO` or `CNF`) must be awaited.

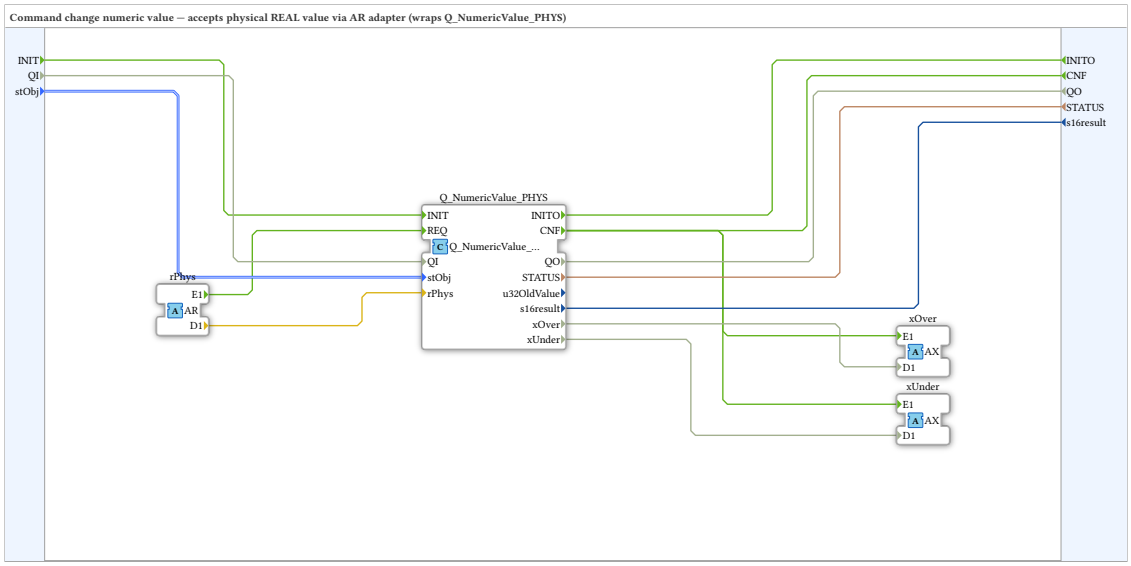
Application Scenarios

- **Vehicle terminal with ISOBUS connection:** Setting target values (e.g., working height, application rate) via user input in physical units (m, kg/h, °C).
- **Remote control of agricultural equipment:** Sending physical values from a controller to an ISOBUS device (e.g., seed drill) without manual raw value conversion.
- **Automated calibration:** Adjusting parameters during operation, where the scaling and offset are derived from a configuration structure (`NumericObjectPool_S`).

Comparison with similar modules



Module	Function	Difference to `Q_NumericValue_PHYS`
`Q_NumericValue` (from `isobus::UT::Q`)	Write a raw (already converted) value	Expects `u32NewValue` directly – without physical conversion and without limit checking
`F_PHYS_TO_RAW`	Pure conversion physical → raw	Returns only `xOver`, `xUnder`, and the raw value – no ISOBUS communication
`Q_NumericValue_PHYS`	Combined conversion + write access	Provides a complete interface for physical values in one step



This function block simplifies application, as the user does not need to program a separate conversion step. It is particularly suitable for controllers that process values in common units.

Conclusion

Q_NumericValue_PHYS` is a practical, standards-compliant function block for ISOBUS communication. It combines the conversion of physical values with write access to numerical objects, thus reducing development effort in agricultural automation. The clear separation of tasks (storage, conversion, bus access) ensures the function block remains maintainable and testable. Outputting limit violation flags enables robust error handling in the application code.

Q_NumericValue_PHYSA

• — ○ • — ○ • — ○ •

Introduction

The function block `Q_NumericValue_PHYSA` serves as a wrapper for the function block `Q_NumericValue_PHYS`. It allows setting a numeric value, which is received as a physical value (`REAL`) via an AR adapter (socket `rPhys`). The function block is designed according to the ISO 11783-6 standard and is suitable for ISOBUS applications that require a physical value input.

Interface Structure

Event Inputs

Name	Type	Description
`INIT`	`EInit`	Service initialization; executed with data input `stObj`

Event Outputs

Name	Type	Description
`INITO`	`EInit`	Confirmation of successful initialization
`CNF`	`Event`	Confirmation of value change performed; Output together with `STATUS` and `s16result`

Data Inputs

Name	Type	Description
`QI`	`BOOL`	Quality Input - TRUE to enable service
`stObj`	`isobus::utils::conversion::phys::NumericObjectPoolObject`	Object pool properties: `u16ObjId` (Object ID), `r32Scale` (Scaling), `i32Offset` (Offset), `u8Decimals` (Decimal places). Default value: `(u16ObjId := ID_NULL, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0)`

Data Outputs

Name	Type	Description
`QO`	`BOOL`	Quality Output - TRUE if service executed successfully

STATUS	STRING	Service status message
s16result	INT	Return value (see documentation for Q_NumericValue)

Adapter

Type	Name	Direction	Description
adapter::types::unidirectional::AR	rPhys	Socket (Input)	Receives the physical value REAL for processing
adapter::types::unidirectional::AX	xOver	Plug (Output)	Signals that the physical value exceeds the upper ISOBUS limit
adapter::types::unidirectional::AX	xUnder	Plug (Output)	Signals that the physical value falls below the lower ISOBUS limit

Quality signals QI/QO: The data input QI (BOOL, initial value TRUE) is associated with the event INIT and is passed through to QI of the internal block Q_NumericValue_PHYS. The data output QO (BOOL) is taken over from Q_NumericValue_PHYS.QO and is associated with the events INITO and CNF.

Valid Object IDs

stObj.u16ObjId is valid for the same object types as the wrapped base block Q_NumericValue_PHYS / Q_NumericValue (Annex F.22, objects with numeric value attribute): Input Boolean Field (7000–7999), Input Number Field (9000–9999), Input List Field (10000–10999), Output Number Field (12000–12999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Number Variable (21000–21999), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object (48000–48999).

ID_NULL (65535) is not a command target but deactivates the FB when used with INIT.

Functionality

1. After the **INIT** event, the function block is initialized with the object pool properties defined in stObj.
2. As soon as a new physical value arrives via the **rPhys** adapter (socket event E1), it is internally forwarded to the bound **Q_NumericValue_PHYS** block.
3. The Q_NumericValue_PHYS processes the value (taking scaling, offset, and decimal places into account) and triggers the **CNF** event.
4. The **CNF** event simultaneously outputs the status (STATUS), the return value (s16result), and the threshold indicators xOver and xUnder.
5. The outputs xOver and xUnder are provided as AX adapters to inform higher-level logic whether the entered value is outside the permissible ISOBUS range.

Technical Features

- The function block (FB) is a **pure adapter wrapper component**. The actual logic resides in the internally used Q_NumericValue_PHYS.
- The parameters for scaling and offset are configured via the **structure NumericObjectPool_S** – this allows for flexible adaptation to different physical units.
- Communication is **event-driven** via the adapters AR (value input) and AX (limit signal output). This enables modular integration into existing ISOBUS communication sequences.

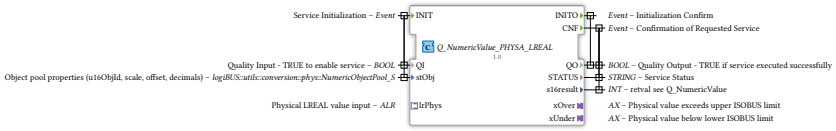
State Overview

The function block itself does not have an explicit state machine. The initialized state is established by the first INIT event. Subsequent value changes via rPhys.E1 lead directly to processing and output. Error states are communicated via the output STATUS.

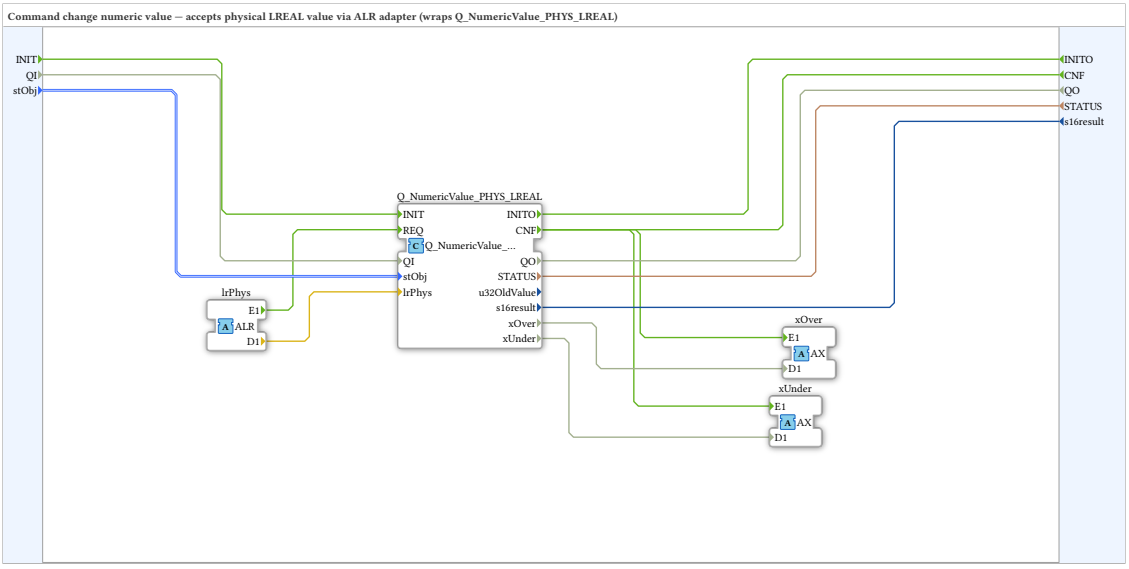
Application Scenarios

- **ISOBUS APP Control:** Setting a numeric value (e.g., setpoint for machine parameters) from a physical sensor value connected via an adapter.
- **Real to ISOBUS Format Conversion:** The function block handles the conversion of physical values to the internal integer format using scaling and offset.

- **Limit Monitoring:** The outputs `xOver` and `xUnder` allow the higher-level controller to react to exceedances or falls below limits.



Comparison with Similar Function Blocks



Function Block	Description	Difference
`Q_NumericValue_PHYS`	Direct function block for physical values	`Q_NumericValue_PHYSA` wraps this function block and adds explicit adapter outputs (`xOver`, `xUnder`) for limit signals
`Q_NumericValue`	Basic Function Block for Numeric Values (No Physical Conversion)	`Q_NumericValue_PHYSA` is specifically designed for real-world physical values and includes scaling/offset functionality.

Conclusion

The `Q_NumericValue_PHYSA` simplifies the integration of physical values into ISOBUS systems by encapsulating adapter communication and directly signaling limit values. Reusing the proven `Q_NumericValue_PHYS` ensures robust and standards-compliant logic.

Q_NumericValue_PHYSA_LREAL

• — ○ • — ○ • — ○ •

Introduction

The function block **Q_NumericValue_PHYSA_LREAL** serves as a command for changing a numeric value in the ISOBUS context (ISO 11783-6). It receives a physical LREAL value via the **ALR** adapter and handles the actual processing via the embedded function block **Q_NumericValue_PHYS_LREAL**. The function block uses adapter interfaces for physical value input as well as for signaling when the permissible range limits are exceeded or fallen below.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Initialization of the function block (with stObj).

Event Outputs

Name	Type	Comment
INITO	EInit	Confirmation of successful initialization.
CNF	Event	Confirmation of the requested value change (contains STATUS and s16result).

Data Inputs

Name	Type	Comment
QI	BOOL	Quality Input - TRUE to enable service
stObj	logiBUS::utils::conversion::phys::NumericObjectPool_S	Properties of the object pool (ObjID, scale, offset, decimal places). Initial: (u16ObjId := ID_NULL, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0).

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service status message.
s16result	INT	Return value – see Q_NumericValue (result of the value change request).

Adapters

Sockets (Input Adapters)

Name	Type	Comment
lrPhys	ALR (unidirectional)	Input for the physical LREAL value (triggered via E1).

Plugs (Output Adapters)

Name	Type	Comment
xOver	AX (unidirectional)	Signals that the physical value exceeds the upper ISOBUS limit.
xUnder	AX (unidirectional)	Signals that the physical value falls below the lower ISOBUS limit.

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Q_NumericValue_PHYS_LREAL`. The data output `QO` (BOOL) is taken over from `Q_NumericValue_PHYS_LREAL.QO` and is associated with the events `INITO` and `CNF`.

Valid Object IDs

`stObj.u16ObjId` is valid for the same object types as the wrapped base block `Q_NumericValue_PHYS_LREAL` / `Q_NumericValue` (Annex F.22, objects with numeric value attribute): Input Boolean Field (7000–7999), Input Number Field (9000–9999), Input List Field (10000–10999), Output Number Field (12000–12999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Number Variable (21000–21999), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object (48000–48999).

ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`.

Functionality

1. **Initialization** (`INIT`): The function block is initialized with the object pool properties (`stObj`). The event is forwarded directly to the inner block `Q_NumericValue_PHYS_LREAL`. Upon successful initialization, `INITO` is triggered.
2. **Value Change**: As soon as the event `E1` arrives at the adapter `lrPhys`, the physical LREAL value is transferred to the inner block via the data connection `lrPhys.D1`, triggering the event `REQ`.
3. **Result**: The inner block performs the actual processing. The status (`STATUS`) and the return value (`s16result`) are output via `CNF`. Simultaneously, the plugs `xUnder` and `xOver` can signal whether the incoming value violates the defined ISOBUS limits.
4. The output events of the inner block (`INITO`, `CNF`, `xUnder.E1`, `xOver.E1`) are forwarded directly to the corresponding outputs of `Q_NumericValue_PHYSA_LREAL`.

Technical Features

- **Wrapper Design**: The block encapsulates the function block `Q_NumericValue_PHYS_LREAL` and provides a more convenient physical interface via adapters.
- **Adapter-based communication**: Value input and limit signaling are handled via unidirectional adapters (`ALR`, `AX`), which facilitates encapsulation and reuse in different contexts.
- **Configurable object pool parameters**: The object ID, scaling, offset, and decimal places are defined via `stObj`, allowing the block to be flexibly adapted to various sensor or actuator values.
- **Standard compliance**: The function block (FB) is developed according to ISO 11783-6 (ISOBUS) and optimized for agricultural applications.

State overview

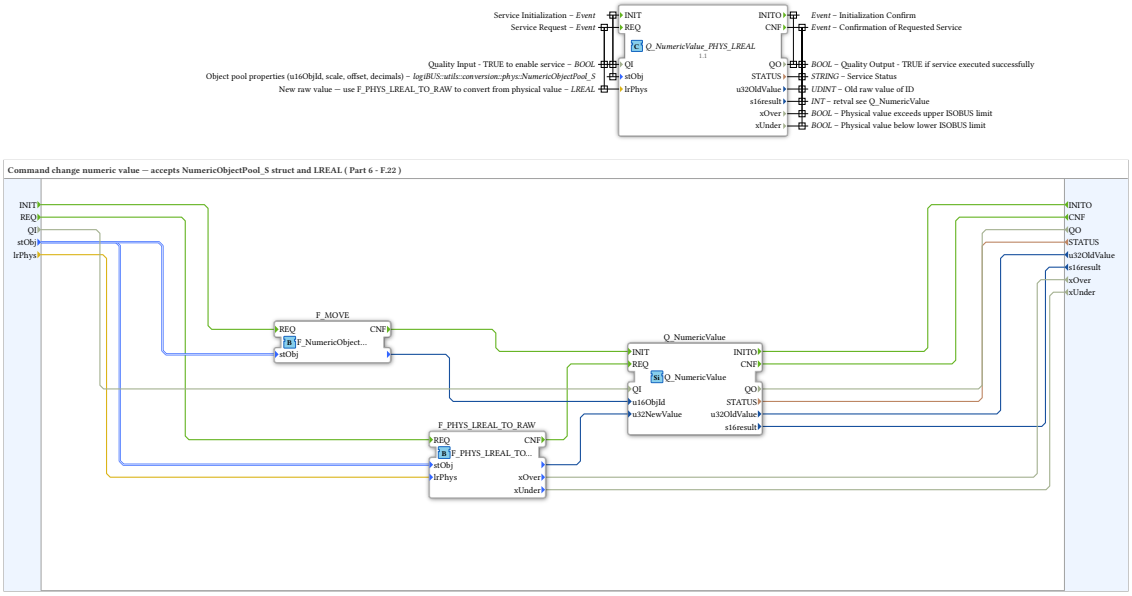
An explicit state machine is not represented in the XML, as the FB is implemented as a pure network consisting of an internal building block. However, the typical behavior follows a simple sequence:

- **Idle** – waits for INIT.
- **Initialized** – after INIT and before the first value changes.
- **Processing** – from the E1 trigger (REQ) until the CNF event is received.
- **Completion** – output of STATUS/s16result via CNF, followed by readiness resumption.

Application Scenarios

- **ISOBUS Command**: Changing a setpoint (e.g., speed, position, pressure) in an agricultural control unit, where the value is available as a physical quantity (LREAL).
- **Limit Monitoring**: Used in applications that require additional alarms or responses when permissible range limits are exceeded (e.g., for sensor data) (via `xOver` / `xUnder`).
- **Scaled Values**: Using scaling and offset parameters to convert raw ISOBUS values into user-friendly physical units.

Comparison with Similar Function Blocks



In direct comparison to the inner function block **Q_NumericValue_PHYS_LREAL**, the **Q_NumericValue_PHYSA_LREAL** offers a higher level of abstraction:

- Instead of direct input/output signals, communication is implemented via adapters – this allows for loose coupling in modular control architectures.
- The outer function block does not add its own logic, but simplifies integration through the adapter-based interface (e.g., `ALR` input).
- Unlike pure function blocks with fixed data ports, `Q_NumericValue_PHYSA_LREAL` can be flexibly adapted to different environments without having to change the signal paths in the network.

Conclusion

The **Q_NumericValue_PHYSA_LREAL** is a practical wrapper function block that simplifies physical value changes in the ISOBUS context via adapters. It combines the proven logic of `Q_NumericValue_PHYS_LREAL`With a convenient, adapter-based interface for LREAL inputs and limit signaling. Thanks to its configurable object pool parameters and compliance with ISO 11783-6, it is particularly suitable for use in modular agricultural control systems.

Q_NumericValue_PHYS_LREAL

• — ○ • — ○ • — ○ •

Introduction

The function block **Q_NumericValue_PHYS_LREAL** is used to set a numeric value as a physical quantity via ISOBUS (ISO 11783-6). It receives a physical value of type `LREAL`, automatically converts it into the required raw value, and sends the corresponding command to the connected device. This complies with the specification in Part 6, Annex F.22. The function block encapsulates the necessary steps of the physical conversion and the actual command execution, allowing the user to work directly with physical units.

Interface Structure

Event Inputs

Event	Description
`INIT`	Initializes the function block with the object pool properties (`stObj`).
`REQ`	Starts processing: the physical value (`lrPhys`) is sent to the target object.

Event Outputs

Event	Description
`INITO`	Acknowledges successful initialization.
`CNF`	Acknowledges command execution; the output data is valid.

Data Inputs

Name	Type	Description
`QI`	BOOL	Quality input, `TRUE` enables the service (default `TRUE`)
`stObj`	`logiBUS::utils::conversion::phys::NumericObjectPool_S`	Object pool properties (object ID, scale, offset, decimal places). Default value: `(u16ObjId := ID_NULL, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0)`.

lrPhys	LREAL	The physical value (e.g., pressure, temperature) to be sent. Note: Before transmission, the value should be converted using F_PHYS_LREAL_TO_RAW if necessary; the function block performs this conversion automatically internally.

Data Outputs

Name	Type	Description
QO	BOOL	Quality output, TRUE if the service was executed successfully
STATUS	STRING	Status message of the service performed.
u32OldValue	UDINT	Original raw value of the object before the change.
s16result	INT	Return value (see Q_NumericValue).
xOver	BOOL	TRUE if the physical value exceeds the upper ISOBUS limit.
xUnder`	BOOL	TRUE if the physical value falls below the lower ISOBUS limit.

Adapter

None.

Valid Object IDs

stObj.u16ObjId is valid for the same object types as the internally used Q_NumericValue (Annex F.22, objects with numeric value attribute): Input Boolean Field (7000–7999), Input Number Field (9000–9999), Input List Field (10000–10999), Output Number Field (12000–12999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Number Variable (21000–21999), Object Pointer (27000–27999), Output List Object (37000–37999), External Object Pointer (43000–43999), Animation Object (44000–44999), Scaled Graphic Object (48000–48999).

ID_NULL (65535) is not a command target but deactivates the FB when used with INIT.

Functionality

Quality handling (QI/QO): The input QI (BOOL, default TRUE) is associated with the events INIT and REQ; TRUE enables the service. The output QO (BOOL) is associated with INITO and CNF and indicates with TRUE that the service was executed successfully. QI is passed through to Q_NumericValue.QI, and Q_NumericValue.QO is passed through to QO.

The function block works internally with three subordinate function blocks:

1. **F_MOVE** – On a INIT event, the passed structure stObj (object ID, scale, offset, decimal places) is copied to the internal Q_NumericValue.
2. **F_PHYS_LREAL_TO_RAW** – On a REQ event, the physical value lrPhys is converted into an ISOBUS raw value using the parameters stored in stObj.
3. **Q_NumericValue** – The generated raw value, along with the object ID, is then passed to the actual command block, which executes the command on the bus.

The outputs STATUS, u32OldValue, and s16result originate directly from Q_NumericValue. The overflow/underflow messages (xOver, xUnder) are provided by the conversion function.

Technical Features

- **Automatic Conversion**: The user does not need to manually convert physical values into raw values; this is done transparently within the function block.
- **Default Values**: If no specific object pool properties are passed, the function block uses sensible defaults (scaling 1.0, offset 0, no decimal places). The object ID is then ID_NULL.
- **Limit Check**: The outputs xOver and xUnder signal whether the passed physical value is outside the range permitted for ISOBUS. This allows applications to react early.
- **Cache Storage**: The initialization (INIT) copies the object properties only once and stores them for later REQ calls.

State Overview

The function block does not have an explicit state machine in the sense of an ECC, but operates event-driven according to the following logic:

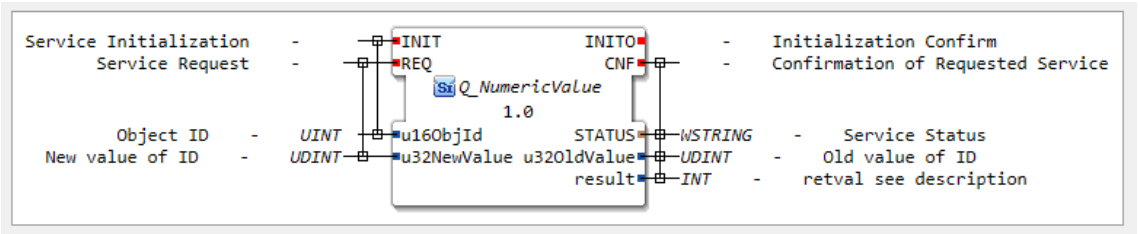
State / Sequence	Description
Initialization	After a `INIT` event, the object properties are stored internally. Then, `INITO` is sent.
Send Command	After a `REQ` event, the physical value is converted, the command is issued, and upon completion, `CNF` is sent with the result data.
Error Handling	If an overflow/underflow occurs during the conversion, `xOver` or `xUnder`, respectively, are set before the command is issued. An erroneous command is signaled by `s16result` and the status message.

Application Scenarios

- **Control of ISOBUS Devices**: Setting setpoints for actuators (e.g., valves, drives) in physical units such as pressure (bar, kPa), temperature (°C), or fill level.

Error Handling - **Agricultural Machinery**: Change operating parameters (e.g., application rate, speed) directly from a control application.

- **Test and Simulation Environments**: Easily send physical values without having to worry about raw value conversion.

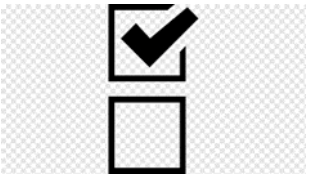


Comparison with Similar Blocks

- **`Q_NumericValue` (without PHYS)**: Expects the raw value (UDINT) directly. The user must perform the conversion manually. `Q_NumericValue_PHYS_LREAL` encapsulates this step and improves the readability and maintainability of applications that work with physical quantities.
- **`Q_NumericValue_PHYS_REAL`** (analogous for REAL type): Functions identically, but with single-precision accuracy. For applications requiring higher accuracy (LREAL), this block is the right choice.

Conclusion

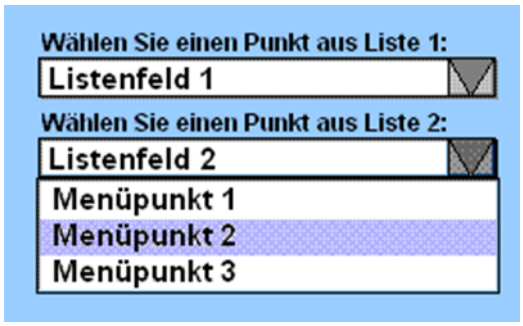
Q_NumericValue_PHYS_LREAL` is a practical and standards-compliant function block that simplifies integration with the ISOBUS system. The integration of physical conversion eliminates manual conversion logic, reducing the potential for errors and increasing reusability. This module is particularly suitable for control applications where physical values must be transmitted with high accuracy.



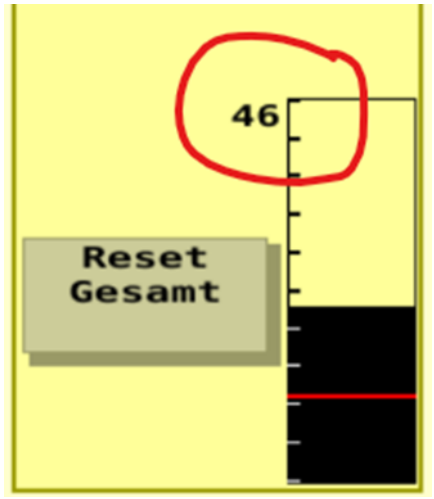
Q_NumericValue

Normative Reference: This function block refers to section ISO 11783-6 F.22 Change Numeric Value command CAUTION: This command can be called as often as desired by the application programmer; however, excessively frequent calls can severely overload the ISOBUS, therefore this function block should be used with caution.

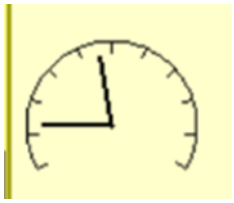
The purpose of this function block is to update one of the following objects displayed on a VT:



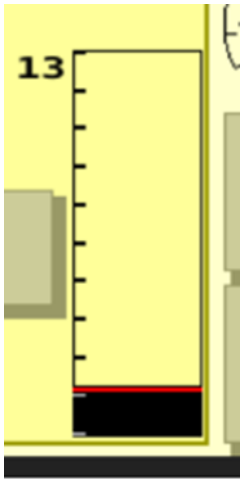
- Boolean input field: 1 byte for TRUE/FALSE



- Number input field: 4 bytes for integer input



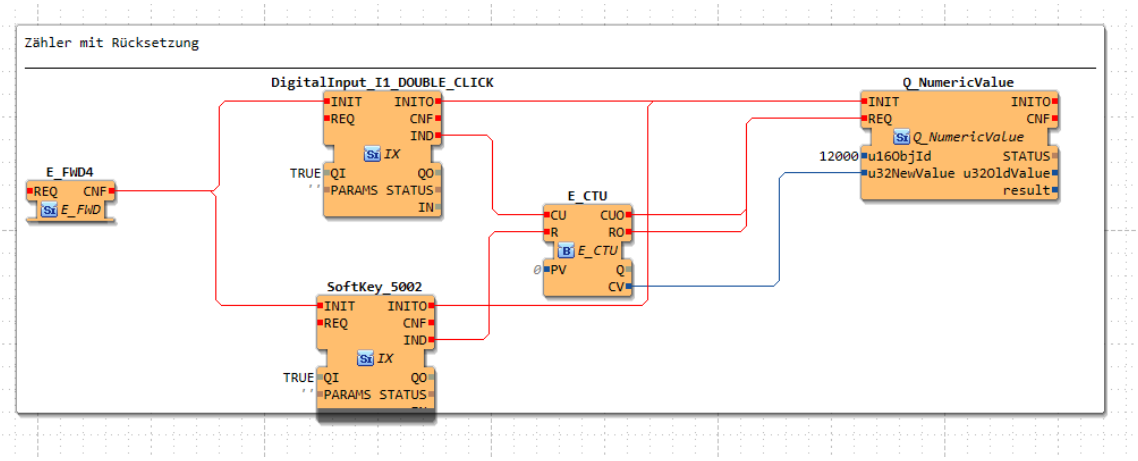
- List input field: 1 byte for list index



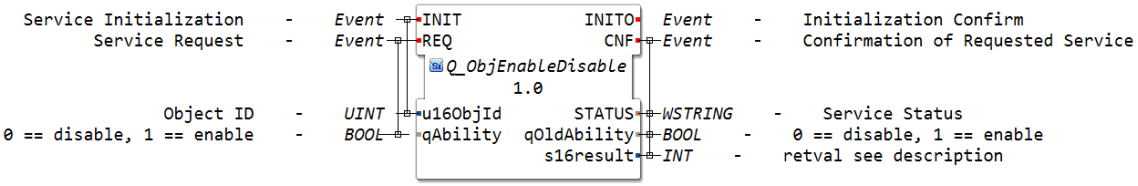
- List output field: 1 byte for list index
- (same as list input field, but not present in VT3)
- Number output field: 4 bytes for integer output

- Meter: 2 bytes for integer value

- Linear bar graph: 2 bytes for integer value



- Arched bar graph: 2 bytes for integer value



- Number variable: 4 bytes for integer value
- The Number variable cannot be displayed directly on the screen, but it can be linked to all previously mentioned objects; advantage: multiple links are possible.
- Object pointer: 2 bytes for Object ID
- Useful for showing and hiding other objects instead of the pointer.

Q_ObjEnableDisable

• — ○ • — ○ • — ○ •

Introduction

The **Q_ObjEnableDisable** is a standards-compliant function block for enabling/disabling input objects in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.4) specification for VT input elements.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID)
- `REQ`: Activation/Deactivation Request

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Operation Confirmation

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Object ID (16-bit)
- `qAbility` (BOOL): Activation Status (TRUE=activate, FALSE=deactivate)

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `qOldAbility` (BOOL): Previous activation status
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` — valid object types (Annex F.4): Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Input List Field (10000–10999), Animation Object (44000–44999).

ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`. Any ID outside these ranges is invalid for commanding.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with target object ID
- `INITO` confirms operational readiness

1. **Status Change**:

- `REQ` with desired activation state
- Changes the object's interaction capability
- `CNF` returns operational status and previous state

1. **Special Cases**:

- VT_E_HANDLE_INVALID is returned for invalid object IDs

Technical Features

✓ **ISO ISO 11783-6 compliant** (F.4) ✓ **Simple Binary Control** (Enabled/Disabled) ✓ **State Feedback** (Previous State) ✓ **Broad Object Support** (All Input Elements)

Status Reference

qAbility	Object State
FALSE (0)	Disabled (gray)
TRUE (1)	Enabled (normal)

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful Execution
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	VT not ready
−21	VT_E_NO_INSTANCE	No VT client available
−128	VT_E_HANDLE_INVALID	Invalid object ID
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance
−130	VT_E_NOT_ALIVE	VT not active

Application Scenarios

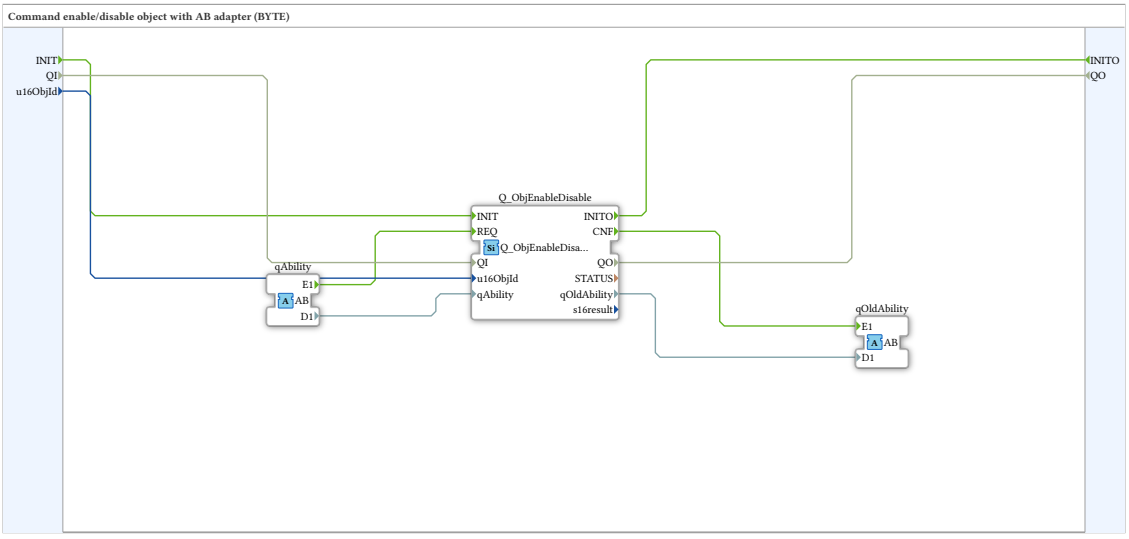
- **Form Control**: Conditional input approval
- **Security Features**: Block critical input
- **Workflow Management**: Step-by-step approval
- **Diagnostic Modes**: Input restrictions

⚖️ Comparison with similar building blocks

Feature	Q_ObjEnableDisable	VtInputControl	VtObjectState
ISO Standard	✓	✖	✖
Binary Control	✓	✓	✖
Feedback	✓	✖	✓
Object Type	Input Objects	All	All

Conclusion

The Q_ObjEnableDisable block provides essential input control:



- **Simple**: Clear activation logic
- **Reliable**: Integrated error detection
- **Flexible**: For all input element types

Essential for:

- Interactive forms
- Secure user interfaces
- State-driven applications

Q_ObjEnableDisable_AB

• – ○ • – ○ • – ○ •

Introduction

The function block `Q_ObjEnableDisable_AB` serves as a wrapper that enables the control of a binary object (switching on/off) via a unidirectional **AB adapter (BYTE)**. It encapsulates the logic of the block `isobus::UT::Q::Q_ObjEnableDisable` and provides its functionality via the standardized adapter interfaces `qAbility` (socket) and `qOldAbility` (plug). The function block is suitable for connecting to adapter-based systems, e.g., for the remote control of actuators.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Service initialization: starts the internal function block and passes the object ID.

Event Outputs

Event	Type	Description
INITO	EInit	Confirmation of successful initialization.

Data Inputs

Name	Type	Description
QI	BOOL	Quality Input - TRUE to enable service
u16ObjId	UINT	Unique identifier of the object to be controlled.

Data Outputs

Apart from QO, there are no dedicated data outputs – the remaining output data is provided via the adapter plug.

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully

Adapter

Adapter Type	Direction	Description
Socket qAbility	Input	Unidirectional AB adapter: receives the command (BYTE). 0 = disable, 1 = enable, 0xFF = undefined.
Plug qOldAbility	Output	Unidirectional AB adapter: returns the previous state of the object (same encoding).

Quality signals QI/QO: The data input QI (BOOL, initial value TRUE) is associated with the event INIT and is passed through to QI of the internal block Q_ObjEnableDisable. The data output QO (BOOL) is taken over from Q_ObjEnableDisable.QO and is associated with the event INITO.

Valid Object IDs

The validity rules of the internal base function block Q_ObjEnableDisable apply:

u16ObjId — valid object types (Annex F.4): Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Input List Field (10000–10999), Animation Object (44000–44999).

ID_NULL (65535) is not a valid command target but deactivates the FB when used with INIT.

Functionality

The FB acts as a bridge between an AB adapter (BYTE) and the internal function block Q_ObjEnableDisable. The processes are as follows:

1. **Initialization**

An INIT event with a valid object ID (u16ObjId) is forwarded to the internal FB. The internal FB is initialized and reports this via INITO.

1. **Control**

A BYTE value is received via socket qAbility. The event qAbility.E1 triggers the internal FB (event REQ). The data value from qAbility.D1 is passed to the internal function block (FB).

The internal FB processes the command and sets the object's state accordingly. The previous state is passed via the internal connection to the plug `qOldAbility`. The event `CNF` of the internal FB is output as `qOldAbility.E1`.

1. **Feedback**

The plug `qOldAbility` provides the object's previous state (BYTE) and the associated event, allowing a downstream function block to react to state changes.

Technical Features

- **Adapter-Based Encapsulation**

The FB uses the standardized unidirectional AB adapter, which allows for easy integration into existing adapter networks.

- **Typical BYTE Encoding**

0→ `disable`,1→ `enable`,0xFF` ⟶ undefined (error or no change). This convention is used for both input and output.

- **Initialization with Object ID Only**

The INIT event must be triggered with a valid `u16ObjId`. The function block itself does not store any persistent configuration.

- **Event-Driven Processing**

Control is exclusively via the events of the adapter socket. No state change occurs without an event on `qAbility.E1`.

State Overview

The function block does not have its own explicit state machine – the state logic resides entirely within the internal function block `Q_ObjEnableDisable`. Nevertheless, the following operating states can be derived:

State	Description
Idle	After successful initialization (INITO sent), the function block (FB) waits for an event at socket `qAbility`.
Processing	An incoming event at `qAbility.E1` is processed; the internal FB executes the switchover.
Completed	Processing complete – the new (or old) state is available at the plug, and event `qOldAbility.E1` is output.

Error states (e.g., invalid object ID, faulty INIT sequence) are handled by the internal FB and can be signaled via return values or special BYTE codes (`0xFF`).

Application Scenarios

- **Remote Control of a Binary Output**

A higher-level control block sends the command "On" or "Off" via an AB adapter. The FB executes the command and reports back the previous state.

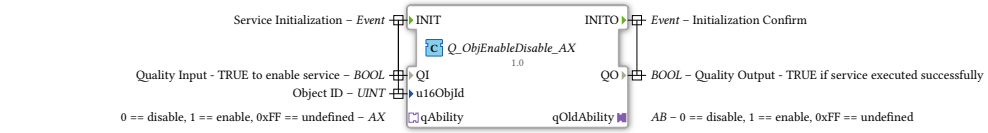
- **State Query Without Change**

By sending the code `0xFF`, the current state can be queried without making any changes.

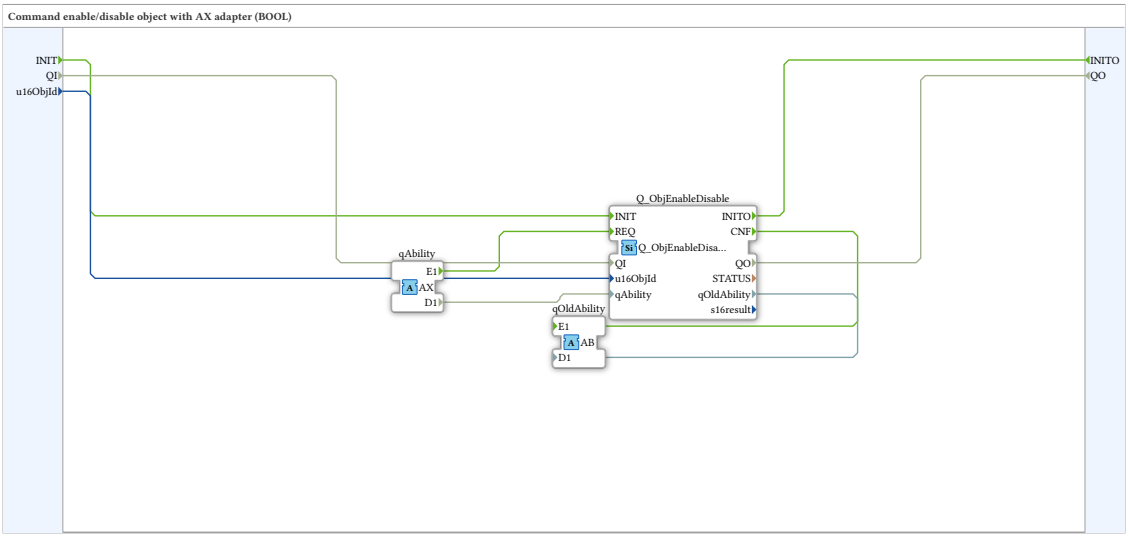
- **Integration into Adapter-Based Service Interfaces**

The FB serves as a converter between an AB adapter (e.g., from an HMI or remote control) and a functional block that requires a native ISOBUS interface.

Comparison with Similar Blocks



Block	Difference
`Q_ObjEnableDisable` (direct)	Requires native event and data interfaces without adapters. `Q_ObjEnableDisable_AB` adds adapter compatibility.



`Q_ObjEnableDisable_BB` (hypothetical)	Would use a bidirectional BB adapter. This FB uses the simpler unidirectional AB adapter.
Generic “CommandOnOff”	Is typically not targeted to a specific object (ID) and does not provide status feedback via adapters.

Conclusion

The FB `Q_ObjEnableDisable_AB` is a useful wrapper that makes the functionality of an ISOBUS object switch accessible via the standardized AB adapter. It facilitates integration into modular adapter networks and reduces wiring effort. The simple interface with only one event input for control and feedback via the plug makes it particularly suitable for reusable components in automation technology.

Q_ObjEnableDisable_AX

• – ○ • – ○ • – ○ •

Introduction

The function block **Q_ObjEnableDisable_AX** is a composite function block that serves as an adapter wrapper for the internal function block `Q_ObjEnableDisable`. It enables the control of an enable/disable command (BOOL) via a unidirectional AX adapter (socket) and returns the previous state via an AB adapter (plug). This function block is typically used in ISOBUS-based control systems.

Interface Structure

Event Inputs

Event	Type	Comment
`INIT`	EInit	Initialization of the function block; the object ID (u16ObjId) is passed.

Event Outputs

Event	Type	Comment
`INITO`	EInit	Confirmation of successful initialization.

Data Inputs

Name	Type	Comment
QI	BOOL	Quality Input - TRUE to enable service
u16ObjId	UINT	Object ID set during the INIT event.

Data Outputs

Apart from QO, there are no direct data outputs; the previous state is output via the adapter plug qOldAbility.

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully

Adapter

Name	Type	Direction	Comment
qAbility	adapter::types::unidirectional::AX	Socket	Receives the Enable/Disable command (0 = disable, 1 = enable, 0xFF = undefined).
qOldAbility	adapter::types::unidirectional::AB	Plug	Returns the object's previous state (same encoding).

Quality signals QI/QO: The data input QI (BOOL, initial value TRUE) is associated with the event INIT and is passed through to QI of the internal block Q_ObjEnableDisable. The data output QO (BOOL) is taken over from Q_ObjEnableDisable.QO and is associated with the event INITO.

Valid Object IDs

The validity rules of the internal base function block Q_ObjEnableDisable apply:

u16ObjId — valid object types (Annex F.4): Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Input List Field (10000–10999), Animation Object (44000–44999).

ID_NULL (65535) is not a valid command target but deactivates the FB when used with INIT.

Functionality

1. **Initialization**

An INIT event at input INIT sets the desired object ID (u16ObjId) and initializes the internal block Q_ObjEnableDisable. After successful initialization, the event INITO is output.

1. **Signal Processing**

- A new command is received via the socket adapter qAbility:
- The adapter's event E1 triggers the REQ input of the internal block.
- The data D1 (0/1/0xFF) is forwarded to the input qAbility of the internal block.
- The internal block processes the command, activates or deactivates the object with the given ID, and outputs the previous state.
- The acknowledgment CNF of the internal block is transferred to the event E1 of the plug adapter qOldAbility.
- The previous state is provided via the data output D1 of the plug adapter.

1. **Output of Previous State**

The adapter plug qOldAbility provides the state before the last change as a BOOL value (0/1/0xFF). The event connection ensures that the output event occurs at the correct time.

Technical Features

- This function block encapsulates the logic of the more complex Q_ObjEnableDisable and offers a simplified interface via two standardized adapters (AX/AB).
- Adapter socket qAbility expects unidirectional communication (value transfer only), while adapter plug qOldAbility returns the result.

- The object ID is set only during INIT; changing the ID during operation is not supported.

State Overview

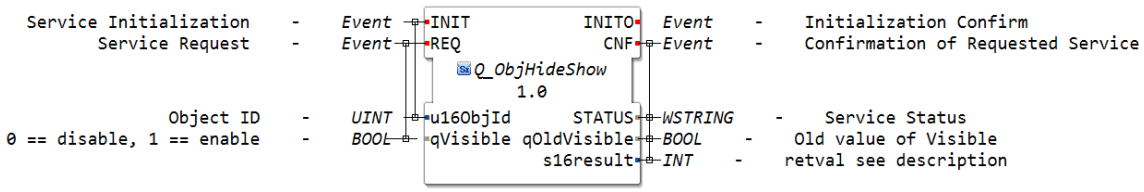
The FB `Q_ObjEnableDisable_AX` itself does not have its own state machine. The internal state logic is implemented by the included function block `Q_ObjEnableDisable`. Its typical states are:

- **IDLE** – Waiting for a command (REQ).
- **Processing** – Processing the command (e.g., sending a CAN message).
- **Done** – Command completed, output of the previous state, and return to IDLE.

Application Scenarios

- **ISOBUS Control**: Enabling/disabling an agricultural device (e.g., valve, lighting) based on a Boolean signal from an AX adapter.
- **Universal Adapter**: Integrating enable/disable functions into systems that use standardized unidirectional adapters.
- **State Feedback**: Capturing the previous state for diagnostic or monitoring purposes.

Comparison with Similar Function Blocks

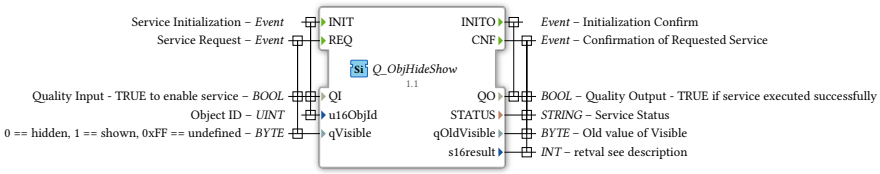


Function Block	Interface	Special Feature
Q_ObjEnableDisable	Direct event/data inputs	Requires separate Boolean inputs and events.
Q_ObjEnableDisable_AX	AX/AB Adapter	Easy integration into adapter-based architectures; reduces wiring effort.

The AX wrapper does not add new functionality but optimizes the connection to existing adapter communication.

Conclusion

The **Q_ObjEnableDisable_AX** function block is a practical adapter wrapper that simplifies the control of an ISOBUS object using enable/disable commands via a unidirectional AX adapter. It encapsulates the internal logic, enables clean interface separation, and returns the previous state via an AB adapter. This function block is particularly suitable for modular control architectures based on standardized adapter types.



Q_ObjHideShow

• — ○ • — ○ • — ○ •

Introduction

The **Q_ObjHideShow** is a standards-compliant function block for controlling the visibility of container objects in Virtual Terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.2) specification for VT containers.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with Container Object ID)
- `REQ`: Visibility Change Request

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Container Object ID (16-bit)
- `qVisible` (BOOL): Visibility Status (TRUE=show, FALSE=hide)

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `qOldVisible` (BOOL): Previous visibility status
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` — valid object types (Annex F.2): Container (3000–3999).

ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`. Any ID outside this range is invalid for commanding.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with container object ID
- `INITO` confirms operational readiness

1. **Visibility Change**:

- `REQ` with desired visibility status
- Changes the display of the container and all contained objects
- `CNF` returns operational status and previous state

1. **Special Cases**:

- VT_E_HANDLE_INVALID is returned for invalid object IDs

Technical Features

✓ **ISO 11783-6 compliant** (F.2) ✓ **Cascading effect** (Affects contained objects) ✓ **Instant GUI update** ✓ **State retention** (Remembers previous state)

State reference

qVisible	Container state
FALSE (0)	Invisible
TRUE (1)	Visible

Return codes (s16result)

Code	Constant	Meaning				
0	VT_E_NO_ERR	Successful execution				

−6	VT_E_OVERFLOW	Buffer overflow				
−8	VT_E_NOACT	VT not ready		−21	VT_E_NO_INSTANCE	No VT client available
−128	VT_E_HANDLE_INVALID	Invalid container ID				
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance				
−130	VT_E_NOT_ALIVE	VT not active				

Application Scenarios

- **Dynamic Interfaces**: Context-sensitive displays
- **Screen Manager**: View switching
- **Alarm Management**: Fault message containers
- **User Guidance**: Step-by-step instructions

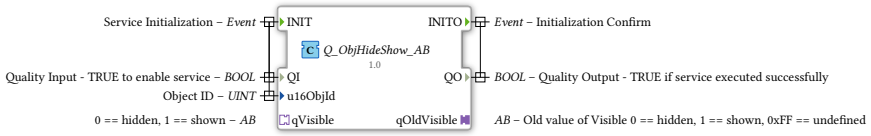
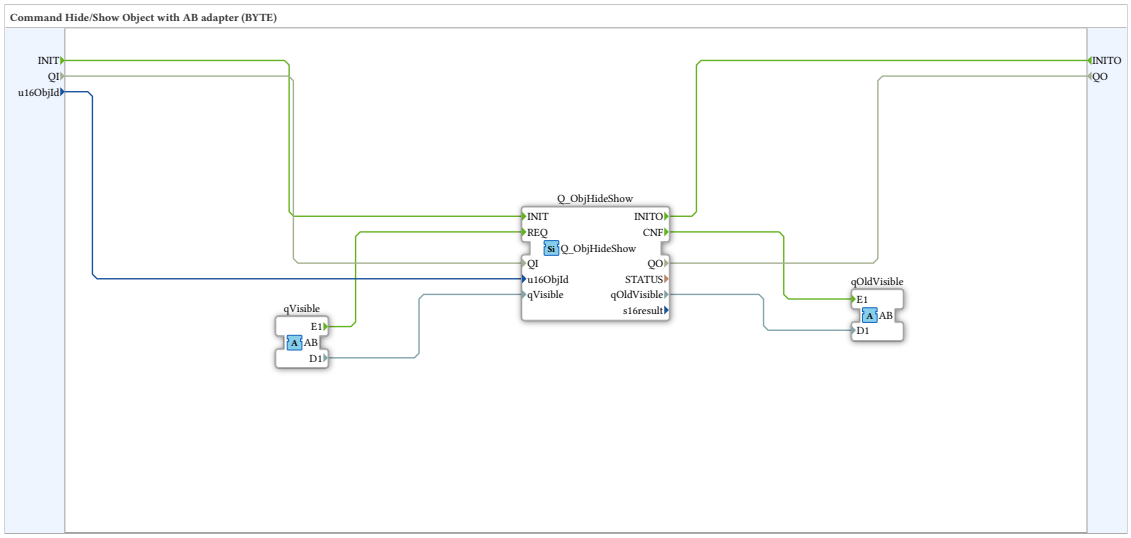
🛠️ Related Exercises

- Exercise_014

Conclusion



The Q_ObjHideShow block offers centralized visibility control:



- **Efficient**: Instant GUI update
- **Comprehensive**: Affects all container elements
- **Reliable**: ISO-compliant implementation

Essential for:

- Adaptive user interfaces
- Complex form hierarchies
- State-driven visualizations

Q_ObjHideShow_AB

• – ○ • – ○ • – ○ •

Introduction

The function block **Q_ObjHideShow_AB** serves as a wrapper for the function block `Q_ObjHideShow` and enables hiding or showing an object via an **AB adapter** (unidirectional, BYTE). It encapsulates the direct control of the internal function block and provides an adapter-based interface that promotes loose coupling in the application.

Interface Structure

Event Inputs

Event	with variables	Comment
`INIT`	`QI`, `u16ObjId`	Service Initialization; Object ID is passed

Event Outputs

Event	Comment
`INITO`	Initialization confirmed

Data Inputs

Name	Type	Comment
`QI`	BOOL	Quality Input - TRUE to enable service
`u16ObjId`	UINT	Object ID

Data Outputs

Apart from `QO`, there are no explicit data outputs at the FB level. The remaining output data is provided via the adapter `qOldVisible`.

Name	Type	Comment
`QO`	`BOOL`	Quality Output - TRUE if service executed successfully

Adapters

Direction	Name	Type	Comment

Socket (Input)	qVisible	adapter::types::unidirectional::AB	Target Visibility: 0 = hidden, 1 = displayed
Plug (Output)	qOldVisible	adapter::types::unidirectional::AB	Previous Visibility Value: 0 = hidden, 1 = displayed, 0xFF = undefined

Quality signals QI/QO: The data input QI (BOOL, initial value TRUE) is associated with the event INIT and is passed through to QI of the internal block Q_ObjHideShow. The data output QO (BOOL) is taken over from Q_ObjHideShow.QO and is associated with the event INITO.

Valid Object IDs

The validity rules of the internal base function block Q_ObjHideShow apply:
u16ObjId — valid object types (Annex F.2): Container (3000–3999).
ID_NULL (65535) is not a valid command target but deactivates the FB when used with INIT.

Functionality

1. **Initialization**

An event at input INIT initializes the internal function block Q_ObjHideShow. The passed u16ObjId identifies the object to be controlled. After successful startup, the event INITO is output.

1. **Visibility Control**

As soon as an event (E1) arrives at the socket adapter qVisible, the corresponding data value (D1) is read and forwarded to the internal function block (FB). The internal FB then sets the object's visibility accordingly (0 = hidden, 1 = displayed).

1. **Feedback**

After the action is executed, the internal FB sends the event CNF to the plug adapter qOldVisible. The previous visibility state is provided as a data value (D1) on qOldVisible. This allows the calling component to query the previous state.

Technical Features

- **Wrapper Concept**: The function block (FB) encapsulates the direct use of Q_ObjHideShow and replaces the loose event/data connection with standardized AB adapters, enabling a modular and reusable interface.
- **AB Adapter (Unidirectional, BYTE)**: Communication takes place via a unidirectional adapter that transmits only one event and one associated byte at a time. This simplifies integration into adapter-based architectures.
- **State Maintenance**: The internal FB stores the last visibility state; with each new command, the previous state is reported back to the output adapter.
- **Undefined Value (0xFF)**: The output qOldVisible can return the value 0xFF if the previous state is unknown (e.g., after a restart without prior initialization).

State Overview

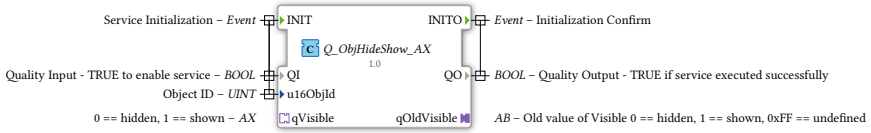
The FB itself does not have its own state machine. Its behavior is entirely determined by the embedded function block Q_ObjHideShow. The following generally applies:

- **After INIT**: The function block is ready for operation and waits for events from the socket adapter qVisible.
- **On every incoming socket event**: Visibility is set, and the result is reported back via the plug adapter.

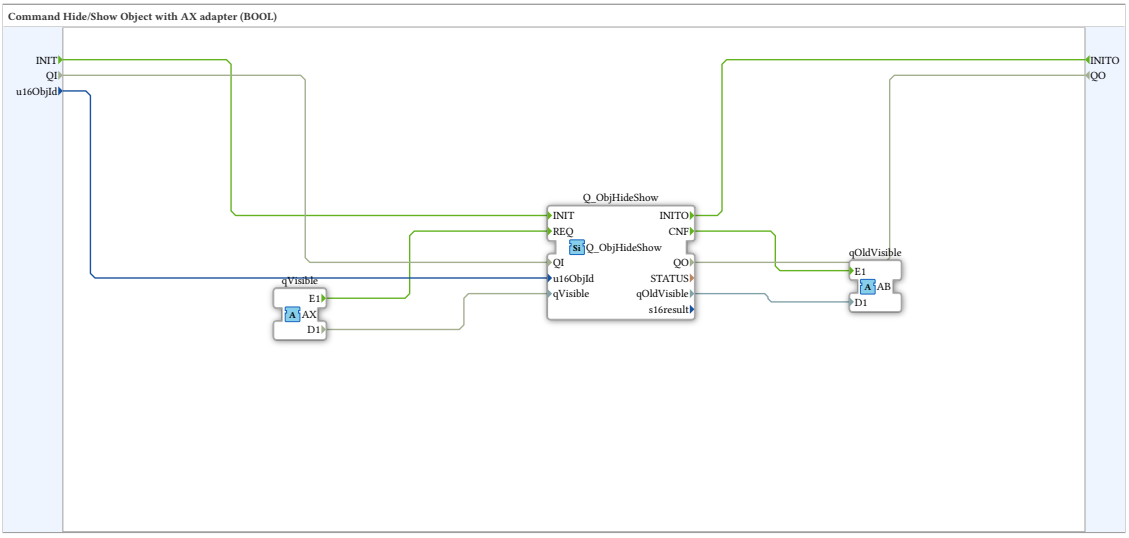
Application Scenarios

- **Visualization Control**: Showing and hiding graphical objects (e.g., in HMI systems) based on binary or numerical control values.
- **State Feedback**: Monitoring of visibility changes; the previous visibility state can be used for logic decisions or logging.
- **Adapter-Based Automation**: Integration into a system that relies on adapter interfaces to achieve interchangeability and decoupling.

Comparison with Similar Function Blocks



Function Block	Properties
`Q_ObjHideShow` (direct)	Event/data interface without adapter; direct connection required
`Q_ObjHideShow_AB` (this function block)	Uses AB adapters for loose coupling; easier integration into adapter-based networks
Other AB-based wrappers	Similar concept for other commands (e.g., `Q_ObjMove_AB`), but specifically designed for visibility



The main advantage of the wrapper lies in its adaptation to the AB adapter interface without changing the actual functionality.

Conclusion

The function block `Q_ObjHideShow_AB` represents an adapter-based, reusable component for controlling the visibility of objects. By encapsulating the internal function block and using unidirectional AB adapters, a clean separation of control logic and execution is achieved. It is particularly suitable for modular automation solutions that rely on loose coupling and standardized interfaces.

Q_ObjHideShow_AX

• – ○ • – ○ • – ○ •

Introduction

The function block **Q_ObjHideShow_AX** serves as an adapter wrapper for the existing function block `Q_ObjHideShow`. It allows the consistent hiding and showing of an object (Hide/Show) via a unidirectional AX adapter. The visibility value is passed as a Boolean state (`0` = hidden, `1` = shown).

Interface Structure

Event Inputs

Name	Type	Comment	With Variable
`INIT`	EInit	Service Initialization	`QI`, `u16ObjId`

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirmation

Data Inputs

Name	Type	Comment
QI	BOOL	Quality Input - TRUE to enable service
u16ObjId	UINT	Object Identification

Data Outputs

Apart from QO, this function block does not have its own data outputs. The old visibility value is output via the plug adapter qOldVisible.

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully

Adapter

Direction	Name	Type	Comment
Socket	qVisible	unidirectional::AX	Input of the new visibility value (0 = hidden, 1 = shown)
Plug	qOldVisible	unidirectional::AB	Output of the previous visibility value (0/1/0xFF)

Quality signals QI/QO: The data input QI (BOOL, initial value TRUE) is associated with the event INIT and is passed through to QI of the internal block Q_ObjHideShow. The data output QO (BOOL) is taken over from Q_ObjHideShow.QO and is associated with the event INITO.

Valid Object IDs

The validity rules of the internal base function block Q_ObjHideShow apply:
u16ObjId — valid object types (Annex F.2): Container (3000–3999).
ID_NULL (65535) is not a valid command target but deactivates the FB when used with INIT.

Functionality

1. The function block is initialized via the event INIT, and the object ID (u16ObjId) is passed to the internal function block Q_ObjHideShow.
2. As soon as an event arrives at socket qVisible (associated with the internal function block REQ), the new visibility value (qVisible.D1) is forwarded to the internal function block.
3. The internal function block performs the switchover and outputs the old value via its event CNF. This is reported externally via the plug qOldVisible (event E1 and data D1).
4. The output INITO signals the successful completion of the initialization.

Technical Features

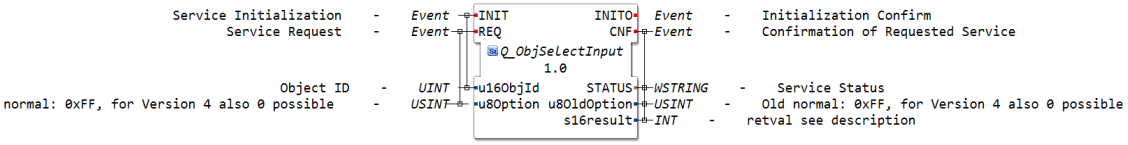
- **Adapter Encapsulation:** The function block uses the standardized adapter types AX (for input) and AB (for output), allowing seamless integration into adapter-based ISOBUS networks.
- **Reuse:** The actual logic is implemented by the proven FB Q_ObjHideShow – the wrapper simply adds the adapter interface.
- **Boolean Control:** The visibility value is transmitted as a simple Boolean value (via the AX adapter), which simplifies its use in typical on/off scenarios.

State Overview

The function block does not have an explicitly visible state machine. It undergoes an initialization step (INIT → INITO) and then reacts cyclically to incoming events at socket qVisible (REQ → CNF). However, the internal function block Q_ObjHideShow can maintain an implicit state (e.g., the currently displayed visibility).

Application Scenarios

- Showing/hiding controls on an ISOBUS terminal.
- Controlling the display of symbols or text fields depending on user input or system states.
- A unified interface for all objects that are to be connected via adapters.

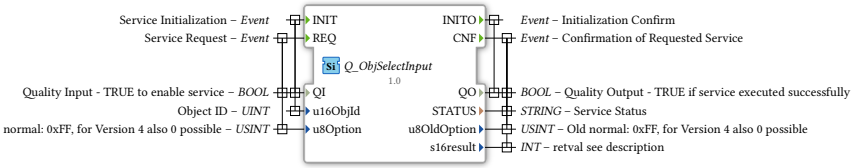


Comparison with similar function blocks

The direct function block `Q_ObjHideShow` requires separate event and data connections for control. The wrapper function block `Q_ObjHideShow_AX` encapsulates these connections in two standardized adapters (AX/AB), thus simplifying integration into existing adapter-based architectures. Furthermore, the old visibility value is automatically provided via the plug adapter.

Conclusion

The **Q_ObjHideShow_AX** is a practical wrapper that transfers the proven functionality of `Q_ObjHideShow` into an adapter-based interface. It enables clean, modular integration of Hide/Show commands and facilitates reuse in complex ISOBUS control systems.



Q_ObjSelectInput

• — ○ • — ○ • — ○ •

Introduction

The **Q_ObjSelectInput** is a standards-compliant function block for the programmatic selection of input fields in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.6) specification for VT input elements.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID)
- `REQ`: Selection Request (with option parameter)

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Selection Confirmation

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Input Object ID (16-bit)
- `u8Option` (USINT): Selection Option (0x00 or 0xFF)

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `u8OldOption` (USINT): Previous selection option
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` — valid object types (Annex F.6): Key (5000–5999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Input List Field (10000–10999).

ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`. Any ID outside these ranges is invalid for commanding.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with target object ID
- `INITO` confirms operational readiness

1. **Field selection**:

- `REQ` with selection option
- Sets focus on the input field
- `CNF` returns operational status and previous option

1. **Options**:

- `0xFF`: Standard selection (VT version 3+)
- `0x00`: Extended selection (VT version 4+ only)

Technical Special Features

✓ **ISO 11783-6 compliant** (F.6) ✓ **VT version dependent** (Option 0x00 only available from VT4 onwards) ✓ **Instant focus change** ✓ **Feedback of previous state**

Option Reference

u8Option	Description	VT Version
0xFF	Standard selection	3+
0x00	Extended selection	4+

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful execution
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	VT Not Ready
−21	VT_E_NO_INSTANCE	No VT Client Available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT Instance
−130	VT_E_NOT_ALIVE	VT Not Active

Application Scenarios

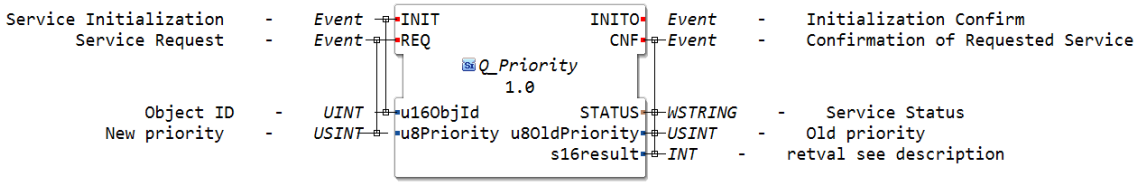
- **Form Navigation**: Automatic Field Selection
- **Input Assistants**: Guided Operation
- **Error Management**: Direct Jump to Error Fields
- **Touch Optimization**: Programmatic Focus Control

⚖️ Comparison with Similar Function Blocks

Feature	Q_ObjSelectInput	VtFocusControl	VtInputSelector

ISO Standard	✓	✖	✖
VT Version 4+	✓	✖	✓
Option Control	✓	✖	✖
Feedback	✓	✖	✓

Conclusion

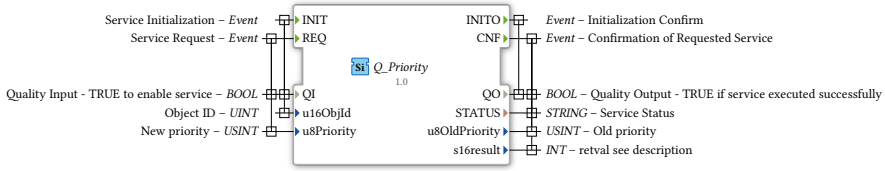


The Q_ObjSelectInput block offers precise input field control:

- **Efficient**: Direct focus change
- **Flexible**: Version-specific options
- **Reliable**: ISO-compliant implementation

Essential for:

- Professional form applications
- Guided user processes
- Touchscreen-optimized interfaces



Q_Priority

• — ○ • — ○ • — ○ •

Introduction

The **Q_Priority** is a standards-compliant function block for priority control of alarm masks in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.40) specification for VT alarm management.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with Alarm Mask ID)
- `REQ`: Priority Change Request

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Alarm Mask Object ID (16-bit)
- `u8Priority` (USINT): New Priority (0-255)

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message

- `u8OldPriority` (USINT): Previous priority
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` addresses the **Alarm Mask** whose priority is changed (F.40):
AlarmMask: 2000–2999
ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with alarm mask ID
- `INITO` confirms operational readiness

1. **Priority change**:

- `REQ` with new priority value
- Updates the alarm display order
- `CNF` provides result status and previous value

1. **Priority logic**:

- Lower numbers = Higher priority
- Affects alarm display order

Technical features

✓ **ISO 11783-6 compliant** (F.40)
✓ **Real-time Prioritization** (Immediate Effect) ✓ **Traceability** (Previous Priority) ✓ **Wide Value Range** (0-255)

Priority Reference

Priority	Typical Use
0-31	Critical System Alarms
32-63	Important Process Alarms
64-127	Standard Warnings
128-255	Informational Messages

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful Change
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	VT Not Ready
−21	VT_E_NO_INSTANCE	No VT Client Available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT Instance
−130	VT_E_NOT_ALIVE	VT Not Active

Application Scenarios

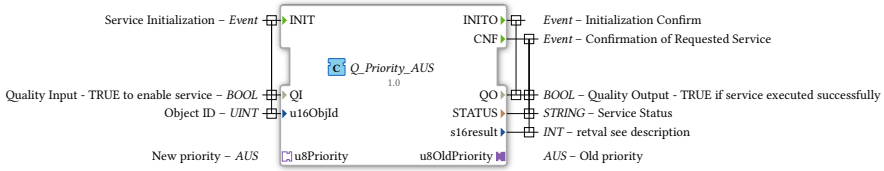
- **Alarm Management**: Dynamic Priority Adjustment
- **Process Control**: Importance Classification
- **Diagnostic Systems**: Escalation Management

- **Maintenance Modes**: Temporary Priority Changes

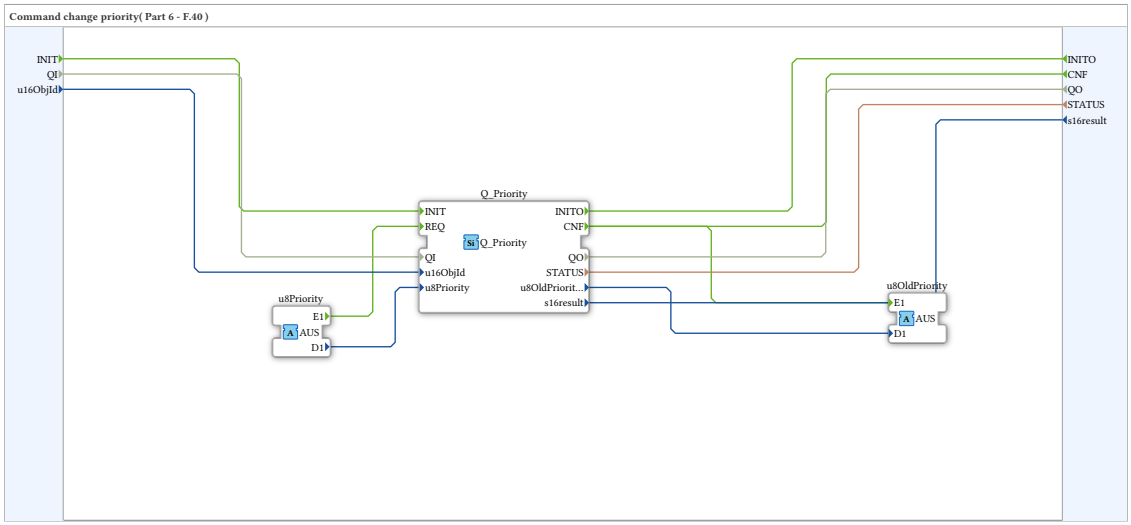
⚖️ Comparison with Similar Components

Feature	Q_Priority	VtAlarmPriority	VtEventManager
ISO Standard	✓	✖	✖
Real-time effect	✓	✓	✖
Value range	0-255	0-127	0-31
Feedback	✓	✖	✓

Conclusion



The Q_Priority block offers essential alarm control:



- **Dynamic**: Immediate priority adjustment
- **Transparent**: Feedback of the previous state
- **Robust**: Full ISO compliance

Essential for:

- Professional alarm management systems
- Process-critical applications
- Flexible diagnostic solutions

Q_Priority_AUS

• — ○ • — ○ • — ○ •

Introduction

The Q_Priority_AUS function block is used to change the priority of an alarm mask according to ISO 11783-6 (Part 6, F.40). An initialization process identifies the alarm mask, after which a new priority can be set. Confirmation of the service and the old priority value are output.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Service initialization; executed with the data input `u16ObjId`.

Event Outputs

Event	Type	Description
INITO	EInit	Confirmation of successful initialization.
CNF	Event	Confirmation of the requested service; output with `STATUS` and `s16result`.

Data Inputs

Name	Type	Description	Initial Value
QI	BOOL	Quality Input - TRUE to enable service	TRUE
u16ObjId	UINT	Object ID of the alarm mask	ID_NULL

Data Outputs

Name	Type	Description
QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service status (e.g., error or success message)
s16result	INT	Return value as described (see Functionality)

Adapter

Name	Type	Direction	Description
u8Priority	OFF (unidirectional)	Socket	New priority (sent via the adapter)
u8OldPriority	OFF (unidirectional)	Plug	Old priority (received via the adapter)

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Q_Priority`. The data output `QO` (BOOL) is taken over from `Q_Priority.QO` and is associated with the events `INITO` and `CNF`.

Valid Object IDs

The function block wraps **Q_Priority** (F.40). `u16ObjId` addresses the **Alarm Mask** whose priority is changed:

AlarmMask: 2000–2999

ID_NULL (65535) is not a valid command target but deactivates the FB when used with `INIT`.

Functionality

After triggering `INIT` with the valid object ID of the alarm mask, the function block initializes the internal communication. As soon as an event arrives via the `u8Priority` adapter, the service for changing the priority is executed. The module sends the new priority to the virtual terminal and, upon completion, outputs confirmation via `CNF`, including the status and result value. Simultaneously, the previous priority (if available) is returned via the adapter `u8OldPriority`.

The module sends the new priority to the virtual terminal and, upon completion, outputs confirmation via `CNF`. **Return Values (s16result):**

- **VT_E_NO_ERR (0)** – Success
- **VT_E_OVERFLOW (-6)** – Buffer Overflow
- **VT_E_NOACT (-8)** – Command Not Possible in Current State

- **VT_E_NO_INSTANCE (-21)** – No VT Client Available
- **VT_E_ISO_INSTANCE_INVALID (-129)** – Connection Instance Invalid
- **VT_E_NOT_ALIVE (-130)** – Instance Valid, but VT Inactive

Technical Features

- The function block is based on the ISO 11783-6 protocol and uses unidirectional adapters for data transmission.
- Initialization expects a valid object ID; an invalid value (ID_NULL) results in no service.
- The error codes are standardized and enable easy diagnostics at the VT level.
- The internal logic delegates the actual priority change to the embedded function block `Q_Priority`.

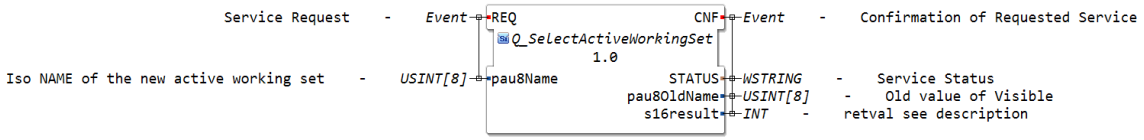
State Overview

The function block does not have an explicitly displayed state machine. Sequence:

1. **INIT** ⟶ Initialization waits for a valid object ID.
2. After successful initialization ⟶ **INITO** is active.
3. The request (REQ) is initiated via the adapter `u8Priority`.
4. After processing ⟶ **CNF** with result.

Application Scenarios

- Changing the priority of an alarm mask in a virtual terminal of agricultural machinery (e.g., an ISOBUS-compliant control unit).
- Integration into a controller that needs to dynamically set different alarm levels (e.g., from “low” to “high” in the event of a critical incident).

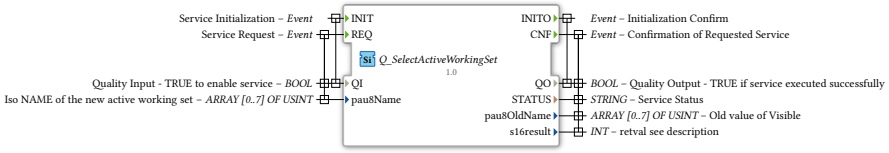


Comparison with Similar Function Blocks

- **Q_Priority** (without OFF): Offers the same core functionality but requires separate data lines for priority and age value. This function block encapsulates input and output via adapters, thus facilitating modular use in hierarchical networks.
- **Q_AlarmMask_Select**: Selects an alarm mask but does not change the priority. Q_Priority_OFF adds this functionality.

Conclusion

The Q_Priority_OFF function block implements a standardized, robust interface for changing the priority of alarm masks according to ISO 11783-6. Due to its adapter-based data transmission and the clear separation of initialization and service execution, it is particularly suitable for modular agricultural control systems.



Q_SelectActiveWorkingSet

• — ○ • — ○ • — ○ •

Introduction

The **Q_SelectActiveWorkingSet** is a standards-compliant function block for controlling active workspaces in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.64) specification for VT systems from version 6 onwards.

Interface Structure

Event Inputs

- `INIT`: Initialization Request
- `REQ`: Workspace Change Request

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `pau8Name` (USINT[8]): ISO NAME of the new active workspace

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `pau8OldName` (USINT[8]): ISO NAME of the previous workspace
- `s16result` (INT): ISO-compliant result code

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` without parameters
- `INITO` confirms operational readiness

1. **Workspace change**:

- `REQ` with 8-byte ISO NAME of the target workspace
- Performs context change
- `CNF` returns operational status and previous workspace

1. **ISO NAME format**:

- 8-byte array according to ISO 11783-5 specification

Technical features

✓ **ISO 11783-6 Compliant** (F.64) ✓ **Exclusive to VT Version 6+** ✓ **Full Context Switch** (All associated resources) ✓ **Traceability** (Previous workspace)

ISO NAME Structure

Byte	Content
0-1	Vendor ID
2-3	Device ID
4-5	Device Instance
6-7	Workspace ID

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful Switch
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	VT not ready

−21	VT_E_NO_INSTANCE	No VT client available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance
−130	VT_E_NOT_ALIVE	VT not active

Application Scenarios

- **Multi-Client Systems**: Device switching
- **User Profiles**: Individual work environments
- **Process Phases**: Operating mode switching
- **Diagnostic Management**: Service/Normal mode

⚖️ **Comparison with similar building blocks**

Feature	Q_SelectActiveWorkingSet	VtContextSwitch	VtWorkspaceManager
ISO Standard	✓	✖	✖
VT Version	6+	All	All
ISO NAME	✓	✖	✖
Feedback	✓	✖	✓

Conclusion

The Q_SelectActiveWorkingSet building block offers centralized workspace control:

- **Secure**: ISO-compliant identification
- **Efficient**: Complete context switching
- **Transparent**: Previous state traceable

Essential for:

- Complex multi-client systems
- Flexible user environments
- Process-oriented VT applications

Q_SelectColourMap

• — ○ • — ○ • — ○ •

Introduction

The **Q_SelectColourMap** is a standards-compliant function block for managing color palettes in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.60) specification for VT systems from version 4 onwards.

Interface Structure

Event Inputs

- `INIT`: Initialization Request
- `REQ`: Color Palette Change Request

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjIdColourMap` (UINT): Color Palette Object ID or 0xFFFF for the default palette

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `u16OldObjIdColourMap` (UINT): Previous color palette ID
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjIdColourMap` addresses (bytes 2,3) per Annex F.60:

- **ColourMap**: 39000 – 39999 (VT version 4 and later)
- **ColourPalette**: 45000 – 45999 (VT version 6 and later, Annex F.60)
- **FFFF16**: restores the default colour table (A.3)

Implementation note (VTClientHelper): `iso_is_colour_map_id` accepts only the ColourMap range. In addition, ID_NULL (65535) is swallowed by `cmd_select_colour_map_or_palette`, which answers with VT_E_NO_ERR (0) without sending any command to the VT — the documented FFFF value for restoring the default palette therefore currently does not work (known deviation).

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` without parameters
- `INITO` confirms operational readiness

1. **Pallet Change**:

- `REQ` with target color palette ID
- Global color management change
- `CNF` provides operational status and previous palette

1. **Special Values**:

- `0xFFFF`: Sets the default ISO color table

Technical Features

✓ **ISO 11783-6 compliant** (F.60) ✓ **Global effect**: Affects all workspaces ✓ **Long execution time**: For complex palettes ✓ **Traceability**: Previous palette can be saved

Color Palette Reference

Value	Meaning
0x0001-FFFE	User-defined palettes
0xFFFF	ISO Standard Palette (A.3)

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful switch
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	VT Not Ready
−21	VT_E_NO_INSTANCE	No VT Client Available

−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT Instance
−130	VT_E_NOT_ALIVE	VT Not Active

Application Scenarios

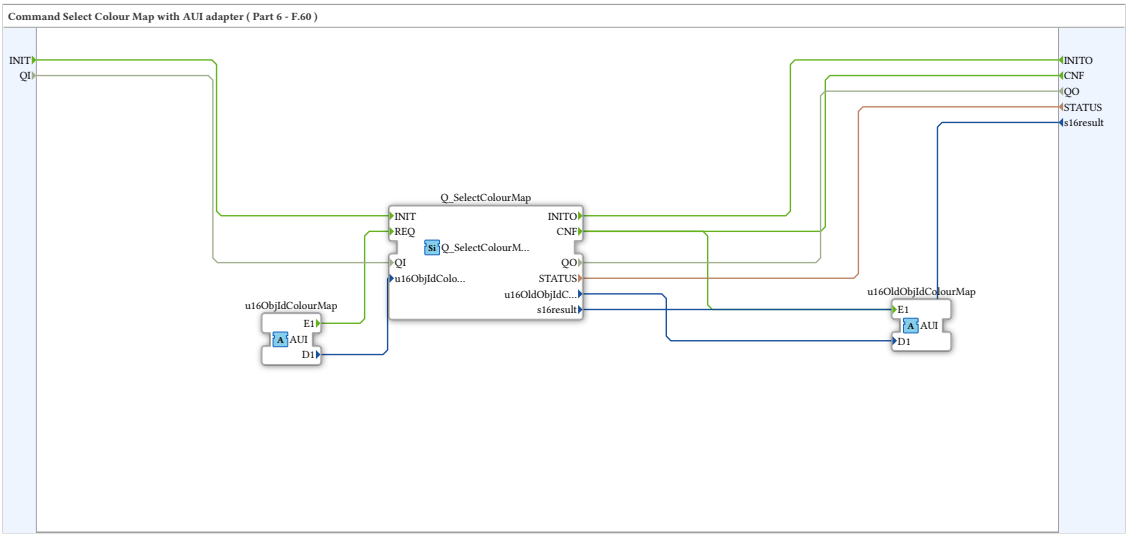
- **Design Change**: Dynamic Color Schemes
- **Night Mode**: Eye-Friendly Palettes
- **Brand Specifics**: Corporate Design
- **Accessibility**: High-Contrast Modes

⚖️ Comparison with Similar Components

Feature	Q_SelectColourMap	VtColorManager	VtPaletteControl
ISO Standard	✓	✖	✖
Global Effect	✓	✖	✓
Standard Palette	✓	✖	✖
Feedback	✓	✖	✓

Conclusion

The Q_SelectColourMap module offers professional color management:



- **Comprehensive**: Global color control
- **Flexible**: User and standard palettes
- **Reliable**: ISO-compliant implementation

Essential for:

- Design-oriented applications
- Adaptive visualization systems
- Brand-specific interfaces

Q_SelectColourMap_AUI

• – ○ • – ○ • – ○ •

Introduction

The **Q_SelectColourMap_AUI** function block is an AUI adapter wrapper for **Q_SelectColourMap** (ISO 11783-6, Part 6 – F.60). It enables selecting the active Colour Map / palette on an ISOBUS Virtual Terminal using AUI adapter connections.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Service Initialization

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirm
CNF	Event	Confirmation of Requested Service

Data Inputs

Apart from QI, there are no direct data inputs — Colour Map IDs are handled via AUI adapters.

Name	Type	Initial value	Comment
QI	BOOL	TRUE	Quality Input - TRUE to enable service

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service Status
s16result	INT	Command return code

Adapters

Type	Name	Direction	Comment
adapter::types::unidirectional::AUI16ObjIdColourMap	u16ObjIdColourMap	Socket (Input)	New Colour Map Object ID (39000–39999 for ColourMap, 45000–45999 for ColourPalette, ID_NULL / 0xFFFF for default table)
adapter::types::unidirectional::AUI16OldObjIdColourMap	u16OldObjIdColourMap	Plug (Output)	Previous Colour Map Object ID

Quality signals QI/QO: The data input QI (BOOL, initial value TRUE) is associated with the event INIT and is passed through to QI of the internal block Q_SelectColourMap. The data output QO (BOOL) is taken over from Q_SelectColourMap.QO and is associated with the events INITO and CNF.

Functionality

Encapsulates inner FB Q_SelectColourMap (*isobus::UT::Q::Q_SelectColourMap*). An event on u16ObjIdColourMap.E1 triggers REQ on the inner FB with the ID from u16ObjIdColourMap.D1. Upon completion, the previous ID is output via u16OldObjIdColourMap.D1 and CNF.

Technical Features

- **AUI Adapter Integration:** Adapter-driven selection of Colour Maps via u16ObjIdColourMap socket.

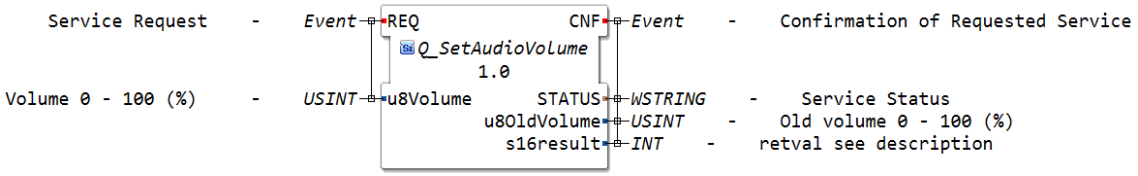
- **ID Ranges per ISO 11783-6 F.60:**
  - `ColourMap`: 39000–39999 (VT version 4 and later)
  - `ColourPalette`: 45000–45999 (VT version 6 and later)
  - `ID_NULL` (`0xFFFF` / 65535): Restores the default colour table.
- **Implementation Limitations (VTClientHelper):**
  - `VTClientHelper::iso_is_colour_map_id` currently only accepts the range 39000–39999 (`ColourPalette` IDs 45000–45999 are rejected).
  - `cmd_select_colour_map_or_palette` consumes `ID_NULL` (`0xFFFF`), returns `VT_E_NO_ERR` (0), and sends no VT command. Restoring the default colour table is therefore currently not supported.

State Overview

Delegates state processing to inner `Q_SelectColourMap`.

Application Scenarios

- Dynamic colour scheme switching (e.g. day/night mode) on ISOBUS VT terminals via AUI adapters.



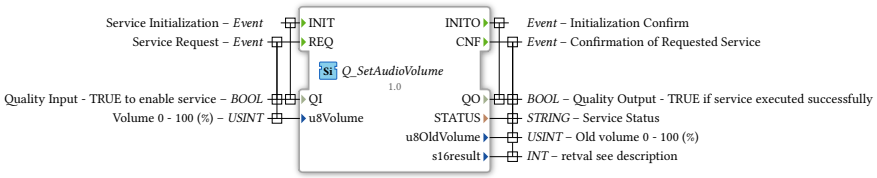
Comparison with Similar Blocks

Wraps `Q_SelectColourMap` with AUI adapter socket and plug for seamless integration into adapter networks.

Conclusion

Q_SelectColourMap_AUI is the adapter wrapper for Colour Map selection in ISOBUS VT applications.

Q_SetAudioVolume



• – ◦ • – ◦ • – ◦ •

Introduction

The **Q_SetAudioVolume** is a standards-compliant function block for volume control in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.12) specification for VT audio control.

The F.12 command addresses the VT's **audio device** directly — it does **not reference any object**, so this block has no Object ID input. The message has a fixed length of 8 bytes; byte 2 carries the volume percentage (0% – 100%).

Interface Structure

Event Inputs

- `INIT`: Initialization Request
- `REQ`: Volume Change Request

Event Outputs

- `INITO`: Initialization Acknowledgement
- `CNF`: Change Acknowledgement

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service

- `u8Volume` (USINT): Volume Value (0-100%)

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operating Status Message
- `u8OldVolume` (USINT): Previous Volume Setting
- `s16result` (INT): ISO-compliant result code

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` without parameters
- `INITO` confirms operational readiness

1. **Volume Control**:

- `REQ` with desired volume level
- Changes the global VT volume
- `CNF` returns operating status and previous value

1. **Value Range**:

- 0%: Muted
- 100%: Maximum volume

Technical Features

✓ **ISO 11783-6 compliant** (F.12) ✓ **Global audio control** ✓ **Percentage control** (0-100%) ✓ **Traceability** (Previous Setting)

Volume Reference

Value	Meaning
0	Mute
50	Medium Volume
100	Maximum Volume

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful Change
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	VT Not Ready
−21	VT_E_NO_INSTANCE	No VT Client Available
−128	VT_E_HANDLE_INVALID	Invalid Audio Configuration
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance
−130	VT_E_NOT_ALIVE	VT not active

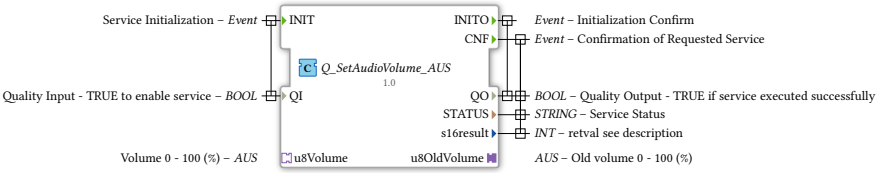
Application Scenarios

- **Alarm Management**: Adjustable warning signals
- **Voice Output**: Volume adjustment
- **Ease of Use**: User-defined audio settings
- **Night Mode**: Automatic volume reduction

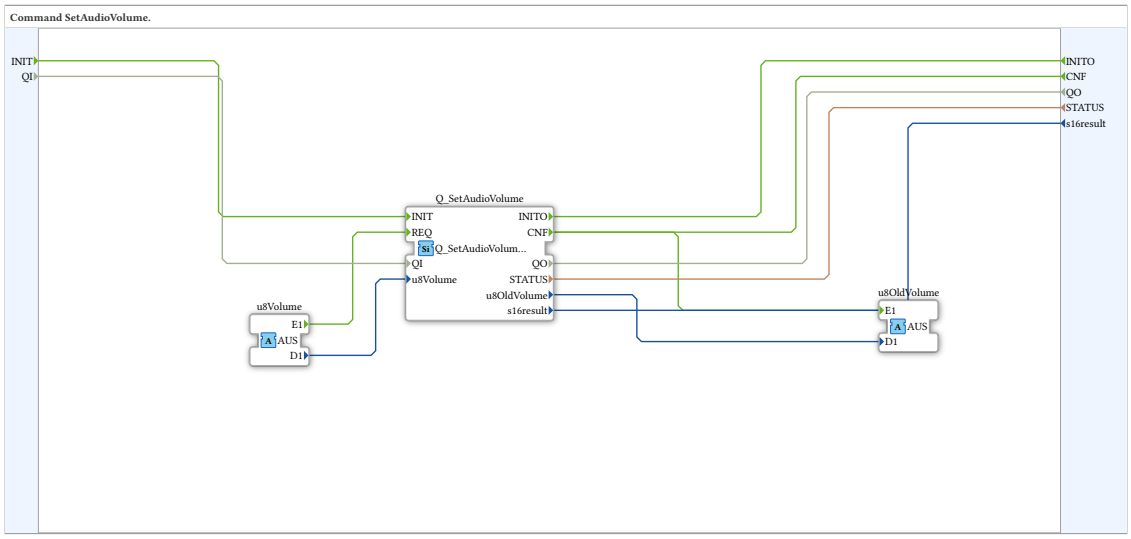
⚖️ Comparison with similar components

Feature	Q_SetAudioVolume	VtAudioControl	VtSoundManager
ISO Standard	✓	✖	✖
Value Range	0-100%	0-255	0-10 steps
Global Effect	✓	✓	✖
Feedback	✓	✖	✓

Conclusion



The Q_SetAudioVolume module offers precise audio control:



- **Intuitive**: Percentage-based control
- **Reliable**: ISO-compliant implementation
- **Flexible**: For all audio outputs

Essential for:

- Professional alarm systems
- Voice-controlled applications
- User-friendly interfaces

Q_SetAudioVolume_AUS

• – ○ • – ○ • – ○ •

Introduction

The Q_SetAudioVolume_AUS function block is a composite function block (FB) that executes the “SetAudioVolume” command according to ISO 11783-6 on a Virtual Terminal (VT). It encapsulates the base function block Q_SetAudioVolume and provides an adapter-based interface for setting the volume and reading back the previous value. The FB initializes itself via the INIT event input and acknowledges this with INITO. A new volume value can then be passed via the u8Volume adapter, whereupon the command is triggered and the result is output via CNF with STATUS and s16result.

Interface Structure

Event Inputs

- **INIT** (EInit): Service initialization. Triggers the initialization of the internal function block. Associated with `QI`.

Event Outputs

- **INITO** (EInit): Confirmation of successful initialization. Associated with `QO`.
- **CNF** (Event): Confirmation of the requested service. Outputted after setting the volume. Contains the output data STATUS and s16result. Associated with `QO`.

Data Inputs

Apart from `QI`, the FB has no direct data inputs. Volume input is via the u8Volume adapter.

Name	Type	Initial value	Comment
`QI`	`BOOL`	`TRUE`	Quality Input - TRUE to enable service

Data Outputs

- **QO** (BOOL): Quality Output - TRUE if service executed successfully.
- **STATUS** (STRING): Service status message.
- **s16result** (INT): Command return value. Possible values:
- 0 (VT_E_NO_ERR): Success.
- −6 (VT_E_OVERFLOW): Buffer overflow.
- −8 (VT_E_NOACT): Command not possible in the current state.
- −21 (VT_E_NO_INSTANCE): No VT client available.
- −129 (VT_E_ISO_INSTANCE_INVALID): Connection instance invalid.
- −128 (VT_E_HANDLE_INVALID): Handle invalid.
- −130 (VT_E_NOT_ALIVE): VT not active.

Adapters

- **u8Volume** (Socket): Unidirectional adapter of type OFF. Receives the desired volume as a value between 0 and 100%.
- **u8OldVolume** (Plug): Unidirectional adapter of type OFF. Outputs the volume level (0–100%) valid before the command.

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Q_SetAudioVolume`. The data output `QO` (BOOL) is taken over from `Q_SetAudioVolume.QO` and is associated with the events `INITO` and `CNF`.

Functionality

After startup, the FB is initialized via the INIT input. The internal block Q_SetAudioVolume is prepared, and INITO signals its readiness. As soon as a new volume value is received via the u8Volume adapter (event E1 of the adapter), the command to change the volume is sent to the VT. Upon completion of the process, CNF is triggered, and the output variables STATUS and s16result contain the result. Simultaneously, the previous volume value is output via the u8OldVolume adapter, allowing external logic to read the old value.

The possible error codes correspond to the ISO11783-6 definitions and cover typical VT error situations.

Technical Features

- The function block is implemented as a composite block that uses the basic function block Q_SetAudioVolume from the isobus library.
- The interface uses only adapters for data transmission, resulting in loose coupling and flexible wiring.
- The adapters are of type “unidirectional::OFF” and enable event-driven data transmission.
- The function block (FB) is designed for use in ISOBUS systems according to ISO 11783-6.

State Overview

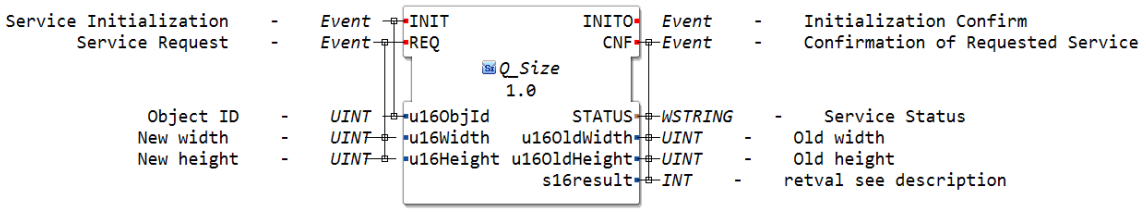
Since this is a composite block with an internal FB, there is no explicit top-level state machine. The FB goes through the following phases:

1. Initialization (INIT received ⟶ INITO sent)
2. Ready (waits for volume change via u8Volume adapter)
3. Processing (internal command is executed)
4. Result output (CNF with STATUS/s16result)

A detailed state machine is implemented in the internal block Q_SetAudioVolume.

Application Scenarios

- Agricultural machine control: Adjusting the volume of voice outputs or warning tones from the virtual terminal.
- Integration into ISOBUS-compliant applications that change audio settings via the operator terminal.
- Combination with other VT command blocks such as Q_SelectAudioOutput, Q_Beep, etc.

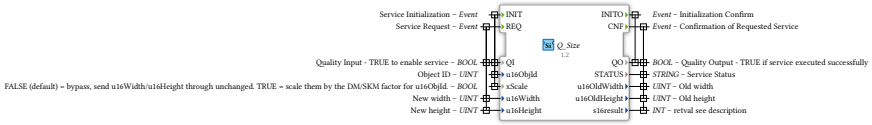


Comparison with similar blocks

The Q_SetAudioVolume_AUS block differs from a direct Q_SetAudioVolume block in its use of adapters for data transmission. While Q_SetAudioVolume may have direct data inputs (e.g., u8Volume as VarDeclaration), the adapter variant allows for decoupled, event-driven communication. Similar adapter blocks exist for other VT commands, resulting in a consistent design pattern.

Conclusion

Q_SetAudioVolume_AUS is a specialized function block for volume control of an ISOBUS VT. The adapter-based interface ensures a clear separation between the control and data layers. The block provides complete feedback on the success of the command and is suitable for reliable use in agricultural control systems.



Q_Size

• — ○ • — ○ • — ○ •

Introduction

The **Q_Size** is a standards-compliant function block for resizing objects in Virtual Terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.18) specification for VT objects.

Interface Structure

Event Inputs

- `INIT`: Initialization request (with object ID and xScale)
- `REQ`: Resize request

Event Outputs

- `INITO`: Initialization acknowledgment
- `CNF`: Resize acknowledgment

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Object ID (16-bit)
- `xScale` (BOOL): If TRUE, `u16Width`/`u16Height` are scaled by the DM/SKM factor for `u16ObjId` before sending; if FALSE (default) they are passed through unchanged.

- `u16Width` (UINT): New width in pixels
- `u16Height` (UINT): New height in pixels

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `u16OldWidth` (UINT): Previous width
- `u16OldHeight` (UINT): Previous height
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` — valid object types (Annex F.18, objects with sizeable attribute): Container (3000–3999), Button (6000–6999), Input Boolean Field (7000–7999), Input String Field (8000–8999), Input Number Field (9000–9999), Input List Field (10000–10999), Output String Field (11000–11999), Output Number Field (12000–12999), Output Line (13000–13999), Output Rectangle (14000–14999), Output Ellipse (15000–15999), Output Polygon (16000–16999), Meter (17000–17999), Linear Bar Graph (18000–18999), Arched Bar Graph (19000–19999), Output List Object (37000–37999), Animation Object (44000–44999).

ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`. Any ID outside these ranges is invalid for commanding.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with target object ID
- `INITO` confirms operational readiness

1. **Resize**:

- `REQ` with new dimensions
- Dynamically adjusts the object geometry
- `CNF` provides operational status and previous dimensions

1. **Unit of measurement**:

- All values in screen pixels

Technical Features

✓ **ISO 11783-6 compliant** (F.18) ✓ **Dynamic resizing** (real-time update) ✓ **Comprehensive object support** ✓ **Traceability** (previous dimensions)

Size reference

Parameter	Value range	Description
Width	1-65535 pixels	Horizontal extent
Height	1-65535 pixels	Vertical extent

Return codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful change
−6	VT_E_OVERFLOW	Buffer Overflow
−8	VT_E_NOACT	VT Not Ready
−21	VT_E_NO_INSTANCE	No VT Client Available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT Instance

−130	VT_E_NOT_ALIVE	VT Not Active

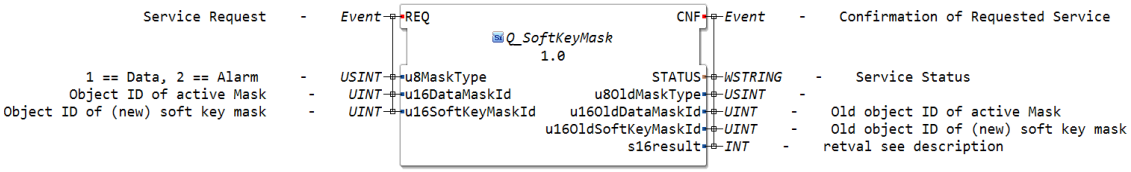
Application Scenarios

- **Responsive Designs**: Adapting to Display Sizes
- **Zoom Functions**: Dynamic Scaling
- **Layout Manager**: Automatic Size Optimization
- **Animation Control**: Size Change Effects

⚖️ Comparison with Similar Building Blocks

Feature	Q_Size	VtResizeObject	VtGeometryManager
ISO Standard	✓	✖	✖
Real-time Update	✓	✓	✖
2D Control	✓	✓	✓
Feedback	✓	✖	✓

Conclusion

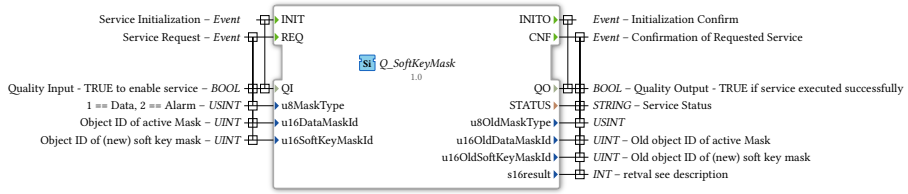


The Q_Size block offers precise size control:

- **Flexible**: Pixel-accurate adjustment
- **High-Performance**: Instant display updates
- **Reliable**: ISO-compliant implementation

Essential for:

- Adaptive User Interfaces
- Dynamic Visualizations
- Professional VT Applications



Q_SoftKeyMask

• — ○ • — ○ • — ○ •

Introduction

The **Q_SoftKeyMask** is a standards-compliant function block for managing softkey masks in virtual terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.36) specification for VT systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request
- `REQ`: Screen Change Request

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Change Confirmation

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u8MaskType` (USINT): Screen Type (1=Data, 2=Alarm)
- `u16DataMaskId` (UINT): Object ID of the Active Screen
- `u16SoftKeyMaskId` (UINT): Object ID of the New Softkey Screen

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational status message
- `u8OldMaskType` (USINT): Previous screen type
- `u16OldDataMaskId` (UINT): Previous data mask ID
- `u16OldSoftKeyMaskId` (UINT): Previous softkey screen ID
- `s16result` (INT): ISO-compliant result code

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` without parameters
- `INITO` confirms operational readiness

1. **Screen change**:

- `REQ` with screen type, data mask ID, and new softkey screen
- Linkes softkeys to the active screen
- `CNF` provides operating status and previous configuration

1. **Mask Types**:

- `1`: Data Mask Link
- `2`: Alarm Mask Link

Valid Object IDs

The function block addresses **two distinct Object IDs**, each with its own validity rules:

Valid values for u16DataMaskId (data or alarm mask)

The Change Soft Key Mask command (Annex F.36) associates a Soft Key Mask with a Data Mask or an Alarm Mask. `u16DataMaskId` is valid if it falls within one of the following ISO 11783-6 ID ranges:

Object type	ID range
DataMask	1000 – 1999
AlarmMask	2000 – 2999

Valid values for u16SoftKeyMaskId (soft key mask)

`u16SoftKeyMaskId` is valid if it falls within the ISO 11783-6 ID range of a Soft Key Mask:

Object type	ID range
SoftKeyMask	4000 – 4999

Note: ID_NULL (65535) is not a command target but can be used in INIT to deactivate the FB. Any data/alarm mask ID outside the ranges above, or any soft key mask ID that is not a SoftKeyMask, is invalid for commanding — independent of each other.

Technical Features

✓ **ISO 11783-6 compliant** (F.36) ✓ **Dual Mask Types** (Data/Alarms) ✓ **Dynamic Reassignment** ✓ **Traceability** (Previous Configuration)

Mask Type Reference

Value	Type	Description
1	Data	Normal Data Mask
2	Alarm	Alarm Mask Link

Return Codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Successful switch
−6	VT_E_OVERFLOW	Buffer overflow
−8	VT_E_NOACT	VT not ready
−21	VT_E_NO_INSTANCE	No VT client available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance
−130	VT_E_NOT_ALIVE	VT not active

Application Scenarios

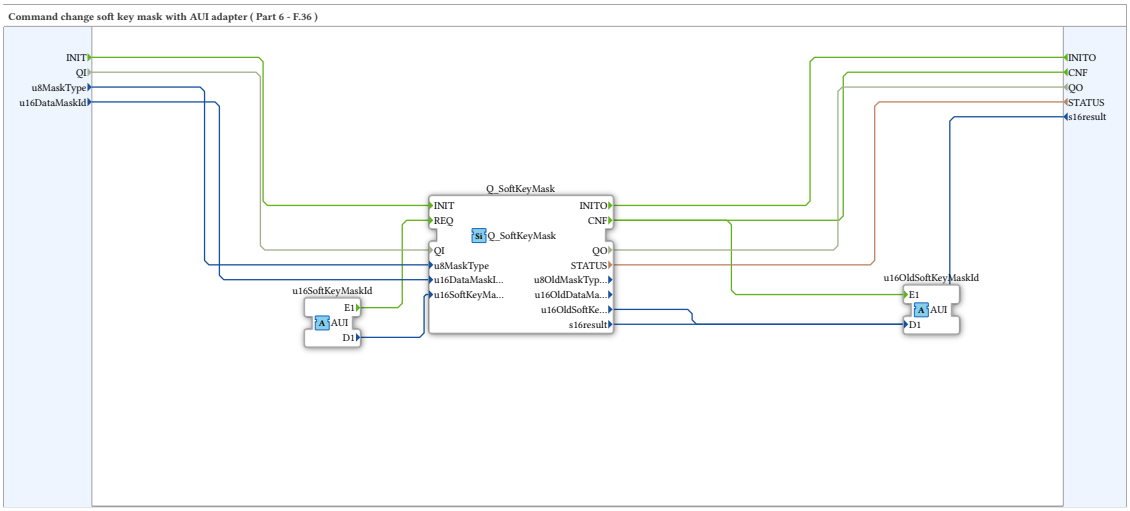
- **Context-Sensitive Softkeys**: Function Switching
- **Alarm Management**: Special Alarm Softkeys
- **Mask Hierarchies**: Dynamic Key Assignments
- **User Guidance**: Adaptive User Interfaces

⚖️ **Comparison with Similar Components**

Feature	Q_SoftKeyMask	VtKeyMapping	VtMaskLinker
ISO Standard	✓	✖	✖
Mask Types	2 (Data/Alarm)	1 (Universal)	1 (Data)
Feedback	✓	✖	✓
Real-Time Switching	✓	✓	✖

Conclusion

The Q_SoftKeyMask module offers flexible softkey control:



- **Context-sensitive**: Different mask types
- **Dynamic**: Instant reassignment
- **Reliable**: ISO-compliant implementation

Essential for:

- Professional user interface concepts
- Complex mask hierarchies
- Adaptive VT applications

Q_SoftKeyMask_AUI

• – ○ • – ○ • – ○ •

Introduction

The **Q_SoftKeyMask_AUI** function block is an AUI adapter wrapper for **Q_SoftKeyMask** (ISO 11783-6, Part 6 – F.36). It enables switching the active soft key mask on an ISOBUS Virtual Terminal using AUI adapter connections.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Service Initialization

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirm
CNF	Event	Confirmation of Requested Service

Data Inputs

Name	Type	Comment
QI	BOOL	Quality Input - TRUE to enable service
u8MaskType	USINT	Mask Type (1: DataMask, 2: AlarmMask)
u16DataMaskId	UINT	Object ID of target Data/AlarmMask

Data Outputs

Name	Type	Comment

QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service Status
s16result	INT	Command return code

Adapters

Type	Name	Direction	Comment
adapter::types::unidirectional::AUI16SoftKeyMaskId	u16SoftKeyMaskId	Socket (Input)	New soft key mask Object ID
adapter::types::unidirectional::AUI16OldSoftKeyMaskId	u16OldSoftKeyMaskId	Plug (Output)	Previous soft key mask Object ID

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Q_SoftKeyMask`. The data output `QO` (BOOL) is taken over from `Q_SoftKeyMask.QO` and is associated with the events `INITO` and `CNF`.

Functionality

Encapsulates inner FB `Q_SoftKeyMask` (*isobus::UT::Q::Q_SoftKeyMask*). An event on `u16SoftKeyMaskId.E1` triggers `REQ` on the inner FB, which switches the soft key mask. Upon completion, the previous soft key mask ID is output via `u16OldSoftKeyMaskId.D1` and `u16OldSoftKeyMaskId.E1`.

Technical Features

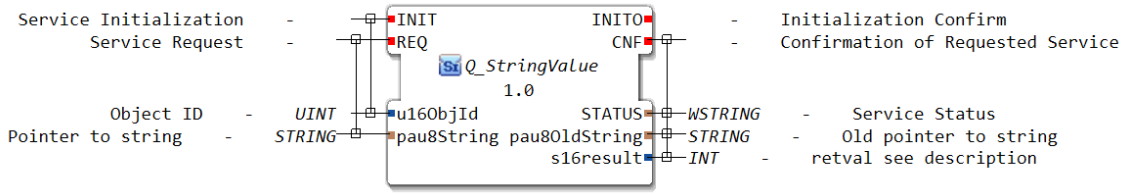
- **Adapter-driven Softkey Control:** Flexible switching of soft key layouts via AUI adapters.
- **ISOBUS Standard Compliance:** Complies with ISO 11783-6 F.36.

State Overview

Delegates state processing to inner `Q_SoftKeyMask`.

Application Scenarios

- Dynamic soft key layout switching in ISOBUS VT terminals via AUI adapters.

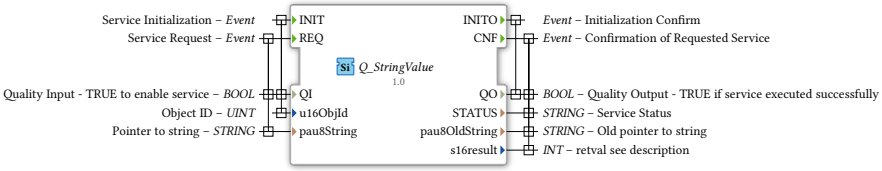


Comparison with Similar Blocks

Wraps `Q_SoftKeyMask` with an AUI adapter interface for integration into adapter networks.

Conclusion

Q_SoftKeyMask_AUI is the adapter wrapper for soft key mask switching in ISOBUS VT applications.



Q_StringValue

• – ○ • – ○ • – ○ •

Introduction

The **Q_StringValue** is a standards-compliant function block for dynamic text updates in Virtual Terminals, developed under the EPL-2.0 license. Version 1.0 implements the ISO 11783-6 (Part 6 - F.24) specification for VT text objects.

Interface Structure

Event Inputs

- `INIT`: Initialization Request (with object ID)
- `REQ`: Text Change Request

Event Outputs

- `INITO`: Initialization Confirmation
- `CNF`: Change Confirmation

Data Inputs

- `QI` (BOOL, default `TRUE`): Quality input – `TRUE` enables the service
- `u16ObjId` (UINT): Text Object ID (16-bit)
- `pau8String` (STRING): New Text Value (null-terminated)

Data Outputs

- `QO` (BOOL): Quality output – `TRUE` if the service was executed successfully
- `STATUS` (STRING): Operational Status Message
- `pau8OldString` (STRING): Previous text value
- `s16result` (INT): ISO-compliant result code

Valid Object IDs

`u16ObjId` — valid object types (Annex F.24, objects with string value attribute): Input String Field (8000–8999), Output String Field (11000–11999), String Variable (22000–22999), Input Attributes (26000–26999).

Data length / Transport Protocol: The F.24 command has a **variable data length** (command frame: Object ID, string byte count, string value). Strings that fit into a single CAN message are sent directly; longer strings are transmitted using the ISO 11783 **transport protocol**. Per Annex F.24 the transferred string may be shorter than the target object's length attribute (the VT pads it with space characters), but the number of transferred bytes shall not exceed the target object's length attribute.

ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`. Any ID outside these ranges is invalid for commanding.

Functionality

Quality handling (QI/QO): The input `QI` (BOOL, default `TRUE`) is associated with the events `INIT` and `REQ`; `TRUE` enables the service. The output `QO` (BOOL) is associated with `INITO` and `CNF` and indicates with `TRUE` that the service was executed successfully.

1. **Initialization**:

- `INIT` with target object ID
- `INITO` confirms operational readiness

1. **Text Update**:

- `REQ` with new text string
- Immediately updates the VT text object
- `CNF` returns operational status and previous text

1. **String Requirements**:

- Maximum `ISO_VTC_CMD_STR_MAX_LENGTH` including null termination
- Must be null-terminated

Technical Features

✓ **ISO 11783-6 compliant** (F.24)
  ✓ **Real-time text update** (FIFO-based)
  ✓ **Null termination required**
  ✓ **Traceability** (Previous text value)

String format

Parameters	Requirements
Maximum length	ISO_VTC_CMD_STR_MAX_LENGTH
Termination	'\0' at the end is mandatory
Character set	ISO-8859-1 (Latin-1) recommended

Return codes (s16result)

Code	Constant	Meaning
0	VT_E_NO_ERR	Update successful
−6	VT_E_OVERFLOW	String too long or buffer full
−8	VT_E_NOACT	VT not ready
−21	VT_E_NO_INSTANCE	No VT client available
−129	VT_E_ISO_INSTANCE_INVALID	Invalid VT instance
−130	VT_E_NOT_ALIVE	VT not active

Application Scenarios

- **Dynamic Displays**: Measured values, status messages
- **Language Switching**: Multilingual texts
- **Process Visualization**: Real-time data
- **User Communication**: Dialogs and prompts

⚖️ **Comparison with similar building blocks**

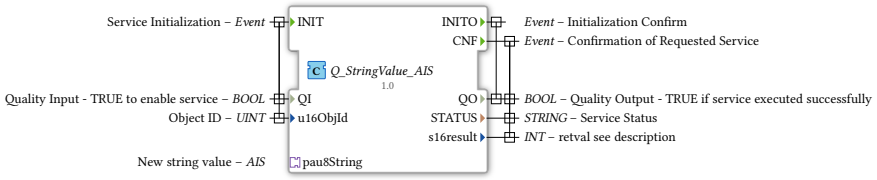
Feature	Q_StringValue	VtTextUpdate	VtStringManager
ISO Standard	✓	✖	✖
FIFO Update	✓	✖	✓
Length Check	✓	✓	✖
Feedback	✓	✖	✓

🛠️ **Related Exercises**

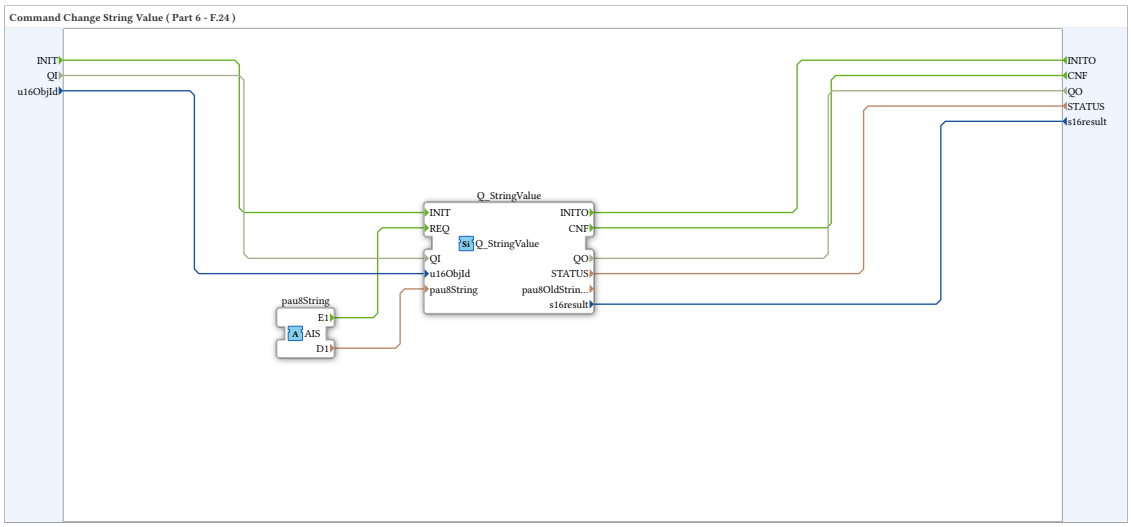
- Exercise_012c

Conclusion

The Q_StringValue block offers efficient text management:



- **High-performance**: Direct FIFO update
- **Secure**: Integrated length check
- **Flexible**: For all text object types



Essential for:

- Dynamic process visualization
- Multilingual applications

- Real-time data display

Q_StringValue_AIS

• — ○ • — ○ • — ○ •

Introduction

The function block **Q_StringValue_AIS** implements the “Command Change String Value” service according to ISO 11783-6 (Part 6, Section F.24). It is used to send a new string value to a connected device via an ISOBUS network. The block encapsulates all the logic for initialization, sending the command, and returning the result. The new string value is input via a unidirectional adapter (AIS), which provides the actual data.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Service initialization, sets the object ID

Event Outputs

Event	Type	Comment
INITO	EInit	Confirmation of successful initialization
CNF	Event	Confirmation of the requested service (result)

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	TRUE	Quality Input - TRUE to enable service
u16ObjId	UINT	ID_NULL	Object ID of the value to be changed

Data Outputs

Name	Type	Comment
QO	BOOL	Quality Output - TRUE if service executed successfully
STATUS	STRING	Service status (e.g., “IDLE”, “BUSY”, “ERROR”)
s16result	INT	Return value (see service description)

Adapter

Name	Type	Comment
pau8String	adapter::types::unidirectional::AIS	Returns the new string value

Quality signals QI/QO: The data input `QI` (BOOL, initial value `TRUE`) is associated with the event `INIT` and is passed through to `QI` of the internal block `Q_StringValue`. The data output `QO` (BOOL) is taken over from `Q_StringValue.QO` and is associated with the events `INITO` and `CNF`.

Valid Object IDs

`u16ObjId` is valid for the same object types as the wrapped base block `Q_StringValue` (Annex F.24, objects with string value attribute): Input String Field (8000–8999), Output String Field (11000–11999), String Variable (22000–22999), Input Attributes (26000–26999). The F.24 variable data length / ISO transport protocol behaviour of `Q_StringValue` also applies.

ID_NULL (65535) is not a command target but deactivates the FB when used with `INIT`.

Functionality

The function block internally contains an instance of the function block `Q_StringValue` (from the library `isobus::UT::Q`), which performs the actual ISOBUS communication. The wiring is as follows:

1. **Initialization**: An INIT event at the input activates the internal `Q_StringValue` function block. The provided `u16ObjId` is forwarded to this device.
2. **Triggering the Service**: As soon as the adapter `pau8String` receives an event (E1), the REQ event of the internal block is triggered. Simultaneously, the string value is passed to `Q_StringValue.pau8String` via the adapter’s data output D1.
3. **Feedback**: After processing is complete, the internal block outputs the events `INITO` and `CNF`, whose output data (`STATUS`, `s16result`) are directly passed to the corresponding outputs of the overall block.

All the logic is implemented in the included `Q_StringValue` block; the `Q_StringValue_AIS` serves as a specialized package with an adapter input.

Technical Features

- The block complies with the **ISO 11783-6** (ISOBUS) specification, Part 6, “Command Change String Value” service.
- The implementation uses a **unidirectional adapter** (`adapter::types::unidirectional::AIS`) that only transmits data from the host to the block. This simplifies integration into control systems where the new string value is provided asynchronously.
- The initial value of `u16ObjId` is `ID_NULL` – this must be set to a valid object ID before first use.
- The outputs `STATUS` and `s16result` provide the status and return value of the service as soon as the `CNF` event is triggered. The exact values are defined in the underlying service description.

State Overview

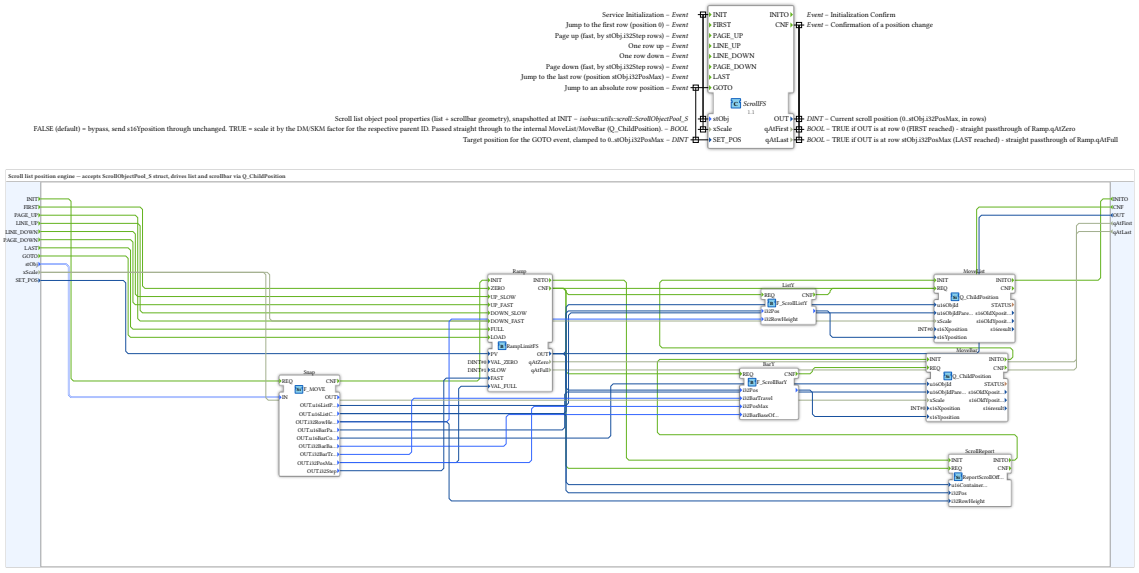
The function block itself does not have an explicit internal state machine, as the state logic is entirely contained within `Q_StringValue`. Essentially, the following phases can be distinguished:

- **Idle**: After starting or after a successful/failed execution – the function block waits for an INIT or an event on the adapter.
- **Initialization**: Active through INIT until the INITO event is sent.
- **Service Active**: After being triggered by the adapter, until the CNF event arrives.
- **Errors**: In case of invalid parameters or communication errors, a corresponding status/return value is provided.

Application Scenarios

- **ISOBUS Command:** Changing a string parameter on an agricultural device (e.g., machine name, task, variable name) via the ISOBUS network.
- **Control Systems:** Connection to a PLC or HMI that provides the new string value via an adapter (e.g., from a text box, a database field, or a communication channel).
- **Test Environments:** Simulating the service for development and testing purposes.

Comparison with Similar Function Blocks



The `Q_StringValue_AIS` function block is a specialized variant of the `Q_StringValue` function block, which already includes all ISOBUS communication. The difference lies in the input interface: While `Q_StringValue` receives the string value via a standard data input `pau8String` (of type `STRING` array), `Q_StringValue_AIS` uses an adapter (AIS) that can supply data asynchronously. The adapter enables loose coupling and facilitates reuse in different contexts, for example, when the string value is provided by another, independent function block.

Other similar function blocks from the ISO 11783-6 family handle different data types (e.g., `Q_NumberValue_AIS` for numeric values).

Conclusion

The `Q_StringValue_AIS` is a practical, standards-compliant function block for modifying string values in an ISOBUS context. Using an adapter makes integration flexible and modular. It is particularly suitable for applications where the new value is provided asynchronously or from external sources. The clear separation of initialization and service execution, as well as the standardized outputs, facilitate debugging and reuse.

ScrollFS

• — ○ • — ○ • — ○ •

Introduction

`ScrollFS` is the pure position engine of a scrollable VT list: it holds the current row position (0… `i32PosMax`), reacts to navigation events (line/page up/down, first/last, absolute position) and writes the matching Y offset for both the list content and the scrollbar thumb via two `Q_ChildPosition` calls (ISO 11783-6 F.16, “Change Child Location”) to the VT. It reads **no** physical buttons or input fields — that’s what ScrollFS_PHYS_Softkey and ScrollFS_PHYS_Button are for, which wrap `ScrollFS` internally. See `Workspace_Scroll/SCROLL_KONZEPT.md` in the `4diac_training1` project for the full derivation.

Interface Structure

Event Inputs

- `INIT`: Snapshots the configuration (`stObj`) and takes `xScale`.
- `FIRST`: Jumps to the first row (position 0).

- PAGE_UP: Page up (fast, by stObj.i32Step rows).
- LINE_UP: One row up.
- LINE_DOWN: One row down.
- PAGE_DOWN: Page down (fast, by stObj.i32Step rows).
- LAST: Jumps to the last row (position stObj.i32PosMax).
- GOTO: Jumps to an absolute row position (SET_POS), clamped to 0…stObj.i32PosMax.

Event Outputs

- CNF: Confirms a position change, delivers OUT, qAtFirst and qAtLast.

Data Inputs

- stObj (isobus::utils::scroll::ScrollObjectPool_S): list/bar geometry (container IDs, row height, bar offsets, i32PosMax, i32Step) — snapshotted once at INIT.
- xScale (BOOL, default FALSE): FALSE = bypass, s16Yposition is sent through unchanged; TRUE = scale it by the DM/SKM factor for the respective parent ID. Passed straight through to the internal MoveList/MoveBar (Q_ChildPosition).
- SET_POS (DINT): Target position for GOTO.

Data Outputs

- OUT (DINT): Current scroll position (0…stObj.i32PosMax, in rows).
- qAtFirst (BOOL): TRUE if OUT is at row 0 (start of the list reached).
- qAtLast (BOOL): TRUE if OUT is at stObj.i32PosMax (end of the list reached).

Adapters

No adapters available.

Functionality

ScrollFS wires five blocks together into a complete position engine:

1. **Snap** (F_MOVE, DataType = ScrollObjectPool_S): snapshots stObj once at INIT, after which all nine geometry fields are permanently available as Snap.OUT.<field>.
2. **Ramp** (RampLimitFS, package eclipse4diac::signalprocessing): the actual position state machine, reused directly (no separate state machine needed). The eight ScrollFS events map 1:1 to RampLimitFS events:

ScrollFS event	RampLimitFS event	Effect on OUT
FIRST	ZERO	OUT := 0
PAGE_UP	DOWN_FAST	OUT -= stObj.i32Step (clamped at 0)
LINE_UP	DOWN_SLOW	OUT -= 1 (clamped at 0)
LINE_DOWN	UP_SLOW	OUT += 1 (clamped at i32PosMax)
PAGE_DOWN	UP_FAST	OUT += stObj.i32Step (clamped at i32PosMax)
LAST	FULL	OUT := stObj.i32PosMax
GOTO	LOAD (with PV := SET_POS)	OUT := SET_POS, clamped to 0…i32PosMax

VAL_ZERO := 0, VAL_FULL := Snap.OUT.i32PosMax, SLOW := 1, FAST := Snap.OUT.i32Step. 3. **ListY** (F_ScrollListY) and **BarY** (F_ScrollBarY): on every Ramp.CNF, compute the Y offset for the list and the scrollbar from Ramp.OUT. 4. **MoveList** and **MoveBar** (each a Q_ChildPosition): write the computed Y values to the VT — MoveList moves Container_Scrolling_Content within Container_Scrolling_Parent, MoveBar moves Container_Scrollbar_Content within Container_Scrollbar_Parent. Both have a fixed s16Xposition := 0 (vertical scrolling only). 5. **ScrollReport** (ReportScrollOffset): on every Ramp.CNF (and initially on Ramp.INIT0), reports the current scroll position (pixel offset = Ramp.OUT * Snap.OUT.i32RowHeight) for container Snap.OUT.u16ListContentId to the ECU visibility gate (VtMaskVisibility) so visible elements can be precisely filtered for VT refreshes.

Ramp.qAtZero/Ramp.qAtFull are passed through unchanged as qAtFirst/qAtLast.

Technical Details

- **`F_MOVE` snapshot for struct access**: `Snap.IN`/`.OUT` are generically `ANY`-typed; an `ANY` connection (here: the concretely-typed `stObj` into the generic `Snap.IN`) in 4diac always needs a `MOVE` block in between, never directly. Every individual struct field addressed via `Snap.OUT.<field>` needs its own `Parameter Name="OUT.<field>"` entry with `Attribute Name="Visible" Value="true"` on the `Snap` instance - without it, the network won't compile.
- **Init chain is serial, not parallel**: `Snap.CNF` triggers `Ramp.INIT`; only after `Ramp.INITO` do `MoveList.INIT` and `MoveBar.INIT` fire - guaranteeing `VAL_ZERO`/`VAL_FULL`/`SLOW`/`FAST` are set in `Ramp` before any position value is written to the VT.
- **`ListY`/`BarY` are concretely typed** (`DINT`/`INT`, see F_ScrollListY, F_ScrollBarY) - so no extra `MOVE` anchor is needed between them and `Ramp.OUT`, even though `Ramp.OUT` itself comes from a generic `RampLimitFS` instance.

State Overview

The only state lives in `Ramp` (`RampLimitFS`): `OUT` persists between events, each navigation event changes it incrementally or jumps directly. `qAtFirst`/`qAtLast` are recomputed on every change, never maintained separately.

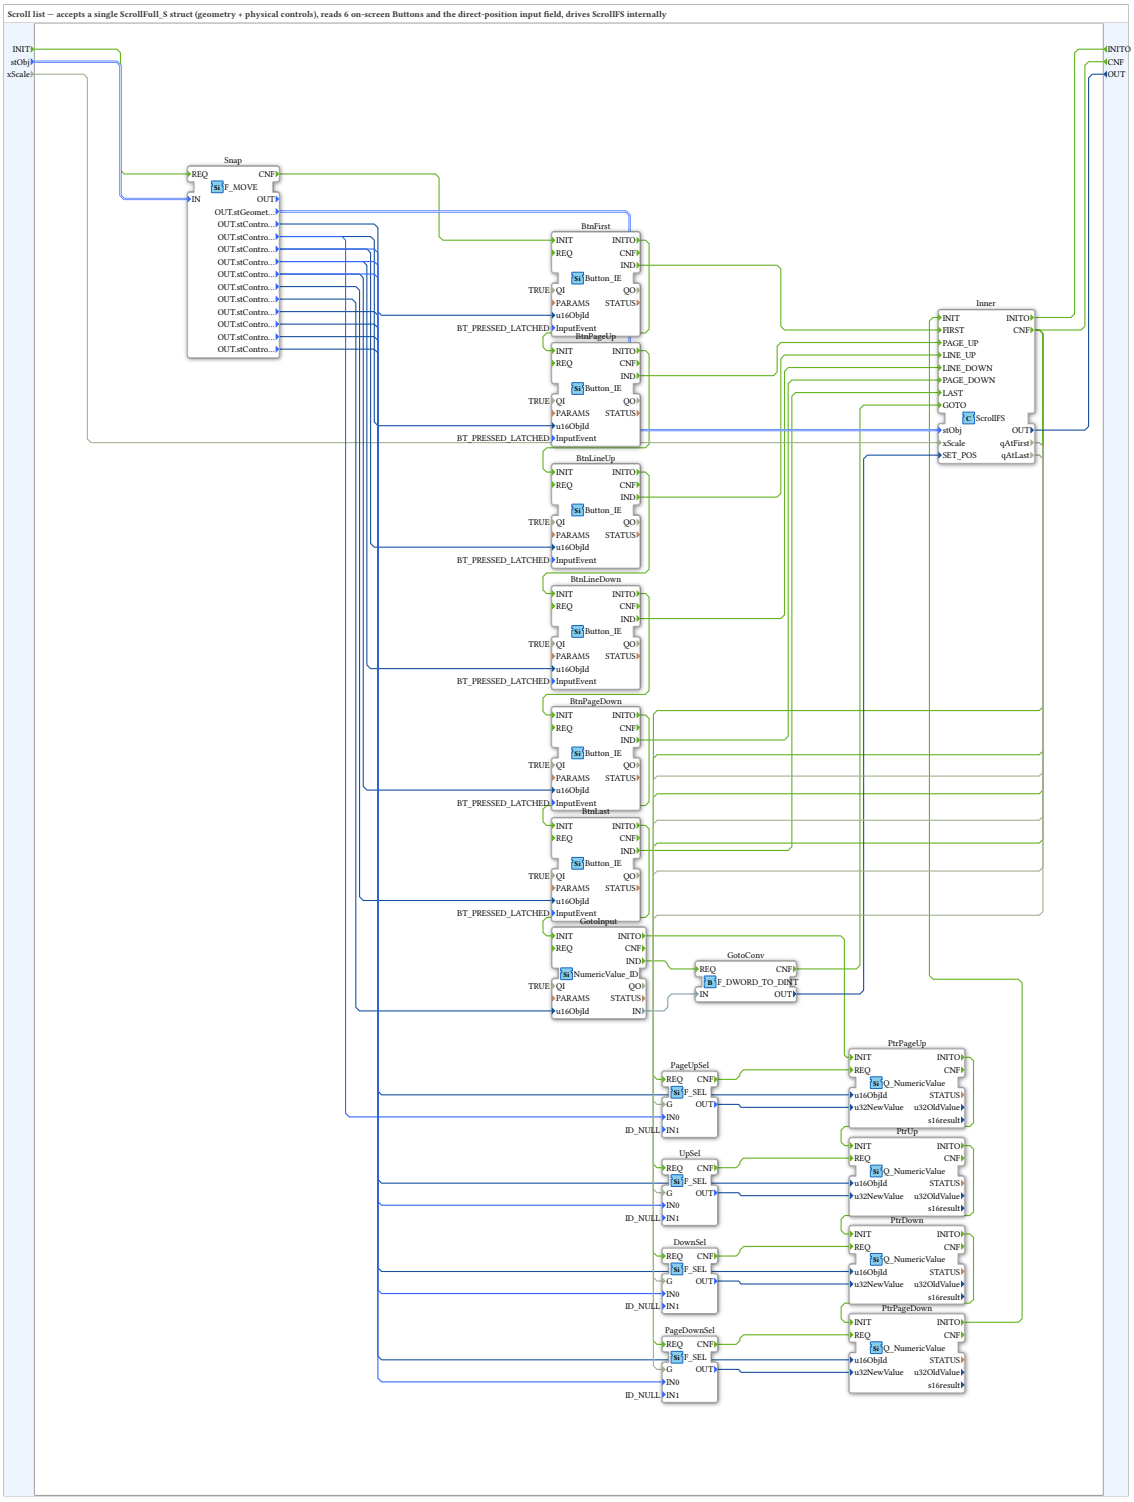
Application Scenarios

- Never used directly — always wrapped by ScrollFS_PHYS_Softkey (softkeys) or ScrollFS_PHYS_Button (on-screen buttons), which derive the eight navigation events from physical button presses.

⚖️ Comparison with Similar Blocks

- **Versus `RampLimitFS`**: `ScrollFS` is at its core a `RampLimitFS` with VT wiring - the position math itself (clamping, limit flags) lives entirely in `RampLimitFS`; `ScrollFS` only adds struct configuration, row/bar conversion, and writing to the VT.

🛠️ Related Exercises



- No standalone exercise example — see `Workspace_Scroll/SCROLL_KONZEPT.md` (project `4diac_training1`) for the full derivation against a real pool.

Conclusion

`ScrollFS` bundles the position state, limit detection, and VT write access of a scrollable list into a single, reusable composite block — independent of whether it's later operated via softkeys or on-screen buttons.

ScrollFS_PHYS_Button

• — ○ • — ○ • — ○ •

Introduction

`ScrollFS_PHYS_Button` is structurally identical to ScrollFS_PHYS_Softkey — the same finished, drop-in scroll block, the same `ScrollFull_S` constant, the same limit hiding — but reads the 6 controls as on-screen `Button` objects (`Button_IE`, listening for `BT_PRESSED_LATCHED`) instead of physical `SoftKey` objects. Intended for masks that need scrolling without a softkey column available (e.g. touch operation). The 6 IDs in `ScrollControls_S` then point at `Button` instead of `SoftKey` objects; otherwise `ScrollFull_S`/`ScrollControls_S` are unchanged. See `Workspace_Scroll/SCROLL_KONZEPT.md` (project `4diac_training1`) for the full derivation.

Interface Structure

Event Inputs

- `INIT`: Snapshots the complete configuration (`stObj`) (with `stObj`, `xScale`).

Event Outputs

- `INITO`: Initialization confirmation.
- `CNF`: Confirms a position change, delivers `OUT`.

Data Inputs

- `stObj` (`isobus::utils::scroll::ScrollFull_S`): complete configuration (geometry + control IDs), snapshotted at `INIT`.
- `xScale` (BOOL): FALSE (default) = bypass, TRUE = scale by the DM/SKM factor. Passed straight through to the internal `ScrollFS` instance.

Data Outputs

- `OUT` (DINT): Current scroll position (0…`stObj.stGeometry.i32PosMax`, in rows).

Adapters

No adapters available.

Functionality

Identical to ScrollFS_PHYS_Softkey, with one difference: the 6 controls are `Button_IE` instances (`BtnFirst`, `BtnPageUp`, `BtnLineUp`, `BtnLineDown`, `BtnPageDown`, `BtnLast`) listening for `BT_PRESSED_LATCHED` instead of `SK_PRESSED`. Everything else - direct entry via `NumericValue_ID+F_DWORD_TO_DINT`, the internal ScrollFS position engine, limit hiding via `F_SEL+Q_NumericValue` on the 4 ObjectPointer IDs - is identical to `ScrollFS_PHYS_Softkey`.

Technical Details

See ScrollFS_PHYS_Softkey, “Technical Details” section - everything described there (F_SEL direction, ObjectPointer vs. Key ID, serial init chain) applies unchanged. The only difference is the control type (`Button_IE` instead of `Softkey_IE`).

State Overview

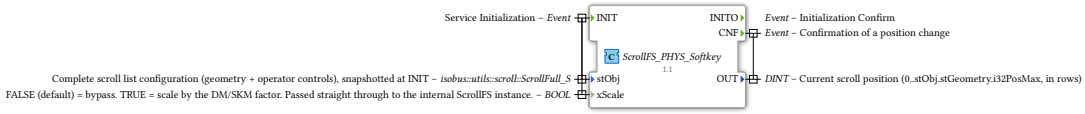
Same as ScrollFS_PHYS_Softkey - no state of its own beyond what `Inner` (`ScrollFS`/`RampLimitFS`) holds.

Application Scenarios

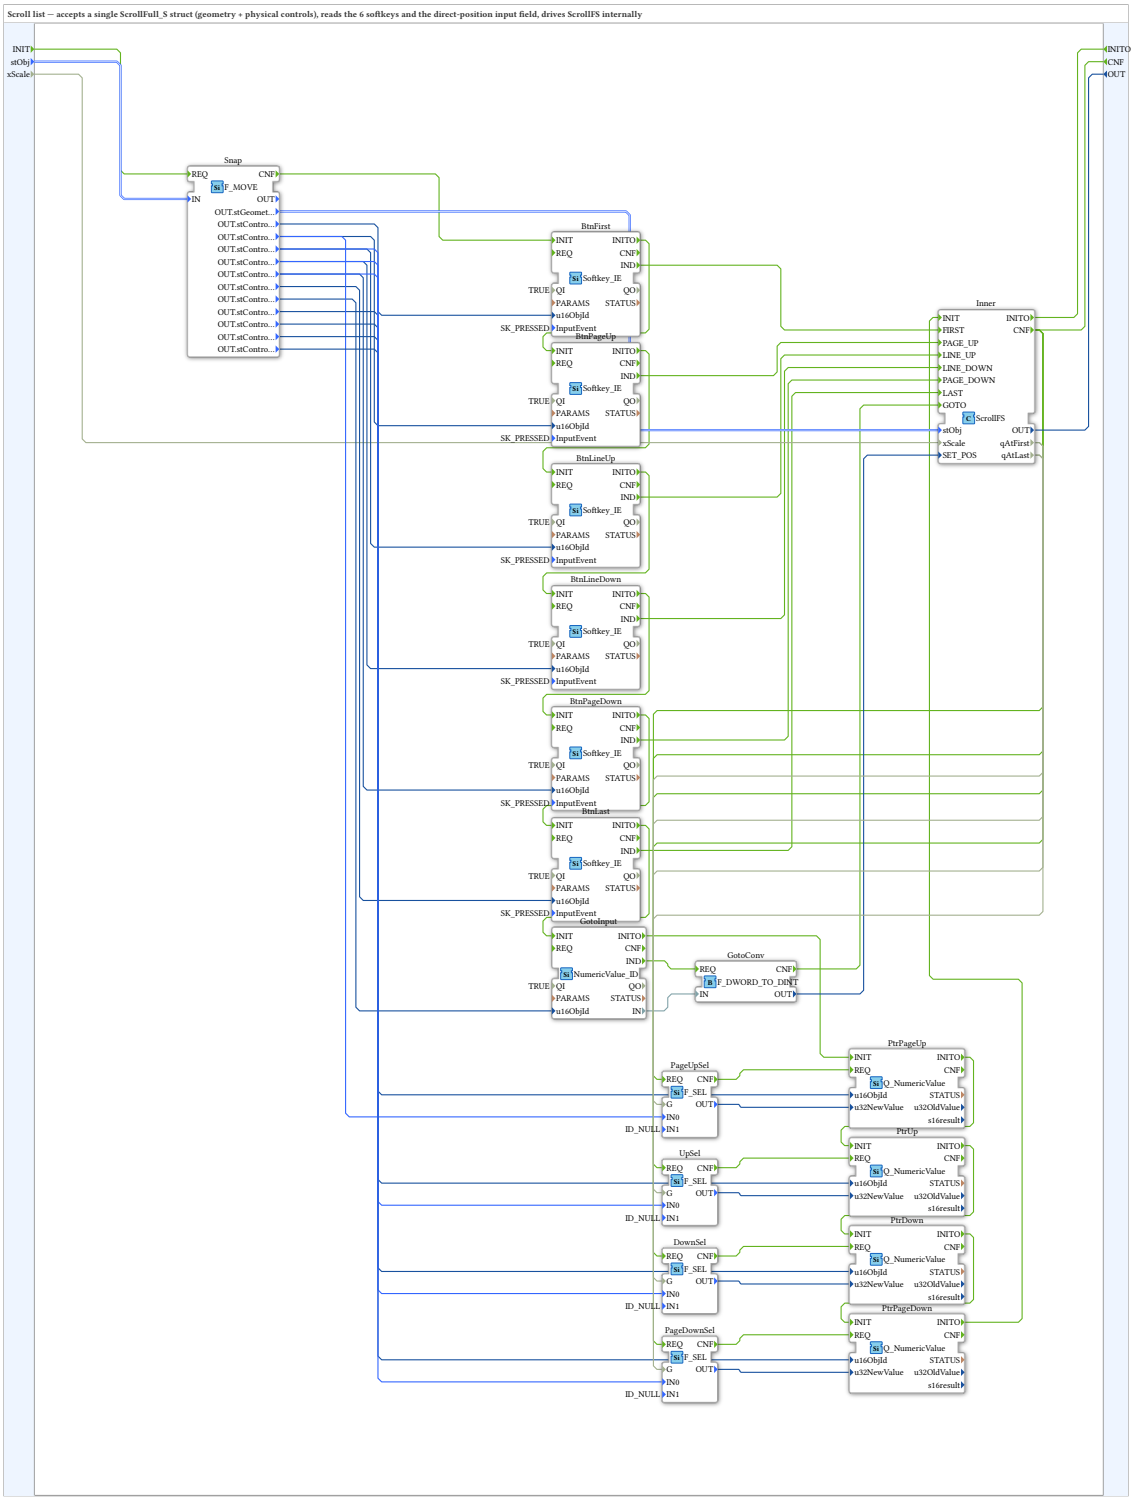
- Scrollable lists on masks without a softkey column, especially on touch-capable terminals where on-screen buttons are preferred over physical softkeys.

⚖️ Comparison with Similar Blocks

- **Versus `ScrollFS_PHYS_Softkey`**: identical except for the control type (`Button_IE`/`BT_PRESSED_LATCHED` instead of `Softkey_IE`/`SK_PRESSED`). See ScrollFS_PHYS_Softkey for the full description.
- **Versus `ScrollFS`**: `ScrollFS_PHYS_Button` is the practical wrapper - `ScrollFS` itself knows nothing about physical controls, only abstract navigation events.



🛠️ Related Exercises



- No standalone exercise example — see `Workspace_Scroll/SCROLL_KONZEPT.md` (project `4diac_training1`).

Conclusion

`ScrollFS_PHYS_Button` offers the same finished scroll functionality as `ScrollFS_PHYS_Softkey`, just for on-screen buttons instead of softkeys - which variant fits depends solely on which object type the controls are built as in the pool.

ScrollFS_PHYS_Softkey

• — ○ • — ○ • — ○ •

Introduction

ScrollFS_PHYS_Softkey is the finished, drop-in block for a scrollable VT list operated via softkeys: feed it a ScrollFull_S constant (as generated by GcfScript.py from the ISO-Designer pool) and it wires up the 6 physical softkeys, the direct-entry field, and the internal position engine ScrollFS itself — including automatic hiding of the scroll buttons at each list limit. Two lists on one mask = two instances, each with its own ScrollFull_S constant. See Workspace_Scroll/SCROLL_KONZEPT.md (project 4diac_training1) for the full derivation.

Interface Structure

Event Inputs

- INIT: Snapshots the complete configuration (stObj), with xScale.

Event Outputs

- CNF: Confirms a position change, delivers OUT.

Data Inputs

- stObj (isobus::utils::scroll::ScrollFull_S): complete configuration (geometry + control IDs), snapshotted at INIT.
- xScale (BOOL, initial value FALSE): FALSE = bypass, TRUE = scale by the DM/SKM factor. Passed straight through to the internal ScrollFS instance.

Data Outputs

- OUT (DINT): Current scroll position (0…stObj.stGeometry.i32PosMax, in rows).

Adapters

No adapters available.

Functionality

1. **Snap** (F_MOVE, DataType = ScrollFull_S): snapshots stObj at INIT, after which geometry and all control IDs are available as Snap.OUT.stGeometry/ Snap.OUT.stControls.<field>.
2. **6× Softkey_IE** (BtnFirst, BtnPageUp, BtnLineUp, BtnLineDown, BtnPageDown, BtnLast), each listening for SK_PRESSED, u16ObjId taken from the corresponding Snap.OUT.stControls.u16Btn*Id — their IND event directly fires the matching ScrollFS navigation event on Inner.
3. **GotoInput** (NumericValue_ID) + **GotoConv** (F_DWORD_TO_DINT): reads the direct-entry field (u16GotoInputId) and feeds the value as SET_POS into Inner.GOTO.
4. **Inner** (ScrollFS): the actual position engine, see ScrollFS. Inner.OUT is passed through directly as OUT.
5. **Limit hiding** - one chain of F_SEL + Q_NumericValue per direction (up side: BtnPageUp+BtnLineUp, down side: BtnPageDown+BtnLineDown), triggered on every position change (Inner.CNF):
   - F_SEL.G := Inner.qAtFirst (up side) or Inner.qAtLast (down side)
   - F_SEL.IN0 := the real SoftKey ID (Snap.OUT.stControls.u16Btn*Id) - value when **not** at the limit
   - F_SEL.IN1 := ID_NULL - value once the limit is reached (F_SEL.OUT := G ? IN1 : IN0)
   - Q_NumericValue.u16ObjId := the matching ObjectPointer ID (Snap.OUT.stControls.u16Btn*PtrId), .u32NewValue := F_SEL.OUT
   - Result: the SoftKeyMask's ObjectPointer points at ID_NULL at the limit (button disappears), otherwise at the real SoftKey (button visible).

Technical Details

- **F_SEL direction is not symmetric**: F_SEL.OUT := G ? IN1 : IN0 - if IN0/IN1 are swapped, the button shows exactly when it should disappear (and vice versa). This ordering (IN0 = visible value, IN1 = ID_NULL) was swapped in an earlier version and had to be corrected.
- **Q_NumericValue on the ObjectPointer instead of "Hide/Show Object"**: Object Pointers are not hidden/shown via the ISO 11783-6 "Hide/Show Object" command (Annex F.2, valid for Container only), but via "Change Numeric Value" (Annex F.22) applied directly to the ObjectPointer's own ID - that changes what the pointer targets (ID_NULL = points at nothing = invisible). Reference pattern: Uebung_015 (project 4diac_training1).
- **Don't confuse the ObjectPointer ID with the Key ID**: Snap.OUT.stControls.u16Btn*Id is the **real** SoftKey object ID (target for Softkey_IE.u16ObjId **and** for F_SEL.IN0), Snap.OUT.stControls.u16Btn*PtrId is the ID of the **ObjectPointer** that points at that SoftKey inside

the SoftKeyMask tree (target for `Q_NumericValue.u16ObjId`) - both are resolved automatically from the pool by `GcfScript.py` (the SoftKeyMask child is the ObjectPointer, whose target is the real SoftKey via a `CProxy` indirection).
- **Serial init chain**: `Snap.CNF → BtnFirst.INIT → … → BtnLast.INIT → GotoInput.INIT → PtrPageUp.INIT → PtrUp.INIT → PtrDown.INIT → PtrPageDown.INIT → Inner.INIT` - each block only initializes once the previous one is done (`INITO` chain), matching the pattern used in ScrollFS.

State Overview

No state of its own beyond what `Inner` (`ScrollFS`/`RampLimitFS`) holds. Limit hiding is purely event-driven — every position change recomputes the visibility state of all four buttons, not just on the actual limit transition.

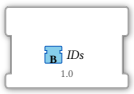
Application Scenarios

- Any scrollable VT list operated via physical softkeys (e.g. long selection lists, diagnostic/status overviews) - see `Workspace_Scroll` in project `4diac_training1` for a real, tested example.

⚖️ Comparison with Similar Blocks

- **Versus `ScrollFS`**: `ScrollFS_PHYS_Softkey` is the practical wrapper - `ScrollFS` itself knows nothing about physical controls, only abstract navigation events.
- **Versus `ScrollFS_PHYS_Button`**: identical structure and limit hiding, but reads the 6 controls as on-screen `Button` objects (`BT_PRESSED_LATCHED`) instead of `SoftKey` objects - for masks without a softkey column, or touch operation. See ScrollFS_PHYS_Button.

🛠️ Related Exercises



- No standalone exercise example — see `Workspace_Scroll/SCROLL_KONZEPT.md` (project `4diac_training1`).

Conclusion

`ScrollFS_PHYS_Softkey` is the complete, production-ready scroll block for softkey-operated lists - including automatic hiding of the navigation buttons at the limits, without the control application having to check limits or redirect Object Pointers itself.

const

IDs

• – ◦ • – ◦ • – ◦ •

Introduction

The global constant package `IDs` provides a collection of predefined, immutable values (constants) that can be used within function blocks of the IEC 61499 runtime environment. These constants primarily serve to improve the readability and maintainability of the source code by replacing magic numbers with meaningful identifiers. The package is defined in the namespace `isobus::UT::Q::const`.

Interface Structure

Because it is a package of global constants, it does not have event- or data-flow-based interfaces in the conventional sense of a function block. The constants are static and can be referenced directly by their names.

Event Inputs

Not present.

Event Outputs

Not present.

Data Inputs

Not present.

Data Outputs

Not present.

Adapters

Not present.

Functionality

The constants are replaced by their predefined values when the application is compiled. They behave like literals but have a semantic name. The constants included in the package are:

- `ID_NULL`: Represents an invalid or uninitialized identifier (ID) of type `UINT` with the hexadecimal value `16#FFFF` (decimal 65535).
- `ID_OFF`: Represents a special identifier value that signals "Off" or "Inactive," of type `UINT` with the value `16#0` (decimal 0).
- `GLOBAL`: An identifier of type `USINT` with the value `16#FF` (decimal 255), typically used for global or broadcast addressing.
- `OFF`: A simple status value of type `USINT` for the "Off" state with the value `16#0` (decimal 0).

Technical Features

- **Typing:** The constants are strongly typed (`UINT`, `USINT`). This ensures type safety when using them in assignments and comparisons.
- **Initial Value:** Each constant is assigned a fixed, unchanging initial value upon declaration.
- **Namespace:** The constants are encapsulated in the package `isobus::UT::Q::const`, preventing name conflicts with other libraries.

State Overview

Since these are static, constant values, there is no state machine.

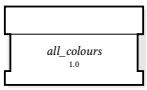
Application Scenarios

- **Initialization:** Assigning a defined initial value (e.g., `ID_NULL`) to variables that will later receive a valid ID.
- **Comparison:** Checking whether a received or read ID corresponds to a specific value (e.g., `IF receivedID = IDs.ID_OFF THEN ...`).
- **Parameterization:** Using constants as meaningful parameters in function blocks instead of direct numerical values.
- **Command and Status Values:** Using `OFF` and `GLOBAL` to control processes or address devices in a network.

⚖️ Comparison with Similar Blocks

Unlike function blocks (FBs) with algorithms and event handling, this package simply provides data. It is comparable to:

- **ENUM Data Types:** While ENUMs define a list of named integer values of a type, this package defines individual, loose constants of various types.
- **#define-Preprocessor Directives (in C):** Both replace a name with a value. However, the constants in `IDs` are type-safe and manageable in the 4diac IDE.



Conclusion

The global constant package `IDs` is a simple yet useful tool for structured programming in 4diac. It improves code quality, reduces typos in numeric values, and makes the programmer's intent explicit. Its use is especially recommended in larger projects or when working with protocols like ISOBUS, where special identifier values are common.

all_colours

• – ◦ • – ◦ • – ◦ •

Introduction

The GlobalConstants block **all_colours** provides an extensive color palette with 256 defined colors (0 to 255). Each color is defined as a constant of type `USINT` and has a fixed numerical value. The comments contain the corresponding hexadecimal code, the RGB value, and English and German color names. Colors 0 to 231 correspond to the standardized ISOBUS color space, while colors 232 to 255 are reserved for manufacturer-specific purposes and are assigned a neutral gray.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The colors are not provided via dedicated output variables, but are declared as global constants (`COLOR_0` … `COLOR_255`). These can be directly referenced by other function blocks.

Adapters

None.

Functionality

The function block declares the constants at system startup. The values are pre-initialized and remain unchanged throughout runtime. All constants are immediately valid and can be used in other function blocks without additional initialization. The numbering follows the ISOBUS standard, with the first 16 colors (0–15) covering the basic palette and the subsequent colors (16–231) containing more finely graduated shades.

Technical Features

- **Type:** `USINT` (0–255)
- **Standard Compliance:** Colors 0–231 are defined according to ISOBOBus; the remaining 24 entries (232–255) are manufacturer-specific and set to the same gray value (`#808080`).
- **Naming:** The designations `COLOR_0` … `COLOR_255` enable simple numerical referencing in algorithms or visualizations.
- **No Runtime Dependency:** The function block has no internal states or algorithms – it serves solely to provide constants.

State Overview

This function block has no state machines, as it is a purely declarative collection of constants.

Application Scenarios

- **ISOBUS-compliant UI development** in agricultural technology (terminals, machine controls)
- **Color coding of status information** (e.g., green = active, red = alarm, yellow = warning)
- **Standardization of colors** across multiple components or projects – all participants use the same color definition.

Comparison with similar function blocks

Unlike a typical `FUNCTION_BLOCK`, which processes input/output data and is controlled by events, `all_colours` is a **GlobalConstants** function block. It has no dynamic interfaces and no executable logic. Similar function blocks include, for example, `E_CTD` (counter) or `F_TRIG` (edge detection), which, however, exhibit active behavior. Other constant collections (e.g., physical units or thresholds) follow the same declarative pattern.

Conclusion

The `all_colours` function block provides a standardized, easily reusable color palette for ISOBUS applications. Clear numbering and comprehensive comments ensure consistent color usage across different modules and developers. Reserved colors (232–255) are available for customization.

colours

• – ○ • – ○ • – ○ •

Introduction

The global constant package `colours` defines a set of named constants for color values. These constants represent a set of 16 predefined colors, encoded by numeric values of type `USINT` (Unsigned Short Integer). Using such constants improves the readability and maintainability of IEC 61499 applications because meaningful identifiers like `COLOR_RED` or `COLOR_BLUE` can be used instead of magic numbers.

Interface Structure

A global constant package is not a function block in the classical sense; therefore, no event or data interfaces exist. Instead, the package provides a collection of constant declarations that can be imported and used in other function blocks or programs within the same project or namespace.

Event Inputs

Not applicable. Global constants do not have event inputs.

Event Outputs

Not applicable. Global constants do not have event outputs.

Data Inputs

Not applicable. Global constants do not have data inputs.

Data Outputs

Not applicable. Global constants do not have data outputs.

Adapters

Not applicable. Global constants do not have adapter interfaces.

How it Works

The `colours` package declares 16 constants of data type `USINT`. Each constant is assigned a fixed numeric value that represents a specific color. The values range from `USINT#0` to `USINT#15`. Once the package is imported into an application or function block, these constant names can be used wherever a `USINT` value is expected. The compiler replaces the constant name with the assigned numeric value during compilation.

Technical Details

- **Data Type:** All constants are of type `USINT` (Unsigned Short Integer), an unsigned 8-bit data type.
- **Value Range:** The defined values range from 0 to 15 and thus fit well within the value range of the `USINT` type.
- **Naming Convention:** The constant names follow the convention `COLOR_<FARBNAME>` (e.g., `COLOR_GREEN`), making them easily identifiable.
- **Compilation:** Values declared as `CONSTANT` are set at compile time and cannot be changed at runtime.

State Overview

Not applicable. Because they are static, unchanging values, global constants do not have a state machine.

Application Scenarios

This constant package is particularly useful in applications that require a limited color palette for user interfaces, visual status indicators (e.g., on HMIs or operator terminals), or for indicating process states. Typical use cases include:

- **Visualization:** Assigning colors to different machine states (e.g., Green = Operation, Red = Fault, Yellow = Warning).
- **ISOBUS-compliant applications (UT/Universal Terminal):** Standardizing color values in agricultural applications that use the ISOBUS protocol to ensure consistent display across different terminal devices.
- **Code improvement:** Replacing opaque numerical values in algorithms or configurations with self-explanatory identifiers.

⚖️ Comparison with similar building blocks

Unlike function blocks that execute logic or process data, a global constant package simply provides named values. Alternatives include:

1. **Direct use of numerical values:** Leads to code that is less readable and harder to maintain ("magic numbers").
2. **Defining constants within each function block:** Leads to redundancy and makes it difficult to centrally modify values.
3. **Using Enum Types:** Offers even greater type safety, but is not directly available as a global construct in the IEC 61499 standard library. Using `USINT` constants is a practical and widely used alternative.

Conclusion

The global constant package `colours` is a simple yet effective tool for structuring and improving IEC 61499 applications. By providing a standardized color palette as named constants, it promotes code quality, facilitates maintenance, and supports the development of consistent and understandable control applications, especially in the context of ISOBUS and visual interfaces.

####### AID

AID_AM

• – ◦ • – ◦ • – ◦ •

Introduction

The **AID_AM** global constant block defines attribute identifiers used within the ISO 11783 (ISOBUS) application layer for **Alarm Mask objects**. These constants provide standardized numeric IDs that allow applications to read or set specific attributes of an alarm mask, such as background colour, associated soft key mask, alarm priority, and acoustic signal configuration. The block is part of a package named `isobus::UT::Q::const::AID` and is intended to be used in 4diac-IDE projects that interact with ISOBUS terminals or implement virtual terminals.

Interface Structure

Since `AID_AM` is a **global constants** block, it does not contain event or data input/output ports. Instead, it exposes a set of compile-time constant values that can be referenced globally within the application.

Data Constants

Constant Name	Type	Initial Value	Description
`BACKGROUND_COLOUR`	`USINT`	1	Attribute ID for the background colour index of an Alarm Mask.
`SOFT_KEY_MASK`	`USINT`	2	Attribute ID for the object ID of a Soft Key Mask associated with the Alarm Mask.
`ALARM_PRIORITY`	`USINT`	3	Attribute ID for the alarm priority (0 = High, 1 = Medium, 2 = Low).

ACOUSTIC	USINT	4	Attribute ID for the acoustic signal setting (0 = highest priority, 1 = medium, 2 = lowest, 3 = silent).

Note: The constant values themselves are the attribute IDs that are used when communicating with an ISOBUS object pool or handling alarm mask properties.

Functionality

The primary purpose of AID_AM is to provide a human-readable and self-documenting set of constants that map to the numeric attribute IDs defined in the ISOBUS standard for alarm masks. Instead of hard-coding numeric values directly in function blocks or algorithms, developers can reference these constants to improve code clarity and maintainability. For example, to set the background colour of an alarm mask, one would use AID_AM.BACKGROUND_COLOUR as the attribute ID in a corresponding service call.

Technical Features

- **Standard Compliance**: The constants are aligned with ISO 11783-6 attribute definitions for Alarm Mask objects.
- **Type Safety**: All constants are declared as USINT (unsigned 8-bit integer), matching the expected attribute ID range (0–255).
- **Global Scope**: Being GLOBAL CONSTANT, they are accessible from any function block or resource in the project without explicit import.
- **Documentation**: Each constant includes a descriptive comment explaining its meaning and possible values.

State Overview

As a constants block, AID_AM has no internal state, states, or state transitions. It represents a static set of values that are available throughout the execution of the application.

Application Scenarios

- **Virtual Terminal Integration**: When implementing an ISOBUS virtual terminal or client, these constants are used to build or modify alarm mask attribute messages (e.g., Set Attribute, Get Attribute).
- **Alarm Handling**: In an agricultural machine control system, the constants help manage alarm priorities, acoustic feedback, and visual appearance of alarms on the terminal.
- **Object Pool Creation**: Developers creating an ISOBUS object pool for a terminal can use these IDs to correctly encode attribute references.

Comparison with Similar Blocks

AID_AM is one of several attribute-identifier constant blocks defined in the same package (e.g., AID_WK, AID_AR, etc.). While other blocks define attribute IDs for working sets, soft key masks, or other object types, AID_AM specifically targets alarm masks. Its simplicity lies in the absence of any logic or interface; it purely provides constants. Unlike a complex function block, it cannot fail, execute, or be reused in a state machine; it exists only to be referenced.

Conclusion

The AID_AM global constants block is a small but essential utility for ISOBUS applications dealing with alarm masks. By centralizing the attribute IDs, it reduces the risk of typing errors, improves code readability, and ensures consistency across the project. It is a perfect example of using compile-time constants to bring clarity to a standards-based communication protocol.

AID_AO

• – ◦ • – ◦ • – ◦ •

Introduction

AID_AO is a global constant definition block used in the 4diac IDE for the ISO 11783 (ISOBUS) Virtual Terminal protocol. It defines the attribute identifiers (AID) for animation objects (AO) within an ISOBUS Universal Terminal (UT) object pool. The block provides symbolic constant names that map to numerical attribute IDs, making configuration code more readable and maintainable when working with animation objects.

Interface Structure

AID_AO is a GlobalConstants type, not a function block or adapter. It contains no event or data interfaces. Instead, it exposes a set of global constant values of type USINT, available throughout the package `isobus::UT::Q::const::AID`.

Event Inputs

None.

Event Outputs

None.

Data Inputs

The following constants are defined as global, read-only values:

Name	Type	Value	Description
WIDTH	USINT	1	AID_AO_WIDTH – Width in pixels.
HEIGHT	USINT	2	AID_AO_HEIGHT – Height in pixels.
REFRESHINT	USINT	3	AID_AO_REFRESHINT – Refresh interval.
VALUE	USINT	4	AID_AO_VALUE – Current value.
ENABLED	USINT	5	AID_AO_ENABLED – 0 = Stopped, 1 = Animating.
FICHILDINDEX	USINT	6	AID_AO_FICHILDINDEX – First child index.
LACHILDINDEX	USINT	7	AID_AO_LACHILDINDEX – Last child index.
DEFCHILDINDEX	USINT	8	AID_AO_DEFCHILDINDEX – Default child index.
OBJECTS	USINT	9	AID_AO_OBJECTS – Options: Bit 0 = Animation Sequence (0 = Single Shot, 1 = Loop); Bits 1–2 = Disabled Behaviour (0 = Pause, 1 = Reset to First, 2 = Default Object, 3 = Blank).

Data Outputs

None.

Adapters

None.

Functionality

The AID_AO global constants serve as named references for the attribute IDs that configure and control ISOBUS animation objects. Each constant corresponds to a specific attribute used in the UT object pool:

- **WIDTH** and **HEIGHT** define the pixel dimensions of the animation object.
- **REFRESHINT** specifies the refresh interval for animation updates.
- **VALUE** holds the current animation value.
- **ENABLED** controls whether the animation is stopped or running.
- **FICHILDINDEX**, **LACHILDINDEX**, and **DEFCHILDINDEX** identify the first, last, and default child object indices respectively.
- **OBJECTS** packs two configuration options into one byte: the animation sequence mode (single shot or loop) and the behaviour when the animation is disabled (pause, reset to first, show default object, or blank).

These constants improve code readability and reduce the risk of errors that would occur if raw numeric IDs were used directly.

Technical Features

- Compliant with IEC 61499-1 standard for GlobalConstants.
- All constants are of type USINT (8-bit unsigned integer).
- Values are fixed at compile time and cannot be modified during runtime.
- The block is defined within the package namespace `isobus::UT::Q::const::AID`.

- The OBJECTS constant demonstrates bitwise encoding of multiple configuration flags into a single byte.

State Overview

Not applicable. AID_AO is a passive constant definition and does not implement stateful or sequential behaviour.

Application Scenarios

AID_AO is applied in ISOBUS Virtual Terminal applications where animation objects are configured and dynamically controlled. Typical use cases include:

- Setting the dimensions of an animation object via WIDTH and HEIGHT.
- Configuring the refresh rate with REFRESHINT.
- Starting or stopping animations using ENABLED.
- Reading or setting the current animation value via VALUE.
- Managing child object ordering with FICHILDINDEX, LACHILDINDEX, and DEFCHILDINDEX.
- Selecting animation mode (loop vs. single shot) and disabled behaviour through OBJECTS.

Comparison with Similar Blocks

AID_AO belongs to a family of attribute ID constant definitions used in ISOBUS VT contexts. Unlike function blocks, which encapsulate behaviour and state transitions, AID_AO provides only static constant values. It is comparable to other AID constant groups (e.g., for object types or control functions) but focuses specifically on animation objects. Its advantage lies in providing a single, consistent source of truth for animation attribute identifiers, eliminating magic numbers in application code.

Conclusion

AID_AO is a compact and well-structured global constant set that centralises all animation object attribute identifiers in an ISOBUS environment. By offering symbolic names for numeric IDs and encoding complex options into a single byte, it enhances code clarity, maintainability, and correctness. It is a fundamental building block for developers implementing ISOBUS Virtual Terminal animations within the 4diac IDE.

AID_AUXC2

• – ◦ • – ◦ • – ◦ •

Introduction

The AID_AUXC2 global constants provide the attribute identifiers for the Auxiliary Control Designator Type 2 (AuxC2) object within the ISOBUS (ISO 11783) protocol. These constants define the numeric IDs used to reference the pointer type and object ID attributes of an auxiliary control designator of type 2. The constants belong to the package `isobus::UT::Q::const::AID` and are used to standardize attribute access in ISOBUS device implementations.

Interface Structure

AID_AUXC2 is a global constant container and does not expose a runtime interface. Consequently, it has no event or data inputs/outputs or adapters.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None. The following global constants are provided instead:

Constant	Data Type	Initial Value	Description
`PTR_TYPE`	USINT	`USINT#1`	Attribute ID 1 (`AID_AUXC2_PTR_TYPE`) – Pointer Type. Defines what the pointer of the AuxC2 object references: 0 = Points to Aux Object, 1 = Points to Aux Function/Input, 2 = Points to Working Set owner of pointer, 3 = Points to Working Set owner of assigned function/input.

OBJ_ID	USINT	USINT#2	Attribute ID 2 (AID_AUXC2_OBJ_ID) – Object ID. Contains the object ID of a referenced Auxiliary Function or Auxiliary Input object, or NULL.

Data Outputs

None.

Adapters

None.

Functionality

The AID_AUXC2 constants are used as attribute identifiers when accessing the properties of an Auxiliary Control Designator Type 2 object in an ISOBUS system. In the ISOBUS standard, every object property is addressed via an attribute ID. These constants map the human-readable property names (PTR_TYPE, OBJ_ID) to their numeric attribute identifiers (1 and 2).

By using these pre-defined constants, application code can avoid magic numbers and ensure compliance with the ISOBUS attribute ID scheme. The PTR_TYPE constant distinguishes between different pointer destinations, while OBJ_ID specifies the referenced auxiliary object.

Technical Features

- **Global constant container**: The constants are declared as GLOBALCONSTANTS and can be referenced throughout a 4diac-IDE project without instantiation.
- **Unsigned short integer type**: Both constants are of type USINT (8-bit unsigned integer) which matches the ISOBUS attribute ID field size.
- **Pre-initialized values**: The initial values correspond to the official ISOBUS attribute IDs.
- **Package scoping**: The constants are located in the package isobus::UT::Q::const::AID, providing a clear namespace for auxiliary control designator constants.
- **SPDX-License-Identifier**: The implementation is provided under the Eclipse Public License 2.0.

State Overview

Since AID_AUXC2 is a compile-time constant set, it does not maintain any runtime state. No state transitions or lifecycle management is required.

Application Scenarios

The AID_AUXC2 constants are intended to be used in ISOBUS-compliant agricultural machinery control systems that implement the Auxiliary Control Designator Type 2 functionality. Typical applications include:

- ISOBUS Universal Terminal (UT) implementations that need to read or write the auxiliary control designator properties.
- Implement control ECU (Tractor-Implement Management) software that processes AuxC2 objects.
- Diagnostic and configuration tools that operate on the auxiliary control interface.

Comparison with Similar Blocks

The AID_AUXC2 constants are specifically tailored for Auxiliary Control Designator Type 2 objects. Other constant sets exist in the isobus::UT::Q::const::AID package for different object types (e.g., auxiliary control designator type 1). While those sets share the same pattern of numeric attribute IDs, their actual values and semantics differ based on the respective object type. The AID_AUXC2 set focuses solely on the two attributes required to define a type 2 pointer and its referenced object.

Conclusion

The AID_AUXC2 global constants provide a standardized, type-safe way to reference the attribute IDs of Auxiliary Control Designator Type 2 objects in ISOBUS applications. By encapsulating the numeric IDs as named constants, the component enhances code readability, reduces error-proneness, and ensures interoperability with the ISOBUS protocol specification.

AID_AUXF2

• – ◦ • – ◦ • – ◦ •

Introduction

AID_AUXF2 is a `GLOBALCONSTANTS` type in 4diac-ide that defines the object attribute IDs of an ISO 11783 ISOBUS Auxiliary Function Type 2 (AUX-F2) object. It is not an executable function block, but a compile-time constant container that makes object attribute IDs available as named symbols. The constants are part of the namespace `isobus::UT::Q::const::AID`.

Interface Structure

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

AID_AUXF2 does not have a dynamic IEC 61499 interface with event or data ports. Instead, it provides the following global constants:

Constant	Type	Value	Description
`BACKGROUND_COLOUR`	`USINT`	`USINT#1`	Background colour index attribute ID.
`FUNC`	`USINT`	`USINT#2`	Function attribute ID. Value is a bitmask: bits 0-4 = auxiliary function type (0-14), bit 5 = critical control, bit 6 = assignment restriction, bit 7 = single-assignment.

Functionality

The purpose of AID_AUXF2 is to provide named constants for the attribute IDs used by an Auxiliary Function Type 2 object. The two constants allow application code to refer to AUX-F2 attributes without using hard-coded integer values.

- `BACKGROUND_COLOUR` identifies the background colour index attribute.
- `FUNC` identifies the auxiliary function attribute and describes the function as a bitmask.

Because these values are global constants, they can be used in expressions, comparisons, or case selections without requiring runtime initialization or additional storage.

Technical Features

- Defined as `GLOBALCONSTANTS`, not as an executable function block.
- Both constants are of type `USINT`.
- `BACKGROUND_COLOUR` has the fixed value `1`.
- `FUNC` has the fixed value `2`.
- The constants are available in the namespace `isobus::UT::Q::const::AID`.
- The container has no events, data inputs, data outputs, adapters, or algorithms.
- The `FUNC` attribute uses bits 0-4 for the auxiliary function type, bit 5 for critical control, bit 6 for assignment restriction, and bit 7 for single-assignment.

State Overview

Not applicable. A `GLOBALCONSTANTS` type has no ECC state machine, no execution states, and no runtime behavior. The constants are static and are available to all IEC 61499 resources that reference this definition.

Application Scenarios

- **ISOBUS Virtual Terminal applications**: Use `AID_AUXF2.BACKGROUND_COLOUR` and `AID_AUXF2.FUNC` as attribute IDs when working with Auxiliary Function Type 2 objects.

- **Object pool generation**: Reference the constants when creating or modifying AUX-F2 object attributes in an ISOBUS object pool.
- **Readability improvement**: Replace numeric attribute IDs with symbolic names to reduce errors and improve code maintainability.

Example usage:

```
IF attrID = AID_AUXF2.FUNC THEN
    (* Process auxiliary function bitmask *)
END_IF
```

Comparison with Similar Blocks

AID_AUXF2 is not a function block and therefore cannot be compared with function blocks in terms of events, states, or data flow. It is best compared with other global constant containers that define ISOBUS object attribute IDs. Similar containers exist for other auxiliary function object types, such as Auxiliary Function Type 1 or Type 3. The main difference is the object type being addressed and the set of attribute IDs defined by each container. AID_AUXF2 is specifically dedicated to the Auxiliary Function Type 2 object and defines the two attribute IDs relevant for this object.

Conclusion

AID_AUXF2 is a compact global constant definition that provides named attribute IDs for ISOBUS Auxiliary Function Type 2 objects. By defining `BACKGROUND_COLOUR` and `FUNC` as named constants, it improves code clarity, reduces the use of magic numbers, and supports maintainable VT application development in 4diac-ide.

AID_AUXI2

• – ◦ • – ◦ • – ◦ •

Introduction

AID_AUXI2 is a global constant definition within the `isobus::UT::Q::const::AID` package of the 4diac-ide environment. It encapsulates a set of attribute identifiers (AIDs) specifically related to the ISO 11783 (ISOBUS) Auxiliary Input Type 2 object. These constants are used to reference individual attributes of an Auxiliary Input Type 2 object when interacting with ISOBUS virtual terminal data structures. The definition provides stable, human-readable symbolic names for the underlying attribute ID values, improving code clarity and maintainability in ISOBUS application implementations.

Interface Structure

Since AID_AUXI2 is a global constant definition rather than a function block, adapter, or subapplication, it does not expose event/data interfaces or adapters. Instead, it declares two global constants that can be referenced by other FB types across the project.

Constant	Type	Initial Value	Description
`BACKGROUND_COLOUR`	`USINT`	`1`	Attribute ID 1: Background colour index of the auxiliary input type 2 object.
`FUNC`	`USINT`	`2`	Attribute ID 2: Bitmask encoding the auxiliary function type (bits 0–4), critical control flag (bit 5), reserved bit (bit 6, set to 0), and single-assignment flag (bit 7).

Event Inputs

- None (not applicable for a global constant definition).

Event Outputs

- None (not applicable for a global constant definition).

Data Inputs

- None (not applicable for a global constant definition).

Data Outputs

- None (not applicable for a global constant definition).

Adapters

- None (not applicable for a global constant definition).

Functionality

The AID_AUXI2 global constants provide the numeric attribute ID values used to address attributes of an Auxiliary Input Type 2 (AUXI2) object within an ISOBUS virtual terminal. The constants enable code to refer to these attributes symbolically rather than using magic numbers:

- `BACKGROUND_COLOUR` is the attribute ID for the background colour index of the object.
- `FUNC` is the attribute ID for the function descriptor, a bitmask with the following layout:
  - Bits 0–4: Auxiliary function type (values 0–14).
  - Bit 5: Critical Control flag.
  - Bit 6: Reserved, must be set to 0.
  - Bit 7: Single-assignment flag.

These constants are intended to be used in conjunction with ISOBUS object pool manipulation APIs, where an attribute ID is required to specify which property of an object is being read or written.

Technical Features

- **Fixed Identification**: Each constant maps directly to a standardized ISOBUS attribute ID (1 and 2 respectively).
- **Type Safety**: Constants are declared as `USINT` (unsigned short integer), matching the ISOBUS attribute ID data type.
- **Single Assignment**: Defined as `VAR_GLOBAL CONSTANT`, the values are immutable at runtime.
- **Bit-Level Semantics**: The `FUNC` constant encodes multiple flags in a single byte, requiring bitwise operations to decode or set individual bits.
- **Package Organization**: Placed in the `isobus::UT::Q::const::AID` package namespace for structured reuse across FBs.

State Overview

A global constant definition is stateless. There is no internal state, no initialization sequence, and no runtime transitions. The values are available immediately once the containing project is loaded and remain constant throughout the execution lifetime.

Application Scenarios

- **ISOBUS Virtual Terminal Implementation**: When constructing an Auxiliary Input Type 2 object in an object pool, developers use `AID_AUXI2.BACKGROUND_COLOUR` to set or read the background colour attribute.
- **Auxiliary Function Configuration**: The `FUNC` constant is used when configuring the functional behaviour of an auxiliary input (e.g., setting the function type, marking an input as critical, or enforcing single assignment).
- **Attribute Iteration**: The constants can be used as enumeration values when building generic attribute-handling routines for AUXI2 objects.
- **Protocol Debugging**: In diagnostic tools, the symbolic names make trace logs and breakpoints more readable than raw attribute ID numbers.

Comparison with Similar Blocks

AID_AUXI2 is part of a family of attribute ID constant sets for different ISOBUS object types (e.g., `AID_AUXI1`, `AID_AUXI2`, `AID_*`). Compared to similar constant sets:

- It is specific to the Auxiliary Input Type 2 object, thus its attribute list covers only background colour and function descriptor.
- It does not contain attributes for labels, visibility, or other object properties that are common in other object type constant sets (e.g., Button, Output, or Input Boolean objects).
- Its `FUNC` constant provides a richer bitmask definition than simpler attribute constants, reflecting the unique capabilities of auxiliary input objects.
- Unlike FB-based implementations, it offers no processing logic, only the constant data, making it lighter and purely declarative.

Conclusion

AID_AUXI2 is a concise and well-structured global constant definition that encapsulates the essential attribute IDs for ISOBUS Auxiliary Input Type 2 objects. By providing symbolic names for the background colour and function descriptor attributes, it enhances the readability and type safety of ISOBUS application code. Its stateless, immutable nature makes it a reliable and reusable building block within the 4diac-ide environment for agricultural machinery communication systems.

AID_BO

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_BO` global constants type defines symbolic names for the attribute identifiers used to describe a button object in the ISOBUS (ISO 11783) standard. These identifiers are used when reading or writing button properties via the ISO-11783 protocol, providing a clear and maintainable way to refer to numeric attribute codes in application code.

Interface Structure

Since `AID_BO` is a global constants type, it does not contain any input or output variables in the traditional function-block sense. Instead, it exposes a set of read-only constant values that can be used throughout the application. These constants are listed below under **Data Outputs** for clarity, although they are not dynamic outputs.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The following global constants are available within the `isobus::UT::Q::const::AID` package.

Constant Name	Type	Value (USINT)	Description
`WIDTH`	USINT	1	`AID_BO_WIDTH` – Width of the button in pixels.
`HEIGHT`	USINT	2	`AID_BO_HEIGHT` – Height of the button in pixels.
`BACKGROUND_COLOUR`	USINT	3	`AID_BO_BACKGROUND_COLOUR` – Background colour index.
`BORDER_COLOUR`	USINT	4	`AID_BO_BORDER_COLOUR` – Border colour index.
`KEY_CODE`	USINT	5	`AID_BO_KEY_CODE` – Key code associated with the button.
`OPTIONS`	USINT	6	`AID_BO_OPTIONS` – Bitmask containing several options:- Bit 0: latchable- Bit 1: state (0 = released, 1 = latched)- Bit 2: suppress border- Bit 3: transparent background- Bit 4: disabled- Bit 5: no border

Adapters

None.

Functionality

The `AID_BO` constants serve as a centralised registry for button object attribute identifiers. In an ISOBUS application, object attributes are addressed by numeric IDs. Using symbolic constants improves code readability and reduces the risk of errors caused by hard-coded numeric values. The package name

`isobus::UT::Q::const::AID` indicates that these constants belong to the ISOBUS utility toolkit (`UT`) and are part of the `Q` – likely "query" or "quick" – subcomponent.

The `OPTIONS` constant is particularly important as it encapsulates a bit-coded behaviour of the button. Applications can evaluate individual bits to determine the button's properties (e.g., whether it is latchable, its current latched state, whether the border is suppressed, etc.).

Technical Features

- **Data type**: All constants are of type `USINT` (unsigned short integer, 8-bit).
- **Initial values**: Each constant is explicitly initialised to its corresponding attribute ID.
- **Package**: `isobus::UT::Q::const::AID` – the global constants are grouped under this package, allowing namespaces to be used in IEC 61499 applications.
- **Compatibility**: The identifiers follow the official ISO 11783-6 (ISOBUS) attribute definitions, ensuring interoperability with other ISOBUS-compliant devices.
- **Source availability**: The original source code is embedded in the XML, making the definitions self-contained and accessible for reference.

State Overview

The `AID_BO` type has no dynamic state information. It is a static collection of constants that do not change during runtime. The values are fixed at compile time and remain unchanged throughout the execution of the application.

Application Scenarios

Typical use cases for `AID_BO` include:

- **Implementation of an ISOBUS-VT (Virtual Terminal) client**: When constructing or updating a button object on the VT, the application needs to send attribute IDs for width, height, background colour, etc. Using `AID_BO` constants makes the code self-documenting and less prone to mistakes.
- **Parsing feedback messages**: When the VT sends back the current state of a button (e.g., latched or released), the application can interpret the `OPTIONS` value by referencing the bits defined in this constant.
- **Maintenance and debugging**: Developers can trace protocol messages more easily when symbolic names are used in log output.

Comparison with Similar Blocks

While `AID_BO` is a global constants type, other similar constant types may exist for other ISOBUS objects (e.g., `AID_AL` for alarm objects, `AID_NM` for numerical display, etc.). These constants typically follow the same pattern – each object type has a dedicated set of attribute identifiers defined as USINT constants. The advantage of such symbolic constants over raw numbers is consistency and clarity across a project. Compared to function blocks, `AID_BO` does not contain any logic or user interface; it is purely a data dictionary.

Conclusion

The `AID_BO` global constants provide a well-structured and standardised way to reference button object attributes in an ISOBUS application. By using these symbolic names, developers can write more reliable and maintainable code, reduce the chance of encoding errors, and improve overall readability of IEC 61499 applications that interface with ISOBUS virtual terminals. The explicit packaging under `isobus::UT::Q::const::AID` further enhances modularity and integration into larger projects.

AID_CO

• – ◦ • – ◦ • – ◦ •

Introduction

AID_CO is a global constants definition block within the ISOBUS UT (Universal Terminal) interface library, specifically in the `isobus::UT::Q::const::AID` package. It defines constant attribute identifiers (IDs) used to reference attributes of container objects (CO) in ISOBUS object pool implementations. These attribute IDs conform to ISO 11783-6 (ISOBUS) standards for Universal Terminal object containers.

The constants map semantic meanings (e.g., width, height, hidden state) to numeric attribute IDs used in communication between a Virtual Terminal (VT) and an implement ECU.

Interface Structure

This component is not a function block or adapter; it defines global compile-time constants. As such, it has no event inputs/outputs, no data I/O ports, and no adapters in the runtime sense. The constants act as named identifiers for use in application logic.

Event Inputs

Not applicable – no event inputs are defined in this global constants container.

Event Outputs

Not applicable – no event outputs are defined in this global constants container.

Data Inputs

Not applicable – this global constants container does not accept external data inputs.

Data Outputs

Not applicable – this global constants container does not provide dynamic data outputs. Instead, it exposes the following compile-time constants:

Constant	Type	Value	Attribute ID	Description
`WIDTH`	USINT	1	AID_CO_WIDTH	Maximum width of the container's area in pixels. Objects or portions outside this area are clipped.
`HEIGHT`	USINT	2	AID_CO_HEIGHT	Maximum height of the container's area in pixels. Objects or portions outside this area are clipped.
`HIDDEN`	USINT	3	AID_CO_HIDDEN	0 = FALSE, 1 = TRUE. Indicates whether this container and its child objects are hidden.

Adapters

Not applicable – no adapters are defined.

Functionality

The AID_CO global constants provide numeric identifiers for the standard attributes of ISOBUS container objects. These constants are used when constructing attribute lists in object pool building or when setting/reading object attributes at runtime via the ISOBUS protocol. Using named constants instead of raw numeric values improves code readability and maintains compliance with the ISO 11783-6 specification.

- `WIDTH` (1) and `HEIGHT` (2) define the clipping boundary of the container's drawing area.
- `HIDDEN` (3) controls the visibility of the container and its child objects.

Technical Features

- Defined in the `isobus::UT::Q::const::AID` package.
- All constants are of type `USINT` (Unsigned Short Integer) with explicit initialization.
- Values are aligned with the ISO 11783-6 attribute ID enumeration for container objects.
- Constant values are compile-time evaluated and cannot be changed at runtime.
- License: Eclipse Public License 2.0 (EPL-2.0).
- Version: 1.0, published 2026-06-20.

State Overview

This component has no internal state machine or runtime states. It is a purely declarative constants container. All values are constant and available at compile time.

Application Scenarios

- **ISOBUS Object Pool Generation:** Use `AID_CO.WIDTH`, `AID_CO.HEIGHT`, and `AID_CO.HIDDEN` when creating container object attributes in an object pool for a Virtual Terminal.
- **VT Runtime Communication:** Refer to these constants when setting or requesting container object attributes over the ISOBUS network.
- **Clipping and Visibility Control:** Apply the `HIDDEN` attribute (value 3) to show or hide containers dynamically, and `WIDTH`/`HEIGHT` to define the container's clipping rectangle.

Comparison with Similar Blocks

In the ISOBUS `AID_*` constant families, `AID_CO` is responsible for container object attributes specifically. Similar constant groups include:

- `AID_OB` – object base attributes.
- `AID_WO` – working set attributes.
- `AID_OK` – object key attributes.

While those constants define attributes for other object types (e.g., buttons, keys, working sets), `AID_CO` focuses exclusively on container objects as defined in ISO 11783-6. Compared to generic numeric literals, using `AID_CO` constants increases readability and reduces the risk of using incorrect attribute IDs.

Conclusion

The `AID_CO` global constants block provides a standardized, human-readable set of attribute identifiers for ISOBUS container objects. It is a lightweight, compile-time-only component that aids in implementing ISO 11783-6 compliant object pools and VT communication logic. Its use improves maintainability and ensures consistency across applications using the `isobus::UT::Q::const::AID` library.

AID_CP

• – ◦ • – ◦ • – ◦ •

Introduction

The **AID_CP** global constants definition provides a set of named constant values used as attribute identifiers for colour palette objects in the ISOBUS (ISO 11783) protocol context. It is part of the `isobus::UT::Q::const::AID` package and contains a single constant, `OPTIONS`, which is used to reference the options attribute of a colour palette object.

Interface Structure

Since `AID_CP` is a global constants declaration (not a function block, adapter, or subapplication), it does not define event or data interfaces in the traditional sense. However, for consistency with the documentation template, the following sections explicitly state that no I/O elements are present.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

The sole constant defined within `AID_CP` is:

- **OPTIONS** (USINT) – Value `USINT#1`. This constant represents the attribute ID for the “Options” field of a colour palette object. According to the ISOBUS specification, the options attribute is always set to 0, but the constant is defined to standardise access to it in code.

Functionality

The purpose of `AID_CP` is to provide a central, reusable definition for the colour palette object attribute identifier. By using this constant, developers can avoid hard-coding numeric values in their logic and can ensure consistency across the system. The constant `OPTIONS` is intended to be used wherever the options attribute of a colour palette object needs to be referenced, e.g., in get/set operations or in communication frames.

Technical Features

- **Constant Data Type:** `USINT` (unsigned short integer, 8–bit).
- **Initial Value:** `1` (although the comment notes that the actual option value is always `0`; the constant serves as an attribute ID, not as a value).
- **Namespace:** The constant is defined within the `isobus::UT::Q::const::AID` package, aligning with ISOBUS utility layer conventions.
- **Packaging:** The XML declaration includes a standard identification and version information, making it suitable for exchange in 4diac-ide projects.

State Overview

As a global constants object, `AID_CP` does not have internal states or transitions. It is a compile-time constant set; its value is fixed at design time and does not change during runtime.

Application Scenarios

Typical use cases include:

- Implementing ISOBUS colour palette management in agricultural machinery control systems.
- Providing a shared constant for attribute identification across multiple function blocks or applications that handle colour palette objects.
- Serving as a reference in test and simulation environments where colour palette attributes are accessed.

Comparison with Similar Blocks

Unlike function blocks (which encapsulate behaviour and have event/data interfaces) or adapters (which define communication patterns), `AID_CP` is a passive data container. It cannot be instantiated or executed; it simply provides named constants. Similar global constants objects in the ISOBUS domain exist for other object types (e.g., AID_GA for geometric attributes), each following the same pattern of defining attribute IDs as named constants.

Conclusion

The `AID_CP` global constants object defines a single, well-documented constant (`OPTIONS`) for colour palette object attribute identification. It contributes to code clarity and maintainability by centralising an otherwise numeric value in a descriptive, reusable form. This approach aligns with best practices for ISOBUS development in the 4diac environment.

AID_DM

• – ◦ • – ◦ • – ◦ •

Introduction

AID_DM is a global constant definition used within 4diac IDE to define attribute identifiers for data mask objects in the ISOBUS protocol. It provides symbolic constants for background colour and soft key mask attributes, promoting code readability and maintainability in ISOBUS-based applications.

Interface Structure

Event Inputs

None applicable – this is a global constant definition, not a function block.

Event Outputs

None applicable.

Data Inputs

None applicable.

Data Outputs

None applicable.

Adapters

None applicable.

Functionality

This global constant set defines two `USINT` constants:

- `BACKGROUND_COLOUR` (value 1): corresponds to the attribute ID `AID_DM_BACKGROUND_COLOUR`, used to specify the background colour index of a data mask.
- `SOFT_KEY_MASK` (value 2): corresponds to the attribute ID `AID_DM_SOFT_KEY_MASK`, used to specify the object ID of a Soft Key Mask associated with the data mask.

These constants are intended to be used in ISOBUS-based applications to reference these attribute IDs symbolically, improving clarity and reducing hard-coded numeric values.

Technical Features

- Defined in package `isobus::UT::Q::const::AID`.
- Uses data type `USINT` (unsigned short integer).
- Constant values are preinitialized: 1 and 2.
- The constants are global and read-only within the 4diac environment.

State Overview

Not applicable – this definition does not contain states or state machines; it is a static data definition.

Application Scenarios

- Developing ISOBUS-compliant applications that require referencing Data Mask attributes.
- Used in conjunction with ISOBUS object pool management to set or query background colour and soft key mask attributes.
- Provides a centralized and standardised way to access these attribute identifiers in 4diac projects.

Comparison with Similar Blocks

Since this is a global constant definition, it is similar to other constant collections in 4diac that define attribute or parameter IDs. For example, other `AID_*` global constants might define attribute IDs for different ISOBUS objects. This particular set focuses solely on Data Mask attributes, making it lightweight and specific.

Conclusion

AID_DM is a simple yet essential global constant definition for ISOBUS data mask attribute management. By providing symbolic names for the background colour and soft key mask attribute IDs, it enhances code clarity and reduces the risk of hard-coded numbers. It is a foundational building block for ISOBUS applications within 4diac.

AID_EIA

• – ◦ • – ◦ • – ◦ •

Introduction

AID_EIA is a global constants block defined for the ISOBUS (ISO 11783) protocol, specifically addressing the Extended Input Attributes object. It provides a single constant that defines the validation type for the extended input attribute data set. This constant is used to indicate how the validity of characters in the extended input attributes is determined, enabling compliant implementations to interpret the attribute correctly.

Interface Structure

Since AID_EIA is a global constants block, it does not possess any event, data, or adapter interfaces. It encapsulates constant values that can be referenced by other function blocks or applications within a 4diac project.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The block defines the constant `VALTYPE` which is of type `USINT` and is initialized to the value `USINT#1`. According to the comment, this constant represents the validation type for extended input attributes:

- `0` means valid characters are listed.
- `1` means invalid characters are listed.

By setting the default value to `1`, the block indicates that the extended input attribute data uses a list of invalid characters for validation. This value is intended to be used in the context of the ISOBUS Extended Input Attributes object, where a validation type of `1` corresponds to the specification that the character set is defined by an exclusion list.

The constant is declared as a global constant within the package `isobus::UT::Q::const::AID`, making it accessible to any FB or application that needs to reference the validation type for extended input attributes.

Technical Features

- **Type**: `USINT` (Unsigned Short Integer, 8-bit).
- **Initial Value**: `USINT#1`.
- **Visibility**: Global constant, accessible from any FB.
- **Purpose**: Specifies the validate type for ISOBUS extended input attributes.
- **Standard Compliance**: Aligned with the ISOBUS (ISO 11783) standard, particularly the Extended Input Attributes object definition.

State Overview

As a global constants block, AID_EIA has no states or state transition logic. The value of `VALTYPE` is fixed at initialization and remains constant throughout the runtime of the system. No dynamic behavior is associated with this block.

Application Scenarios

AID_EIA is typically used in ISOBUS-based agricultural machinery or implement control systems where the `Extended Input Attributes` object (AID) is implemented. The constant can be referenced in any function block that needs to interpret or generate extended input attribute data, ensuring consistent handling of character validation across the system. For example, a display module or a control unit may use this constant to determine whether to treat the attribute data as a list of valid or invalid characters when processing user input or configuration data.

Comparison with Similar Blocks

In the ISOBUS standard, similar global constants exist for other object types (e.g., Input Attributes, Output Attributes). While those constants may define different validation mechanisms, AID_EIA specifically targets the Extended Input Attributes object. Unlike function blocks that process data, AID_EIA provides a static configuration parameter, making it comparable to other global constant definitions in 4diac such as `AID_VAL` or `AID_FMT`, but focused solely on the validation type.

Conclusion

AID_EIA is a simple yet essential global constants block that encapsulates the validation type for ISOBUS Extended Input Attributes. By providing a standardized constant value, it eliminates the risk of hard-coded values scattered across different function blocks and ensures compliance with the ISOBUS specification. Its integration into 4diac projects is straightforward, and it serves as a reference for any FB that handles extended input attribute data.

AID_EX

• − ◦ • − ◦ • − ◦ •

Introduction

The AID_EX global constant block defines a set of external object attribute identifiers used within the ISOBUS (ISO 11783) communication framework. These constants serve as standardized references for accessing and managing external object attributes in agricultural equipment control systems. The block provides a compact and reusable collection of attribute IDs, ensuring consistency across distributed application components.

Interface Structure

As a global constant block, AID_EX exposes no event inputs, event outputs, data inputs, or adapters. It solely provides constant data values that can be referenced by other function blocks or applications. The constants are defined as USINT (unsigned short integer) type with predefined initial values.

Data Outputs

Constant Name	Type	Initial Value	Description
OPTIONS	USINT	USINT#1	Bitmask: Bit 0 = Enabled (allows referenced NAME WS to reference listed objects).
NAME_0	USINT	USINT#2	External object attribute ID for NAME_0.
NAME_1	USINT	USINT#3	External object attribute ID for NAME_1.

No Event Inputs, Event Outputs, Data Inputs, or Adapters are present.

Functionality

The AID_EX block encapsulates three constant attribute IDs essential for ISOBUS external object handling. The OPTIONS constant is a bitmask that controls accessibility of referenced object lists, while NAME_0 and NAME_1 provide unique identifiers for two distinct attribute names. These constants are designed to be used in conjunction with the UT::Q package for unified tractor-implement communication, enabling consistent attribute addressing across different software modules.

Technical Features

- **Data Type:** All constants are of type USINT (8-bit unsigned integer).
- **Predefined Values:** Constants are initialized with fixed values to ensure uniform behavior.
- **Package Association:** Belongs to the package isobus::UT::Q::const::AID, facilitating modular integration.
- **Static Nature:** The block is completely static and has no runtime execution behavior; it only provides compile-time constants.

State Overview

Since AID_EX is a constant definition block, it maintains no runtime state. All values are predetermined and immutable, making the block inherently stateless and safe for concurrent use in distributed systems.

Application Scenarios

- **ISOBUS Implement Control:** Used to reference external object attributes in implements that follow the ISOBUS standard.
- **Configuration Management:** Provides a centralized location for attribute IDs, simplifying updates and maintenance.
- **Inter-module Communication:** Ensures consistent attribute identification across multiple function blocks within an application.

Comparison with Similar Blocks

Unlike typical function blocks (FBs) that process events and data, AID_EX serves as a static data repository. It is similar to a constant library or parameter set but without any dynamic behavior. Compared to other global constant blocks, AID_EX is specialized for ISOBUS attribute IDs, offering a focused set of constants with clear documentation. Its simplicity contrasts with more complex FB types that contain multiple interfaces and execution logic.

Conclusion

The AID_EX global constant block provides a straightforward and standardized way to define external object attribute IDs for ISOBUS applications. Its static, typed constants ensure consistency and reduce the risk of misidentification. By centralizing these IDs, the block promotes maintainability and interoperability within agricultural control systems.

AID_EXOP

• − ◦ • − ◦ • − ◦ •

Introduction

AID_EXOP is a global constant definition used in the IEC 61499 (4diac-ide) environment. It defines attribute identifiers for the **External Object Pointer** object type within the ISOBUS (ISO 11783) protocol stack. These constants are used to reference specific attributes of external object pointers in a standardized, human-readable way, replacing raw numeric IDs in application code.

This definition is part of a package named isobus::UT::Q::const::AID and is intended to be used as a shared set of constants across multiple function blocks or applications. The constant values are defined as USINT (unsigned short integer) literals.

Interface Structure

Since AID_EXOP is a global constant definition, it does **not** expose any event, data, or adapter interfaces. It is not a function block or subapplication instance; it merely provides constant values that can be referenced by other FB types.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None. The variables defined here are compile-time constants, not runtime data inputs.

Data Outputs

None.

Adapters

None.

Global Constants

The following table lists all constants defined by AID_EXOP:

Constant Name	Type	Value	Description
DEF_OBJ_ID	USINT	USINT#1	Default Object ID to display if an external ID is not valid or is NULL. This corresponds to the attribute AID_EXOP_DEF_OBJ_ID.
EXT_REF_NAME_ID	USINT	USINT#2	Attribute ID for the external reference name. Corresponds to AID_EXOP_EXT_REF_NAME_ID.
EXT_OBJ	USINT	USINT#3	Attribute ID for the external object itself. Corresponds to AID_EXOP_EXT_OBJ.

These constants are declared as VAR_GLOBAL CONSTANT and are therefore immutable and accessible from any FB or function within the same project that includes this definition.

Functionality

The primary purpose of AID_EXOP is to provide a consistent set of attribute ID constants for the ISOBUS **External Object Pointer** object. In ISOBUS implementations, object pools and virtual terminals exchange object attribute data using numeric identifiers. Using named constants improves code readability and maintainability, and reduces the risk of typographical errors.

When used in conjunction with other ISOBUS-related function blocks (e.g., those handling object pool management or VT communication), these constants are referenced to read or modify external object pointer attributes, such as the default object ID, reference name, or the external object handle.

Technical Features

- **Type:** `USINT` (unsigned 8-bit integer), suitable for attribute IDs in the ISOBUS standard (range 0–255).
- **Initialization:** Each constant has an explicit initializer using the `USINT#` literal syntax.
- **Persistence:** Declared as `VAR_GLOBAL CONSTANT`, meaning the values are fixed at compile time and cannot be changed at runtime.
- **Package:** Located in `isobus::UT::Q::const::AID`, indicating its association with ISOBUS utility and constant definitions.
- **Compatibility:** The constants follow the naming and numbering conventions of the ISOBUS AID (Attribute ID) specification, allowing direct mapping to protocol-level identifiers.

State Overview

This definition has no runtime state. It is a purely static set of constants. There are no state transitions, initialization procedures, or execution steps associated with it. The values are available as soon as the containing application or library is loaded.

Application Scenarios

`AID_EXOP` is typically used in ISOBUS applications where external object pointers are managed:

- **Virtual Terminal (VT) implementations:** Referencing the default object ID or external object attributes when building or updating object pools.
- **Task controllers:** Handling external objects like implements or sensors, where pointer attributes need to be queried or set.
- **Diagnostic and status display:** Determining which object to display when an external ID is invalid or NULL.
- **Protocol adaptation:** Mapping internal data structures to ISOBUS attribute IDs for communication with other ISOBUS nodes.

Example usage in ST (Structured Text):

```
// Use the default object ID constant
myObject := DEF_OBJ_ID;
```

Comparison with Similar Blocks

Similar global constant definitions in ISOBUS contexts are typically created for other object types, such as `AID_OBJ`, `AID_OP`, or `AID_DP`. These follow the same pattern:

- `AID_EXOP` – External Object Pointer attribute IDs
- `AID_OP` – Object Pointer attribute IDs
- `AID_DP` – Device Process Data attribute IDs

The main difference between these definitions is the set of attributes they contain and their numeric values. `AID_EXOP` specifically addresses the three attributes listed above, whereas other definitions may have more entries. All such constant sets serve the same purpose: providing named references to numeric protocol identifiers, improving code clarity and reducing maintenance effort.

Conclusion

`AID_EXOP` is a compact but essential set of global constants for ISOBUS external object pointer attribute IDs. While it has no executable interface, it plays a key role in making PLC and industrial automation code more readable and robust. By using these named constants instead of raw numbers, developers can avoid errors and ensure compliance with the ISOBUS protocol specification. Its integration into 4diac-based projects is straightforward, and it forms part of a broader library of protocol-related constants.

AID_EXRN

• – ◦ • – ◦ • – ◦ •

Introduction

AID_EXRN is an IEC 61499 global constants container defined for the 4diac-IDE. It provides symbolic constant values for the object attribute identifiers used by the external reference name object. This XML

type is not a regular executable function block; it is a global constants class intended to be shared across an application or project. It is part of the package `isobus::UT::Q::const::AID`.

Interface Structure

Event Inputs
None. AID_EXRN does not define any event inputs.

Event Outputs
None. AID_EXRN does not define any event outputs.

Data Inputs
None. AID_EXRN does not define any data inputs.

Data Outputs
None. AID_EXRN does not define any data outputs.

Adapters
None. AID_EXRN does not define any adapters.

Functionality
AID_EXRN defines a set of constant attribute identifiers for the external reference name object. These constants allow algorithms to use meaningful symbolic names instead of raw numeric values.

The following constants are declared:

Constant	Value	Meaning
`OPTIONS`	`USINT#1`	Attribute ID 1: `AID_EXRN_OPTIONS`; bitmask with bit 0 = Enabled, allowing external reference by NAME WS.
`NAME_0`	`USINT#2`	Attribute ID 2: `AID_EXRN_NAME_0`.
`NAME_1`	`USINT#3`	Attribute ID 3: `AID_EXRN_NAME_1`.

These values are fixed at global constant declaration time and can be referenced from other IEC 61499 elements such as algorithms and expressions.

Technical Features
- The XML root element is `GlobalConstants`, not a regular function block type.
- All declared constants use the `USINT` data type.
- The constants are declared with initial values and are globally available.
- The package name is `isobus::UT::Q::const::AID`.
- The compiler package is also `isobus::UT::Q::const::AID`.
- The constants are intended for ISOBUS-related use cases, specifically for external reference name attribute handling.

State Overview
AID_EXRN has no execution state machine. Because it is a global constants class, it does not contain `START`, `STOP`, or any internal algorithmic states. It is passive and simply provides constant data to the surrounding application.

Application Scenarios
AID_EXRN is useful in applications that need to interact with ISOBUS external reference name objects. Typical use cases include:

- Setting or reading attributes of an external reference name object.
- Checking or configuring the `OPTIONS` bitmask to enable external references by NAME WS.
- Writing maintainable algorithms that use symbolic constants instead of hard-coded attribute IDs.

Comparison with Similar Blocks
A regular function block typically has event inputs, event outputs, data inputs, data outputs, and internal state. AID_EXRN has none of these. It is comparable to other IEC 61499 global constants groups, but it

is specialized for external reference name attribute IDs. This makes it similar to a shared enumeration or constant header in conventional programming languages.

Conclusion

AID_EXRN is a small, focused global constants definition that centralizes the attribute IDs used by the external reference name object. It improves readability, maintainability, and consistency in ISOBUS-related 4diac-IDE applications.

AID_FA_FILL

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_FA_FILL` global constant set defines attribute identifiers for the **Fill Attributes Object** within the ISO 11783 (ISOBUS) protocol. These constants are used to reference specific fill properties inside a fill attributes object, enabling consistent and readable access to fill type, colour, and pattern settings across ISOBUS applications. The constants are defined as `USINT` (unsigned short integer) values and are intended to be used with the ISOBUS virtual terminal implementation.

Interface Structure

Since `AID_FA_FILL` is a global constants block, it does not contain event or data inputs/outputs in the conventional function block sense. Instead, it exposes three constant values that can be referenced globally within your IEC 61499 application.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

The following table summarises the constants provided by this global constants block:

Constant Name	Type	Value	Description
`FILL_TYPE`	`USINT`	`1`	Attribute ID 1: Fill type. Values: 0 = no fill, 1 = fill with line colour, 2 = fill with specified colour, 3 = fill with pattern.
`COLOUR`	`USINT`	`2`	Attribute ID 2: Colour index used for filling.
`PATTERN`	`USINT`	`3`	Attribute ID 3: Pattern index used for filling.

These constants are defined as `CONSTANT` in the `VAR_GLOBAL_CONSTANT` section, meaning they are immutable and globally accessible.

Functionality

The constants in `AID_FA_FILL` are used to address fields within an ISOBUS Fill Attributes object. In ISOBUS, objects like fill attributes are stored as records with indexed elements. By using these predefined attribute IDs, application logic can reliably refer to the correct data element without hard-coding numeric values, improving readability and maintainability.

For example, to set the fill type of a fill attributes object, an application would use `AID_FA_FILL.FILL_TYPE` as the attribute identifier, and the corresponding value would be one of the allowed fill type codes.

Technical Features

- **Global Constants**: The definitions are located in a global constants block, making them available to all function blocks and resources in the 4diac IDE project.
- **Data Type**: All constants are of type `USINT` (unsigned 8-bit integer), which is sufficient for the small enumeration values and colour indices used.
- **Constant Declaration**: The `CONSTANT` keyword ensures that these values cannot be modified at runtime, providing safety and preventing accidental changes.
- **Standard Compliance**: The constants follow the ISOBUS standard for attribute IDs, specifically for the Fill Attributes Object.

State Overview

This global constants block has no internal states or state machines; it is purely a declarative element.

Application Scenarios

The `AID_FA_FILL` constants are typically used in applications that interact with the ISOBUS Virtual Terminal (VT) or implement ISOBUS-compliant functions. Example use cases include:

- Setting up a fill attributes object in a VT display.
- Modifying the fill type of a graphic element (e.g., a bar graph or gauge) based on user input or process conditions.
- Writing colour or pattern selections to a VT object.

Comparison with Similar Blocks

There are other global constant blocks in the ISOBUS library, such as `AID_FA_LINE` or `AID_FA_TEXT`, which define attribute IDs for line and text attributes respectively. These follow the same pattern: a set of `USINT` constants representing attribute indices. Compared to those, `AID_FA_FILL` focuses exclusively on fill-related attributes, providing a clear separation of concerns.

Conclusion

The `AID_FA_FILL` global constant block provides a clean, standards-based way to reference fill attribute IDs in ISOBUS applications. By using these constants, developers can avoid magic numbers, improve code clarity, and ensure alignment with the ISOBUS specification. It is a fundamental building block for any function block that needs to manage fill attributes on a virtual terminal.

AID_FA_FONT

• − ◦ • − ◦ • − ◦ •

Introduction

This global constant type defines the attribute identifiers (AID) used for the **Font Attributes Object** within the ISOBUS Universal Terminal (UT) protocol. The constants map to specific attribute indices that are used to access and modify font properties on a virtual terminal. These IDs are essential for any IEC 61499 application that communicates with ISOBUS compliant displays.

Interface Structure

As a global constant type, `AID_FA_FONT` does not provide event or data inputs/outputs like function blocks. Instead, it exposes a set of named constants that can be referenced throughout the project. The constants are defined as unsigned short integers (USINT) and are listed below.

Event Inputs

Not applicable – this type does not process events.

Event Outputs

Not applicable – this type does not generate events.

Data Inputs

The type defines the following constants, which can be used directly in IEC 61499 logic:

Constant Name	Type	Value	Description
`COLOUR`	USINT	1	Attribute ID for the font colour index.

SIZE	USINT	2	Attribute ID for the font size.
FONT_TYPE	USINT	3	Attribute ID for the font type (e.g., sans-serif, serif).
STYLE	USINT	4	Attribute ID for the font style – a bitmask (see details below).

Data Outputs

Not applicable – constants are not outputs.

Adapters

Not applicable – this type does not use adapters.

Functionality

The AID_FA_FONT constants are used to address specific attributes of the Font Attributes Object in the ISOBUS object dictionary. When an application needs to read or write a font property, it passes the corresponding constant as the attribute identifier in the service request. This ensures correct and consistent access across different implementations.

The **STYLE** attribute is a bitmask with the following meanings per bit (bit 0 is least significant):

Bit	Meaning
0	Bold
1	Crossed Out
2	Underlined
3	Italic
4	Inverted
5	Flashing inverted
6	Flashing hidden
7	Proportional rendering

Technical Features

- All constants are of type USINT (unsigned 8-bit integer).
- Values are predefined and must not be changed at runtime.
- The constants are grouped under the package isobus::UT::Q::const::AID.
- They follow the ISOBUS 61499-1 standard for object attributes.
- The type is intended to be used with the ISOBUS UT communication stack.

State Overview

Not applicable – the type does not contain state machines or dynamic behavior.

Application Scenarios

- **Setting font properties on a Virtual Terminal** – When a client application wants to change the font of a label or text object, it uses the appropriate constant (e.g., AID_FA_FONT::COLOUR) to specify the attribute to modify.
- **Reading font attributes** – To retrieve the current font settings, the same attribute IDs are used in read requests.
- **Building ISOBUS diagnostic tools** – Developers can use the well-defined constants to implement testing or monitoring applications for UT communication.

Comparison with Similar Blocks

Unlike function blocks that process data or events, AID_FA_FONT is a read-only constant type. Similar global constant types exist for other object attribute IDs (e.g., AID_FA_* for different object types) and are part of the same isobus::UT::Q::const package. The distinguishing feature of this type is its specific set of attribute identifiers for font objects, ensuring standardised naming and values.

Conclusion

AID_FA_FONT provides a standardised and maintainable way to reference font attribute IDs in ISOBUS UT applications. By using these constants, developers avoid hard-coded magic numbers, reduce errors, and improve code clarity. The type is an essential building block for any IEC 61499 application that interacts with ISOBUS virtual terminals.

AID_GC

• − ◦ • − ◦ • − ◦ •

Introduction

The AID_GC definition provides a standardized set of global constants used to identify attribute IDs for Graphic Context (GC) objects in ISOBUS-based agricultural systems (ISO 11783-6). These constants simplify referencing common graphical parameters—such as viewport dimensions, colours, and formatting—within control applications and human-machine interfaces. The values are defined as unsigned short integers (USINT) and are intended to be used as attribute identifiers when configuring graphic context objects.

Interface Structure

Event Inputs

None – this is not a function block with event interfaces. It constitutes a set of global constant declarations.

Event Outputs

None – no event outputs are defined.

Data Inputs

None – the definition does not provide any data input ports. All values are statically defined constants.

Data Outputs

None – no data output ports are present.

Adapters

None – no adapters are associated with this definition.

Functionality

The primary purpose of AID_GC is to offer a readable and consistent way to refer to attribute IDs of ISOBUS graphic context objects. Each named constant corresponds to a numeric attribute ID, enabling developers to avoid hard-coded numbers in their code. The constants cover:

- Viewport properties (width, height, position, zoom)
- Canvas dimensions
- Cursor coordinates
- Colour settings (foreground, background, transparency)
- Referencing font, line, and fill attribute objects
- Format and option flags

The following table lists all defined constants:

Constant Name	Type	Initial Value	Description
VP_WIDTH	USINT	USINT#1	Viewport width attribute ID
VP_HEIGHT	USINT	USINT#2	Viewport height attribute ID
VP_X	USINT	USINT#3	Viewport X coordinate attribute ID
VP_Y	USINT	USINT#4	Viewport Y coordinate attribute ID
CANVAS_WIDTH	USINT	USINT#5	Canvas width attribute ID
CANVAS_HEIGHT	USINT	USINT#6	Canvas height attribute ID
VP_ZOOM	USINT	USINT#7	Viewport zoom attribute ID

GR_CURSOR_X	USINT	USINT#8	Graphic cursor X coordinate attribute ID
GR_CURSOR_Y	USINT	USINT#9	Graphic cursor Y coordinate attribute ID
FG_COLOUR	USINT	USINT#10	Foreground colour index attribute ID
BACKGROUND_COLOUR	USINT	USINT#11	Background colour index attribute ID
FONT_ATT	USINT	USINT#12	Object ID reference for a Font Attributes object
LINE_ATT	USINT	USINT#13	Object ID reference for a Line Attributes object
FILL_ATT	USINT	USINT#14	Object ID reference for a Fill Attributes object
FORMAT	USINT	USINT#15	Canvas type: 0 = Monochrome, 1 = 4-bit colour, 2 = 8-bit colour
OPTIONS	USINT	USINT#16	Bitmask: Bit 0 = Transparency (0 = opaque, 1 = transparent), Bit 1 = Colour mode
TRANS_COLOUR	USINT	USINT#17	Transparency colour attribute ID

Technical Features

- **Data Type**: All constants are of type `USINT` (unsigned short integer).
- **Initialization**: Each constant is initialized with a distinct numeric value, directly mapping to the attribute ID it represents.
- **Package Association**: The constants are defined in the package `isobus::UT::Q::const::AID`, providing a clear namespace for ISOBUS constant definitions.
- **Standards Compliance**: The definitions follow the IEC 61499-1 standard for global constants, as indicated in the identification section.
- **Documentation**: Each constant is accompanied by a comment that includes its numeric ID and, where applicable, a description of its purpose (e.g., `BACKGROUND_COLOUR` indicates it stores a colour index; `FORMAT` explains the canvas colour depth).

State Overview

This definition does not introduce any stateful behavior. The constants are immutable and purely declarative. No state transitions, timers, or conditional logic are present.

Application Scenarios

- **Graphic Context Configuration**: In ISOBUS terminals, these constants are used to set or query attributes of graphic context objects, such as defining the size of the drawing area or selecting colour modes.
- **HMI Development**: Developers can reference these constants to avoid magic numbers when programming user interface elements, improving code readability and maintainability.
- **Cross-Platform Consistency**: By using standardized attribute IDs, applications can ensure consistent behavior across different ISOBUS implementations.
- **Protocol Integration**: The constants align with the ISOBUS protocol's attribute numbering, simplifying integration with low-level communication layers.

Comparison with Similar Blocks

While no direct function blocks are compared here, `AID_GC` can be considered analogous to other constant sets used in ISOBUS, such as attribute IDs for object pools (`AID_OP`) or working sets (`AID_WS`). In comparison:

- **Readability**: Named constants provide a clearer alternative to raw numeric IDs.
- **Maintainability**: Centralizing attribute IDs in one location reduces the risk of errors when the protocol evolves.
- **Portability**: Following the official ISOBUS numbering ensures that code is interoperable across compliant devices.

Conclusion

AID_GC is a vital set of global constants for ISOBUS graphic context handling. It offers a structured, documented, and standardized way to reference critical graphical attributes, reducing development effort and enhancing reliability in agricultural automation systems. Its integration into the package isobus::UT::Q::const::AID underscores its role as a foundational building block for ISOBUS-based applications.

AID_GD

• – ◦ • – ◦ • – ◦ •

Introduction

The AID_GD global constants library defines attribute identifiers for graphic data (PNG) objects. It is used within the ISO-bus (ISOBUS) ecosystem to identify and manage graphic data attributes, specifically for PNG image encoding. The constants are defined as global constant variables, providing a single, standardized reference for graphic data attributes in accordance with ISO 11783-14 (ISOBUS) conventions.

This component is part of the isobus::UT::Q::const::AID package and is intended to be used by function blocks and other modules that need to reference graphic data attribute identifiers. It contains a single constant, FORMAT, which specifies the graphic type. The initial value USINT#1 indicates the PNG format, restricted to 32-bit RGBA maximum.

Interface Structure

Since AID_GD is a global constants library, it does not provide event, data, or adapter interfaces. It defines only constant values accessible globally.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None. The constant value FORMAT is a global constant, not a data input.

Data Outputs

None.

Adapters

None.

Functionality

The primary purpose of AID_GD is to define a global constant, FORMAT, that stores the graphic data format identifier. This constant is used to indicate the encoding type of graphic data (e.g., PNG) within ISOBUS applications. By centralizing this value, consistency and maintainability are ensured across all modules that reference graphic data attributes.

The constant is defined as:

- **FORMAT** (USINT, initial value USINT#1) – Specifies the graphic type. The value 1 corresponds to the PNG format, as per the comment: *"1: AID_GD_FORMAT - Graphic type: 0 = PNG, restricted to 32bit RGBA maximum."* Note: The comment appears to have a typo (0 vs 1), but the actual initial value is 1, and the intended meaning is that PNG is the graphic type.

Technical Features

- **Global Constant** – The constant is declared in a global constants block, making it accessible throughout the entire application without requiring instantiation.
- **Data Type** – USINT (unsigned short integer, 8-bit) ensures a small and efficient representation.
- **Standard Compliance** – The package name isobus::UT::Q::const::AID indicates alignment with ISOBUS standardized attribute IDs.
- **Initialization** – The constant is initialized to USINT#1, which is the predefined value for the PNG format.

State Overview

As a constants library, AID_GD does not maintain any internal state. It consists solely of compile-time constants that are immutable during runtime. No state transitions or lifecycle management are involved.

Application Scenarios

Typical use cases for AID_GD include:

- **ISOBUS Object Pool Generation** – When constructing object pools for virtual terminals, graphic data (e.g., icons or images) must be associated with format identifiers. AID_GD provides the correct attribute ID to be referenced.
- **Graphic Data Handling** – Function blocks responsible for processing or displaying graphic data can use FORMAT to determine whether the incoming data is PNG or another supported format.
- **Inter-Module Coordination** – Since the constant is global, multiple blocks can access the same format definition without risk of inconsistency.

Comparison with Similar Blocks

Compared to other global constant libraries in the ISOBUS environment (e.g., attribute IDs for object types, color definitions), AID_GD is specifically focused on graphic data format attributes. While similar libraries might contain multiple constants for various attribute IDs, AID_GD currently exposes only one constant, FORMAT. This makes it lightweight and specialized. It does not compete with function blocks that perform processing logic; rather, it supplies a static configuration value for those blocks.

Conclusion

AID_GD is a minimalistic but essential global constants definition that standardizes the graphic data format attribute identifier for PNG objects in ISOBUS applications. By using this constant, developers ensure that all references to graphic data formats remain consistent and easily maintainable. Its simple design—a single immutable value—makes it a reliable and efficient building block for larger ISOBUS-based systems.

AID_IB

• – ◦ • – ◦ • – ◦ •

Introduction

The AID_IB type is a global constant definition that provides the standardized attribute identifiers for **Input Boolean objects** within the ISOBUS (ISO 11783) Universal Terminal (UT) protocol. These constants serve as semantic keys for accessing and manipulating the various attributes of an input boolean UI element. By centralizing these identifiers, the type ensures consistent and maintainable code when constructing or modifying ISOBUS object pools.

This definition is part of the isobus::UT::Q::const::AID package and adheres to the IEC 61499-1 standard for data representation.

Interface Structure

Since AID_IB is a global constant type rather than a traditional function block, it does not expose event or data ports for execution. Instead, it provides a set of immutable constant values that are referenced globally by application logic and service interface function blocks when handling input boolean objects.

Event Inputs

None. This type defines constants only and has no event-driven behaviour.

Event Outputs

None. No event generation occurs from this type.

Data Inputs

None in the conventional FB sense. The constants defined within this type serve as reference data values that are used as inputs to other function blocks or service sequences.

Data Outputs

None in the conventional FB sense. The constant values are accessed directly by name from any part of the application where the type is referenced.

Adapters

No adapters are provided. The constants are intended to be used as direct scalar references in ISOBUS-related processing blocks.

Functionality

The `AID_IB` constant set enumerates the six standard attribute identifiers defined for an Input Boolean object in the ISOBUS UT specification. Each constant maps an attribute name to its numeric identifier used in object pool definition and command payloads:

Constant Name	Value	Description
`BACKGROUND_COLOUR`	1	Index of the background colour used by the input boolean object.
`WIDTH`	2	Width of the object in pixels.
`FG_COLOUR`	3	Object ID of a Font Attributes object used to determine the font colour for the displayed text or symbol.
`VARIABLE_REF`	4	Object ID of a Number Variable object to which the input value is bound. If NULL, the value is stored directly in the object.
`VALUE`	5	Current value of the input field: `0` represents FALSE, any value greater than zero represents TRUE.
`ENABLED`	6	Operational state of the object: `0` = disabled, `1` = enabled.

Use of these constants avoids hard-coded magic numbers in application code, improves readability, and ensures that attribute references remain aligned with the ISOBUS specification even if identifiers change in future revisions.

Technical Features

- **Data type:** All constants are declared as `USINT` (unsigned short integer, 8-bit range 0–255), sufficient for all defined attribute identifiers.
- **Immutability:** All constants are declared as `CONSTANT`, preventing accidental modification at runtime.
- **Standard compliance:** The identifiers correspond to the attribute IDs defined by the ISO 11783-6 / ISOBUS UT standard for the Input Boolean object type.
- **Namespace packaging:** The constants reside in the `isobus::UT::Q::const::AID` package, allowing clean import and preventing naming collisions.
- **Inline documentation:** Each constant carries a descriptive comment and its corresponding numeric attribute ID for quick cross-referencing.
- **Direct initialisation:** Initial values are assigned using type-qualified literals (e.g., `USINT#1`), ensuring type safety.

State Overview

As a set of compile-time constants, `AID_IB` has no runtime state machine. The values are fixed at compile time and remain invariant for the lifetime of the application. The only relevant "state" is the numeric value of each attribute identifier, which must match the ISOBUS UT specification for correct behaviour.

Application Scenarios

Typical use cases for the `AID_IB` constants include:

- **Object pool generation:** When building an ISOBUS Virtual Terminal object pool, these constants are used as attribute selectors in service requests (e.g., setting the background colour of an input boolean button).
- **Runtime attribute modification:** Applications that need to dynamically change the appearance or behaviour of an input boolean object (for example, toggling its enabled state) reference `AID_IB.ENABLED` or `AID_IB.VALUE` to form the correct command payloads.
- **HMI configuration:** When configuring input fields for operator interaction, such as toggle switches or buttons that represent boolean settings, these identifiers route configuration data to the correct attribute.
- **Value binding:** The `VARIABLE_REF` constant is used to link an input boolean object to a Number Variable object, enabling bidirectional data exchange between the terminal and the implement controller.

Comparison with Similar Blocks

The ISOBUS UT specification defines attribute ID sets for several object types. `AID_IB` covers the Input Boolean object specifically. Comparable constant sets exist for:

- **Input Numeric (AID_IN):** Uses additional attributes such as decimal places, minimum/maximum value, and format for numeric input fields.
- **Output Boolean (AID_OB):** Shares attributes like `BACKGROUND_COLOUR`, `FG_COLOUR`, and `WIDTH` but adds attributes for flash state, line selection indication, and active state colour.
- **Object itself (AID_OBJ):** Represents generic object attributes common to all UT objects, such as position, size, and visibility.

Unlike those broader sets, `AID_IB` focuses exclusively on the boolean input semantics, and omits properties that are only relevant to output or numeric objects — keeping the constant list concise and purpose-specific.

Conclusion

The `AID_IB` global constant type provides a clean, standardised, and type-safe way to reference Input Boolean object attribute identifiers in ISOBUS Universal Terminal applications. Its use eliminates magic numbers, improves code readability and maintainability, and guarantees alignment with the relevant protocol specifications. By incorporating these constants into object pool generation and runtime control logic, developers can build robust and portable ISOBUS HMI components with minimal risk of misaddressing.

AID_IL

• − ◦ • − ◦ • − ◦ •

Introduction

AID_IL is a global constant group used in 4diac-IDE-based ISOBUS applications. It defines the attribute identifiers for an **Input List** object of an ISOBUS Universal Terminal (UT). The constant group is not a function block or adapter; it provides a named, reusable set of numeric attribute IDs that are used when constructing or manipulating an Input List object in an ISOBUS object pool.

By using the constants defined here, application code avoids “magic numbers” and becomes more readable and maintainable.

Interface Structure

AID_IL is a global constant list and therefore does not expose an IEC 61499 function block interface. It has no event inputs, event outputs, data inputs, data outputs, or adapters. Its interface consists solely of compile-time constant values.

Event Inputs

None. AID_IL is not an executable function block and defines no event inputs.

Event Outputs

None. AID_IL has no event outputs and cannot trigger further processing.

Data Inputs

None. The constants are global values and are not provided through a data input interface.

Data Outputs

None as a block interface. However, the defined constants can be read globally as `AID_IL.<CONSTANT_NAME>`, for example `AID_IL.WIDTH`.

Adapters

None. AID_IL defines no adapter sockets or plugs.

Functionality

AID_IL centralizes the attribute IDs of an ISOBUS UT **Input List** object. The following constants are defined:

Constant	Type	Value	Description

WIDTH	USINT	1	AID_IL_WIDTH – Width of the input list in pixels.
HEIGHT	USINT	2	AID_IL_HEIGHT – Height of the input list in pixels.
VARIABLE_REF	USINT	3	AID_IL_VARIABLE_REF – Object ID of a Number Variable object that is linked to the selected list item.
VALUE	USINT	4	AID_IL_VALUE – Selected list index, from 0 to 254, or 255 if no item is selected.
OPTIONS	USINT	5	AID_IL_OPTIONS – Bitmask for input list options. Bit 0 controls whether the object is enabled; bit 1 controls real-time editing.

All constants are declared as USINT, an unsigned short integer value in the range 0 to 255. They are defined globally in the constant package:
isobus::UT::Q::const::AID

Technical Features

- Provides five named constants for Input List object attributes.
- All constants use the USINT data type.
- The values correspond to the attribute IDs used by the ISOBUS Universal Terminal protocol.
- The constant group can be reused in multiple function blocks without duplicate definitions.
- The included OPTIONS bitmask supports two distinct configuration flags in a single attribute.
- Because the constants are compile-time constants, they do not consume runtime resources and cannot be changed accidentally during execution.

State Overview

AID_IL is not stateful. It defines fixed values that are resolved at compile time. There is no initialization procedure, no internal state machine, and no runtime behavior. The values remain constant for the entire lifetime of the application.

Application Scenarios

AID_IL is typically used when an ISOBUS UT object pool or a client function block needs to set or query attributes of an Input List object. For example:

- Setting the width and height of an Input List object.
- Linking the Input List to a Number Variable object that stores the selected item.
- Reading or setting the currently selected list index.
- Changing the enabled state or activating real-time editing through the options bitmask.

Using AID_IL.WIDTH instead of the literal value 1 makes the application code easier to understand and to migrate if the attribute numbering changes.

Comparison with Similar Blocks

AID_IL is not a function block, so it cannot be directly compared to blocks that process events or data. Instead, it serves a similar role to an enumeration or a set of preprocessor constants in other programming languages.

Compared to a typical constant function block that outputs a single value, AID_IL provides multiple related constants in one global namespace. Compared to an adapter, it does not define a communication interface. Its main advantage is that all Input List attribute IDs are collected in one place and can be used consistently across many applications.

Conclusion

AID_IL is a small but useful global constant group for ISOBUS Universal Terminal applications. It defines the attribute IDs for an Input List object and helps keep application code readable, consistent, and independent from hard-coded numeric IDs. Although it has no executable interface, it is a valuable library element in 4diac-IDE-based ISOBUS projects.

AID_IN

• – ◦ • – ◦ • – ◦ •

Introduction

AID_IN is a global constants container used in 4diac-ide for ISO 11783 / ISOBUS applications. It defines the numeric attribute IDs for an Input Number object on a Virtual Terminal. The provided XML declares named constants of type `USINT` with values from `1` to `15`, allowing the attribute IDs to be referenced by meaningful names instead of magic numbers.

Although the XML structure resembles an IEC 61499 type definition, AID_IN is not a function block, adapter, or subapplication. It is a compile-time constants definition intended for use in ISOBUS-related logic.

Interface Structure

The AID_IN element does not define an IEC 61499 function block interface. It contains no event inputs, event outputs, data inputs, data outputs, or adapters. Its complete interface is represented by the global constants described in the Functionality section.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

AID_IN provides the attribute identifiers for an ISOBUS Input Number object. Each constant represents a specific attribute ID that can be used when reading from or writing to an ISOBUS Virtual Terminal.

The following table lists all defined constants:

Constant	Value	Description
`WIDTH`	`USINT#1`	Width in pixels.
`HEIGHT`	`USINT#2`	Height in pixels.
`BACKGROUND_COLOUR`	`USINT#3`	Background colour index.
`FONT_ATT`	`USINT#4`	Object ID of a Font Attributes object.
`OPTIONS`	`USINT#5`	Bitmask: Bit 0 = Transparent, Bit 1 = Display leading zeros, Bit 2 = Display zero as blank, Bit 3 = Truncate decimals.
`VARIABLE_REF`	`USINT#6`	Object ID of a Variable object.
`MIN_VALUE`	`USINT#7`	Minimum value.
`MAX_VALUE`	`USINT#8`	Maximum value.
`OFFSET`	`USINT#9`	Offset.
`SCALE`	`USINT#10`	Scale.
`NUMB_DECIMALS`	`USINT#11`	Number of decimals.
`FORMAT`	`USINT#12`	Decimal display format. `0` means fixed format decimal, `1` means exponential format.
`JUSTIFICATION`	`USINT#13`	Justification. Bits 0-1 define horizontal alignment, bits 2-3 define vertical alignment.

VALUE	USINT#14	Current value.
OPTIONS_2	USINT#15	Bitmask: Bit 0 = Enabled, Bit 1 = Real-time editing.

Technical Features

- Declared as an XML `<GlobalConstants>` element.
- Defined in the package namespace `isobus::UT::Q::const::AID`.
- All constants use the `USINT` data type.
- Each constant has an initial value equal to its corresponding ISOBUS attribute ID.
- The constants are intended for use in ISOBUS Virtual Terminal object handling.
- The `OPTIONS`, `JUSTIFICATION`, and `OPTIONS_2` constants encode their settings as bitmasks.
- No runtime behavior, algorithm, or state logic is included.

State Overview

AID_IN has no state machine and no runtime state. It is a purely declarative element. All values are fixed at compile time and do not change during program execution.

Application Scenarios

AID_IN is useful in ISOBUS applications that need to configure or update Input Number objects on a Virtual Terminal. Typical scenarios include:

- Creating attribute lists for ISOBUS object updates.
- Reading or writing Input Number object properties.
- Improving code readability by using symbolic names such as `WIDTH` or `VALUE` instead of numeric attribute IDs.
- Supporting maintainable, reusable ISOBUS communication logic in 4diac-ide.

Comparison with Similar Blocks

AID_IN is not a function block and cannot be directly compared with execution blocks such as controllers or converters. It belongs to a family of constant containers used for different ISOBUS object types. Similar constants may exist for other object attributes, such as output numbers, bar graphs, or text objects. The main difference between such containers is the set of attribute IDs and the meanings associated with them.

Conclusion

AID_IN provides a clear and maintainable way to handle ISOBUS Input Number object attribute IDs in 4diac-ide. By replacing numeric literals with named constants, it helps avoid errors, improves readability, and supports consistent communication with ISOBUS Virtual Terminals.

AID_IP

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_IP` global constants type defines a set of constant values used within the ISOBUS (ISO 11783) utility layer for handling input attributes. Specifically, it provides the validation type constant that controls how input attribute validation is performed. This type is part of the `isobus::UT::Q::const::AID` package and is intended to be included globally in IEC 61499 applications that deal with ISO-bus device communication.

Interface Structure

Since `AID_IP` is a **global constants** definition, it does not possess a traditional event/data input or output interface. Instead, it exposes a global constant that can be accessed by any function block or application component. The following sections list the available constant as part of the interface.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The following global constant is defined:

Constant Name	Data Type	Initial Value	Description
`VALIDATION_TYPE`	`USINT`	`USINT#1`	Specifies the validation type: `0` = valid characters are listed, `1` = invalid characters are listed.

Adapters

None.

Functionality

The sole purpose of `AID_IP` is to provide a standardized, globally accessible constant for the validation mechanism of input attribute strings. By setting `VALIDATION_TYPE` to either `0` or `1`, the system can adapt its parsing and validation logic for input attributes. This constant is typically used in conjunction with other ISOBUS utility function blocks to ensure consistent behavior across an application.

Technical Features

- **Single Global Constant**: Only one constant is defined, reducing complexity and potential runtime overhead.
- **USINT Data Type**: The constant is stored as an unsigned short integer, suitable for small numeric flags.
- **Pre-initialized**: The constant is pre-set to `1` (invalid-character listing) at compile time, ensuring immediate usability without external configuration.
- **Namespace**: Belongs to the `isobus::UT::Q::const::AID` package, providing a clear hierarchical structure for related constants.

State Overview

As a global constants type, `AID_IP` does not contain any state machines, execution states, or dynamic behavior. Its value is fixed and immutable during runtime.

Application Scenarios

- **ISOBUS Input Validation**: When implementing the ISO 11783 utility layer, `VALIDATION_TYPE` can be used to switch between two validation modes for input attribute strings.
- **Configuration-Free Systems**: Because the constant is pre-defined, developers can rely on a consistent validation strategy without manual setup.
- **Multi-Device Coordination**: Global constants help ensure that all parts of a distributed IEC 61499 application agree on the same validation rule.

Comparison with Similar Blocks

Unlike function blocks (FBs) that have explicit event and data interfaces, `AID_IP` is purely a data definition. It is similar to global variable lists in other PLC programming environments but with the additional benefit of type-safe, constant-qualified definitions. FBs that require validation logic can read this constant directly, avoiding duplicate or conflicting definitions.

Conclusion

The `AID_IP` global constants type fulfills a focused but essential role in ISOBUS-based automation systems. By providing a single, well-defined constant for validation type selection, it promotes code consistency and maintainability. Its simple structure and predetermined default value make it an unobtrusive yet valuable component for applications that handle ISO-bus input attributes.

AID_IS

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_IS` global constant set defines attribute identifiers used for **Input String objects** in the context of ISOBUS (ISO 11783) Universal Terminal (UT) applications. These constants allow standardized access

to the properties of an input string object, such as width, height, background colour, font attributes, and various behavioural options. They are defined as compile-time constants of type `USINT` and are intended to be referenced in function blocks or logic that interact with ISOBUS UT object pools.

Interface Structure

This element is a global constants set and does not conform to the traditional function block interface (no events, no data I/O, no adapters). However, for documentation purposes, the constants are listed under the data section.

Event Inputs

None.

Event Outputs

None.

Data Inputs

The following constants are provided and can be used as data sources in any function block logic:

Name	Type	Initial Value	Description
`WIDTH`	USINT	1	1: AID_IS_WIDTH – Width in pixels.
`HEIGHT`	USINT	2	2: AID_IS_HEIGHT – Height in pixels.
`BACKGROUND_COLOUR`	USINT	3	3: AID_IS_BACKGROUND_COLOUR – Background colour index.
`FONT_ATT`	USINT	4	4: AID_IS_FONT_ATT – Object ID of a Font Attributes object.
`INP_ATT`	USINT	5	5: AID_IS_INP_ATT – Object ID of an Input Attributes / Extended Input Attributes object.
`OPTIONS`	USINT	6	6: AID_IS_OPTIONS – Options bitmask.
`VARIABLE_REF`	USINT	7	7: AID_IS_VARIABLE_REF – Object ID of a String Variable object.
`JUSTIFICATION`	USINT	8	8: AID_IS_JUSTIFICATION – Justification: Bits 0-1 (Horizontal: 0=Left, 1=Middle, 2=Right), Bits 2-3 (Vertical: 0=Top, 1=Middle, 2=Bottom).
`ENABLED`	USINT	9	9: AID_IS_ENABLED – 0 = Disabled, 1 = Enabled.

Data Outputs

None.

Adapters

None.

Functionality

The `AID_IS` constants act as predefined attribute identifiers for an input string object within an ISOBUS UT object pool. By using these constants, application logic can unambiguously refer to specific properties (e.g., width, height, background colour, font, options, reference to a string variable, justification, and enabled state) when reading or modifying the object's attributes via the standard ISOBUS service interfaces. The numeric values correspond to the attribute IDs defined in the ISOBUS standard for input string objects.

Technical Features

- **Type:** All constants are of type `USINT` (unsigned 8-bit integer).
- **Values:** The identifiers are sequential from 1 to 9, matching the official ISOBUS specification for input string object attributes.
- **Compile-time constants:** Declared as `VAR_GLOBAL CONSTANT`, they are resolved during compilation, offering performance benefits and guaranteeing immutability.

- **Namespace:** The constants belong to the package `isobus::UT::Q::const::AID`, ensuring a clear hierarchical organisation.

State Overview

This global constant set does not maintain any state. It provides static values that are available globally throughout the application. There are no runtime modifications, and the constants remain fixed for the entire execution.

Application Scenarios

The `AID_IS` constants are used in IEC 61499 applications that interact with ISOBUS Universal Terminal objects, particularly when a task requires:

- Configuring an input string object's dimensions or appearance.
- Changing the font or background colour.
- Setting or retrieving the associated string variable.
- Adjusting text justification or enabling/disabling the input field.
- Reading or writing options bitmask values.

For example, a function block controlling a text entry field might use `AID_IS.WIDTH` and `AID_IS.HEIGHT` to specify the size in its object pool creation request.

Comparison with Similar Blocks

While this element is not a function block, it is comparable to other **attribute ID constant sets** defined in the same package (e.g., `AID_IS` for input strings, or analogous sets for Output String, Number, etc.). The key difference is that each set defines attribute IDs for a specific object type, allowing developers to use mnemonic names instead of raw numeric values, reducing errors and improving code readability. Unlike function blocks, it provides no algorithmic functionality; it purely supplies constant data.

Conclusion

The `AID_IS` global constant set is a vital building block for ISOBUS UT applications, offering a clear and standardized way to reference attributes of input string objects. Its use enhances maintainability and compliance with the ISOBUS standard, making it an essential component for developers working with the 4diac-ide environment in agricultural or mobile machinery contexts.

AID_KG

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_KG` global constant set defines standardized attribute identifiers for ISO-bus key group objects. It is part of the `isobus::UT::Q::const` package and provides fixed numeric values that unambiguously reference specific object attributes, such as availability options and naming information. These constants simplify integration with ISO-bus communication stacks and ensure consistent code across applications.

Interface Structure

Event Inputs

None – this is a global constant definition, not a function block with event inputs.

Event Outputs

None – no event outputs are provided.

Data Inputs

None – the block does not accept any variable inputs; all values are instantiated as compile-time constants.

Data Outputs

None – the constants are accessible globally by their symbolic names (e.g., `OPTIONS`, `NAME`) and are not exchanged via formal output connections.

Adapters

None – no adapter interfaces are defined.

Functionality

The purpose of AID_KG is to centralize and standardize the numeric identifiers used for key group object attributes in ISO-bus systems. It declares two constants:

Constant Name	Type	Value	Description
OPTIONS	USINT	1	Bitmask that defines attribute availability: Bit 0 = Available, Bit 1 = Transparent.
NAME	USINT	2	Object ID of an output string or object pointer containing the attribute name.

These constants are used in conjunction with ISO-bus protocol operations to reference specific attributes without hard-coding numeric literals, improving readability and maintainability of code.

Technical Features

- **Compile-time constants**: Values are defined as GLOBALCONSTANTS in the IEC 61499 environment, ensuring that they are immutable and available throughout the application.
- **Type safety**: All constants are declared as USINT (unsigned short integer) to ensure compatibility with ISO-bus attribute fields.
- **Package organization**: The constants reside in the isobus::UT::Q::const::AID package, allowing for structured inclusion and avoiding name conflicts.
- **Simple integration**: The constants can be directly referenced in function blocks, algorithms, or other parts of the application without additional configuration.

State Overview

Since AID_KG defines static constants, it does not possess any runtime state. The values are fixed at compile time and do not change during execution. Therefore, there is no state machine, no initialization, and no internal variables to manage.

Application Scenarios

- **ISO-bus object modeling**: When implementing object dictionaries or key groups, OPTIONS and NAME are used to set or query attribute flags and naming data.
- **Protocol-related function blocks**: Blocks that interact with ISO-bus objects can use these constants to identify attributes during read/write operations.
- **Cross-component consistency**: By referencing the same constants in multiple FBs, the risk of attribute ID mismatches is eliminated, simplifying maintenance and diagnosis.

Comparison with Similar Blocks

- **vs. local constants**: Unlike local constants within an FB, AID_KG is globally accessible, avoiding duplication across multiple FBs and ensuring a single source of truth.
- **vs. enumeration types**: Enumerations provide symbolic names but are not necessarily bound to numeric values; AID_KG explicitly maps symbolic names to fixed integer IDs, which is required for wire-level protocol compatibility.
- **vs. configuration parameters**: Unlike configurable parameters, these constants are pre-defined and cannot be altered at runtime, which is appropriate for protocol-fixed identifiers.

Conclusion

AID_KG is a lightweight, standardized global constant set that defines essential attribute identifiers for ISO-bus key group objects. Its use promotes code clarity, reduces errors, and supports portable, maintainable applications within the 4diac-IDE environment. Though it contains no dynamic logic, it plays a fundamental role in ensuring consistent object attribute handling across a distributed system.

AID_LA

• − ◦ • − ◦ • − ◦ •

Introduction

AID_LA is a set of global constants that define the attribute identifiers for the ISO 11783 (ISOBUS) **Line Attributes Object**. These constants are used to address specific properties of a line object within a Virtual Terminal (VT) – primarily the line colour, line width, and line art. The constants are defined as USINT

(Unsigned Short Integer) values and are intended to be used as object attribute IDs when reading or writing line properties via the ISOBUS protocol.

The values correspond to the standard attribute IDs as specified in the ISOBUS VT standard:

- `1` – Line Colour
- `2` – Line Width
- `3` – Line Art (bit pattern for line style)

These constants simplify the development of VT applications by providing a human-readable symbolic name for each attribute ID, avoiding magic numbers in the application logic.

Interface Structure

Since AID_LA is a global constants container (not a function block or adapter), it does not have event inputs, event outputs, data inputs, data outputs, or adapters. Instead, it provides three global constants that can be referenced from any part of an IEC 61499 application.

Event Inputs

None – AID_LA defines only constants, no event inputs.

Event Outputs

None – AID_LA defines only constants, no event outputs.

Data Inputs

None – AID_LA defines only constants, no data inputs.

Data Outputs

None – AID_LA defines only constants, no data outputs.

Adapters

None – AID_LA is not an adapter type.

Functionality

The constant container `AID_LA` provides symbolic names for the three line attribute identifiers. The constants are defined as:

Constant Name	Type	Value	Description
`LINE_COLOUR`	`USINT`	`1`	Attribute ID for line colour (AID_LA_LINE_COLOUR)
`LINE_WIDTH`	`USINT`	`2`	Attribute ID for line width (AID_LA_LINE_WIDTH)
`LINE_ART`	`USINT`	`3`	Attribute ID for line art – a bit pattern where each bit represents a paintbrush spot (AID_LA_LINE_ART)

These constants are intended to be used in conjunction with VT line objects. For example, when setting the colour of a line, an application would use `AID_LA.LINE_COLOUR` as the attribute ID in the appropriate ISO 11783 command.

Technical Features

- **Data Type**: All constants are of type `USINT` (unsigned 8-bit integer), sufficient for the attribute IDs.
- **Namespace**: The constants are declared inside a package `isobus::UT::Q::const::AID`, ensuring a clear naming structure for reuse in larger projects.
- **Initialisation**: Each constant is explicitly initialised with a literal value (`USINT#1`, `USINT#2`, `USINT#3`), making the assignment unambiguous.
- **IEC 61499 Compatibility**: The constants are defined as `VAR_GLOBAL CONSTANT`, which is the IEC 61499 mechanism for global constants, accessible from any FB network.

State Overview

AID_LA is a static, immutable container. It has no internal states, no execution logic, and no lifecycle. The constants are available at compile time and remain unchanged during runtime.

Application Scenarios

Typical usage scenarios include:

- **VT Screen Design**: When building a VT page that contains a line object, the developer needs to specify the line colour, width, or style. Instead of using numeric codes directly, the developer can reference these constants for better readability and maintainability.
- **Runtime Attribute Configuration**: In a control application that dynamically changes a line's appearance (e.g., highlighting a boundary), the constant is used as the attribute ID in the `SetLineAttributes` or similar. This ensures the correct attribute is addressed.
- **Diagnostics and Logging**: When logging VT object properties, the symbolic name can be used for clarity.

Comparison with Similar Blocks

In the ISOBUS context, there are other attribute ID constant sets, for example:

- **AID_OO** – Object identifiers for object attributes.
- **AID_PO** – Point attributes.
- **AID_AO** – Auxiliary Object attributes.

AID_LA is specifically focused on line attributes. Compared to equivalent numeric literals, the constant set offers the advantage of:

- **Readability**: `AID_LA.LINE_COLOUR` is self-documenting.
- **Maintainability**: If the underlying ID ever changes (unlikely), the definition can be updated in a single place.
- **Type Safety**: Using `USINT` ensures the value fits the expected range for attribute IDs.

Conclusion

The `AID_LA` global constants provide a clean and standardised way to referencing line attribute IDs in ISOBUS VT applications. They are simple, well-defined, and align with the ISO 11783 standard. By using these constants, developers reduce the risk of errors and improve the clarity of their code, making the implementation of VT line objects more straightforward and robust.

AID_NV

• – ◦ • – ◦ • – ◦ •

Introduction

This global constant definition provides a symbolic name for the attribute ID of a number variable object in the ISO 11783 (ISOBUS) protocol. It defines the constant `VALUE`, which is assigned the numeric value `1`, corresponding to the `AID_NV_VALUE` – the "current value" attribute of a number variable. The constant is intended for use in IEC 61499 applications that interact with ISOBUS object dictionaries, improving code clarity and maintainability.

Interface Structure

As a global constants type, this element does not contain any event inputs, event outputs, data inputs, data outputs, or adapters. The following sections are therefore not applicable and are listed for completeness.

Event Inputs

None (not applicable for global constants).

Event Outputs

None (not applicable for global constants).

Data Inputs

None (not applicable for global constants).

Data Outputs

None (not applicable for global constants).

Adapters

None (not applicable for global constants).

Functionality

The primary purpose of this constant is to assign a human-readable identifier to the numeric attribute ID used in ISOBUS communication. Specifically, it defines the attribute ID for the "current value" of a number variable object. When developing IEC 61499 function blocks that read or write number variable values, this constant can be used to specify the target attribute without hard-coding the raw numeric value.

Technical Features

- **Type**: Global Constants (IEC 61499-1)
- **Constant Definition**:
  `VALUE : USINT := 1` (comment: `1: AID_NV_VALUE - Current value`)
- **Package/Namespace**: `isobus::UT::Q::const::AID` (set via `CompilerInfo`)
- **Standard Compliance**: IEC 61499-1
- **Version**: 1.0

State Overview

Since this is a static constant definition, it does not possess any runtime state. The value is fixed at compile time and remains constant throughout the execution of the application.

Application Scenarios

This constant is particularly useful in industrial automation applications that implement the ISOBUS protocol, such as agricultural machinery control systems. For example, when creating a function block to read the current numeric value from a tractor implement's object dictionary, the constant `AID_NV.VALUE` can be passed as the attribute ID parameter, ensuring that the correct attribute is addressed.

Comparison with Similar Blocks

In the ISOBUS context, global constants are defined for various object types (e.g., analog, digital, string) and their corresponding attributes. Compared to function blocks that handle data processing or communication, this constant is a static helper that simplifies code and reduces the risk of using incorrect attribute IDs. Similar constants would exist for other object attributes, each serving as a named reference to a specific numeric identifier.

Conclusion

The `AID_NV` global constant provides a well-defined, documented identifier for the "current value" attribute of number variable objects in ISOBUS. Its use promotes code readability, reduces maintenance overhead, and aligns with IEC 61499 best practices for separating constant definitions from application logic.

AID_OABG

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_OABG` global constant set provides symbolic names for the attribute identifiers (AIDs) of an **Output Arched Bar Graph (OABG)** object as specified by the ISOBUS Virtual Terminal (VT) standard. Instead of using magic numbers, applications can reference these constants to set or modify OABG attributes, improving code readability and maintainability. This constant set is defined in the package `isobus::UT::Q::const::AID` and is intended for use in IEC 61499 applications running on 4diac-ide.

Interface Structure

This global constant set does not define a standard function block interface with event or data inputs/outputs. It is a collection of compile-time constants that can be used anywhere a USINT attribute ID is required. The following sections are included for completeness, but they are not applicable to a constant set.

Event Inputs

None – no event inputs are defined.

Event Outputs

None – no event outputs are defined.

Data Inputs

None – no data inputs are defined.

Data Outputs

None – no data outputs are defined.

Adapters

None – no adapters are defined.

Functionality

Each constant in `AID_OABG` corresponds to a specific attribute of an OABG object, as defined by the ISOBUS standard. The following table lists all constants, their attribute identifiers, and their meaning:

Constant Name	Value	Attribute Description
`WIDTH`	1	Width in pixels
`HEIGHT`	2	Height in pixels
`COLOUR`	3	Colour index
`TARGET_LINE_COLOUR`	4	Target line colour
`OPTIONS`	5	Bitmask: Bit 0=Draw border, Bit 1=Draw target line, Bit 2=Undefined (set to 0), Bit 3=Bar graph type (0=filled, 1=single line), Bit 4=Deflection (0=anticlockwise, 1=clockwise)
`START_ANGLE`	6	Start angle in degrees
`END_ANGLE`	7	End angle in degrees
`BAR_GRAPH_WIDTH`	8	Bar graph width
`MIN_VALUE`	9	Minimum scaled value
`MAX_VALUE`	10	Maximum scaled value
`VARIABLE_REF`	11	Object ID of a Variable object
`TARGET_VAL_VAR_REF`	12	Object ID of a Variable object for target value
`TARGET_VALUE`	13	Target value
`VALUE`	14	Current value

These constants are all of type `USINT` and are initialized with their numeric attribute ID values. They are intended to be used in conjunction with VT commands such as those that set attribute values (e.g., `SetAttribute`).

Technical Features

- **Type:** All constants are `USINT` (unsigned 8-bit integer), matching the attribute ID type in the ISOBUS standard.
- **Package:** `isobus::UT::Q::const::AID`
- **Compliance:** The constants follow the attribute numbering defined in ISO 11783-6 for the OABG object.
- **Read-only:** The constants are `VAR_GLOBAL CONSTANT`, meaning they cannot be modified at runtime.
- **Use in 4diac-ide:** The constants can be directly referenced in ST or FBD code, e.g., `AID_OABG.WIDTH`.

State Overview

Not applicable. This constant set does not contain any stateful elements. It merely provides static definitions.

Application Scenarios

- **Creating an OABG object:** When creating a new output arched bar graph on an ISOBUS VT, the application must supply attribute IDs for properties such as width, height, colours, and angles. Using `AID_OABG.*` ensures correct values.
- **Modifying OABG attributes:** When sending a `SetAttribute` command to a VT, the attribute ID parameter can be set using these constants, avoiding hard-coded numbers.
- **Reading OABG status:** When querying the current value or target value, the attribute ID can be referenced symbolically.
- **Cross-platform consistency:** By using a central constant set, the same attribute IDs are guaranteed across different parts of an application, reducing the risk of inconsistency.

Comparison with Similar Blocks

Similar global constant sets exist for other VT objects, such as `AID_OARG` (Output Arched Bar Graph) or `AID_OMSG` (Output Message), each defining attribute IDs for their respective object types. Compared to using raw numeric literals, these constant sets improve code readability and maintainability. They also align with the ISOBUS standard, ensuring compatibility with various VT implementations. Unlike function blocks, they do not process data or events, but they serve as essential building blocks in the development of IEC 61499 applications for agricultural machinery.

Conclusion

The `AID_OABG` global constant set is a simple yet valuable utility for developers working with ISOBUS Virtual Terminal objects. By providing symbolic names for all attribute IDs of an output arched bar graph, it eliminates magic numbers and promotes clear, maintainable application code. It is an integral part of the `isobus::UT::Q::const` package and should be used whenever OABG attributes are accessed in 4diac-ide projects.

AID_OE

• – ◦ • – ◦ • – ◦ •

Introduction

The **AID_OE** global constant group defines the attribute identifiers (AIDs) for **Output Ellipse** objects within the ISOBUS (ISO 11783) object pool. It is part of the `isobus::UT::Q::const::AID` package and provides a standardized set of constant values used to reference specific attributes of an ellipse object (e.g., line style, size, type, angles, fill properties). These constants are essential for correctly reading and writing object attributes when configuring or updating an ellipse on a Virtual Terminal (VT) in agricultural machinery.

Interface Structure

This global constant group does not possess an event or data interface typical of function blocks. Instead, it exposes a set of read-only constant values that can be used globally within the IEC 61499 application.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None (the constants are global, not interface-specific).

Adapters

None.

Functionality

The `AID_OE` constants represent the numeric attribute identifiers for an output ellipse object as defined by the ISOBUS standard. Each constant corresponds to a specific attribute that can be queried or modified via

the object pool services. The values are fixed and immutable, ensuring consistent communication between the VT and the implement controller.

The constants and their meanings are:

Constant Name	Value	Description
LINE_ATT	1	Object ID of a Line Attributes object.
WIDTH	2	Width in pixels.
HEIGHT	3	Height in pixels.
ELLIPSE_TYPE	4	Ellipse type: 0=Closed Ellipse, 1=Open Ellipse, 2=Closed Segment, 3=Closed Section.
START_ANGLE	5	Start angle of the ellipse (in degrees).
END_ANGLE	6	End angle of the ellipse (in degrees).
FILL_ATT	7	Object ID of a Fill Attributes object.

Technical Features

- **Data Type**: All constants are of type `USINT` (unsigned short integer, 8-bit).
- **Fixed Values**: The values are pre-assigned and cannot be changed at runtime.
- **Global Scope**: The constants are accessible from any FB or resource within the 4diac project, promoting code readability and maintainability.
- **Standard Compliance**: They follow the ISOBUS 11783 object pool attribute definitions for output ellipses.
- **Package Location**: Defined within the `isobus::UT::Q::const::AID` namespace, grouping related attribute constants.

State Overview

This global constant group has no state information. It is a static definition file – its values remain unchanged throughout the application lifetime. There are no operational states, transitions, or internal logic.

Application Scenarios

- **Object Pool Creation**: When building an ISOBUS object pool that includes ellipse objects, these constants are used to set or retrieve specific ellipse properties such as width, height, or type.
- **Dynamic Attribute Updates**: In a running VT application, if the implement controller needs to modify an ellipse's dimensions or appearance, it uses these AIDs as command identifiers in the `Change Object Attribute` service.
- **Consistency Across Projects**: By referencing these constants instead of hard-coded numbers, developers avoid errors and improve code clarity.
- **Interoperability**: Ensures that all ellipse-related attributes use standardized identifiers, facilitating communication between equipment from different manufacturers.

Comparison with Similar Blocks

Unlike function blocks that process data or events, `AID_OE` is a passive constant container. It does not execute logic, consume CPU time, or require instantiation. In comparison:

- **Function Blocks** (e.g., `ELLIPSE_CTRL`) actively manage and update ellipse objects, often using these AIDs internally.
- **Other Global Constant Groups** (e.g., `AID_OL` for output line objects) serve the same purpose but for different object types. `AID_OE` specifically targets ellipses, ensuring accurate attribute mapping.
- **Constants vs. Variables**: Constants are immutable, whereas variables can change. Using constants helps prevent accidental modification of critical attribute identifiers.

Conclusion

The `AID_OE` global constant group provides a reliable, standardised set of attribute identifiers for ISOBUS output ellipse objects. It simplifies object pool management, enhances code maintainability, and ensures compliance with international agricultural communication standards. By leveraging these constants,

developers can focus on application logic without worrying about numeric identifier collisions or inconsistencies.

AID_OL

• – ◦ • – ◦ • – ◦ •

Introduction

`AID_OL` is a 4diac-ide global constants definition, not a function block, adapter, or subapplication. It defines a set of named `USINT` constants used as attribute IDs for ISOBUS output line objects. The constant group is part of the package `isobus::UT::Q::const::AID` and is intended to make object pool definitions more readable and maintainable.

Interface Structure

`AID_OL` does not provide an IEC 61499 event/data interface. It is a global constant collection that can be referenced by name inside other IEC 61499 elements.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None. The constants are not runtime input signals; they are globally defined compile-time values.

Data Outputs

None.

Adapters

None.

Defined Constants

Constant	Type	Initial Value	Description
`LINE_ATT`	`USINT`	`1`	Object ID of a Line Attributes object.
`WIDTH`	`USINT`	`2`	Width in pixels.
`HEIGHT`	`USINT`	`3`	Height in pixels.
`LINE_DIR`	`USINT`	`4`	Line direction: `0` = top-left to bottom-right, `1` = bottom-left to top-right.

Functionality

The purpose of `AID_OL` is to centralize the numeric attribute IDs for ISOBUS output line objects. Instead of using hard-coded numbers in function block logic, applications can reference these symbolic constants. This improves readability and reduces the risk of errors when multiple parts of an application need the same attribute IDs.

The constant group contains four attributes that are relevant for configuring line objects in an ISOBUS Virtual Terminal object pool:

- `LINE_ATT` identifies the line attributes object.
- `WIDTH` and `HEIGHT` describe the line dimensions in pixels.
- `LINE_DIR` defines the drawing direction of the line.

Technical Features

- Defined as a `GlobalConstants` element in 4diac-ide.
- Uses the IEC 61499 `USINT` data type.
- Contains fixed initial values assigned at declaration.
- Packaged under `isobus::UT::Q::const::AID`.

- Can be reused across multiple FBs, subapplications, and systems.
- Provides symbolic names for numeric ISOBUS attribute IDs.

State Overview

Not applicable. `AID_OL` is a constant definition and does not contain state machines, execution states, or dynamic runtime behavior.

Application Scenarios

- Building ISOBUS object pools with output line objects.
- Setting line attributes such as width, height, and direction in a Virtual Terminal screen.
- Replacing magic numbers in IEC 61499 applications with meaningful symbolic constants.
- Sharing a common definition of output line attribute IDs across multiple function blocks or projects.

Comparison with Similar Blocks

`AID_OL` can be compared with other ISOBUS attribute ID constant groups, typically named `AID_*`. While function blocks and adapters define runtime behavior, `AID_OL` only provides static constant values. Its main advantage over inline numeric literals is centralization and consistency. Similar constant groups exist for other ISOBUS object types and provide the same style of symbolic access.

Conclusion

`AID_OL` is a compact global constants group for ISOBUS output line object attribute IDs. It defines four `USINT` constants in a named package, making them easy to reuse in 4diac-ide applications. Although it has no function block interface or runtime state, it contributes to cleaner, more maintainable ISOBUS object pool handling.

AID_OLA

• – ◦ • – ◦ • – ◦ •

Introduction

`AID_OLA` is a set of global constants used in ISOBUS (ISO 11783) applications to identify attribute IDs for **Output List Objects** (OLA). It defines numeric identifiers for common attributes of a list object, such as its width, height, variable reference, and selected value. These constants are intended to be used together with the ISOBUS Virtual Terminal (VT) protocol to avoid hard-coding attribute IDs in application code, making the code more readable and maintainable.

Interface Structure

As a **global constants** group, `AID_OLA` does not expose any event or data interface. It is not a function block, adapter, or subapplication. Instead, it provides a set of constant values that can be referenced throughout the application.

Event Inputs

Not applicable.

Event Outputs

Not applicable.

Data Inputs

Not applicable.

Data Outputs

Not applicable.

Adapters

Not applicable.

Functionality

The constants defined in `AID_OLA` correspond to the attribute identifiers used in the ISOBUS **Output List Object** (Object type 1, “Output List”). The following attributes are defined:

Constant	Value	Description
WIDTH	1	AID_OLA_WIDTH – Width of the output list in pixels.
HEIGHT	2	AID_OLA_HEIGHT – Height of the output list in pixels.
VARIABLE_REF	3	AID_OLA_VARIABLE_REF – Object ID of a Number Variable linked to the list.
VALUE	4	AID_OLA_VALUE – Selected list index (0 to 254), or 255 if no item is chosen.

These constants should be used when constructing or interpreting VT command messages that manipulate an output list object.

Technical Features

- **Data type:** All constants are of type USINT (unsigned short integer, 8-bit).
- **Range:** The values are fixed within the range 1–4, corresponding to the official ISOBUS attribute identifiers.
- **Package:** The constants are declared in the package isobus::UT::Q::const::AID.
- **Initialization:** Each constant is explicitly initialized with its numeric value using the USINT# prefix.
- **Compatibility:** Designed for use with 4diac IDE and ISOBUS-capable control systems.

State Overview

Since AID_OLA is a constant definition, no stateful behavior exists. The values are immutable at runtime and do not change during execution.

Application Scenarios

AID_OLA is typically used in applications that implement an ISOBUS Virtual Terminal client or a control function that interacts with a VT. For example:

- **Setting the size of an output list:** When creating or updating an output list object, the WIDTH and HEIGHT attributes must be transmitted with the correct IDs. Using AID_OLA.WIDTH and AID_OLA.HEIGHT avoids magic numbers.
- **Linking a variable:** The VARIABLE_REF constant is used when associating a number variable with the list object, enabling bidirectional data exchange.
- **Reading the user selection:** The VALUE constant identifies the attribute that holds the currently selected index. This allows the application to query the selected element from the VT.

Comparison with Similar Blocks

AID_OLA is one of many global constant sets defined for ISOBUS object attributes. Similar groups exist for other object types, such as AID_OUTPUT_STRING, AID_NUMBER_VARIABLE, AID_KEY, etc. The main advantage of using such constant groups is that they provide a single source of truth for attribute IDs, reducing errors and improving code clarity. Unlike function blocks, they do not have execution logic, but they are often used together with function blocks that implement VT protocol handling.

Conclusion

The AID_OLA global constants provide a clean, standardised way to reference Output List Object attribute IDs in ISOBUS applications. By using these named constants, developers can ensure correct and maintainable code when working with Virtual Terminal objects. Although it is not a functional block itself, it is an essential building block for ISOBUS communication logic.

AID_OLBG

• – ◦ • – ◦ • – ◦ •

Introduction

The AID_OLBG Global Constants definition provides a structured set of named constants that identify attribute IDs for an **Output Linear Bar Graph** object in ISOBUS-based communication systems (ISO 11783). These constants serve as a lookup table for object attribute identifiers used when configuring or updating linear bar graph elements on virtual terminals. The constants correspond to the attribute IDs defined in the ISOBUS Object Pool specification, enabling consistent and readable access to these identifiers in IEC 61499 applications.

Interface Structure

Since AID_OLBG is a global constant definition rather than a function block, it does not contain event inputs, event outputs, data inputs/outputs, or adapters. Instead, it exposes a set of compile-time constants (all of type USINT) that can be referenced throughout an application. The following list enumerates these constants and their meanings.

Data Constants

Constant Name	Type	Value	Description
WIDTH	USINT	1	Attribute ID for width in pixels (AID_OLBG_WIDTH).
HEIGHT	USINT	2	Attribute ID for height in pixels (AID_OLBG_HEIGHT).
COLOUR	USINT	3	Attribute ID for the colour index (AID_OLBG_COLOUR).
TARGET_LINE_COLOUR	USINT	4	Attribute ID for the target line colour (AID_OLBG_TARGET_LINE_COLOUR).
OPTIONS	USINT	5	Attribute ID for the options bitmask (AID_OLBG_OPTIONS).
NUMB_TICKS	USINT	6	Attribute ID for the number of ticks (AID_OLBG_NUMB_TICKS).
MIN_VALUE	USINT	7	Attribute ID for the minimum value (AID_OLBG_MIN_VALUE).
MAX_VALUE	USINT	8	Attribute ID for the maximum value (AID_OLBG_MAX_VALUE).
VARIABLE_REF	USINT	9	Attribute ID for the reference to a Variable object (AID_OLBG_VARIABLE_REF).
TARGET_VAL_VAR_REF	USINT	10	Attribute ID for the target value variable reference (AID_OLBG_TARGET_VAL_VAR_REF).
TARGET_VALUE	USINT	11	Attribute ID for the target value (AID_OLBG_TARGET_VALUE).
VALUE	USINT	12	Attribute ID for the current value (AID_OLBG_VALUE).

Functionality

The primary purpose of AID_OLBG is to provide a named, type-safe collection of ISOBUS attribute IDs for an output linear bar graph object. In ISOBUS object pool implementations, each visual object (such as a bar graph) has a set of configurable attributes, each identified by a numeric ID. The constants defined here map human-readable names to these numeric IDs, allowing application developers to:

- Refer to attribute IDs by meaningful names instead of raw numeric literals.
- Ensure consistency across multiple functions and blocks that interact with the same bar graph.
- Simplify maintenance by centralizing the attribute ID definitions in one location.

The underlying ISO 11783 specification defines these attributes as AID_OLBG_* IDs. This constant set is packaged under the isobus::UT::Q::const::AID namespace and is intended for use in ISOBUS virtual terminal implementations.

Technical Features

- **Data Type Consistency**: All constants are declared as USINT (unsigned short integer), aligning with the ISOBUS attribute ID data type.
- **Namespace Organization**: The constants reside in the package isobus::UT::Q::const::AID, preventing name collisions and improving modularity.
- **Global Scope**: Declared as VAR_GLOBAL CONSTANT, the identifiers are accessible from any resource or function block within the IEC 61499 application.
- **Compile-Time Values**: As constants, their values are resolved at compile time, enabling compiler optimizations and reducing runtime overhead.
- **Documentation via Comments**: Each constant is annotated with its corresponding ISOBUS attribute ID name and description.

State Overview

The `AID_OLBG` definition does not maintain runtime states or internal state machines. It is a static, constant collection that remains unchanged during execution. Its "state" is fixed at compile time and does not influence runtime behavior beyond providing constant values.

Application Scenarios

Typical use cases for `AID_OLBG` include:

- **ISOBUS Virtual Terminal Displays**: Configuring a linear bar graph object on a virtual terminal by setting its attributes (size, colour, range, ticks, etc.).
- **Object Pool Construction**: Building or modifying an ISOBUS object pool where bar graph attribute IDs must be explicitly referenced.
- **Command/Response Handling**: Interpreting or constructing command messages that update bar graph properties using attribute IDs.
- **Cross-Component Communication**: Passing attribute IDs between function blocks that manage virtual terminal objects, ensuring consistent referencing.

For example, when a function block needs to update the `MIN_VALUE` attribute of a bar graph, it can use the constant `AID_OLBG.MIN_VALUE` instead of the literal `7`.

Comparison with Similar Blocks

Within the same `isobus::UT::Q::const::AID` package, there may exist similar global constant definitions for other object types (e.g., output text, output meter, or input objects). In contrast to a function block that performs logic or data transformation, these constant definitions are pure data collections. Their main advantages include:

- **Clarity**: Named constants reduce the risk of using incorrect attribute IDs.
- **Maintainability**: Changes to attribute ID values (should the ISOBUS standard evolve) require a single edit.
- **Self-Documentation**: The declaration includes descriptive comments and initial values, making the mapping explicit.

Compared to using raw numeric literals within application logic, `AID_OLBG` ensures that all references are consistent and auditable.

Conclusion

The `AID_OLBG` global constants definition provides a clean, standardized mechanism for referencing output linear bar graph attribute IDs in ISOBUS applications. By centralizing these IDs as named constants, it promotes code readability, maintainability, and correctness. It is an essential component for developers working with ISOBUS virtual terminals, serving as a reliable reference layer between the IEC 61499 application logic and the ISO 11783 object model.

AID_OLRL

• − ◦ • − ◦ • − ◦ •

Introduction

The `AID_OLRL` global constant set defines a collection of attribute identifiers used in the context of object label reference lists within the ISOBUS UT (Universal Terminal) protocol. These constants serve as predefined numeric values that facilitate the identification and handling of labelled objects in agricultural machinery communication. This constant set is part of the `isobus::UT::Q::const::AID` namespace and provides a single, clearly named constant for use in application logic.

Interface Structure

As a global constant set, `AID_OLRL` does not expose events, data inputs/outputs, or adapters. Instead, it provides a static value that can be referenced by other function blocks or applications.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The AID_OLRL constant set defines a single constant:

Constant Name	Data Type	Initial Value	Description
NUMB_LABELLED_OBJ	USINT	USINT#1	Attribute ID for the number of labelled objects that follow in an object label reference list.

This constant is intended to be used when constructing or parsing object label reference lists, ensuring consistent identification of the "number of labelled objects" field across different implementations.

Technical Features

- **Data Type**: USINT (unsigned short integer), occupying 1 byte.
- **Initial Value**: 1, representing the standard attribute ID for the number of labelled objects.
- **Namespace**: isobus::UT::Q::const::AID (accessed as AID_OLRL.NUMB_LABELLED_OBJ).
- **Compliance**: Aligns with ISO 11783 (ISOBUS) standards for UT functional objects.

State Overview

Not applicable – this is a constant set and does not maintain any runtime state.

Application Scenarios

- Used when decoding or encoding object pool transfer messages that include object label reference lists.
- Helps to write robust code that avoids hard-coded attribute IDs.
- Serves as a reference for developers implementing ISOBUS UT clients or servers.

Comparison with Similar Blocks

Similar global constant sets exist for other attribute groups (e.g., AID_OL for object labels). Unlike function blocks, this constant set provides no processing capability; it simply offers named numeric constants. When compared to direct literals, using the constant improves code readability and maintainability.

Conclusion

The AID_OLRL global constant set is a simple, yet essential, component for applications dealing with ISOBUS object label reference lists. By defining the NUMB_LABELLED_OBJ constant, it standardizes the representation of this attribute ID, reducing the risk of errors and enhancing code clarity.

AID_OM

• – ◦ • – ◦ • – ◦ •

Introduction

AID_OM is a global constant definition set used in the context of ISOBUS virtual terminal (VT) applications. It defines attribute identifiers (IDs) for the **Output Meter** object, which is a graphical element used to display a value on a scale, typically with a needle and tick marks. The constants provide a standardized, human-readable way to reference the attributes of an output meter when constructing or modifying VT object data.

This global constant set belongs to the package isobus::UT::Q::const::AID and contains twelve USINT (unsigned short integer) constants, each representing a specific attribute ID (1 to 12) of the output meter object according to the ISOBUS standard ISO 11783.

Interface Structure

Since AID_OM is a global constants definition rather than a function block, adapter, or subapplication, it does not expose any runtime interface. The following sections reflect the standard FB interface structure

and are marked “Not applicable” where no corresponding members exist. The actual constant definitions are listed in the **Global Constants** subsection.

Event Inputs

Not applicable – `AID_OM` defines no event inputs.

Event Outputs

Not applicable – `AID_OM` defines no event outputs.

Data Inputs

Not applicable – `AID_OM` defines no data inputs, as it is a set of compile-time constants.

Data Outputs

Not applicable – `AID_OM` defines no data outputs.

Adapters

Not applicable – `AID_OM` contains no adapter instances.

Global Constants

The following table lists all constants defined in `AID_OM`. Each constant holds the numeric attribute ID used for the corresponding output meter property in a VT object.

Constant Name	Type	Value	Attribute ID	Description
`WIDTH`	USINT	1	1	Width in pixels (AID_OM_WIDTH).
`NEEDLE_COLOUR`	USINT	2	2	Needle colour index (AID_OM_NEEDLE_COLOUR).
`BORDER_COLOUR`	USINT	3	3	Border colour index (AID_OM_BORDER_COLOUR).
`ARC_THICK_COLOUR`	USINT	4	4	Arc thickness / colour index (AID_OM_ARC_THICK_COLOUR).
`OPTIONS`	USINT	5	5	Bitmask options: Bit 0 = Draw Arc, Bit 1 = Draw Border, Bit 2 = Draw Ticks, Bit 3 = Deflection direction (0 = anticlockwise, 1 = clockwise).
`NUMB_TICKS`	USINT	6	6	Number of tick marks (AID_OM_NUMB_TICKS).
`START_ANGLE`	USINT	7	7	Start angle of the scale (AID_OM_START_ANGLE).
`END_ANGLE`	USINT	8	8	End angle of the scale (AID_OM_END_ANGLE).
`MIN_VALUE`	USINT	9	9	Minimum displayed value (AID_OM_MIN_VALUE).
`MAX_VALUE`	USINT	10	10	Maximum displayed value (AID_OM_MAX_VALUE).
`VARIABLE_REF`	USINT	11	11	Object ID of a Variable object (AID_OM_VARIABLE_REF).
`VALUE`	USINT	12	12	Current value shown by the meter (AID_OM_VALUE).

Functionality

The `AID_OM` constants serve as static symbolic references for the attribute identifiers of an ISOBUS output meter object. When a control application needs to create, modify, or read an output meter object on a VT,

it uses these constants to specify which attribute is being addressed. For example, setting the `OPTIONS` attribute to a desired bitmask requires referring to it as `AID_OM.OPTIONS` rather than using the raw numeric ID 5.

Because the constants are defined once in a central location, they improve code readability, reduce the risk of typographical errors, and simplify maintenance if attribute IDs ever change in the future.

Technical Features

- **Type**: All constants are of type `USINT` (8-bit unsigned integer).
- **Initial Values**: Each constant is explicitly initialized to its attribute ID value (1 to 12) using typed literals (e.g., `USINT#1`).
- **Package**: `isobus::UT::Q::const::AID` – indicates the constant set belongs to the ISOBUS utility toolkit, within the object-oriented VT class hierarchy.
- **Standard Compliance**: The constants follow the attribute ID numbering defined by ISO 11783 (ISOBUS) for the Output Meter object.
- **No Runtime Side Effects**: As a `GlobalConstants` definition, it only influences compilation and does not occupy runtime memory or trigger logic execution.

State Overview

Not applicable – `AID_OM` contains no state information, no state machines, and no execution logic. It is a purely declarative constant set.

Application Scenarios

- **VT Object Construction**: When building an output meter object via a control function, use the constants to populate attribute fields in a structured way.
- **Dynamic Update**: When updating the meter's current value (`VALUE`), the constant can be used to set the corresponding attribute in a VT command without hard-coding numeric IDs.
- **Configuration**: Use `OPTIONS` to configure the visual appearance (arc, border, ticks, deflection direction) of the meter.
- **Scaling**: Use `MIN_VALUE`, `MAX_VALUE`, `START_ANGLE`, and `END_ANGLE` to define the scale's range and angular span.

Comparison with Similar Blocks

`AID_OM` is one of several global constant definitions under the `isobus::UT::Q::const::AID` package. Similar sets exist for other VT object types (e.g., output line, output rectangle, etc.), each following the same pattern: a collection of `USINT` constants with values matching the standard attribute IDs. The advantage of this approach over raw numeric literals is consistent naming, centralized documentation, and compile-time type safety. In contrast to function blocks or subapplications, `AID_OM` provides no algorithmic behavior – it serves purely as a reference library for application developers.

Conclusion

The `AID_OM` global constants set provides a clean, standardized, and type-safe means of referencing output meter attribute IDs in ISOBUS VT applications. By using these symbolic constants instead of raw numbers, developers can write more readable, maintainable, and error-resistant code when working with output meter objects.

AID_ON

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_ON` set of global constants defines the attribute identifiers (IDs) used for the **Output Number Object** within the ISO 11783 (ISOBUS) User Interface (UI) standard. These constants map human-readable names to numeric attribute codes, which are employed when reading or writing properties of an output number object on a Virtual Terminal or similar device.

This constant set is part of the `isobus::UT::Q::const::AID` package and provides a consistent way to reference object attributes without hard-coding numeric values in application logic.

Interface Structure

`AID_ON` is not a function block or adapter; it is a collection of constant definitions. Therefore, it does not have event or data inputs/outputs in the traditional sense. The following sections reflect the standard documentation structure for function blocks, but here they are marked as **not applicable**.

Event Inputs

None – `AID_ON` defines only global constants.

Event Outputs

None – `AID_ON` defines only global constants.

Data Inputs

None – `AID_ON` defines only global constants.

Data Outputs

None – `AID_ON` defines only global constants.

Adapters

None – `AID_ON` is a constant set, not a block with adapters.

Functionality

The `AID_ON` constants assign symbolic names to the attribute identifiers (1 to 12) used by the ISO 11783 Output Number Object. Each constant is of type `USINT` and has a fixed initial value corresponding to its attribute ID. These identifiers are used, for example, when constructing or parsing CAN messages that manipulate the properties of a number display object.

The following table summarises the constants:

Constant Name	Value	Description
`WIDTH`	1	Width in pixels.
`HEIGHT`	2	Height in pixels.
`BACKGROUND_COLOUR`	3	Background colour index.
`FONT_ATT`	4	Object ID of a Font Attributes object.
`OPTIONS`	5	Options bitmask.
`VARIABLE_REF`	6	Object ID of a Number Variable object.
`OFFSET`	7	Offset to be applied to the value for display.
`SCALE`	8	Scale to be applied to the value for display.
`NUMB_DECIMALS`	9	Number of decimals to display after the decimal point.
`FORMAT`	10	Format: 0 = fixed decimal, 1 = exponential.
`JUSTIFICATION`	11	Justification: bits 0-1 horizontal, bits 2-3 vertical.
`VALUE`	12	Current value before scaling.

Technical Features

- **Type:** All constants are declared as `USINT` (unsigned short integer).
- **Initial Values:** Each constant is initialised with its numeric attribute ID as a `USINT#` literal.
- **Package:** The constants are defined in the package `isobus::UT::Q::const::AID`.
- **Compatibility:** Complies with the IEC 61499 standard and is intended for use in 4diac-IDE projects interacting with ISOBUS virtual terminals.

State Overview

`AID_ON` does not represent a state machine; it is a set of constant values. There are no states or transitions.

Application Scenarios

- **ISOBUS Virtual Terminal Development:** The constants are used when building or interpreting commands that set or query attributes of an output number object on a Virtual Terminal.
- **HMI Design in Agricultural Machinery:** Developers can reference `AID_ON_WIDTH`, `AID_ON_HEIGHT`, etc., to configure display elements programmatically.
- **Protocol Implementation:** When constructing CAN messages according to the ISOBUS standard, these constants provide a clear and maintainable mapping.

Comparison with Similar Blocks

`AID_ON` is a global constants collection, not a function block. Similar constant sets exist for other object types (e.g., `AID_OFF` for input number objects) and are typically named with the prefix `AID_` followed by the object type. The key difference is that `AID_ON` specifically covers attributes of the **output number** object, whereas other sets cover different object categories. Using such named constants improves code readability and reduces errors compared to using raw numerical IDs.

Conclusion

The `AID_ON` constant set provides a clean, standardised way to refer to attribute identifiers of ISO 11783 Output Number Objects. By using these symbolic names, developers can write more maintainable and portable code for ISOBUS-based HMI applications in the 4diac environment.

AID_OP_POLY

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_OP_POLY` global constants set defines the attribute identifiers (IDs) for an **Output Polygon** object in the ISO 11783 (ISOBUS) protocol. These constants are used in the object pool definition to reference the geometric and rendering properties of a polygon, enabling standardized communication between tractor-implements and the virtual terminal. The set provides symbolic names for the numeric attribute IDs, improving code readability and maintainability.

Interface Structure

`AID_OP_POLY` is a **global constant set** within the 4diac-IDE environment. It does not expose any operational interface, such as event inputs/outputs, data inputs/outputs, or adapters. Instead, it provides compile-time constant values that can be imported and used anywhere in the automation project.

Event Inputs

None – the constant set is passive and does not react to events.

Event Outputs

None – no events are generated.

Data Inputs

None – values are not dynamically changeable.

Data Outputs

None – constants are only read at build time.

Adapters

None – no adapters are required or provided.

Functionality

The constants in `AID_OP_POLY` represent the attribute IDs defined by the ISOBUS standard for an **Output Polygon** object. Each ID is a fixed numeric value (USINT) that corresponds to a specific attribute in the object's definition. By using these symbolic names, developers can avoid hard-coding magic numbers and ensure compliance with the standard. The set includes attributes for:

- **Width** of the polygon outline (in pixels)
- **Height** of the polygon (in pixels)
- **Line Attributes** – reference to a Line Attributes object (ID)

- **Fill Attributes** – reference to a Fill Attributes object (ID)
- **Polygon Type** – convex, non-convex, complex, or open

These constants are typically used in conjunction with the `AID_OP_*` series to build complete ISOBUS object pools.

Technical Features

- **DataType**: All constants are of type `USINT` (unsigned short integer, 8-bit) with initial values from 1 to 5.
- **Namespace**: The constants reside in the package `isobus::UT::Q::const::AID`.
- **Scope**: Declared as `GLOBALCONSTANT` entities, they are globally accessible within the 4diac project after the defining library is imported.
- **Compatibility**: Compliant with IEC 61499-1 and the ISOBUS object pool specification.

Constant	Value	Description
`WIDTH`	`USINT#1`	Attribute ID for polygon width in pixels.
`HEIGHT`	`USINT#2`	Attribute ID for polygon height in pixels.
`LINE_ATT`	`USINT#3`	Object ID of a Line Attributes object for the polygon's outline.
`FILL_ATT`	`USINT#4`	Object ID of a Fill Attributes object for the polygon's interior.
`POLYGON_TYPE`	`USINT#5`	Polygon type: 0=Convex, 1=Non-Convex, 2=Complex, 3=Open.

State Overview

The `AID_OP_POLY` constant set is **stateless**. It contains only constant values that are evaluated at compile time; there is no runtime state machine or dynamic behavior. The constants are immutable and do not change during execution.

Application Scenarios

- **ISOBUS Object Pool Definition**: Used when defining an Output Polygon within a Virtual Terminal object pool, to set attributes like outline width, fill style, and polygon type.
- **Custom Implementations**: Developers implementing ISOBUS-compliant control systems can include these constants to avoid errors in attribute ID assignments.
- **Tooling and Simulation**: May be used by simulation and test tools to validate object pool structures.

Comparison with Similar Blocks

In the 4diac-IDE environment, several global constant sets exist for different object types (e.g., `AID_OP_LINE`, `AID_OP_RECT`). Like `AID_OP_POLY`, they provide symbolic names for attribute IDs of their respective geometric objects. The structure is analogous, but the actual attribute IDs and meanings differ. For example, `AID_OP_RECT` includes attributes for corner radius and line style, while `AID_OP_POLY` focuses on polygon-specific properties like polygon type and width/height.

Conclusion

The `AID_OP_POLY` global constant set is a convenient and standard-compliant way to reference the attribute IDs of an ISOBUS Output Polygon object. By using the symbolic names instead of raw numbers, IEC 61499 applications become more readable, less error-prone, and easier to maintain. The constant set is stateless, integrates seamlessly with 4diac-IDE, and directly supports the creation of robust ISOBUS object pools.

AID_OP_PTR

• – ◦ • – ◦ • – ◦ •

Introduction

The **AID_OP_PTR** global constant container defines the object pointer attribute identifiers used in the ISOBUS (ISO 11783) protocol stack. It centralizes the enumeration of object pointer attributes, ensuring consistent and unambiguous references across the system. This resource is part of the `isobus::UT::Q::const::AID` package and provides a single constant, `VALUE`, representing the current value attribute.

Interface Structure

As a global constant container, **AID_OP_PTR** does not expose any event or data interfaces. It only provides a set of compile-time constants that can be referenced globally by other function blocks and modules.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The primary purpose of **AID_OP_PTR** is to supply a stable, well-defined identifier for the object pointer value attribute. The constant `VALUE` is defined as:

- **Name**: `VALUE`
- **Data Type**: `USINT` (Unsigned Short Integer)
- **Initial Value**: `USINT#1`
- **Semantic**: `1: AID_OP_PTR_VALUE` – Current value.

This constant can be used in the implementation of ISOBUS object pools, especially when handling object pointer references. By referencing `AID_OP_PTR.VALUE` (or the equivalent qualified name), developers avoid hard-coding numeric literals and ensure clarity and maintainability.

Technical Features

- **Type**: `USINT` – Provides a compact 8-bit unsigned representation, sufficient for attribute identifiers.
- **Initialization**: The constant is defined with an explicit initial value (`USINT#1`), guaranteeing a predictable default.
- **Namespace**: Lives under `isobus::UT::Q::const::AID`, which organizes all object attribute identifiers in a hierarchical manner.
- **Compatibility**: Works seamlessly with 4diac-IDE projects that require global constant definitions for protocol-specific parameters.

State Overview

Since **AID_OP_PTR** is a constant container, it does not have any runtime state or transitions. The value of `VALUE` remains fixed throughout the execution of the application.

Application Scenarios

- **ISOBUS Object Pool Implementation**: When defining object pointers (e.g., for the Virtual Terminal), the attribute ID `1` is required to denote the current value. Using `AID_OP_PTR.VALUE` ensures correct interpretation across different implementations.
- **Protocol Extensions**: If additional object pointer attributes are introduced in future revisions, they can be appended to this constant container, maintaining a single source of truth.
- **Code Clarity**: Enhances readability by giving a meaningful name to the numeric ID `1`, making the code self-documenting.

Comparison with Similar Blocks

Unlike other ISOBUS constant blocks (such as `AID_PTR`, `AID_OBJECT`, or `AID_VIRTUAL_TERMINAL`), **AID_OP_PTR** specifically focuses on object pointer attributes. It follows the same pattern of defining `USINT` constants for each attribute ID, but its purpose is limited to the object pointer context. This separation keeps the constant sets logically organized and prevents accidental reuse of identifiers.

Conclusion

AID_OP_PTR is a small but essential constant container in the ISOBUS stack. By providing the standard object pointer attribute ID, it supports the correct implementation of object pools and contributes to the maintainability and portability of industrial automation applications using the 4diac-IDE. Its simplicity and clear definition make it a reliable building block for any ISOBUS-compliant system.

AID_OR

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_OR` global constants block defines a set of attribute identifiers used for output rectangle objects in the ISOBUS (ISO 11783) agricultural electronics protocol. These constants provide a standardized way to reference the attributes of an output rectangle, such as line style, width, height, line suppression, and fill attributes. The values are defined as unsigned short integers (USINT) and are intended to be used in conjunction with object pool definitions and communication interfaces.

Interface Structure

The `AID_OR` block does not contain any event inputs, event outputs, or adapters. It solely provides a collection of data constants that can be referenced globally throughout a 4diac application.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The following table lists the constant data values defined by this block. They are accessible as read-only variables.

Name	Type	Value	Comment
`LINE_ATT`	USINT	1	Object ID of a Line Attributes object.
`WIDTH`	USINT	2	Width in pixels.
`HEIGHT`	USINT	3	Height in pixels.
`LINE_SUPPR`	USINT	4	Line suppression attribute.
`FILL_ATT`	USINT	5	Object ID of a Fill Attributes object.

Adapters

None.

Functionality

The global constants are designed to be used as arguments when creating or modifying output rectangle objects in an ISOBUS object pool. By referencing these named constants instead of hard-coded numeric values, the application code becomes more readable, self-documenting, and less error-prone. For example, when setting the width attribute of a rectangle, the constant `AID_OR.WIDTH` can be used to indicate that the following value refers to the width in pixels.

Technical Features

- **Type:** All constants are of type `USINT` (unsigned short integer), capable of representing values from 0 to 255.
- **Package:** The constants belong to the package `isobus::UT::Q::const::AID`, which organizes them within the namespace hierarchy.

- **Initialization:** Each constant is initialized with a specific attribute ID, ensuring consistent behavior across all referencing components.
- **Read-Only:** These are global constants and cannot be modified at runtime, providing compile-time safety.

State Overview

Since `AID_OR` contains only constants, there is no runtime state or dynamic behavior. The values are fixed at compile time and remain constant throughout the execution of the application.

Application Scenarios

- **Object Pool Creation:** When constructing an ISOBUS object pool, the developer can use these constants to define properties of output rectangle objects, such as line type, dimensions, or fill style.
- **Communication Parameterization:** The constants can be passed to commands that update the attributes of a rectangle object on a virtual terminal or control unit.
- **Code Maintainability:** Using named constants improves code clarity and makes it easier to update attribute IDs if the ISOBUS specification changes, since only the constant definitions need to be modified.

Comparison with Similar Blocks

In the same package, there may be similar global constant blocks for other object types (e.g., `AID_OT` for output text, `AID_OB` for output bar). `AID_OR` specifically focuses on output rectangle attributes, providing a distinct set of IDs tailored to that object type. Unlike function blocks that encapsulate logic, `AID_OR` is a pure data definition unit, making it lightweight and universally applicable.

Conclusion

The `AID_OR` global constants block is an essential utility for any ISOBUS-based application that deals with output rectangle objects. It centralizes attribute identifiers, promotes code reuse, and ensures consistency across different modules. By adopting these constants, developers can build more robust and maintainable agricultural automation systems.

AID_OS

• − ◦ • − ◦ • − ◦ •

Introduction

The **AID_OS** global constant set defines the attribute identifiers (IDs) for the **Output String (OS) object** within the ISO 11783 (ISOBUS) protocol, specifically for the Working Set (WS) and Virtual Terminal (VT) layers. These IDs are used to reference specific attributes of an output string object when interacting with the object pool via the ISOBUS service primitives. The set is part of a larger collection of constant definitions that simplify and standardize the handling of object attributes in 4diac-based ISOBUS applications.

The constants are of type `USINT` (unsigned short integer) and range from 1 to 7, each corresponding to a unique attribute of the output string object, such as width, height, background color, font attributes, options, variable reference, and justification.

Interface Structure

This global constant set does not represent a function block, adapter, or subapplication. Instead, it provides a set of named constants that can be used directly in IEC 61499 applications to access the respective attribute IDs. The “interface” of the set is therefore the list of constants it exposes.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None directly. However, the constants serve as data values that can be passed to function blocks or functions that require an attribute ID.

Data Outputs

The following global constants are defined and can be referenced anywhere in the application:

Constant Name	Value	Description
WIDTH	USINT#1	1: AID_OS_WIDTH – Width in pixels.
HEIGHT	USINT#2	2: AID_OS_HEIGHT – Height in pixels.
BACKGROUND_COLOUR	USINT#3	3: AID_OS_BACKGROUND_COLOUR – Background colour index.
FONT_ATT	USINT#4	4: AID_OS_FONT_ATT – Object ID of a Font Attributes object.
OPTIONS	USINT#5	5: AID_OS_OPTIONS – Bitmask: Bit 0 = Transparent, Bit 1 = Auto-Wrap, Bit 2 = Wrap on Hyphen.
VARIABLE_REF	USINT#6	6: AID_OS_VARIABLE_REF – Object ID of a Variable object.
JUSTIFICATION	USINT#7	7: AID_OS_JUSTIFICATION – Justification: Bits 0-1 (Horizontal: 0=Left, 1=Middle, 2=Right), Bits 2-3 (Vertical: 0=Top, 1=Middle, 2=Bottom).

Adapters

None.

Functionality

The AID_OS constant set is used to map symbolic names to numeric attribute IDs for an ISOBUS Output String object. When an application needs to read or write an attribute of such an object (e.g., via the Set_Attribute or Get_Attribute services), it can use these constants instead of hard-coded numeric values. This improves code readability, maintainability, and reduces the risk of errors.

The constants are declared as global constants within the namespace isobus::UT::Q::const::AID, ensuring they are globally accessible and immutable. They are compiled directly into the application and occupy no runtime memory beyond the constant literals.

Technical Features

- **Type**: USINT (unsigned 8-bit integer)
- **Range**: 1 to 7 (inclusive)
- **Namespace**: isobus::UT::Q::const::AID
- **Immutability**: The constants are declared as CONSTANT and cannot be modified at runtime.
- **Direct Usage**: May be used in any IEC 61499 FB or ST code without further instantiation.
- **Documentation**: Each constant is accompanied by a comment describing its corresponding ISOBUS AID_OS_* definition.

State Overview

Not applicable. This is a constant set without internal states or dynamic behavior.

Application Scenarios

Typical use cases for AID_OS include:

- **ISO 11783 Virtual Terminal Implementations**: When developing a VT client or server that manages output string objects, these constants are used to construct attribute access commands.
- **Object Pool Manipulation**: When reading or modifying object attributes in an ISOBUS object pool, the constants provide a clear mapping.
- **Diagnostic and Monitoring Tools**: Applications that inspect or alter output string properties (e.g., text alignment, transparency, size) can use these IDs to identify the target attribute.
- **Integration with 4diac Function Blocks**: In 4diac, function blocks that handle ISOBUS communication can accept these constants as inputs to specify which attribute to target.

Comparison with Similar Blocks

In the same ISOBUS context, other constant sets exist for different object types, such as:

- AID_OBJ – general object attributes
- AID_AB – for Alphanumeric Input objects

- AID_WS – for Working Set objects
- AID_OS is specifically tailored to the Output String object.

Unlike a function block, AID_OS does not execute logic or contain state; it is purely a data definition. It serves as a companion to function blocks that implement the ISOBUS communication services, providing a consistent and readable way to reference attribute IDs.

Conclusion

AID_OS is a compact and essential set of global constants that encapsulate the attribute identifiers of the ISOBUS Output String object. By using these symbolic constants, developers can write clearer, more maintainable 4diac applications that interact with ISOBUS VTs. The set is well-documented, follows the standard naming convention, and aligns with the Eclipse 4diac ecosystem's philosophy of modular and reusable components.

AID_PG

• – ◦ • – ◦ • – ◦ •

Introduction

The AID_PG global constants set defines the attribute identifiers (IDs) for **Picture Graphic (PG)** objects within ISO 11783 (ISOBUS) object pools. These constants are used by function blocks and applications to reference specific properties of picture graphic objects, such as their dimensions, transparency settings, and colour format. By using symbolic names instead of raw numeric values, the code becomes more readable, self-documenting, and resilient against changes in the underlying protocol specifications.

Interface Structure

AID_PG is not a function block or adapter but a collection of global constants. It does not possess dynamic interfaces such as events, data inputs/outputs, or adapters. Instead, it provides a set of named constant values that can be referenced throughout a 4diac project.

Event Inputs

None. The constants set does not process events.

Event Outputs

None. The constants set does not generate events.

Data Inputs

None. The constants set does not accept any data inputs.

Data Outputs

The following global constants are defined, serving as static attribute IDs for picture graphic objects:

Constant	Type	Initial Value	Description
WIDTH	USINT	1	Attribute ID for the width of the picture graphic in pixels (AID_PG_WIDTH).
OPTIONS	USINT	2	Attribute ID for an options bitmask – bit 0: transparent, bit 1: flashing, bit 2: run-length encoded (RLE) (AID_PG_OPTIONS).
TRANSPARENCY_COLOUR	USINT	3	Attribute ID for the transparency colour index (AID_PG_TRANSPARENCY_COLOUR).
ACTUAL_WIDTH	USINT	4	Attribute ID for the actual width in pixels (AID_PG_ACTUAL_WIDTH).
ACTUAL_HEIGHT	USINT	5	Attribute ID for the actual height in pixels (AID_PG_ACTUAL_HEIGHT).
FORMAT	USINT	6	Attribute ID for the picture graphic format: 0 = monochrome, 1 = 4-bit colour, 2 = 8-bit colour (AID_PG_FORMAT).

Adapters

None. The constants set does not contain any adapter instances.

Functionality

The `AID_PG` constants serve as standardised numeric identifiers for the attributes of a picture graphic object in an ISOBUS object pool. When a function block needs to read or write a picture graphic attribute (e.g., during object pool construction, dynamic updates, or diagnostics), it can use these constants as the attribute ID parameter. This approach ensures interoperability with ISOBUS terminals and simplifies the maintenance of object pool definitions.

Technical Features

- All constants are of type `USINT` (unsigned short integer), requiring only a single byte of storage.
- The values are fixed at compile time and cannot be modified during runtime.
- The constant names follow an intuitive naming convention that corresponds to the official ISOBUS attribute names.
- The constants are defined in a namespace (`isobus::UT::Q::const::AID`) to avoid naming conflicts with other global constants.

State Overview

Not applicable – a global constants set does not have a state machine. It provides static data that remains unchanged throughout the execution of the application.

Application Scenarios

The `AID_PG` constants are predominantly used in ISOBUS compatible agricultural machinery and control systems. Typical scenarios include:

- **Object pool generation** – when creating or uploading graphic objects to a Virtual Terminal, the attribute IDs for picture graphics are required to set properties such as width, height, transparency, and format.
- **Dynamic graphic updates** – in applications that modify picture graphics at runtime (e.g., displaying changing weather maps or yield data), these constants allow efficient access to the respective attributes.
- **Diagnostics and debugging** – during development, referencing attribute IDs by symbolic constants enhances code readability and reduces the risk of using incorrect numeric values.

Comparison with Similar Blocks

In ISOBUS, each object type (e.g., Object, Button, Output, Input, Meter, BarGraph, etc.) has its own set of attribute ID constants. The `AID_PG` set is specifically dedicated to Picture Graphic objects. Comparable constants sets include:

- `AID_OBJ` for general object attributes,
- `AID_BAR` for bar graph attributes,
- `AID_BTN` for button attributes,
- `AID_INP` for input attributes.

Unlike function blocks, these constants do not contain logic or processing capabilities; they merely provide a structured, named collection of numeric IDs that facilitate the implementation of ISOBUS communication.

Conclusion

The `AID_PG` global constants set provides a clean and standardised way to reference Picture Graphic object attribute IDs in 4diac IDE projects targeting ISOBUS applications. By using these symbolic constants, developers can avoid hard-coded numeric values, improve code maintainability, and ensure full compliance with the ISO 11783 standard. Although it is not an executable functional element, it plays a crucial supporting role in the development of robust and interoperable agricultural automation systems.

AID_SG

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_SG` global constant set defines attribute identifiers for scaled graphic objects in the ISOBUS Universal Terminal (UT) protocol. These constants are used to reference specific properties of scaled

graphical elements, such as width, height, scaling behavior, options, and value, within a 4diac-based control application. They are part of the `isobus::UT::Q::const::AID` package and are intended to improve code readability and maintainability by providing symbolic names for numeric attribute IDs.

Interface Structure

As a set of global constants, `AID_SG` does not possess an event or adapter interface. The following sections describe the available data constants.

Event Inputs

None.

Event Outputs

None.

Data Inputs

The following constants are defined globally and can be used directly within function blocks or programs:

Name	Type	Value	Description
`WIDTH`	`USINT`	`USINT#1`	`AID_SG_WIDTH` – Width in pixels.
`HEIGHT`	`USINT`	`USINT#2`	`AID_SG_HEIGHT` – Height in pixels.
`SCALE_TYPE`	`USINT`	`USINT#3`	`AID_SG_SCALE_TYPE` – Scaling and justification encoding (see bit field description below).
`OPTIONS`	`USINT`	`USINT#4`	`AID_SG_OPTIONS` – Bitmask; Bit 0 = Flashing.
`VALUE`	`USINT`	`USINT#5`	`AID_SG_VALUE` – Current value of the scaled graphic object.

Data Outputs

None.

Adapters

None.

Functionality

The constants in `AID_SG` provide standardized identifiers for the attributes of scaled graphic objects as defined by the ISOBUS standard. The `SCALE_TYPE` constant encapsulates both scaling behaviour (bits 0–2) and horizontal/vertical justification (bits 3–6). The `OPTIONS` constant is used to enable additional visual effects, such as flashing. These constants are intended to be used in conjunction with ISOBUS UT services that read or write object properties – they map directly to the attribute ID numbers defined in the protocol.

Technical Features

- All constants are of type `USINT` (unsigned short integer), occupying one byte.
- Values are fixed at compile time and cannot be changed during runtime.
- The `SCALE_TYPE` field is a packed bit field:
  - Bits 0–2: Scaling value – `0` = no scale, `1` = scale to width, `2` = scale to height, `3` = scale to width and height, `4` = scale to fit.
  - Bits 3–4: Horizontal justification – `0` = left, `1` = middle, `2` = right.
  - Bits 5–6: Vertical justification – `0` = top, `1` = middle, `2` = bottom.
- The `OPTIONS` constant currently defines only bit 0 (flashing); remaining bits are reserved for future use.

State Overview

Not applicable – global constants do not have state.

Application Scenarios

These constants are typically used in ISOBUS UT applications where scaled graphic objects (e.g., gauges, bars, or image containers) need to be configured or dynamically updated. For example:

- Setting the scaling parameters of a graphic element using `SCALE_TYPE`.
- Reading or writing the `VALUE` attribute to update the displayed value.

- Enabling or disabling flashing via the `OPTIONS` bitmask.

By referencing these constants, developers avoid hard-coding numeric attribute IDs, reducing the risk of errors and improving code clarity.

Comparison with Similar Blocks

Other global constant sets exist for different ISOBUS object types, such as `AID_OBJ` for general objects or `AID_TXT` for text objects. `AID_SG` is specifically tailored to scaled graphic objects and provides only the attributes relevant to that class. Unlike an FB, it has no executable logic; it serves purely as a lookup table for attribute identifiers.

Conclusion

The `AID_SG` global constant set is a lightweight but essential component for ISOBUS UT development in 4diac. It encapsulates the numeric attribute IDs for scaled graphic objects in an easy-to-use symbolic form, supporting both readability and portability. Its fixed definitions align with the ISOBUS standard, making it a reliable building block for agricultural control systems.

AID_SK

• – ◦ • – ◦ • – ◦ •

Introduction

AID_SK is a global constant container that defines attribute identifiers (IDs) for soft key objects in an ISOBUS Virtual Terminal (VT) environment. It provides standardized numeric constants used to reference specific properties of soft keys during communication between the control function and the VT.

The constants are defined as unsigned 8-bit integers (USINT) and are part of the `isobus::UT::Q::const::AID` package. They serve as a central source of truth for soft key attribute IDs, ensuring consistency across applications and reducing the risk of hard-coded values.

Interface Structure

AID_SK is a global constant definition and does not expose any event interfaces, data inputs/outputs, or adapters. It contains only predefined constant values.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The purpose of AID_SK is to provide two constant values that correspond to the attribute IDs used in ISOBUS VT soft key objects:

- `BACKGROUND_COLOUR` (value = 1): This ID refers to the background colour index of a soft key.
- `KEY_CODE` (value = 2): This ID is used by the VT to report the code in a **Soft Key Activation** message.

By defining these values as global constants, all parts of an application can reference them by name rather than by numeric literals, improving code readability and maintainability.

Technical Features

- **Constants**: Both constants are of type `USINT` (unsigned 8-bit integer).
- **Initial Values**: Predefined fixed values: `BACKGROUND_COLOUR = 1`, `KEY_CODE = 2`.

- **Package**: The constants are encapsulated in the `isobus::UT::Q::const::AID` package, following the ISOBUS naming conventions.
- **Read-Only**: These are global constants, meaning they cannot be modified at runtime.

State Overview

Not applicable – AID_SK is a static constant container and has no runtime state or behavior.

Application Scenarios

AID_SK is typically used in ISOBUS VT applications, particularly when implementing soft key interactions. For example:

- When configuring a soft key's background colour, the application can use `AID_SK.BACKGROUND_COLOUR` to refer to the corresponding attribute ID.
- When handling a **Soft Key Activation** event, the VT sends a key code that matches `AID_SK.KEY_CODE`. Applications can compare or utilize this value to identify which soft key was activated.

This constant container helps standardize attribute IDs across different parts of an application and aligns with the ISOBUS standard's definitions.

Comparison with Similar Blocks

In the same package `isobus::UT::Q::const::AID`, other constant containers exist for different object types (e.g., `AID_OK` for object keys, `AID_AT` for attributes, etc.). AID_SK specifically focuses on soft key attributes. Compared to other constants, AID_SK defines only two IDs that are directly related to soft keys, making it a minimal and focused constant set.

Conclusion

AID_SK provides two essential constant values for soft key attribute IDs in ISOBUS VT applications. By centralizing these definitions, it promotes code clarity, reduces errors, and aligns with standard ISOBUS conventions. The constant container is simple, yet crucial for any application involving soft key configuration or activation handling.

AID_SKM

• – ◦ • – ◦ • – ◦ •

Introduction

AID_SKM is a global constants block that defines attribute identifiers for the soft key mask object within the ISOBUS virtual terminal. It serves as a central repository for constant values, ensuring consistent referencing and maintainability across the automation system.

Interface Structure

AID_SKM does not possess conventional function block interfaces such as event or data inputs/outputs, nor does it contain adapters. Instead, it declares global constants that are accessible system-wide.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The block provides the following global constant, which is treated as a read-only output value:

Name	Type	Initial Value	Comment
BACKGROUND_COLOUR	USINT	USINT#1	1: AID_SKM_BACKGROUND_COLOUR – Background colour index.

Adapters

None.

Functionality

AID_SKM encapsulates constant definitions used for encoding and decoding soft key mask object attributes. The sole constant `BACKGROUND_COLOUR` represents the attribute identifier for the background colour index of the soft key mask, aligning with the ISOBUS standard.

Technical Features

- **Global Scope:** The constant is declared as `VAR_GLOBAL CONSTANT`, making it available in all POUs and configurations within the project.
- **Standard Compliance:** The attribute identifier follows the ISOBUS 11783-14 numbering scheme, facilitating interoperability with other virtual terminal implementations.
- **Type Safety:** The constant is explicitly typed as `USINT` (unsigned short integer), preventing inadvertent type mismatches.

State Overview

As a global constants block, AID_SKM is stateless. Its value is fixed at initialization and remains unchanged during runtime.

Application Scenarios

- **VT Screen Development:** Use `AID_SKM.BACKGROUND_COLOUR` when constructing or modifying soft key masks in order to set the background colour attribute.
- **Protocol Encoding:** When packing or unpacking ISOBUS commands that involve soft key mask attributes, this constant provides the correct attribute ID for the background colour.
- **Configuration Consistency:** Replacing hard-coded numeric values with named constants enhances code readability and reduces errors during maintenance.

Comparison with Similar Blocks

Unlike function blocks that process events or data, AID_SKM is a global constant container. Similar global constant blocks may exist for other object types (e.g., `AID_KI` for key masks), but they share the same principle: defining immutable attribute identifiers in a centralized location. Compared to using literals directly, a dedicated constant block improves traceability and simplifies future updates.

Conclusion

AID_SKM serves as a well-defined source for the soft key mask background colour attribute identifier. By using this global constant, developers ensure compliance with the ISOBUS standard while maintaining clean and maintainable code within 4diac-IDE environments.

AID_TYPE

• – ◦ • – ◦ • – ◦ •

Introduction

`AID_TYPE` is a global constant definition used in isobus-based applications. It defines a single constant named `OBJ_TYPE` of type `USINT` with an initial value of `0`. This constant represents the Object Type attribute identifier for an AID (Application Identification) message, as specified in the ISO 11783 (ISOBUS) standard.

Interface Structure

Since `AID_TYPE` is a GlobalConstants block, it does not contain typical FB interfaces such as event inputs, data inputs, or adapters. Instead, it exposes a single global constant:

Data Inputs

None.

Data Outputs

None.

Adapters

None.

However, the constant OBJ_TYPE is globally accessible to any FB or application that needs to reference the Object Type identifier.

Functionality

AID_TYPE provides a standardized, constant value for the Object Type attribute ID in ISOBUS communication. The constant OBJ_TYPE is assigned the value 0, which corresponds to the AID_TYPE_OBJ_TYPE attribute. This constant is used to identify the type of object in AID messages, helping to ensure consistency across different implementations.

Technical Features

- **Type:** USINT (Unsigned Short Integer, 8-bit)
- **Initial Value:** 0 (using IEC 61131-3 notation USINT#0)
- **Scope:** Global constant, accessible throughout the entire 4diac application.
- **Package Context:** Defined within the package isobus::UT::Q::const::AID.

State Overview

Global constants have no runtime state. The value of OBJ_TYPE is fixed at 0 and cannot be modified during execution.

Application Scenarios

- **ISOBUS Message Handling:** When constructing or parsing AID messages, the constant can be used to set or compare the Object Type field.
- **System Consistency:** Provides a single source of truth for the Object Type identifier, reducing the risk of hardcoding errors across multiple FBs or modules.

Comparison with Similar Blocks

Unlike function blocks or adapters, GlobalConstants blocks do not process events or data. Their purpose is to define reusable constants. Similar global constant blocks might define other attribute IDs (e.g., AID_ATTRIBUTE, AID_VALUE) but AID_TYPE specifically focuses on the Object Type attribute.

Conclusion

AID_TYPE is a simple, yet essential global constant definition that standardizes the Object Type attribute ID for ISOBUS AID messages. By using this constant, developers can avoid magic numbers and improve maintainability of their 4diac applications.

AID_WM

• – ◦ • – ◦ • – ◦ •

Introduction

The AID_WM global constant group defines attribute identifiers for window mask objects within the ISOBUS (ISO 11783) Universal Terminal protocol. These constants are used as keys to reference specific attributes when reading or writing window mask object properties through the ISOBUS communication interface. They belong to the isobus::UT::Q::const::AID package and are defined in the namespace of the 4diac-ide development environment.

Interface Structure

Since AID_WM is defined as a global constants group rather than a function block, it does not expose event inputs, event outputs, data inputs, data outputs, or adapter interfaces. Instead, it provides a set of named constant values that can be referenced throughout the application. The following constant values are available within this group:

Data Constants

Constant Name	Data Type	Initial Value	Description
BACKGROUND_COLOUR	USINT	USINT#1	Attribute ID 1: Window mask background colour index.
OPTIONS	USINT	USINT#2	Attribute ID 2: Bitmask for window mask options.

NAME	USINT	USINT#3	Attribute ID 3: Object ID of an Output String or Object Pointer containing the window mask name.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The AID_WM constants serve as identifiers matching the attribute IDs defined by the ISOBUS standard for window mask objects. When interacting with a window mask object on an ISOBUS Universal Terminal, these IDs are used in command and response messages to denote which specific attribute of the object is being addressed.

- **BACKGROUND_COLOUR** refers to the colour index used to render the background of the window mask. The colour index is typically interpreted according to the terminal's colour palette.
- **OPTIONS** is a bitmask that encodes configuration flags for the window mask: Bit 0 indicates availability (when set to 0, the window is disabled or blanked), and Bit 1 indicates transparency (when set, the window does not use a background colour).
- **NAME** provides a reference to another object (an Output String or Object Pointer) that contains the display name of the window mask.

By using these predefined constants, applications avoid hardcoded numeric values and improve code readability and maintainability.

Technical Features

- **Data Type**: All constants are of type USINT (Unsigned Short Integer, 8 bits).
- **Initial Values**: Each constant is initialized with its corresponding attribute ID value.
- **Namespace**: The constants reside in the isobus::UT::Q::const::AID package, which organizes attribute ID constants systematically for ISOBUS object types.
- **Licensing**: The original source is provided under the Eclipse Public License 2.0 (EPL-2.0).
- **Compiler Compatibility**: The package is intended for use with the 4diac-ide compiler environment targeting IEC 61499 applications.

State Overview

The AID_WM constant group does not maintain any runtime state. It is a compile-time constant definition, and all values are statically initialized. No state transitions or lifecycle management apply.

Application Scenarios

The AID_WM constants are used in agricultural machinery and implement control systems where a Universal Terminal (UT) communicates with an implement ECU (Electronic Control Unit) via the ISOBUS network. Typical application scenarios include:

- **Window Mask Creation**: When defining a window mask object on the UT, the application uses AID_WM constants to specify which attribute to set during initialization.
- **Attribute Retrieval**: When requesting the current value of a window mask attribute (e.g., background colour), the constant IDs are inserted into the command message.
- **Dynamic Configuration**: The OPTIONS constant allows runtime toggling of the window's availability or transparency, for instance, to disable a menu entry when a function is not operational.

- **UI Text Management**: The `NAME` constant is used to associate a text object with a window mask, enabling dynamic label changes.

Comparison with Similar Blocks

Within the same ISOBUS attribute ID constant family, similar groups exist for other object types, such as:

- **`AID_BTC`** – Button and ButtonMask attribute IDs.
- **`AID_OS`** – Output String attribute IDs.
- **`AID_ALM`** – Alarm object attribute IDs.
- **`AID_EP`** – External Input/Output Point attribute IDs.

While all these groups follow the same pattern of defining USINT constants for attribute IDs, `AID_WM` specifically targets window mask objects. Unlike a function block, which provides executable logic and event-driven behavior, `AID_WM` is purely a data declaration that supplies numeric identifiers. This makes it similar to enumerations or `#define` constants in traditional programming, but with the advantage of being a strongly typed global constant within the 4diac-ide environment.

Conclusion

The `AID_WM` global constants provide a standardized, readable way to reference window mask object attributes in ISOBUS applications. By encapsulating the attribute IDs as named constants, the group enhances code maintainability and reduces the risk of errors from magic numbers. As part of the broader `isobus::UT::Q::const::AID` package, it integrates seamlessly with other attribute ID constants, supporting a coherent development approach for ISO 11783-compliant systems in 4diac-ide.

AID_WS

• – ◦ • – ◦ • – ◦ •

Introduction

AID_WS is a set of global constants used in the ISOBUS (ISO 11783) working set object attribute identifiers. These constants define the attribute IDs (AIDs) for working set objects, which are essential for identifying and manipulating properties of a working set within an ISOBUS VT (Virtual Terminal) system. The constants provide a standardized way to reference background colour, selectable state, and the active mask of a working set, ensuring consistent and reliable communication between the VT and the implement control unit (ECU).

This global constants type is part of the `isobus::UT::Q::const::AID` package and is intended to be used in applications that implement ISOBUS-based user interface components. By using these predefined constants, developers can avoid magic numbers and improve code readability and maintainability.

Interface Structure

AID_WS is a global constants definition and does not have any event inputs, event outputs, data inputs, data outputs, or adapters. However, it exposes a set of constant values that can be referenced globally within the IEC 61499 application. These constants are listed below as equivalent to data outputs for clarity.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The following constant values are defined by AID_WS and are accessible globally:

Constant Name	Type	Value	Description
`BACKGROUND_COLOUR`	`USINT`	1	Attribute ID for the background colour index of a working set.
`SELECTABLE`	`USINT`	2	Attribute ID indicating whether the working set can be selected by the operator (0 = FALSE, 1 = TRUE).

ACTIVE_MASK	USINT	3	Attribute ID for the object ID of the data or alarm mask to be displayed when the working set is active.

Adapters

None.

Functionality

The AID_WS constants are used to access and manipulate attributes of working set objects in an ISOBUS environment. Each constant corresponds to a specific attribute ID defined in the ISOBUS standard (Part 1 – Part 8, especially Part 6 for Virtual Terminal). By using these constants in conjunction with service functions or protocol requests, an application can query or set the background colour, selectable flag, or active mask of a working set.

The values are defined as `USINT` (unsigned short integer) and follow the AID numbering scheme from the ISOBUS standard. For example, the background colour attribute is assigned ID 1, the selectable attribute ID 2, and the active mask attribute ID 3. This mapping is consistent across all ISOBUS-compliant implementations.

Technical Features

- **Global Availability**: The constants are defined as `VAR_GLOBAL CONSTANT`, meaning they are accessible from any function block or resource within the same application without explicit declaration.
- **Type Safety**: All constants are of type `USINT`, which matches the attribute ID data type used in ISOBUS protocol messages.
- **Documentation**: Each constant is accompanied by a comment explaining its meaning, derived from the ISOBUS standard.
- **Compatibility**: The constants align with the ISOBUS attribute IDs, ensuring interoperability with other ISOBUS-compliant devices.
- **No Dynamic Behavior**: As a global constants type, AID_WS does not contain any logic or state; it is purely a definition.

State Overview

Since AID_WS is a constant definition, it has no runtime state. The values are fixed at compile time and cannot be modified during execution. This ensures that all references to these attributes are consistent throughout the application.

Application Scenarios

AID_WS is typically used in ISOBUS Virtual Terminal (VT) implementations, particularly in function blocks that handle working set objects. Common use cases include:

- Creating or configuring a working set on a VT by assigning the background colour index.
- Determining whether a working set is selectable and acting accordingly.
- Setting the active mask (data or alarm) that should be displayed when the working set becomes active.

For example, a function block might use `AID_WS::BACKGROUND_COLOUR` in a request to set the background of a working set, or it might parse a response and use `AID_WS::SELECTABLE` to check the selectable status.

Comparison with Similar Blocks

In ISOBUS systems, several other attribute ID sets exist for different object types, such as AID_OM (Object Masks), AID_AUX (Auxiliary Functions), etc. AID_WS specifically targets the working set object, while other constants sets would be used for other object types. Unlike function blocks that execute algorithms, AID_WS is a data definition, so it cannot be compared to functional blocks in terms of behavior. However, it serves a similar purpose to other global constant types: providing named, standardized values to avoid hardcoded numbers.

Conclusion

AID_WS provides a clear and standardized set of constant definitions for working set attribute IDs in ISOBUS applications. By using these constants, developers can write more readable and maintainable code that is compliant with the ISOBUS standard. The absence of dynamic behavior ensures reliability and consistency. This global constants type is an essential building block for any IEC 61499 application that interacts with ISOBUS Virtual Terminal working sets.

AID_WSSC

• – ◦ • – ◦ • – ◦ •

Introduction

The `AID_WSSC` global constants definition provides a set of predefined attribute identifiers for **Working Set Special Controls** objects in the ISO 11783 (ISOBUS) environment. These constants are used to reference specific attributes when interacting with such objects in a tractor-implement control system. The definition is part of the `isobus::UT::Q::const::AID` package, enabling consistent and readable addressing of these attributes across different parts of an industrial automation application.

Interface Structure

This element is a **global constants** block, not a conventional function block. As such, it does not have any event inputs, event outputs, or adapters. Instead, it exposes a set of constant values that can be directly referenced in the application logic.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

Constant Name	Data Type	Initial Value	Comment
`NUMOFBYTES`	`USINT`	`USINT#1`	Number of bytes to follow in this object (attribute ID 1).
`COLOUR_MAP`	`USINT`	`USINT#2`	Object ID of a Colour Map object, or NULL (attribute ID 2).
`COLOUR_PALETTE`	`USINT`	`USINT#3`	Object ID of a Colour Palette object, or NULL (attribute ID 3).

These constants are read-only and can be used anywhere in the program to refer to the corresponding attribute IDs.

Adapters

None.

Functionality

The `AID_WSSC` constants define the attribute identifiers used for the **Working Set Special Controls** object as specified by the ISO 11783 standard. In practice, these constants are used when constructing or interpreting ISOBUS messages that deal with working set special controls, such as setting or retrieving colour map or palette information. By using these named constants, the code becomes self-documenting and avoids magic numbers.

The values are fixed at:

- `NUMOFBYTES` = 1 (the attribute that indicates the number of bytes following in the object)
- `COLOUR_MAP` = 2 (the attribute that stores the object identifier of a colour map, or NULL)
- `COLOUR_PALETTE` = 3 (the attribute that stores the object identifier of a colour palette, or NULL)

Technical Features

- **Data Type:** All constants are of type `USINT` (unsigned short integer, 8-bit).
- **Initial Values:** Explicitly set to `USINT#1`, `USINT#2`, and `USINT#3` respectively, ensuring deterministic behaviour.
- **Package:** Declared in `isobus::UT::Q::const::AID`, which organizes the constant group under a dedicated namespace.

- **Compatibility:** Conforms to the IEC 61499 standard for global constants, making it usable in 4diac-IDE and other compliant environments.

State Overview

This block contains no state variables and does not maintain any runtime state. The constants are always available and immutable during the execution of the application. Therefore, no state diagram is applicable, and the behaviour is consistent throughout the entire runtime.

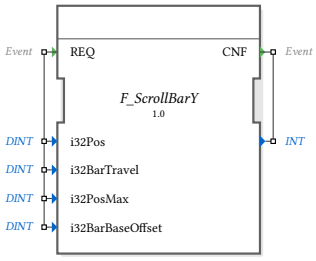
Application Scenarios

- **ISOBUS Object Pool Management:** When a working set special controls object is created or modified, the corresponding attribute IDs can be set using these constants, e.g., `AID_WSSC.NUMOFBYTES` to specify the length of the object.
- **Colour Configuration:** The `COLOUR_MAP` and `COLOUR_PALETTE` constants are used to assign colour resources to working set special controls, enabling a consistent visual representation on the virtual terminal.
- **Protocol Message Construction:** In communication tasks, these constants help to construct or parse messages that carry attribute information, improving code readability and reducing the risk of logical errors.

Comparison with Similar Blocks

Similar global constant definitions exist for other ISOBUS object types, such as:

- `AID_WSC` (Working Set Controls)
- `AID_VC` (Virtual Terminal Controls)
- `AID_IS` (Input/Output Objects)



While those also provide numeric attribute IDs as constants, `AID_WSSC` specifically targets the *Working Set Special Controls* object. Its constants are tailored to the attributes defined for that object type, making it distinct in purpose and usage. In contrast to ordinary function blocks, this global constants block does not execute any logic and does not participate in data or event flow; it simply offers named integer values.

Conclusion

The `AID_WSSC` global constants block is a simple but essential component for IEC 61499 and ISOBUS applications. By encapsulating attribute identifiers in named constants, it enhances code maintainability and reduces the chance of errors when dealing with working set special controls. Its integration into the 4diac-IDE environment follows standard practice and allows for direct reuse across projects. As a static definition, it serves as a reliable reference for developers implementing ISOBUS-compliant functionality.

helpers

F_ScrollBarY

• – ◦ • – ◦ • – ◦ •

Introduction

The `F_ScrollBarY` function computes, from the current scroll position (in rows), the Y offset for the scrollbar content container (`Container_Scrollbar_Content.Top`), so the bar "thumb" proportionally reflects the list position. It's the scrollbar counterpart to F_ScrollListY and is used internally by the `ScrollFS` scroll block (package `isobus::UT::Q`).

Interface Structure

Event Inputs

- `REQ`: Calculation request, reads `i32Pos`, `i32BarTravel`, `i32PosMax` and `i32BarBaseOffset`.

Event Outputs

- `CNF`: Confirms the calculation and delivers the return value (unnamed `OutputVar`, addressed via `<InstanceName>.` with a trailing dot).

Data Inputs

- `i32Pos` (DINT): Current scroll position in rows (0…`i32PosMax`).
- `i32BarTravel` (DINT): Available travel distance of the thumb (viewport height − thumb height).
- `i32PosMax` (DINT): Maximum scroll position (last valid row).
- `i32BarBaseOffset` (DINT): `Top` value of `Container_Scrollbar_Content` at position 0 — must match the thumb's fixed internal `Top` position in magnitude, with the opposite sign, so the thumb lands at net Y = 0 when `i32Pos = 0`.

Data Outputs

- *(unnamed)* (INT): `Container_Scrollbar_Content.Top` value (`s16Yposition` for `Q_ChildPosition`).

Adapters

No adapters available.

Functionality

The calculation is a single formula:
`OUT := DINT_TO_INT(i32BarBaseOffset + (i32Pos * i32BarTravel) / i32PosMax)`
At `i32Pos = 0`, `OUT = i32BarBaseOffset` (thumb at the start of the list); at `i32Pos = i32PosMax`, `OUT = i32BarBaseOffset + i32BarTravel` (thumb at the end of the list). Everything in between is linearly interpolated.

Technical Details

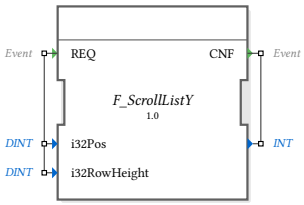
- **`DINT_TO_INT` cast**: same as `F_ScrollListY` — the calculation runs in `DINT`, the result is only converted to `INT` at the end (`Q_ChildPosition.s16Yposition`).
- **Integer division**: `(i32Pos * i32BarTravel) / i32PosMax` rounds down (integer division) — with a small `i32BarTravel` relative to `i32PosMax`, the thumb can stay put for several position steps before visibly moving. Unnoticeable in practice, since `i32BarTravel` is typically much larger than `i32PosMax`.
- **Concretely typed, no `ANY`**: like `F_ScrollListY` — fixed `DINT`/`INT` typing, no `MOVE` anchor needed when wiring it up.

State Overview

Stateless — every `REQ` recomputes the result immediately from the current input values.

Application Scenarios

- Used exclusively inside `ScrollFS` to recompute `Container_Scrollbar_Content.Top` on every position change — running in parallel with `F_ScrollListY` for the list itself, sharing the same `i32Pos` value as its source.



⚖️ Comparison with Similar Blocks

- **Versus `F_ScrollListY`**: same basic idea (row position to pixel offset), but scaled to the (smaller) scrollbar span instead of a direct multiplication by the row height, plus a base offset. See F_ScrollListY.

Conclusion

The scrollbar counterpart to `F_ScrollListY` — the same row position drives both the list and the scrollbar through two separate, concretely typed formulas, each with its own scaling.

F_ScrollListY

• — ◦ • — ◦ • — ◦ •

Introduction

The `F_ScrollListY` function computes, from the current scroll position (in rows) and the row height (in pixels), the Y offset that `Container_Scrolling_Content.Top` needs so the correct row appears inside the viewport. It's a pure calculation helper for the `ScrollFS` scroll block (package `isobus::UT::Q`) and is used internally there.

Interface Structure

Event Inputs

- `REQ`: Calculation request, reads `i32Pos` and `i32RowHeight`.

Event Outputs

- `CNF`: Confirms the calculation and delivers the return value (unnamed `OutputVar`, addressed via `<InstanceName>.` with a trailing dot — the IEC 61131-3 convention for a function's own return value).

Data Inputs

- `i32Pos` (DINT): Current scroll position in rows (0…`i32PosMax`).
- `i32RowHeight` (DINT): Row height in pixels.

Data Outputs

- *(unnamed)* (INT): `Container_Scrolling_Content.Top` value (`s16Yposition` for `Q_ChildPosition`).

Adapters

No adapters available.

Functionality

The calculation is a single formula:
`OUT := DINT_TO_INT(-(i32Pos * i32RowHeight))`
The larger `i32Pos` gets, the more negative `Top` becomes — the content container shifts up, later rows scroll into the viewport. At `i32Pos = 0`, `Top = 0` (start of the list, no offset).

Technical Details

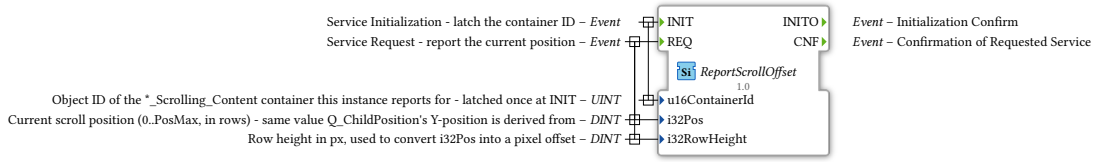
- **`DINT_TO_INT` cast**: The internal calculation runs in `DINT` (32-bit); the result is only converted to `INT` (16-bit) at the end, because `Q_ChildPosition.s16Yposition` expects an `INT` (ISO 11783-6 F.16, "Change Child Location").
- **Concretely typed, no `ANY`**: Unlike generic blocks such as `F_MOVE` or `F_SEL`, all inputs/outputs are fixed-typed (`DINT`/`INT`) — so wiring it inside `ScrollFS` needs no `MOVE` anchor, even though the value originates from other generic/struct fields.

State Overview

Stateless — every `REQ` recomputes the result immediately from the current input values.

Application Scenarios

- Used exclusively inside `ScrollFS` to recompute `Container_Scrolling_Content.Top` on every position change.



⚖️ Comparison with Similar Blocks

- **Versus `F_ScrollBarY`**: both compute a Y offset from the scroll position, but `F_ScrollBarY` additionally scales it to the (smaller) scrollbar span and applies an offset — see F_ScrollBarY.

Conclusion

A small, robust calculation function — responsible for exactly one conversion (row position to list pixel offset), concretely typed and side-effect free.

ReportScrollOffset

• – ○ • – ○ • – ○ •

Introduction

`ReportScrollOffset` is a helper Service Interface block from package `isobus::UT::Q::helpers`. It sits inside the ScrollFS FBNetwork structure (parallel to `MoveList` and `ListY`) and reports the current scroll offset (row index `i32Pos` × row height `i32RowHeight` in pixels) for container `u16ContainerId` to the ECU visibility gate (`VtMaskVisibility`).

Interface Structure

Event Inputs

- `INIT`: Service interface initialization (`With u16ContainerId`).
- `REQ`: Reports a position change (`With i32Pos`, `With i32RowHeight`).

Event Outputs

- `INITO`: Initialization confirmation.
- `CNF`: Position report confirmation.

Data Inputs

- `u16ContainerId` (UINT): Object ID of the `*_Scrolling_Content` container.
- `i32Pos` (DINT): Current row position (0…i32PosMax).
- `i32RowHeight` (DINT): Row height in pixels for pixel offset conversion.

Data Outputs

No data outputs.

Adapters

No adapters available.

Functionality

1. At `INIT`, latches the container ID `u16ContainerId`.
2. On each `REQ` event, calculates `PixelOffset := i32Pos * i32RowHeight` and forwards it to the ECU visibility gate (`VtMaskVisibility_OnScroll`).
3. The ECU gate uses this information to restrict VT updates (e.g. `Q_*` commands) to rows currently visible on screen.

Attribute

Attribute_ID

• – ◦ • – ◦ • – ◦ •

Introduction

`Attribute_ID` is an input service interface function block for double word input data (`DWORD`). It reads an attribute of a VT object (object ID `u16ObjId`, attribute ID `u8AID`) and provides its value as `DWORD` at output `IN`.

Interface Structure

Event Inputs

- **INIT** (`EInit`): service initialisation
  - Associated with: `QI`, `PARAMS`, `u16ObjId`, `u8AID`
- **REQ**: service request
  - Associated with: `QI`

Event Outputs

- **INITO** (`EInit`): initialisation confirmation
  - Associated with: `QO`, `STATUS`
- **CNF**: confirmation of the requested service
  - Associated with: `QO`, `STATUS`, `IN`
- **IND**: indication from the resource

- Associated with: `QO`, `STATUS`, `IN`

Data Inputs

- **QI** (`BOOL`): event input qualifier
- **PARAMS** (`STRING`): service parameters
- **u16ObjId** (`UINT`): object ID, initial value `ID_NULL`
- **u8AID** (`USINT`): attribute ID of the object

Data Outputs

- **QO** (`BOOL`): event output qualifier
- **STATUS** (`STRING`): service status
- **IN** (`DWORD`): input data from the resource

Adapters

No adapter interfaces available.

Functionality

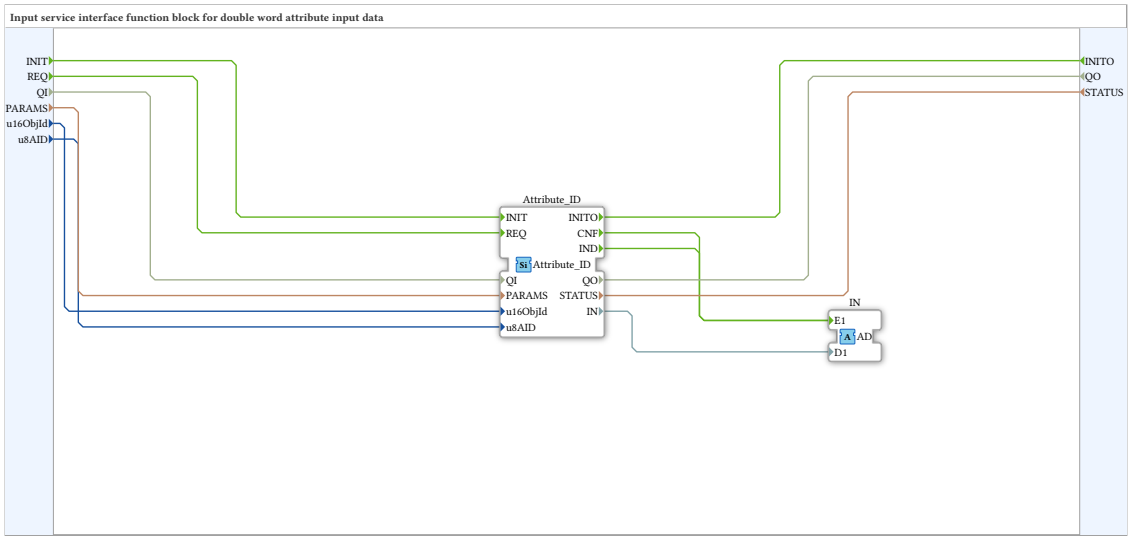
The function block is a service interface FB without an internal implementation in the type (interface declaration). `INIT` initialises the service with `QI`, `PARAMS`, `u16ObjId` and `u8AID` and is confirmed with `INITO`. `REQ` issues a request that is confirmed with `CNF`; `IND` signals an indication from the resource. In all three cases `QO`, `STATUS` and (for `CNF`/`IND`) the value `IN` are output.

Technical Details

- Uses the data type `DWORD` (32 bit) for the attribute value
- The attribute ID to read is given via the data input `u8AID`
- The object ID is preset with `ID_NULL` (`isobus::UT::Q::const::IDs::ID_NULL`)
- Originally created by fortiss GmbH (Monika Wenger, 2017) as an input service interface

Application Scenarios

- Reading attribute values (e.g. attribute ID of an object in the VT) in ISOBUS applications

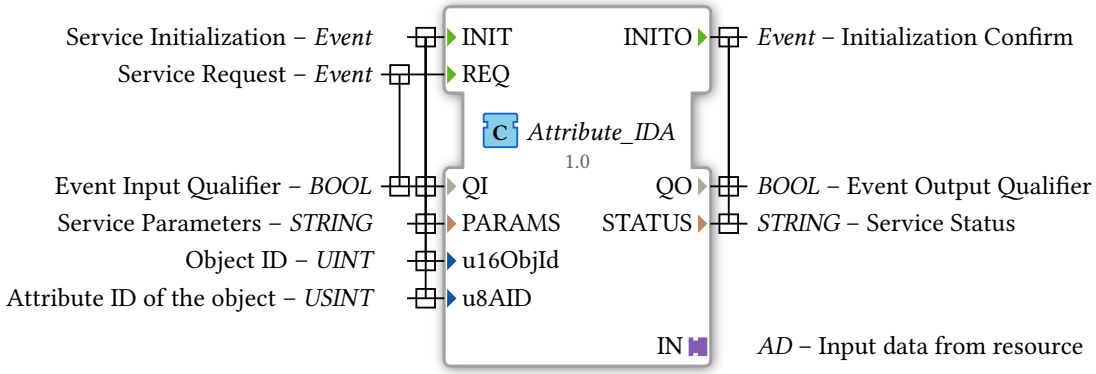


⚖ Comparison with Similar Building Blocks

- NumericValue_ID has the same service interface but reads the numeric value of an object and has no `u8AID` input.

Conclusion

`Attribute_ID` delivers the attribute value of a VT object as `DWORD` through a service interface.



Attribute_IDA

• – ○ • – ○ • – ○ •

Introduction

`Attribute_IDA` is an input service interface function block for double word attribute data (`DWORD`). It encapsulates `Attribute_ID` and provides the read attribute value of a VT object (object ID `u16ObjId`, attribute ID `u8AID`) not via a data output but via the adapter plug `IN` (`AD`). Event and value are bundled in one adapter connection.

Function Blocks (FBs) Used

Sub-blocks: Attribute_IDA

- **Type**: Composite function block
- **Internal FBs used**:
  - **Attribute_ID**: `isobus::UT::io::Attribute::Attribute_ID` - reads the attribute of the VT object
- **Import**: `isobus::UT::Q::const::IDs::ID_NULL`

Interface Structure

Event Inputs

- **INIT** (`EInit`): Service initialization
  - Associated with: `QI`, `PARAMS`, `u16ObjId`, `u8AID`
- **REQ**: Service request
  - Associated with: `QI`

Event Outputs

- **INITO** (`EInit`): Initialization confirmation
  - Associated with: `QO`, `STATUS`

Data Inputs

- **QI** (`BOOL`): Event input qualifier
- **PARAMS** (`STRING`): Service parameters
- **u16ObjId** (`UINT`, initial value `ID_NULL`): Object ID
- **u8AID** (`USINT`): Attribute ID of the object

Data Outputs

- **QO** (`BOOL`): Event output qualifier
- **STATUS** (`STRING`): Service status

Adapters

- **IN** (plug): `adapter::types::unidirectional::AD` - input data from the resource (event `E1`, data `D1` with the `DWORD` attribute value)

Program Flow and Connections

- `INIT` ⟶ `Attribute_ID.INIT`; `REQ` ⟶ `Attribute_ID.REQ`; `Attribute_ID.INITO` ⟶ `INITO`
- `Attribute_ID.IND` ⟶ `IN.E1` and `Attribute_ID.CNF` ⟶ `IN.E1`
- `u16ObjId`, `u8AID`, `PARAMS`, `QI` ⟶ like-named inputs of `Attribute_ID`
- `Attribute_ID.IN` ⟶ `IN.D1`
- `Attribute_ID.STATUS` ⟶ `STATUS`; `Attribute_ID.QO` ⟶ `QO`

Technical Details

- Both `IND` and `CNF` of the inner block trigger `IN.E1`; the value is present at `IN.D1` in each case
- The adapter bundles event and data flow in one connection line
- Version 1.0 (2026-09-15)

Application Scenarios

- Reading attribute values of a VT object and further processing via `AD` adapters, e.g. via `AD_TO_AX` converters

⚖️ Comparison with Similar Blocks

- Attribute_ID provides `IN` as a data output and `CNF/IND` as event outputs, whereas `Attribute_IDA` bundles both in the adapter `IN`.

Summary

`Attribute_IDA` provides the attribute value of a VT object as a `DWORD` via an `AD` adapter.

Aux_IE

• – ◦ • – ◦ • – ◦ •

Introduction

The Aux_IE function block is an input service interface function block for event input data. It is used to process auxiliary inputs and enables the recognition of various input events such as pressing, releasing, single-clicking, double-clicking, etc.

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- Linked to: QI, PARAMS, u16ObjId, InputEvent
- **REQ**: Service Request
- Linked to: QI

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service Request
- Linked to: QO, STATUS
- **IND**: Display of Resource
- Linked to: QO, STATUS

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service parameters
- **u16ObjId** (UINT): Object ID, initial value: ID_NULL
- **InputEvent** (AuxiliaryState_S): Identifies the event (Down, Up, Single-Click, Double-Click, etc.), initial value: Invalid

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (STRING): Service status

Adapters

No adapter interfaces are available.

Functionality

The Aux_IE block processes auxiliary input events and provides a standardized interface for communication with input devices. During initialization (INIT), the service parameters and object ID are configured. Service requests can be made via REQ events, while IND events indicate incoming signals from the resource.

Technical Features

- Uses specific ISOBUS data types for agricultural machinery
- Supports various input event types via the AuxiliaryState structure
- Initialization with standardized NULL values (ID_NULL)
- String-based status feedback

State Overview

The block has an initialization state (INIT/INITO) and operational states for service requests (REQ/CNF) as well as resource indicators (IND).

Application Scenarios

- Control of agricultural machinery via auxiliary inputs
- Processing of user interactions in ISOBUS systems
- Recognition of complex input patterns (single click, double click)
- Integration into control systems for agricultural machinery

⚖️ Comparison with Similar Blocks

Compared to simple digital input blocks, Aux_IE offers enhanced functionality for recognizing more complex input events and is specifically optimized for ISOBUS environments.

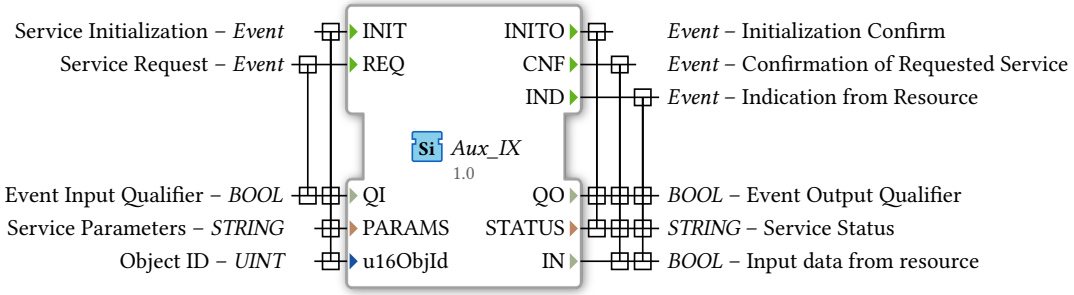
Conclusion



The The Aux_IE function block provides a powerful interface for processing auxiliary input events in ISOBUS-based control systems and enables the reliable detection of various user interactions.

Aux_IX

• – ◦ • – ◦ • – ◦ •

Introduction

The Aux_IX function block is a service interface function block for Boolean input data. It serves as an interface for input services and enables communication with resources for querying digital input signals.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block with the parameters QI, PARAMS, and u16ObjId
- **REQ**: Service Request - Triggers a service request with the qualifier QI

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms the initialization with QO and STATUS
- **CNF**: Acknowledgement of Requested Service Request - Returns QO, STATUS, and IN data
- **IND**: Resource Indication - Signals data availability with QO, STATUS, and IN data

Data Inputs

- **QI**: BOOL - Event Input Qualifier
- **PARAMS**: STRING - Service Parameter
- **u16ObjId**: UINT - Object ID with initial value ID_NULL

Data Outputs

- **QO**: BOOL - Event Output Qualifier
- **STATUS**: STRING - Service Status
- **IN**: BOOL - Input data from the resource

Adapter

No adapter interfaces are available.

Functionality

The Aux_IX function block operates as an input service interface for Boolean data. During initialization (INIT), the service parameters and the object ID are configured. Service requests (REQ) trigger the querying of input data from the associated resource. The data is returned via the CNF and IND events, with the STATUS output providing information about the success or failure of the operation.

Technical Features

- Uses specific TypeHash identification for 4diac
- Initializes the object ID with a default value (ID_NULL)
- Supports configurable service configuration via STRING parameters
- Provides both request-based (CNF) and event-based (IND) data output

State Overview

The function block goes through the following states:

1. **Not Initialized**: Before INIT processing
2. **Initialized**: After successful INIT processing with INITO confirmation
3. **Ready**: Can process REQ requests
4. **Active**: During data retrieval from the resource

Application Scenarios

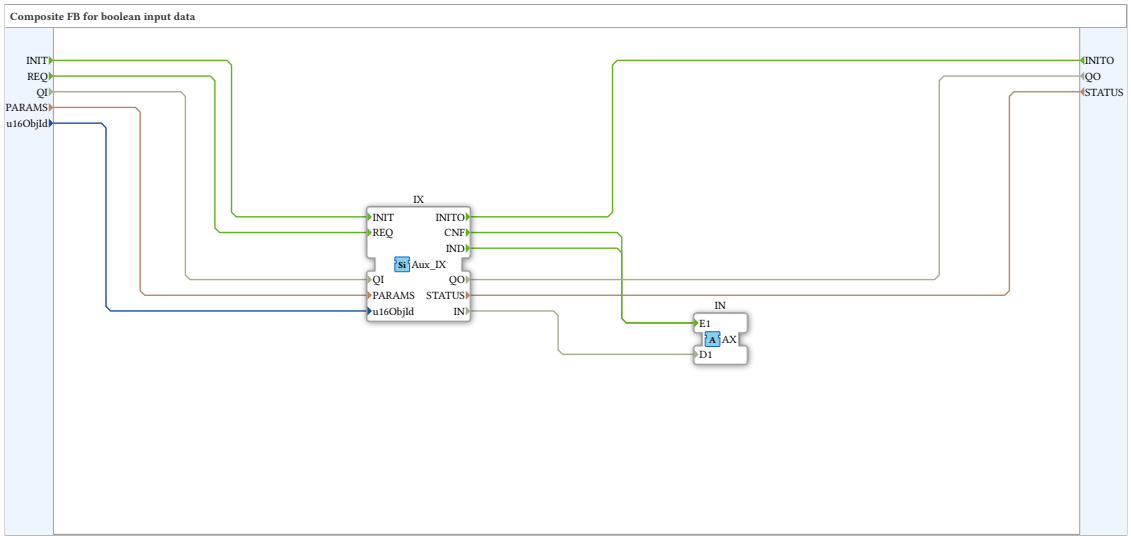
- Querying digital input signals in control systems
- Integrating hardware inputs into IEC 61499 applications
- Monitoring switch states and sensors
- Implementing standardized input interfaces in distributed systems

⚖️ Comparison with Similar Function Blocks

In Compared to simple digital input blocks, Aux_IX offers enhanced service functionality with configurable settings, status feedback, and both request-driven and event-driven data provisioning.

🛠️ Related Exercises

- Exercise_010b1



Conclusion

The Aux_IX function block provides a robust and flexible solution for integrating Boolean input data into IEC 61499-based control systems. Its service-oriented architecture and comprehensive status feedback make it particularly suitable for demanding industrial applications with high requirements for reliability and diagnostic capabilities.

Aux_IXA

• – ○ • – ○ • – ○ •

Introduction

The Aux_IXA is a composite function block for processing Boolean input data. It serves as a wrapper for the basic function block Aux_IX and provides an extended interface for integration into ISOBUS-compatible systems.

Interface Structure

Event Inputs

- **INIT**: Service initialization with the associated data QI, PARAMS, and u16ObjId
- **REQ**: Service request with the associated data QI

Event Outputs

- **INITO**: Initialization confirmation with the associated data QO and STATUS

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - Qualifier for event inputs
- **PARAMS**: Service Parameters (STRING) - Configuration parameters for the service
- **u16ObjId**: Object ID (UINT) - Object identifier with initial value ID_NULL

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - Qualifier for event outputs
- **STATUS**: Service Status (STRING) - Service status information

Adapter

- **IN**: Unidirectional AX-type adapter for data communication

Functionality

The Aux_IXA acts as a composite block that encapsulates the basic function block Aux_IX. Upon an INIT event, all parameters are forwarded to the internal IX block. REQ events trigger service requests, while INITO confirms successful initialization. The IN adapter enables bidirectional communication with external components.

IN

Technical Features

- Integration into ISOBUS environments through a special package structure
- Use of TypeHash for type identification
- Unidirectional adapter for standardized interfaces
- Initialization with a NULL object ID as the default value

State Overview

The block goes through the following states:

1. **Not Initialized**: Before the INIT event
2. **Initialization**: During INIT processing
3. **Ready**: After successful initialization (INITO)
4. **Service Mode**: During REQ event processing

Application Scenarios

- ISOBUS-compatible agricultural machinery control
- Boolean signal processing in agricultural technology systems
- Wrapper implementation for existing I/O functionality

- Parameter configuration for auxiliary inputs

⚖️ Comparison with Similar Blocks

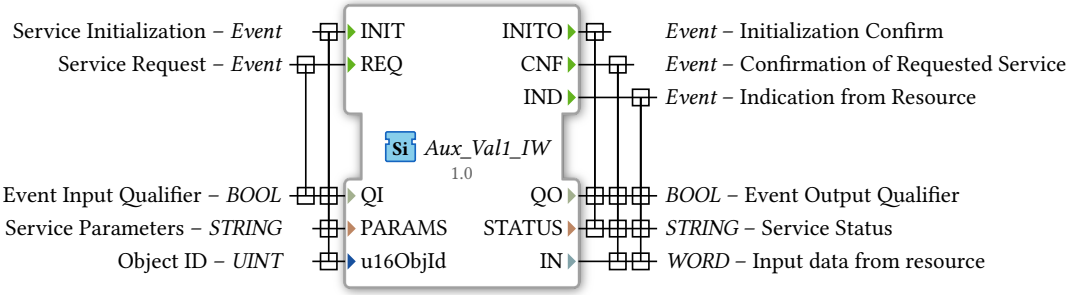
Compared to simple Boolean input blocks, Aux_IXA offers:

- Extended parameterization options
- ISOBUS specification
- Adapter-based interface
- Composite structure for improved reusability

🛠️ Related exercises

- Exercise_010b1_AX

Conclusion



The Aux_IXA represents a robust composite function block for Boolean input data processing in ISOBUS environments. Its clear interface definition and adapter integration enable flexible integration into complex agricultural control systems.

Aux_Val1_IW

• – ◦ • – ◦ • – ◦ •

Introduction

The Aux_Val1_IW function block is an input service interface function block for word input data. It serves as an interface between the control logic and external resources for processing 16-bit word input data in an ISOBUS context.

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- Linked to: QI, PARAMS, u16ObjId
- **REQ**: Service Request
- Linked to: QI

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service Request
- Linked to: QO, STATUS, IN
- **IND**: Resource Indication
- Linked to: QO, STATUS, IN

Data Inputs

- **QI**: Event Input Qualifier (BOOL)
- **PARAMS**: Service Parameters (STRING)
- **u16ObjId**: Object ID (UINT) Initial value: ID_NULL

Data Outputs

- **QO**: Event output qualifier (BOOL)

- **STATUS**: Service status (STRING)
- **IN**: Input data from the resource (WORD)

Adapter

No adapter interfaces are available.

Functionality

This function block enables communication with external resources for capturing Word input data. The INIT initialization configures the service parameters and the object ID. The REQ request triggers data collection, while IND events signal asynchronous data updates from the resource.

Technical Features

- Uses WORD data type for 16-bit data acquisition
- ISOBUS-compatible interface
- Supports asynchronous data indications
- Initialization with configurable parameters
- Error status feedback via STATUS output

State Overview

The function block goes through the following main states:

1. **Not Initialized**: Waiting for INIT event
2. **Initialized**: Ready for REQ requests
3. **Active**: Processing data requests and indications
4. **Error**: Status message in case of problems

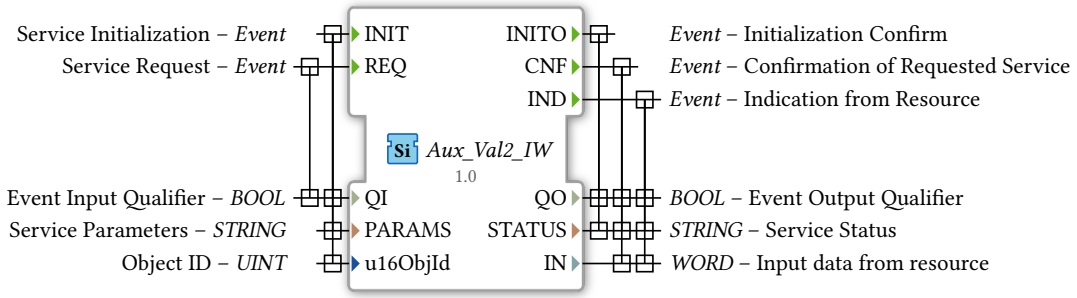
Application Scenarios

- ISOBUS-based agricultural machinery control
- Acquisition of 16-bit sensor data
- Communication with external I/O modules
- Automation systems in agricultural technology

⚖️ Comparison with Similar Blocks

Compared to simple input blocks, Aux_Val1_IW offers extended ISOBUS functionality with configurable initialization, status feedback, and asynchronous Indication mechanisms.

Conclusion



The Aux_Val1_IW function block provides a robust and flexible solution for capturing word input data in ISOBUS environments, with comprehensive error handling and configurable service parameters.

Aux_Val2_IW

• – ◦ • – ◦ • – ◦ •

Introduction

The Aux_Val2_IW is an input service interface function block for word input data. This block serves as an interface for communication with resources and enables the processing of 16-bit word input data in distributed automation systems.

Interface Structure

Event Inputs
- **INIT**: Service Initialization - Initializes the function block with parameters
- **REQ**: Service Request - Triggers a service request

Event Outputs
- **INITO**: Initialization Acknowledgement - Confirms successful initialization
- **CNF**: Confirmation of Requested Service - Acknowledges a service request
- **IND**: Indication from Resource - Signals incoming data from the resource

Data Inputs
- **QI** (BOOL): Event Input Qualifier - Enables/disables processing
- **PARAMS** (STRING): Service Parameters - Configuration parameters for the service
- **u16ObjId** (UINT): Object ID - Identifier for the data object (initial value: ID_NULL)

Data Outputs
- **QO** (BOOL): Event output qualifier - Output processing status
- **STATUS** (STRING): Service status - Service status feedback
- **IN** (WORD): Input data from the resource - The received 16-bit word data

Adapters
No adapter interfaces are available.

Functionality
This function block acts as a service interface for word input data. During INIT initialization, the service parameters and object ID are configured. Service requests can be made via REQ events, which are acknowledged with CNF events. When data is received from the resource, an IND event is issued containing the received word data.

Technical Features
- Processes 16-bit Word data types (WORD)
- Supports configurable object IDs for data identification
- Provides comprehensive status feedback on the SERVICE status
- Enables parameterizable service configuration

State Overview
The function block goes through the following states:

1. **Not Initialized**: Before INIT initialization
2. **Initialized**: After successful INIT processing with INITO confirmation
3. **Ready**: For REQ requests and IND indications
4. **Service Active**: During the processing of service requests

Application Scenarios
- Reading 16-bit sensor data in distributed systems
- Communication with ISOBUS-compatible devices
- Input of Word data in automation applications
- Interface to external resources for data acquisition

⚖️ Comparison with Similar Blocks
Compared to simpler input blocks, it offers Aux_Val2_IW offers extended service functionality with configurable settings, status feedback, and object identification. It is specifically designed for processing 16-bit word data.

Conclusion
The Aux_Val2_IW function block provides a powerful service interface for processing word input data in industrial automation systems. Its extensive configurability and status feedback make it particularly suitable for demanding applications with high requirements for reliability and diagnostic capabilities.

AuxiliaryState

• – ◦ • – ◦ • – ◦ •

Introduction

AuxiliaryState is a collection of global constants for auxiliary inputs in ISOBUS systems. These constants define various states of auxiliary inputs, typically used for control functions in agricultural and mobile machinery.

Interface Structure

AuxiliaryState consists of global constants and is not a function block in the traditional sense. Therefore, this component does not have any event or data interfaces.

Event Inputs

- Not available (Global Constants)

Event Outputs

- Not available (Global Constants)

Data Inputs

- Not available (Global Constants)

Data Outputs

- Not available (Global Constants)

Adapters

- Not available

Functionality

AuxiliaryState defines a set of predefined constants for the data type `AuxiliaryState_S`. Each constant represents a specific state of an auxiliary input with a corresponding numeric value and optional additional parameters.

Technical Features

- All constants are of type `isobus::UT::io::Auxiliary::IN::AuxiliaryState_S`
- The value ranges from 0 to 255
- Some constants also contain the flag `bCyclic := FALSE`
- The structure follows ISOBUS standards for agricultural control systems

State Overview

The defined constants include the following states:

Constant	Value	Description
`AuxDisabled`	0	Off - reverse, down, left, or not pressed
`AuxDisabled_START`	0	Off - reverse, down, left, or not pressed (with bCyclic=FALSE)
`AuxEnabled`	1	On - forward, up, right, or pressed
AuxEnabled_START`	1	On - forward, up, right, or pressed (with bCyclic=FALSE)
AuxHeld`	2	Held (forward, up, or right)
AuxHeld_START`	2	Held (forward, up, or right) (with bCyclic=FALSE)
AuxEnabledBackwards`	4	Currently on - backward, down, or left

AuxHeldBackwards`	8	Held (backward, down, or left)
AuxHeldBackwards_START`	8	Held (backward, down, or left) (with bCyclic=FALSE)
`AuxDefault`	9	Default value
`Invalid`	255	Invalid value

Application Scenarios

- Control of hydraulic functions in tractors
- Operation of implements via ISOBUS interfaces
- Status monitoring of auxiliary functions in mobile machinery
- Implementation of standardized input states in agricultural control systems

⚖️ Comparison with similar blocks

Unlike function blocks with active logic, AuxiliaryState consists of passive constant definitions that can be used as reference values in other function blocks. They offer a standardized way to define auxiliary states in ISOBUS environments.

Conclusion

AuxiliaryState provides a comprehensive collection of standardized constants for handling auxiliary inputs in ISOBUS systems. The clear definition of the different states enables a consistent implementation of control logic across different systems and facilitates the maintainability and readability of the code.

AuxiliaryState_S

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `AuxiliaryState_S` is a structured data structure (struct) that represents the state of an auxiliary input. It is used in the context of the ISOBUS interface (ISO 11783) for communication in agricultural and forestry machinery. This data type encapsulates both the actual value of the input and control information for its cyclic transmission.

Interface Structure

AuxiliaryState_S` is a structured data type (struct) and therefore does not have event or adapter interfaces in the conventional sense of a function block. Its structure consists of the following two data fields:

Data Inputs

(Not applicable – This is a data type, not a function block)

Data Outputs

(Not applicable – This is a data type, not a function block)

Structured Data Fields

Name	Data Type	Initial Value	Comment
`value`	`USINT` (0…255)	255	Represents the value of the auxiliary input.
`bCyclic`	`BOOL`	`TRUE`	Controls the cyclic transfer. When set to `FALSE`, the message is not repeated every 200 ms.

Functionality

This data type serves as a container for information about an auxiliary input. The field `value` stores the actual, read value. The initial value of 255 can represent an invalid or undefined state. The field `bCyclic` is a control flag that influences the transmission behavior in an ISOBUS network. According to the comment, when `bCyclic = TRUE` is set, the corresponding message is sent cyclically every 200 milliseconds by default. If `bCyclic` is set to `FALSE`, this regular repetition is omitted, which can reduce network traffic if the value does not change frequently.

Technical Features

- **ISOBUS Context:** This data type is specifically designed for ISOBUS communication (package `isobus::UT::io::Auxiliary::IN`).
- **Cycle Control:** The integrated cyclic control (`bCyclic`) is a characteristic feature that takes bus communication efficiency into account.
- **Initial Values:** Both fields have defined initial values (`value=255`, `bCyclic=TRUE`), ensuring deterministic initialization.

State Overview

(Not applicable – This is a passive data type without state machines.)

Application Scenarios

This struct is typically used as a data input or output in function blocks (FBs) that process or control ISOBUS auxiliary inputs. Examples include:

- Function blocks (FBs) for reading the state of switches, potentiometers, or sensors configured as auxiliary inputs.
- FBs that process auxiliary input values and forward them to other system components.
- FBs that determine whether a value needs to be updated and sent based on the `bCyclic` flag.

⚖️ Comparison with similar function blocks

As a pure data type, a direct comparison with function blocks is not meaningful. Within the ISOBUS data types, it could be compared to simpler data types such as a pure `USINT` for the value. The advantage of `AuxiliaryState_S` lies in the extension with the meta-information for transmission control (`bCyclic`), which enables higher integration and more efficient communication in the ISOBUS network.

Conclusion

AuxiliaryState_S` is a specialized, structured data type for ISOBUS communication. It offers an elegant way to encapsulate not only the value of an auxiliary input, but also an important protocol attribute for its cyclic transmission. Its use promotes the clarity and maintainability of applications that implement ISOBUS I/O functionalities.

Aux_QD

• – ◦ • – ◦ • – ◦ •

Introduction

The Aux_QD function block is an output service interface module for processing double-word output data (DWORD). It serves as an interface for auxiliary output functions and supports various auxiliary types for flexible data output.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **OUT** (DWORD): Output Data for the Resource
- **iInpNr** (INT): Auxiliary Array Number (corresponds to the order in the pool, initial value: 0)

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status Information

Adapters

No adapter interfaces are available.

Functionality

The Aux_QD block processes double-word data (32-bit) and outputs it via auxiliary interfaces. During initialization (INIT), the service parameters are configured. The output data is sent to the corresponding resource via the REQ event. The block supports multiple auxiliary types and allows the parallel output of both values in a single operation.

Technical Features

- Supports Auxiliary Types: 0, 1, 2, 3, 4, 6, 11, 12, 13
- Processes 32-bit DWORD data
- Initial value for iInpNr is 0 (first auxiliary array in the pool)
- Parallel output of both values is possible in one operation

State Overview

The block has two main states:

1. **Initialization State**: Processing the INIT request with parameter configuration
2. **Operating State**: Processing REQ requests with data output

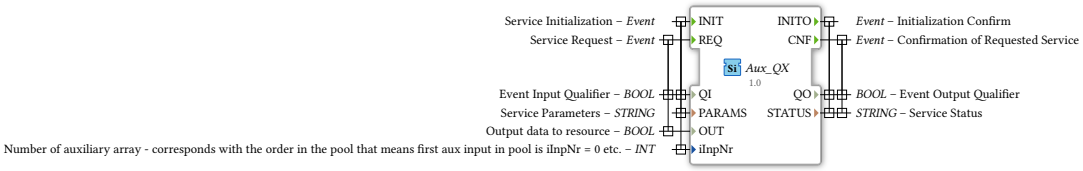
Application Scenarios

- ISOBUS-compatible control systems
- Agricultural machine controls
- Industrial automation systems
- Embedded systems with auxiliary interfaces

⚖️ Comparison with Similar Blocks

Compared to simple output blocks, Aux_QD offers extended functionality for auxiliary interfaces and supports specific ISOBUS-compatible data types. Its parallel output capability distinguishes it from sequential output blocks.

Conclusion



The Aux_QD function block represents a powerful solution for outputting double-word data via auxiliary interfaces. Its ISOBUS compatibility and support for various auxiliary types make it particularly suitable for demanding automation applications in industrial and mobile systems.

Aux_QX

• – ◦ • – ◦ • – ◦ •

Introduction

The Aux_QX function block is an output service interface function block for Boolean output data. It serves as an interface to auxiliary output devices and enables the control of Boolean output signals via a defined service mechanism.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **OUT** (BOOL): Output Data for the Resource
- **iInpNr** (INT): Auxiliary Array Number - corresponds to the order in the pool (the first aux input in the pool has iInpNr = 0, etc.)

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status

Functionality

The The Aux_QX function block implements a standardized service interface for Boolean output data. Upon receiving an INIT event, the service is initialized, using the PARAMS and iInpNr parameters for configuration. The REQ event triggers the output of the Boolean value to the specified auxiliary resource. Each operation is acknowledged by corresponding confirmation events (INITO, CNF).

Technical Features

- Supports addressing auxiliary outputs via the iInpNr parameter
- Flexible parameter configuration via STRING parameters
- Complete status feedback via the STATUS output
- Qualified event handling via QI/QO signals

State Overview

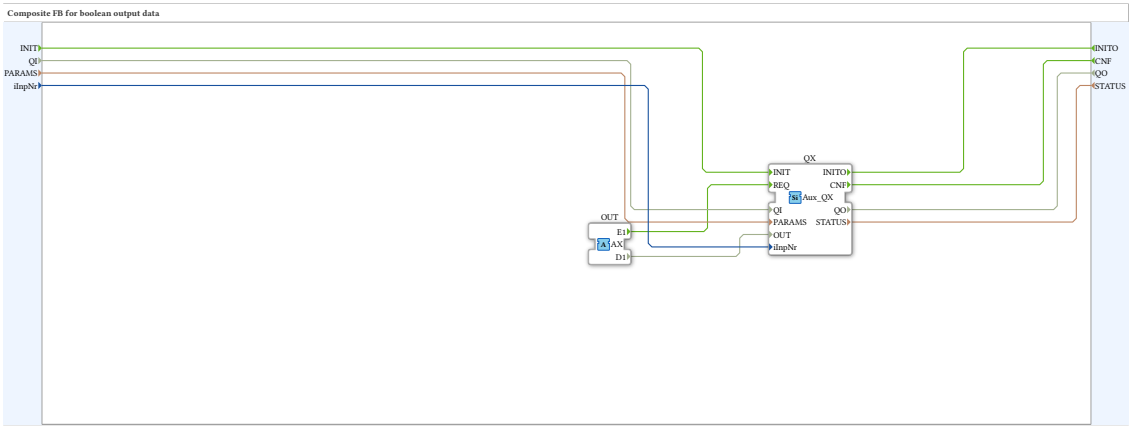
The function block follows a typical service interface pattern with initialization and operating states. After successful initialization (INIT → INITO), service requests (REQ → CNF) can be processed.

Application Scenarios

- Control of auxiliary output devices in ISOBUS environments
- Connection of Boolean actuators in agricultural machinery
- Integration into control systems for auxiliary functions
- Universal Boolean output interface in distributed automation systems

⚖️ Comparison with similar blocks

Compared to simple Boolean output blocks, Aux_QX offers extended service functionality with initialization sequences, parameter configuration, and detailed status management. Specific addressing via iInpNr enables integration into complex device pools. ...

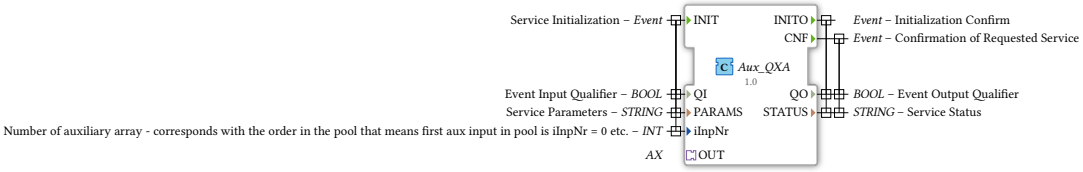


🛠️ Related Exercises

- Exercise_003c_sub

Conclusion

The Aux_QX function block represents a robust and standardized solution for controlling Boolean auxiliary outputs. Its comprehensive service interface and flexible configurability make it particularly suitable for use in professional automation environments with ISOBUS compatibility.



Aux_QXA

• – ○ • – ○ • – ○ •

Introduction

The Aux_QXA is a composite function block for outputting Boolean data. It serves as an interface for auxiliary outputs in ISOBUS-compatible systems and enables the control of Boolean output signals via standardized interfaces.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- Linked to: QI, PARAMS, iInpNr

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service
- Linked to: QO, STATUS

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameter
- **iInpNr** (INT): Auxiliary Output Array Number (corresponds to the order in the pool, where the first auxiliary input has iInpNr = 0)

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status

Adapter

- **OUT**: Unidirectional adapter of type AX
- Position: x="–400", y="1000"

Functionality

The Aux_QXA function block acts as a wrapper for the internal Aux_QX block. Upon initialization (INIT event), the configuration parameters are passed and the internal block is initialized. Output requests can be sent via the OUT adapter, which are then processed by the internal block. Acknowledgement is provided via the CNF and INITO output events.

Technical Features

- Uses a unidirectional adapter for output communication
- Supports configurable service configuration via STRING parameters
- Allows addressing of multiple auxiliary outputs via the iInpNr parameter
- Implements standardized initialization and acknowledgment protocols

State Overview

The function block goes through the following states:

1. **Not Initialized**: Before the INIT event
2. **Initialization**: During INIT processing
3. **Ready**: After successful initialization (INITO)
4. **Active**: During output processing (CNF)

Application Scenarios

- Control of Boolean actuators in agricultural machinery
- ISOBUS-compatible auxiliary outputs in tractors and implements
- Automated control systems in agricultural technology
- Networked control of peripheral devices

⚖️ Comparison with Similar Blocks

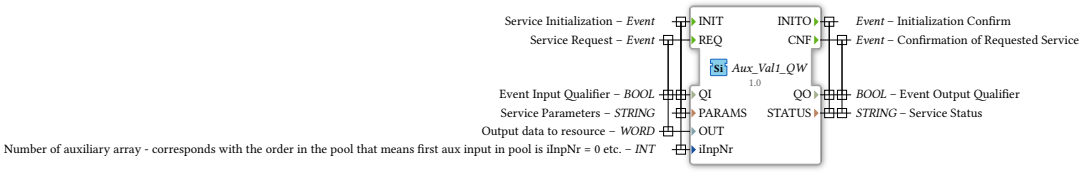
Compared to simple Boolean output blocks, this offers Aux_QXA:

- Extended parameterization via STRING parameters
- ISOBUS compatibility
- Standardized initialization procedures
- Adapter-based interface for extended communication

🛠️ Related Exercises

- Exercise_003c_sub_AX

Conclusion



The Aux_QXA function block provides a robust and standards-compliant solution for controlling Boolean auxiliary outputs in ISOBUS systems. Its modular architecture and extended parameterization options make it particularly suitable for complex control tasks in modern agricultural technology.

Aux_Val1_QW

• – ○ • – ○ • – ○ •

Introduction

The Aux_Val1_QW is an output service interface function block for word output data. This block serves as an interface to auxiliary output resources and enables the output of 16-bit data words to external peripheral devices.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event

- **REQ**: Service Request Event

Event Outputs
- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Execution

Data Inputs
- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **OUT** (WORD): Output Data for the Resource
- **iInpNr** (INT): Auxiliary Array Number - corresponds to the order in the pool (the first aux input in the pool has iInpNr = 0, etc.)

Data Outputs
- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status

Adapter

No adapter interfaces available.

Functionality

This function block initializes and controls auxiliary output devices via the ISOBUS UT protocol stack. During initialization (INIT event), the service parameters are configured and the auxiliary device is set up accordingly. Upon service requests (REQ event), the WORD data is sent to the configured output device. The block supports various auxiliary device types and provides status feedback on the success or failure of operations.

Technical Features
- Supports Auxiliary Types: 0, 1, 2, 3, 4, 6, 11, 12, 13
- Uses WORD data type (16-bit) for output data
- Implements ISOBUS UT protocol for auxiliary I/O
- Provides detailed status information via STRING output
- Allows configuration of multiple auxiliary devices via iInpNr parameters

State Overview

The function block has two main operating states:

1. **Initialization State**: Processes the INIT request and configures the auxiliary device
2. **Service State**: Processes REQ requests and outputs data to the configured device

Application Scenarios
- Control of auxiliary output devices in mobile machinery
- ISOBUS-compliant peripheral control
- Agricultural and construction machinery applications
- Connectivity of Word-based output devices via the UT protocol

⚖️ Comparison with Similar Function Blocks

Compared to simple digital output blocks, Aux_Val1_QW offers advanced functionality for ISOBUS environments, including parameterization, status feedback, and support for various auxiliary device types. The WORD data width enables the control of more complex peripheral devices compared to simple BOOL output blocks.

Conclusion

The Aux_Val1_QW function block represents a robust and standards-compliant solution for controlling auxiliary WORD output devices in ISOBUS environments. Its flexible configurability and comprehensive status feedback make it particularly suitable for demanding industrial and mobile applications.

Button

🎧 Podcast

ButtonActivationCode

• – ○ • – ○ • – ○ •

Introduction

ButtonActivationCode is a collection of global constants for processing button activations in ISOBUS-compatible systems. These constants define various states and events that can occur when buttons are pressed and are primarily used in agricultural applications.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

No adapters available

Functionality

The ButtonActivationCode constants define various button activation states as structured data types of type `ButtonActivationCode_S`. Each constant represents a specific key state and contains a numeric code as well as optional additional parameters.

Technical Features

- **Transmission Repetition Rate**: On key press/release and every 200 ms while the key is held
- **Lockable Keys**: Do not repeat while the key is held
- **ISOBUS Compatibility**: Specifically designed for ISOBUS Virtual Terminal (VT) systems
- **Structured Constants**: Uses a structured data type with code values and additional flags

State Overview

Constant	Code	Description
BT_RELEASED_UNLATCHED	0	Key has been unlocked or released (state change)
BT_PRESSED_LATCHED	1	Button was “pressed” or locked (state change)
BT_STILL_HELD	2	Button is still being held (lockable buttons do not repeat)
BT_STILL_HELD_START	2	Button is still being held (with bCyclic := FALSE)
BT_ABORTED	3	Button press aborted (applies to VT version 4 and higher)
Invalid	255	Invalid state

Application Scenarios

- Controlling agricultural machinery via ISOBUS Virtual Terminal
- Implementing button logic in operator panels
- Processing button inputs in vehicle control systems
- Developing user interfaces for agricultural applications

⚖️ Comparison with similar function blocks

Compared to simple digital inputs, ButtonActivationCode offers a finely granular state representation for buttons, specifically tailored to the requirements of ISOBUS systems. The constants support advanced button functions such as locking mechanisms and cancel functions.

Conclusion

ButtonActivationCode provides a standardized method for handling button activations in ISOBUS environments. The defined constants enable consistent and reliable processing of button inputs across different systems, which is particularly important in safety-critical agricultural applications.

ButtonActivationCode_S

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `ButtonActivationCode_S` is a structured data structure (struct) used to configure the activation of a button in a control system. It defines an activation code and a control flag for the repeat logic. This data type is part of the `isobus::UT::io::Button` package.

Interface Structure

Since this is a data type and not a function block, there are no event or adapter interfaces. The structure consists exclusively of data fields.

Data Inputs

(Not applicable - This is a data type, not a function block)

Data Outputs

(Not applicable - This is a data type, not a function block)

Structured Data Fields

The following fields form the internal structure of the data type `ButtonActivationCode_S`:

Name	Data Type	Initial Value	Comment
`code`	`USINT`	255	Defines the specific activation code for the button.
`bCyclic`	`BOOL`	TRUE	Controls the cyclic behavior. If set to `FALSE`, activation is not repeated every 200 ms.

Functionality

The structure `ButtonActivationCode_S` serves as a container for configuration data.

- The field `code` uniquely identifies the button within the system. The default value of 255 can be interpreted as an inactive or undefined state.
- The field `bCyclic` determines the timing behavior when the button is continuously pressed. With `TRUE` (default), the corresponding event is repeatedly triggered at a fixed interval (e.g., every 200 ms). With `FALSE`, the event is triggered only once when the button is pressed (and possibly released), even if the button is held down.
•

Technical Features

- **Initial Values:** Both fields of the structure have predefined initial values, ensuring reliable initialization.
- **Comment:** The field `bCyclic` contains a helpful comment that explains the specific effect (`do not repeat every 200ms`) directly in the declaration.

- **Type Hash:** The data type contains an attribute (`eclipse4diac::core::TypeHash`) used for type checking and versioning within the 4diac environment.

State Overview

(Not applicable - This is a static data type without state machines.)

Application Scenarios

This struct is typically used as an input or configuration parameter for function blocks that process button inputs, e.g.:

- In a human-machine interface (HMI) for configuring softkeys.
- – In machine controls for parameterizing physical control buttons.
- Wherever a distinction needs to be made between a single and repeated action upon button press.

⚖️ Comparison with similar function blocks

As a pure data type, `ButtonActivationCode_S` is comparable to other structured data types (STRUCTs) in 4diac, such as `DATE_AND_TIME`. Its specific purpose is to bundle the parameters relevant for button control (`code` for identification, `bCyclic` for timing behavior) into a single, reusable unit.

Conclusion

The data type `ButtonActivationCode_S` is a simple yet essential structure for the standardized configuration of button behavior in 4diac-based control applications. By encapsulating the code and the repetition flag, it promotes code reusability and readability. The integrated initial values and clear comments contribute to robustness and ease of use.

Button_IE

• – ◦ • – ◦ • – ◦ •

Introduction

The Button_IE function block is an input service interface function block for event input data. It serves as an interface for button events in control systems and enables the processing of various button activities such as pressing, releasing, or multiple clicks.

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- **REQ**: Service Request

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Request
- **IND**: Resource Indication

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **u16ObjId** (UINT): Object ID (Initial Value: ID_NULL)

- **InputEvent** (ButtonActivationCode_S): Identifies the event (Down, Up, Single-Click, Double-Click, etc.) with the initial value “Invalid”

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status

Adapter

No adapter interfaces available.

Functionality

The Button_IE function block processes button events via the ISOBUS-UT protocol. During initialization (INIT), the service parameters and object ID are configured. The block can detect and process various button activities such as single click, double click, press, and release. Incoming events from the hardware resource are reported via the IND output.

Technical Features

- Uses ISOBUS-UT-specific data types for button activation codes
- Supports initialization with specific object IDs
- Provides comprehensive status feedback via the STATUS output
- Implements qualified event processing via QI/QO signals

State Overview

The function block has an initialization state (INIT/INITO) and operational states for service requests (REQ/CNF), as well as asynchronous event indications (IND). The exact state machine depends on the implementation.

Application Scenarios

- Agricultural control systems with ISOBUS compatibility
- Operator panels with push-button inputs
- Machine controls with event-based inputs
- Systems that need to distinguish between different push-button activities

⚖️ Comparison with similar building blocks

Compared to simple digital input blocks, Button_IE offers advanced functionality for push-button-specific events such as multiple clicks and distinguishes between different activation states. Its ISOBUS integration makes it particularly suitable for agricultural applications.

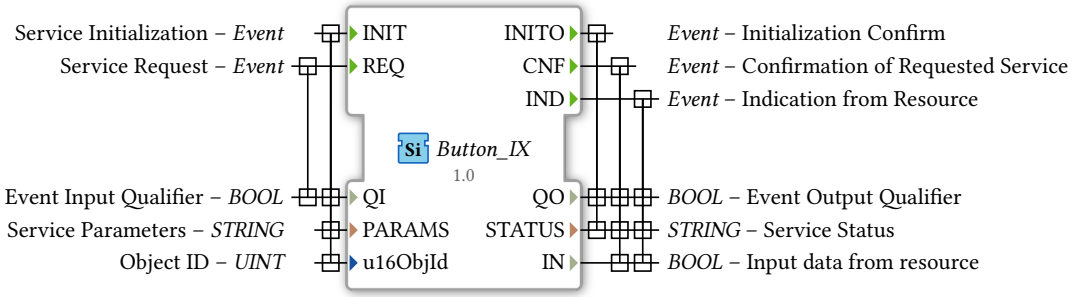
Conclusion



Button_IE is a specialized function block for The processing of button events in ISOBUS environments. Its ability to distinguish between different button activities and provide comprehensive status information makes it particularly suitable for demanding control applications in agricultural engineering and related fields.

Button_IX

• – ◦ • – ◦ • – ◦ •

Introduction

Button_IX is a service interface function block for Boolean input data, specifically designed for processing key presses in 4diac systems. This block serves as an interface between the application logic and physical input devices such as pushbuttons or switches.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Request
- **IND**: Indication from Resource Interface

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **u16ObjId** (UINT): Object ID with Initial Value ID_NULL

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status Information
- **IN** (BOOL): Input Data from the Resource

Adapter

None Adapter interfaces are available.

Functionality

The Button_IX function block manages the entire lifecycle of a keystroke. During initialization (INIT event), the service parameters are configured and the system is prepared for operation. The REQ event triggers a current query of the input state, while the IND event signals asynchronous state changes of the keystroke.

Technical Features

- Supports ISOBUS-compliant communication
- Uses specific TypeHash identification for 4diac
- Integrates object ID management for device identification
- Provides comprehensive status feedback via the STATUS output

State Overview

The function block goes through the following main states:

1. **Not Initialized**: Waiting for an INIT event
2. **Initialized**: Ready for REQ and IND events
3. **Active**: Processing input requests and indications
4. **Error**: In case of invalid parameters or communication problems

Application Scenarios

- Operator panels in industrial control systems
- Machine control with push-button inputs
- ISOBUS-compatible agricultural machinery control systems
- Safety-critical input systems with status monitoring

⚖️ Comparison with Similar Blocks

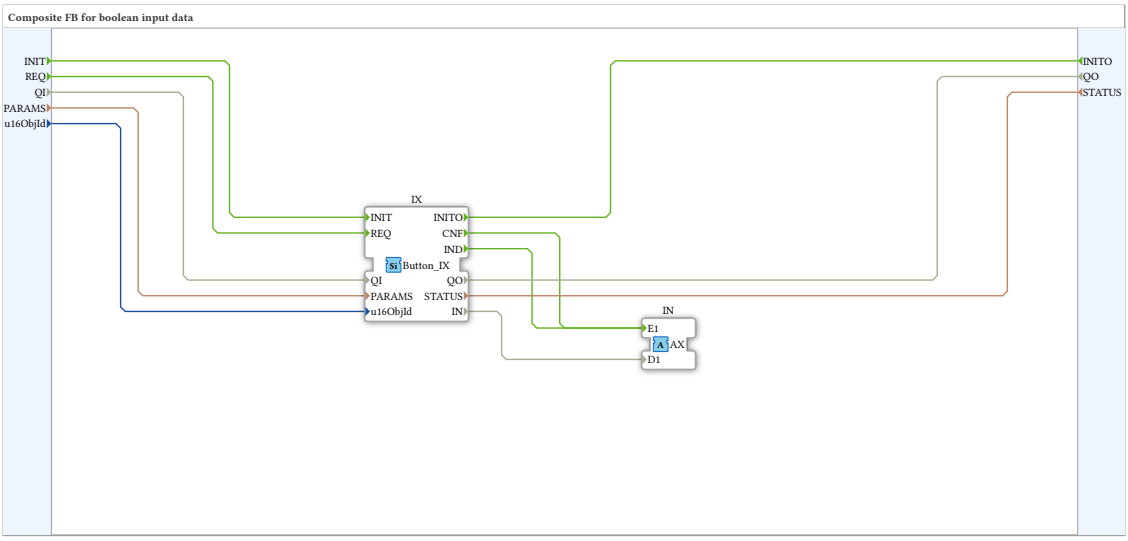
Compared to simple digital input blocks, Button_IX offers extended functionalities such as:

- Configurable service configuration
- Detailed Status Feedback
- ISOBUS Integration
- Asynchronous Event Handling

🛠️ Related Exercises

- Exercise_010a2
- Exercise_010a3

Conclusion



The Button_IX function block provides a robust and flexible solution for integrating keystrokes into 4diac-based control systems. Its comprehensive interface and status management make it particularly suitable for demanding industrial applications that require reliable and monitorable input processing.

Button_IXA

• – ○ • – ○ • – ○ •

Introduction

Button_IXA is a composite function block for processing Boolean input data. The block serves as an interface for button inputs and provides standardized processing of switching states in automation systems.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - triggered by QI, PARAMS, and u16ObjId
- **REQ**: Service Request - triggered by QI

Event Outputs

- **INITO**: Initialization Acknowledgement - triggered by QO and STATUS

Data Inputs

- **QI**: Event Input Qualifier (BOOL)
- **PARAMS**: Service Parameters (STRING)
- **u16ObjId**: Object ID (UINT) - Initial Value: ID_NULL

Data Outputs

- **QO**: Event Output Qualifier (BOOL)
- **STATUS**: Service Status (STRING)

Adapters

- **IN**: Unidirectional Adapter from Type adapter::types::unidirectional::AX

Functionality

The Button_IXA function block acts as a wrapper around the internal Button_IX block. During initialization (INIT), the configuration parameters are passed and the internal block is configured. Service requests (REQ) trigger the query of the button state. The IN adapter serves as the interface for the actual button input.

Technical Features

- Uses ISOBUS-compliant types and adapters
- Supports object identification via u16ObjId
- Flexible parameterization via STRING parameters
- Unidirectional adapter interface for input data

State Overview

The function block has the following main states:

- Not initialized: Waiting for an INIT event
- Initialized: Ready for REQ requests
- Active: Processing button inputs via the adapter

Application Scenarios

- Button inputs in agricultural machinery
- ISOBUS-compatible control systems
- Boolean input processing in distributed automation systems
- Operator panels and control panels

⚖️ Comparison with Similar Function Blocks

Compared to simple Boolean input blocks, Button_IXA offers:

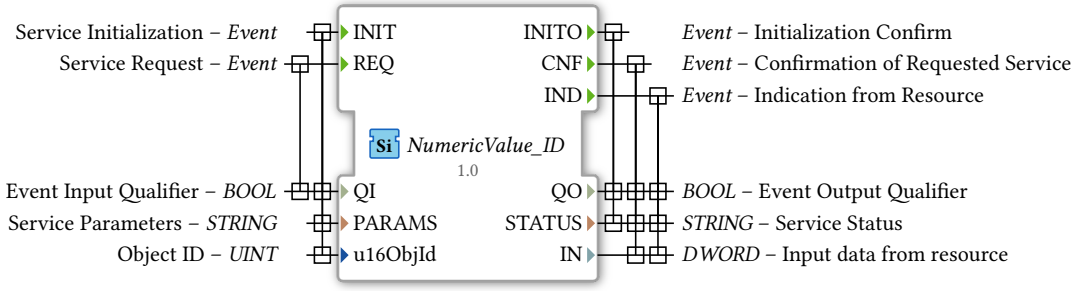
- ISOBUS compatibility
- Extended parameterization options
- Standardized status feedback
- Adapter-based architecture for improved reusability

🛠️ Related Exercises

- Exercise_010a2_AX
- Exercise_010a3_AX

Conclusion

Button_IXA is a specialized function block for the reliable processing of button inputs in ISOBUS environments. Its modular architecture and standardized interfaces make it ideally suited for use in complex agricultural automation systems.



NumericValue

NumericValue_ID

• – ◦ • – ◦ • – ◦ •

Introduction

The NumericValue_ID function block is an input service interface function block for double-word input data (DWORD). It serves as an interface for communication with resources and enables the processing of numeric input values in ISOBUS-compatible systems.

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- Linked to: QI, PARAMS, u16ObjId
- **REQ**: Service Request
- Linked to: QI

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service Request
- Linked to: QO, STATUS, IN
- **IND**: Resource Indication
- Linked to: QO, STATUS, IN

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **u16ObjId** (UINT): Object ID with Initial Value ID_NULL

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (STRING): Service status
- **IN** (DWORD): Input data from the resource

Adapter

No adapter interfaces are available.

Functionality

The function block initializes itself via the INIT event and can make service requests via REQ. Upon successful initialization, it returns INITO, while CNF and IND represent acknowledgments of service requests and indications from the resource, respectively. Data is transmitted via DWORD values (32-bit), which are provided via the IN output.

Technical Features

- Uses DWORD data type for numeric input values
- ISOBUS-compatible implementation
- Initialization with standardized object ID (ID_NULL)
- String-based status feedback
- Supports configurable service configuration

State Overview

The function block goes through the following states:

1. **Not Initialized**: Before INIT call
2. **Initialized**: After successful INIT processing
3. **Service Active**: During active REQ requests
4. **Data Provisioning**: During active IND indication

Application Scenarios

- Agricultural control systems (ISOBUS)
- Industrial automation with numeric sensor data
- Embedded systems with double-word data processing
- Systems with standardized object identifications

⚖️ Comparison with Similar Blocks

Compared to simple input blocks, NumericValue_ID offers extended service functionality with initialization procedures, Status feedback and configurable options. Its specific focus on ISOBUS environments distinguishes it from generic input blocks.

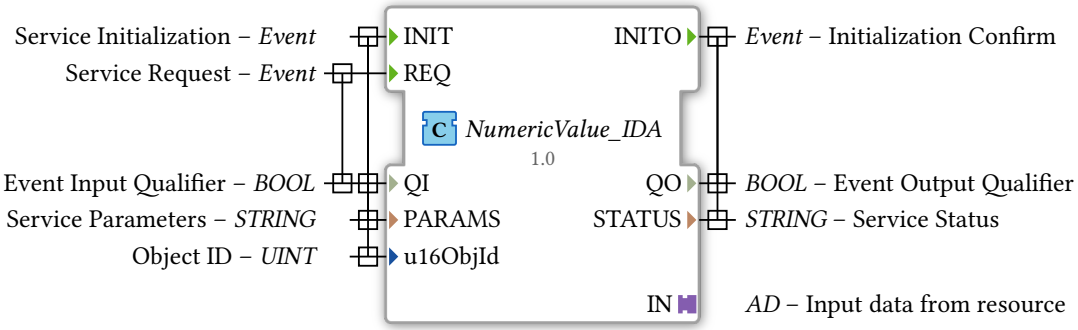
- Exercise_103

Conclusion

The NumericValue_ID function block provides a robust solution for processing double-word input data in ISOBUS-based systems. Its structured initialization, clear status feedback, and flexible parameterization make it ideally suited for industrial applications with high demands on reliability and diagnostic capabilities.



NumericValue_IDA

• – ○ • – ○ • – ○ •

Introduction

The function block **NumericValue_IDA** is a service interface function block specifically designed for processing numeric input data (double word input data) in the context of ISOBUS universal terminals (UTs). It serves to transfer changes to numeric values made on a user interface (e.g., a tractor terminal) into the control logic. Unlike standard input blocks, this block does not provide the received data via direct data outputs, but rather via an adapter connection (`IN`). It encapsulates the functionality of the block `NumericValue_ID` and redirects its signals to an adapter interface.

Interface Structure

The function block has standard initialization and request events as well as specific configuration parameters. The actual data transfer takes place via the adapter.

Event Inputs

- **INIT** (Type: `EInit`): Service initialization. Used to start and configure the function block.
- **REQ** (Type: `Event`): Service request. Can be used to update the status or request a specific interaction (depending on the internal implementation of the service layer).

Event Outputs

- **INITO** (Type: `EInit`): Initialization confirmation. Indicates whether the function block has been successfully configured.

Data Inputs

- **QI** (Type: `BOOL`): Event Input Qualifier. Enables the execution of actions associated with the events.
- **PARAMS** (Type: `STRING`): Service parameter for specific configurations of the underlying service layer.
- **u16ObjId** (Type: `UINT`): Object ID. References the specific numeric input object on the Universal Terminal (UT) whose value is to be monitored. The default value is `ID_NULL`.

Data Outputs

- **QO** (Type: `BOOL`): Event Output Qualifier. Indicates whether the last operation (e.g., initialization) was successful.
- **STATUS** (Type: `STRING`): Service status. Contains error codes or status messages for diagnostic purposes.

Adapter

- **IN** (Type: `adapter::types::unidirectional::AD`):
- This is a unidirectional adapter plug ("Input data from resource").
- It combines the event signal (E1) and the data signal (D1), which contains the current numeric value from the terminal.
- The adapter is triggered when the internal `NumericValue_ID` block sends a `IND` (Indication) or `CNF` (Confirmation) event.

Functionality

The **NumericValue_IDA** acts as a wrapper for the internal block `NumericValue_ID`.

1. **Initialization:** The connection to the specific object on the ISOBUS terminal is established via the event `INIT` and the data inputs `PARAMS` and `u16ObjId`.
2. **Data Reception:** When the value of the referenced object on the terminal changes or is updated by the system, the internal block receives this information.
3. **Forwarding:** The internal block forwards the new value (`IN`) and the associated event to the adapter `IN` of the **NumericValue_IDA**.

- The adapter's event `E1` is triggered.
- The adapter's data point `D1` provides the numerical value.

This mechanism enables clean encapsulation of communication, where the application logic only needs to connect to the adapter `IN` to react to value changes.

Technical Features

- **Composition:** The function block is implemented as a composite function block (FB) that uses instances from the package `isobus::UT::io::NumericValue`.
- **Adapter Usage:** The special feature lies in the use of the adapter `AD` for data output. This reduces the visual complexity in the function block diagram, as data and event flow are bundled in a single connection line.
- **ISOBUS Context:** This function block is explicitly designed for use in the ISOBUS stack (ISO 11783), as indicated by the use of `u16ObjId` to identify UT objects.

Status Overview

Since this is a composite function block, its status is primarily determined by its internal service blocks.

- **Not Initialized:** After startup or during `QI=FALSE` and `INIT`.
- **Initialized / Ready:** After successful `INIT` (`QO=TRUE`). The function block listens for updates from the terminal.
- – **Error:** If `QO=FALSE` and `STATUS` contain an error message (e.g., invalid object ID).

Application Scenarios

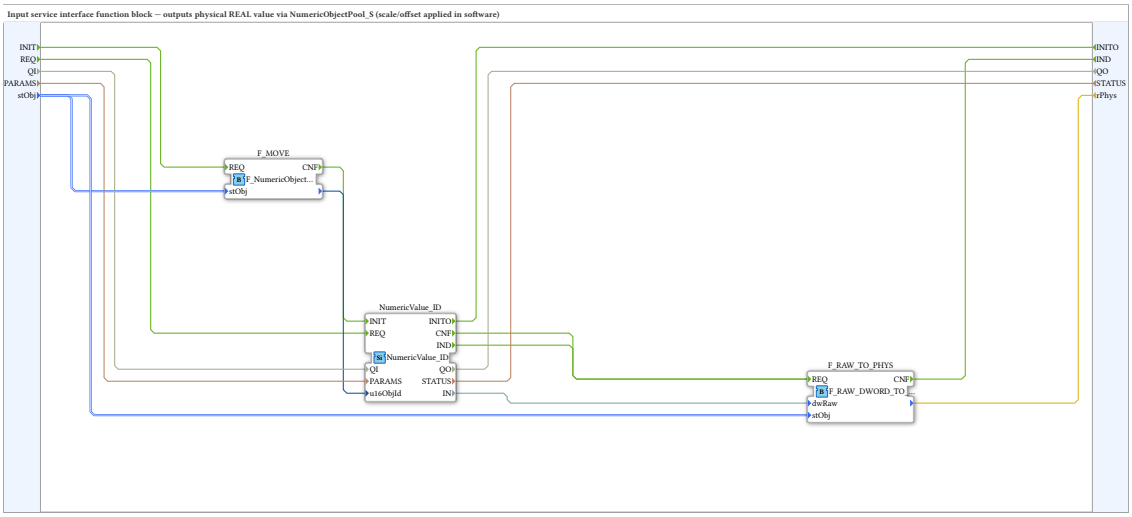
- **Setpoint Input:** An operator enters a quantity (e.g., application rate in liters) or a target speed on the terminal. This function block receives the value.
- **Parameterization:** Setting machine parameters via numeric fields on the display.
- **Modular Applications:** Used in applications that rely heavily on adapter connections to avoid the "spaghetti code" of parallel event and data lines.

⚖️ Comparison with Similar Function Blocks

- **NumericValue_ID:** This is the internal base function block. It offers the same functionality but provides the data via classic `IND`/`CNF` events and a `IN` data output. **NumericValue_IDA** is the adapter version of this function block.
- **Other `_IDA` function blocks:** Similar to `Button_IDA` (for buttons) or `String_IDA` (for text), this function block follows the design pattern of providing terminal input via adapters.
-

🛠️ Related Exercises

- Exercise_011_AUDI



Conclusion

The **NumericValue_IDA** is a specialized interface block for ISOBUS applications in 4diac. By using an adapter for data output, it enables compact and clear routing of numerical input values in the function block diagram. It is ideally suited for developers who prefer a structured and modular application architecture and need to process numerical input from the Universal Terminal.

NumericValue_PHYS

(Image not available)

• – ○ • – ○ • – ○ •

Introduction

The function block **NumericValue_PHYS** is an input service interface block according to ISO 11783-6. It returns a physical REAL value by reading a raw digital value (DWORD) from the ISOBUS object pool and converting it into a physical value, taking into account a predefined scaling and offset. The conversion is performed entirely in software (within the function block).

Interface Structure

Event Inputs

Event	Type	With Variables	Comment
INIT	EInit	QI, PARAMS, stObj	Initialize the block
REQ	Event	QI	Request a new physical value

Event Outputs

Event	Type	With variables	Comment

INITO	EInit	QO, STATUS	Confirm initialization
IND	Event	QO, STATUS, rPhys	Output the calculated physical value

Data Inputs

Variable	Type	Comment
QI	BOOL	Input qualifier (enables processing)
PARAMS	STRING	Service parameter (e.g., configuration string)
stObj	logiBUS::utils::conversion::phys::NumericObjectPool_S	Object pool properties: Object ID (16 bits), scaling, offset, decimal places

Data Outputs

Variable	Type	Comment
QO	BOOL	Output qualifier (processing status)
STATUS	STRING	Status message (error or success message)
rPhys	REAL	Physical value after applying scaling/offset

Adapters

No adapters available.

Functionality

The internal process is controlled via the INIT and REQ events and utilizes four sub-function blocks:

1. **INIT**

- The passed structure parameter `stObj` is copied via the sub-function block `F_MOVE` (of type `iec61131::selection::F_MOVE`).
- The copied value (`stObj.u16ObjId`) is forwarded to the sub-function block `NumericValue_ID`, which is thereby initialized (`NumericValue_ID.INIT`).

1. **REQ** (or re-output after INIT)

- The sub-function block `NumericValue_ID` is triggered by `REQ`. It outputs a raw DWORD value from the ISOBUS object pool via its output `IN`.

This DWORD value is converted into an unsigned 32-bit integer (`UDINT`) via `F_DWORD_TO_UDINT`.

The sub-module `F_RAW_TO_PHYS` receives the integer value and the original structure `stObj` (scaling, offset, decimal places) and calculates the physical REAL value from it (`rPhys`).

Finally, the output `IND` is activated, and the calculated value is output at the data output `rPhys`. ...``

The chaining ensures that the current raw value is read from the object pool and calculated for each REQ.

Technical Features

- **Standard Compliance**: The function block complies with the ISO 11783-6 standard (ISOBUS).
- **Software Scaling**: Unlike purely hardware interfaces, the conversion (scaling/offset) is performed within the function block, allowing for flexible adaptation without changing the peripherals.
- **Reusable Sub-Function Blocks**: The sub-function blocks used (`NumericValue_ID`, `F_DWORD_TO_UDINT`, `F_RAW_TO_PHYS`, `F_MOVE`) are standardized logiBUS or IEC 61131 function blocks and can be used in other contexts.
- **Object Pool Structure**: The input structure `stObj` contains all necessary parameters (object ID, scale, offset, decimal places) and can be managed centrally.

State Overview

The function block does not have an explicit state machine but reacts purely event-driven. The process is divided into two main phases:

- **Initialization Phase** (Event `INIT` ⟶ `INITO`):

Acceptance and storage of the configuration (`stObj`), initialization of `NumericValue_ID`.

- **Operation Phase** (Event `REQ` ⟶ `IND`):

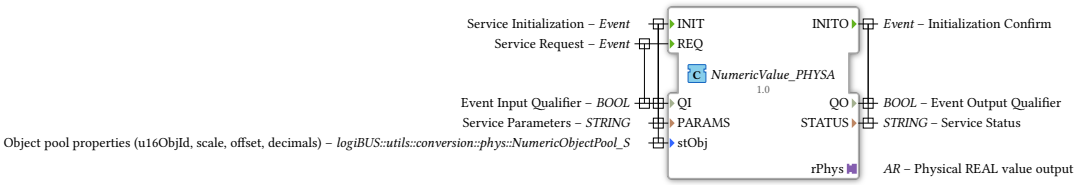
Reading the raw value, conversion, and output of the physical value.
After successful initialization, `REQ` can be executed any number of times.

Application Scenarios

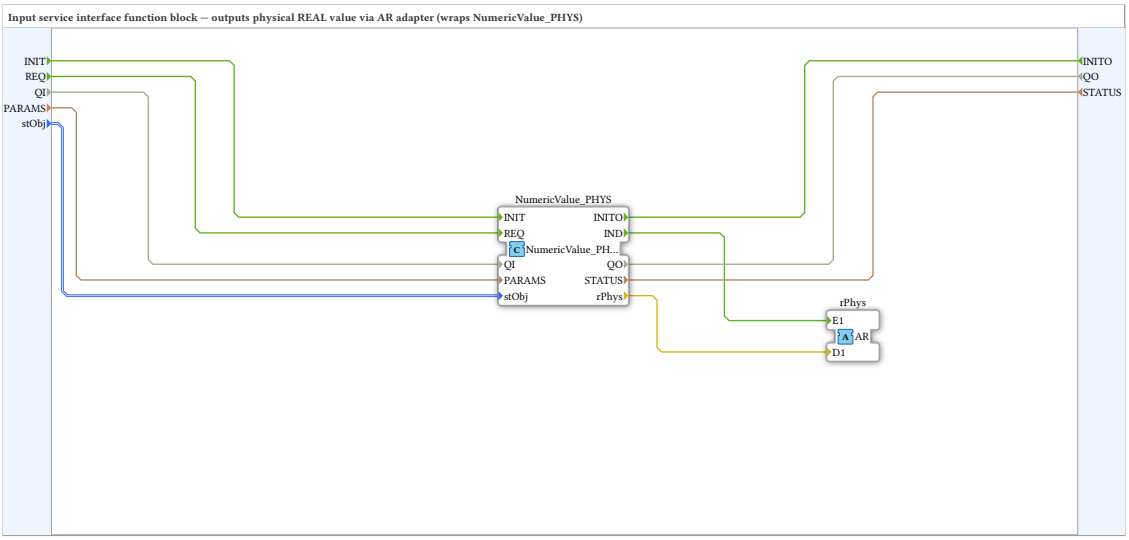
- **ISOBUS Vehicle Control**: Reading sensor data (e.g., speed, pressure, temperature) from the ISOBUS object pool and converting it into physical units.
- **Agricultural Automation**: Processing measured values from ISOBUS-compatible devices (tractors, implements) for further control or visualization.
- **Test and Simulation Environments**: Replacing real hardware components with software emulation using defined scaling.

Comparison with Similar Components

- **NumericValue_ID**: Returns only the raw DWORD value without scaling/offset. `NumericValue_PHYS` extends this value with the physical conversion.



NumericValue_ID: Returns only the raw DWORD value without scaling/offset. - **Analog input blocks** (e.g., `AI_SCALED`) in PLC systems: These often scale directly in the hardware driver. `NumericValue_PHYS`, on the other hand, operates purely in software and is therefore more flexible with regard to parameterization.



- **logiBUS blocks such as `F_RAW_TO_PHYS`**: These are used internally by `NumericValue_PHYS`; this function block encapsulates the entire chain from ID query to final output.

Conclusion

The function block `NumericValue_PHYS` offers a clean and standards-compliant way to convert ISOBUS objects into physical values with integrated scaling and offset correction. By using modular sub-components and parameterization via a structure variable, it is easy to maintain and reusable. It is particularly suitable for applications requiring software-controlled conversions without affecting the hardware configuration.

NumericValue_PHYSA

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **NumericValue_PHYSA** is an input service interface function block (SIFB) according to ISO 11783-6. Its function is to provide a physical REAL value via an AR adapter (adapter type *unidirectional::AR*). Internally, it encapsulates the block `NumericValue_PHYS` and all its logic for converting and providing the value.

Interface Structure

Event Inputs

Name	Type	Description
INIT	Initializes the block (with parameters and object pool)	
REQ	Event	Triggers the output of the current physical value

Event Outputs

Name	Type	Description
INITO	EInit	Confirmation of successful initialization

Data Inputs

Name	Type	Description
QI	BOOL	Input qualifier (enables/controls processing)
PARAMS	STRING	Parameters for the service (e.g., configuration string)
stObj	*NumericObjectPool_S*	Object pool properties: Object ID (UINT16), scale, offset, decimal places

Data Outputs

Name	Type	Description
QO	BOOL	Output qualifier (indicates successful processing)
STATUS	STRING	Status message (OK or error text)

Adapter

Name	Type	Description
rPhys	*adapter::types::unidirectional::AR*	Adapter interface for outputting the physical REAL value (event channel `E1` and data channel `D1`)

Functionality

This function block is implemented as a wrapper around the internal function block `NumericValue_PHYS`. All inputs and outputs are directly connected to the inner function block:

- Events `INIT` and `REQ` are forwarded directly to `NumericValue_PHYS`.
- The initialization confirmation event `INITO` of the inner function block is routed externally.
- The output event `IND` of `NumericValue_PHYS` is connected to the event input `rPhys.E1` of the adapter, so that the adapter receives an event with each new value calculation.
- Events `INIT` and `REQ` are forwarded directly to `NumericValue_PHYS`.
- The initialization confirmation event `INITO` of the inner function block is routed externally. - The data inputs (`QI`, `PARAMS`, `stObj`) are wired to the inner FB.

- The data outputs (`QO`, `STATUS`) come directly from the inner FB.
- The physical REAL value from `NumericValue_PHYS.rPhys` is placed on the data channel `rPhys.D1` of the adapter plug.

Thus, the FB is a pure connector that extends the functionality of `NumericValue_PHYS` with a standardized adapter interface, without implementing any additional logic itself.

Technical Features

- **Data Types Used:** The physical properties of the measured value (scaling, offset, decimal places) are defined via the structured type `logiBUS::utils::conversion::phys::NumericObjectPool_S`.
- **Adapter Coupling:** The AR adapter (unidirectional) enables loose coupling to subsequent function blocks that consume the physical value.
- **Type Hash:** The function block carries an attribute `eclipse4diac::core::TypeHash` to identify the exact version.
- **No Internal State Machine:** The function block delegates all state logic to the encapsulated function block.

State Overview

Since the FB (Function Block) does not have its own state machine, its state is entirely determined by its internal state:

1. **Initialization Phase:** After the event `INIT`, the FB is configured. It is only operational after `INITO`.
2. **Operation Phase:** With each `REQ` event, the current physical value is calculated and output via the adapter.
3. **Error State:** In case of faulty initialization or invalid parameters, `STATUS` is populated with a corresponding text message, and `QO` is set to FALSE.

Application Scenarios

- **ISOBUS Control Units:** This function block is ideally suited for converting sensor data (e.g., speed, pressure, temperature) into a standardized adapter interface, as required in agricultural machinery according to ISO 11783-6.
- **Measurement Acquisition with Scaling:** Raw values can be converted into physical units using the parameter structure with individual offsets and scaling factors.
- **Modular Systems:** The adapter interface allows multiple output blocks to be easily connected to various consumers (e.g., visualization, logic).

Comparison with Similar Function Blocks

- **NumericValue_PHYS** (without the "A" suffix): The pure function block without an adapter interface. It provides the physical value only as a data output (`rPhys`). This function block adds the adapter plug to enable coupling via a standardized channel.
- **NumericValue_RAW / NumericValue_SCALED** (hypothetical): These blocks would deliver raw or scaled values without reference to an object pool. In contrast, `NumericValue_PHYSA` uses the structure `NumericObjectPool_S` with explicit conversion parameters.

Conclusion

The function block `NumericValue_PHYSA` offers a clean, adapter-based interface for outputting physical REAL values. By encapsulating all the conversion logic in `NumericValue_PHYS`, it remains lean and maintainable. Its use is recommended wherever ISO 11783-6 compliant physical measurement values need to be provided in a modular automation system.

SoftKeyActivationCode

• – ◦ • – ◦ • – ◦ •

Introduction

SoftKeyActivationCode is a collection of global constants for processing softkey events in ISOBUS-compatible systems. These constants define various activation states of softkeys on virtual terminals and are used to control user interactions in agricultural machinery.

Interface Structure

SoftKeyActivationCode consists of global constants and not a function block. Therefore, there are no event or data interfaces in the conventional sense.

Constant Definitions

- **SK_RELEASED**: Softkey released (state change) - Code: 0
- **SK_PRESSED**: Softkey pressed (state change) - Code: 1
- **SK_STILL_HELD**: Softkey still held - Code: 2
- **SK_STILL_HELD_START**: Softkey still held (start) - Code: 2, bCyclic: FALSE
- **SK_ABORTED**: Softkey press aborted (applies to VT version 4 and higher) - Code: 3
- **Invalid**: Invalid state - Code: 255

Functionality

The constants represent different activation states of softkeys in ISOBUS systems. They are used to indicate the status of user interactions with virtual terminals. The transmission repetition rate is 200 ms when a soft key is pressed/released and every 200 ms when a soft key is held.

Technical Features

- All constants are of type `isobus::UT::io::Softkey::SoftKeyActivationCode_S`
- The constants are defined as global constants and can be used system-wide
- The abort functionality (SK_ABORTED) is only available in Virtual Terminal version 4 and higher
- The constant SK_STILL_HELD_START additionally contains a Boolean parameter `bCyclic`

Application Scenarios

- Control of user interfaces in agricultural machinery
- Processing of touch inputs on ISOBUS-compatible displays
- Implementation of softkey interactions in Virtual Terminal applications
- Status monitoring of user inputs in real-time control systems

⚖️ Comparison with Similar Blocks

Unlike function blocks, global constants do not offer active functionality but merely serve to standardize state values. They are comparable to ENUM definitions in other programming languages.

Conclusion

SoftKeyActivationCode provides a standardized collection of constants for softkey processing in ISOBUS environments. Using these constants enables a uniform and maintainable implementation of user interactions in agricultural control systems.

SoftKeyActivationCode_S

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `SoftKeyActivationCode_S` is a structured data structure (struct) used to configure the activation of a softkey in an ISOBUS-compliant system. It defines the specific activation code and a control flag for the key press repetition frequency.

Interface Structure

This is a data type and therefore does not have event or adapter interfaces in the conventional sense of a function block. The structure consists of the following data fields:

Data Inputs

(Not applicable – this is a data type)

Data Outputs

(Not applicable – this is a data type)

Data Fields (Structure Components)

Name	Data Type	Initial Value	Comment
`code`	`USINT`	255	Defines the numeric code that identifies the specific softkey.
`bCyclic`	`BOOL`	TRUE	Controls the cyclic sending of the key code. With `FALSE`, the key is not repeatedly sent every 200ms.

Functionality

The structure `SoftKeyActivationCode_S` serves as a container for configuration data. The value in the field `code` corresponds to a specific key on a virtual or physical terminal. The field `bCyclic` allows you to control the behavior when a key is held down. If set to `TRUE` (default), the key press is repeatedly sent at a defined interval (e.g., every 200 ms) as long as the key remains pressed. With `FALSE`, only a single event is triggered upon the initial key press.

Technical Features

- **Initial Values:** Both fields have predefined initial values. The default value `255` for `code` can be interpreted as "invalid" or "unconfigured" code.
- **ISOBUS Context:** This data type is part of the `isobus::UT::io::Softkey` package, indicating its use in ISOBUS Virtual Terminal (VT) or similar I/O contexts.
- **Cycle Control:** Precise control of the repetition rate via `bCyclic` is crucial for user-friendly and reliable keyboard input, especially with long data fields or list controls.

State Overview

(Not applicable – this is a passive data type without a state machine.)

Application Scenarios

This data structure is typically used as an input or configuration parameter for function blocks that:

1. Emulate or control the virtual keyboard input of an ISOBUS terminal.
2. Process softkey events in application logic (e.g., menu navigation, value input).
3. Dynamically configure the key assignment or key behavior of a device.

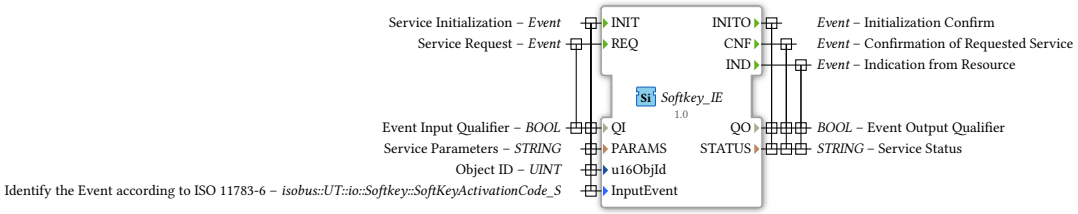
⚖️ Comparison with Similar Blocks

Unlike a function block (FB), `SoftKeyActivationCode_S` is a pure **data type** (struct). It does not contain any algorithms or event-driven logic.

- **Similarity to `E_SR` or `E_RS`:** These are function blocks with memory functionality and internal state logic. `SoftKeyActivationCode_S`, on the other hand, is a pure data carrier.
- **Comparison with simple data types:** Unlike atomic types such as `INT` or `BOOL`, this struct combines two logically related pieces of information (`code` and behavior `bCyclic`) into a single, reusable unit.

Conclusion

The data type `SoftKeyActivationCode_S` is an essential auxiliary structure for controlling softkey input in ISOBUS environments. By encapsulating the key code and repeat behavior in a single struct, configuration is simplified and code reusability is increased. Its clear structure and sensible default values make it a robust building block for developing terminal I/O logic.



Softkey_IE

🎧 Podcast

- ISO 11783-6: Understanding Softkeys and the Virtual Terminal – Your Key to Agricultural Machinery Mechatronics

Introduction

The Softkey_IE function block is an input service interface function block for event input data, specifically designed for processing softkey events according to ISO 11783-6. It serves as an interface between the application logic and the physical softkey input devices in agricultural and mobile machinery.

Interface Structure

Event Inputs

- **INIT**: Service initialization with parameters QI, PARAMS, u16ObjId, and InputEvent
- **REQ**: Service request with parameter QI

Event Outputs

- **INITO**: Initialization acknowledgment with parameters QO and STATUS
- **CNF**: Acknowledgement of the requested service request with parameters QO and STATUS
- **IND**: Indication from the resource with parameters QO and STATUS

Data Inputs

- **QI** (BOOL): Event input qualifier
- **PARAMS** (STRING): Service parameter
- **u16ObjId** (UINT): Object ID with initial value ID_NULL
- **InputEvent** (SoftKeyActivationCode_S): Identifies the event according to ISO 11783-6 with initial value “Invalid”

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (STRING): Service status

Adapters

No adapter interfaces available.

Functionality

The Softkey_IE function block manages communication with softkey input devices according to the ISO bus standard 11783-6. During initialization (INIT), the service parameters and object ID are configured. Service requests (REQ) trigger the corresponding functionality, while indications (IND) signal incoming events from the physical softkeys.

Technical Features

- Supports ISO 11783-6 standard for agricultural vehicles
- Uses a specific SoftKeyActivationCode structure for event identification

- Integrates object ID management for device identification
- Provides comprehensive status feedback via STRING parameters

State Overview

The function block has an initialized state and an operating state. After successful INIT initialization, the block switches to the operating state, in which REQ requests can be processed and IND events can be received.

Application Scenarios

- Control of operator panels in agricultural machinery
- Implementation of softkey functionalities in mobile work equipment
- ISOBUS-compliant input processing in vehicles
- User interfaces for complex machine controls

⚖️ Comparison with Similar Blocks

Compared to generic input blocks, Softkey_IE offers specific ISO 11783-6 compliance and is optimized for the requirements of agricultural and mobile work equipment. The integration of SoftKeyActivationCode enables standardized event handling.

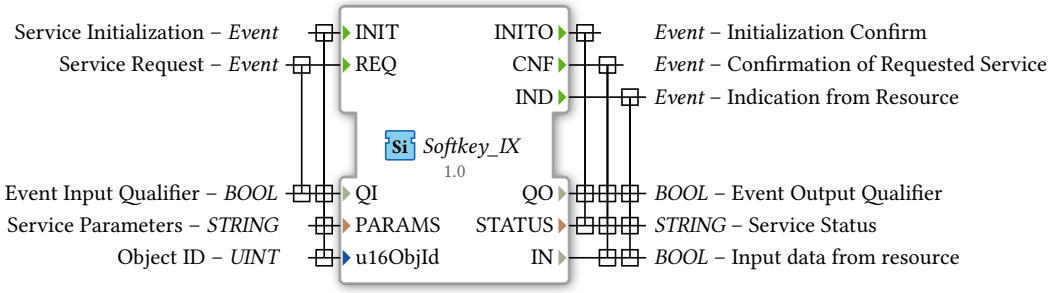
Conclusion

The Softkey_IE function block represents a specialized solution for softkey event processing in ISO 11783-6 compliant systems. Its standardized interface and comprehensive status feedback make it ideally suited for use in complex mobile machine control systems.

Softkey_IX



🎧 Podcast

- ISO 11783-6: Understanding Softkeys and the Virtual Terminal – Your Key to Agricultural Machinery Mechatronics

Introduction

The Softkey_IX is a service interface function block for Boolean input data, serving as an input interface for softkey functionalities. This block enables communication with resources and the processing of keyboard input in control systems.

•

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- Linked to: QI, PARAMS, u16ObjId
- **REQ**: Service Request
- Linked to: QI

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service Function
- Linked to: QO, STATUS, IN
- **IND**: Indication from Resource
- Linked to: QO, STATUS, IN

Data Inputs

- **QI**: BOOL - Event Input Qualifier
- **PARAMS**: STRING - Service Parameter
- **u16ObjId**: UINT - Object ID (Initial Value: ID_NULL)

Data Outputs

- **QO**: BOOL - Event output qualifier
- **STATUS**: STRING - Service status
- **IN**: BOOL - Input data from the resource

Adapters

No adapter interfaces are available.

Functionality

The Softkey_IX function block acts as an intermediary between the application logic and physical or virtual input devices. During initialization (INIT), the service parameters are configured. Service requests can be made via REQ events, which are acknowledged by CNF events. IND events signal asynchronous input from the resource.

Technical Features

- Uses ISOBUS-compatible object identification
- Supports configurable service configuration via STRING parameters
- Offers both synchronous (CNF) and asynchronous (IND) operating modes
- Initialization with a standardized object ID (ID_NULL)

State Overview

The function block goes through the following main states:

1. **Not Initialized**: Before INIT processing
2. **Initialized**: After successful INIT processing
3. **Ready**: Can process service requests
4. **Active**: Processes current inputs

Application Scenarios

- Operator panels in mobile machinery
- Virtual keyboards in industrial plants
- Softkey implementations in vehicle systems
- User interfaces for ISOBUS-compatible devices

⚖️ Comparison with Similar Blocks

Compared to simple digital input blocks, Softkey_IX offers extended service functionalities with configurable settings and ISOBUS compatibility. The IND functionality enables asynchronous event handling, which is not available with purely query-based function blocks.

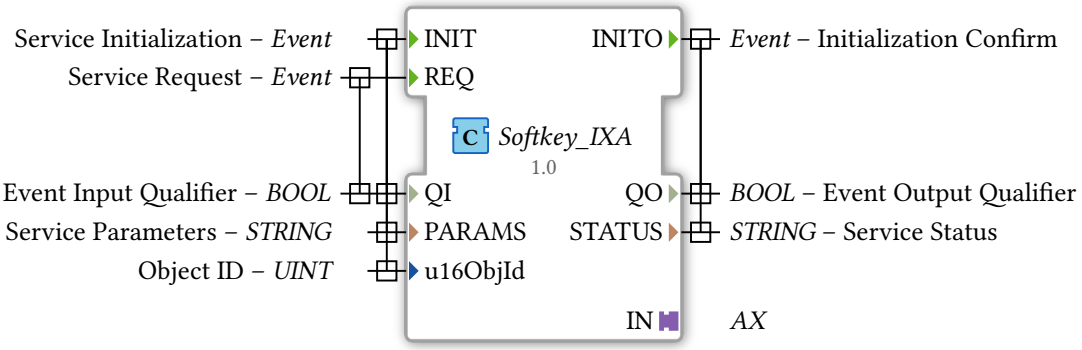
Conclusion

The Softkey_IX function block represents a flexible and standardized solution for softkey inputs in industrial control systems. Its ISOBUS compatibility and comprehensive service interface make it particularly suitable for demanding applications in mobile machinery and industrial plants.

Softkey_IXA



🎧 Podcast

- ISO 11783-6: Understanding Softkeys and the Virtual Terminal – Your Key to Agricultural Machinery Mechatronics

Introduction

Softkey_IXA is a composite function block for processing Boolean input data. The block serves as an interface for softkey operations and enables the initialization and querying of input states via standardized ISOBUS communication protocols.

Interface Structure

Event Inputs

- **INIT**: Service initialization event with the associated data QI, PARAMS, and u16ObjId
- **REQ**: Service request event with the qualifier QI

Event Outputs

- **INITO**: Initialization confirmation with the output data QO and STATUS

Data Inputs

- **QI**: BOOL - Event Input Qualifier
- **PARAMS**: STRING - Service Parameter
- **u16ObjId**: UINT - Object ID with initial value ID_NULL

Data Outputs

- **QO**: BOOL - Event Output Qualifier
- **STATUS**: STRING - Service Status

Adapters

- **IN**: Adapter of type adapter::types::unidirectional::AX for unidirectional communication

Functionality

The composite function block Softkey_IXA encapsulates the internal function block Softkey_IX and acts as an intermediary between external calls and the actual softkey functionality. During initialization (INIT), parameters are passed to the internal block, and during service requests (REQ), the corresponding queries are executed. The IN adapter enables communication with external components.

Technical Features

- Uses ISOBUS-specific types and constants
- Supports object identification via u16ObjId
- Flexible parameter passing via STRING parameters
- Unidirectional adapter interface for extended communication

State Overview

The function block has two main states:

1. **Initialization State**: Processing of INIT events with parameter passing
2. **Service State**: Processing of REQ requests and return of results

Application Scenarios

- Agricultural operator terminals with softkey functionality
- ISOBUS-compatible control systems
- Applications with Boolean input queries
- Systems with configurable service interfaces

⚖️ Comparison with Similar Blocks

Compared to simple Boolean input blocks, Softkey_IXA offers extended ISOBUS compatibility, configurable service interfaces, and adapter-based extensibility. The composite structure allows for a clear separation between interface logic and core functionality.

🛠️ Related exercises

StringValue_AIS

• – ○ • – ○ • – ○ •

Introduction

The **StringValue_AIS** function block is a service interface function block for providing string input data. It serves as an interface between an external resource (e.g., ISOBUS Universal Terminal) and the control logic. The block initializes communication, processes requests, and passes status information to the application.

Interface Structure

Event Inputs

Event	Type	With Variables	Description
INIT	EInit	QI, PARAMS, u16ObjId	Initializes the service and passes qualifiers, parameters, and object IDs.
REQ	Event	QI	Requests a data query or processing.

Event Outputs

Event	Type	With Variables	Description
INITO	EInit	QO, STATUS	Confirms initialization and provides status information.

Data Inputs

Variable	Type	Initial Value	Description
QI	BOOL	–	Qualifier for events (TRUE = active).
PARAMS	STRING	–	Service parameters (e.g., configuration data).
u16ObjId	UINT	ID_NULL	Object ID referenced in the log.

Data Outputs

Variable	Type	Description
QO	BOOL	Output qualifier (service acknowledgment).
STATUS	STRING	Service status message (e.g., error message or success message).

Adapters

Adapter	Type	Direction	Description
IN	adapter::types::unidirectional::AIS	Input	Unidirectional adapter for data exchange with an external resource (e.g., a hardware interface).

Functionality

The **StringValue_AIS** block encapsulates an internal service block **StringValue_IS** and controls its event and data flows. Upon an INIT event, the input parameters (QI, PARAMS, u16ObjId) are forwarded to the internal block, which initializes the communication. The INITO event output signals success (QO, STATUS).

A REQ event triggers a further query—the internal block sends the request (e.g., reading a string value) to the external resource via the **IN** adapter. The response is received asynchronously via the adapter (IND or CNF event) and returned as a STATUS/QO output.

The connections are hard-coded in the FB network:

- **INIT** and **REQ** are routed to the internal function block **StringValue_IS**.
- The response events **IND** and **CNF** of the internal function block are routed to the adapter output **IN.E1**.
- The data lines **QI**, **PARAMS**, and **u16ObjId** feed the internal function block, while **IN.D1** (from the adapter) and **STATUS**/**QO** are passed to the outputs of the function block.

Technical Features

- The function block is designed as a **Service Interface Function Block (SIFB)** and is suitable for integration into an ISOBUS-compliant control environment.
- The interface uses a **unidirectional adapter (AIS)**, which transmits data exclusively from the resource to the controller.
- The initial value of `u16ObjId` is set to `ID_NULL` – a placeholder that must be replaced with a valid object ID during the initialization step.
- The implementation is licensed under the **Eclipse Public License 2.0**.
- The component uses an internal type hash mechanism for integrity checking.

State Overview

An explicit state machine is not represented in the XML. The component operates in an event-driven manner:

- **IDLE**: Waiting for INIT.
- **INIT completed**: Initialization complete, waiting for REQ.
- **IN processing**: After REQ, the request is sent to the adapter; the response is asynchronous.

The response via INITO signals the completion of initialization, while the STATUS output reflects the current state of the service.

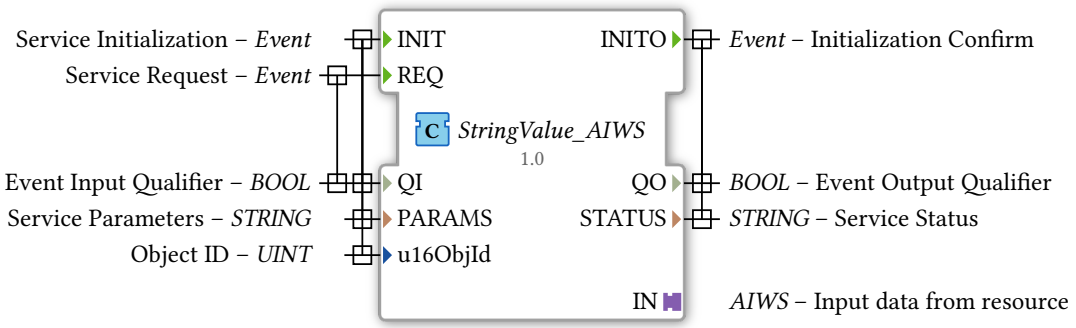
Application Scenarios

- **ISOBUS UT Connection**: Reading a text field (e.g., machine name, field label) from a Universal Terminal.
- **Configuration Interface**: Accepting string parameters from a higher-level control system.
- **Data Logging**: Capturing external strings (e.g., barcode scanner, serial numbers) for further processing.

Comparison with Similar Modules

- **IntegerValue_AIS**: Similar structure, but for integer data. It differs only in the data type of the output value.
- **CommandValue_AIS**: Offers bidirectional communication (send/receive) and expects a command format.
- **StringValue_AIS** is specifically optimized for receiving strings and requires no response other than status.

Conclusion



The **StringValue_AIS** is a specialized service interface module for receiving string data via a unidirectional adapter. It simplifies the integration of external text sources into automation systems and provides a clean separation between communication services and application logic. Thanks to its standardized interface (event/data connections), it can be flexibly integrated into 4diac IDE projects.

StringValue_AIWS

• – ○ • – ○ • – ○ •

Introduction

The function block **StringValue_AIWS** is an input-service interface block for processing wide-string data (UTF-16) in an ISOBUS context. It provides an adapter-based interface through which external resources can input strings. The block acts as a wrapper for the internal block *StringValue_IWS* and offers a standardized initialization and request interface.

Interface Structure

Event Inputs

Event	Type	With Variables	Comment
INIT	EInit	QI, PARAMS, u16ObjId	Service Initialization
REQ	Event	QI	Service Request (Query)

Event Outputs

Event	Type	With Variables	Comment
INITO	Initialization	QO, STATUS	Initialization Acknowledgement

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	–	Event Qualifier (Share)
PARAMS	STRING	–	Service Parameter (e.g., Configuration String)
u16ObjId	UINT	ID_NULL	Object ID (e.g., ISOBUS Object Identifier)

Data Outputs

Name	Type	Comment
QO	BOOL	Output Qualifier (Status of Last Operation)
STATUS	STRING	Status message (e.g., error message or success message)

Adapter

Name	Type	Comment
IN	adapter::types::unidirectional::AIWS	Input of wide-string data from the resource (unidirectional)

The adapter IN receives the actual strings and makes them available to the function block. The connection is established via the event line E1 and the data channel D1.

Functionality

The function block initializes the internal *StringValue_IWS* function block via the event INIT. The parameters QI, PARAMS, and u16ObjId are passed to this event. After successful initialization, the event INITO is triggered, and the output variables QO and STATUS are set.

The event REQ initiates a request to provide a new wide-string value. The actual string is delivered asynchronously via the adapter IN: As soon as the internal module receives a new string, it sends an event (IND or CNF) to the adapter output E1, and the data is then passed to the connected resource via the data channel D1.

The module encapsulates all the logic for initialization and communication with the underlying wide-string service and provides a uniform adapter interface to the outside.

Technical Features

- **Wide-String Support**: The module is designed for UTF-16 (Wide Strings) and is therefore particularly suitable for international character sets (Unicode).
- **Adapter-based communication**: The use of a unidirectional adapter (AIWS) allows for a clean separation between service logic and the resource interface.
- **ISOBUS compliance**: The object ID (u16ObjId) is assigned the initial value ID_NULL, indicating ISOBUS-specific assignment.
- **Event-driven processing**: Both initialization and data requests are triggered by explicit events, making the function block suitable for use in time-critical environments.

State overview

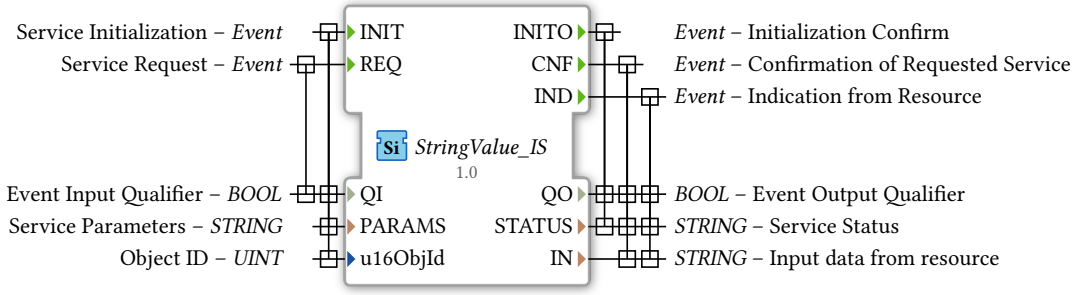
The function block does not have an explicit state machine; its behavior is controlled by events:

1. **Idle state** – The function block waits for INIT or REQ.
2. **Initialization** – After INIT, the parameters are passed to the internal function block; outputs QO and STATUS are updated, and INITO is sent.
3. **Request State** – After REQ, a data request is initiated. The response is asynchronous via the adapter IN (event E1).
4. **Error Handling** – If an error occurs during initialization, QO is set to FALSE, and a corresponding message STATUS is output.

Application Scenarios

- **Input of Unicode text** into agricultural operator terminals (ISOBUS-UT) – e.g., for vehicle names, field names, or product designations.
- **Configuration interface** for ISOBUS devices that require wide-string parameters.
- **Connection of external input devices** (keyboards, touchscreens) to an ISOBUS control unit via a standardized adapter interface.

Comparison with Similar Modules



Module	Interface	Special Feature
StringValue_AIWS	Adapter (Input)	Receives wide-strings via the adapter AIWS
StringValue_IWS	Direct Events/Data	Internal logic, no adapter interface
StringValue (Standard)	Events/Data	Simple Wide-String Input (without adapter)

The StringValue_AIWS stands out due to its adapter-based interface, which enables loose coupling between resource and service. It is particularly suitable for modular systems where the data source can change dynamically.

Conclusion

The **StringValue_AIWS** is a robust input-service interface block for wide-string data in ISOBUS systems. By combining event-driven initialization, adapter communication, and a clear interface structure, it provides a reliable foundation for processing Unicode text in industrial applications. The separation of service logic and resource interface simplifies the maintainability and reusability of the block.

StringValue_IS

• – ◦ • – ◦ • – ◦ •

Introduction

The **StringValue_IS** function block is an input service interface function block (Input SIFB) for receiving string data from a resource. It serves as a standardized interface for integrating external string information into the 4diac environment. Typical applications include connecting to ISOBUS systems, where strings such as names, status messages, or identifiers are received.

Interface Structure

Event Inputs

Event	Type	Description	Data Carried
`INIT`	EInit	Service Interface Component Initialization	`QI`, `PARAMS`, `u16ObjId`
`REQ`	Event	Request for data query or update	`QI`

Event Outputs

Event	Type	Description	Data Carried
`INITO`	EInit	Confirmation of successful initialization	`QO`, `STATUS`
`CNF`	Event	Confirmation of executed request	`QO`, `STATUS`, `IN`
`IND`	Event	Asynchronous indication – new input data from the resource	`QO`, `STATUS`, `IN`

Data Inputs

Name	Type	Initial Value	Description
`QI`	BOOL	–	Event Qualifier: Controls the execution of the associated events
`PARAMS`	STRING	–	Service parameter (e.g., configuration of access to the resource)
`u16ObjId`	UINT	`ID_NULL`	Object ID that identifies the string to be read from the resource

Data Outputs

Name	Type	Description
`QO`	BOOL	Event Qualifier: Indicates whether the output provides valid data
`STATUS`	STRING	Service status message (e.g., error codes or success message)

IN	STRING	Received string from the resource

Adapter

This function block does not have any adapter interfaces.

Functionality

The **StringValue_IS** function block operates according to the standard scheme of a service interface function block for data input:

1. **Initialization (INIT)**

The function block is configured by creating a INIT event. The parameters QI (qualifier), PARAMS (service parameter), and u16ObjId (object ID) are passed. After successful initialization, the function block confirms with the event INITO and returns the status via QO and STATUS.

1. **Request (REQ)**

A REQ event triggers an active data query from the resource. The qualifier QI is evaluated. The response is returned with the event CNF. The received string is then available at the output IN.

1. **Asynchronous Indication (IND)**

The resource can send new data at any time. The function block signals this via the event IND. Simultaneously, the current data is provided at output IN, and the status is provided via QO and STATUS.

The outputs IN, QO, and STATUS are updated with each of the events CNF and IND and can be used immediately by subsequent function blocks.

Technical Features

- **Object ID:**

The input u16ObjId is predefined with the initial value ID_NULL. Before first use, a valid object ID must be set. The actual meaning of the ID depends on the underlying resource protocol (e.g., ISOBUS object number).

- **Service Parameter (PARAMS):**

This string input is used to pass configuration-specific parameters (e.g., bus address, communication path). The exact syntax depends on the implemented driver.

- **Typical Event Sequence:**

INIT→INITO→ (possibly repeatedREQ↔CNFor asynchronousIND`).

- **Error Handling:**

Errors are signaled via the STATUS output and can be used for error diagnosis.

State Overview

The function block goes through the following basic states (not explicitly modeled in the XML, but typical for SIFBs):

- **Not Initialized:** After the system starts. Only INIT is processed.
- **Initialized:** After successful INITO. The function block is ready for REQ and can receive asynchronous IND.
- **Request in Progress:** After a REQ until the arrival of CNF. No further requests are processed during this time.
- **Error State:** In case of communication errors. Can be reset by re-running INIT.

Application Scenarios

- **ISOBUS Control Units:**

Receiving strings such as device names, variable names, or status messages from an ISOBUS server.

- **User Interfaces:**

Reading text data sent from an external HMI or operator panel.

- **Configuration Data:**

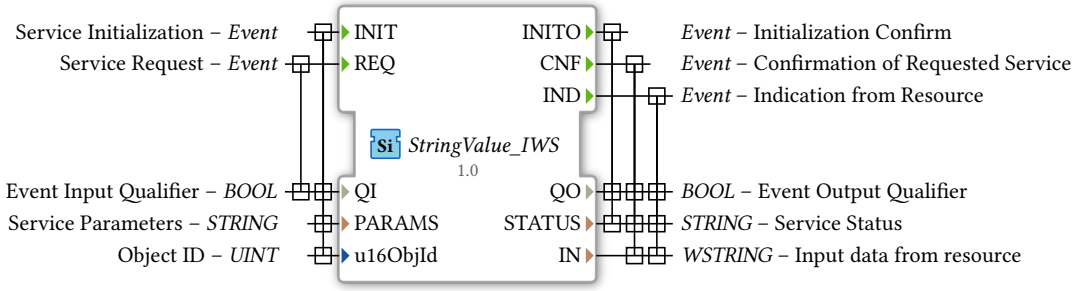
Retrieving string parameters from a central configuration service.

Comparison with Similar Function Blocks

Function Block	Data Type	Special Feature
`BOOL_IS`	BOOL	Simple Boolean inputs (e.g., switches)
`INT_IS`	INT	Integer inputs (e.g., counter readings)
REAL_IS`	REAL	Floating-point inputs (e.g., measured values)
StringValue_IS`	STRING	Strings – for names, descriptions, irregularly formatted data

StringValue_ISexpands the family of input SIFBs with the flexible data typeSTRING`, which is characterized by variable length and content.

Conclusion



The **StringValue_IS** is an essential component for integrating string-based data into 4diac. It offers a standardized interface to the resource, enables both active queries and asynchronous indications, and can be flexibly configured using the parameters `PARAMS` and `u16ObjId`. Its use simplifies integration with protocols such as ISOBUS and increases the reusability of application logic.

]

StringValue_IWS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **StringValue_IWS** is a service interface function block (SIFB) responsible for receiving wide strings (*Wide String*, `WSTRING`) as input data from a resource-side source (e.g., hardware interface, bus system). It provides a standardized interface for managing initialization, cyclic/demand-driven data retrieval, and asynchronous indications. This function block is typically found in ISOBUS-based control environments or other fieldbus systems that process Unicode-encoded text data.

Interface Structure

Event Inputs

Event	Comment	Accompanying Data
`INIT`	Service Initialization	`QI`, `PARAMS`, `u16ObjId`
`REQ`	Service Request	`QI`

Event Outputs

Event	Comment	Accompanying Data

INITO	Initialization Confirmation	QO, STATUS
CNF	Confirmation of requested action	QO, STATUS, IN
IND	Asynchronous indication from the resource	QO, STATUS, IN

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	–	Event input qualifier
PARAMS	STRING	–	Service parameter (e.g., port/device configuration)
u16ObjId	UINT	ID_NULL	Object ID for identifying the data source

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Status or Error Message
IN	WSTRING	Received Input Data (Wide String)

Adapter

None.

Functionality

The StringValue_IWS follows the typical behavior of a service interface function block:

1. **Initialization (INIT → INITO)**

The service is started by triggering the INIT event. The qualifier QI determines whether the initialization is active (TRUE) or disabling (FALSE). Necessary configuration parameters (e.g., bus address, protocol options) are passed using PARAMS. The object ID u16ObjId specifies which data source (e.g., a particular ISOBUS object) is to be addressed. After successful initialization, INITO is output; QO and STATUS indicate the initial state.

1. **Request (REQ → CNF)**

The REQ event triggers an explicit data query. The function block retrieves a new value from the connected device (e.g., via a driver). The response is provided via the output IN (as WSTRING) and the status STATUS. Simultaneously, the CNF event is sent.

1. **Asynchronous Indication (IND)**

If the resource provides new data without being prompted (e.g., when an input is changed), the IND event is triggered. IN then contains the current data, and STATUS the corresponding status. This output can be used in parallel with the CNF event.

The event outputs QO always return the current qualifier value (usually QI upon successful operation, otherwise FALSE). The status STATUS contains human-readable error or success messages.

Technical Features

- **Wide Strings (WSTRING)**

This function block uses WSTRING (UTF-16 encoded) to correctly transmit international character sets, special characters, and emojis. This is particularly important in ISOBUS agricultural technology, for example, when operator terminals display Unicode text.

- **Object ID u16ObjId**

The initial value ID_NULL is inherited from the imported constant isobus::UT::Q::const::IDs::ID_NULL. A valid object ID must be set before the INIT action to address the correct data source.

- **Service Interface Character**

The function block is implemented as a SIFB and expects a resource-side implementation (driver). The actual communication with the hardware or bus system takes place outside the function block and is abstracted via the event/data interfaces.

- **Use of `eclipse4diac::core::TypeHash`**

This attribute serves for runtime identification of the type and is used for dynamic function block instances.

State Overview

An explicit state engine is not defined in the XML; however, the following implicit process emerges from the SIFB semantics:

1. **IDLE** – Waiting for `INIT` or the first `REQ`.
2. **INIT** – Initialization phase; after successful execution, transition to **READY**.
3. **READY** – Ready for `REQ` or `IND`. Briefly enters **BUSY** upon `REQ`, then returns to **READY**.
4. **INDICATION** – Asynchronous data indexing; returns to **READY** after processing.
5. **ERROR** – In case of errors (e.g., communication interruption), `STATUS` is set and the block remains in place until `INIT` is sent again (with `QI=FALSE` as a possible reset).

Application Scenarios

- **ISOBUS Terminal (UT) – Unicode Text Input**

Receiving user input such as machine names, addresses, or diagnostic texts from an operator terminal via ISOBUS.

- **Universal Interface for Character Input**

Connecting external sensors or input devices that deliver character strings in UTF-16 format (e.g., barcode scanners, RFID readers with text output).

- **Diagnostics and Logging Interface**

Captures status messages, warnings, or error texts from a control unit for forwarding to an HMI or cloud connection.

Comparison with similar function blocks

Function block	Type	Difference
`StringValue_IWS` (present)	`WSTRING`	Receives UTF-16 encoded strings.
`StringValue_IWS` (standard version)	`STRING`	Receives ASCII/UTF-8 strings, lower character coverage.
`AnalogInput_IWS`	`REAL`	Receives analog measured values, not strings.
`EventInput_IWS`	–	Event interface only, no data.

The `StringValue_IWS`is specifically designed for processing Unicode text and is therefore suitable for international or character set-heavy applications.

Conclusion

The `StringValue_IWS` is an essential component for integrating text input into IEC 61499-based control systems, especially in ISOBUS environments. Its support for `WSTRING`, the clean separation of initialization, request, and asynchronous indication, and the flexible object ID addressing make it a robust solution for receiving long strings from distributed resources.

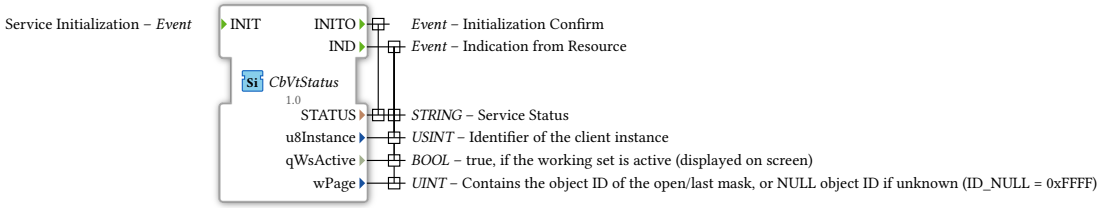
status



CbVtStatus

• — ○ • — ○ • — ○ •

Introduction

The **CbVtStatus** is a standardized callback module for virtual terminal page changes, developed under the EPL 2.0 license. Version 1.0 supports ISO 11783-6 (ISOBUS) in agricultural tax systems.

Interface Structure

Event Inputs

- `INIT`: Initialization Request

Event Outputs

- `INITO`: Initialization Confirmation (with STATUS)
- `IND`: Page Change Indication (with page info, `STATUS`, `wPage`, `qWsActive`, `u8Instance`, `wSKM_Scal`, `w_DMScal`, `u8SKM_Number`, `qScalingTestEnabled`)

Data Outputs

- `STATUS` (STRING): Operational Status
- `u8Instance` (USINT): Client Instance Identifier
- `qWsActive` (BOOL): Workload Status
- `wPage` (UINT): Object ID of the open/last mask, or `ID_NULL` (0xFFFF) if unknown
- `wSKM_Scal` (UINT): Softkey mask scaling factor (PoolSoftKeyMaskScalFaktor), unit 1/10000 (10000 = 100%); possibly overridden by SCALING-TEST
- `w_DMScal` (UINT): Data mask scaling factor (PoolDataMaskScalFaktor), unit 1/10000 (10000 = 100%); possibly overridden by SCALING-TEST
- `u8SKM_Number` (USINT): Number of physical softkeys (VT_PHYSICALSOFTKEYS/sknu), valid range 6..11; possibly overridden by SCALING-TEST
- `qScalingTestEnabled` (BOOL): `TRUE` if the SCALING-TEST override (`[ScalingTest] enable=1` in `settings.ini`) is active

Functionality

1. **Initialization**:

- Event `INIT` starts setup
- Event `INITO` confirms with STATUS

1. **Page Change**:

- Event `IND` is triggered on screen change
- Returns: Page ID, Active Status, Instance Number

1. **Operation**:

- Real-time monitoring of the VT status
- Multi-ECU capable architecture

Technical Features

✓ **ISO 11783-6 compliant** ✓ **Deterministic** behavior ✓ **Multi-ECU support** ✓ **Plug-in capable** architecture

Supported Operating Modes

Mode	Description
Single device	Standard operation with u8Instance=0
Multi-ECU	Parallel Instances (1-255)
Diagnostics	STATUS Messages for Service

Application Scenarios

- **Tractor Control Units**: Operator Screen Monitoring
- **Harvesting Machines**: Work Data Display
- **Diagnostic Tools**: VT Status Monitoring
- **Multi-Display Systems**: Synchronization

⚖️ **Comparison with Similar Modules**

Feature	CbVtStatus	VtPageManager	VtEventLogger
Page Switch	✓	✓	✖
Multi-ECU	✓	✖	✖
STATUS feedback	✓	✖	✓

Error Handling

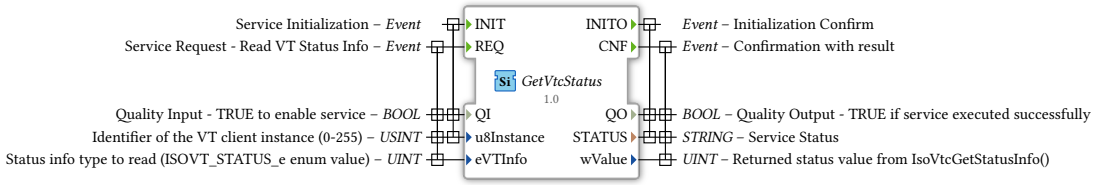
- Invalid Page ID:
- STATUS = “ERR_INVALID_PAGE”
- wPage = 0xFFFF
- Initialization Error:
- STATUS = “ERR_INIT_FAILED”
- System in Safe State

🛠️ **Related Exercises**

- Exercise_012
- Exercise_012a
- Exercise_012b
- Exercise_012c

Conclusion

The CbVtStatus module is essential for ISOBUS-compliant agricultural systems:



- Robust page change management
- Full ISO 11783-6 compatibility
- Proven architecture In series production

Especially valuable for manufacturers of:

- Tractor control units
- Harvesting machine control systems
- ISOBUS diagnostic devices

The standardized implementation enables reliable operation in heterogeneous system environments.

GetVtcStatus

• – ○ • – ○ • – ○ •

Introduction

The function block **GetVtcStatus** is a Service Interface Block (SIFB) that encapsulates the function `IsoVtcGetStatusInfo()` from the ISOBUS driver. It enables the reading of various status information from a VT client and the connected Virtual Terminal (VT). The block was developed according to the ISO 11783-6 standard and is suitable for integration into ISOBUS applications.

Interface Structure

Event Inputs

Event	Type	Description	Data Carried
`INIT`	EInit	Initializes the function block.	`QI`, `u8Instance`
`REQ`	Event	Requests the reading of a status value.	`QI`, `u8Instance`, `eVTInfo`

Event Outputs

Event	Type	Description	Data Carried
`INITO`	EInit	Confirmation of initialization.	`QO`, `STATUS`
`CNF`	Event	Confirmation of the read request with result.	`QO`, `STATUS`, `wValue`

Data Inputs

Name	Type	Initial Value	Description
`QI`	BOOL	–	Quality input: TRUE activates the service.
`u8Instance`	USINT	–	VT client instance identifier (0–255).
`eVTInfo`	UINT	0	Type of status information to query (values from the enumeration `ISOVT_STATUS_e`).

Data Outputs

Name	Type	Description
`QO`	BOOL	Quality output: TRUE upon successful execution.
`STATUS`	STRING	Service status – contains a textual response.
`wValue`	UINT	The value returned by `IsoVtcGetStatusInfo()` (dependent on `eVTInfo`).

Adapters

No adapters available.

Functionality

1. **Initialization**

The module is activated by the event `INIT`. The parameter `QI` must be set to TRUE for the service to start. The VT client instance to be used is specified via `u8Instance`. After successful initialization, the event `INITO` is sent with the output data `QO` and `STATUS`.

1. **Reading Status Information**

The event `REQ` initiates a specific query. The desired status value must be selected from the enumeration `ISOVT_STATUS_e` using `eVTInfo` (see the list in the technical specifications). Internally, the function block calls the function `IsoVtcGetStatusInfo()` and sends the event `CNF` upon completion. The outputs contain:

- `QO` = TRUE if the read operation was successful,
- `STATUS` = description of the result,
- `wValue` = the retrieved numerical value.

If `QI` is FALSE during the REQ call, the service is not executed and a corresponding error status is returned.

Technical Features

- The function block is implemented as a **Service Interface Block** (SIFB) and accesses the system-level ISOBUS driver library.
- The possible values for `eVTInfo` (ISOVT_STATUS_e) are:

Value	Label	Description
0	VT_SOURCE_ADDRESS	Source address of the VT
2	VT_HND	CF handle of the VT
3	CF_SOURCE_ADDRESS	Source address of the VT client
4	CF_HND	CF handle of the VT client
6	ID_VISIBLE_DATA_MASK	Data mask open on the VT
7	ID_VISIBLE_SOFTKEY_MASK	Softkey mask open on the VT
8	VT_BUSY_CODE	Busy code of the VT status message
9	AUXUNITS_TYPE1_ONBUS	TRUE if a Type 1 auxiliary device is on the bus
11	VT_ALIVE	VT unreachable for more than 3 seconds
12	VT_DOWNLOAD_FINISHED	Full announcement completed
13	VT_POOL_ACTIVE_onVT	Pool (selected) active on the VT
14	VT_STATEOFANNOUNCING	Announcing status
15	WS_VERSION_NR	Working Set version number
16	VT_NUMBOFVERSIONSTRINGS	Number of VT version strings sent
17	VT_NAVSOFTKEYS	Navigation softkeys (version 4)
18	VT_SOFTKEYXDOT	Softkey identifier – pixel X
19	VT_SOFTKEYYDOT	Softkey identifier – pixel Y
20	VT_VIRTUALSOFTKEYS	Number of virtual softkeys
21	VT_PHYSICALSOFTKEYS	Number of physical softkeys
25	VT_BOOTTIME	VT boot time
26	VT_GRAPHICTYPE	VT hardware graphics type
29	VT_VERSIONNR	Version of Working Set VT

- The function block supports both initialization and repeated calls to read operations, allowing different status values to be queried within a loop.

State Overview

The function block implements simple state-driven logic:

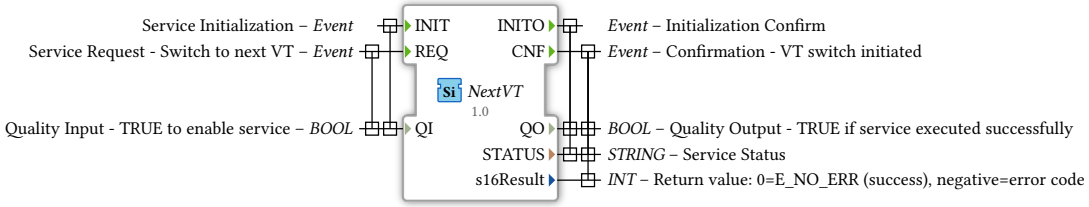
1. **Start State** – The function block waits for the event `INIT`.
2. **Initialization** – Upon receiving `INIT` (with a valid QI), the service is initialized. If successful, `INITO` is sent with QO=TRUE. If an error occurs, QO=FALSE and a corresponding STATUS are sent.
3. **Ready** – After successful initialization, any number of `REQ` events can be processed. Each `REQ` call triggers a call to `IsoVtcGetStatusInfo()` and the subsequent sending of `CNF`.
4. **Error Handling** – If an internal error occurs during a REQ, `CNF` is output with QO=FALSE and an error description in `STATUS`.

Application Scenarios

- **Diagnostics and Monitoring** of an ISOBUS system: Reading the current VT address, graphics type, or boot time.
- **Detection of VT Availability** by querying `VT_ALIVE` and `VT_DOWNLOAD_FINISHED`.
- **Control of the softkey configuration** by querying the number of physical and virtual softkeys (`VT_PHYSICALSOFTKEYS`, `VT_VIRTUALSOFTKEYS`).
- **Comparison of the working set version** between different components using `VT_VERSIONNR` and `WS_VERSION_NR`.

Comparison with similar modules

Similar modules such as `GetVtPool` or `GetVtObject` focus on reading pool or object data. The `GetVtcStatus` module, on the other hand, is specifically designed for accessing the general VT client status. It provides a direct interface to the system status properties of the ISOBUS specification and complements function blocks that access mask or softkey information.



Conclusion

The function block `GetVtcStatus`It provides a compact and standards-compliant way to access the system-level status data of an ISOBUS virtual terminal. Its clear interface and diverse query options make it a valuable tool for implementing diagnostic, monitoring, and configuration functions in agricultural control systems.

Numerical Index (UT)

Here you will find all exercises from the `UT` workspace in ascending order. …

NextVT

• – ◦ • – ◦ • – ◦ •

Introduction

The **NextVT** function block is a service interface block that enables switching to the next available Virtual Terminal (VT) in an ISOBUS network (ISO 11783-6). It encapsulates the functionality of `VTC_NextVTButtonPressed()` from the ISOBUS driver examples and allows seamless switching between multiple VT devices.

Interface Structure

Event Inputs

Event	Data Type	With Variables	Description
INIT	EInit	QI	Service Initialization. Triggered to configure the block.

REQ	Event	QI	Service request. Starts the process to switch to the next available VT.

Event Outputs

Event	Data Type	With Variables	Description
INITO	EInit	QO, STATUS	Initialization confirmation. Signals whether the initialization was successful.
CNF	Event	QO, STATUS, s16Result	Switchover confirmation. Outputs as soon as the switch to the next VT has been initiated.

Data Inputs

Variable	Type	Description
QI	BOOL	Quality input. TRUE activates the service. FALSE means no action is taken.

Data Outputs

Variable	Type	Description
QO	BOOL	Quality output. TRUE if the service was successful.
STATUS	STRING	Status message regarding the result of the last operation.
s16Result	INT	Return value: 0 = E_NO_ERR (successful), negative value = error code.

Adapters

No adapters available.

Functionality

When a **REQ** event is received, the block performs the following steps:

1. **Determine list of all VTs** – All virtual terminals available on the ISOBUS network are identified using `IsoClientsReadListofExtHandles()`.
2. **Find currently connected VT** – The currently used VT is identified using `IsoVtcGetStatusInfo(VT_HND)`.
3. **Determine next VT** – The next entry after the current VT is selected from the list (cyclic sequence).
4. **Execute switchover** – The switchover to the next VT is initiated using `IsoVtcMultipleNextVT()`.

- **Error case:** If only one VT is present on the bus or the switchover fails, a negative return value (`s16Result`) and a corresponding status message are output.
- **Important Note:** The application must enter a safe state after calling this block, as the connection to the current VT is lost during the transition.

Technical Features

- **Standard Compliance:** The block is based on ISO 11783-6 (ISOBUS) and implements the VT switching function according to the standard.
- **Service Interface Block:** Execution is asynchronous; the **CNF** event signals the completion of the switching process.
- **Initialization:** Before first use, the block must be initialized via the **INIT** event to allocate internal resources.

State Overview

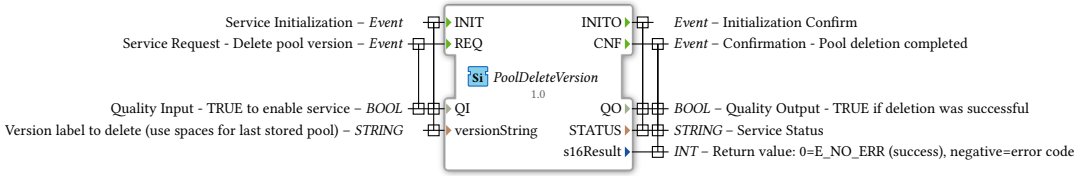
The block does not have explicit states in its XML definition. Its behavior is determined by event-driven processing:

- **Initialization Phase:** After **INIT** with `QI=TRUE`, initialization is performed and acknowledged by **INITO**.

- **Operational Phase:** After **REQ** with `QI=TRUE`, the switching process is initiated. Upon completion, the **CNF** event occurs.
- **Error Handling:** In case of errors, `QO=FALSE` and a corresponding error code are set in `s16Result`.

Application Scenarios

- **ISOBUS Machine Operation:** Switching between multiple Virtual Terminals in agricultural vehicles, e.g., to switch between the display and the on-board computer.
- **Multi-Monitor Systems:** Switching the active display to a different VT device on the network.
- **Diagnostics and Testing:** Simulating the pressing of the "Next VT" button during the development of ISOBUS-compliant applications.



Comparison with Similar Blocks

- **VTSelection** (hypothetical): A block that selects a specific VT object instead of simply jumping to the next one. NextVT is simpler and follows standard key logic.
- **VTConnect** (hypothetical): Establishes a direct connection to a named VT. NextVT, on the other hand, works automatically and does not require a target address.

Conclusion

The **NextVT** function block is a specialized service interface block for ISOBUS applications that enables standards-compliant switching to the next available virtual terminal. Its simple interface (INIT, REQ) and clear error feedback make it ideally suited for integration into control software that requires flexible VT selection. However, the application must account for the brief connection interruption.

PoolDeleteVersion

• – ○ • – ○ • – ○ •

Introduction

The service interface block `PoolDeleteVersion` deletes a stored object pool version from the non-volatile memory of a Virtual Terminal (VT). It encapsulates the function `VTC_PoolDeleteVersion()` from the ISOBUS driver. The block calls `IsoVtcCmd_DeleteVersion()` to remove the specified pool version.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Service Initialization
REQ	Event	Service Request – Delete Pool Version

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Confirmation
CNF	Event	Confirmation – Deletion complete

Data Inputs

Name	Type	Comment	Initial Value
QI	BOOL	Quality Input – TRUE activates the service	

versionString	STRING	Version label to be deleted (space for last saved version)	' '

Data Outputs

Name	Type	Comment
QO	BOOL	Quality output – TRUE on successful deletion
STATUS	STRING	Service status
s16Result	INT	Return value: 0 = E_NO_ERR (success), negative = error code

Adapter

None.

Functionality

The block is initialized via the event input `INIT`, passing the version number to be deleted (`versionString`). After successful initialization, an event `REQ` triggers the deletion process. The block calls the system-level function `IsoVtcCmd_DeleteVersion()`, which removes the specified pool version from the VT's flash memory. The result is signaled via the outputs `QO`, `STATUS`, and `s16Result`, triggering a corresponding confirmation event (`CNF` or `INITO`).

Technical Specifications

- `versionString` must be null-terminated or exactly 32 bytes long (ISO V11+).
- If a string consisting of spaces (' ') is passed, the function deletes the last stored pool version.
- Maximum version entry length: 32 bytes.
- The block is designed as a Service Interface Block (SIB) for ISOBUS communication (ISO 11783-6).

State Overview

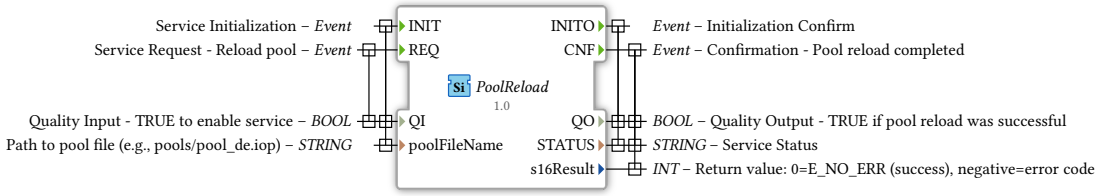
The block does not have any explicitly defined states in the XML. Control is event-driven via `INIT` and `REQ`:

1. **Initialization** (INIT) → Acknowledge (INITO)
2. **Request** (REQ) → Acknowledge (CNF) with result

Failed initialization or deletion is signaled by `QO=FALSE` and the corresponding `STATUS` message.

Application Scenarios

- Deleting old pool versions before uploading a new version
- Freeing up flash memory space on the VT
- Removing corrupted or no longer needed pool versions
- Resetting to the factory-stored version by deleting all user-defined versions



Comparison with Similar Blocks

There is no direct comparison to other function blocks. This block is specifically for managing ISOBUS object pools in VT flash memory.

Conclusion

PoolDeleteVersion` provides a standardized and reliable way to delete stored object pool versions from the flash memory of a virtual terminal. Its simple event-driven interface makes it easy to integrate into automation and control applications. Adherence to ISO specifications (version string length, spaces for the last version) makes the block particularly robust for use in agricultural machinery according to ISO 11783.

PoolReload

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `PoolReload` is a service interface block according to ISO 11783-6 (ISOBUS). It enables the reloading or updating of the object pool of a Virtual Terminal (VT) during application runtime. This block is typically used, for example, to switch between different language variants or to dynamically load modified pool files without requiring a system restart.

Interface Structure

Event Inputs

Event	Type	Comment
`INIT`	`EInit`	Service initialization (with parameters `QI` and `poolFileName`)
`REQ`	`Event`	Service request – performs pool reloading (with `QI`)

Event Outputs

Event	Type	Comment
`INITO`	`EInit`	Initialization confirmation (outputs `QO` and `STATUS`)
`CNF`	`Event`	Confirmation – Pool reload complete (outputs `QO`, `STATUS`, and `s16Result`)

Data Inputs

Name	Type	Comment
`QI`	`BOOL`	Quality Input: `TRUE` activates the service
`poolFileName`	`STRING`	Path to the pool file (e.g., `pools/pool_de.iop`)

Data Outputs

Name	Type	Comment
`QO`	`BOOL`	Quality Output: `TRUE`, if the reload was successful
`STATUS`	`STRING`	Service status (e.g., error message or success message)
`s16Result`	`INT`	Return value: `0` = `E_NO_ERR` (success), negative values correspond to error codes

Adapter

No adapters available.

Functionality

This function block encapsulates the ISOBUS function `VTC_PoolReload()`. The process is divided into the following steps:

1. **Initialization (`INIT`)**

- The pool data is loaded from the file specified in `poolFileName`.
- The pool is opened for the configured color depth.

- After successful loading, the function block returns a confirmation message via `INITO`.

1. **Service Execution (`REQ`)**

- This function block calls `IsoVtcPoolUpdate()` to update the pool on the VT.
- Optionally, ID range modes can be applied for pool manipulation.
- Upon completion of the operation, a `CNF` event is triggered, reporting success or failure (via `s16Result`).

Technical Features

- **Standard Compliance**: This function block complies with the ISOBUS standard ISO 11783-6 (Agricultural vehicles – Virtual Terminal).
- **File Path**: By default, the pool file is expected to be located at `pools/pool_de.iop`. However, the path can be configured via the input `poolFileName`.
- **File Path**: By default, the pool file is expected to be located at `pools/pool_de.iop`. However, the path can be configured via the input `poolFileName`. - **Runtime Update**: Unlike a static pool import, this function block allows a dynamic update without requiring an application restart.
- **Error Handling**: The output `s16Result` returns the detailed ISOBUS error code (0 = success, negative values = error).

State Overview

The function block can go through the following basic states:

State	Description
IDLE	Waiting for an INIT event.
INIT_PENDING	Initialization is being performed; upon completion, `INITO` is sent.
READY	Ready for `REQ` after successful initialization.
REQ_PENDING	Pool reloading is in progress; Upon completion, `CNF` is sent.
ERROR	If initialization or reloading fails, an error status is reported, and the function block remains in the error state until it is re-initialized.

Application Scenarios

- **Language Switching**: During runtime, it is possible to switch between different language variants (e.g., German, English) by replacing the pool file.
- **Dynamic Pool Updates**: New screens or symbols can be loaded without restarting the entire VT – useful for firmware updates or field modifications.
- **Last-Minute Changes**: Modified pool files can be quickly loaded during commissioning.

Comparison with Similar Function Blocks

Function Block	Description
PoolLoader`	Loads the pool only at system startup; no reloading at runtime.
PoolActivate`	Switches between already loaded pools, but requires prior loading.
PoolReload`	Combines loading and updating in one step and enables dynamic reloading during runtime.

Conclusion

The `PoolReload` function block is a specialized service interface module for ISOBUS virtual terminals that enables flexible reloading and updating of object pools at runtime. It simplifies language switching, dynamic updates, and facilitates the maintenance of VT applications. Its clear event interface and detailed error feedback make it well-suited for use in agricultural control systems.

2.10.2.5 pgn

ADDRESS

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `ADDRESS` is a global constant block that defines special address constants for use in ISOBUS-based applications. It provides predefined values for source and destination addresses (SA), which are particularly important in ISOBUS communication. This block serves to make the source code more readable and maintainable by replacing magic numbers with meaningful names.

Interface Structure

This block is a `GlobalConstants` block and therefore does not have traditional event or data interfaces. Instead, it defines constants that can be used globally in other function blocks of the `isobus::pgn` package.

Event Inputs

Not present.

Event Outputs

Not present.

Data Inputs

Not present.

Data Outputs

Not present.

Adapters

Not present.

Functionality

The block `ADDRESS` declares two constants:

1. `NULL_A` (Type: `BYTE`, Value: `254`): This constant represents the NULL address (`0xFE`). Messages with this source address (SA) may only be sent by a sender that has a network manager.
2. `GLOBAL_A` (Type: `INT`, Value: `255`): This constant represents the global address (`0xFF`). This address is used exclusively in the Destination Address Field to broadcast a message to all participants in the network.

These constants are inserted into the code at compile time and cannot be changed at runtime.

Technical Features

- **Type Difference:** It is noteworthy that `NULL_A` is declared as `BYTE` and `GLOBAL_A` as `INT`. However, both values are within the representable range of both data types. The use of `INT` for `GLOBAL_A` could indicate future extensibility or compatibility with other parts of the system.
- **Package Assignment:** This block is part of the `isobus::pgn` package, indicating its use in the Parameter Group Number (PGN) communication of the ISOBUS protocol.

State Overview

Since it is a constant block, it has no state machine and no internal states.

Application Scenarios

The `ADDRESS` block is used in ISOBUS applications, for example, in agricultural machinery (tractors, implements). Typical scenarios include:

- **Message Configuration:** These constants are used to populate the source or destination address field when constructing PGN (Parameter Group Number) messages.
- **Network Management:** The `NULL_A` address is used in special network management messages.
- **Broadcast Communication:** The `GLOBAL_A` address is used to send commands or data to all connected devices on the ISOBUS network.

⚖️ Comparison with Similar Function Blocks

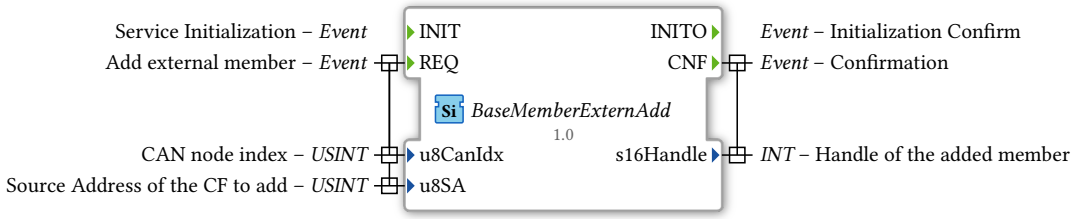
There is no directly equivalent function block in the IEC 61499 standard library, as global constants are a language-specific extension (derived from Structured Text) within the 4diac IDE. A similar purpose could be achieved by:

- **Direct Value Input (Magic Numbers):** Directly writing the values `254` or `255` in the code is possible, but poor practice, as it impairs readability and maintainability.

There is no directly equivalent function block in the IEC 61499 standard library, as global constants are a language-specific extension (derived from Structured Text) within the 4diac IDE. * **Constant Blocks in Other Languages:** In function block programming languages like CFC or SFC, comparable constants are often defined in separate header files or global variable lists.

The advantage of the `ADDRESS` block lies in its centralized, package-bound definition and semantic clarity.

Conclusion



The `ADDRESS` function block is a simple yet essential building block for developing ISOBUS-compliant applications in the 4diac IDE. It improves code quality by replacing special numerical values with self-explanatory identifiers, thus preventing errors and simplifying maintenance. Its use is particularly recommended for implementing network management and broadcast functionalities.

]

BaseMemberExternAdd

Adds an external member to the network list manually. The use of this function is not ISO 11783 Part 5 conform. Use this function only if you must communicate with an external CF, that does not send an address claimed message. An address claimed message from an external CF with the same source address will replace this manual added member entry. The function works independently from the configuration of the #CFG_PARAM_EXTERNAL_ADDR_CLAIM parameter. The added CF will be set to announced in the next iso_DlCyclicGlobal() run.

Interface

Event inputs

Name	Comment	With
INIT	Service Initialization	
REQ	Add external member	u8SA, u8CanIdx

Event Outputs

Name	Comment	With

INITO	Initialization Confirm	
CNF	Confirmation	s16Handle

Input Vars

Name	Type	Initial Value	Comment
u8CanIdx	USINT	NODE1	CAN node index
u8SA	USINT		Source Address of the CF to add

Output Vars

Name	Type	Comment
s16Handle	INT	Handle of the added member

CAN_MSG

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `CAN_MSG` is a structured type definition (struct) for representing a classic CAN message frame (without a transport protocol, TP). It serves as a container for the essential attributes of a CAN message, including priority, payload length, and the actual data buffer. This type is intended for use in function blocks that implement CAN communication in an IEC 61499 system.

Interface Structure

Since `CAN_MSG` is a data type and not a function block, there are no event or adapter interfaces. The structure is defined exclusively by its data members.

Data Inputs

(Not applicable – Data Type)

Data Outputs

(Not applicable – Data Type)

Event Inputs

(Not applicable – Data Type)

Event Outputs

(Not applicable – Data Type)

Adapters

(Not applicable – Data Type)

Functionality

The `CAN_MSG` type is a passive data structure. It encapsulates the information relevant for a CAN message:

1. **Priority (`u8Priority`)**: Defines the arbitration priority on the CAN bus. A lower numerical value corresponds to a higher priority.
2. **Data Length (`u16DaSize`)**: Specifies the actual number of bytes used in the data buffer (0 to 8). 3. **Data Buffer (`data`)**: An 8-byte array that stores the message payload. Unused bytes are initialized with a default value.

This structure can be used as an input or output data type for function blocks that send, receive, process, or log CAN messages.

Technical Features

- **Fixed Buffer Size**: The data array is statically dimensioned to a length of 8 bytes, which corresponds to the maximum payload length of a standard CAN frame.
- **Initialization**: By default, the data array is pre-populated with the hexadecimal value `16#FF` (decimal 255) in all 8 positions. The data length `u16DaSize` defaults to `0`, and the priority `u8Priority` defaults to `7` (lowest priority).
- **Type Safety**: Using a structured type instead of individual variables improves maintainability and clarity in the function block connection view.

State Overview

(Not applicable – the data type has no behavior or state machine.)

Application Scenarios

The `CAN_MSG` type is fundamental for:

- **CAN Sender FBs**: An FB that receives a `CAN_MSG` type as an input and sends its contents as a physical CAN frame to the bus.
- **CAN Receiver FBs**: An FB that packs received CAN frames into a variable of type `CAN_MSG` and forwards them to downstream logic.
- **Message Construction**: FBs that construct a valid `CAN_MSG` structure for later transmission from individual values (e.g., from sensor FBs).
- **Message Filtering/Processing**: FBs that analyze and process incoming `CAN_MSG` structures based on priority, data content, or length.

⚖️ Comparison with similar building blocks

As a data type, `CAN_MSG` is comparable to other structured types in 4diac that represent communication protocols (e.g., `UDP_PACKET`, `MODBUS_MSG`). Its specific characteristic is its close mapping to the hardware properties of the CAN bus protocol (priority, 8-byte limit). Unlike a TP-based message type (e.g., for ISO 11783 or CANopen), it lacks fields for packetization, sequence numbers, or specific protocol headers.

Conclusion

The `CAN_MSG` data type provides an essential and well-structured foundation for implementing CAN bus communication in 4diac-based control systems. By consolidating priority, length, and data into a single type, the handling of CAN messages in function block networks is significantly simplified and standardized. Its use is recommended for all applications requiring direct access to CAN frames.

CF_INFO_T

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `CF_INFO_T` (Control Function Information Type) is a structured data component used within ISO 11783 (ISOBUS) communication. It serves for the standardized representation and management of information about a participant (control function or user) in the ISOBUS network. This type definition summarizes all essential characteristics and states of a network participant in a single data structure.

Interface Structure

CF_INFO_T` is a structured data type and does not have any event or adapter interfaces in the conventional sense of a function block. Its structure consists exclusively of data elements (variables).

Data Inputs

Not present, as it is a pure data type.

Data Outputs

Not present, as it is a pure data type.

Data Elements (Structure)

The internal structure of type `CF_INFO_T` consists of the following elements:

Name	Type	Comment / Description	Initial Value
`s16Handle`	`INT`	Network member handle of the Control Function (CF) / User. Serves as a unique identifier within the application.	`UNVALID`
`u8SourceAddress`	`BYTE`	Source Address (SA) of the Control Function (CF) / User in the ISOBUS network.	`NULL_A`
`u8CanIdx`	`BYTE`	CAN bus node / index of the control function (CF) / user. Identifies the physical bus node.	–
`au8Name`	`isobus::pgn::CF_NAME_T`	The ISOBUS name of the control function. This is a 64-bit unique identifier according to ISO 11783-5.	–
`eIsoUserFunct`	`SINT`	Internally used CF function type (e.g., work device, terminal, task controller).	`undefined`
`bExternalCf`	`BOOL`	Indicates whether it is an external CF in the CAN network (`TRUE`) or not.	–
`bIsAnnounced`	`BOOL`	`TRUE` if the CF is active and fully announced in the network.	–
`bIsActive`	`BOOL`	NIU-specific (Network Interface Unit): `TRUE` if the CF is not in an error state or logged off.	–

Functionality

The data type `CF_INFO_T` is a passive data storage structure. It is used to store the state and identity of an ISOBUS network participant and to exchange this information between different components of a control application. The information it contains is typically read, written, and interpreted by other function blocks responsible for network management (e.g., address assignment, name management) or application logic.

Technical Features

- **Typedef for ISOBUS:** Specifically designed for use in ISO 11783 environments (agricultural machinery).
- **State Flags:** Contains several Boolean flags (`bIsAnnounced`, `bIsActive`) that represent the lifecycle and operating state of a function block.
- **Initial Values:** Critical identifiers such as `s16Handle` and `u8SourceAddress` are initialized with defined constants (`UNVALID`, `NULL_A`) to ensure an invalid output state.
- **Integration:** Uses the user-defined type `isobus::pgn::CF_NAME_T` to map the 64-bit ISOBUS name.

State Overview

Since this is a data type and not an active function block, there is no state machine. The "state" is described by the combination of the included data fields, in particular by the flags:

- **Invalid/Inactive:** `s16Handle == UNVALID`, `bIsAnnounced == FALSE`
- **Valid & Active:** `s16Handle != UNVALID`, `bIsAnnounced == TRUE`, `bIsActive == TRUE`
- **Valid & Faulty/Inactive:** `s16Handle != UNVALID`, `bIsActive == FALSE`

Application Scenarios

- **Participant Management:** In an ISOBUS manager block that manages a list of all known network participants (`CF_INFO_T[]`).

- **Diagnostics and Display:** Forwarding participant information to a diagnostic or display system to show the network status.
- **Command Forwarding:** As a parameter for communication blocks to specifically address messages to a particular CF (identified by `u8SourceAddress` and `au8Name`).
- **Filtering:** Logic blocks can use the fields `eIsoUserFunct` or `bExternalCf` to decide whether messages from a specific CF should be processed.

⚖️ Comparison with Similar Blocks

CF_INFO_Tis not a function block and therefore cannot be directly compared with blocks such asE_SRorE_CYCLE. Within ISOBUS communication, it is comparable to other structured data types that bundle network or device information (e.g., PGN_INFO_T` for Parameter Group Numbers). Its unique feature lies in the specific compilation of data required for the identification and state management of a control function.

Conclusion

The data type `CF_INFO_T` is a fundamental and essential component for implementing ISOBUS-enabled control applications in 4diac. It provides a standardized, type-safe method for grouping and transporting all relevant information about a network participant. Its use increases code reusability and ensures consistency in network communication logic.

]

CF_NAME_T

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `CF_NAME_T` is a structured data type used in the 4diac IDE to model ISO CF (Communication Function) or user information data arrays. It serves as a type definition for a fixed-length byte array and is typically used in the context of ISOBUS PGN (Parameter Group Number) communication.

Interface Structure

CF_NAME_T` is a structured data type (STRUCT) and has no event or adapter interfaces. Its structure consists of a single data field.

Data Inputs

This data type itself has no inputs. It defines the structure for data.

Data Outputs

This data type itself has no outputs. It defines the structure for data.

Structured Elements

- **`data`** (BYTE[0..7]): An array of exactly 8 bytes (`BYTE`). Each element in the array is initialized to the hexadecimal value `16#FF` (decimal 255) by default. This represents a typical “invalid” or “empty” initial state in communication protocols.

Functionality

The data type `CF_NAME_T` encapsulates a byte array with a fixed length of 8 bytes. Its main function is to provide a type-safe and reusable definition for data packets exchanged in ISOBUS-based control systems. The predefined initialization of all bytes to `0xFF` ensures that instances of this type begin in a known, neutral state.

Technical Features

- **Fixed Array Size:** The array is limited to indices 0 through 7, corresponding to a fixed length of 8 bytes. This is a common size for many message blocks in fieldbus systems.

- **Predefined Initialization:** All array elements are automatically initialized with the value `16#FF` when a variable of this type is declared, unless otherwise specified.
- **ISOBUS Context:** This type is part of the `isobus::pgn` package, indicating its specific use in agricultural and mobile machine control systems (ISOBUS, ISO 11783).
-

Application Scenarios

This data type is primarily used to represent the payload of ISOBUS PGN messages within function blocks (FBs). Typical applications include:

- Declaring input or output variables in FBs that send or receive ISOBUS messages.
- Structuring data for communication between different electronic control units (ECUs) in a mobile machine.
- Using it as part of a larger, structured data type that combines multiple parameters of a complex message.

⚖️ Comparison with Similar Blocks

CF_NAME_T` is a data type, not a function block. It can be compared to other structured data types (STRUCT) in 4diac that define arrays. Its distinguishing features are its fixed 8-byte length and its ISOBUS-specific semantics. A generic `ARRAY [0..7] OF BYTE` would be functionally similar, but it lacks the type-safe reusability and contextual reference.

Conclusion

The `CF_NAME_T` data type is a specialized, reusable construct for the 4diac IDE that standardizes and simplifies the handling of 8-byte data blocks in ISOBUS applications. Its fixed size and predefined initialization increase the reliability and readability of application code based on the ISO 11783 standard.

CommunicationPartners

• – ○ • – ○ • – ○ •

Introduction

CommunicationPartners` is a global constant data set used in the context of ISOBUS PGN (Parameter Group Number) communication. It serves to provide a predefined communication partner, in this case the global address, as a constant configuration for other function blocks. This simplifies the configuration of ISOBUS network components by defining frequently used addresses centrally and for reuse.

Interface Structure

Because it is a global constant data set, `CommunicationPartners` does not have event-driven or data-flow-based interfaces in the conventional sense of a function block. Instead, it provides a named, constant variable for the entire application.

Data Inputs

None.

Data Outputs

None.

Event Inputs

None.

Event Outputs

None.

Adapters

None.

Functionality

The data record `CommunicationPartners` declares a global constant named `GLOBAL` of data type `isobus::pgn::CF_INFO_T`. This structure is initialized with a value that sets the field `s16Handle` to the predefined value `GLOBAL_A` from the imported constant `isobus::pgn::ADDRESS::GLOBAL_A`.

During application compilation and execution, this constant is stored in memory and can be referenced by any function block within the project that requires an ISOBUS address of type `CF_INFO_T`. Using this constant ensures that the global address is used consistently and without typos throughout the code.

Technical Details

- **Data Type:** The constant is of type `isobus::pgn::CF_INFO_T`. This is likely a structured (STRUCT) or enumeration (ENUM) type specifically defined for the ISOBUS communication configuration.
- **Initialization:** Initialization occurs directly in the declaration using the structured initialization `(s16Handle := GLOBAL_A)`.
- **Import:** The data record imports an external constant (`GLOBAL_A`) from the package `isobus::pgn::ADDRESS`. This demonstrates a modular architecture where address definitions are maintained centrally.
- – **Compilation:** The `CompilerInfo` tag indicates that this element is part of the `isobus::pgn` package and is relevant for code generation.

State Overview

Since this is a static, constant definition, there is no state machine or mutable state.

Application Scenarios

- **ISOBUS Network Configuration:** Used when a function block needs to send a message to all participants in the ISOBUS network (broadcast). The constant `GLOBAL` represents this broadcast address.
- **Simplifying Parameterization:** In complex applications with many communicating blocks, using `CommunicationPartners.GLOBAL` replaces the repeated, hard-coded entry of the global address, thus increasing maintainability.
- **Reference for other constants:** Can serve as a basis for defining further, more specific communication partner constants (e.g., `IMPLEMENT`, `TOOL`).

⚖️ Comparison with similar building blocks

- **Direct value assignment:** Instead of using `CommunicationPartners.GLOBAL`, a developer could also directly assign the value `GLOBAL_A` to each data input of a function block. However, using the constants is cleaner, more type-safe, and easier to modify.
- **Other address constants:** Within the same package (`isobus::pgn::ADDRESS`), similar constants for other addresses likely exist (e.g., `NULL_A`, `TOOL_A`). `CommunicationPartners` encapsulates a specific selection or combination of these addresses in a context relevant to the application.
- **Parameter FBs vs. Global Constants:** An alternative approach would be a function block that receives its target address as a configurable parameter. Global constants, on the other hand, are simpler and more direct if the value remains unchanged for the entire runtime of the application.

Conclusion

The global constant dataset `CommunicationPartners` is a simple yet useful auxiliary construct for developing ISOBUS-enabled controllers in 4diac. It promotes the principles of "Don't Repeat Yourself" (DRY) and centralized configuration management by defining the frequently used global ISOBUS address in a single, easily visible location. Its use reduces potential sources of error and facilitates future network configuration adjustments.

]

HANDLE

• – ◦ • – ◦ • – ◦ •

Introduction

The `HANDLE` constant is a global constant definition for the 4diac IDE, used in the context of ISOBUS protocol and parameter group number (PGN) processing. It defines special values to identify invalid or global addressing targets within an ISOBUS network. These constants serve as central reference values for function blocks that use handle-based communication.

Interface Structure

This is a global constant definition and therefore does not have event or data interfaces in the conventional sense of a function block. Instead, it provides named constants that can be used in other blocks.

Event Inputs

Not present. This definition does not contain any event inputs.

Event Outputs

Not present. This definition does not contain any event outputs.

Data Inputs

Not present. This definition does not contain any data inputs.

Data Outputs

Not present. This definition does not contain any data outputs.

Adapters

Not present. This definition does not contain any adapter interfaces.

Functionality

The `HANDLE` constant defines two symbolic names for special integer values:

1. `UNVALID`: Represents an invalid or unused handle with the value `-1` (decimal) or `0xFFFF` (hexadecimal). This value can be used to indicate that a handle is not initialized, an operation has failed, or a resource is unavailable.
2. `GLOBAL`: Represents a pseudo-handle with the value `32767` (decimal) or `0x7FFF` (hexadecimal). This value is used to address a global destination (broadcast) within the ISOBUS network, rather than a specific individual device.

These constants are typically used in the data connections or internal logic of other functional blocks (e.g., for ISOBUS communication) to improve code readability and maintainability, rather than using magic numbers directly in the code.

Technical Details

- **Packet Assignment:** The constants are assigned to the `isobus::pgn` package, which clearly defines their use in ISOBUS PGN communication.
- **Typing:** Both constants are of type `INT` (Integer).
- **Initialization:** The values are assigned directly upon declaration (`InitialValue`).
- **Visibility:** As global constants (`GLOBALCONSTANTS`), they are visible and usable within the defined package (`isobus::pgn`) for all function blocks contained within it.

State Overview

Since this is a static constant definition, there is no state machine or mutable state.

Application Scenarios

- **Initializing Handles:** When a system starts, communication handles can be initialized with the value `UNVALID` to indicate their "empty" state.
- **Error Handling:** Function blocks that return handles (e.g., after opening a connection) can return `UNVALID` to indicate an error.
- **Broadcast Communication:** A sender block can use the `GLOBAL` handle to address a message to all participants in the ISOBUS network instead of a specific receiver.
- **Comparisons:** The readability of conditions such as `IF currentHandle = UNVALID THEN ...` or `IF targetHandle = GLOBAL THEN ...` is significantly improved.

⚖️ Comparison with Similar Blocks

- **`CONSTANT` Function Block:** A generic `CONSTANT` block can output a fixed value but is an instance within a function block network. The `HANDLE` global constant is a central, package-wide definition that does not need to be instantiated and is referenced directly by its name.
- **Direct Value Input:** Instead of using `UNVALID` or `GLOBAL`, the numeric values (`-1`, `32767`) could be entered directly into the blocks. However, using the constants is significantly better practice, as it makes the code more self-explanatory and resistant to changes (changes only need to be made in one place).

Conclusion

The `HANDLE` global constant is a simple yet essential tool for developing ISOBUS-compliant applications in 4diac. It improves code quality by assigning meaningful names to two frequently used, special handle values. Using this promotes readable, maintainable, and fault-tolerant code in function blocks that use ISOBUS PGN addressing.

]

ISONETEVENT_T

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `ISONETEVENT_T` is a structured type used to describe a network event within an ISOBUS network. It encapsulates all relevant information needed to identify and process an event related to the management of network participants (control functions). This type is typically used in callback functions to report changes in the network's state.

Interface Structure

The structure `ISONETEVENT_T` consists of the following six elements:

Data Elements

- **`eNetEvent`** (Type: `USINT`, Initial value: `ISO_NETEVENT_e::Isonet_Last`)
- **Description:** Indicates which specific event occurred in the network member management (e.g., connection establishment, termination, address change).
- **`eMemberRefer`** (Type: `SINT`, Initial value: `ISOUSERHOME_e::notdef`)
- **Description:** Identifies which network member is affected by the event. Specifies whether it is the callback owner, another internal, or an external Control Function (CF).
- **`s16OwnCfHnd`** (Type: `INT`)

Description: The CF handle of the entry for which the callback was triggered. This identifies the local representation of the affected network participant.

- **`s16Handle`** (Type: `INT`)

Description: The network member handle of the involved control function or user. This is the handle of the CF that caused the event (Event Source CF Handle).

- **`u8SAMember`** (Type: `USINT`)

Description: The current source address (SA) of the network member at the time of the event.

- – **cfName** (Type: `isobus::pgn::CF_NAME_T`)

Description: The ISOBUS name of the involved control function. This name is a unique identifier according to the ISOBUS standard.

Functionality

The structure `ISONETEVENT_T` functions as a container or message object. When a relevant network event occurs (defined by `eNetEvent`), an instance of this structure is populated with the current data and passed to a registered callback function. The contained data enables the receiving software component to accurately classify the event and identify the affected network entities (`eMemberRefer`, `s16OwnCfHnd`, `s16Handle`), their current address (`u8SAMember`), and their ISOBUS name (`cfName`).

Technical Details

- **Type:** This is a `StructuredType` within the 4diac IDE.
- **Initial Values:** Two elements (`eNetEvent`, `eMemberRefer`) have defined initial values that reference enumerated types (`ISO_NETEVENT_e`, `ISOUSERHOME_e`). This ensures a defined initial state.
- **ISOBUS Integration:** The structure is specifically designed for the ISOBUS context, as evidenced by the use of the type-specific `CF_NAME_T` and the parameter designations (SA, CF).
- **Compiler Package:** The data type is assigned to the package `isobus::pgn`, indicating its association with ISOBUS Parameter Group Number (PGN) processing.
-

Application Scenarios

This data type is primarily used in scenarios where an application needs to be informed about dynamic changes in the ISOBUS network. Examples include:

- Monitoring the appearance or disappearance of electronic control units (ECUs) on the network.
- Responding to address changes of network participants.
- Implementing user-defined logic when establishing or terminating a connection to a specific CF.
- Logging network activity for diagnostic purposes.

⚖️ Comparison with Similar Building Blocks

Within the 4diac type library, various structured data types exist for communication protocols. Unlike generic communication structures (such as those for TCP/IP), `ISONETEVENT_T` is highly specialized for the event messages of the ISOBUS protocol stack, particularly the network management (NM) component. Other ISOBUS-related types might focus more on the exchange of process data (PGN data).

Conclusion

The data type `ISONETEVENT_T` is an essential tool for developing ISOBUS-enabled applications in 4diac that need to react to network events. It provides a standardized, information-rich interface for receiving and processing callback-based event notifications from the ISOBUS network stack. Its use promotes a decoupled and event-driven architecture in the control software.

ISOUSERHOME_e

- – ◦ • – ◦ • – ◦ •

Introduction

The function block `ISOUSERHOME_e` is a **constant definition** (GlobalConstants) and not an executable function block in the traditional sense. It defines an enumeration of integer constants used to describe the network origin or destination of an event or message in an ISOBUS context (ISO 11783). These constants

are typically used in other function blocks to identify the source or receiver of data within a controller network.

Interface Structure

Because it is a constant definition, `ISOUSERHOME_e` does not have event- or dataflow-based interfaces like a standard function block. Instead, it provides named constants.

Event Inputs

Not present.

Event Outputs

Not present.

Data Inputs

Not present.

Data Outputs

Not present.

Adapters

Not present.

Functionality

This block defines four symbolic constants of type `SINT` (short integer):

- `intern` (value: 0): Identifies an internal control function (CF) or an internal user within a device or logical unit.
- `network` (value: 1): Identifies an external CF or an external user on the network.
- `thisMember` (value: 2): Specifies that an event or message is intended for this specific internal CF or user.
- `notdef` (value: −1): Indicates that the value is invalid or undefined.

These constants can be imported and used throughout the application to make code more readable and maintainable, instead of directly using magic numbers (such as 0, 1, 2, −1).

Technical Details

- **Type:** `GlobalConstants` according to IEC 61499-1.
- **Data Range:** The constants are of type `SINT` (8-bit signed integer).
- **Package:** The block is part of the `isobus::pgn` package, indicating its use in the context of ISOBUS Parameter Group Numbers (PGNs).

State Overview

Not applicable, as this is a static constant definition without state machines or behavior.

Application Scenarios

These constants are primarily used in ISOBUS-compliant control systems in agricultural machinery, for example, in tractors and their implements. Typical applications include:

- **Message Filtering:** A receiver block can use the `ISOUSERHOME_e` value to determine whether an incoming ISOBUS message is intended for its own device (`thisMember`), another device on the network (`network`), or for internal processing (`intern`).
- **Message Construction:** A sender block can set this value to identify the intended recipient of a sent message.
- **Status Feedback:** A block can return the status `notdef` if the origin or destination of a message cannot be determined.
- **Message Construction:**

⚖️ Comparison with Similar Building Blocks

- **`E_SR` or `E_RESTART`:** These are executable basic function blocks with event logic. `ISOUSERHOME_e`, on the other hand, is a pure data definition without logic.

- **User-Defined Data Types (DT):** Similar to a structured data type (STRUCT) or an enumeration (ENUM), `ISOUSERHOME_e` is used to encode semantic meaning. The difference lies in the IEC 61499 specification: `GlobalConstants` are intended for immutable values that are valid project-wide.
- **Direct Use of Numeric Values:** Using `ISOUSERHOME_e.intern` in the code is significantly more meaningful and less error-prone than directly using the number `0`.

Conclusion

ISOUSERHOME_e` is an essential auxiliary construct for developing clear and maintainable ISOBUS applications in 4diac. By providing meaningful constant names, it abstracts from the underlying numeric values, thus improving the readability and robustness of the system design. It is a data-level component that supports the communication logic in higher-level function blocks.

]

ISO_CAN_NODE

• – ◦ • – ◦ • – ◦ •

Introduction

The global constant file `ISO_CAN_NODE` defines a set of numeric constants for identifying CAN (Controller Area Network) nodes within a 4diac project. It serves to abstract and standardize node addresses, thereby improving the readability and maintainability of applications that operate with multiple CAN buses.

Interface Structure

This element is a collection of global constants and does not have event- or data-flow-driven interfaces like a function block.

Data Constants

The file defines the following constants of type `USINT` (Unsigned Short Integer):

Name	Type	Initial Value	Comment
`NODE1`	USINT	0	Identifier for CAN 1
`NODE2`	USINT	1	Identifier for CAN 2
`NODE3`	USINT	2	Identifier for CAN 3
`NODE4`	USINT	3	Identifier for CAN 4
`INVALID`	USINT	USINT#16#FF	Identifier for an invalid or unconfigured CAN node (decimal: 255)

Functionality

The constants are inserted into the code at compile time. Instead of using direct numerical values (such as `0` or `1`) in function blocks that control CAN communication, developers can use descriptive names (`NODE1`, `NODE2`, etc.). This makes the code more intuitive and facilitates future modifications, as the actual addresses are managed centrally in one location.

The value `INVALID` (255) represents a reserved value, typically used to indicate an uninitialized, faulty, or non-existent node.

Technical Details

- **Packet Mapping:** The constants are mapped to the package `isobus::pgn`, indicating use in the context of ISOBUS (ISOBUS, agricultural machinery) and Parameter Group Numbers (PGN). * **Data Type:** All

constants are of type `USINT`, which allows a value range from 0 to 255 and is common for CAN node addresses.
- **Hexadecimal Notation:** The value for `INVALID` is defined in hexadecimal notation (`16#FF`), which corresponds to the decimal number 255.

State Overview

Since these are static constants, no state machine exists.

Application Scenarios

- **Multi-CAN Systems:** In controllers that communicate with multiple independent CAN buses (e.g., a main bus and a drive bus) to uniquely address the buses.
- **ISOBUS Applications:** For configuring virtual terminals (VTs), task controllers (TCs), or other devices in an agricultural ISOBUS network.
- **Error Handling:** The constant `INVALID` can be used as a return value or initial value in function blocks to indicate that no valid CAN node has been selected or detected.

⚖️ Comparison with Similar Function Blocks

- **Direct Values:** The alternative approach would be the direct use of numeric literals (0, 1, 2, ...) in the code. Using `ISO_CAN_NODE` is superior to this approach in terms of code quality and maintainability.
- **Enumerations (ENUM):** In some programming languages or function block types, similar constructs could be defined as enumerations. Global constants are a simple and widely used means of implementing this pattern in IEC 61499.

Conclusion

The `ISO_CAN_NODE` constant file is a simple yet valuable tool for the structured development of CAN-based control applications in 4diac. It promotes clean, self-explanatory code and centralizes configuration data, reducing errors and simplifying adjustments. Its use is particularly recommended in projects with multiple CAN nodes or in ISOBUS environments.

]

ISO_NETEVENT_e

• – ◦ • – ◦ • – ◦ •

Introduction

The global constant file `ISO_NETEVENT_e` defines an enumeration of event types for network management in an ISOBUS-compatible system. It provides named, integer constants that represent various state changes and events in the network, such as adding or removing devices or address conflicts. Using these constants improves the readability and maintainability of the source code.

Interface Structure

ISO_NETEVENT_e is a **global constant file** and not a function block. Therefore, it does not have event or data interfaces in the conventional sense. Instead, it provides a collection of constants (VAR_GLOBAL CONSTANT`) that can be used system-wide.

Data Inputs

Not applicable. This resource defines constants, not inputs.

Data Outputs

Not applicable. This resource defines constants, not outputs.

Event Inputs

Not applicable.

Event Outputs

Not applicable.

Adapters

Not applicable.

Functionality

This file declares a set of constants of type `USINT` (Unsigned Short Integer, 8-bit). Each constant is assigned a unique numeric value and a descriptive name. These constants can be imported and used in other function blocks or programs to identify network events or query states, instead of using magic numbers in the code.

Technical Details

- **Type:** All constants are of type `USINT`.
- **Initialization:** Each constant is initialized with a unique value (0 to 9) upon declaration.
- **Conditional Compilation:** The constants `Isonet_HsiActive` and `Isonet_HsiInactive` are marked as conditional constants (originally from C code). Their use may depend on the definition of a preprocessor symbol (`CCI_HSI`).
- **Package Assignment:** The constants are assigned to the package `isobus::pgn`, indicating their use in the context of ISOBUS protocol handling (Parameter Group Number).

State Overview

Not applicable. Constants have no state.

Application Scenarios

These constants are typically used in function blocks that:

1. Implement ISOBUS network management (address claiming, network management). 2. Monitor and respond to network events (e.g., address conflicts).
2. Manage the status of other network participants (controller applications, ECUs).
3. Provide diagnostic or logging functions that record network events.

⚖️ Comparison with similar building blocks

Unlike function blocks (FBs) or basic function blocks (BFBs), a global constant file does not contain any executable logic or algorithms. It is comparable to a header file in C/C++ or a `ENUM` in higher-level programming languages. Its sole purpose is to define immutable values for the entire application.

Conclusion

The `ISO_NETEVENT_e` is an essential resource for the structured development of ISOBUS applications in the 4diac IDE. It standardizes the coding of network management events, promotes code clarity, and reduces errors that can arise from the use of undifferentiated numerical values. Its integration is particularly beneficial for complex, network-based control systems in the agricultural and mobile machinery sectors.

]

NAMEFIELD_T

• – ◦ • – ◦ • – ◦ •

Introduction

The data type `NAMEFIELD_T` represents a structured data component for mapping the ISO 11783 (ISOBUS) NAME field according to Part 5 of the standard and the Implemented Function Module (IFM) conventions. This structured data type serves for the unique identification and addressing of electronic control units

(ECUs) in an ISOBUS network. It combines all parameters required for device identification into a single data structure.

Interface Structure

NAMEFIELD_T` is a structured data type (STRUCT) consisting of ten individual variables. Each variable corresponds to a defined part of the 64-bit NAME field in the ISOBUS protocol.

Data Inputs

(As a structured data type, `NAMEFIELD_T` has no events, only data fields. These are listed here as components of the structure.)

Name	Data Type	Initial Value	Comment
`bSelfConf`	`BOOL`	`TRUE`	Indicates whether it is a self-configurable address ECU.
`bIndGroup`	`BYTE`	`16#FF`	Assigns the NAME to an industry group (range 0-7).
`bDevClassInst`	`BYTE`	`16#FF`	Identifier if a device class occurs multiple times on the network (0..15).
bDevClass`	`BYTE`	`16#FF`	ISO-defined device class (0..127).
bReserved`	`BOOL`	`TRUE`	Reserved bit (not used).
bFunction`	`BYTE`	`16#FF`	ISO-defined function, corresponds to the Source Address (SA) (0..255).
bFunctionInst`	`BYTE`	`16#FF`	Subgroup of a function (0..31).
bEcuInstance`	`BYTE`	`16#FF`	Indicates which control unit is assigned to a specific function (0..7).
wManufCode`	`WORD`	`16#FFFF`	ISO-defined manufacturer code (0..2047).
dwIdentNumb`	`DWORD`	`16#FFFFFFFF`	Unique serial number; used when the NAME is not unique within the same network (0 to 2,097,151).

Data Outputs

(Not applicable, as this is a data-only type.)

Adapters

(Not applicable, as this is a data-only type.)

Functionality

The `NAMEFIELD_T` data type is a passive data structure. Its primary function is the structured storage and transmission of the parameters that together form the 64-bit ISOBUS NAME. Each variable within the structure occupies a specific bit range within this overall field. The initial values (`16#FF`, `16#FFFF`, `16#FFFFFFFF`) typically represent an undefined or unassigned state.

Technical Features

- **Bit-accurate mapping:** The structure directly maps the binary layout of the ISO NAME field, enabling efficient serialization and deserialization for communication via the CAN bus protocol.
- **Initial values:** The selected initial values (maximum values for the respective data types) clearly indicate an uninitialized or placeholder state.
- **ISOBUS compliance:** The naming and division of the fields strictly adhere to the ISO 11783-5 specification and the extended IFM conventions.

State overview

Since this is a data type and not a function block, there is no state machine. The “state” is defined by the specific values of the ten included variables.

Application Scenarios

The data type `NAMEFIELD_T` is primarily used in ISOBUS-compliant control applications, for example, in agricultural and forestry technology or construction machinery.

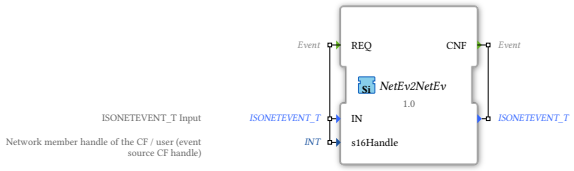
- **Device Identification:** As part of messages (e.g., in the Address Claim process) to identify a participant in the network.
- **Data Storage:** For storing the device's own identity within ECU software.
- **Filtering:** For configuring message filters based on device class, function, or manufacturer.
- **Diagnostics:** For uniquely identifying devices in diagnostic and configuration tools.
-

⚖️ Comparison with Similar Function Blocks

Unlike function blocks (FBs) such as `E_SR` or `E_CYCLE`, `NAMEFIELD_T` is a pure **data type** (structured data type). It contains no algorithms, events, or executed code.

- **Similarity to other STRUCTs:** It is comparable to other structured data types in 4diac (e.g., for complex measured values), but is specifically designed for the ISOBUS protocol.
- **Difference to Basic Data Types:** While basic types such as `INT` or `BOOL` hold individual values, `NAMEFIELD_T` groups several logically related values into a single unit.
-

Conclusion



The data type `NAMEFIELD_T` is an essential tool for developing ISOBUS-compliant control applications with 4diac FORTE. It abstracts the complex bit structure of the ISO NAME field into an easily manageable, strongly typed data structure. This promotes code reusability, improves readability, and reduces errors when handling device identification data. Its use is standards-compliant and recommended for all projects implementing ISOBUS communication.

- 🌐 Eclipse 4diac IDE & color reference on ms-muc-docs.de

]

NetEv2NetEv

• – ○ • – ○ • – ○ •

Introduction

The function block `NetEv2NetEv` is used to manipulate network events (NetEv) within an ISOBUS-based system. Its primary purpose is to take an incoming network event record and overwrite a specific value—the network member handle. The block thus functions as a simple converter or adapter for ISONETEVENT_T data structures.

Interface Structure

Event Inputs

- **REQ**: This event triggers the processing of the function block. It is linked to the data inputs `IN` and `s16Handle`.

Event Outputs

- **CNF**: This event signals the completion of processing. It is triggered after the processing of the `REQ` event and is linked to the (empty) data output that returns the manipulated `ISONETEVENT_T` structure.

Data Inputs

- **IN** (`isobus::pgn::ISONETEVENT_T`): The input for the original network event data structure to be manipulated.
- **s16Handle** (`INT`): The new network member handle to be written to the passed `ISONETEVENT_T` structure. This value identifies the controller/function (CF) or user that serves as the source of the event.

Data Outputs

- **<leer>** (`isobus::pgn::ISONETEVENT_T`): The output returns the manipulated `ISONETEVENT_T` data structure. The output name is empty, and the data type is identical to that of the input `IN`.

Adapters

This function block does not use any adapters.

Operation

The operation of the `NetEv2NetEv` block is deterministic and simple:

1. The function is executed when a `REQ` event occurs.
2. The entire contents of the input data structure `IN` are copied to the output data structure.
3. The entire contents of the input data structure `IN` are copied to the output data structure. 3. The field `.s16Handle` within this copied output structure is then overwritten with the value of the input `s16Handle`.
4. The `CNF` event is triggered to signal the output of the modified data set.

This block only modifies the specified handle field. All other fields of the `ISONETEVENT_T` structure remain unchanged.

Technical Features

- **Data Type**: This block specifically works with the data type `isobus::pgn::ISONETEVENT_T`. The exact structure of this type is defined in the underlying `isobus::pgn` library.
- **Direct Assignment**: The implementation uses a direct assignment in Structured Text (ST). No additional logic, validation, or error handling is performed.
- **Naming Convention**: The data output has no explicit name, which is permitted in 4diac. It is referenced via the `CNF` event.

State Overview

The function block has no internal state or memory. Its behavior is purely combinatorial: On every `REQ` event, the described operation is immediately performed, and a `CNF` event is generated.

Application Scenarios

- **Handle Override in Event Streams**: In networks where events are forwarded between different controllers (CFs), the source handle (`s16Handle`) may need to be adjusted to correctly identify the current sender.
- **Event Proxy/Adapter**: This block can be used as a simple proxy to assign a new source identifier to incoming network events before forwarding them to downstream processing logic.
- **Testing and Simulation**: For simulating network events from various virtual sources (CFs) within a test setup.

⚖️ Comparison with Similar Blocks

- **E_SR (SR Flip-Flop) or E_D_FF (D Flip-Flop)**: These blocks have internal state (memory). `NetEv2NetEv` is stateless and only manipulates incoming data.
- **E_SELECT / E_MUX**: These blocks select between different data sources or pass them through. `NetEv2NetEv` actively modifies a portion of the incoming data.
- **E_R_TRIG / E_F_TRIG**: These are pure event triggers without data manipulation. `NetEv2NetEv` is a data processing block.
- **Generic ASSIGN Blocks**: A simple `ASSIGN` block copies an input value 1:1 to the output. `NetEv2NetEv` is a specialized `ASSIGN` block for the type `ISONETEVENT_T`, which performs a targeted modification (handle override).

🛠️ Related Exercises

- Exercise_128
- Exercise_128b
- Exercise_134

Conclusion

The `NetEv2NetEv` function block is a specialized, lightweight tool for ISOBUS applications. It fulfills a clear and necessary niche task: overriding the source handle in network event records. Its simple, stateless implementation makes it robust and predictable. For developers working with ISOBUS PGNs and network events, it provides a useful tool for correctly identifying and customizing data flows.

NmGetCfInfo

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `NmGetCfInfo` is used within an ISOBUS network to retrieve information about connected communication partners (Connected CFs). It allows both internal and external participants in the network to be identified and their details to be recorded. This block is part of ISOBUS PGN communication and is typically used for network management tasks.

Interface Structure

Event Inputs

- **INIT (Type: EInit)**: Initializes the service. When triggered, the configured data inputs are accepted and the initialization process is started.
- **RSP (Type: Event)**: Acknowledges receipt of an indication (`IND`). This event signals to the module that a previously sent indication has been processed.

Event Outputs

- **INITO (Type: EInit)**: Confirms successful completion of initialization.
- **IND (Type: Event)**: Triggered to forward a received network indication (e.g., detected communication partners) to the application.

Data Inputs

- **u8CanIdx (Type: USINT, Initial Value: ISO_CAN_NODE::INVALID)**: Identifies the CAN node used (CAN controller index).
- **member (Type: SINT, Initial Value: ISOUSERHOME_e::notdef)**: Defines the membership or role of the requesting participant in the network.
- **address (Type: isobus::pgn::NAMEFIELD_T)**: The address of the other network participant for whom information is to be retrieved.
- **mask (Type: isobus::pgn::NAMEFIELD_T)**: A bitmask that specifies which parts of the address should be considered during the search. Only set bits (1) are evaluated.

Data Outputs

- **bwaitingForRSP (Type: BOOL)**: Indicates whether the function block is currently waiting for a response (`RSP`) to a sent indication.
- **sNetEv (Type: isobus::pgn::ISONETEVENT_T)**: Contains details of the network event that occurred (e.g., error or status).

- **sCfInfo (Type: isobus::pgn::CF_INFO_T)**: The retrieved information about the found communication partner (CF = Communication Function).
- **sNameField (Type: isobus::pgn::NAMEFIELD_T)**: The ISOBUS name of the detected communication partner.

Adapter

This function block does not use any adapter interfaces.

Functionality

1. **Initialization**: The block is configured by triggering the `INIT` event. The passed parameters (`u8CanIdx`, `member`, `address`, `mask`) define the context and target of the query. After successful initialization, `INITO` is output.
2. **Query and Indication**: After initialization, the module begins searching for suitable communication partners in the network based on the `address` and `mask` events. If a participant is found, the module triggers the `IND` event and makes the found information available in the data outputs `sCfInfo` and `sNameField`. Simultaneously, `bwaitingForRSP` is set to `TRUE`.
3. **Response Processing**: The higher-level application acknowledges receipt of the indication by sending the `RSP` event. The function block then reverts from `bwaitingForRSP` to `FALSE`. This handshake mechanism ensures secure transmission.

Technical Features

- The function block implements a request-response protocol (`IND`/`RSP`) for reliable communication.
- The use of a bit-based `mask` enables flexible search queries, e.g., for participants of a specific device class.
- The data types (`ISONETEVENT_T`, `CF_INFO_T`, `NAMEFIELD_T`) are specific to ISOBUS PGN communication and contain structured information according to the ISO 11783 standard.
-

Status Overview

1. **Inactive**: Before initialization.
2. **Initialized**: After `INITO`. The function block is ready for operation and can process requests.
3. **Waiting for RSP**: After `IND` is triggered. The function block waits for confirmation (`RSP`) from the application before performing further actions.

Application Scenarios

- **Network Discovery**: When a device starts up, to identify all active participants in the ISOBUS network.
- **Diagnostics and Monitoring**: To monitor whether specific expected control units (e.g., of an implement) are connected and reachable.
- **Dynamic Configuration**: To obtain information about newly added devices and adapt the application accordingly.

⚖️ Comparison with Similar Modules

Unlike simple read or query modules, `NmGetCfInfo` is specifically designed for querying ISOBUS-specific network information. It offers more context (through `member`, `address`, `mask`) and structured result data (`CF_INFO_T`) than a generic communication module. Modules like `E_SWITCH` or `E_DEMUX` only forward events, while `NmGetCfInfo` performs active network communication and protocol handling.

Modules like `E_SWITCH` or `E_DEMUX` only forward events, while `NmGetCfInfo` performs active network communication and protocol execution.

Conclusion

The `NmGetCfInfo` function block is a An essential tool for managing ISOBUS networks, it abstracts the complex protocol communication required to detect network participants into an easy-to-use, event-driven interface. Its ability to search for participants and return detailed information makes it valuable for robust and intelligent agricultural control systems.

NmSetName

• — ○ • — ○ • — ○ •

Introduction

The function block `NmSetName` converts a structured name field definition into a compact, 8-byte ISO NAME according to the ISO 11783-5 specification (section 5.1.2). This block is an essential component for device identification and addressing in ISOBUS networks (agricultural and forestry machinery). It performs the bit-accurate mapping of the individual fields of a `NAMEFIELD_T` structure to the corresponding byte array of a `CF_NAME_T`.

Interface Structure

Event Inputs

- **REQ**: This event triggers the conversion. Upon arrival, the incoming data is processed at input `psNameField`.

Event Outputs

- **CNF**: This event signals the completion of processing. It is generated after the successful conversion of the input data.

Data Inputs

- **psNameField** (`isobus::pgn::NAMEFIELD_T`): The input structure containing all individual components of an ISOBUS name (such as manufacturer code, device class, function instance, etc.) in a format easily manageable for the programmer.

Data Outputs

- **(Unnamed)** (`isobus::pgn::CF_NAME_T`): This output provides the resulting 8-byte ISO NAME array (`data[0]` to `data[7]`), which can be used directly in ISOBUS messages.

Adapters

This function block does not use any adapters.

Functionality

The block operates as a pure data transformer. When triggered by the `REQ` event, it reads the values from the input structure `psNameField` and distributes them bitwise across the eight bytes of the output array according to the ISO standard. The logic consists of a sequential sequence of bitwise operations (AND, OR, SHL) and type conversions. Each line in the ST code sets specific bits in a particular byte of the `CF_NAME_T`

output, while the remaining bits remain unchanged (masked by the `AND` operations). After all bytes are set, the `CNF` event is output.

Technical Features

- **Bitwise Processing:** The core functionality is based on precise bitwise operations to pack the complex structure of the ISO NAME into a compact byte array.
- **Type Safety:** Explicit type conversions (e.g., `DWORD_TO_BYTE`, `WORD_TO_BYTE`) are used to ensure correct data handling.
- **Standard Compliance:** The implementation strictly adheres to the bit mapping as defined in ISO 11783-5.
- **Stateless:** The block has no internal state between calls. The output depends solely on the current input data.

State Overview

The function block is stateless. Its behavior can be described as a simple, deterministic function:

1. **Waiting:** The block waits for the `REQ` event.
2. **Processing:** At `REQ`, the input data is processed and the output array is calculated.
3. **Confirming:** Immediately after the calculation, the `CNF` event is output.

The block then returns directly to the wait state (1).

Application Scenarios

- **Initializing an ISOBUS Node:** When an electronic control unit (ECU) starts up in an ISOBUS network, its unique NAME must be constructed from configurable parameters (e.g., from an NVRAM) and entered into the communication stack.
- **Dynamic Device Configuration:** In systems where device properties (e.g., function instance) can change at runtime, this block is used to generate the new, valid NAME.
- **Test and Simulation Tools:** For generating correct ISO NAMEs for simulating various virtual devices in an ISOBUS network.

⚖️ Comparison with Similar Blocks

- **Counterpart `NmGetName`:** While `NmSetName` packs a structured description into a byte array, a hypothetical `NmGetName` block would perform the reverse operation: It extracts the individual fields from a given ISO NAME byte array and presents them in a `NAMEFIELD_T` structure. `NmSetName` is thus the "encoder," and its counterpart would be the "decoder."
- **Generic Byte Packers:** Unlike generic function blocks that serialize arbitrary data structures, `NmSetName` is specifically optimized for the ISO 11783 NAME structure, thus guaranteeing compliance with the standard without additional configuration.

🛠️ Related Exercises

- Exercise_121

Conclusion

The `NmSetName` function block is a specialized, indispensable component for ISOBUS communication. It abstracts the complex, bit-accurate composition of the ISO NAME according to the standard and provides the user with a simple, structured interface. Its deterministic and stateless operation makes it robust and easy to integrate into control sequences for device initialization and configuration.

NmSetNameField

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `NmSetNameField` converts an ISO NAME, as defined in ISO 11783-5 (section 5.1.2), into a structured representation. An ISO NAME is an 8-byte identifier used in agricultural and forestry machinery (ISOBUS) for the unique identification of electronic control units (ECUs). This function block extracts the individual fields from the byte array and populates a corresponding data structure (`NAMEFIELD_T`). This facilitates further processing and evaluation of the device information in an IEC 61499 application.

Interface Structure

Event Inputs

- **REQ**: Starts processing. Upon receiving this event, the value at `au8IsoName` is processed.

Event Outputs

- **CNF**: Triggered as soon as the conversion is complete and the structured data is available at the output.

Data Inputs

- **au8IsoName** (`isobus::pgn::CF_NAME_T`): An 8-byte array containing the raw ISO NAME according to ISO 11783-5.

Data Outputs

- **(no explicit name)** (`isobus::pgn::NAMEFIELD_T`): The output variable contains the structured breakdown of the ISO NAME. The exact structure of the `NAMEFIELD_T` structure is defined by the `isobus::pgn` library used.

Adapters

This function block does not use any adapters.

Functionality

When the `REQ` event is triggered, the function block processes the incoming byte array `au8IsoName`. The Structured Text (ST) implementation extracts the individual components of the ISO NAME bit- and byte-wise and assigns them to the corresponding fields of the `NAMEFIELD_T` output structure. The logic follows the bit mapping exactly as defined in ISO 11783-5, section 5.1.2. After the calculations are complete, the `CNF` event is set to signal the successful completion of the operation.

Technical Features

- **Bit Manipulation:** This block uses logical AND operations (`AND`), shift operations (`SHL`, `SHR`), and type conversions (`BYTE_TO_WORD`, `BYTE_TO_DWORD`) to isolate the relevant bits from the input array.
- **Library Dependency:** This block depends on the data types `CF_NAME_T` and `NAMEFIELD_T` from the `isobus::pgn` library. The exact definition of these types (e.g., the field names in `NAMEFIELD_T`) is outside this block.
- **Library Dependency:** This block depends on the data types `CF_NAME_T` and `NAMEFIELD_T` from the `isobus::pgn` library. The precise definition of these types (e.g., the field names in `NAMEFIELD_T`) is outside this block.
- – **Deterministic:** The operation is purely data-driven and has no internal state. With the same input, it always produces the same output.

State Overview

The function block has no persistent internal state. It behaves like a pure function:

1. **Wait/Idle State:** The block waits for the `REQ` event.
2. **Processing State:** At `REQ`, the input data is processed and the output structure is calculated. This state is instantaneous (no delay).
3. **Output:** Immediately after the calculation, the `CNF` event is triggered and the calculated `NAMEFIELD_T` structure is output. The block then returns to the wait state.

Application Scenarios

- **ISOBUS Device Identification:** In an ISOBUS network manager that needs to decode incoming NAME data from connected ECUs to identify device type, manufacturer, and instance.
- **Diagnostics and Logging:** For clear display and logging of device names in a human-readable, structured format instead of the raw 8-byte value.
- **Filtering and Addressing:** As a preprocessing step to make decisions about further communication based on specific fields (such as device class or manufacturer code).
- **ISOBUS Device Identification:**

⚖️ Comparison with Similar Components

- **Counterpart `NmGetIsoName`:** A hypothetical complementary component would perform the reverse operation: It would take a `NAMEFIELD_T` structure as input and generate the corresponding 8-byte `CF_NAME_T` array. `NmSetNameField` is the decoder; its counterpart would be the encoder.
- **Generic Byte Parsers:** Unlike generic byte-to-structure converters, this block is specifically tailored to the ISO NAME format and contains the exact bit logic of the standard. Using this specialized block reduces errors and increases maintainability in the ISOBUS context.

Conclusion

The `NmSetNameField` function block is an essential tool for working with ISOBUS networks in 4diac. It abstracts the complex bit manipulation required to interpret the ISO NAME and provides the information in an easily processed, structured format. Its use promotes correct, standards-compliant applications and significantly improves the readability of the source code.

PgnDef

• – ◦ • – ◦ • – ◦ •

Introduction

PgnDef` is a collection of global constants for the 4diac IDE that defines Parameter Group Numbers (PGNs) for ISOBUS and NMEA 2000 communication protocols. These constants represent numeric identifiers for specific message types used in agricultural and maritime vehicle networking. The collection serves as a central reference library for accessing standardized PGNs in IEC 61499 applications, thus improving code readability and maintainability.

Interface Structure

PgnDefis `aGlobalConstants` element and therefore does not have event- or data-flow-based interfaces in the conventional sense of a function block. Instead, it provides a collection of constants that can be declared and used in other function blocks or programs.

Event Inputs

Not present. This is a constant definition.

Event Outputs

Data Inputs

Data Outputs

Adapters

How it Works

PgnDefitself has no executable logic. It simply defines an extensive list of constants of the data typeUDINT (Unsigned Double Integer). Each constant is a PGN value initialized in hexadecimal notation (UDINT#16#XXXX) and contains a human-readable comment with the PGN name and often a reference to the corresponding standard (e.g., ISO 11783-7). Other function blocks can import these constants via their fully qualified names (e.g., isobus::pgn::PGN_HEARTBEAT`) and use them in their logic to identify or generate messages.

Technical Features

- **Extensive Coverage:** The collection contains PGNs from a variety of standards, including ISO 11783 (ISOBUS, Parts 3-7, 12, 13), SAE J1939 (71, 73, 75), and NMEA 2000.
- **Organized Structure:** The constants are commented in logical groups (PDU1/Group Functions, PDU2, J1939-71, ISO 11783-7, Diagnostics (J1939-73), Generator Sets (J1939-75), NMEA).
- **Data Type:** All PGNs are defined as `UDINT` (32-bit, unsigned), which corresponds to the addressable range of the protocols.
- **Package Assignment:** The constants are assigned to the package `isobus::pgn`, which ensures clear namespace separation.

State Overview

Not applicable, as this is a static constant declaration.

Application Scenarios

- **ISOBUS ECU Development:** For developing electronic control units (ECUs) for tractors or implements that communicate via an ISOBUS network.
- **NMEA 2000 Integration:** In maritime applications for integrating ship electronics such as GPS receivers, depth sounders, or engine controls.
- **Protocol Implementation:** As a basis for implementing protocol stacks (e.g., for transport protocols such as TP/CM or ETP/CM).
- **Message Filtering:** In gateway or bridge function blocks to filter and forward incoming messages based on their PGN.
- **Diagnostic Tools:** In applications for diagnosing and monitoring vehicle networks, to correctly name and display received messages.

⚖️ Comparison with Similar Blocks

- **Simple `VAR_GLOBAL CONSTANT` Declarations:** `PgnDef` offers the advantages of centralization, reusability, and avoidance of redundancy and typos compared to constants declared manually in the function block.
- **Enumerations (ENUM):** While ENUMs in IEC 61499 can be used for ordered lists, `PgnDef` is better suited as a collection of discrete, not necessarily consecutive, values. Constants also offer more flexibility in value assignment (hexadecimal).
- **Specific Protocol Function Blocks:** Unlike function blocks that implement a specific protocol function (e.g., a `ADDRESS_CLAIM` function block), `PgnDef` is purely a reference tool and contains no active logic.

Conclusion

The `PgnDef` constant collection is an essential tool for developing IEC 61499-based applications in the domains of mobile machinery (ISOBUS) and marine electronics (NMEA 2000). It promotes standardization, improves code quality through enhanced readability, and reduces errors through the use of centrally defined and tested values. For any developer working with these protocols in 4diac, `PgnDef` is a valuable and likely indispensable resource.

USERFUNC_e

• – ◦ • – ◦ • – ◦ •

The global constant `USERFUNC_e` defines an enumeration of numeric values that represent specific device functions or roles within an ISOBUS network. It serves for the standardized and readable identification of various ISOBUS device types and functions in control applications. USERFUNC_eis a collection of global constants and not a function block. Therefore, there are no event or data interfaces in the conventional sense. The structure consists exclusively of named constants of typeSINT` (short integer).

Not applicable. This resource provides constants and has no inputs.

Not applicable. The constants are referenced directly in the application code.

Data Outputs

Data Inputs

Interface Structure

Introduction

Adapters

Not applicable.

Functionality

USERFUNC_eis a collection of predefined constant values. Each name (e.g.,task_controller) is associated with a fixed numeric value (e.g., 1`). These constants can be used throughout the application to identify device roles, perform comparisons, or set parameters, significantly improving code maintainability and readability compared to directly using "magic numbers."

- **Data Type:** All constants are of type `SINT` (8-bit signed integer).
- **Range:** The defined values range from `-1` (`undefined`) to 21.
- **ISOBUS Compliance:** The designations and values are based on the device functions defined in the ISOBUS standard (ISO 11783).
- **Special Values:**
- `undefined` (-1): Indicates an undefined or unknown function.
- `all_clients` (20) & `all_server` (21): Values for broadcast or group addressing.

Not applicable. Constants have no state.

- **Device Identification:** In a task controller, `IF device_function = USERFUNC_e.virtual_terminal THEN ...` can be used to check whether a connection to a terminal exists.
- **Message Filtering:** Filtering of ISOBUS messages (PGNs) based on the source or destination device function.
- **Configuration:** Parameterization of network services that should only be available for specific device roles (e.g., `file_server`).
- **Diagnostics:** Readable output of device roles in diagnostic logs or on user interfaces.

Unlike function blocks that contain active logic, `USERFUNC_e` is a passive data type/constant definition. It is comparable to a `ENUM` data type in higher-level programming languages or a `CONSTANT` section in Structured Text (ST). Its primary purpose is to provide semantically meaningful names for numeric values used in the ISOBUS context.

The global constant `USERFUNC_e` is an essential tool for developing readable and maintainable ISOBUS applications in 4diac. It abstracts the raw, standard-defined numeric values for device functions into

meaningful identifiers, thus significantly contributing to error prevention and improved code quality. Its use is recommended for all projects that work with ISOBUS device communication.

Const

Global_NAME_Functions

• – ◦ • – ◦ • – ◦ •

Introduction

`Global_NAME_Functions` is a global constant group (GlobalConstants) used within 4diac-IDE applications that interface with ISOBUS (ISO 11783) / SAE J1939 networks. It provides a set of named, industry non-specific constants that represent the **Function** attribute of the **NAME** parameter group (J1939-21 / ISO 11783-7). Each byte value uniquely identifies the functional role of an electronic control unit (ECU) within a vehicle or machine network.

The constants act as a uniform vocabulary for classifying ECUs, allowing control logic to interpret NAME messages and to generate consistent, standards-compliant identifiers. The group is compiled into the `isobus::pgn::const` package and can be referenced throughout 4diac-IDE applications.

Interface Structure

This element is a **GlobalConstants** block, not a function block, adapter, or subapplication. It exposes no runtime inputs, outputs, events, or adapters. Instead, it provides a collection of global constants that applications can read symbolically.

Event Inputs

None – a global constant group has no event inputs.

Event Outputs

None – a global constant group has no event outputs.

Data Inputs

None – all entries are constants (`VAR_GLOBAL CONSTANT`) and are not modifiable at runtime.

Data Outputs

The following BYTE constants are defined. Values follow the SAE J1939 / ISO 11783 NAME function code assignment and may be used wherever an ECU function identifier is required.

Constant	Value	Description
`F_ENGINE`	0	Engine – typically the mechanical power source / engine management system.
`F_AUX_POWER_UNIT`	1	Auxiliary Power Unit (APU) – power source for operating systems without the prime drive engine.

F_ELEC_PROPULSION_CONTROL	2	Electric Propulsion Control – control system for electrically powered drive mechanisms.
F_TRANSMISSION	3	Transmission – alters speed vs. torque output of the engine.
F_BATTERY_PACK_MONITOR	4	Battery Pack Monitor – monitors charge, temperature, and power remaining.
F_SHIFT_CONTROL_CONSOLE	5	Shift Control/Console – determines and transmits desired gear, range, and operating mode.
F_POWER_TAKEOFF_MAIN_OR_REAR	6	Power Take-Off (Main/Rear) – controls mechanical power for auxiliary items.
F_AXLE_STEERING	7	Axle Steering – adjusts attack angle as a function of steering.
F_AXLE_DRIVE	8	Axle Drive.
F_BRAKES_SYSTEMCONTROL	9	Brakes System Controller – electronically controls the service braking system.
F_BRAKES_STEER_AXLE	10	Brakes Steer Axle – actuates service brakes on a steered axle.
F_BRAKES_DRIVE_AXLE	11	Brakes Drive Axle – actuates service brakes on a drive axle.
F_RETARDER_ENGINE	12	Retarder Engine – controls engine retarder capabilities.
F_RETARDER_DRIVELINE	13	Retarder Driveline – controls driveline retarder capabilities.
F_CRUISE_CONTROL	14	Cruise Control – maintains vehicle speed at a fixed operator-selectable value.
F_FUEL_SYSTEM	15	Fuel System – controls fuel flow from tank to engine and back.
F_STEERING_CONTROL	16	Steering Controller – controls steering in steer-by-wire systems.
F_SUSPENSION_STEER_AXLE	17	Suspension Steer Axle – control system for a steered axle suspension.
F_SUSPENSION_DRIVE_AXLE	18	Suspension Drive Axle – control system for a driven axle suspension.
F_INSTRUMENT_CLUSTER	19	Instrument Cluster – gauge display mounted in the cab.
F_TRIP_RECORDER	20	Trip Recorder – accumulates data versus travel.
F_CAB_CLIMATE_CONTROL	21	Cab Climate Control – controls climate within the cab.
F_AERODYNAMIC_CONTROL	22	Aerodynamic Control – modifies drag by altering body panels.
F_VEHICLE_NAVIGATION	23	Vehicle Navigation – physical location and driving instructions.

F_VEHICLE_SECURITY	24	Vehicle Security – compares operator-provided data sequences against references.
F_NETWORK_INTERCONNECT_UNIT	25	Network Interconnect ECU – connects different network segments (bridge/gateway).
F_BODY_CONTROLLER	26	Body Controller – handles suspension control for body sections and body components.
F_POWER_TAKEOFF_SECONDARY_OR_FRONT	27	Power Take-Off (Secondary/Front) – controls mechanical power for auxiliary items.
F_OFF_VEHICLE_GATEWAY	28	Off Vehicle Gateway – connects vehicle network(s) to off-vehicle systems.
F_VTERMINAL	29	Virtual Terminal (in cab) – general purpose ISOBUS display.
F_MANAGEMENT_COMPUTER	30	Management Computer – manages vehicle systems such as the powertrain.
F_PROPULSION_BATTERY_CHARGER	31	Propulsion Battery Charger – charges propulsion batteries from an off-board source.
F_HEADWAY_CONTROLLER	32	Headway Controller – forward-looking collision avoidance/warning and speed matching.
F_SYSTEM_MONITOR	33	System Monitor.
F_HYDRAULIC_PUMP_CONTROLLER	34	Hydraulic Pump Controller – provides hydraulic power for installed equipment.
F_SUSPENSION_SYSTEM_CONTROLLER	35	Suspension System Controller – coordinates overall vehicle suspension.
F_PNEUMATIC_SYSTEM_CONTROLLER	36	Pneumatic System Controller.
F_CAB_CONTROLLER	37	Cab Controller – groups cab-located vehicle functions.
F_TIRE_PRESSURE_CONTROL	38	Tire Pressure Control – centralised tire inflation.
F_IGNITION_CONTROL_MODULE	39	Ignition Control Module – alters engine ignition.
F_SEAT_CONTROL	40	Seat Control – controls operator/passenger seats.
F_LIGHTING_OPERATOR_CONTROLS	41	Lighting Operator Controls – transmits operator lighting control messages.
F_WATER_PUMP_CONTROL	42	Water Pump Control – controls a vehicle-mounted water pump.
F_TRANSMISSION_DISPLAY	43	Transmission Display – displays transmission information (e.g., gear).
F_EXHAUST_EMISSION_CONTROL	44	Exhaust Emission Control.
F_VEHICLE_DYNAMIC_STABILITY_CONTROL	45	Vehicle Dynamic Stability Control.
F_OIL_SENSOR_UNIT	46	Oil Sensor Unit.
F_INFORMATION_SYSTEM_CONTROLLER	47	Information System Controller – manages vehicle application information.

F_RAMP_CONTROL	48	Ramp Control – loading/unloading (chairlift, ramps, lifts, tailgates).
F_CLUTCH_CONVERTER_CONTROL	49	Clutch/Converter Control – handles torque converter lock-up.
F_AUXILIARY_HEATER	50	Auxiliary Heater – heating without the prime drive engine.
F_FORWARD_LOOKING_COLLISION_WARNING_SYSTEM	51	Forward-Looking Collision Warning System – detects and warns of impending collisions.
F_CHASSIS_CONTROLLER	52	Chassis Controller – controls chassis components.
F_ALTERNATOR_CHARGING_SYSTEM	53	Alternator/Charging System – primary on-board charging controller.
F_COMMUNICATIONS_UNIT_CELLULAR	54	Communications Unit, Cellular – communicates via the cellular telephone system.
F_COMMUNICATIONS_UNIT_SATELLITE	55	Communications Unit, Satellite – communicates via a satellite system.
F_COMMUNICATIONS_UNIT_RADIO	56	Communications Unit, Radio – communicates via terrestrial point-to-point.
F_AUXILIARY_DEVICE	57	Steering Column Unit – gathers operator inputs from steering column switches/levers.
F_FAN_DRIVE_CONTROL	58	Fan Drive Control – controls the main engine cooling fan.
F_STARTER	59	Starter – initiates rotation of a stopped engine.
F_CAB_DISPLAY	60	Cab Display – elaborate in-cab display (greater than 30 ASCII characters).
F_FILESERVER	61	File Server / Printer – printing or file storage unit on the network.
F_ON_BOARD_DIAGNOSTIC_UNIT	62	On-Board Diagnostic Unit – permanently mounted diagnostic tool.
F_ENGINE_VALVE_CONTROLLER	63	Engine Valve Controller – manipulates engine intake/exhaust valve actuation.
F_ENDURANCE_BRAKING	64	Endurance Braking – all devices enabling low-wear speed reduction on long descents.
F_GAS_FLOW_MEASUREMENT	65	Gas Flow Measurement – provides gas flow rate and associated parameter measurements.
F_I_O_CONTROLLER	66	I/O Controller – reports and/or controls external input/output channels.
F_ELECTRICAL_SYSTEM_CONTROLLER	67	Electrical System Controller – includes load centers, fuseboxes, power distribution.
F_AFTERTREATMENT_SYSTEM_GAS_MEASUREMENT	68	Aftertreatment System Gas Measurement – measures gas properties (e.g., NOx, oxygen).
F_ENGINE_EMISSION_AFTERTREATMENT_SYSTEM	69	Engine Emission Aftertreatment System.
F_AUXILIARY_REGENERATION_DEVICE	70	Auxiliary Regeneration Device – used as part of an aftertreatment system.

F_TRANSFER_CASE_CONTROL	71	Transfer Case Control – selects number of drive wheels (e.g., 2WD/4WD).
F_COOLANT_VALVE_CONTROLLER	72	Coolant Valve Controller – controls coolant flow for thermal management.
F_ROLLOVER_DETECTION_CONTROL	73	Rollover Detection Control – detects vehicle rollover.
F_LUBRICATION_SYSTEM	74	Lubrication System – pumps lubricant to machine/vehicle joints.
F_SUPPLEMENTAL_FAN	75	Supplemental Fan – additional cooling fan beyond the primary fan.
F_TEMPERATURE_SENSOR	76	Temperature Sensor – devices which measure temperature.
F_FUEL_PROPERTIES_SENSOR	77	Fuel Properties Sensor – measures fuel properties.
F_FIRE_SUPPRESSION_SYSTEM	78	Fire Suppression System.
F_POWER_SYSTEMS_MANAGER	79	Power Systems Manager – manages power output of one or more power systems.
F_ELECTRIC_POWERTRAIN	80	Electric Powertrain – controls and coordinates an electric drive system.
F_HYDRAULIC_POWERTRAIN	81	Hydraulic Powertrain – controls and coordinates a hydraulic drive system.
F_FILE_SERVER	82	File Server – file storage unit on the network.
F_PRINTER	83	Printer – printing unit on the network.
F_START_AID_DEVICE	84	Start Aid Device – controls hardware (glow plug, grid heater) assisting engine start.
F_ENGINE_INJECTION_CONTROL_MODULE	85	Engine Injection Control Module – direct or port injection of fuel.
F_EV_COMMUNICATION_CONTROLLER	86	EV Communication Controller – manages connection to an external power source (EVSE).
F_DRIVER_IMPAIRMENT_DEVICE	87	Driver Impairment Device – prevents vehicle start due to driver impairment (e.g., alcohol interlock).
F_ELECTRIC_POWER_CONVERTER	88	Electric Power Converter – inverter/converter transforming AC/DC power.
F_SUPPLY_EQUIPMENT_COMMUNICATION_CONTROLLER_SECC	89	Supply Equipment Communication Controller (SECC) – part of an EV charging station.
F_VEHICLE_ADAPTER_COMMUNICATION_CONTROLLER_VACC	90	Vehicle Adapter Communication Controller (VACC) – controller inside the adapter between EVSE connector and vehicle inlet.
F_ACCESSORY_ELECTRIC_MOTOR_CONTROLLER	91	Accessory Electric Motor Controller – operates and monitors electrified accessories.
F_CURRENT_SENSOR	92	Current Sensor – measures electrical current.

F_FUEL_CELL_SYSTEM	93	Fuel Cell System – converts fuel (e.g., hydrogen) to electricity.
F_AUXILIARY_DISPLAY	94	Auxiliary Display – display inside/outside the cab, separate from Cab Display.
F_NOT_AVAILABLE	255	Not-available function; placeholder for all undefined functions.

Adapters

None – a global constant group does not provide adapter interfaces.

Functionality

The `Global_NAME_Functions` constants represent the **Function** field of the NAME parameter group used in J1939-21 / ISO 11783-7. Each ECU on an ISOBUS network announces its role through the NAME, and the Function code disambiguates which of the many possible vehicle/machine subsystems the node implements.

For 4diac-IDE applications, these constants are used primarily in two ways:

- **Decoding** incoming NAME messages to identify the functional role of remote ECUs, enabling role-based routing, diagnostics, or coordination logic.
- **Encoding** a local ECU's Function code when constructing a NAME message, ensuring the node appears with the correct classification on the network.

The values follow the industry-standard, non-specific function list and are kept as plain `BYTE` constants so they can be directly embedded in parameter groups (e.g., within the NAME 8-byte data structure).

Technical Features

- **Data Type:** All constants are of type `BYTE` (8-bit unsigned integer).
- **Range:** Values 0 to 94 are assigned to specific functions; value 255 is used as the "not available" placeholder. Values 95 to 254 are not defined within this group.
- **Declaration:** Entries are declared as `VAR_GLOBAL CONSTANT`, making them read-only and globally accessible within the project.
- **Packaging:** The constants are compiled into the `isobus::pgn::const` package, allowing include/reference from other 4diac-IDE artifacts.
- **Compliance:** The mapping matches the industry non-specific function definitions of ISOBUS/J1939, which is referenced as the "other" category in the ISO 11783 standard (distinct from industry-specific groups, e.g., agricultural or construction).
- **Standard Reference:** The definitions align with the NAME Function assignment list published at isobus.net (function/name index).

State Overview

Not applicable. `Global_NAME_Functions` is a pure constant group and does not contain state machines, internal variables, or runtime-modifiable data. Its values are fixed at compile time and remain constant during application execution.

Application Scenarios

- **ECU Role Identification:** In an ISOBUS master/slave controller, read an incoming NAME message and compare its Function byte against constants such as `F_ENGINE` or `F_CRUISE_CONTROL` to determine which type of device is present and how to interact with it.
- **NAME Construction:** When building a NAME parameter group for a local node (e.g., a general-purpose display, a hydraulics controller, or an auxiliary power unit), assign the corresponding constant to the Function field for standards-compliant network participation.
- **Diagnostic & Monitoring Tools:** Display meaningful textual descriptions of remote ECUs based on their function code, enabling service tools to show a human-readable role for each address on the bus.
- **Function-Specific Logic:** Implement distributed logic that adapts behavior based on the function of a counterpart, for example, coupling a headway controller with a brake system controller.
- **Placeholder & Unassigned Handling:** Use `F_NOT_AVAILABLE` as a safe default for nodes that do not (yet) claim a specific function, or for masking undefined codes in protocol stacks.

Comparison with Similar Blocks

Within the ISOBUS/J1939 NAME specification, the Function field is only one of several attributes that together form the unique NAME of an ECU/component. Other global constant groups typically cover:

Attribute	Purpose	Example Values
Function (this group)	Identifies the subsystem role of the node	Engine, Transmission, Brakes, Display
ECU Instance	Differentiates multiple ECUs with the same function	0, 1, 2…
Industry Group	Classifies the application domain (non-specific, agriculture, construction, etc.)	Global, Agricultural, Construction/Mining
Vehicle System	Identifies the particular vehicle system instance	Powertrain, Chassis, Cab
Arbitrary Address Capable	Indicates if the unit supports arbitrary address claiming	yes/no

While the Function group is “industry non-specific”, other constant groups assign values for specific industry-related functions (e.g., agricultural implements). The distinction is important when building networks that must interoperate across standards: the non-specific codes guarantee a common baseline, whereas industry-specific codes extend the set for a vertical domain.

Conclusion

`Global_NAME_Functions` provides a complete, standards-aligned set of BYTE constants for the Function attribute of ISOBUS/J1939 NAME messages. By centralizing these codes in a global, read-only constant group, 4diac-IDE applications can reliably decode and encode the functional role of ECUs without scattering magic numbers through the control logic. Its coverage of 95 defined values plus the `F_NOT_AVAILABLE` placeholder makes it suitable for a wide range of vehicle and machinery automation tasks, from engine and transmission control to EV charging communication and auxiliary displays.

IG0_Device_Classes

• – ◦ • – ◦ • – ◦ •

Introduction

This global constants block defines industry group 0 specific device classes for vehicle systems, according to ISO 11783 (ISOBUS) PGN constants. It provides two standard constants to identify device classes for non-specific systems and unavailable systems.

Interface Structure

This element is a global constants definition, not a function block; therefore, it has no event or data inputs/outputs or adapters.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The constants provide standard values for device class identification in vehicle systems. They are used to indicate that a device class is non-specific (value 0) or not available (value 127). These constants are intended to be referenced in other parts of the system to avoid magic numbers and ensure consistency.

Technical Features

- **Data Type:** BYTE (8-bit unsigned integer)
- **Constants:**
  - `DC_NON_SPECIFIC_SYSTEM` = 0
  - `DC_NOT_AVAILABLE` = 127
- Defined as global constants, accessible across the project.
- Part of the `isobus::pgn::const` package.

State Overview

Not applicable; constants do not have states.

Application Scenarios

- Use `DC_NON_SPECIFIC_SYSTEM` to indicate that a device class is not specifically defined or is a generic system.
- Use `DC_NOT_AVAILABLE` to indicate that the device class information is not available or unknown.
- These constants can be used in PGN (Parameter Group Number) processing for ISOBUS compliant devices.

Comparison with Similar Blocks

This is a constants definition; typical alternatives might be direct literals, but using named constants improves maintainability and readability. Similar constants may exist for other industry groups; this one focuses on vehicle systems.

Conclusion

`IG0_Device_Classes` provides a standardized set of device class constants for ISOBUS vehicle systems, ensuring consistent and self-documenting code.

IG1_Device_Classes

• – ◦ • – ◦ • – ◦ •

Introduction

The `IG1_Device_Classes` is a global constants definition used in the 4diac IDE environment, specifically designed for Industry Group 1 (IG1) of ISO 11783 (ISOBUS) applications. It provides a set of predefined, application-independent device class identifiers that represent different types of vehicle systems within the agricultural and forestry domain. These constants allow consistent referencing of device classes throughout a project, enhancing code readability and maintainability.

Interface Structure

This element is not a function block (FB) or adapter, but rather a global constants container. Consequently, it does not expose event inputs, event outputs, data inputs, data outputs, or adapters in the conventional sense. The information it provides is a set of constant values that can be used globally within the application.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None (the constants are accessible as global read-only values, not as classical block outputs).

Adapters

None.

Functionality

The global constants defined here correspond to the device class byte values used in ISOBUS Parameter Group Numbers (PGNs) to indicate the type of vehicle system. They cover the most common categories as specified by the Industry Group 1 standard:

Constant Name	Value (BYTE)	Description
`DC_NON_SPECIFIC_SYSTEM`	0	Device Class / Vehicle System: Non-specific System
`DC_TRACTOR`	1	Device Class / Vehicle System: Tractor
`DC_TRAILER`	2	Device Class / Vehicle System: Trailer
`DC_NOT_AVAILABLE`	127	Device Class / Vehicle System: Not Available

These constants are intended to be used wherever a device class needs to be compared or set, ensuring that the same numeric values are always referenced by meaningful symbolic names.

Technical Features

- **Data Type:** All constants are of type `BYTE` (8-bit unsigned integer), matching the ISOBUS device class encoding.
- **Initial Values:** Each constant is assigned a fixed initial value that cannot be changed at runtime.
- **Global Scope:** The constants are declared as `VAR_GLOBAL CONSTANT`, making them accessible from any function block or sub-application within the project.
- **Standard Compliance:** The values follow the ISOBUS 11783 standard, specifically the Industry Group 1 device class assignments.
- **Namespace Organisation:** The associated `CompilerInfo` indicates that the constants belong to the `isobus::pgn::const` package, providing a clear logical grouping.

State Overview

Not applicable – this element does not contain any internal state or runtime behaviour. It is a static definition.

Application Scenarios

- **ISOBUS Communication:** When implementing ISOBUS communication stacks or interacting with electronic control units (ECUs), the device class is often embedded in a PGN. These constants can be used to set or decode the device class field.
- **Fleet Management:** In applications that differentiate between tractors, trailers, or other implements, these constants allow clear, error-free classification.
- **Configuration Tools:** Software tools that configure vehicle systems can utilise these constants to present user-friendly names instead of raw numeric values.
- **Testing and Simulation:** During simulation of ISOBUS messages, the constants help generate realistic data without hard-coding magic numbers.

Comparison with Similar Blocks

Other global constant definitions exist for other Industry Groups (e.g., `IG0_Device_Classes`, `IG2_Device_Classes`), each containing a different set of device classes. In contrast, this set is specific to Industry Group 1, focusing on tractors, trailers, and non-specific systems. There are also byte-enumeration type definitions (e.g., enum data types in ST) that could serve a similar purpose, but global constants are simpler and require no additional data types. When compared to hard-coded literals, using these constants significantly improves code maintainability and reduces mistakes.

Conclusion

`IG1_Device_Classes` provides a compact and standardised set of global constants for representing ISOBUS Industry Group 1 device classes. Even though it is not a function block, it plays a vital role in the development of ISOBUS-based applications by promoting code readability, consistency, and compliance with international standards. Its simplicity and global availability make it an indispensable building block for any project involving tractor, trailer, or other non-specific agricultural vehicle systems.

IG1_NAME_Functions

• – ◦ • – ◦ • – ◦ •

Introduction

The `IG1_NAME_Functions` global constant definition belongs to the ISO 11783 (ISOBUS) protocol stack and provides a standardized set of byte-valued constants for identifying **Industry Group 1 (IG1)** specific function types within a vehicle's electronic control unit (ECU) network. This constant set is used to populate the Function field of the ISO 11783 NAME parameter, enabling unambiguous identification of the role each ECU plays on the bus.

The constants are organized according to the three device classes within Industry Group 1: non-specific systems, tractors, and trailers. Each constant maps a semantic function name to a numeric code that can be transmitted and interpreted across the bus network.

Interface Structure

Note: This artifact is a global constants definition, not a function block, adapter, or subapplication. Therefore, it does not expose event or data ports. The "interface" represents the set of named constant values that can be referenced globally by IEC 61499 applications.

Event Inputs

None. The `IG1_NAME_Functions` constant group defines data values only and does not provide any event inputs.

Event Outputs

None. There are no event outputs defined in this constant group.

Data Inputs

None. The constants are static and read-only at runtime; they cannot be modified via data inputs.

Data Outputs

The following global constants are made available to IEC 61499 applications for reference:

System Group	Constant Name	Type	Value	Description
Non-specific System	`F_TACHOGRAPH`	BYTE	128	Non-specific system, function: Tachograph
Non-specific System	`F_DOOR_CONTROLLER`	BYTE	129	Non-specific system, function: Door Controller
Non-specific System	`F_ARTICULATION_TURNTABLE_CONTROL`	BYTE	130	Non-specific system, function: Articulation Turntable Control – controls the articulation turntable for joined-body buses
Non-specific System	`F_BODY_TO_VEHICLE_INTERFACE_CONTROL`	BYTE	131	Non-specific system, function: Body-to-Vehicle Interface Control – manages interaction between vehicle functions and body functions
Non-specific System	`F_SLOPE_SENSOR`	BYTE	132	Non-specific system, function: Slope Sensor – measures a slope along an axis
Non-specific System	`F_RETARDER_DISPLAY`	BYTE	134	Non-specific system, function: Retarder Display – shows retarder information

				(driveline, exhaust, or engine)
Non-specific System	F_DIFFERENTIAL_LOCK_CONTROLLER	BYTE	135	Non-specific system, function: Differential Lock Controller
Non-specific System	F_LOW_VOLTAGE_DISCONNECT	BYTE	136	Non-specific system, function: Low-Voltage Disconnect – monitors starting battery voltage and disconnects auxiliary loads
Non-specific System	F_ROADWAY_INFORMATION	BYTE	137	Non-specific system, function: Roadway Information – provides information about the roadway in which the vehicle is traveling
Non-specific System	F_AUTOMATED_DRIVING	BYTE	138	Non-specific system, function: Automated Driving – hardware and software capable of performing part or all of the dynamic driving task
Non-specific System	F_NOT_AVAILABLE	BYTE	255	Non-specific system, function: Not Available – placeholder until an explicit function is assigned
Tractor	F_TRACTOR_FORWARD_ROAD_IMAGE_PROCESSING	BYTE	128	Tractor, function: Forward Road Image Processing – determines vehicle position from lane markings (advisory/warning only)
Tractor	F_TRACTOR_FIFTH_WHEEL_SMART_SYSTEM	BYTE	129	Tractor, function: Fifth Wheel Smart System – systems related to fifth wheel coupler operation and safety monitoring
Tractor	F_TRACTOR_CATALYST_FLUID_SENSOR	BYTE	130	Tractor, function: Catalyst Fluid Sensor – measures catalyst fluid temperature, level, and quality
Tractor	F_TRACTOR_ADAPTIVE_FRONT_LIGHTING_SYSTEM	BYTE	131	Tractor, function: Adaptive Front Lighting System – adjusts front lighting for current operating conditions
Tractor	F_TRACTOR_IDLE_CONTROL_SYSTEM	BYTE	132	Tractor, function: Idle Control System – automatically starts and stops the engine to reduce excess idle time
Tractor	F_TRACTOR_USER_INTERFACE_SYSTEM	BYTE	133	Tractor, function: User Interface System – two-way interface for climate, system parameters, and other settings

Tractor	F_TRACTOR_NOT_AVAILABLE	BYTE	255	Tractor, function: Not Available – placeholder until an explicit function is assigned
Trailer	F_TRAILER_NOT_AVAILABLE	BYTE	255	Trailer, function: Not Available – placeholder until an explicit function is assigned

Adapters

None. The constant group does not use or provide adapter interfaces.

Functionality

The IG1_NAME_Functions constant set serves as a lookup table for ISO 11783 NAME function codes within Industry Group 1. When composing an ECU NAME message, an application selects the appropriate constant based on the device's role (e.g., a tachograph, a door controller, or a slope sensor). The selected byte value is then encoded into the NAME field and broadcast on the bus, allowing other ECUs to determine the capability and purpose of the sending device.

The naming convention follows the pattern F_<SYSTEM>_<FUNCTION> where the system prefix is omitted for non-specific system functions, and the value space is organized so that each device class (non-specific, tractor, trailer) has its own starting code range. The value 255 is reserved in every system group to indicate that no specific function has been assigned yet.

Technical Features

- **Data Type:** All constants are declared as BYTE (8-bit unsigned) to fit the ISO 11783 NAME function field.
- **Value Ranges:** Within each system group, valid function codes start at 128 and increase sequentially. The value 255 is universally used as the "Not Available" placeholder.
- **Grouping:** Constants are logically grouped by device class – non-specific system, tractor, and trailer – following the DC_* (Device Class) definitions of the ISO 11783 standard.
- **Global Scope:** Being declared as VAR_GLOBAL CONSTANT, the constants are available throughout an IEC 61499 application without additional instantiation.
- **Compiler Hint:** The bundled compiler information (isobus::pgn::const) indicates that the constants are intended to be used within the ISOBUS PGN (Parameter Group Number) namespace, aiding tool-based integration.

State Overview

The IG1_NAME_Functions constant group is entirely static and stateless. There is no runtime state machine associated with it. The values are fixed at compile time and do not change during execution. Consequently, there are no states, transitions, or lifecycle operations to describe.

Application Scenarios

- **ECU Identification:** A control application that needs to send its NAME to the ISOBUS network can reference F_SLOPE_SENSOR (for a slope sensor) or F_TRACTOR_FIFTH_WHEEL_SMART_SYSTEM (for a tractor's fifth wheel system) to correctly advertise its function.
- **Function Assignment:** During system commissioning, a device may be programmed with F_NOT_AVAILABLE (255) until its final function is determined, ensuring it is recognized as placeholder equipment on the bus.
- **Multi-Function Devices:** A body controller that manages both doors and articulation turntable controls can use the corresponding constants to indicate multiple capabilities (if the underlying protocol supports multiple NAME entries).
- **Diagnostics and Monitoring:** Service tools can map received NAME function codes back to human-readable names using these constants, simplifying troubleshooting.

Comparison with Similar Blocks

The IG1_NAME_Functions constant group is specific to **Industry Group 1** of the ISO 11783 standard. Similar constant sets exist for other industry groups (e.g., IG0 – agriculture-specific, IG2 – forestry), each defining their own function codes. The key difference is that IG1 covers general freight and passenger vehicle applications (tractors, trailers, and non-specific systems) and therefore includes function codes such as tachograph, door controller, and automated driving which are not present in other groups.

In contrast to a typical IEC 61499 function block, which contains event and data interfaces along with an execution algorithm, this constant group has no executable behavior. It is a pure data artifact that serves as a shared vocabulary for function naming. It may be complemented by a separate adapter or function block that performs the actual encoding/decoding of NAME messages, but the constant group itself remains passive.

Conclusion

The `IG1_NAME_Functions` global constants provide a standardized, easy-to-reference mapping of ISO 11783 Industry Group 1 function codes. By centralizing the function definitions in a single location, it reduces the risk of value collisions and improves code readability across ISOBUS-related IEC 61499 applications. The constants are applicable to a wide range of vehicle control scenarios, from simple trailer monitoring to complex automated driving systems, and are an essential building block for any compliant ISOBUS implementation targeting agricultural, construction, or commercial vehicles.

IG1_Source_Addresses

• – ◦ • – ◦ • – ◦ •

Introduction

The **IG1_Source_Addresses** GlobalConstants package defines a set of named constant values representing the ISO 11783 (ISOBUS) **Industry Group 1 specific source addresses** for the J1939-style network. These constants map human-readable device identifiers (e.g., `SA_AUTOMATED_DRIVING_CONTROLLER_1`) to their assigned byte values in the range 128–247, a range reserved for Industry Group 1 (non-standard, agriculture/forestry oriented) ECU source addresses.

The constant definitions are provided as global read-only variables of type `BYTE`, enabling embedded logic blocks and application components to reference specific source addresses by name rather than by numeric literals. This improves code readability, reduces the risk of typing errors, and centralizes the address mapping for maintenance.

The package is organized as a `GLOBALCONSTANTS` block in compliance with the IEC 61499-1 standard and is intended to be included in projects that communicate over ISOBUS networks.

Interface Structure

Since this element is a **GlobalConstants** definition and not a function block, it does not expose event inputs, event outputs, data inputs, data outputs, or adapters. Instead, it provides a set of **global constant data elements** of type `BYTE` that can be used throughout an application. The following table lists all defined constants with their assigned values and comments.

Data Constants

Constant Name	Value (BYTE)	Description
`SA_RESERVED_128`	128	Reserved for future assignment by SAE; available for self-configurable ECUs
`SA_AUTOMATED_DRIVING_CONTROLLER_2`	156	Automated Driving Controller 2 (second instance)
`SA_ELECTRIC_PROPULSION_CONTROL_UNIT_3`	157	Electric Propulsion Control Unit #3
`SA_AUTOMATED_DRIVING_CONTROLLER_1`	158	Automated Driving Controller 1
`SA_ROADWAY_INFORMATION_SYSTEM`	159	Roadway Information System
`SA_ADVANCED_EMERGENCY_BRAKING_SYSTEM`	160	Advanced Emergency Braking System
`SA_FIFTH_WHEEL_SMART_SYSTEMS`	161	Fifth Wheel Smart Systems
`SA_SLOPE_SENSOR`	162	Slope Sensor
`SA_CATALYST_FLUID_SENSOR`	163	Catalyst Fluid Sensor
`SA_ON_BOARD_DIAGNOSTIC_UNIT_2`	164	On Board Diagnostic Unit #2
`SA_REAR_STEERING_AXLE_CONTROLLER_2`	165	Rear Steering Axle Controller #2

SA_REAR_STEERING_AXLE_CONTROLLER_3	166	Rear Steering Axle Controller #3
SA_INSTRUMENT_CLUSTER_2	167	Instrument Cluster #2 (auxiliary display)
SA_TRAILER_5_BRIDGE	168	Trailer #5 Bridge
SA_TRAILER_5_LIGHTING_ELECTRICAL	169	Trailer #5 Lighting-Electrical
SA_TRAILER_5_BRAKES_ABS_EBS	170	Trailer #5 Brakes (ABS-EBS)
SA_TRAILER_5_REEFER	171	Trailer #5 Reefer
SA_TRAILER_5_CARGO	172	Trailer #5 Cargo
SA_TRAILER_5_CHASSIS_SUSPENSION	173	Trailer #5 Chassis-Suspension
SA_OTHER_TRAILER_5_DEVICES	174	Other Trailer #5 Devices
SA_OTHER_TRAILER_5_DEVICES_175	175	Other Trailer #5 Devices (subnetwork)
SA_TRAILER_4_BRIDGE	176	Trailer #4 Bridge
SA_TRAILER_4_LIGHTING_ELECTRICAL	177	Trailer #4 Lighting-Electrical
SA_TRAILER_4_BRAKES_ABS_EBS	178	Trailer #4 Brakes (ABS-EBS)
SA_TRAILER_4_REEFER	179	Trailer #4 Reefer
SA_TRAILER_4_CARGO	180	Trailer #4 Cargo
SA_TRAILER_4_CHASSIS_SUSPENSION	181	Trailer #4 Chassis-Suspension
SA_OTHER_TRAILER_4_DEVICES	182	Other Trailer #4 Devices
SA_OTHER_TRAILER_4_DEVICES_183	183	Other Trailer #4 Devices (subnetwork)
SA_TRAILER_3_BRIDGE	184	Trailer #3 Bridge
SA_TRAILER_3_LIGHTING_ELECTRICAL	185	Trailer #3 Lighting-Electrical
SA_TRAILER_3_BRAKES_ABS_EBS	186	Trailer #3 Brakes (ABS-EBS)
SA_TRAILER_3_REEFER	187	Trailer #3 Reefer
SA_TRAILER_3_CARGO	188	Trailer #3 Cargo
SA_TRAILER_3_CHASSIS_SUSPENSION	189	Trailer #3 Chassis-Suspension
SA_OTHER_TRAILER_3_DEVICES	190	Other Trailer #3 Devices
SA_OTHER_TRAILER_3_DEVICES_191	191	Other Trailer #3 Devices (subnetwork)
SA_TRAILER_2_BRIDGE	192	Trailer #2 Bridge
SA_TRAILER_2_LIGHTING_ELECTRICAL	193	Trailer #2 Lighting-Electrical
SA_TRAILER_2_BRAKES_ABS_EBS	194	Trailer #2 Brakes (ABS-EBS)
SA_TRAILER_2_REEFER	195	Trailer #2 Reefer
SA_TRAILER_2_CARGO	196	Trailer #2 Cargo
SA_TRAILER_2_CHASSIS_SUSPENSION	197	Trailer #2 Chassis-Suspension
SA_OTHER_TRAILER_2_DEVICES	198	Other Trailer #2 Devices
SA_OTHER_TRAILER_2_DEVICES_199	199	Other Trailer #2 Devices (subnetwork)
SA_TRAILER_1_BRIDGE	200	Trailer #1 Bridge
SA_TRAILER_1_LIGHTING_ELECTRICAL	201	Trailer #1 Lighting-Electrical

SA_TRAILER_1_BRAKES_ABS_EBS	202	Trailer #1 Brakes (ABS-EBS)
SA_TRAILER_1_REEFER	203	Trailer #1 Reefer
SA_TRAILER_1_CARGO	204	Trailer #1 Cargo
SA_TRAILER_1_CHASSIS_SUSPENSION	205	Trailer #1 Chassis-Suspension
SA_OTHER_TRAILER_1_DEVICES	206	Other Trailer #1 Devices
SA_OTHER_TRAILER_1_DEVICES_207	207	Other Trailer #1 Devices (subnetwork)
SA_RESERVED_208	208	Reserved for future assignment by SAE (208–227)
SA_STEERING_INPUT_UNIT	228	Steering Input Unit
SA_BODY_CONTROLLER_2	229	Body Controller #2
SA_BODY_TO_VEHICLE_INTERFACE_CONTROL	230	Body-to-Vehicle Interface Control
SA_ARTICULATION_TURNTABLE_CONTROL	231	Articulation Turntable Control
SA_FORWARD_ROAD_IMAGE_PROCESSOR	232	Forward Road Image Processor
SA_DOOR_CONTROLLER_3	233	Door Controller #3
SA_DOOR_CONTROLLER_4	234	Door Controller #4
SA_TRACTOR_TRAILER_BRIDGE_2	235	Tractor/Trailer Bridge #2
SA_DOOR_CONTROLLER_1	236	Door Controller #1 (driver side)
SA_DOOR_CONTROLLER_2	237	Door Controller #2 (co-driver side)
SA_TACHOGRAPH	238	Tachograph
SA_ELECTRIC_PROPULSION_CONTROL_UNIT_1	239	Electric Propulsion Control Unit #1
SA_ELECTRIC_PROPULSION_CONTROL_UNIT_2	240	Electric Propulsion Control Unit #2
SA_WWH_OBD_TESTER	241	WWH-OBD Tester
SA_ELECTRIC_PROPULSION_CONTROL_UNIT_4	242	Electric Propulsion Control Unit #4
SA_BATTERY_PACK_MONITOR_1	243	Battery Pack Monitor #1
SA_BATTERY_PACK_MONITOR_2_APU_4	244	Battery Pack Monitor #2 / APU #4
SA_BATTERY_PACK_MONITOR_3_APU_3	245	Battery Pack Monitor #3 / APU #3
SA_BATTERY_PACK_MONITOR_4_APU_2	246	Battery Pack Monitor #4 / APU #2
SA_AUXILIARY_POWER_UNIT_APU_1	247	Auxiliary Power Unit (APU) #1

Event Inputs

Not applicable – this is a global constant definition, not a function block.

Event Outputs

Not applicable.

Data Inputs

Not applicable.

Data Outputs

Not applicable – the constants are global read-only values that may be referenced by any application component.

Adapters

Not applicable.

Functionality

The primary functionality of `IG1_Source_Addresses` is to provide a **centralized, named mapping** of ISOBUS source addresses for devices belonging to Industry Group 1. In an ISOBUS network, every electronic control unit must use a unique source address (0–253) to identify itself in transmitted messages. Industry Group 1 covers agricultural and forestry equipment, and the SAE J1939-based address allocation assigns specific addresses to device classes within this group.

By referencing the constants defined here, an application can:

- Assign a source address to a local ECU during network initialization.
- Filter incoming messages based on the source address of the transmitting device.
- Configure diagnostic or monitoring functions that need to distinguish between different controllers.
- Ensure that address values are consistent across the entire project without hard-coding numeric values.

The constant names follow a descriptive convention (prefix `SA_` followed by the device designation), which makes the purpose of each address immediately understandable in code.

Technical Features

- **Data type:** All constants are of type `BYTE` (unsigned 8-bit integer), which matches the J1939/ISOBUS source address width.
- **Address range:** Covers the Industry Group 1 range from 128 to 247, including reserved gaps (128–155, 208–227) and the explicitly defined addresses 156–247.
- **Reserved entries:** Two constants (`SA_RESERVED_128` and `SA_RESERVED_208`) explicitly declare the start of reserved ranges, allowing applications to check for reserved addresses.
- **Self-configuration support:** The comment for `SA_RESERVED_128` notes that the range 128–155 is "available for use by self-configurable ECUs," indicating support for dynamic address assignment.
- **Trailer subsystem addressing:** For each of the five possible trailers, seven addresses are defined (bridge, lighting/electrical, brakes/ABS-EBS, reefer, cargo, chassis/suspension, and other devices), allowing a full topology of towed equipment to be addressed.
- **Electric vehicle integration:** Multiple addresses for electric propulsion control units (ECUs #1–#4) and battery pack monitors are included, reflecting modern electric-drivetrain requirements.
- **IEC 61499 compliance:** The constants are declared within a `GlobalConstants` block, conforming to the IEC 61499-1 standard for global data in distributed industrial-process measurement and control systems.

State Overview

This element is **stateless**. It does not implement a state machine or exhibit runtime behavior – it simply provides compile-time constant values. Once defined, the values are immutable and available throughout the application lifecycle. There are no states to transition between, and no events trigger changes to the constants.

Application Scenarios

- **ISOBUS controller development:** A tractor or implement ECU that needs to claim a source address can assign the address from this constant set during startup, e.g., `SA_AUTOMATED_DRIVING_CONTROLLER_1` (158) for an autonomous driving controller.
- **Message filtering and routing:** A gateway or bridge (e.g., `SA_TRACTOR_TRAILER_BRIDGE_2`) can use these constants to discriminate messages from different trailer subsystems and forward them to appropriate network segments.
- **Diagnostics:** An on-board diagnostic unit (`SA_ON_BOARD_DIAGNOSTIC_UNIT_2`, `SA_WWH_OBD_TESTER`) can reference these constants to implement diagnostic services that query specific ECUs.
- **Electric vehicle fleets:** With addresses for propulsion control units and battery monitors, an electric tractor or implement can use these constants to manage the communication with multiple high-voltage components.
- **Multi-trailer configurations:** Agricultural operations that pull one or more trailers (e.g., grain carts, sprayers) can use the trailer-specific addresses to monitor and control lighting, brakes, reefers, and cargo conditions for each trailer individually.

Comparison with Similar Blocks

- **vs. generic constant definitions:** Most IEC 61499 projects define constants individually within function blocks or applications. `IG1_Source_Addresses` centralizes a large set of related constants in one global namespace, improving consistency and reducing duplication.
- **vs. hard-coded numeric values:** Using named constants eliminates the risk of typos and makes code self-documenting. Numeric address assignments are often scattered and error-prone when repeated.
- **vs. a function block with output pins:** A function block could expose source address values via output data ports, but it would need to be instantiated and would introduce runtime dependency. Global constants are available immediately without instantiation, making them more efficient for constant data.
- **vs. other ISOBUS address constant sets:** A similar GlobalConstants block for other industry groups (e.g., Group 2 addresses 0–127 or Group 3 addresses 248–253) would complement this file. This block specifically covers Group 1, while other groups would contain their own dedicated constants.

Conclusion

The **IG1_Source_Addresses** GlobalConstants block is an essential building block for any ISOBUS-based application developed in 4diac-ide. It provides a comprehensive, well-documented set of byte constants representing Industry Group 1 source addresses, covering propulsion, braking, towing, trailer, and body control systems. By using these named constants, developers ensure that their applications are readable, maintainable, and consistent with the SAE J1939 address allocation scheme. The stateless nature and global availability of the constants make them easy to integrate into any IEC 61499 application, improving both development efficiency and network interoperability.

IG2_Device_Classes

• – ◦ • – ◦ • – ◦ •

Introduction

The `IG2_Device_Classes` type defines a set of global constants for **Industry Group 2** (vehicle systems) as specified by the ISOBUS standard (ISO 11783). These constants provide standardized BYTE values that identify the device class of agricultural equipment, such as tractors, harvesters, and sprayers. They are intended for use in 4diac applications that communicate via ISOBUS and need to assign or decode device class information in PGN (Parameter Group Number) messages.

Interface Structure

This type is a **global constant definition**, not a function block, adapter, or subapplication. Consequently, it possesses no event or data interfaces. The constants themselves are the entire content of this type.

Event Inputs

Not applicable — no event inputs are defined.

Event Outputs

Not applicable — no event outputs are defined.

Data Inputs

Not applicable — no data inputs are defined.

Data Outputs

Not applicable — no data outputs are defined.

Adapters

Not applicable — no adapter interfaces are defined.

Functionality

The primary purpose of `IG2_Device_Classes` is to supply a consistent, human-readable set of constants that map to the device class codes used in ISOBUS. Each constant is declared as a `BYTE` (8-bit unsigned integer) with a fixed value. These constants are typically referenced in FB code (e.g., in ST or Structured Text) to set or compare the device class field of a message, ensuring that all parts of an application use the same numeric representation.

The following table lists all constants defined in this type:

Constant Name	Value (BYTE)	Description
DC_NON_SPECIFIC_SYSTEM	0	Non-specific system
DC_TRACTOR	1	Tractor
DC_TILLAGE	2	Tillage
DC_SECONDARY_TILLAGE	3	Secondary tillage
DC_PLANTERS_SEEDERS	4	Planters / Seeders
DC_FERTILIZERS	5	Fertilizers
DC_SPRAYERS	6	Sprayers
DC_HARVESTERS	7	Harvesters
DC_ROOT_HARVESTERS	8	Root harvesters
DC_FORAGE	9	Forage
DC_IRRIGATION	10	Irrigation
DC_TRANSPORT_TRAILER	11	Transport / Trailer
DC_FARM_YARD_OPERATIONS	12	Farm yard operations
DC_POWERED_AUXILIARY_DEVICES	13	Powered auxiliary devices
DC_SPECIAL_CROPS	14	Special crops
DC_EARTH_WORK	15	Earth work
DC_SKIDDER	16	Skidder
DC_SENSOR_SYSTEMS	17	Sensor systems
DC_TIMBER_HARVESTERS	19	Timber harvesters
DC_FORWARDERS	20	Forwarders
DC_TIMBER_LOADERS	21	Timber loaders
DC_TIMBER_PROCESSING_MACHINES	22	Timber processing machines
DC_MULCHERS	23	Mulchers
DC_UTILITY_VEHICLES	24	Utility vehicles
DC_SLURRY_MANURE_APPLICATORS	25	Slurry / Manure applicators
DC_FEEDERS_MIXERS	26	Feeders / Mixers
DC_WEEDERS	27	Weeders – non-chemical weed control
DC_TURF_AND_LAWN_CARE_MOWERS	28	Turf and lawn care mowers
DC_PRODUCT_MATERIAL_HANDLING	29	Product / Material handling
DC_NOT_AVAILABLE	127	Not available

All values are declared as `CONSTANT` and are therefore immutable at runtime. Using these constants instead of raw numeric literals improves code readability and maintainability, especially when dealing with ISOBUS messages that carry device class information.

Technical Features

- **Data type:** `BYTE` (unsigned 8-bit integer)
- **Scope:** Global — accessible from any FB or subapplication in the project
- **Predefined values:** 31 distinct constants covering the standard device classes defined in ISOBUS Industry Group 2

- **Immutability:** Constants are declared with the `CONSTANT` keyword and cannot be changed during execution
- **Standard compliance:** Values match the assignments defined by the ISOBUS standard (ISO 11783)

State Overview

This type is not a stateful entity. It does not contain any state variables, internal algorithms, or event-driven behavior. The constants are static and exist at compile time, providing a fixed mapping between names and numeric codes.

Application Scenarios

Typical use cases for `IG2_Device_Classes` include:

- **Message composition:** When building a PGN that includes a device-class field, assign a constant such as `DC_TRACTOR` to the corresponding byte.
- **Message parsing:** When decoding an incoming PGN, compare the received device-class value with constants to determine the type of equipment.
- **Configuration:** Use the constants in parameter files or configuration dialogs to let users select a device class from a list of human-readable names.
- **Filtering:** In fleet management or diagnostics, filter messages based on the device class to process only relevant data.

By using these global constants, applications avoid magic numbers and stay aligned with the ISOBUS standard, reducing errors and easing code review.

Comparison with Similar Blocks

In the 4diac-IDE environment, `IG2_Device_Classes` is a **global constant type** rather than a function block or adapter. The differences are:

- **Function blocks** contain executable logic and have inputs/outputs, whereas this type only provides named constants.
- **Adapters** define communication interfaces between subapplications; this type has no such capability.
- Compared to a simple variable declaration, using a global constant type centralizes all device-class definitions in one place, simplifying maintenance and ensuring consistency across a project.

Conclusion

The `IG2_Device_Classes` global constants offer a standardized, type-safe method for referencing ISOBUS device classes in 4diac applications. They are invaluable for developers working with agricultural machinery communication, as they eliminate arbitrary numeric values and provide self-documenting code. The constants are easy to include in any FB or subapplication and directly support the requirements of the ISOBUS protocol, making them a fundamental building block for compliant systems.

IG2_NAME_Functions

• – ◦ • – ◦ • – ◦ •

Introduction

The `IG2_NAME_Functions` global constant set defines Industry Group 2 (Agricultural Equipment) specific function codes used in ISO 11783 (ISOBUS) networks. These constants represent the `function` part of the NAME (Name field) of a control function, as specified in ISO 11783-7. The values are used to identify the role of a device or software component on the bus, such as “Spray Rate Control”, “Tillage Depth Control”, or “Product Flow”. This constant set covers a wide range of agricultural applications, from tractors and tillage implements to harvesters, sensor systems, and specialised devices.

The constants are grouped by device class (e.g., Tractor, Tillage, Sprayers, Harvesters) and provide a consistent, human-readable naming scheme for developers working with ISOBUS protocols. Each constant is of type `BYTE` and has a predefined default value that is unique within its device-class context.

Interface Structure

Event Inputs

None – This is a global constant set and does not contain any event inputs.

Event Outputs

None – This is a global constant set and does not contain any event outputs.

Data Inputs

None – This is a global constant set and does not contain any data inputs.

Data Outputs

The set provides a total of **85** constants, each representing a specific function code. They are listed in the following table (grouped by device class, as in the XML).

Constant Name	Value	Short Description (excerpt)
Non-specific System		
F_NON_VIRTUAL_TERMINAL_DISPLAY	128	An operator display that cannot perform as a Virtual Terminal
F_OPERATOR_CONTROLS_MACHINE_SPECIFIC	129	Operator interface controls (auxiliary or proprietary)
F_TASK_CONTROLLER_MAPPING_COMPUTER	130	Task Controller / Mapping Computer
F_POSITION_CONTROL	131	Multiple axis position control of application boom
F_MACHINE_CONTROL	132	General machine control (outputs, ancillary functions)
F_FOREIGN_OBJECT_DETECTION	133	Detection of undesired objects in product flow
F_TRACTOR_ECU	134	Tractor interface unit on the implement bus
F_SEQUENCE_CONTROL_MASTER	135	Master controller in ISO11783-14 sequence control
F_PRODUCT_DOSING	136	Adds active ingredient to liquid carrier
F_PRODUCT_TREATMENT	137	Mixes treatment to dry product
F_RESERVED	138	Reserved for future “all operations stop” function
F_DATA_LOGGER	139	Non-task related data logger
F_DECISION_SUPPORT	140	Configures operation for optimal performance
F_LIGHTING_CONTROLLER	141	Controls electrical lights and status
F_TIM_SERVER	142	Tractor Implement Management (TIM) Server
F_NOT_AVAILABLE	255	Not available / unassigned
Tractor		
F_TRACTOR_AUXILIARY_VALVE_CONTROL	129	Control of tractor-mounted auxiliary valves
F_TRACTOR_REAR_HITCH_CONTROL	130	Rear hitch control
F_TRACTOR_FRONT_HITCH_CONTROL	131	Front hitch control
F_TRACTOR_TRACTOR_MACHINE_CONTROL	132	Machine control (outputs, ancillary functions)
F_TRACTOR_CENTER_HITCH_CONTROL	134	Center hitch control

F_TRACTOR_NOT_AVAILABLE	255	Not available
Tillage		
F_TILLAGE_TILLAGE_MACHINE_CONTROL	132	Control of outputs, ancillary functions
F_TILLAGE_TILLAGE_DEPTH_CONTROL	135	Depth of tillage tool in soil
F_TILLAGE_FRAME_CONTROL	136	Folding/unfolding of frame (transport vs field)
F_TILLAGE_NOT_AVAILABLE	255	Not available
Secondary Tillage		
F_SECONDARY_TILLAGE_SECONDARY_TILLAGE_MACHINE_CONTROL	132	Machine control
F_SECONDARY_TILLAGE_SECONDARY_TILLAGE_DEPTH_CONTROL	135	Depth control for surface preparation
F_SECONDARY_TILLAGE_FRAME_CONTROL	136	Frame control
F_SECONDARY_TILLAGE_NOT_AVAILABLE	255	Not available
Planters/Seeders		
F_PLANTERS_SEEDERS_SEED_RATE_CONTROL	128	Rate of seed placed in soil
F_PLANTERS_SEEDERS_SECTION_ON_OFF_CONTROL	129	On/Off control of individual sections
F_PLANTERS_SEEDERS_POSITION_CONTROL	131	Multiple axis position control (row guidance)
F_PLANTERS_SEEDERS_PLANTERS_SEEDERS_MACHINE_CONTROL	132	Machine control
F_PLANTERS_SEEDERS_PRODUCT_FLOW	133	Product flow measurement
F_PLANTERS_SEEDERS_PRODUCT_LEVEL	134	Product level in bin
F_PLANTERS_SEEDERS_DEPTH_CONTROL	135	Depth of seed/tuber placement
F_PLANTERS_SEEDERS_FRAME_CONTROL	136	Frame control
F_PLANTERS_SEEDERS_DOWN_PRESSURE	137	Ground contact pressure on delivery unit
F_PLANTERS_SEEDERS_NOT_AVAILABLE	255	Not available
Fertilizers		
F_FERTILIZERS_FERTILIZE_RATE_CONTROL	128	Fertilizer rate control
F_FERTILIZERS_SECTION_ON_OFF_CONTROL	129	Section on/off
F_FERTILIZERS_PRODUCT_PRESSURE	130	Monitoring pressure in sprayer booms
F_FERTILIZERS_POSITION_CONTROL	131	Boom position control
F_FERTILIZERS_FERTILIZERS_MACHINE_CONTROL	132	Machine control
F_FERTILIZERS_PRODUCT_FLOW	133	Product flow monitoring
F_FERTILIZERS_PRODUCT_LEVEL	134	Product level in bin
F_FERTILIZERS_HEIGHT_DEPTH_CONTROL	135	Height/depth of boom placement
F_FERTILIZERS_FRAME_CONTROL	136	Frame control
F_FERTILIZERS_NOT_AVAILABLE	255	Not available
Sprayers		
F_SPRAYERS_SPRAY_RATE_CONTROL	128	Rate of crop protection product applied
F_SPRAYERS_SECTION_ON_OFF_CONTROL	129	Section on/off

F_SPRAYERS_PRODUCT_PRESSURE	130	Pressure in delivery booms
F_SPRAYERS_POSITION_CONTROL	131	Boom position control
F_SPRAYERS_SPRAYERS_MACHINE_CONTROL	132	Machine control
F_SPRAYERS_PRODUCT_FLOW	133	Product flow
F_SPRAYERS_PRODUCT_LEVEL	134	Product level in tank
F_SPRAYERS_BOOM_HEIGHT_CONTROL	135	Boom height above soil/crop
F_SPRAYERS_FRAME_CONTROL	136	Frame control
F_SPRAYERS_NOT_AVAILABLE	255	Not available
Harvesters		
F_HARVESTERS_TAILING_MONITOR	128	Monitor quantity of unthreshed material
F_HARVESTERS_HEADER_CONTROL	129	Control of header reel height/rotation
F_HARVESTERS_PRODUCT_LOSS_MONITOR	130	Monitor grain loss to soil
F_HARVESTERS_PRODUCT_MOISTURE	131	Monitor moisture content of grain
F_HARVESTERS_HARVESTER_MACHINE_CONTROL	132	Machine control
F_HARVESTERS_PRODUCT_FLOW	133	Yield rate (grain flow into tank)
F_HARVESTERS_PRODUCT_LEVEL	134	Grain level in tank
F_HARVESTERS_HEADER_HEIGHT_CONTROL	135	Header height above soil / below crop top
F_HARVESTERS_NOT_AVAILABLE	255	Not available
Root Harvesters		
F_ROOT_HARVESTERS_ROOT_HARVESTERS_MACHINE_CONTROL	132	Machine control
F_ROOT_HARVESTERS_PRODUCT_FLOW	133	Product flow into tank
F_ROOT_HARVESTERS_PRODUCT_LEVEL	134	Product level in tank
F_ROOT_HARVESTERS_DEPTH_CONTROL	135	Lifter share depth
F_ROOT_HARVESTERS_NOT_AVAILABLE	255	Not available
Forage		
F_FORAGE_TWINE_WRAPPER_CONTROL	128	Twine wrapping around bale
F_FORAGE_PRODUCT_PACKAGING_CONTROL	129	Packaging process control
F_FORAGE_PRODUCT_MOISTURE	131	Moisture content of forage
F_FORAGE_FORAGE_MACHINE_CONTROL	132	Machine control
F_FORAGE_PRODUCT_FLOW	133	Forage yield rate
F_FORAGE_WORKING_HEIGHT_CONTROL	135	Cutting header height
F_FORAGE_NOT_AVAILABLE	255	Not available
Irrigation		
F_IRRIGATION_NOT_AVAILABLE	255	Not available
Transport/Trailer		
F_TRANSPORT_TRAILER_TRANSPORT_MACHINE_CONTROL	132	Machine control

F_TRANSPORT_TRAILER_UNLOAD_CONTROL	136	Trailer unloading process control
F_TRANSPORT_TRAILER_NOT_AVAILABLE	255	Not available
Farm Yard Operations		
F_FARM_YARD_OPERATIONS_NOT_AVAILABLE	255	Not available
Powered Auxiliary Devices		
F_POWERED_AUXILIARY_DEVICES_POWERED_DEVICES_MACHINE_CONTROL	128	Machine control
F_POWERED_AUXILIARY_DEVICES_NOT_AVAILABLE	255	Not available
Special Crops		
F_SPECIAL_CROPS_SPECIAL_CROP_MACHINE_CONTROL	132	Machine control
F_SPECIAL_CROPS_NOT_AVAILABLE	255	Not available
Earth Work		
F_EARTH_WORK_MATERIAL_RATE_CONTROL	128	Control of material processing rate
F_EARTH_WORK_EARTHWORKS_MACHINE_CONTROL	132	Machine control
F_EARTH_WORK_MATERIAL_FLOW	133	Material flow monitoring
F_EARTH_WORK_MATERIAL_LEVEL	134	Material level monitoring
F_EARTH_WORK_DEPTH_CONTROL	135	Working depth control
F_EARTH_WORK_NOT_AVAILABLE	255	Not available
Skidder		
F_SKIDDER_SKIDDER_MACHINE_CONTROL	132	Machine control
F_SKIDDER_NOT_AVAILABLE	255	Not available
Sensor Systems		
F_SENSOR_SYSTEMS_GUIDANCE_FEELER	128	Mechanical row position sensing
F_SENSOR_SYSTEMS_CAMERA_SYSTEM	129	Camera system for control operations
F_SENSOR_SYSTEMS_CROP_SCOUTING	130	Vegetation parameter measurement
F_SENSOR_SYSTEMS_MATERIAL_PROPERTIES_SENSING	131	Material properties detection (density, particle size, ...)
F_SENSOR_SYSTEMS_INERTIAL_MEASUREMENT_UNIT_IMU	132	Inertial measurement unit
F_SENSOR_SYSTEMS_PRODUCT_FLOW	133	Product flow monitoring
F_SENSOR_SYSTEMS_PRODUCT_LEVEL	134	Product level in tank/bin
F_SENSOR_SYSTEMS_PRODUCT_MASS	135	Product mass monitoring
F_SENSOR_SYSTEMS_VIBRATION_KNOCK	136	Vibration/knock behaviour measurement
F_SENSOR_SYSTEMS_WEATHER_INSTRUMENTS	137	Weather instruments identification
F_SENSOR_SYSTEMS_SOIL_SCOUTING	138	Soil physical parameter measurement
Timber Harvesters		
F_TIMBER_HARVESTERS_TIMBER_HARVESTORS_MACHINE_CONTROL	132	Machine control
Forwarders		
F_FORWARDERS_FORWARDERS_MACHINE_CONTROL	132	Machine control

Timber Loaders		
F_TIMBER_LOADERS_TIMBER_LOADERS_MACHINE_CONTROL	132	Machine control
Timber Processing Machines		
F_TIMBER_PROCESSING_MACHINES_TIMBER_PROCESSING_MACHINE_CONTROL	132	Machine control
Mulchers		
F_MULCHERS_MULCHER_MACHINE_CONTROL	132	Machine control
Utility Vehicles		
F_UTILITY_VEHICLES_UTILITY_MACHINE_CONTROL	132	Machine control
Slurry/Manure Applicators		
F_SLURRY_MANURE_APPLICATORS_SLURRY_MANURE_RATE_CONTROL	128	Rate of product placed on soil
F_SLURRY_MANURE_APPLICATORS_SECTION_ON_OFF_CONTROL	129	Section on/off
F_SLURRY_MANURE_APPLICATORS_PRODUCT_PRESSURE	130	Pressure in delivery booms
F_SLURRY_MANURE_APPLICATORS_SLURRY_MANURE_MACHINE_CONTROL	132	Machine control
F_SLURRY_MANURE_APPLICATORS_PRODUCT_FLOW	133	Product flow
F_SLURRY_MANURE_APPLICATORS_PRODUCT_LEVEL	134	Product level in bin
F_SLURRY_MANURE_APPLICATORS_BOOM_HEIGHT_CONTROL	135	Boom height above soil
Feeders/Mixers		
F_FEEDERS_MIXERS_FEEDER_MIXER_RATE_CONTROL	128	Rate of product distributed to livestock
F_FEEDERS_MIXERS_SECTION_ON_OFF_CONTROL	129	Section on/off (e.g., Left/Center/Right)
F_FEEDERS_MIXERS_PRODUCT_PRESSURE	130	Pressure in delivery units
F_FEEDERS_MIXERS_FEEDER_MIXER_MACHINE_CONTROL	132	Machine control
F_FEEDERS_MIXERS_PRODUCT_FLOW	133	Product flow
F_FEEDERS_MIXERS_PRODUCT_LEVEL	134	Product level in bin
F_FEEDERS_MIXERS_BOOM_HEIGHT_CONTROL	135	Boom height above soil
Weeders		
F_WEEDERS_WEEDER_MACHINE_CONTROL	132	Machine control (non-chemical weed control)
Turf and Lawn Care Mowers		
F_TURF_AND_LAWN_CARE_MOWERS_TURF_AND_LAWN_CARE_MOWERS_MACHINE_CONTROL	132	Machine control for grass cutting
Product/Material Handling		
F_PRODUCT_MATERIAL_HANDLING_PRODUCT_MATERIAL_HANDLING_MACHINE_CONTROL	132	Machine control
F_PRODUCT_MATERIAL_HANDLING_PRODUCT_MATERIAL_HANDLING_PRODUCT_FLOW	133	Product flow
F_PRODUCT_MATERIAL_HANDLING_PRODUCT_MATERIAL_HANDLING_PRODUCT_LEVEL	134	Product level in bin

Adapters

None – The constant set does not contain any adapters.

Functionality

The IG2_NAME_Functions constant set provides a standardised vocabulary for identifying the function of ISOBUS control functions. Each constant corresponds to a byte value that is used in the function field of the NAME message (per ISO 11783-7). This allows devices on an agricultural bus to advertise their capabilities, enabling proper configuration and interoperability. The constants are organised by device class (e.g., Tractor, Harvesters, Sprayers) to simplify lookup and ensure that function codes are unique within a given class.

For a given device class, a device may implement one or more of these functions (e.g., a sprayer might have function codes for boom height control, product flow, and section on/off). The availability of F_*_NOT_AVAILABLE (value 255) indicates that no explicit function has been assigned yet, serving as a placeholder during development.

Technical Features

- **Type:** All constants are of type BYTE (unsigned 8-bit integer).
- **Values:** Assigned values range from 128 to 142 (non-specific system) and 128 to 137 (specific device classes), with 255 universally used as "not available".
- **Grouping:** Constants are grouped into device classes as defined in the ISO 11783 standard (e.g., DC_TRACTOR = 1, DC_TILLAGE = 2, ...). This grouping is reflected in the naming convention: F_<DEVICE_CLASS>_<FUNCTION_NAME>.
- **Naming:** Names are descriptive and follow a pattern F_<device_class>_<specific_function> to avoid collisions (e.g., F_SPRAYERS_BOOM_HEIGHT_CONTROL vs. F_FERTILIZERS_HEIGHT_DEPTH_CONTROL).
- **Purpose:** The constants are intended for use in the NAME field of an ISOBUS device, particularly within the function byte of the "NAME" attribute.

State Overview

This constant set does not represent a state machine; it is a static list of predefined values. However, the presence of a NOT_AVAILABLE (255) constant can be considered a fallback state for devices that have not yet been assigned a specific function. Once a device is configured, its actual function value is set from one of the listed constants. The constants are not subject to runtime changes – they are global immutable values.

Application Scenarios

- **ISOBUS Device Development:** Implementers can include these constants in their code to set the NAME field when initialising a control function on an ISO 11783 bus.
- **Configuration Tools:** Software that configures agricultural equipment can use the constants to allow users to select the correct function from a dropdown or list.
- **Diagnostics and Monitoring:** Tools that analyse bus messages can interpret the function byte using these constants to display meaningful device roles.
- **System Simulation:** Simulation models of agricultural networks can use these constants to model various implement types.

Comparison with Similar Blocks

There is no direct comparison to function blocks, as this is a global constant definition. However, in the context of ISOBUS, comparable constant sets may exist for other industry groups (e.g., Industry Group 1 – forestry, Industry Group 3 – municipal). The structure differs in that those groups would have their own device classes and function codes. This set is specifically tailored for agricultural equipment (Industry Group 2). Unlike a function block, which encapsulates logic and has inputs/outputs, this constant set is purely declarative and serves as a data dictionary.

Conclusion

The IG2_NAME_Functions global constant set is an essential resource for developers working with ISO 11783 (ISOBUS) agricultural networks. It provides a comprehensive, standardised list of function codes covering a wide range of agricultural machinery and sensor systems. By using these constants, developers can ensure consistency and interoperability across different implementations, facilitating seamless communication between tractors, implements, and other devices on the bus.

IG2_Source_Addresses

• – ◦ • – ◦ • – ◦ •

Introduction

The `IG2_Source_Addresses` global constant definition provides a standardized set of source addresses for devices operating in Industry Group 2 (IG2) on an ISO 11783 (ISOBUS) network. These addresses are reserved for specific control functions and are used to uniquely identify devices or services within the network. The constants are defined as `BYTE` values and are intended to be used as preferred or fixed source addresses according to the ISO 11783 standard.

Interface Structure

This global constant type does not contain any event or data inputs. It exposes a collection of constant values as read-only data outputs, which are globally accessible to function blocks and applications within the 4diac-IDE environment.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The following table lists the constant data outputs provided by this global constant type. Each entry represents a fixed source address value.

Name	Type	Initial Value	Description
`SA_RESERVED_128`	`BYTE`	128	Reserved source addresses 128–235 for self-configurable devices.
`SA_DATA_LOGGER`	`BYTE`	236	Data Logger – a server providing LOG functionality per ISO 11783-10.
`SA_TIM_SERVER`	`BYTE`	237	TIM Server – represents a Tractor Implement Management (TIM) server.
`SA_SEQUENCE_CONTROLLER`	`BYTE`	238	Sequence Controller – master in the Sequence Control System (ISO 11783-14).
`SA_POSITION_CONTROL`	`BYTE`	239	Position Control – multiple axial position control of movable device elements.
`SA_TRACTOR_ECU`	`BYTE`	240	Tractor ECU – gateway between tractor and implement bus, representing the tractor.
`SA_TAILINGS_MONITORING`	`BYTE`	241	Tailings Monitoring – monitors quantity of unthreshed material returned to threshing machine.
`SA_HEADER_CONTROL`	`BYTE`	242	Header Control – controls header reel rate and material delivery rate.
`SA_PRODUCT_LOSS_MONITORING`	`BYTE`	243	Product Loss Monitoring – monitors produce loss in harvest processes.
`SA_PRODUCT_MOISTURE_SENSING`	`BYTE`	244	Product Moisture Sensing – monitors produce moisture content.

SA_NON_VIRTUAL_TERMINAL_DISPLAY_IMPLEMENTBUS	BYTE	245	Non-Virtual Terminal Display (Implement Bus) – cab display connected to implement bus.
SA_OPERATOR_CONTROLS_MACHINE_SPECIFIC	BYTE	246	Operator Controls – machine-specific non-auxiliary operator control inputs.
SA_TASK_CONTROL_MAPPING_COMPUTER	BYTE	247	Task Control (Mapping Computer) – responsible for sending, receiving and logging process data.

Adapters

None.

Functionality

The `IG2_Source_Addresses` global constants are used to assign fixed, well-known source addresses to ISOBUS-compliant devices. By referencing these constants, developers ensure that their function blocks or applications use the correct addresses as defined by the ISO 11783 standard. The constants are grouped together to provide a single, maintainable definition for all IG2-specific source addresses, avoiding hard-coded magic numbers in the application logic.

Technical Features

- All constants are of type `BYTE` (range 0–255).
- The values are fixed and cannot be changed at runtime; they are compile-time constants.
- The definition is encapsulated in a global constants type, making the addresses easily reusable across different projects.
- The comments provide a concise description of each source address, aiding documentation and code readability.
- The constants are defined in accordance with the ISO 11783 series, particularly parts 4, 10, and 14.

State Overview

This global constant type does not maintain any internal state; it is a static collection of constant values. There are no state transitions or lifecycle operations. The constants are available immediately upon loading the type into a project.

Application Scenarios

`IG2_Source_Addresses` is typically used in the development of ISOBUS-based agricultural or forestry machinery, where multiple electronic control units (ECUs) need to communicate over the CAN bus. Examples include:

- Implementing a virtual terminal or display interface.
- Developing a tractor-implement management (TIM) system.
- Configuring data loggers or task controllers.
- Setting up position control or header control systems.
- Assigning source addresses during network self-configuration.

Comparison with Similar Blocks

In the 4diac-IDE environment, global constants are commonly used to define fixed configuration values. Similar constants might exist for other industry groups (e.g., IG1, IG3) or for other network-specific parameters. The main advantage of this collection is its focus on IG2 addresses, providing a comprehensive and standardized set that directly corresponds to ISO 11783 recommendations. Compared to using individual magic numbers, these named constants improve code clarity and reduce the risk of address conflicts.

Conclusion

The `IG2_Source_Addresses` global constant type offers a clean and standardized way to manage source addresses for ISO 11783 Industry Group 2 devices. By using these constants, developers can ensure compliance with international standards, simplify network configuration, and enhance the maintainability of their 4diac applications.

IG3_Device_Classes

• – ◦ • – ◦ • – ◦ •

Introduction

The `IG3_Device_Classes` global constant definition provides a standardized set of byte-encoded identifiers for Industry Group 3 (IG3) vehicle systems, specifically those used in construction, agricultural, and mobile machinery applications. These constants align with the SAE J1939 / ISOBUS 11783 protocol family and are intended to be used within PGN (Parameter Group Number) communications to clearly identify the type of system or device class being addressed. By using these symbolic names instead of raw numeric values, source code becomes more readable, maintainable, and less error-prone.

Interface Structure

This element is **not** a function block, adapter, or subapplication. It is a global constant set, which means it has no event inputs, event outputs, data inputs, data outputs, or adapter connections. Instead, it exposes a collection of named constants of type `BYTE` that can be referenced throughout an automation project.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The constants represent the officially assigned device classes for Industry Group 3 as defined by the ISOBUS standard. Each constant holds a distinct integer value (`0` to `17` and `127`) that corresponds to a specific vehicle system or a "not available" state. The values are used in fields of PGN messages to indicate the type of equipment on the network, facilitating correct data interpretation and routing between ECUs.

Technical Features

- **Data Type:** All constants are of type `BYTE`, ranging from 0 to 255.
- **Naming Convention:** Each constant is prefixed with `DC_` (Device Class) and follows a descriptive uppercase name.
- **Value Assignment:** Values are fixed and conform to the ISOBUS specification:
  - `0` – Non-specific system
  - `1` – Skid Steer Loader
  - `2` – Articulated Dump Truck
  - `3` – Backhoe
  - `4` – Crawler
  - `5` – Excavator
  - `6` – Forklift
  - `7` – Four Wheel Drive Loader
  - `8` – Grader
  - `9` – Milling Machine
  - `10` – Recycler and Soil Stabilizer
  - `11` – Binding Agent Spreader
  - `12` – Paver
  - `13` – Feeder
  - `14` – Screening Plant
  - `15` – Stacker
  - `16` – Roller

  - `17` – Crusher
  - `127` – Not Available (used when the class is unknown or not specified)
- **Compiler Integration:** The constant set is declared with a compiler package name `isobus::pgn::const`, indicating that it is part of a C++-like namespace for ISOBUS PGN constants, enabling seamless inclusion in embedded firmware projects.

State Overview

Not applicable – the element defines compile-time constants; no runtime state exists.

Application Scenarios

- **ISOBUS Network Communication:** When constructing or parsing PGNs (e.g., the "Vehicle System" fields), developers can directly use `DC_EXCAVATOR` instead of the numeric value `5`.
- **Device Identification:** In diagnostic or management messages, the constant helps identify the type of attached implement or vehicle, enabling appropriate control and display.
- **Firmware Development:** Embedded software for ECUs can include this constant set to ensure consistent device class reporting across different hardware variants.

Comparison with Similar Blocks

Unlike function blocks that contain algorithms and state machines, this global constant set has no executable logic. It is comparable to header files or enumerations in conventional programming. Other constant sets may exist for different industry groups (e.g., IG1, IG2) or for other PGN parameters, but this specific set focuses solely on IG3 device classes. Using symbolic constants avoids magic numbers and improves code clarity and maintainability.

Conclusion

The `IG3_Device_Classes` constant set is a foundational element for any project that uses ISOBUS (ISO 11783) communication in the construction and agricultural machinery domain. By providing readable, standardized names for device class values, it promotes code consistency, reduces mistakes, and simplifies integration. It is an essential resource for developers working on vehicle control units, implement controllers, or diagnostic tools that interact with IG3 systems.

IG3_NAME_Functions

• – ◦ • – ◦ • – ◦ •

Introduction

The **IG3_NAME_Functions** global constant block defines the standardized function codes (Function field of the ISO 11783 NAME) for machinery belonging to **Industry Group 3**. Industry Group 3 encompasses construction and agricultural equipment, including loaders, excavators, graders, pavers, and other specialized machinery. These constants provide symbolic names for numeric byte values (0x80 to 0xFF) that identify the specific function of an electronic control unit (ECU) or device on an ISOBUS (ISO 11783) network. They facilitate the development of interoperable applications by replacing hard-coded numeric values with human-readable, maintainable constant names.

Interface Structure

This block is a **Global Constants** definition and does not contain any event inputs, event outputs, data inputs, data outputs, or adapter interfaces. It purely defines named constants that can be referenced across the 4diac development environment.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The block defines a set of byte constants grouped by **system categories** (Subsystem ID), following the ISOBUS NAME specification. Each constant has a value in the range **128 to 255** (0x80–0xFF) and corresponds to a specific function code for a given equipment type. The constants are organised as follows:

- **Non-specific system** – Functions applicable to any machine, such as:
  - `F_SUPPLEMENTAL_ENGINE_CONTROL_SENSING` = 128
  - `F_LASER_RECEIVER` = 129
  - `F_LOADER_CONTROL` = 135
  - `F_HYDRAULIC_VALVE_CONTROLLER` = 140
  - `F_JOYSTICK_CONTROL` = 141
  - `F_ALARM_DEVICE` = 146
  - and many others.
- **Skid Steer Loader** – Includes `F_SKID_STEER_LOADER_MAIN_CONTROLLER` = 128.
- **Crawler** – Includes `F_CRAWLER_BLADE_CONTROLLER` = 128.
- **Excavator** – Includes `F_EXCAVATOR_SLOPE_SENSOR` = 128.
- **Grader** – Includes `F_GRADER_HFWD_CONTROLLER` = 128.
- **Other equipment types** – For machines like articulated dump trucks, backhoes, forklifts, milling machines, pavers, etc., a generic `NOT_AVAILABLE` constant (value 255) is defined to be used until a specific function is assigned.

These constants allow developers to build ISOBUS applications that correctly identify the function of an ECU or device when constructing the NAME field, ensuring proper network communication and interpretation.

Technical Features

- **Data Type**: All constants are of type `BYTE` (unsigned 8-bit integer).
- **Value Range**: Values are restricted between 128 (0x80) and 255 (0xFF), as per the ISOBUS standard for function codes.
- **Grouping**: Constants are logically grouped by machine type, using meaningful prefixes (e.g., `F_LASER_`, `F_SKID_STEER_LOADER_`).
- **Standard Compliance**: The values and naming follow the ISO 11783-3 specification for NAME function codes in Industry Group 3.
- **Reusability**: Because these are global constants, they can be used across multiple function blocks and systems within a project without duplication or risk of inconsistent values.

State Overview

Not applicable – This block defines constants and does not have any state behavior.

Application Scenarios

- **ISOBUS Electronic Control Unit (ECU) Development**: Use these constants to set the Function portion of the NAME message when configuring an ECU address assignment.
- **Diagnostic and Monitoring Applications**: Decode received NAME messages to identify the type of equipment connected.
- **Machine-Specific Control Logic**: When implementing features for a specific machine (e.g., a skid steer loader), reference the corresponding constants to ensure the correct function identity.
- **Interoperability Testing**: Verify that generated NAME values comply with the industry standard by comparing against these predefined constants.

Comparison with Similar Blocks

In the ISOBUS system, different industry groups define their own sets of function codes. This block is specifically for **Industry Group 3** (construction and agricultural machinery). For example:

- **IG1** (agricultural equipment) has its own function codes for tractors and implements.
- **IG2** is used for forestry machines.
- **IG3** (this block) covers construction equipment.

The main difference lies in the system categories and the specific functions defined for each machine type. This block provides a comprehensive list for the most common construction machines, while other groups may have fewer or different constants. Additionally, all groups include a `NOT_AVAILABLE` value (255) as a placeholder.

Conclusion

The **IG3_NAME_Functions** global constant block is an essential resource for any ISOBUS-based application targeting construction machinery. By providing clear, descriptive names for function codes, it improves code readability, reduces errors, and ensures compliance with the ISO 11783 standard. Its integration into 4diac-IDE projects simplifies the development of robust, interoperable control systems for the construction industry.

IG3_Source_Addresses

• – ◦ • – ◦ • – ◦ •

Introduction

IG3_Source_Addresses is a global constant definition block used within IEC 61499-based applications to provide predefined ISO 11783 (ISOBUS) source addresses for Industry Group 3. This block defines a set of fixed BYTE values that identify specific device types and reserved address ranges on the ISOBUS network. By centralizing these constants, the block ensures consistent addressing across different function blocks and systems that require ISO 11783 compliant communication.

Interface Structure

This entity is a global constants definition rather than a typical function block. Therefore, it does not expose any event or data inputs/outputs, nor does it include adapters. Instead, it provides a collection of named constants that can be referenced throughout a project.

Event Inputs

None. This block does not have any event inputs.

Event Outputs

None. This block does not have any event outputs.

Data Inputs

None. This block does not accept any runtime data inputs.

Data Outputs

None in the traditional sense. However, the defined constants act as read-only values that can be read from other blocks. The following table lists all constants defined in this block:

Constant Name	Type	Value	Description
SA_RESERVED_128	BYTE	128	Source Address: thru 207 are reserved for future assignment by SAE - Used for dynamic address assignment (self-configurable)
SA_RESERVED_208	BYTE	208	Source Address: thru 223 are reserved for future assignment - Used for individual preassigned addresses
SA_ROTATION_SENSOR	BYTE	224	Source Address: Rotation Sensor - A device that measures the rotational angle around an axis.
SA_LIFT_ARM_CONTROLLER	BYTE	225	Source Address: Lift Arm Controller - Controls the lift arms and tilt functions on a construction loader, skid steer loader, or similar machine.

SA_SLOPE_SENSOR	BYTE	226	Source Address: Slope Sensor - A device that measures the slope along an axis.
SA_MAIN_CONTROLLER_SKID_STEER_LOADER	BYTE	227	Source Address: Main Controller - Skid Steer Loader - Primary system controller for skid steer loader
SA_LOADER_CONTROL	BYTE	228	Source Address: Loader Control - Controls the hydraulic system of the loader attachment of a loader/backhoe, wheel loader, skid steer, or similar vehicle
SA_LASER_TRACER	BYTE	229	Source Address: Laser Tracer - A device that receives a laser strike and reports the vertical and horizontal position.
SA_LAND_LEVELING_SYSTEM_DISPLAY	BYTE	230	Source Address: Land Leveling System Display - This device displays position information at a remote location.
SA_SINGLE_LAND_LEVELING_SYSTEM_SUPERVISOR	BYTE	231	Source Address: Single Land Leveling System Supervisor - This device is the Land Leveling System Supervisor for a single control loop.
SA_LAND_LEVELING_ELECTRIC_MAST	BYTE	232	Source Address: Land Leveling Electric Mast - A device that moves a Sensor to maintain a specific position.
SA_SINGLE_LAND_LEVELING_SYSTEM_OPERATOR_INTERFACE	BYTE	233	Source Address: Single Land Leveling System Operator Interface - A component that allows the user to control the Land Leveling System and display information about the operation of the system.
SA_LASER_RECEIVER	BYTE	234	Source Address: Laser Receiver - A device that receives a laser strike, and reports the specific position.
SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_1	BYTE	235	Source Address: Supplemental Sensor Processing Unit #1
SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_2	BYTE	236	Source Address: Supplemental Sensor Processing Unit #2
SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_3	BYTE	237	Source Address: Supplemental Sensor Processing Unit #3
SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_4	BYTE	238	Source Address: Supplemental Sensor Processing Unit #4
SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_5	BYTE	239	Source Address: Supplemental Sensor Processing Unit #5
SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_6	BYTE	240	Source Address: Supplemental Sensor Processing Unit #6
SA_ENGINE_MONITOR_1	BYTE	241	Source Address: Engine Monitor #1
SA_ENGINE_MONITOR_2	BYTE	242	Source Address: Engine Monitor #2
SA_ENGINE_MONITOR_3	BYTE	243	Source Address: Engine Monitor #3
SA_ENGINE_MONITOR_4	BYTE	244	Source Address: Engine Monitor #4

SA_ENGINE_MONITOR_5	BYTE	245	Source Address: Engine Monitor #5
SA_ENGINE_MONITOR_6	BYTE	246	Source Address: Engine Monitor #6
SA_ENGINE_MONITOR_7	BYTE	247	Source Address: Engine Monitor #7

Adapters

None. This block does not contain any adapters.

Functionality

The IG3_Source_Addresses block provides a centralized and standardized set of source addresses for devices operating in Industry Group 3 of the ISO 11783 (ISOBUS) protocol. Source addresses are essential for uniquely identifying devices on the CAN-based network. By defining them as named constants, the block removes ambiguity in application logic and simplifies maintenance. Devices such as sensors, controllers, and monitors can reference these constants directly, ensuring that the correct address is used without manual hard-coding.

Technical Features

- All constants are of type BYTE, ranging in value from 128 to 247.
- Values 128 and 208 represent reserved address ranges as defined by the SAE and are used for dynamic address assignment and individual preassigned addresses, respectively.
- Values 224 through 234 are assigned to specific device functions such as rotation sensors, lift arm controllers, slope sensors, loaders, laser tracers, land leveling equipment, and laser receivers.
- Values 235 through 240 are reserved for supplemental sensor processing units.
- Values 241 through 247 are assigned to engine monitors (up to 7 monitors).
- The block is defined as a global constant container, making the constants visible to all function blocks within the project without duplication.

State Overview

This block does not have an internal state machine or execute any runtime behavior. It is a static definition entity. The constants it defines are immutable and do not change during the execution of an application.

Application Scenarios

- **ISOBUS Implement Control:** When building a control system for agricultural or construction machinery that uses ISOBUS, these constants can be used to assign source addresses to the various electronic control units (ECUs).
- **Sensor Integration:** Connecting rotation sensors, slope sensors, or laser receivers to an ISOBUS network, ensuring each device uses the correct predefined address.
- **Engine Monitoring:** Using the engine monitor address constants to identify up to seven engine monitoring devices on a machine.
- **Reserved Address Handling:** Applications that need to dynamically assign addresses can use the reserved address constants (SA_RESERVED_128 and SA_RESERVED_208) as starting points for self-configuration or preassigned address management.

Comparison with Similar Blocks

In contrast to IEC 61499 function blocks that process data via event and data connections, this block is purely declarative. It serves a similar purpose to other global constant containers, such as `IG1_Source_Addresses` or `IG2_Source_Addresses`, which define source addresses for Industry Groups 1 and 2. The main difference lies in the specific device types and address ranges assigned to each industry group. Compared to an ordinary function block, this definition offers no executable logic but provides a clear, reusable reference that enhances maintainability and reduces errors in address allocation.

Conclusion

The IG3_Source_Addresses global constant block provides a well-organized collection of ISO 11783 source addresses for Industry Group 3 devices. It simplifies the development of ISOBUS-compliant applications by offering named, typed constants that are easy to reference and manage. This approach promotes code clarity, consistency, and correct network addressing, making it a valuable building block for machinery control and telemetry systems.

IG4_Device_Classes

• – ◦ • – ◦ • – ◦ •

Introduction

`IG4_Device_Classes` is a global constant container for Industry Group 4 specific device classes, also referred to as vehicle systems. It defines a set of named `BYTE` constants that represent standardized vehicle system categories. These constants are intended for use in ISOBUS/J1939-related applications and PGN processing.

The constant names use the prefix `DC_`, meaning Device Class, and provide readable symbols for numeric codes used to identify vehicle systems.

• – ◦ • – ◦ • – ◦ •

Interface Structure

`IG4_Device_Classes` is not an executable function block, adapter, or subapplication. It does not have an IEC 61499 event/data interface. The following interface categories are therefore not applicable.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

• – ◦ • – ◦ • – ◦ •

Functionality

The main function of `IG4_Device_Classes` is to provide a single source of truth for device class codes related to Industry Group 4 vehicle systems. Instead of using magic numbers in function blocks or ST/CFC applications, a developer can reference the named constants directly.

These constants can be used when constructing or decoding ISOBUS/J1939 device names, vehicle system identifiers, or any protocol data field that uses a `BYTE` value to represent a device class.

• – ◦ • – ◦ • – ◦ •

Technical Features

- All constants are defined as `BYTE` values.
- Values are fixed and read-only.
- Constant names use the `DC_` prefix for consistent identification.
- The constants belong to the compiler package `isobus::pgn::const`.
- The set covers the standard device class values for Industry Group 4 vehicle systems.

Constant	Value	Description
`DC_NON_SPECIFIC_SYSTEM`	0	Non-specific System
`DC_SYSTEM_TOOLS`	10	System tools
`DC_SAFETY_SYSTEMS`	20	Safety systems
`DC_GATEWAY`	25	Gateway
`DC_POWER_MGMT_LIGHTING`	30	Power management and lighting systems
`DC_STEERING_SYSTEMS`	40	Steering systems
`DC_PROPULSION_SYSTEMS`	50	Propulsion systems
`DC_NAVIGATION_SYSTEMS`	60	Navigation systems
`DC_COMMUNICATIONS_SYSTEMS`	70	Communications systems
`DC_INSTRUMENTATION_GENERAL`	80	Instrumentation/general systems
`DC_ENVIRONMENTAL_HVAC`	90	Environmental (HVAC) systems
`DC_DECK_CARGO_FISHING`	100	Deck, cargo, and fishing equipment systems
`DC_NOT_AVAILABLE`	127	Not Available

• – ◦ • – ◦ • – ◦ •

State Overview

Not applicable. `IG4_Device_Classes` is a global constant container and does not define an execution state machine. No states, transitions, or event-driven behavior are associated with this element.

• – ◦ • – ◦ • – ◦ •

Application Scenarios

Typical application areas include:

- ISOBUS/J1939 device name construction.
- Identification of vehicle systems in electronic control units.
- Filtering or routing of messages based on device class.
- Configuration of agricultural or vehicle systems.
- Replacement of numeric constants with readable symbolic names in ST and CFC code.

• – ◦ • – ◦ • – ◦ •

Comparison with Similar Blocks

`IG4_Device_Classes` is not a function block and therefore does not perform calculations or process data flows. In this respect, it is similar to a global variable list or a constant table.

Compared with executable function blocks, it offers the following benefits:

- Fixed, non-modifiable values.
- Global availability across a project.
- Clear symbolic naming.
- Direct support for protocol-specific device class values.

It can be compared with other industry-group-specific constant sets, where the same naming convention is used but the assigned values and device class definitions may differ.

• – ◦ • – ◦ • – ◦ •

Conclusion

`IG4_Device_Classes` provides a clear and maintainable set of `BYTE` constants for Industry Group 4 vehicle device classes. It removes ambiguity from numeric values and supports ISOBUS/J1939 application development by offering meaningful symbolic names. The element is simple, static, and suitable for use wherever device class information must be referenced consistently.

IG4_NAME_Functions

• – ◦ • – ◦ • – ◦ •

Introduction

This global constant list defines the Industry Group 4 (IG4) specific function codes used in ISO 11783 (ISOBUS) networks. It provides a standardized mapping between numeric function identifiers and their meanings within various system categories, such as propulsion, navigation, communications, instrumentation, and more. The constants enable consistent identification of ECU functions across the network.

Interface Structure

Since this is a global constant list rather than a function block, it does not possess a traditional interface with events or adapters. The constants are globally accessible and can be referenced in any function block, subapplication, or script within the project.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

The constants defined in this list serve as global data outputs. They are all of type `BYTE` and carry predefined values that represent specific functions. The constants are grouped by system category, as summarized in the table below:

Constant Name	Value	System	Function Description
F_ALARM_SYSTEM_CONTROL_FOR_MARINE_ENGINES	128	Non-specific System	Alarm System Control for Marine Engines
F_PROTECTION_SYSTEM_FOR_MARINE_ENGINES	129	Non-specific System	Protection System for Marine Engines
F_DISPLAY_FOR_PROTECTION_SYSTEM_FOR_MARINE_ENGINES	130	Non-specific System	Display for Protection System for Marine Engines
F_NOT_AVAILABLE	255	Non-specific System	Not Available
F_SYSTEM_TOOLS_NOT_AVAILABLE	255	System tools	Not Available
F_SAFETY_SYSTEMS_NOT_AVAILABLE	255	Safety systems	Not Available
F_GATEWAY	130	Gateway	Gateway
F_POWER_MGMT_LIGHTING_SWITCH	130	Power management and lighting systems	Switch
F_POWER_MGMT_LIGHTING_LOAD	140	Power management and lighting systems	Load
F_STEERING_SYSTEMS_FOLLOW_UP_CONTROLLER	130	Steering systems	Follow-up Controller
F_STEERING_SYSTEMS_MODE_CONTROLLER	140	Steering systems	Mode Controller
F_STEERING_SYSTEMS_AUTOMATIC_STEERING_CONTROLLER	150	Steering systems	Automatic Steering Controller
F_STEERING_SYSTEMS_HEADING_SENSORS	160	Steering systems	Heading Sensors
F_PROPULSION_SYSTEMS_ENGINEROOM_MONITORING	130	Propulsion systems	Engineroom monitoring
F_PROPULSION_SYSTEMS_ENGINE_INTERFACE	140	Propulsion systems	Engine Interface
F_PROPULSION_SYSTEMS_ENGINE_CONTROLLER	150	Propulsion systems	Engine Controller
F_PROPULSION_SYSTEMS_ENGINE_GATEWAY	160	Propulsion systems	Engine Gateway
F_PROPULSION_SYSTEMS_CONTROL_HEAD	170	Propulsion systems	Control Head
F_PROPULSION_SYSTEMS_ACTUATOR	180	Propulsion systems	Actuator
F_PROPULSION_SYSTEMS_GAUGE_INTERFACE	190	Propulsion systems	Gauge Interface
F_PROPULSION_SYSTEMS_GAUGE_LARGE	200	Propulsion systems	Gauge Large
F_PROPULSION_SYSTEMS_GAUGE_SMALL	210	Propulsion systems	Gauge Small
F_PROPULSION_SYSTEMS_PROPULSION_SENSOR_GATEWAY	220	Propulsion systems	Propulsion Sensors & Gateway
F_NAVIGATION_SYSTEMS_SOUNDER_DEPTH	130	Navigation systems	Sounder, depth
F_NAVIGATION_SYSTEMS	140	Navigation systems	(no specific function description)
AVIGATION_SYSTEMS_GLOBAL_NAVIGATION_SATELLITE_SYSTEM_GNSS	145	Navigation systems	Global Navigation Satellite System (GNSS)
F_NAVIGATION_SYSTEMS_LORAN_C	150	Navigation systems	Loran C

F_NAVIGATION_SYSTEMS_SPEED_SENSORS	150	Navigation systems	Speed Sensors
F_NAVIGATION_SYSTEMS_TURN_RATE_INDICATOR	160	Navigation systems	Turn Rate Indicator
F_NAVIGATION_SYSTEMS_INTEGRATED_NAVIGATION	170	Navigation systems	Integrated Navigation
F_NAVIGATION_SYSTEMS_RADAR_AND_OR_RADAR_PLOTTING	200	Navigation systems	Radar and/or Radar Plotting
TION_SYSTEMS_ELECTRONIC_CHART_DISPLAY_INFORMATION_SYSTEM_ECDIS	205	Navigation systems	Electronic Chart Display & Information System (ECDIS)
F_NAVIGATION_SYSTEMS_ELECTRONIC_CHART_SYSTEM_ECS	210	Navigation systems	Electronic Chart System (ECS)
F_NAVIGATION_SYSTEMS_DIRECTION_FINDER	220	Navigation systems	Direction Finder
UNICATIONS_SYSTEMS_EMERGENCY_POSITION_INDICATING_BEACON_EPIRB	130	Communications systems	Emergency Position Indicating Beacon (EPIRB)
COMMUNICATIONS_SYSTEMS_AUTOMATIC_IDENTIFICATION_SYSTEM	140	Communications systems	Automatic Identification System
F_COMMUNICATIONS_SYSTEMS_DIGITAL_SELECTIVE_CALLING_DSC	150	Communications systems	Digital Selective Calling (DSC)
F_COMMUNICATIONS_SYSTEMS_DATA_RECEIVER	160	Communications systems	Data Receiver
F_COMMUNICATIONS_SYSTEMS_SATELLITE	170	Communications systems	Satellite
F_COMMUNICATIONS_SYSTEMS_RADIO_TELEPHONE_MF_HF	180	Communications systems	Radio-Telephone (MF/HF)
F_COMMUNICATIONS_SYSTEMS_RADIO_TELEPHONE_VHF	190	Communications systems	Radio-Telephone (VHF)
F_INSTRUMENTATION_GENERAL_TIME_DATE_SYSTEMS	139	Instrumentation/general systems	Time/Date systems
F_INSTRUMENTATION_GENERAL_VOYAGE_DATA_RECORDER	140	Instrumentation/general systems	Voyage Data Recorder
F_INSTRUMENTATION_GENERAL_INTEGRATED_INSTRUMENTATION	155	Instrumentation/general systems	Integrated Instrumentation
F_INSTRUMENTATION_GENERAL_GENERAL_PURPOSE_DISPLAYS	165	Instrumentation/general systems	General Purpose Displays
F_INSTRUMENTATION_GENERAL_GENERAL_SENSOR_BOX	170	Instrumentation/general systems	General Sensor Box
F_INSTRUMENTATION_GENERAL_WEATHER_INSTRUMENTS	180	Instrumentation/general systems	Weather Instruments
F_INSTRUMENTATION_GENERAL_TRANSDUCER_GENERAL	190	Instrumentation/general systems	Transducer/general
F_INSTRUMENTATION_GENERAL_NMEA_0183_CONVERTER	200	Instrumentation/general systems	NMEA 0183 Converter
F_ENVIRONMENTAL_HVAC_NOT_AVAILABLE	255	Environmental (HVAC) systems	Not Available
F_DECK_CARGO_FISHING_NOT_AVAILABLE	255	Deck, cargo, and fishing equipment systems	Not Available

Adapters

None.

Functionality

This global constant list provides a centralized set of function identifiers for Industry Group 4 (IG4) as defined in the ISO 11783 / ISOBUS standard. Each constant assigns a unique numeric value (BYTE) to a specific function within a system category. These constants are used in parameter group numbers (PGNs) to identify the source or purpose of a message, enabling correct routing and interpretation of data across the network.

Technical Features

- All constants are of type `BYTE` and defined as global constants.
- Values range from 128 to 255, with `255` commonly used for "Not Available".
- The constants are grouped logically by system (e.g., Propulsion systems, Navigation systems, etc.).
- The list is intended to be used as a reference for mapping function codes in ISOBUS networks.

State Overview

Not applicable. This is a constant definition, not a stateful block.

Application Scenarios

- Referencing function codes when constructing or parsing ISOBUS messages.
- Assigning a function ID to an ECU in a network configuration.
- Ensuring consistent naming and values across multiple function blocks and applications.

Comparison with Similar Blocks

This is not a typical function block but a global constant list. Similar lists exist for other industry groups (e.g., IG1, IG2, IG3, IG5) that define their own specific functions. The structure and usage are analogous, but the actual function codes and system categories differ per industry group.

Conclusion

The IG4_NAME_Functions global constant list is an essential resource for developers working with ISOBUS networks in the marine and heavy-duty vehicle domain. It standardizes function identification, improving interoperability and maintainability of industrial control applications.

IG4_Source_Addresses

• – ◦ • – ◦ • – ◦ •

Introduction

IG4_Source_Addresses is a global constant definition block within the **isobus::pgn::const** package, providing standardized ISOBUS (ISO 11783) source address constants for **Industry Group 4** (Marine applications). It defines 22 named constants covering reserved address ranges and assigned device addresses for marine engine systems, displays, transmissions, and propulsion sensor gateways. These constants are used as symbolic references instead of raw numeric values, improving code readability and maintainability in ISOBUS-based applications targeting marine powertrain and monitoring equipment.

Interface Structure

This element is a **GlobalConstants** container, not a standard function block. It does not expose any event, data, or adapter ports. Instead, it publishes named constants that can be referenced globally within the application project.

Event Inputs

None. Constants blocks do not have event inputs.

Event Outputs

None. Constants blocks do not have event outputs.

Data Inputs

None. The values are statically defined at compile time.

Data Outputs

None. The values are statically defined at compile time.

Adapters

None. This block does not contain adapters.

The following table lists all defined constants (all of type `BYTE`):

Constant Name	Value	Description
`SA_RESERVED_128`	128	Reserved (128–207) for dynamic address assignment
`SA_RESERVED_208`	208	Reserved (208–227) for individual preassigned addresses
`SA_PROPULSION_SENSOR_HUB_GATEWAY_1`	228	Propulsion Sensor Hub & Gateway #1
`SA_PROPULSION_SENSOR_HUB_GATEWAY_2`	229	Propulsion Sensor Hub & Gateway #2
`SA_PROPULSION_SENSOR_HUB_GATEWAY_3`	230	Propulsion Sensor Hub & Gateway #3
`SA_PROPULSION_SENSOR_HUB_GATEWAY_4`	231	Propulsion Sensor Hub & Gateway #4
`SA_TRANSMISSION_3`	232	Transmission ECU #3
`SA_TRANSMISSION_4`	233	Transmission ECU #4
`SA_TRANSMISSION_5`	234	Transmission ECU #5
`SA_TRANSMISSION_6`	235	Transmission ECU #6
`SA_DISPLAY_1_FOR_PROTECTION_SYSTEM_FOR_MARINE_ENGINES`	236	Display #1 for Marine Engine Protection System
`SA_PROTECTION_SYSTEM_FOR_MARINE_ENGINES`	237	Protection System ECU for Marine Engines
`SA_ALARM_SYSTEM_CONTROL_1_FOR_MARINE_ENGINES`	238	Alarm System Control #1 for Marine Engines
`SA_ENGINE_3`	239	Engine ECU #3
`SA_ENGINE_4`	240	Engine ECU #4
`SA_ENGINE_5`	241	Engine ECU #5
`SA_MARINE_DISPLAY_1`	242	Marine Display #1
`SA_MARINE_DISPLAY_2`	243	Marine Display #2
`SA_MARINE_DISPLAY_3`	244	Marine Display #3
`SA_MARINE_DISPLAY_4`	245	Marine Display #4
`SA_MARINE_DISPLAY_5`	246	Marine Display #5
`SA_MARINE_DISPLAY_6`	247	Marine Display #6

Functionality

The constant set implements the ISOBUS source address scheme for Industry Group 4. It covers:

- **Reserved ranges** (128–207 and 208–227) that are kept available for SAE future assignments, distinguishing between dynamically self-configurable addresses and individually preassigned addresses.
- **Propulsion sensor hub gateways** (228–231) for up to four sensor hub/gateway devices.
- **Transmission ECUs** (232–235) for the third through sixth transmission in a multi-transmission marine propulsion system. The first two transmissions are typically defined in other Industry Group constant sets.
- **Marine engine protection and alarm systems** (236–238), including a dedicated display for the protection system.
- **Engine ECUs** (239–241) for engines #3 through #5. Engines #1 and #2 use addresses from lower Industry Group ranges (as defined by the ISOBUS standard).
- **Marine displays** (242–247) for up to six display devices.

Technical Features

- All constants are of type `BYTE` with initial values within the 0–255 range, matching the single-byte address field of ISOBUS (ISO 11783) and SAE J1939.
- The constants are declared as `VAR_GLOBAL CONSTANT`, making them immutable and globally accessible across all function blocks in the project.
- Naming follows a descriptive `SA_` prefix convention, directly mapping the symbolic name to the numeric source address, eliminating the need to memorize raw address values.
- The block is part of the `isobus::pgn::const` package, providing a modular namespace for ISOBUS-related constants.

State Overview

This is a passive data container. It has no runtime state, no internal algorithms, and no transition logic. The values are fixed at compile time and remain constant during execution. Therefore, no state machine or operational states apply.

Application Scenarios

- **Marine engine monitoring systems** – determining the correct source address for engine ECUs when configuring a J1939/ISOBUS network with multiple engines.
- **Multi-transmission marine propulsion control** – assigning addresses for the third through sixth transmission ECUs.
- **Alarm and protection systems** – configuring alarm system control units, protection system displays, and the protection system ECU itself.
- **Display integration** – addressing up to six marine displays on the same bus.
- **Development and test setups** – using the reserved constants to validate dynamic address assignment logic or preconfigured address allocation.

Comparison with Similar Blocks

Aspect	IG4_Source_Addresses	IG0/IG1/IG2/IG3 Source Address Sets
Industry Group	4 (Marine)	0–3 (Other equipment classes)
Address range	128–247 (partially, with gaps)	Varies per group
Content focus	Marine engines, transmissions, displays, protection systems	Agriculture, construction, forestry, etc.
Reserved addresses	128–227 (two separate ranges)	Group-specific

The structure of this constant set follows the same pattern as other Industry Group source address blocks in the `isobus::pgn::const` package. The main difference is the specific device types and the address ranges assigned by the ISOBUS standard for marine applications.

Conclusion

IG4_Source_Addresses provides a complete, standardized set of source address constants for ISOBUS marine applications. It eliminates hard-coded numeric addresses, reduces configuration errors, and ensures compliance with the ISOBUS address allocation scheme. By using these constants in PGN construction and network filtering logic, developers can reliably build interoperable marine powertrain and monitoring systems. The block is particularly useful when a marine bus contains multiple engines, transmissions, sensor hubs, or displays that must be uniquely addressed without conflicts.

IG5_Device_Classes

• – ◦ • – ◦ • – ◦ •

Introduction

The **IG5_Device_Classes** global constants type defines device class identifiers for the Industry Group 5 (IG5) within the ISOBUS protocol. These constants are used to specify the type of vehicle system or equipment in a J1939 network, particularly for industrial-process control stationary applications (e.g., generator sets). The type is part of the `isobus.pgn.const` package and provides named values for the raw BYTE codes that appear in PGNs.

Interface Structure

This type does not represent a typical function block with event or data inputs/outputs. Instead, it declares global constants that can be referenced throughout a 4diac application. The following subsections list the standard interface elements.

Event Inputs

None.

Event Outputs

None.

Data Inputs

None.

Data Outputs

None.

Adapters

None.

Functionality

The **IG5_Device_Classes** type defines two constants:

Constant Name	Value (BYTE)	Description
`DC_INDUSTRIAL_GEN_SET`	`0`	Device class for industrial-process control stationary (generator sets).
`DC_NOT_AVAILABLE`	`127`	Indicates that the device class is not available.

These constants are intended to be used in contexts where a device class needs to be identified in compliance with ISOBUS Industry Group 5 specifications. They help ensure consistent naming and avoid magic numbers in application logic.

Technical Features

- **Type**: Defined as `BYTE` (8-bit unsigned integer), matching the J1939 data size.
- **Package**: `isobus.pgn.const` – grouped with other PGN-related constants.
- **Scope**: Global constants, accessible from any function block within the project.
- **Naming Convention**: Prefix `DC_` (Device Class) followed by a descriptive suffix.
- **Values**: Standardized according to ISOBUS definitions; `0` for generator sets, `127` for "not available".

State Overview

Not applicable – this type does not define any state machines or behavioral states. It solely provides constant values.

Application Scenarios

- **Generator Set Monitoring**: When building an application that reads or writes the device class from a J1939 message, use `DC_INDUSTRIAL_GEN_SET` to identify the device as a stationary generator set.
- **Fallback Handling**: Use `DC_NOT_AVAILABLE` to represent an unknown or uninitialized device class, facilitating error handling or default scenarios.
- **Protocol Compliance**: Referencing these constants ensures that your application adheres to the ISOBUS Industry Group 5 naming and value conventions, improving interoperability.

Comparison with Similar Blocks

Since **IG5_Device_Classes** is a global constant type, it can be compared to other constant types that define device classes for different industry groups (e.g., IG1, IG2). Those would follow a similar pattern but with different value sets and package names. Unlike function blocks or adapters, this type has no runtime behavior; it only provides compile-time constants.

Conclusion

The **IG5_Device_Classes** global constants type offers a clean, portable way to reference Industry Group 5 device class codes in 4diac applications. By using these named constants, developers can avoid hard-coding numeric values, increase code readability, and align with ISOBUS standards. Its simplicity and clear documentation make it a valuable asset for any project dealing with vehicle systems or industrial-process control equipment.

IG5_NAME_Functions

• – ◦ • – ◦ • – ◦ •

Introduction

This document describes the **IG5_NAME_Functions** global constant set, which defines Industry Group 5 (IG5) specific function codes for ISOBUS (ISO 11783) implementation. These constants are used to identify the function of devices and components within the "Industrial-Process Control - Stationary (Gen-Sets)" system category, as well as a general "Not Available" placeholder. The constant set provides a standardized naming convention for referencing these function codes in control logic and data mapping.

Interface Structure

Since **IG5_NAME_Functions** is a global constant definition, it does not contain event inputs, event outputs, data inputs, data outputs, or adapters. It exposes a set of named `BYTE` constants that can be referenced in IEC 61499 applications or 4diac-IDE projects.

Event Inputs

Not applicable – this global constant set does not process events.

Event Outputs

Not applicable – this global constant set does not generate events.

Data Inputs

Not applicable – this global constant set does not have data inputs.

Data Outputs

Not applicable – this global constant set does not have data outputs.

Adapters

Not applicable – this global constant set does not include adapters.

Functionality

The purpose of this global constant set is to provide symbolic names for function codes defined by the ISOBUS Industry Group 5 specification. These codes are used to describe the role or operation of a device connected to an ISOBUS network. By using the constants, applications can avoid hard-coded numeric values and improve readability and maintainability.

The constants defined in this set are:

Constant Name	Value	Description
F_INDUSTRIAL_GEN_SET_SUPPLEMENTAL_ENGINE_CONTROL_SENSING	128	Reserved for supplemental engine control sensing in gen-sets.
F_INDUSTRIAL_GEN_SET_GENERATOR_SET_CONTROLLER	129	Generator set controller for collecting data and controlling the generator.
F_INDUSTRIAL_GEN_SET_GENERATOR_VOLTAGE_REGULATOR	130	Generator voltage regulator for maintaining output voltage.
F_INDUSTRIAL_GEN_SET_CHOKE_ACTUATOR	131	Choke actuator for controlling air flow on a gas engine.
F_WELL_STIMULATION_PUMP	132	Well stimulation pump used in oil and gas drilling applications.

F_INDUSTRIAL_GEN_SET_NOT_AVAILABLE	255	Placeholder for gen-set function when no explicit function is assigned.
F_NOT_AVAILABLE	255	General placeholder for any device whose function is not yet defined.

These constants are used to populate the Function field in ISOBUS parameter groups (PGNs) that transmit device information or operational status.

Technical Features

- **Data Type**: All constants are of type BYTE (8-bit unsigned integer).
- **Compatibility**: The values correspond to the ISO 11783-6 standard for function codes in the industrial/process control domain.
- **Naming Convention**: Each constant follows the pattern F_<SYSTEM>_<FUNCTION> to clearly indicate its intended application area.
- **Reusability**: The constants can be directly referenced in IEC 61499 function block implementations, ST (Structured Text) algorithms, or any other 4diac-IDE programming interface.
- **Documentation**: Each constant carries an inline comment that describes its system and function context.

State Overview

This global constant set does not have a state machine; it defines static values that remain unchanged during runtime. No state transitions, initialization sequences, or internal states are applicable.

Application Scenarios

The IG5_NAME_Functions global constants are typically used in automation projects that involve:

- **Generator Set Control**: Applications monitoring and controlling stationary diesel/gas generator sets used for emergency power or continuous operation.
- **ISOBUS Communication**: Systems that implement ISOBUS PGNs to exchange device function information, such as the "Name" object or function-specific parameters.
- **Oil & Gas Drilling**: Integration of well stimulation pumps that communicate their operational parameters over an ISOBUS network.
- **Device Identification**: Assigning function codes to allow a central controller (e.g., a generator set controller) to identify the type and role of connected peripherals.

In 4diac-IDE, these constants can be imported into a project and used alongside function blocks that require a BYTE input for function selection or reporting.

Comparison with Similar Blocks

Since this is a global constant definition rather than a function block, there is no direct comparison to FB types. However, similar constant sets exist for other Industry Groups (e.g., IG1–IG4, IG6) in the ISOBUS standard. The key difference is the set of specific functions defined for gen-set and oil/gas applications in IG5. If an application requires a different industry group, a corresponding global constant set must be used. This set provides the necessary values for typical IG5 equipment but does not include function codes for other domains.

Conclusion

The IG5_NAME_Functions global constants offer a clean and standardized way to reference ISOBUS function codes for industrial gen-sets and related equipment. By using these constants, developers can ensure compatibility with the ISO 11783 standard, reduce the risk of data misinterpretation, and make their control logic more readable and maintainable. The set covers the most common functions in this domain and provides a universal "Not Available" fallback, making it a practical resource for ISOBUS-based automation projects.

IG5_Source_Addresses

• – ◦ • – ◦ • – ◦ •

Introduction

The **IG5_Source_Addresses** type is a global constants definition set used in the 4diac IDE environment. It provides a collection of predefined ISO 11783 (ISOBUS) Industry Group 5 source addresses (SA). These

constants are employed to uniquely identify electronic control units (ECUs) on a CAN bus network in agricultural and forestry machinery applications, following the SAE J1939 / ISOBUS protocol.

The constants are declared as `BYTE` values and cover the source address range from 128 to 247, which is assigned to various engine, generator, and supplemental sensor processing units within Industry Group 5.

Interface Structure

Event Inputs

Not applicable – this is a global constants type and does not contain any event inputs.

Event Outputs

Not applicable – this is a global constants type and does not contain any event outputs.

Data Inputs

Not applicable – this is a global constants type and does not contain any data inputs.

Data Outputs

Not applicable – the type exports constant values that are globally accessible, but they are not dynamic data outputs of a function block.

Global Constants

The following table lists all constant declarations provided by this type:

Constant Name	Type	Value (decimal)	Description
`SA_RESERVED_128`	BYTE	128	Reserved range (128–207) for future SAE assignment – used for dynamic address assignment
`SA_RESERVED_208`	BYTE	208	Reserved range (208–229) for future assignment – used for individual preassigned addresses
`SA_GENERATOR_VOLTAGE_REGULATOR`	BYTE	230	Generator Voltage Regulator – controls generator output voltage
`SA_ENGINE_3`	BYTE	231	Engine #3 – ECU for the third engine within a system
`SA_ENGINE_4`	BYTE	232	Engine #4 – ECU for the fourth engine within a system
`SA_ENGINE_5`	BYTE	233	Engine #5 – ECU for the fifth engine within a system
`SA_GENERATOR_SET_CONTROLLER`	BYTE	234	Generator Set Controller – used for data collection and control of a generator system
`SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_1`	BYTE	235	Supplemental Sensor Processing Unit #1
`SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_2`	BYTE	236	Supplemental Sensor Processing Unit #2
`SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_3`	BYTE	237	Supplemental Sensor Processing Unit #3
`SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_4`	BYTE	238	Supplemental Sensor Processing Unit #4
`SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_5`	BYTE	239	Supplemental Sensor Processing Unit #5

SA_SUPPLEMENTAL_SENSOR_PROCESSING_UNIT_6	BYTE	240	Supplemental Sensor Processing Unit #6
SA_ENGINE_MONITOR_1	BYTE	241	Engine Monitor #1
SA_ENGINE_MONITOR_2	BYTE	242	Engine Monitor #2
SA_ENGINE_MONITOR_3	BYTE	243	Engine Monitor #3
SA_ENGINE_MONITOR_4	BYTE	244	Engine Monitor #4
SA_ENGINE_MONITOR_5	BYTE	245	Engine Monitor #5
SA_ENGINE_MONITOR_6	BYTE	246	Engine Monitor #6
SA_ENGINE_MONITOR_7	BYTE	247	Engine Monitor #7

Functionality

This global constants type centralizes all Industry Group 5 source addresses in one location. By referencing these named constants, applications and function blocks can avoid hard-coded numeric CAN identifiers, making the system configuration more readable, maintainable, and less error-prone. Each constant corresponds to a specific SA value defined by the ISOBUS/J1939 standard for a particular ECU function. The constants are designed to be used in network layer logic, address claiming procedures, and PGN (Parameter Group Number) filtering within ISOBUS applications.

Technical Features

- **Data Type:** All constants are of type `BYTE` (8-bit unsigned integer), fitting the SA range of 0–255 as defined in the J1939 standard.
- **Address Range:** The defined values cover the Industry Group 5 range (128–247), including reserved addresses, generator-related units, and engine monitoring ECUs.
- **Global Accessibility:** As a `GLOBALCONSTANTS` type, the constants are globally visible throughout the 4diac project once instantiated, enabling consistent use across multiple function blocks and applications.
- **Read-Only:** The constants are immutable; their values cannot be changed at runtime.
- **Standard Compliance:** Values follow the SAE J1939 / ISO 11783 source address assignments for Industry Group 5, ensuring protocol interoperability.

State Overview

Not applicable – this is a global constants type without any internal state machine or runtime behavior. It provides static values only.

Application Scenarios

- **ISOBUS Network Configuration:** Use these constants when configuring the source address (SA) for an ECU in a tractor or implement network.
- **Address Claiming Logic:** Reference the constants in function blocks that perform dynamic address claiming to ensure the correct SA is used for a specific device type.
- **CAN Message Filtering:** Use the constants to filter incoming messages based on the source address of the transmitting ECU.
- **Multi-Engine Systems:** Assign the correct engine SA (e.g., `SA_ENGINE_3`, `SA_ENGINE_4`) when managing multiple engine ECUs on the same bus.
- **Generator Monitoring:** Refer to `SA_GENERATOR_VOLTAGE_REGULATOR` and `SA_GENERATOR_SET_CONTROLLER` to identify generator-related messages.
- **Engine Diagnostics:** Use `SA_ENGINE_MONITOR_1` through `SA_ENGINE_MONITOR_7` to distinguish between up to seven engine monitoring units.

Comparison with Similar Blocks

Unlike function blocks (FBs) or adapters, `IG5_Source_Addresses` is a global constants type, meaning it has no event processing, no execution states, and no data flow. Its purpose is purely declarative. Compared to locally declared variables inside a function block, this global constants type offers:

- **Reusability:** Defined once and used across many FBs and applications.
- **Maintainability:** Updating a constant value in one location propagates to all references.

- **Safety:** Prevents accidental modification during runtime.
- **Standardization:** Enforces consistent naming and values across the entire project.

Other global constants types may exist for other industry groups (e.g., IG1–IG4), but this one is specifically scoped to Industry Group 5, avoiding naming clashes and keeping the address space organized.

Conclusion

The `IG5_Source_Addresses` global constants type provides a clean, standardized way to manage ISO 11783 Industry Group 5 source addresses in a 4diac project. Its fixed, well-documented constant set simplifies development of ISOBUS-compliant applications, improves code readability, and ensures that source addresses are always used consistently across distributed function blocks. It is an essential building block for any agricultural or forestry machinery control system operating on an ISOBUS/CAN network.

Industry_Groups

• – ◦ • – ◦ • – ◦ •

Introduction

This is a global constants group in the 4diac IDE, part of the ISOBUS library. It defines 8 industry group identifiers used in ISOBUS parameter group numbers (PGNs). These constants are of type BYTE and range from 0 to 7, representing different industrial sectors such as agricultural, construction, marine, etc.

Interface Structure

As a GlobalConstants type, it has no event inputs, event outputs, data inputs, data outputs, or adapters. Instead, it provides a set of global constants that can be referenced by other function blocks. The defined constants are listed below:

Constant Name	Type	Initial Value	Comment
IG_GLOBAL	BYTE	0	Industry Group: Global, applies to all
IG_ON_HIGHWAY_EQUIPMENT	BYTE	1	Industry Group: On-Highway Equipment
IG_AGRICULTURAL_AND_FORESTRY_EQUIPMENT	BYTE	2	Industry Group: Agricultural and Forestry Equipment
IG_CONSTRUCTION_EQUIPMENT	BYTE	3	Industry Group: Construction Equipment
IG_MARINE	BYTE	4	Industry Group: Marine
IG_INDUSTRIAL_PROCESS_CONTROL_STATIONARY	BYTE	5	Industry Group: Industrial-Process Control-Stationary (Gen-Sets)
IG_RESERVED_FOR_FUTURE_ASSIGNMENT_BY_SAE	BYTE	6	Industry Group: Reserved for future assignment by SAE
IG_RESERVED_FOR_FUTURE_ASSIGNMENT_BY_SAE_7	BYTE	7	Industry Group: Reserved for future assignment by SAE

Event Inputs

No event inputs are defined.

Event Outputs

No event outputs are defined.

Data Inputs

No data inputs are defined.

Data Outputs

No data outputs are defined.

Adapters

No adapters are defined.

Functionality

The constants defined in this group are used to identify the industry group in ISOBUS PGNs. Each PGN includes a 3-bit industry group field that determines the applicable scope for the message. By using these named constants, application developers can avoid magic numbers and improve code readability and maintainability.

Technical Features

- All constants are of type BYTE and are declared as global constants.
- Values range from 0 to 7, with 6 and 7 reserved for future assignment by SAE.
- The constants are compiled into the package `isobus::pgn::const`, making them accessible across the entire ISOBUS library.

State Overview

Not applicable; this is a constant definition type and does not contain state machines or behavior.

Application Scenarios

These constants are primarily used in the development of ISOBUS-compliant agricultural, construction, and forestry machinery control systems. They are typically referenced when constructing or parsing PGNs to set or interpret the industry group field. For example, an ECU in an agricultural tractor would use `IG_AGRICULTURAL_AND_FORESTRY_EQUIPMENT` (value 2) when sending PGNs.

Comparison with Similar Blocks

Similar global constants groups exist for other ISOBUS enumerations, such as protocol versions, function codes, or address claims. This particular group focuses specifically on industry group identification, making it distinct from other constant sets. Unlike function blocks, it does not provide any processing logic but merely a repository of standard constants.

Conclusion

The `Industry_Groups` global constants group is an essential building block for ISOBUS application development, providing well-defined and standardized identifiers for industry sectors. Its use enhances code clarity and ensures compliance with the ISOBUS standard.

Manufacturer_IDs

• – ○ • – ○ • – ○ •

Introduction

This document describes the **Manufacturer_IDs** global constant set from the ISOBUS protocol library. It defines a comprehensive catalog of numeric identifiers for manufacturers as specified by the ISO 11783 (ISOBUS) standard. These constants are used to unambiguously identify the manufacturer of an electronic control unit (ECU) in parameter group numbers (PGNs) and other ISOBUS messages.

Interface Structure

Since this is a global constant set, it does not have a traditional function block interface with event or data inputs/outputs. Instead, it exposes a large number of named constants, each of type `UINT` (unsigned 16-bit integer), that can be referenced by name in any IEC 61499 application.

Event Inputs

None – this is a data-only constant set.

Event Outputs

None – no event triggers are generated.

Data Inputs

None – constants are read-only and cannot be altered at runtime.

Data Outputs

Each constant acts as an implicit data output. All constants are of type `UINT` and are accessible by their symbol name (e.g., `M_CATERPILLAR`). The set includes over 1,600 named manufacturers, each with a unique value. A few examples are listed below:

Constant Name	Value	Description
`M_FOR_EXPERIMENTAL_OR_DEVELOPMENTAL_USE_ONLY`	0	Reserved for experimental use.
`M_BENDIX_COMMERCIAL_VEHICLE_SYSTEMS`	1	Bendix Commercial Vehicle Systems.
`M_ALLISON_TRANSMISSION`	2	Allison Transmission, Inc.
`M_CATERPILLAR`	8	Caterpillar Inc.
`M_DEERE_AND_COMPANY_PRECISION_FARMING`	12	Deere & Company, Precision Farming.
`M_AGCO`	102	AGCO (formerly AGCO GmbH & Co.).
`M_CNH_INDUSTRIAL_N_V`	94	CNH Industrial N.V.
`M_RAVEN_INDUSTRIES`	151	Raven Industries, Inc.
`M_TRIMBLE`	1856	Trimble Navigation.

The full list is defined in the XML source and includes entries from international manufacturers across agriculture, construction, marine, and automotive sectors.

Adapters

None – this set does not provide adapter interfaces.

Functionality

The primary purpose of these constants is to provide a standardized, human-readable way to refer to manufacturer identification codes in ISOBUS applications. When constructing or parsing ISOBUS messages, developers can reference these constants instead of memorizing numeric codes. The constants are defined with the prefix `M_` for easy identification in code.

Technical Features

- **Data Type:** All constants are of type `UINT` (16-bit unsigned integer), matching the ISO 11783 manufacturer ID field width.
- **Total Count:** Over 1,600 distinct manufacturer entries, including some reserved or unused codes (e.g., `M_UNUSED_64`, `M_UNUSED_76`, `M_UNUSED_228`).
- **Versioning:** The set is versioned; comments next to each constant indicate the date of last update or addition.
- **Global Scope:** As a global constant set, these values are available across all function blocks in an application without explicit wiring.
- **Read-Only:** The constants are declared as `CONSTANT` and cannot be modified during runtime.

State Overview

This constant set does not represent a state machine or dynamic behavior. It is static and immutable; all values are fixed at compile time. Therefore, no state transitions or runtime states exist.

Application Scenarios

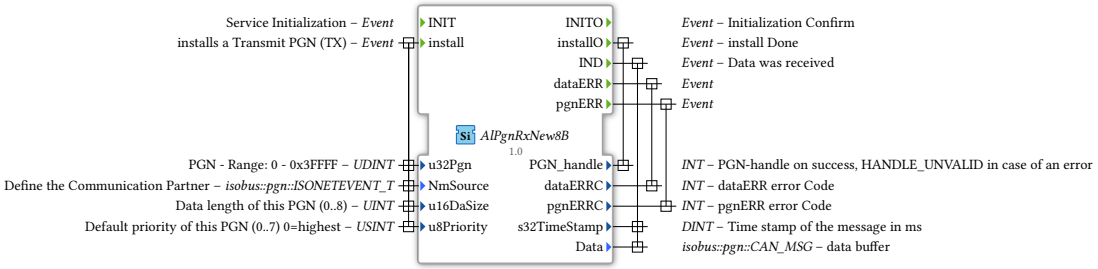
- **ISOBUS ECU Implementation:** When developing an ECU for agricultural or construction equipment, the manufacturer ID must be set according to the ISO 11783 specification. Using these constants ensures that the correct numeric value is used.
- **Message Filtering:** In a diagnostic tool or bus monitor, manufacturer IDs are used to filter or identify messages from specific ECUs. These constants can be used in comparison logic.
- **Configuration and Setup:** When configuring a virtual terminal or task controller, the manufacturer ID of the implement or tractor can be selected from this list.
- **Emulation and Testing:** For simulation or testing, the constant `M_FOR_EXPERIMENTAL_OR_DEVELOPMENTAL_USE_ONLY` (0) can be used to indicate a non-production device.

Comparison with Similar Blocks

This constant set is analogous to other global constant sets in the ISOBUS library, such as `PGN_Constants` or `SPN_Constants`. While those sets define parameter group numbers and suspect parameter numbers, `Manufacturer_IDs` focuses exclusively on manufacturer identification. The key difference is that manufacturer IDs are unique to each equipment manufacturer, while PGNs and SPNs are standardized by the ISOBUS protocol itself. This set is often referenced alongside PGN and SPN definitions to construct complete ISOBUS messages.

Conclusion

The `Manufacturer_IDs` global constant set provides a reliable and comprehensive reference for ISOBUS manufacturer identification. By encapsulating the numeric codes as named constants, it enhances code readability, reduces errors, and simplifies compliance with the ISO 11783 standard. Its use is recommended in any IEC 61499 application that interacts with ISOBUS networks.

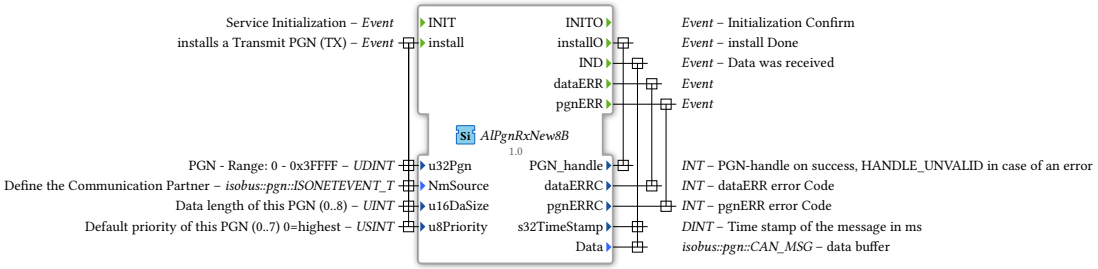


rx

AlPgnRxNew8B

• – ○ • – ○ • – ○ •

Introduction



The function block `AlPgnRxNew8B` is used to receive data via a CAN network according to the ISOBUS standard (ISO 11783). Its main purpose is the installation and management of Parameter Group Numbers (PGNs) for receiving messages and the provision of received data to the application. It is part of a specialized library for ISOBUS communication.

Interface Structure

Event Inputs

- **`INIT`**: Starts the initialization of the function block. Acknowledgement is provided via `INITO`.

* **`install`**: Triggers the installation of a new PGN to be received (Transmit PGN, TX). It expects the associated parameters `u32Pgn`, `NmSource`, `u16DaSize`, and `u8Priority`. Confirmation or the result is reported via `installO`.

Event Outputs

- **`INITO`**: Confirms the completion of initialization (`INIT`).
- **`installO`**: Reports the completion of an installation request. Returns the `PGN_handle` (positive on success, `HANDLE_UNVALID` in case of error).
- **`IND`**: Triggered when new data is received for an installed PGN. Returns the received `Data` and a timestamp `s32TimeStamp`.
- **`dataERR`**: Triggered in case of an error during data reception. Returns an error code `dataERRC`.

- **pgnERR**: Triggered in case of an error related to PGN management (e.g., installation). Returns an error code pgnERRC.

Data Inputs

- **u32Pgn** (UDINT): The Parameter Group Number (PGN) to be installed or monitored. Valid range: 0 to 0x3FFFF.
- **NmSource** (isobus::pgn::ISONETEVENT_T): Defines the communication partner (e.g., a specific node address or a broadcast).
- **u16DaSize** (UINT): The expected data length of the PGN in bytes (0-8).
- **u8Priority** (USINT): The default priority of this PGN (0-7), where 0 represents the highest priority. The initial value is 7 (lowest priority).
-

Data Outputs

- **PGN_handle** (INT): A handle (reference number) for the successfully installed PGN. In case of an error, it contains the value HANDLE_UNVALID.
- **dataERRC** (INT): Error code set when the dataERR event is triggered.
- **pgnERRC** (INT): Error code set when the pgnERR event is triggered.
- **s32TimeStamp** (DINT): Timestamp of the received message in milliseconds. Initial value is −1.
- – **Data** (isobus::pgn::CAN_MSG): The buffer containing the received CAN message data.

Adapter

This function block does not use any adapter interfaces.

Operation

1. **Initialization**: The INIT event makes the function block operational. Upon completion, INITO is triggered.
2. **PGN Installation**: One or more PGNs can be registered for reception via the install event. The block configures internal filters in the CAN stack based on the passed parameters (PGN, source, length, priority). The result (handle or error) is reported back via installO.
3. **Data Reception**: As soon as a message arrives for an installed PGN, the IND event is triggered. The received data (Data) and a timestamp (s32TimeStamp) are then available at the outputs.
4. **Error Handling**: If errors occur during reception (dataERR) or PGN management (pgnERR), the corresponding events are triggered with an error code.

Technical Specifications

- This block is designed to receive PGNs with a data length of up to 8 bytes (hence "8B" in the name).
- It uses specific ISOBUS data types (isobus::pgn::CAN_MSG, isobus::pgn::ISONETEVENT_T) that require integration into an ISOBUS-specific software stack.
- Error handling is divided into two separate channels: dataERR for runtime errors during reception and pgnERR for configuration errors.

State Overview

The block has implicit states:

- **Not Initialized**: Before the first INIT event.
- **Ready**: After successful initialization (INITO). Can receive install requests.
- **Active/Receiving**: After successful installation of at least one PGN. Can trigger IND events for received data.
- **Error**: When an error occurs (pgnERR or dataERR). Depending on the implementation, the block may remain in the error state or become functional again after the cause is resolved.

Application Scenarios

- **Agricultural Machinery Control**: Receiving implement data (e.g., seed drills, fertilizer spreaders) in a tractor's ISOBUS network.
- **Trailer Communication**: Receiving status information (brake pressure, lights, door contacts) from a smart trailer.

- **Implement Monitoring**: Receiving real-time data from sensors on an implement (e.g., seed flow, working width).

⚖️ Comparison with Similar Blocks

- **Generic CAN Receive Blocks**: Unlike generic `CAN_RX` blocks, which process raw CAN IDs and data, `AlPgnRxNew8B` abstracts ISOBUS-specific PGN addressing and management.
- **`E_SR` (Service Interface Function Block)**: While `E_SR` provides a generic server request pattern for services, `AlPgnRxNew8B` is specifically designed for the cyclic or event-driven reception of ISOBUS messages.
- **Blocks for Other Protocols**: Similar blocks exist for other higher-level protocols (e.g., J1939), but they differ in their specific addressing and message formats.
- **`E_SR` (Service Interface Function Block)**: While `E_SR` provides a generic server request pattern for services, `AlPgnRxNew8B` is specifically designed for the cyclic or event-driven reception of ISOBUS messages.
- **Blocks for Other Protocols**: Similar blocks exist for other higher-level protocols (e.g., J1939), but they differ in their specific addressing and message formats.
-

- Exercise_130
- Exercise_134

Conclusion

The `AlPgnRxNew8B` is an essential building block for developing ISOBUS-compatible receiver applications in the 4diac IDE. It encapsulates the complexity of PGN filtering and management and provides the application with a clean, event-driven interface for receiving CAN messages according to the ISO 11783 standard. Its clear separation of configuration (`install`), data transfer (`IND`), and error handling makes it robust and easy to integrate into higher-level control logic.

AlPgnRxNew8B_REQ

• – ○ • – ○ • – ○ •

Introduction

The function block `AlPgnRxNew8B_REQ` is used to request data via an ISOBUS network. It enables the installation of a receive parameter set (RX PGN) and the triggering of a one-time request for this parameter. The block is part of an ISOBUS-specific communication library and handles the interaction with the CAN network protocol according to ISO 11783.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block.
- **install**: Installs a receive parameter set (RX PGN) for subsequent data requests. Triggered with the data `u32Pgn`, `NmSource`, `u16DaSize`, and `u8Priority`.

- **REQ**: Triggers a one-time request for the previously installed RX PGN.

Event Outputs
- **INITO**: Confirms successful initialization.
- **installO**: Confirms successful installation of a PGN. Returns the assigned `PGN_handle`.
- **CNF**: Confirms successful transmission of the request to the network.
- **IND**: Triggered when the requested data message is received. Returns `Data` and `s32TimeStamp`.
- **dataERR**: Signals a data processing error. Returns the error code `dataERRC`.
- **pgnERR**: Signals an error in PGN processing (e.g., during installation). Returns the error code `pgnERRC`.

Data Inputs
- **u32Pgn** (UDINT): The parameter Group Number (PGN) in the range 0 to 0x3FFFF.
- **NmSource** (isobus::pgn::ISONETEVENT_T): Defines the communication partner in the network.
- **u16DaSize** (UINT): The expected data length of the PGN (0-8 bytes).
- **u8Priority** (USINT): The default priority of this PGN (0..7, where 0 is the highest priority). Initial value is 7.

Data Outputs
- **PGN_handle** (INT): A handle to identify the successfully installed PGN. In case of an error, an invalid handle value (`HANDLE_UNVALID`) is returned.
- **dataERRC** (INT): Error code set when the `dataERR` event is triggered.
- **pgnERRC** (INT): Error code set when the `pgnERR` event is triggered.
- **s32TimeStamp** (DINT): Timestamp of the received message in milliseconds. Initial value is −1.
- **Data** (isobus::pgn::CAN_MSG): The buffer containing the received CAN message data.

Adapter

This function block does not use any adapter interfaces.

Operation

The function block operates in two main phases: installation and request.

1. **Installation**: The `install` event configures the parameters for a PGN to be received (number, source, size, priority). The block registers this request in the underlying ISOBUS stack and returns a `PGN_handle` via `installO`. This handle is needed for later references.
2. **Request**: The `REQ` event triggers a one-time request for the most recently installed PGN on the network. After successful transmission of the request, `CNF` is triggered. When the requested message arrives from the defined `NmSource`, it is stored in the `Data` buffer and output along with a timestamp via the `IND` event.

Errors during installation (e.g., invalid PGN) result in the `pgnERR` output. Errors during data reception or processing result in the `dataERR` output.

Technical Specifications
- This block is designed to process PGNs with a data length of up to 8 bytes (`u16DaSize` 0..8).
- Priority management (`u8Priority`) follows the ISOBUS standard.
- Data is provided in a type-safe buffer (`CAN_MSG`).
- Error handling is structured via dedicated event outputs (`pgnERR`, `dataERR`).

Status Overview
1. **Not Initialized**: Before the first `INIT` event.
2. **Initialized / Ready**: After `INITO`. The block can receive `install` events.
3. **PGN Installed**: After successful `installO`. The block is ready to process `REQ` events.
4. **Request Pending**: After `REQ` and before `CNF`. The network request has been sent.
5. **Ready to Receive Data**: After `CNF`. The block is waiting for the incoming message and will trigger `IND` upon receipt.

Application Scenarios

Typical applications are in agricultural or mobile machinery control (ISO 11783 / ISOBUS):

- Querying machine parameters (e.g., speed, temperature) from an implement.
- Requesting configuration data once from a control unit on the network.

- Implementing diagnostic or service tools that need to query specific PGNs.

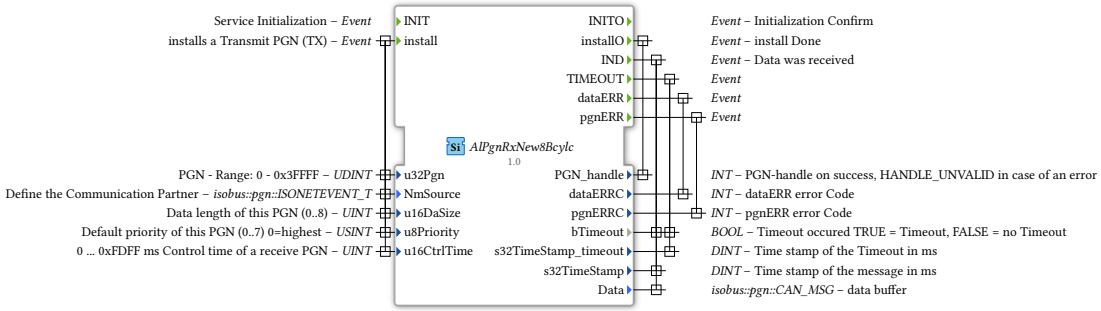
⚖️ Comparison with Similar Blocks

Compared to generic CAN receive blocks, `AlPgnRxNew8B_REQ` is specifically tailored to the ISOBUS protocol and its PGN concept. It abstracts the low-level CAN details (such as ID filtering) and provides a clean interface at the PGN level. Blocks like `E_CYCLE` or `E_DELAY` could be used to implement periodic requests, while `AlPgnRxNew8B_REQ` itself only handles single requests.

🛠️ Related Exercises

- Exercise_132

Conclusion



The `AlPgnRxNew8B_REQ` is a specialized function block for on-demand communication in ISOBUS networks. By separating installation (`install`) and execution (`REQ`), it enables flexible and controlled data requests. Its integrated error handling and type-safe data interface make it a robust component for demanding embedded controllers in agricultural technology.

AlPgnRxNew8Bcylc

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AlPgnRxNew8Bcylc` is used for the cyclical reception of data via an ISOBUS network according to the Parameter Group Number (PGN) protocol. It enables the configuration and monitoring of receive channels for specific PGNs, including the handling of timeouts and error conditions. The block is designed for use in control systems that require reliable and monitored communication with other ISOBUS devices.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block.
- **install**: Installs a new receive channel for a specific PGN. Triggers the configuration with the associated data inputs.

Event Outputs

- **INITO**: Confirms successful initialization.
- **installO**: Signals completion of an installation request. Returns the assigned `PGN_handle`.
- **IND**: Triggered when new data is received for the configured PGN.
- **TIMEOUT**: Signals that a timeout has occurred for the configured PGN.
- **dataERR**: Indicates an error in the received data.
- **pgnERR**: Indicates an error related to the PGN configuration or processing.

Data Inputs

- **u32Pgn** (UDINT): The parameter group number (PGN) to be received. Valid range: 0 to 0x3FFFF.
- **NmSource** (isobus::pgn::ISONETEVENT_T): Defines the communication partner (network management source).
- **u16DaSize** (UINT): The expected data size of the PGN in bytes (0..8).

- **u8Priority** (USINT): The default priority of this PGN (0..7, where 0 is the highest priority). Initial value: 7.
- **u16CtrlTime** (UINT): The control time (timeout time) for receiving this PGN in milliseconds (0 ... 0xFDFF ms). A value of 0 disables timeout monitoring.

Data Outputs

- **PGN_handle** (INT): A handle that identifies the successfully installed receive channel. In case of an error, `HANDLE_UNVALID` is output.
- **dataERRC** (INT): Error code set when the `dataERR` event is triggered.
- **pgnERRC** (INT): Error code set when the `pgnERR` event is triggered.
- **bTimeout** (BOOL): Indicates whether a timeout occurred (`TRUE` = timeout, `FALSE` = no timeout). Initial value: `FALSE`.
- **s32TimeStamp_timeout** (DINT): Timestamp of the timeout in milliseconds.
- **s32TimeStamp** (DINT): Timestamp of the last received message in milliseconds. Initial value: −1.
- **Data** (isobus::pgn::CAN_MSG): Buffer containing the received user data.

Adapters

This function block does not use adapters.

Operation

1. **Initialization**: The `INIT` event makes the function block operational. Confirmation is provided by `INITO`.
2. **Channel Configuration**: A receive channel is configured by the `install` event. The associated parameters (`u32Pgn`, `NmSource`, `u16DaSize`, `u8Priority`, `u16CtrlTime`) define the desired data stream. On successful completion, a unique `PGN_handle` event (`installO`) is returned. On failures, `pgnERR` or `dataERR` is triggered.
3. **Cyclic Reception**: Once a channel is installed, the block listens for messages from the configured PGN at the specified source. Upon receiving a valid message, the data is made available in the `Data` output, and the `IND` event is triggered. The `s32TimeStamp` event is then updated.
4. **Timeout Monitoring**: If `u16CtrlTime` > 0, the block monitors the time between received messages. If no new message is received within this time window, the `TIMEOUT` event is triggered, `bTimeout` is set to `TRUE`, and `s32TimeStamp_timeout` is updated.
5. **Error Handling**: Protocol errors or invalid configurations trigger the corresponding error events (`dataERR`, `pgnERR`) with their associated error codes.

Technical Features

- The block supports the specific data types `isobus::pgn::CAN_MSG` and `isobus::pgn::ISONETEVENT_T` from the ISOBUS PGN library.
- Timeout monitoring is optional and can be disabled by setting `u16CtrlTime` to 0.
- The `PGN_handle` serves as a reference for the installed channel and may be necessary for later management operations (e.g., uninstallation).

Status Overview

1. **Not Initialized**: After startup. Waiting for `INIT`.
2. **Ready**: After successful initialization (`INITO`). Can receive `install` requests.
3. **Ready to Receive (Channel Active)**: After successful installation of a channel (`installO`). Monitors the bus for the configured PGN and triggers `IND` upon receipt or `TIMEOUT` if the monitoring time is exceeded.
4. **Error State**: Signaled by the events `pgnERR` or `dataERR`. The exact error can be found in the respective error code. The block can usually be used again after the cause has been resolved.

Application Scenarios

- **Agricultural Machinery Control**: Receiving implement data (e.g., seed drill status) from an implement on the ISOBUS.
- **Vehicle Diagnostics**: Cyclic reception of engine data (RPM, temperature) for display and monitoring in the terminal.
- **Implement Control**: Receiving setpoint values (e.g., setpoint depth) from an operator console for a hydraulic lower link.

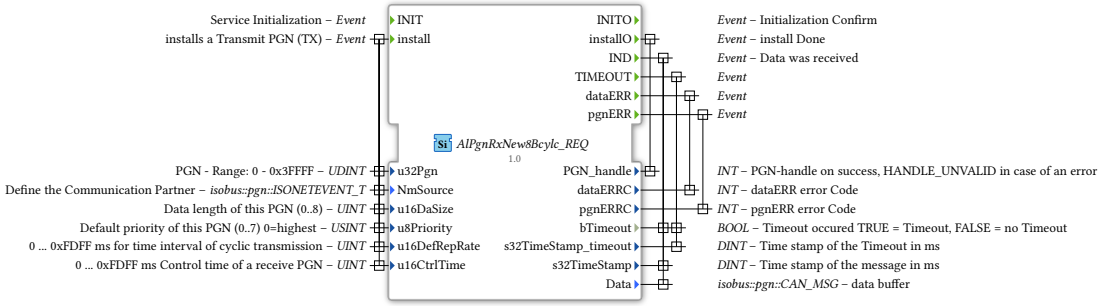
⚖️ Comparison with Similar Blocks

Unlike generic CAN receive blocks, `AlPgnRxNew8Bcylc` is specifically tailored to the ISOBUS PGN protocol. It offers higher abstraction through direct PGN addressing, integrated partner identification (`NmSource`), and automatic timeout management. Simple receive blocks would not provide this protocol layer and management functionality.

🛠️ Related Exercises

- Exercise_131

Conclusion



The `AlPgnRxNew8Bcylc` is an essential building block for robust ISOBUS applications that need to receive cyclic data from other network participants. Its integrated channel management, timing, and error detection features significantly simplify the development of reliable communication interfaces and relieve application developers of the burden of dealing with low-level protocol details.

AlPgnRxNew8Bcylc_REQ

• – ○ • – ○ • – ○ •

Introduction

The function block `AlPgnRxNew8Bcylc_REQ` is used for the cyclical request of data via a CAN network according to the ISOBUS standard (ISO 11783). Its main purpose is the installation and management of receive parameters for specific Parameter Group Numbers (PGNs). The block enables the configuration of cyclical receive and monitors the data flow by triggering corresponding events upon successful receive, timeouts, or errors.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block.
- **install**: Triggers the installation of a receive PGN (RX) with the associated configuration parameters. The data carried are: `u32Pgn`, `NmSource`, `u16DaSize`, `u8Priority`, `u16DefRepRate`, `u16CtrlTime`.

Event Outputs

- **INITO**: Confirms successful initialization.
- **installO**: Signals completion of the installation process. Includes `PGN_handle` as a result.
- **IND**: Triggered when new data is received. Includes `bTimeout`, `s32TimeStamp`, and `Data`. * **TIMEOUT**: Triggered on a control time timeout. Includes `bTimeout` and `s32TimeStamp_timeout`.
- **dataERR**: Indicates an error in the received data. Includes the error code `dataERRC`.
- **pgnERR**: Indicates an error in PGN processing. Includes the error code `pgnERRC`.

Data Inputs

- **u32Pgn** (UDINT): The parameter group number (PGN) to be received. Valid range: 0 to 0x3FFFF.
- **NmSource** (isobus::pgn::ISONETEVENT_T): Defines the communication partner (e.g., a specific node address).
- **u16DaSize** (UINT): The expected data size of the PGN in bytes (0..8).
- **u8Priority** (USINT): The default priority for this PGN (0..7, where 0 is the highest priority). Initial value: 7.

- **u16DefRepRate** (UINT): The expected cyclic transmission interval of the source PGN in milliseconds (0 … 0xFDFF ms).
- **u16CtrlTime** (UINT): The control time in milliseconds (0 … 0xFDFF ms), after which a `TIMEOUT` event is generated if no data is received.

Data Outputs

- **PGN_handle** (INT): A handle (identifier) for the successfully installed PGN. In case of an error, an invalid handle (HANDLE_UNVALID) is returned.
- **dataERRC** (INT): Error code returned for a `dataERR` event.
- **pgnERRC** (INT): Error code returned for a `pgnERR` event.
- **bTimeout** (BOOL): Status flag for a timeout. `TRUE` = timeout occurred, `FALSE` = no timeout. Initial value: `FALSE`.
- **s32TimeStamp_timeout** (DINT): Timestamp in milliseconds at which the timeout was detected.
- **s32TimeStamp** (DINT): Timestamp in milliseconds of the last received valid data record. Initial value: −1.
- **Data** (isobus::pgn::CAN_MSG): Buffer containing the received CAN message data.

Adapter

This function block does not use any adapter interfaces.

Operation

1. **Initialization**: The `INIT` event puts the block into a ready-to-use state, which is acknowledged by `INITO`.
2. **PGN Installation**: The `install` event configures a new receiving PGN. All necessary parameters (PGN, source, data length, etc.) are passed. Upon successful configuration, the block responds with `installO` and delivers a valid `PGN_handle`. Errors trigger either `pgnERR` or `dataERR`.
3. **Cyclic Reception**: After successful installation, the module monitors the CAN bus for messages of the configured PGN and source.
4. **Data Indication**: Upon receiving a valid message, the `IND` event is triggered. The data (`Data`), a timestamp (`s32TimeStamp`), and the timeout status (`bTimeout=FALSE`) are output.
5. **Timeout Monitoring**: If the time since the last received packet exceeds the configured `u16CtrlTime`, the `TIMEOUT` event is triggered. `bTimeout` is set to `TRUE`, and a timestamp (`s32TimeStamp_timeout`) is provided.
6. **Error Handling**: If protocol or data errors occur, the events `pgnERR` and `dataERR`, respectively, are generated with the corresponding error codes.

Technical Features

- This function block is specifically designed for use in ISOBUS environments (agricultural machinery) and utilizes type-safe data types from the `isobus::pgn` library (`CAN_MSG`, `ISONETEVENT_T`).
- Timeout monitoring (`u16CtrlTime`) is independent of the expected transmission interval (`u16DefRepRate`) and serves to enhance robustness by detecting failed communication partners.
- `PGN_handle` enables the unique identification and subsequent management (e.g., uninstallation) of a configured PGN instance within an application.

State Transition Overview

1. **Not Initialized**: After startup. Waiting for `INIT`.
2. **Ready**: After `INITO`. Can receive `install` requests.
3. **Installed**: After successful `installO`. Actively monitors the CAN bus for the configured PGN.

- On reception: Transitions to the “Data Available” state (triggers `IND`), then returns to “Installed”.
- On timeout: Triggers `TIMEOUT`, remains in the “Installed” state (continues monitoring).
- On error: Triggers `pgnERR`/`dataERR`, remains in the “Installed” state.

Application Scenarios

- **ISOBUS Implementations**: Receiving cyclic data (e.g., engine speed, pressure, position) from an electronic control unit (ECU) of an implement on the tractor.
- **Monitoring Functions**: Continuously checks whether a critical component (e.g., motor control) is still functioning and sending data (using `CtrlTime`).
- **Data Logger**: Cyclically collects process data from the CAN network for analysis or storage purposes.

⚖️ Comparison with Similar Blocks

- **E_CTU vs. AlPgnRxNew8Bcylc_REQ**: A simple counter (`E_CTU`) lacks network functionality. This block is a specialized, application-oriented communication block for a specific protocol (ISOBUS).
- **Generic CAN RX Blocks**: Unlike blocks that receive raw CAN IDs and data, this block operates at the higher, standardized PGN level of ISOBUS and handles protocol-specific decoding and parameter management.

🛠️ Related exercises

- Uebung_133

Conclusion

The `AlPgnRxNew8Bcylc_REQ`is an essential component for implementing ISOBUS-compliant receiver functionalities in 4diac. It abstracts the complexity of CAN communication and provides a clean, event-driven interface for reliable, cyclical data acquisition with integrated error and timeout detection. Its use increases the reusability and robustness of control applications in agricultural technology.

tx

AlPgnTxNew8B

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AlPgnTxNew8B` is used to send data over a CAN network according to the ISOBUS standard (ISO 11783). Its main purpose is to install and manage Parameter Group Numbers (PGNs) for transmission (TX) and subsequently send data packets as soon as a local transmit event (`REQ`) occurs. It is designed for applications that require unconfirmed data transmission.

Interface Structure

Event Inputs

- **`INIT`**: Starts the initialization of the function block.
- **`install`**: Triggers the installation of a new Transmit PGN (TX-PGN). The installation is configured using the data inputs linked via `With` (`u32Pgn`, `NmDestin`, `u16DaSize`, `u8Priority`).
- **`REQ`**: Triggers the transmission process for the previously installed PGN. The data to be transmitted is provided via the data input `Data`, which is linked to `With`.

Event Outputs

- **`INITO`**: Confirms successful completion of initialization (`INIT`).
- **`installO`**: Confirms completion of PGN installation. Returns a handle for the installed PGN or an error value via `PGN_handle`.
- **`CNF`**: Confirms that the data was sent successfully (response to `REQ`).
- **`dataERR`**: Indicates an error related to the data being sent (`Data`). Returns an error code via `dataERRC`.
- **`pgnERR`**: Indicates an error related to the PGN installation or usage. Returns an error code via `pgnERRC`.

Data Inputs

- **`u32Pgn`** (UDINT): The Parameter Group Number (PGN) to be installed. Valid range: 0 to 0x3FFFF (decimal 262143).
- **`NmDestin`** (isobus::pgn::ISONETEVENT_T): Defines the communication partner (e.g., broadcast, specific address).
- **`u16DaSize`** (UINT): The data length of the PGN in bytes. Valid range: 0 to 8.
- **`u8Priority`** (USINT): The priority of the message on the CAN bus. Range: 0 (highest) to 7 (lowest). Default value: 7.
- **`Data`** (isobus::pgn::CAN_MSG): The data to be sent, structured as a CAN message.

Data Outputs

- **`PGN_handle`** (INT): A handle (identifier) for the successfully installed PGN. In case of an error, the value `HANDLE_UNVALID` is output.
- **`dataERRC`** (INT): Numeric error code that is set when the `dataERR` event is triggered.
- **`pgnERRC`** (INT): Numeric error code set when the `pgnERR` event is triggered.

Adapter

This function block does not use any adapter interfaces.

Operation

1. **Initialization**: The `INIT` event puts the function block into an operational state. Confirmation is provided by `INITO`.
2. **PGN Installation**: The `install` event configures a specific PGN for data transmission. This sets the PGN number, destination address, data length, and priority. Upon success, `PGN_handle` is returned via `installO`. In case of an error (e.g., invalid parameters), the event `pgnERR` is triggered.
3. **Data Transmission**: As soon as a `REQ` event occurs, the block attempts to send the CAN message provided at the `Data` input using the previously installed PGN configuration. If successful, the `CNF` event is triggered. If an error occurs during transmission (e.g., invalid data), `dataERR` is triggered.

Technical Specifications

- The block is designed for transmitting data packets with a maximum length of 8 bytes (typical for classic CAN frames).
- It implements unacknowledged sending: A `CNF` error simply means that the message has been passed to the lower protocol layer for transmission, not necessarily that it has reached the receiver.
- Error handling is divided into two categories: PGN-related errors (`pgnERR`) and data-related errors (`dataERR`), which simplifies error diagnosis.
- The block uses specific ISOBUS data types (`isobus::pgn::CAN_MSG`, `isobus::pgn::ISONETEVENT_T`).

State Overview

The block implicitly goes through the following main states:

1. **Not Initialized**: After startup. Only the `INIT` input is active.
2. **Initialized / Ready**: After `INITO`. The block can now install PGNs (`install`).
3. **PGN Installed**: After successful `installO`. The block is ready to send data (`REQ`).
4. **Send Active**: During the processing of `REQ`. Transition to state 3 after `CNF` or to an error state after `dataERR`/`pgnERR`.

Application Scenarios

- **Agricultural Machinery Control (ISOBUS)**: Sending machine data (e.g., working speed, PTO speed) to a terminal or other control units in the tractor.
- **Commercial Vehicle Communication**: Transmission of vehicle data (e.g., torque, fuel consumption) within a truck bus system. * **Industrial Automation**: Sending control commands or status information via CAN networks in machines.

⚖️ Comparison with similar blocks

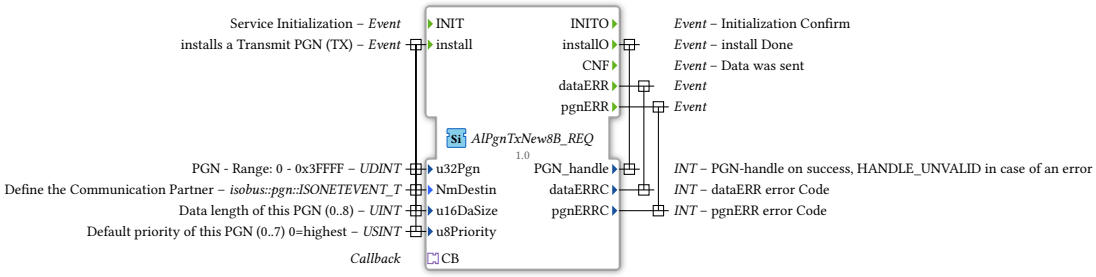
- **`E_SEND` (Standard 61499)**: A generic transmit block. `AlPgnTxNew8B` is specialized for ISOBUS/CAN with PGN management, prioritization, and destination addressing, while `E_SEND` is protocol-agnostic and requires an adapter connection.

- **Acknowledged Transmit Blocks**: `AlPgnTxNew8B` transmits unacknowledged (`CNF`). For acknowledged communication (request/response), other, more specific TX PGN blocks or protocol stacks would be required.

🛠️ Related Exercises

- Exercise_124
- Exercise_128

Conclusion



The `AlPgnTxNew8B` is a specialized function block for reliable, configurable, and unacknowledged data transmission in ISOBUS environments. Its clear separation of configuration (`install`) and operation (`REQ`), as well as its differentiated error feedback, makes it easily maintainable and simple to integrate into higher-level application logic. It is the first choice when CAN messages need to be sent according to the ISOBUS standard with a fixed PGN.

AlPgnTxNew8B_REQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AlPgnTxNew8B_REQ` is used to configure and control the transmission of parameter group numbers (PGNs) in an ISOBUS network (J1939). Its main purpose is to install a new transmit PGN (TX-PGN) in the network. The block responds to a REQ event (J1939 network event) and provides a callback interface for asynchronous feedback on the data transmission status. It is part of a specialized library for ISOBUS communication.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block. Must be triggered before first use.
- **install**: Triggers the installation of a new Transmit PGN (TX). The installation is configured with the data parameters bound to this event (`u32Pgn`, `NmDestin`, `u16DaSize`, `u8Priority`).

Event Outputs

- **INITO**: Confirms successful initialization of the function block.
- **installO**: Signals completion of the installation request. Returns the assigned `PGN_handle` or, in case of an error, an invalid handle.
- **CNF**: Confirms that data was successfully sent. Typically triggered via the callback adapter.
- **dataERR**: Indicates an error related to the data being sent. Returns an error code via `dataERRC`.
- **pgnERR**: Indicates an error related to PGN configuration or management. Returns an error code via `pgnERRC`.

Data Inputs

- **u32Pgn** (UDINT): The parameter group number (PGN) to be installed. Valid range: 0 to 0x3FFFF (decimal 262143).
- **NmDestin** (isobus::pgn::ISONETEVENT_T): Defines the communication partner (destination address) for the PGN. The exact type is defined by the ISOBUS library.
- **u16DaSize** (UINT): The length of the payload for this PGN in bytes. Valid range: 0 to 8.
- **u8Priority** (USINT): The default priority for this PGN. Valid range: 0 (highest) to 7 (lowest). Initial value: 7.

Data Outputs

- **PGN_handle** (INT): A handle (identifier) for the installed PGN. If the installation is successful, it contains a valid, positive value. In case of an error, an invalid handle (e.g., `HANDLE_UNVALID`) is output.
- **dataERRC** (INT): The specific error code when a `dataERR` event occurs.
- **pgnERRC** (INT): The specific error code when a `pgnERR` event occurs.

Adapter

- **CB** (Type: `isobus::pgn::tx::Callback`): A socket adapter that provides a callback interface. Asynchronous feedback (such as the `CNF` event) is reported from the underlying ISOBUS driver system to the function block via this adapter. The function block must be connected to a corresponding plug adapter to receive the feedback.

Operation

1. **Initialization**: First, the `INIT` event must be triggered to make the function block operational. This results in the output of `INITO`.
2. **PGN Installation**: The `install` event starts the configuration process. The function block passes the parameters `u32Pgn`, `NmDestin`, `u16DaSize`, and `u8Priority` to the ISOBUS protocol stack to register a new transmit PGN.
3. **Feedback**: After processing the installation request, the function block responds with the `installO` event and returns `PGN_handle`. This handle must be used for subsequent transmit operations (e.g., with a separate transmit function block).
4. **Asynchronous Operational Feedback**: During operation, when data is sent for the configured PGN, the acknowledgment (`CNF`) or error message (`dataERR`, `pgnERR`) is sent asynchronously via the respective event outputs. The triggering of the `CNF` event is typically controlled by the callback adapter (`CB`).

Technical Features

- This module is specific to ISOBUS/J1939 networks and uses type-safe data structures (`isobus::pgn::ISONETEVENT_T`).
- Error handling is divided into `dataERR` (data error) and `pgnERR` (PGN configuration error), enabling precise error diagnosis.
- Communication with the actual network stack occurs via a callback interface (`CB` adapter), which allows for loose coupling and asynchronous notification.
- `PGN_handle` serves as an abstract reference to the internally managed PGN instance.

State Overview

The component implicitly passes through the following main states:

1. **Not Initialized**: Before the first `INIT` event.
2. **Ready**: After successful initialization (`INITO` received). The function block can now receive `install` requests.
3. **Installation in progress**: After triggering `install`, the function block waits for a response from the protocol stack.
4. **Operational**: After successful `installO`, the PGN is registered in the stack and can be used for transmission. Asynchronous events (`CNF`, `dataERR`, `pgnERR`) can now occur.

Application Scenarios

- **Agricultural Machinery Control**: Integrating a new control unit into an ISOBUS network that needs to regularly send operating data (e.g., engine speed, temperature).
- **Implements**: Dynamic configuration of communication between a tractor and a specific implement that requires an individual PGN for its data.
- **Diagnostic Tools**: A diagnostic tool that temporarily installs a PGN on the network to request specific data or send commands.

⚖️ Comparison with Similar Blocks

- **`E_SEND` / `E_RCV` (Standard 61499)**: These generic communication blocks are protocol-independent. In contrast, `AlPgnTxNew8B_REQ` is specialized for ISOBUS/J1939 and handles the protocol-specific configuration (PGN, priority, destination address) that would have to be manually defined in the data parameters of the standard blocks.

- **Simple TX Blocks**: Other ISOBUS transmit blocks often expect a pre-configured `PGN_handle`. `AlPgnTxNew8B_REQ` is the upstream component that provides precisely this handle by installing a new PGN.

🛠️ Related Exercises

- Exercise_125

Conclusion

The `AlPgnTxNew8B_REQ` is an essential configuration component for ISOBUS communication in 4diac. It abstracts the complex setup of a transmitting PGN in a J1939 network behind a clear, event-driven interface. It separates installation (`install`/`installO`) from operation (`CNF`/`*ERR`).The use of a callback adapter makes it robust and easily integrated into larger control applications for mobile machine communication.

These features, along with the ability to use a callback adapter, make it robust and well-suited for integration into larger control applications for mobile machine communication.—

AlPgnTxNew8Bcycl

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AlPgnTxNew8Bcycl` is used for the cyclic transmission of data over a CAN network according to the ISOBUS standard (ISO 11783). Its main purpose is the installation, configuration, and regular transmission of Parameter Group Numbers (PGNs). It allows the definition of communication properties such as destination address, priority, and transmission interval, and ensures that data is transmitted reliably and at the configured frequency.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block.
- **install**: Installs a new PGN (TX) to be transmitted, along with its associated configuration data. Triggers the processing of the included data inputs (`u32Pgn`, `NmDestin`, `u16DaSize`, `u8Priority`, `u16DefRepRate`, `Data`).
- **UPD**: Updates the payload (`Data`) for the previously installed PGN to use it in the next cyclic transmission.

Event Outputs

- **INITO**: Confirms completion of initialization.
- **installO**: Signals that the installation process is complete. Includes `PGN_handle` as an output value.
- **UPDO**: Confirms that the payload update (`UPD`) was processed successfully.
- **CNF**: Confirms that a data record was sent successfully.
- **dataERR**: Indicates an error related to the payload (`Data`). It carries the error code `dataERRC`.
- **pgnERR**: Indicates an error related to the PGN configuration or management. It carries the error code `pgnERRC`.

Data Inputs

- **u32Pgn** (UDINT): The parameter group number (PGN) to be sent. Valid range: 0 to 0x3FFFF.
- **NmDestin** (isobus::pgn::ISONETEVENT_T): Defines the communication partner (destination address) for the message.
- **u16DaSize** (UINT): The length of the data to be sent in bytes. Valid range: 0 to 8.
- **u8Priority** (USINT): The priority of the message on the CAN bus (0 = highest, 7 = lowest). Default value: 7.
- **u16DefRepRate** (UINT): The cyclic transmission interval in milliseconds (0 … 0xFDFF ms). A value of 0 disables cyclic transmission. Default value: 0.
- **Data** (isobus::pgn::CAN_MSG): The payload to be sent as a PGN.

Data Outputs

- **PGN_handle** (INT): A handle (identifier) for the successfully installed PGN. In case of an error, an invalid handle value (`HANDLE_UNVALID`) is returned.
- **dataERRC** (INT): An error code providing detailed information about a `dataERR` event.
- **pgnERRC** (INT): An error code providing detailed information about a `pgnERR` event.

Adapter

This function block does not use any adapter interfaces.

Operation

1. **Initialization**: After the `INIT` event arrives, the block is made operational. Acknowledgement is provided via `INITO`.
2. **Installation**: The `install` event triggers the configuration of a new cyclic PGN transfer. All associated parameters (`u32Pgn`, `NmDestin`, etc.) are evaluated and stored internally. If successful, a `PGN_handle` is generated and returned with the `installO` event. Errors (e.g., invalid parameters) trigger the `pgnERR` event.
3. **Cyclic Transmission**: If the PGN is installed and `u16DefRepRate` > 0, the block automatically begins sending the payload data stored in `Data` at the defined interval. Each successful transmission is acknowledged by the `CNF` event.
4. **Data Update**: The `UPD` event allows you to change the payload data (`Data`) for the active PGN transmission. The new data will be used in the next cyclic transmission. Receipt of the new data is confirmed with `UPDO`. Incorrect data triggers `dataERR`.

Technical Features

- This block is designed for use in ISOBUS environments (agricultural machinery) and uses specific ISOBUS data types (`ISONETEVENT_T`, `CAN_MSG`).
- Cyclical transmission can be deactivated by setting `u16DefRepRate` to 0, enabling on-demand operation.
- – Error handling is structured via dedicated events (`dataERR`, `pgnERR`), enabling robust integration into higher-level controllers.
- Returning a `PGN_handle` event allows the management of multiple installed PGNs within a single system.

State Overview

1. **Not Initialized**: The block is in a sleep state after startup.
2. **Initialized / Ready**: After `INIT`/`INITO`. The block is waiting for configuration or control events.
3. **PGN Installed**: After successful `install`/`installO`. The PGN is configured, and the internal state for (cyclic) transmission is active.
4. **Send Active**: If `u16DefRepRate` > 0, the block sends data cyclically and fires `CNF` on each successful transmission.
5. **Error State**: When an error occurs (`pgnERR` or `dataERR`). Depending on the error type, the block may be in a waiting state or attempt to re-execute the operation (if implemented in the algorithm).

Application Scenarios

- **ISOBUS-compliant Machine Control**: Cyclic transmission of machine data (e.g., speed, pressure, position) from an electronic control unit (ECU) to a terminal or other network participants.
- **Diagnostic and Monitoring Systems**: Regular transmission of status and operating parameters for monitoring purposes.

- **Implementation of ISOBUS "Fast Packet" protocols**: For PGNs that carry more than 8 bytes of data and therefore need to be transmitted in multiple CAN messages (supported by the `CAN_MSG` data type).

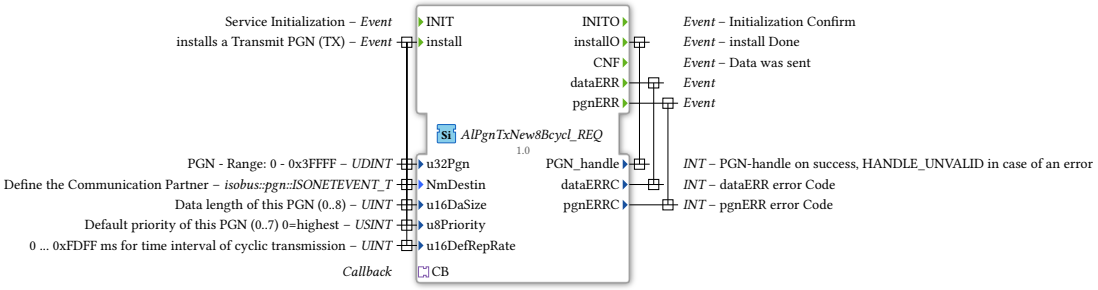
⚖️ Comparison with similar blocks

- **Compared to simple `E_CYC` blocks**: `AlPgnTxNew8Bcycl` is specialized for ISOBUS PGNs and offers integrated handling of priority, target addressing, and error management, while a generic cyclic event generator (`E_CYC`) only provides timing.
- **Compared to generic CAN transmit blocks**: This block abstracts the low-level CAN details (identifier calculation, data frames) and operates directly at the more logical PGN level according to the ISOBUS standard.

🛠️ Related Exercises

- Exercise_127

Conclusion



The `AlPgnTxNew8Bcyclis` a specialized and powerful function block for cyclic data communication in ISOBUS networks. Its clear interface, comprehensive configurability, and integrated error feedback make it ideally suited for the reliable implementation of transmission services in complex, distributed control systems for agricultural machinery.

AlPgnTxNew8Bcycl_REQ

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `AlPgnTxNew8Bcycl_REQ` is used for the cyclic transmission of data over an ISOBUS network. Its main purpose is the installation and management of a Parameter Group Number (PGN) transmit object (TX) that sends data at a defined time interval. A key feature is the integration of a callback adapter, which enables flexible data provisioning.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block.
- **install**: Starts the installation process for a new cyclic transmit PGN. Triggers the configuration with the incoming data.

Event Outputs

- **INITO**: Confirms successful completion of initialization.
- **installO**: Confirms completion of PGN installation. Returns the generated `PGN_handle`.
- **CNF**: Triggered when data has been successfully sent.
- **dataERR**: Indicates an error related to the data being sent. Returns an error code.
- **pgnERR**: Indicates an error related to PGN configuration or management. Returns an error code.

Data Inputs

- **u32Pgn** (UDINT): The parameter Group Number (PGN) to be used. Valid range: 0 to 0x3FFFF.
- **NmDestin** (isobus::pgn::ISONETEVENT_T): Defines the communication partner (destination address) for the transmission.
- **u16DaSize** (UINT): The length of the payload to be transmitted in bytes. Maximum 8 bytes (0..8).

- **u8Priority** (USINT): The priority of the message on the bus (0..7), where 0 is the highest priority. Default value: 7 (lowest).
- **u16DefRepRate** (UINT): The cyclic transmission interval in milliseconds (0 … 0xFDFF ms). A value of 0 disables cyclic transmission. Default value: 0.

Data Outputs

- **PGN_handle** (INT): A unique handle that identifies the installed PGN instance. In case of an error, it contains the value `HANDLE_UNVALID`.
- **dataERRC** (INT): Error code that is set when the `dataERR` event is triggered.
- **pgnERRC** (INT): Error code set when the `pgnERR` event is triggered.

Adapter

- **CB** (Type: `isobus::pgn::tx::Callback`): A socket adapter that provides a callback interface. The function block uses this adapter to request the current payload from the higher-level control algorithm during each cyclic transmission.

Functionality

1. **Initialization**: The `INIT` event prepares the function block for operation. Upon completion, `INITO` is triggered.
2. **PGN Installation**: The `install` event triggers the configuration of a new cyclic transmission PGN. The values present at the data inputs (`u32Pgn`, `NmDestin`, etc.) are used to register the PGN in the ISOBUS stack.
3. **Handle Return**: Upon successful installation, the `installO` event is triggered, and the generated `PGN_handle` is made available at the data output. This handle must be saved for later operations (e.g., uninstallation, modification).
4. **Cyclic Send Operation**: If `u16DefRepRate` > 0, the function block begins sending data at the defined interval.

- Before each send operation, the block requests the current payload data via the `CB` adapter.
- After successful transmission, the `CNF` event is triggered.

1. **Error Handling**: If an error occurs (e.g., invalid configuration, communication problem), either `dataERR` or `pgnERR` is triggered and the corresponding error code is set.

Technical Features

- **Data Length**: Supports the transmission of a maximum of 8 bytes of user data per PGN, which corresponds to a typical ISOBUS data length.
- **Callback Mechanism**: The user data is not stored internally but is dynamically requested via the adapter as needed. This enables efficient and up-to-date data provision.
- **Error Handling**: Separate error events for data-related (`dataERR`) and PGN-related (`pgnERR`) problems allow for differentiated error diagnosis.
- **Initial Value**: The priority (`u8Priority`) and the transmission interval (`u16DefRepRate`) have defined initial values (7 and 0, respectively).

State Overview

The function block implicitly goes through the following main states:

1. **Not Initialized**: The block is inactive after startup.
2. **Initialized (Ready)**: After successful execution of `INIT`/`INITO`, the block waits for an installation request.
3. **PGN Installed (Active)**: After successful execution of `install`/`installO`, the PGN is configured. If `u16DefRepRate` > 0, the block sends data cyclically, triggering `CNF`. It also responds to error conditions.

Application Scenarios

- **Cyclic Status Messages**: Regular transmission of machine status data (e.g., speed, temperature, operating hours) to a display or a higher-level management system.
- **Implementation of ISOBUS "Fast Packet" Protocols**: For PGNs that contain more than 8 bytes of data and are distributed across multiple CAN telegrams, this block can control the cyclic transmission of individual packets.
- **Data Logging**: Cyclic transmission of process data to a data logger or gateway.

⚖️ Comparison with Similar Blocks

- **Vs. One-time transmit blocks (e.g., `AlPgnTx_REQ`): This block is designed for repeated, periodic transmitting, whereas simple TX blocks typically perform a single transmit per trigger event.

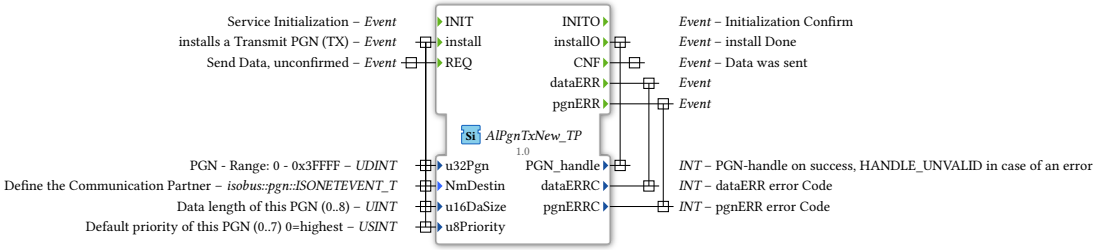
Vs. Blocks with Internal Data Storage: The use of a callback adapter distinguishes this block from those where the data is directly provided at an input. This makes it more flexible when the data changes frequently or originates from complex sources.

-

🛠️ Related Exercises

- Exercise_126
- Exercise_126b
- Exercise_126b2

Conclusion



The `AlPgnTxNew8Bcycl_REQ` is a specialized function block for reliable, cyclical data communication in ISOBUS environments. Its strengths lie in the clear separation of configuration (`install`), dynamic data acquisition (callback adapter), and robust error feedback. It is ideally suited for applications that require regular status updates or process data streams.

AlPgnTxNew_TP

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AlPgnTxNew_TP** is used to transmit data over the ISOBUS/CAN bus based on Parameter Group Numbers (PGN). It enables the registration of a specific PGN and the subsequent transmission of data packets whenever a local request event (REQ) occurs. The block is part of the `isobus::pgn::tx` package and is specifically designed for handling transport protocols or generic PGN transmissions.

Interface Structure

Event Inputs

- **INIT** (Type: `EInit`): Initializes the service. Sets the block to its initial state.
- **install** (Type: `Event`): Installs or registers a transmit PGN. Parameters such as PGN number, destination, data size, and priority are adopted.
- **REQ** (Type: `Event`): Requests data transmission (unacknowledged transmission). Uses the buffer provided in input `Data`.

Event Outputs

- **INITO** (Type: `EInit`): Acknowledges initialization.
- **installO** (Type: `Event`): Acknowledges that the installation process has completed. Returns `PGN_handle`.
- **CNF** (Type: `Event`): Confirmation that the data was sent successfully.
- **dataERR** (Type: `Event`): Signals an error during data transmission or access to the data.
- **pgnERR** (Type: `Event`): Signals an error regarding the PGN configuration or registration.

Data Inputs

- **u32Pgn** (Type: `UDINT`): The parameter group number (PGN) to be sent. The range is between 0 and 0x3FFFF.

- **NmDestin** (Type: `isobus::pgn::ISONETEVENT_T`): Defines the communication partner or the destination in the network (Network Management Destination).
- **u16DaSize** (Type: `UINT`): The length of the data for this PGN in bytes (typically 0 to 8 for standard CAN, but can vary depending on the protocol).
- **u8Priority** (Type: `USINT`): The default priority of this PGN (0 to 7), where 0 is the highest priority. The default value is 7.

Data Outputs

- **PGN_handle** (Type: `INT`): Return value after installation. A valid handle on success, or `HANDLE_UNVALID` in case of failure.
- **dataERRC** (Type: `INT`): Error code output when the event `dataERR` is triggered. * **pgnERRC** (Type: `INT`): Error code output when the event `pgnERR` is triggered.

InOut Variables

- **Data** (Type: `BYTE`, ArraySize: *): A pointer to the data buffer (variable-size byte array). The payload data to be sent is stored here. Declaring it as `InOut` enables efficient memory management without unnecessary copy operations.

Adapters

- This function block does not use any explicit adapter interfaces.

Functionality

The module operates in two main phases:

1. **Configuration (Installation):**

- First, the module must be initialized via `INIT`.
- Then, the PGN is configured via the event `install`. This process defines the PGN ID (`u32Pgn`), the target (`NmDestin`), the size (`u16DaSize`), and the priority (`u8Priority`).
- After successful installation, the event `installO` is triggered, and a `PGN_handle` handle is provided. This handle represents the registered PGN in the system.

1. **Data Transfer:**

- Data must be provided in the `Data` array before it can be sent.
- The `REQ` event triggers the sending process.
- `CNF` is triggered upon successful transmission.
- If problems occur (e.g., invalid data length or bus error), `dataERR` is triggered with the corresponding error code `dataERRC`.

Technical Specifications

- **Variable Array Size:** The `Data` input is defined as the `InOut` variable with `ArraySize="*"`. This means that the function block can work with data buffers of varying sizes, making it flexible for different PGN types.
- **Error Separation:** The function block explicitly distinguishes between errors during PGN setup (`pgnERR`) and errors during runtime data transmission (`dataERR`). This significantly simplifies debugging.
- **ISOBUS Types:** The function block imports specific ISOBUS data types (`isobus::pgn::ISONETEVENT_T`), which requires tight integration into corresponding ISOBUS stacks.

State Overview

The function block has internally implicit states defined by the availability of a valid `PGN_handle`:

- **Not Initialized:** Before `INIT`.
- **Initialized, Not Installed:** After `INIT`, but before successful `install`. Send requests (`REQ`) would fail here.
- **Installed / Ready for Operation:** A valid handle has been created. Data can be sent via `REQ`.

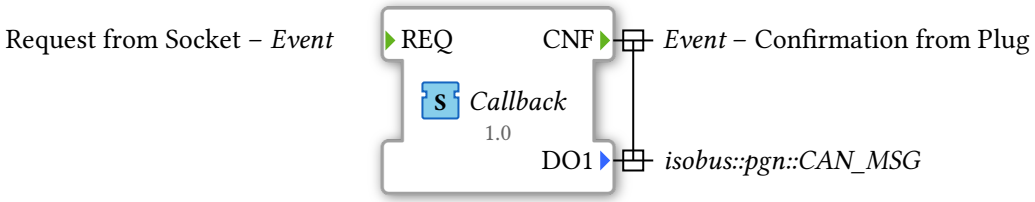
Application Scenarios

- **ISOBUS Device Development:** Implementation of virtual terminals or task controllers that need to send specific PGNs.

- **Sensor Data Transmission:** A sensor module sends measured values to the CAN bus cyclically or based on events.
- **Control Commands:** Sending control messages to actuators in the network (e.g., valves or motors) with a defined priority.

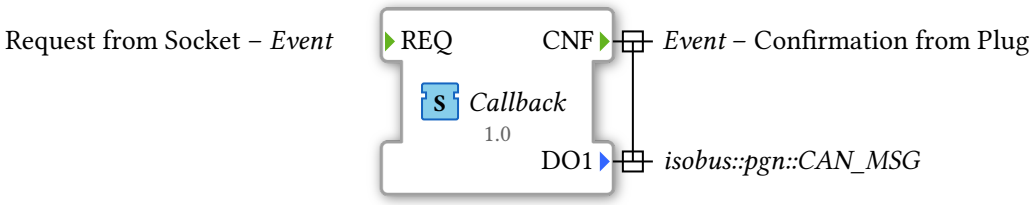
⚖️ Comparison with Similar Function Blocks

- **AlPgnTx vs. AlPgnTxNew_TP:** While older or simpler versions may only support static PGNs, the "New_TP" suffix indicates a revised version that may offer better support for transport protocols (TP) or utilize more modern memory management (via `InOut` variables).
- **Standard CAN_WRITE:** Compared to a generic `CAN_WRITE` function block, `AlPgnTxNew_TP` abstracts the complexity of PGN management (priority, data length, handle management) and is more specifically tailored to the J1939/ISOBUS protocol.
-



🛠️ Related Exercises

- Exercise_128b



Conclusion

The **AlPgnTxNew_TP** is a specialized and robust function block for sending messages in ISOBUS networks. By separating configuration (`install`) and transmission (`REQ`) and utilizing reference data buffers (`InOut`), it is ideally suited for resource-efficient control applications that require precise control over PGN parameters.

CallbackFB

• – ○ • – ○ • – ○ •

Introduction

The `CallbackFB` is a composite function block that simplifies the use of the callback mechanism in subapplications. It serves as a wrapper block to provide a standardized interface for asynchronous communication via a callback adapter. Its primary purpose is to decouple and provide structured handling of acknowledgment messages (`CNF`) and requests (`REQ`) within a function block network.

Interface Structure

Event Inputs

- **`CNF`**: Confirmation Event. This event is received by the connected plug and signals the completion of a request or the arrival of data.

Event Outputs

- **`REQ`**: Request event. This event is triggered by the adapter's internal socket and signals a pending action or data request.

Data Inputs

- **`DI1`**: Data input of type `isobus::pgn::CAN_MSG`. This input carries the CAN message data associated with the incoming `CNF` event.

Data Outputs

- *(No direct data outputs are defined on the function block. The data is forwarded via the adapter.)*

Adapters

- **`PLUG1`**: A plug adapter of type `isobus::pgn::tx::Callback`. This adapter establishes the connection to a corresponding socket adapter in another function block and implements the callback pattern.

Functionality

The `CallbackFB` acts as a transparent intermediary. Its internal network (FBNetwork) connects the public interfaces of the composite function block directly to the pins of the integrated `Callback` adapter (`PLUG1`).

1. An incoming `CNF` event is forwarded directly to the `CNF` input of the `PLUG1` adapter.
2. The data associated with `CNF` (`DI1` of type `isobus::pgn::CAN_MSG`) is simultaneously transferred to the `DO1` data input of the `PLUG1` adapter.
3. When the internal socket of the `PLUG1` adapter triggers a `REQ` event, it is directly forwarded to the public `REQ` event output of the `CallbackFB`.

The module itself does not perform any additional logic or data processing. Its function consists solely of the structured bundling and forwarding of events and data.

Technical Features

- **Typing**: The data input `DI1` uses the specific data type `isobus::pgn::CAN_MSG`, indicating an application in the context of ISOBUS and CAN-based agricultural systems.
- **Adapter Pattern**: All functionality is based on the 61499 adapter concept. The function block (FB) encapsulates a `Plug` and requires a corresponding `Socket` of type `isobus::pgn::tx::Callback` in another function block for operation.
- **Transparency**: As a composite FB without additional algorithms, its behavior is completely defined by the internal connection network and is therefore predictable.

State Overview

Since it is a purely pass-through composite function block without an internal state machine (Basic FB) or cyclic behavior (Service Interface FB), the `CallbackFB` does not have its own state machine. Its "state" is determined by the state of the connected adapter pair (`PLUG1` and its corresponding socket).

Application Scenarios

- **Structuring Subapplications**: In complex subapplications, the `CallbackFB` can be used to provide a clean and reusable interface for callback communication.
- **Decoupling Components**: It enables loose coupling between a service provider (providing the socket) and a service user (using this function block), which improves maintainability and testability.
- **ISOBUS Communication**: A specific application in control systems for agricultural machinery to asynchronously acknowledge or request the transmission of CAN messages (PGNs).
-

⚖️ Comparison with Similar Building Blocks

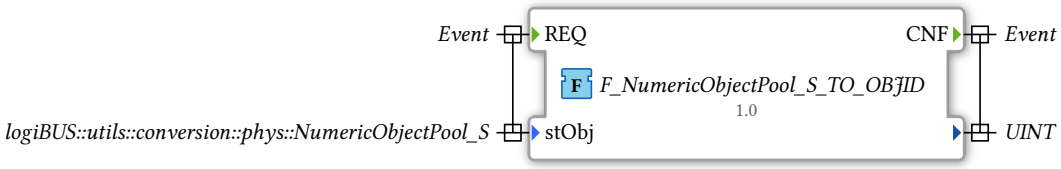
- **Direct Adapter Connection**: Instead of directly integrating a `Callback` adapter into a network, the `CallbackFB` offers a bundled, named interface (`CNF`/`REQ`/`DI1`) that may be more readable in some designs.
- **Simple E_CLASS vs. CallbackFB**: A simple E_CLASS building block (Event Splitter/Merger) could perform similar event routing, but would not provide the type-safe data connection for `isobus::pgn::CAN_MSG` along with the standardized adapter interface.
- **Simple E_CLASS vs. CallbackFB**: * **Generic Wrapper Function Blocks**: Unlike generic wrapper function blocks, `CallbackFB` is specialized for a specific data type and adapter, ensuring type safety and clear semantics.

🛠️ Related Exercises

- Exercise_126b2_sub
- Exercise_126b_sub
- Exercise_12x_sub

Conclusion

CallbackFB` is a useful auxiliary construct for the structured application of the adapter pattern in IEC 61499, especially in the ISOBUS environment. It reduces complexity in the main network by offloading the connection logic for callback communication into a single, reusable composite component. Its strength lies in its simplicity and clarity, as it does not implement any active logic itself. It is the ideal choice when a standardized and type-safe callback interface is required in a subapplication.



2.10.2.6 Utils

Conversion

Numeric Index (conversion)

Here you will find all exercises from the `conversion` workspace, listed in ascending order. ...

F_NumericObjectPool_S_TO_OBJID

• – ◦ • – ◦ • – ◦ •

Introduction

`F_NumericObjectPool_S_TO_OBJID` extracts the ISOBUS object ID (`u16ObjId`) from a `NumericObjectPool_S` structure (`logiBUS::utils::conversion::phys::NumericObjectPool_S`).

Interface Structure

Event Inputs

- **REQ**: execution request (associated with `stObj`)

Event Outputs

- **CNF**: confirmation (associated with the function result)

Data Inputs

- **stObj** (`logiBUS::utils::conversion::phys::NumericObjectPool_S`): object pool structure of a VT number variable

Data Outputs

- **(function result)** (UINT): the object ID `stObj.u16ObjId`

Adapters

No adapters are used.

Functionality

The function consists of a single assignment: `F_NumericObjectPool_S_TO_OBJID := stObj.u16ObjId;`. On `REQ`, the object ID is read from the structure and output with `CNF`.

Technical Details

- Pure function without state, version 1.0 (2026-10-11)
- The output has no name of its own but is the return value of the function
- The function is located in the package `logiBUS::utils::conversion::phys`

Application Scenarios

- Access to the object ID of a VT number variable when a block expects only the plain `UINT` ID instead of the whole `NumericObjectPool_S` structure

Conclusion

`F_NumericObjectPool_S_TO_OBJID` returns the `u16ObjId` of a `NumericObjectPool_S` structure as a `UINT`.

F_PHYS_LREAL_TO_RAW

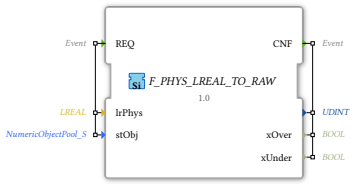


Image not available

• – ◦ • – ◦ • – ◦ •

Introduction

The function block F_PHYS_LREAL_TO_RAW converts a physical measured value in the LREAL data type into an ISOBUS-compliant raw value as a UDINT. Saturation limits are observed, and overflow and underflow states are signaled as Boolean outputs. The conversion follows the ISOBUS formula:

Display value = (Raw value + Offset) · Scaling Raw value = UDINT(UDINT(physical value / scaling) – Offset)

This function block is suitable for applications that need to integrate physical quantities into the ISOBUS protocol, particularly in agricultural and commercial vehicle technology.

Interface Structure

Event Inputs

Event	Description	Accompanying Variables
`REQ`	Starts the conversion	`lrPhys`, `stObj`

Event Outputs

Event	Description	Accompanying Variables
`CNF`	Confirms the conversion is complete	`xOver`, `xUnder`

Data Inputs

Name	Type	Initial Value	Description
`lrPhys`	`LREAL`	–	Physical Input Value (e.g., Temperature, Pressure)
`stObj`	`logiBUS.Utils::conversion::phys::NumericObjectPool_S`	`(u16ObjId := 65535, r32Scale := 1.0, i32Offset := 0, u8Decimals := 0)`	Data Structure with Scaling and Offset Parameters

Data Outputs

Name	Type	Description
(no name)	`UDINT`	Calculated ISOBUS raw value (0 … 4294967295)
`xOver`	`BOOL`	`TRUE`, if the input exceeds the upper limit (overflow)

xUnder	BOOL	TRUE, if the input falls below the lower limit (underflow)

Adapters

This function block does not use adapters.

Functionality

The function block performs the following steps:

1. **Calculation of limits:**

- Lower limit: `i32Offset * r32Scale`
- Upper limit: `(i32Offset + 4294967295) * r32Scale`

1. **Comparison and saturation:**

- If `lrPhys > obere Grenze` is present ⟶ Raw value = **UDINT#4294967295**, `xOver = TRUE`.

If `lrPhys < untere Grenze` is present ⟶ Raw value = **0**, `xUnder = TRUE`.

- Otherwise ⟶ Raw value = `DINT_TO_UDINT( LREAL_TO_DINT( lrPhys / r32Scale ) - i32Offset )`, no overflow/underflow message.

1. **Output:** The calculated raw value is provided at the unnamed `UDINT` output, and the event `CNF` is triggered.

Technical Features

- **ISOBUS Compliance:** The conversion follows the ISOBUS specification exactly (ISO 11783).
- **Saturation Behavior:** Critical ranges are represented by the overflow/underflow outputs `xOver` and `xUnder`, allowing subsequent functions (e.g., alarms) to react.
- **Scaling Unit:** The scaling factor `r32Scale` is of type `REAL` and is directly included in the calculation.
- **Integer Conversion:** The conversion from LREAL via DINT to UDINT is performed using the rounding standard in IEC 61499 (truncation of decimal places).
- **No State Machines:** The function block operates purely functionally without an internal state machine.

State Overview

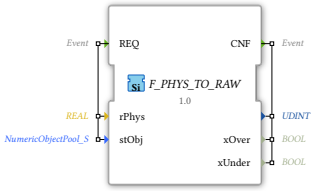
The function block does not have an explicit state machine. The calculation is triggered by the event `REQ`; after one cycle, the result is provided at the data output and the event `CNF` is sent. The execution time is deterministic and depends only on the runtime environment.

Application Scenarios

- **Agricultural Control Units:** Conversion of sensor values (e.g., torque, pressure) into ISOBUS raw data for transmission to terminals or actuators.
- **Diagnostics and Monitoring:** Detection of measurement range exceedances via `xOver`/`xUnder` to trigger warnings.
- **Data Logging:** Preparation of physical measured values for archiving in ISOBUS format.

Comparison with Similar Function Blocks

Typical alternatives are custom-written calculation functions or generic conversion blocks.
The F_PHYS_LREAL_TO_RAW offers the following advantages:



- **Predefined parameterization** via the structure `NumericObjectPool_S` (object ID, scaling, offset, decimal places).
- **Integrated saturation** and limit value monitoring.
- **Reusable** in all logiBUS projects.

Disadvantages compared to a custom solution include the reliance on the ISOBUS formula and the fixed data structure.

Conclusion

The F_PHYS_LREAL_TO_RAW function block is a compact, standards-compliant solution for converting physical measured values into the ISOBUS raw data format. Its saturation logic and monitoring outputs make it robust and reliable for use in industrial and agricultural control systems. The use of predefined structural parameters simplifies integration and reduces the potential for errors during parameterization.

F_PHYS_TO_RAW

• — ○ • — ○ • — ○ •

Introduction

The function block **F_PHYS_TO_RAW** converts a physical REAL value into an ISOBUS raw value (UDINT). Saturation limits are taken into account, and overflow and underflow alarms are issued. The conversion is based on the ISOBUS formula: `Anzeige = (Rohwert + Offset) * Skalierung`. The inverse calculation is: `Rohwert = UDINT(DINT(physikalischer Wert / Skalierung) - Offset)`.

Interface Structure

Event Inputs

Event	Description
REQ	Request to convert the physical value. Executed with the parameters `rPhys` and `stObj`.

Event Outputs

Event	Description
CNF	Confirmation that the conversion is complete. Returns the calculated raw value as well as the alarm flags `xOver` and `xUnder`.

Data Inputs

Variable	Type	Description
rPhys	REAL	The physical value to be converted.
stObj	NumericObjectPool_S	Structure with the parameters `i32Offset` (DINT) and `r32Scale` (REAL) for the ISOBUS formula.

Data Outputs

Variable	Type	Description
*	UDINT	The calculated ISOBUS raw value (function return value). Saturated to the range 0 to 4294967295.
xOver	BOOL	TRUE if the physical value exceeds the upper limit.
xUnder	BOOL	TRUE if the physical value falls below the lower limit.

Adapter

None.

Functionality

The function block first calculates the lower and upper limits:

- Lower limit: `lrLower = Offset * Skalierung`
- Upper limit: `lrUpper = (Offset + 4294967295) * Skalierung`

The physical value is then compared to these limits:

1. **Overflow (xOver = TRUE):** If `rPhys > lrUpper`, the raw value is set to the maximum UDINT value (4294967295).
2. **Underflow (xUnder = TRUE):** If `rPhys < lrLower`, the raw value is set to 0.
3. **Normal range:** Within the valid range, the raw value is calculated using the formula `UDINT(DINT(rPhys / Skalierung) - Offset)`.

This calculation is performed within the structured text code for each REQ event.

Technical Features

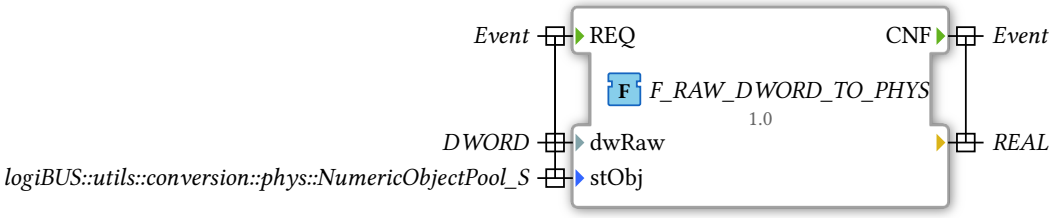
- The return type is UDINT, and saturation is applied to the full value range from 0 to 4294967295.
- The offset and scaling data are read from an external structure (`NumericObjectPool_S`), typically provided by the ISOBUS object pool.
- The function block does not use internal states; the calculation is purely combinatorial and is performed completely anew with each REQ.
- The conversion from REAL to DINT is performed using `REAL_TO_DINT`, which can lead to rounding errors with large values.

State Overview

The function block does not have an explicit state machine. It operates statelessly based on the current inputs. The output is recalculated with each REQ event.

Application Scenarios

- **ISOBUS Control Units:** Conversion of sensor readings (e.g., temperature, pressure) into ISOBUS-compliant raw data values for display on a terminal.
- **Agricultural Machinery Control:** Conversion of physical quantities that are represented with a specific scale and offset in the ISOBUS diagnostic protocol.
- **Test and Simulation Environments:** Generation of ISOBUS raw values from simulated physical values.



Comparison with Similar Function Blocks

Function blocks like `F_RAW_TO_PHYS` perform the inverse conversion (raw value ⟶ physical value). While this function block converts the physical quantity into the raw value, `F_PHYS_TO_RAW` additionally provides saturation and alarm signaling for overflow and underflow. Unlike general arithmetic function blocks, it is specifically designed for the ISOBUS convention with offset and scaling.

Conclusion

The `F_PHYS_TO_RAW` function block is a specialized module for ISOBUS conversion with integrated range monitoring. It offers a simple and robust interface for integrating physical measured values into the ISOBUS protocol and ensures that the raw value always remains within the valid range. The alarm outputs enable immediate fault detection in the event of limit violations.

F_RAW_DWORD_TO_PHYS

• – ◦ • – ◦ • – ◦ •

Introduction

The function `F_RAW_DWORD_TO_PHYS` converts an ISOBUS raw value (`DWORD`) into a physical `REAL` value. The ISOBUS formula is: `display = (raw + offset) * scale`.

Interface Structure

Event Inputs

- **REQ**: starts the conversion. Associated data: `dwRaw`, `stObj`.

Event Outputs

- **CNF**: signals the completed conversion. The result is available at the data output.

Data Inputs

- **dwRaw** (`DWORD`): ISOBUS raw value
- **stObj** (`logiBUS::utils::conversion::phys::NumericObjectPool_S`): object pool properties of the number variable (offset `i32Offset`, scale `r32Scale`)

Data Outputs

- **(unnamed)** (`REAL`): physical value (return value of the function)

Adapters

No adapters available.

Functionality

1. `dwRaw` is interpreted as an unsigned number (`DWORD_TO_UDINT`) and widened to `LINT` (`i64Raw`).
2. `stObj.i32Offset` is used as `LINT` without conversion (`i64Offset`).
3. The result is `LINT_TO_REAL(i64Raw + i64Offset) * stObj.r32Scale`.

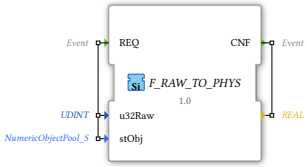
Example: `raw = 50000`, `scale = 0.01`, `offset = -100000` ⟶ `50000 + (-100000) = -50000` ⟶ `-50000 * 0.01 = -500.0`.

Technical Details

- Implemented as an ST function (`FUNCTION ... : REAL`) in package `logiBUS::utils::conversion::phys`.
- The intermediate values are `LINT` to avoid overflow.
- The raw value is treated as an unsigned bit pattern and then widened to 64 bits.

Application Scenarios

- Converting ISOBUS raw values (e.g. from a VT number variable) into physical quantities



⚖️ Comparison with Similar Building Blocks

- F_RAW_TO_PHYS and F_RAW_TO_PHYS_LREAL are related conversions; the opposite direction is provided by F_PHYS_TO_RAW and F_PHYS_LREAL_TO_RAW.

Conclusion

`F_RAW_DWORD_TO_PHYS` converts an ISOBUS `DWORD` raw value into a `REAL` value using offset and scale from the object pool.

F_RAW_TO_PHYS

• — ○ • — ○ • — ○ •

Introduction

The function block **F_RAW_TO_PHYS** converts an ISOBUS raw value of type `UDINT` into a physical value of type `REAL`. The conversion is performed according to the standardized ISOBUS formula: display = (raw + offset) * scale`

It is typically used in agricultural control systems to convert sensor data or actuator values between the CAN-based ISOBUS signal layer and the application.

Interface Structure

Event Inputs

Name	Type	Description
REQ	Event	Starts the conversion of a raw value (using `u32Raw` and `stObj`).

Event Outputs

Name	Type	Description
CNF	Event	Confirms that the calculation is complete and the output value is valid.

Data Inputs

Name	Type	Description
u32Raw	UDINT	The raw integer value (e.g., from an ISOBUS message object).
stObj	`NumericObjectPool_S`	Structure containing the offset (`i32Offset : DINT`) and the scaling factor (`r32Scale : REAL`).

Data Outputs

Name	Type	Description
(no explicit name)	REAL	The calculated physical value, output as a floating-point number.

Adapters

None.

Functionality

When an event occurs at the **REQ** input, the function block performs the following calculation:

1. The raw value `u32Raw` is converted from `UDINT` to `LINT` (64-bit to prevent overflows during addition).
2. The offset `stObj.i32Offset` is also extended to `LINT`.
3. Both values are added: `(u32Raw + stObj.i32Offset)`.
4. The intermediate result is converted to `REAL` and multiplied by the scaling factor `stObj.r32Scale`.

Result: `REAL := (LINT(UDINT(u32Raw)) + LINT(stObj.i32Offset)) * stObj.r32Scale`

Example (from the source code documentation):

- Raw value = 50000
- Scaling = 0.01
- Offset = −100000
- Calculation: `(50000 + (-100000)) * 0,01 = (-50000) * 0,01 = -500,0`

The result is available at the data output after the **CNF** event.

Technical Features

- The function block uses **`LINT`** (64-bit integer) as an intermediate type to reliably prevent overflow when adding `UDINT` and `DINT` (e.g., large positive values with large negative values).
- Raw value = 50000
- Scaling = 0.01
- Offset = −100000
- Calculation = `(50000 + (-100000)) * 0,01 = (-50000) * 0,01 = -500,0`

- The function block uses **`LINT`** (64-bit integer) as an intermediate type to reliably prevent overflow when adding `UDINT` and `DINT` (e.g., large positive values with large negative values). - The output variable has no name of its own – in the 4diac IDE, it is automatically displayed as `OUT` or can be referenced via the interface.
- Offset and scaling are configured via an external structure (`NumericObjectPool_S`), which typically originates from a pool object that bundles all parameters of an ISOBUS object.

State Overview

The function block has **no** internal states or memory. Each call processes the current input data and simultaneously generates the output value. It is therefore a pure **combinatorial logic function block**.

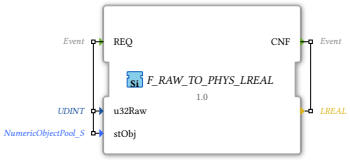
Application Scenarios

- **ISOBUS control units** (tractors, implements) – conversion of raw CAN data into physical units (e.g., pressure, position, speed).
- **Agricultural Applications** – Conversion of sensor values from the ISOBUS protocol into displayable values.
- **Test and Simulation Environments** – Replication of the ISOBUS conversion for development and verification purposes.

Comparison with Similar Function Blocks

- **F_RAW_TO_PHYS** is specifically designed for the ISOBUS formula `(raw + offset) * scale` and uses the data types common there (`UDINT`, `DINT`).
- General converter function blocks (e.g., `LREAL_TO_REAL`) do not offer offset scaling logic and therefore must be manually supplemented with this calculation.

Other ISOBUS-specific function blocks, such as `F_PHYS_TO_RAW`, reverse the operation (converting from physical value to raw value).



Conclusion

The **F_RAW_TO_PHYS** function block is a useful and cleanly implemented component for ISOBUS data conversion. The use of 64-bit intermediate values prevents overflow, and encapsulating the parameters in a structure facilitates reuse in projects that utilize the `NumericObjectPool` concept. It is suitable for both production use and rapid prototyping in the field of agricultural control systems.

F_RAW_TO_PHYS_LREAL

• – ○ • – ○ • – ○ •

Introduction

The function block `F_RAW_TO_PHYS_LREAL` converts a raw ISOBUS integer value (UDINT) into a physical floating-point value (LREAL). The conversion follows the standardized ISOBUS formula: display = (raw + offset) * scale`

The block is optimized for use in agricultural control systems (ISOBUS) and uses the provided parameters from a pool of numeric objects.

Interface Structure

Event Inputs

Name	Type	With Variables
REQ	Event	u32Raw, stObj

The function block is triggered by an event at input `REQ`.

Event Outputs

Name	Type	With Variables
CNF	Event	(none)

After successful calculation, the result is acknowledged via event `CNF`.

Data Inputs

Name	Type	Description
u32Raw	UDINT	Raw value from the ISOBUS bus (0 … 4294967295)
stObj	NumericObjectPool_S	Structure with the conversion parameters: `i32Offset` (DINT) and `r32Scale` (REAL)

Data Outputs

Name	Type	Description
(no name)	LREAL	Calculated physical value (IEEE double precision)

The output signal has no explicit name but represents the directly calculated LREAL value.

Adapter

None.

Functionality

The function block is activated via the event `REQ`. The input data is read in, and the following calculation is performed:

1. The 32-bit raw value `u32Raw` (UDINT) is converted unsigned to a 64-bit integer (LINT).
2. The offset value `stObj.i32Offset` (DINT) is also converted to LINT and added to the raw value.
3. The sum (LINT) is converted to an LREAL.
4. The intermediate result is multiplied by the scaling factor `stObj.r32Scale` (REAL).
5. The final result is available as an LREAL at the output.
6. The event `CNF` is then triggered.

Type conversion ensures that large UDINT values (e.g., 4,000,000,000) can be processed without information loss.

Technical Features

- **Enhanced Accuracy**: The intermediate step via LINT prevents overflows during addition with large raw values and negative offsets.
- **ISOBUS Compliance**: The formula `display = (raw + offset) · scale` complies with the ISOBUS standard ISO 11783.
- **Parameterization via Structure**: All conversion coefficients are provided via the structure `NumericObjectPool_S`, making the function block universally applicable to various sensors and devices.
- **Single-Cycle Processing**: The calculation is performed without state storage within a single cycle.

State Overview

The function block does not have an internal state machine, as it is a pure transformation function. It follows this sequence:

1. Wait for `REQ` (idle state)

2. At `REQ` ⟶ calculation ⟶ output of the result ⟶ trigger `CNF` ⟶ return to idle state

Application Scenarios

- **Agricultural Engineering**: Conversion of ISOBUS raw values (e.g., speeds, pressures, flow rates) into physical units such as °/s, bar, or l/min.
- **Vehicle Control**: Processing of CAN data from tractors, harvesters, or application systems.
- **Simulation**: Replication of ISOBUS sensor data in test environments where raw values from a database with different scales are processed.

Comparison with Similar Function Blocks

Function Block	Input Data Type	Output Data Type	Special Features
`F_RAW_TO_PHYS_LREAL`	UDINT	LREAL	Double precision, LINT intermediate step
`F_RAW_TO_PHYS_REAL`	UDINT	REAL	Single precision, reduced computational load
`F_RAW_TO_PHYS_LINT`	UDINT	LINT	Output as integer, without scaling
`F_RAW_TO_PHYS_INT`	UINT	REAL	Only positive raw values, smaller range

This function block offers the highest precision and is recommended for applications requiring large ranges or fine increments.

Conclusion

F_RAW_TO_PHYS_LREAL` is a reliable and accurate converter for ISOBUS raw data processing.

By using LINT as the buffer and LREAL as the output type, rounding errors are minimized and large value ranges are covered. The module is particularly suitable for safety-critical or precision agricultural applications and can be flexibly adapted to various measured variables via its configurable structure.

FB_RS_T_FF

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `FB_RS_T_FF` implements a bistable, reset-dominant latch with an additional toggle function. It combines the properties of an RS flip-flop (set and reset) with the ability to toggle the output on each rising edge of the clock signal. The reset input has priority, followed by the set input, and then the toggle function.

Interface Structure

Event Inputs

Event	Comment
`REQ`	Normal execution request – triggers the processing of the input signals.

Event Outputs

Event	Comment
`CNF`	Confirms execution after the output `Q1` has been calculated.

Data Inputs

Variable	Type	Comment
`S`	BOOL	Set – sets the output `Q1` to `TRUE`, provided `R1` is not active at the same time.
`R1`	BOOL	Reset (dominant) – sets the output `Q1` to `FALSE` and takes precedence over `S` and Toggle.
`CLK`	BOOL	Clock – clock generator for the Toggle function; on a rising edge, `Q1` is inverted if neither Reset nor Set is active.

Data Outputs

Variable	Type	Comment
`Q1`	BOOL	Latch output – displays the current stored state.

Adapters

This function block has no adapter interfaces.

Functionality

The following algorithm is executed for each event `REQ`:

- **Reset dominant**: If `R1 = TRUE` occurs, `Q1` is immediately set to `FALSE` – regardless of any other inputs.
- **Set**: If `R1 = FALSE` and `S = TRUE` occur, `Q1` is set to `TRUE`.
- **Toggle**: If neither Reset nor Set is active (`R1 = FALSE`, `S = FALSE`), the toggle mechanism is triggered: If `CLK` assumes the value `TRUE` and a rising edge is detected (i.e., `CLK` was `FALSE` in the previous call, stored in the internal variable `EDGE`), then `Q1` is inverted (`Q1 := NOT Q1`).

If CLK assumes the value TRUE and a rising edge is detected (i.e., CLK was FALSE in the previous call, stored in the internal variable EDGE), then Q1 is inverted (Q1 := NOT Q1). - The internal variable EDGE is then set to the current value of CLK to detect edges for the next call.

The algorithm is implemented in ST code as follows:

``structured text IF R1 THEN Q1 := BOOL#FALSE; ELSIF S THEN Q1 := BOOL#TRUE; ELSIF CLK AND NOT EDGE THEN Q1 := NOT Q1; END_IF; EDGE := CLK;

Technical Features

- **Reset Dominance**: The R1 input has the highest priority; when set, it overrides both Set and Toggle commands.
- **Edge Detection**: The toggle occurs only on a rising edge of CLK (transition from FALSE to TRUE), which is implemented by the internal variable EDGE.
- **Initial State**: The internal variable EDGE is initialized with TRUE, preventing an unintended toggle from being triggered on the first call, as the condition CLK AND NOT EDGE would otherwise be met at a static TRUE level.
- **Data Type**: All inputs and outputs are of type BOOL.

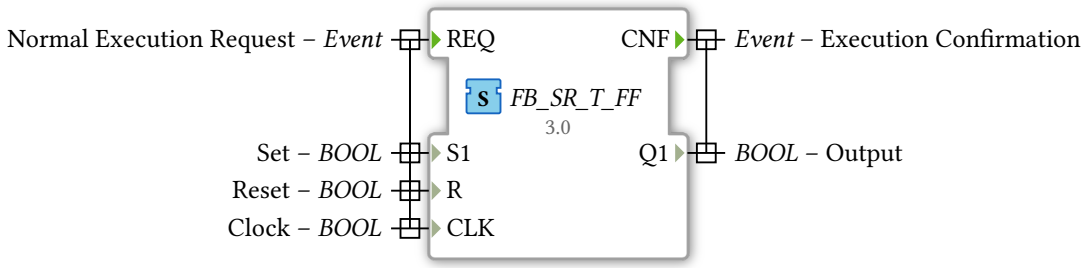
State Overview

The function block does not have an explicit state machine; the state is implicitly represented by the internal variables Q1 and EDGE. A state table summarizes the behavior:

Current Q1	R1	S	CLK (rising edge)	New Q1
x	TRUE	x	x	FALSE
x	FALSE	TRUE	x	TRUE
x	FALSE	FALSE	TRUE (and previously FALSE)	NOT Q1
x	FALSE	FALSE	FALSE or no edge	unchanged

Application Scenarios

- **Reset-dominant control** with additional switching option, e.g., for manual override in safety circuits.
- **Toggle function** on clock edges, e.g., as a frequency divider or switch in digital logic circuits.
- **Combined set/reset/toggle control** in automation systems, where an output can be set by sensor signals and toggled by a push button.



Comparison with similar components

- **RS flip-flop**: Pure RS without toggle; FB_RS_T_FF extends it with a toggle function.
- **Toggle flip-flop (T-FF)**: Pure toggle without set/reset; this component combines both functions, with the toggle only being executed when set/reset is inactive.
- **JK flip-flop**: Offers similar flexibility (set, reset, toggle) but requires two event inputs (e.g., for J and K). FB_RS_T_FF simplifies the interface to one event input and three Boolean values.

Conclusion

FB_RS_T_FF` is a versatile function block that combines a reset-dominant latch with an edge-triggered toggle function. It is suitable for applications requiring both fixed set and reset signals as well as switchable state transitions. Its clear prioritization (Reset > Set > Toggle) and built-in edge detection make it robust and easy to integrate into control logic.

FB_SR_T_FF

• – ◦ • – ◦ • – ◦ •

Introduction

The function block FB_SR_T_FF implements a bistable, set-dominant RS flip-flop with an additional toggle function. The circuit combines the behavior of an SR latch (set-dominant) with an edge-triggered T flip-flop, which toggles its output state on each clock cycle when neither set nor reset is active.

Interface Structure

Event Inputs

Name	Type	Comment
REQ	Event	Normal execution command (triggers processing)

Event Outputs

Name	Type	Comment
CNF	Event	Execution Confirmation

Data Inputs

Name	Type	Initial Value	Comment
S1	BOOL	-	Set Input (Dominant)
R	BOOL	-	Reset Input
CLK	BOOL	-	Clock Signal (Rising Edge Triggers Toggle)

Data Outputs

Name	Type	Initial Value	Comment
Q1	BOOL	-	Output Signal

Adapter

No adapters available.

Functionality

The function block is activated by an event at input REQ. On each execution, inputs S1, R, and CLK are sampled, and the internal state (Q1) is updated according to the following rules:

1. **Set Dominance:** If S1 = TRUE is active, Q1 is set to TRUE (regardless of R and CLK).
2. **Reset:** If S1 = FALSE and R = TRUE are already set, Q1 will be set to FALSE.

Reset: If S1 = FALSE and R = TRUE are already set, then Q1 will be set to FALSE. … 3. **Toggle on rising edge:** If neither S1 nor R are active (S1 = FALSE and R = FALSE, respectively), and the current value of CLK is TRUE, whereas it was FALSE in the previous cycle (i.e., rising edge), the output Q1 is inverted (Q1 := NOT Q1). Otherwise, Q1 remains unchanged.

The internal auxiliary flag EDGE stores the last state of CLK to enable edge detection. Initially, it is EDGE = TRUE, so no rising edge is detected on the first execution unless CLK is FALSE from the start.

The algorithm is implemented in Structured Text (ST), and the acknowledgment event CNF is sent after each execution.

Technical Features

- **Set-dominant behavior:** As long as S1 = TRUE is active, R is ignored. This prevents the undefined state of a classic RS flip-flop.

The algorithm is implemented in Structured Text (ST), and the acknowledgment event CNF is sent after each execution. - **Edge-Triggered Toggle:** The toggle function is triggered only on a rising edge of CLK,

not on every clock cycle. This makes the behavior deterministic and allows synchronization with the clock signal.

- **Internal Edge Storage:** The internal marker `EDGE` stores the previous value of `CLK`. Initially set to `TRUE`, it prevents the first cycle from triggering the toggle.
- **Cyclic Processing:** Processing can be called any number of times; the function depends only on the current input values and the stored edge state.

State Overview

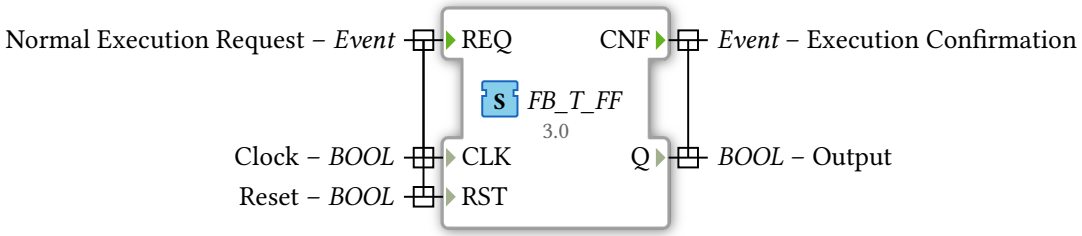
The function block has a functional state machine with one state, `REQ`. This state executes the algorithm and then sends `CNF`. There are no other explicit states in the automaton, as the flip-flop behavior is purely data-driven within the algorithm.

State	Incoming Events	Action	Outgoing Events
REQ	REQ	Execute the algorithm, update `Q1` and `EDGE`	CNF

Application Scenarios

- **Control with Set/Reset Priority:** This function block is suitable for applications where Set takes precedence over Reset (e.g., safety circuits).
- **Toggle Function with Clock:** Combined with a clock, the output can toggle on every clock pulse, as long as no set or reset request is present. This can be used, for example, for modular counters or state machines.
- **Edge-Triggered Circuits:** In automation processes where state changes are only permitted at specific times (e.g., sampling).

Comparison with Similar Components



Compared to a pure SR flip-flop (e.g., `SR_FF`), this component offers a built-in toggle function that can invert the output on every clock cycle. Compared to a T flip-flop (`T_FF`), this component also has set and reset inputs with dominance. The classic JK flip-flop has two controlling inputs (J, K) without dominance, while this component represents a combination of set-dominant and edge-triggered toggle functionality.

Conclusion

The `FB_SR_T_FF` is a versatile, compact function block that combines the features of a set-dominant RS flip-flop and an edge-triggered T flip-flop. Thanks to its simple interface (one event input, three Boolean inputs), it can be easily integrated into existing control logic and is suitable for a wide variety of applications requiring a prioritized set/reset operation with an additional toggle function. Its implementation in structured text ensures clear readability and easy customization.

FB_T_FF

[[Image of the function block – shown in the 4diac IDE as a symbol with an event input REQ, output CNF, data inputs CLK (BOOL) and RST (BOOL), and data output Q (BOOL)]]

• – ◦ • – ◦ • – ◦ •

Introduction

The **FB_T_FF** (Toggle Flip-Flop) implements an edge-triggered, asynchronously resettable frequency divider or toggle switch. On each rising clock edge at the **CLK** input, the output **Q** is inverted (toggled). A high level at the **RST** input immediately resets **Q** to `FALSE`. This function block is particularly suitable for binary state transitions in control sequences.

Interface Structure

Event Inputs

Event	Associated Data	Description
REQ	CLK, RST	Normal execution job; triggers the algorithm

Event Outputs

Event	Associated Data	Description
CNF	Q	Confirms execution, returns the current value of Q

Data Inputs

Name	Type	Description
CLK	BOOL	Clock signal (edge detection)
RST	BOOL	Asynchronous reset (active high)

Data Outputs

Name	Type	Description
Q	BOOL	Output – toggles on rising CLK edge, unless reset is active

Adapters

No adapters available.

Functionality

This function block is called using the **REQ** event. On each call, the internal variable **EDGE** (Bool, initial TRUE) is updated as follows:

1. **Reset priority:** If RST = TRUE is active, Q is immediately set to FALSE.
2. **Edge detection:** If RST is not active and the condition CLK AND NOT EDGE is met, there is a **rising edge** of CLK. In this case, Q is inverted to Q := NOT Q.
3. **Edge detection:** If RST is not active and the condition CLK AND NOT EDGE is met, there is a **rising edge** of CLK. In this case, Q is inverted to Q := NOT Q. 3. **Storage:** After evaluation, EDGE := CLK is set so that the edge can be detected on the next call.

The algorithm is executed in the internal **REQ** state; after the algorithm, the **CNF** event is sent.

Technical Features

- **Immediate Edge Detection:** A rising edge is detected by comparing the current CLK value with the previous one (stored in EDGE). This is a typical software implementation of an edge-triggered flip-flop.
- **Asynchronous Reset:** The reset takes effect immediately with each call, regardless of the clock edge.
- **Initial State:** Q is undefined after the function block starts; it is only set by the first REQ call or a reset. The internal **EDGE** is initially set to TRUE, ensuring that the first rising edge (from FALSE to TRUE) is correctly detected.

State Overview

The function block is implemented as a **SimpleFB** with a single EC state:

State	Incoming Events	Outgoing Action	Outgoing Event
REQ	REQ	Execute algorithm REQ (Toggle/Reset logic)	CNF

The state is immediately reactivated after processing; there are no wait or follow-up states.

Application Scenarios

- **Frequency Divider:** Applying a square wave signal to CLK; half the frequency appears at Q.

- **Binary State Change:** Switching a light or valve on each clock pulse.
- **Reset-Proof Toggle:** By controlling RST, the output can be forced into a defined default state.
- **Pulse Counter:** Combining several FB_T_FFs in series results in a binary counter.

Comparison with Similar Function Blocks

Function Block	Property
SR Flip-Flop	Set and reset via separate inputs; no toggle behavior.
D-Flip-Flop	Takes the value of D on the clock edge; no toggle, no reset integrated.
FB_T_FF	Inverts the output on each rising edge; asynchronous reset possible.

The **FB_T_FF** is therefore ideal for simple switching tasks where no set/reset input is required.

Conclusion

The **FB_T_FF** implements a robust, edge-triggered toggle flip-flop with asynchronous reset. Its compact implementation makes it suitable for time-critical control systems in automation technology where reliable state transitions are required. Edge detection is cleanly implemented in software and requires no additional hardware.

The **FB_T_FF** is therefore ideal for simple switching tasks where a set/reset input is not needed. —

2.10.3.4 Bosch

Numeric Index (Bosch)

Numeric Index{index} single: Numerischer Index (bosch) Here you will find all exercises from the bosch workspace, listed in ascending order. ...

FB_MM710_IMU

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **FB_MM710_IMU** is a service-oriented module (SIFB) for connecting the Bosch MM7.10 IMU sensor via CAN/J1939. It enables the reading of acceleration, yaw rate, and tilt values, as well as the monitoring of system and error states. The FB encapsulates all CAN communication and signal processing and provides the data in a standardized format via event and data outputs.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Initialization of the module. This event sets the CAN parameters (index, source address) and the activation qualifier QI.

Event Outputs

Event	Type	Description
INITO	EInit	Confirmation of successful initialization (QO = TRUE) or error message.
IND	Event	Indication from the resource: fires on every cycle without an active error and also publishes the reset of `bCommError`/`bCRCError` to FALSE. Provides QO, STATUS, all measurement and status values (`rAcc*`, `rRate*`, `rRoll`, `rPitch`, `rYaw`, `rTempRateZ`, `uiHW_Index`, `eStatus*`, `bAllSignalsReady`, `uiSysStatus`, `uiSysStatus5`, `uiSysDiag`, `uiMessageCounter`).
ERROR	Event	Fires only when an error actually occurs (entry trigger); provides QO, STATUS, `bCommError`, `bCRCError`, and `sErrorMsg`. The reset of `bCommError`/`bCRCError` to FALSE is not reported here but via IND.

Data Inputs

Variable	Type	Description
QI	BOOL	Activation Qualifier: Initialization (INIT) is only performed if QI = TRUE.
PARAMS	STRING	Service parameter, e.g., CAN interface configuration (optional).
u8CanIdx	USINT	CAN node index (default initial value: `INVALID`).
SA	BYTE	Source address for J1939 communication (initial value: `16#DA`).

Data Outputs

| Variable | Type | Description | | |-----|---|-------| | QO | BOOL | Initialization confirmation (TRUE = successful). | | STATUS | STRING | Status message (e.g., “Initialized,” “Error”). | | rAccX, rAccY, rAccZ | REAL | Acceleration values in the X, Y, and Z directions [m/s²]. | | rRateX, rRateY, rRateZ | REAL | Rotation rates around the respective axis [deg/s]. | | rRoll, rPitch, rYaw | REAL | Tilt angle (roll, pitch, yaw) [deg]. | | rTempRateZ | REAL | Sensor temperature [°C]. | | uiHW_Index | UINT | Hardware Index (0 = MM5.10, 1 = MM7.10). | | eStatusAccX … eStatusAccZ | BYTE | Acceleration signal quality (individually `eStatusAccX`, `eStatusAccY`, `eStatusAccZ`; 0 = ready, 1..7 = error). | | eStatusRateX … eStatusRateZ | BYTE | Rotation rate signal quality (individually `eStatusRateX`, `eStatusRateY`, `eStatusRateZ`; 0 = ready, 1..7 = error). | | bAllSignalsReady | BOOL | TRUE if all signal statuses are 0. | | uiSysStatus | BYTE | System status from TX message 1. | | uiSysStatus5 | BYTE | System status from TX message 2. | | uiSysDiag | BYTE | System diagnostic code (from TX2). | | uiMessageCounter | UINT | Message counter (0..15) for timeout monitoring. | | bCommError | BOOL | TRUE on CAN timeout. | bCRCError | BOOL | TRUE on failed CRC check. | sErrorMsg | STRING | Error text (e.g., “CAN timeout”). |

Adapter

No adapters defined.

Functionality

Upon receiving **INIT** with QI = TRUE, the FB_MM710_IMU initializes the CAN communication and the internal receive buffer. After successful initialization, **INITO** is set with QO = TRUE. The block has no request input: once valid data is received from the sensor, **IND** is output on every cycle without an active error and all data outputs are updated. If a communication or CRC error occurs, or if the message counter exceeds a timeout, **ERROR** is set.

The signal statuses (eStatus*) enable individual fault analysis for each axis. The hardware index distinguishes between older MM5.10 and current MM7.10 sensors.

Technical Features

- **CAN/J1939 Protocol** – Uses a fixed source address (default: `16#DA`).
- **Timeout Monitoring** – The `uiMessageCounter` (0-15) is incremented with each valid message; if it fails to increment, a communication error is reported after 16 missing messages.
- **Signal Status Bits** – Provide more granular information than simple "ready/error" flags.
- **CRC Check** – Faulty CAN frames are detected and reported via `bCRCError` and **ERROR**.
- **Hardware Differentiation** – `uiHW_Index` enables adaptive behavior for different sensor versions.

State Overview

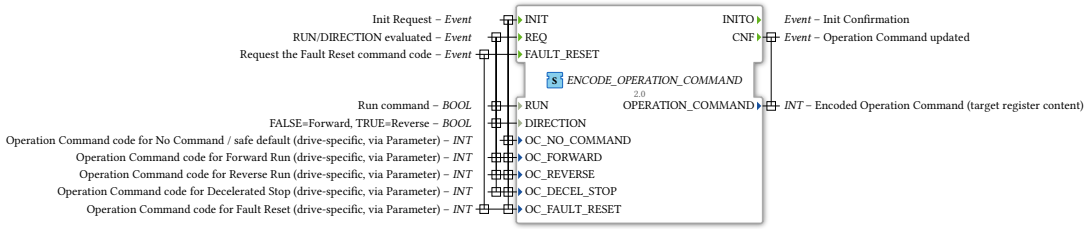
The module goes through the following states (not explicitly as ECC, but inferable from its behavior):

1. **Inactive** – After startup, waiting for INIT.
2. **Initializing** – After an INIT event; establishing CAN communication.
3. **Ready** – After successful INITO; waiting for sensor messages.
4. **Data Received** – After a successful CAN message; IND is sent.
5. **Error** – In case of timeout or CRC error; ERROR is sent (fallback to Ready after error handling).

Application Scenarios

- **Mobile Machinery** – Tilt and acceleration monitoring of excavators, cranes, or forklifts.
- **Vehicle Dynamics** – Acquisition of roll, pitch, and yaw angles for stability control.
- **Industrial Robots** – Monitoring of vibrations and unexpected movements.
- **IoT Sensor Nodes** – Integration into higher-level controllers via CAN bus.

Comparison with Similar Function Blocks



Compared to simple IMU drivers (e.g., via SPI/I²C), this function block offers direct integration into J1939 networks. The signal status bits enable diagnostics that are often lacking in standard function blocks. The integrated hardware index (MM5.10 / MM7.10) allows for easy migration. Other CAN IMU modules may use proprietary message formats, while this module is based on the open J1939 standard.

Conclusion

The FB_MM710_IMU is a powerful module for the reliable acquisition of IMU data in CAN-based automation systems. Its comprehensive status and error information supports complete diagnostics, and its simple parameterization via INIT makes it highly versatile. It is an ideal choice, especially in safety-critical applications using J1939.

2.10.3.5 drives

ENCODE_OPERATION_COMMAND

• – ○ • – ○ • – ○ •

Introduction

ENCODE_OPERATION_COMMAND builds the Operation Command word for a VFD/drive from RUN/DIRECTION, or from an explicit Fault Reset event. The block is generic for any drive whose control word follows the common Run/Direction/Stop-plus-Fault-Reset pattern (Modbus, CANopen PZD1, Profibus PPO, etc.) - all concrete command codes are supplied by the caller via Parameter, so the block itself carries no brand-specific knowledge, only the encoding shape.

The name Operation Command (rather than Control Word) is deliberate: Control Word is CANopen-specific terminology, whereas Operation Command is the vendor-neutral term used by e.g. the DELIXI H300 manual.

Interface Structure

Event Inputs

- **INIT**: Initialization - sets OPERATION_COMMAND to OC_NO_COMMAND once.
- **REQ**: Re-evaluate RUN/DIRECTION and encode OPERATION_COMMAND accordingly.
- **FAULT_RESET**: Request the Fault Reset command code, independent of the current RUN/DIRECTION state.

Event Outputs

- **INITO**: Initialization confirmation.
- **CNF**: OPERATION_COMMAND updated.

Data Inputs

- **RUN** (BOOL): Run command.
- **DIRECTION** (BOOL): FALSE=Forward, TRUE=Reverse.
- **OC_NO_COMMAND** (INT): Command code for "no command"/safe default (drive-specific, via Parameter).
- **OC_FORWARD** (INT): Command code for Forward Run (drive-specific, via Parameter).
- **OC_REVERSE** (INT): Command code for Reverse Run (drive-specific, via Parameter).
- **OC_DECEL_STOP** (INT): Command code for Decelerated Stop (drive-specific, via Parameter).
- **OC_FAULT_RESET** (INT): Command code for Fault Reset (drive-specific, via Parameter).

Data Outputs

- **OPERATION_COMMAND** (INT): Encoded Operation Command word (target register content).

Functionality

The block has no real state machine (no <ECC> with transition conditions) - each event independently triggers exactly one algorithm:

1. **INIT**: Sets OPERATION_COMMAND := OC_NO_COMMAND before the first REQ/FAULT_RESET arrives.
2. **REQ**: If RUN = TRUE, encodes OC_FORWARD or OC_REVERSE depending on DIRECTION; if RUN = FALSE, encodes OC_DECEL_STOP.
3. **FAULT_RESET**: Overwrites OPERATION_COMMAND once with OC_FAULT_RESET, independent of the current RUN/DIRECTION state - the next REQ encodes normally again afterwards.

Technical Features

- **All command codes are parameters, no hardcoded knowledge.** The block itself knows no drive-specific numeric values; OC_* are supplied by the caller via Parameter.
- **Renamed in version 2.0**: Formerly ENCODE_CONTROLWORD/CW_*/CONTROL_WORD, since "Control Word" is CANopen-specific terminology. Semantics unchanged, only names generalized.
- **Generalized from H300_ENCODE_CONTROLWORD** (version 1.0): Originally written for one specific drive type, then generalized to the generic Run/Direction/Stop-plus-Fault-Reset pattern.

Application Scenarios

- Driving a VFD/drive over a fieldbus control word (Modbus holding register, CANopen PZD1, Profibus PPO) where Run/Direction/Stop and an explicit Fault Reset are encoded in a single word.
- Generic block for multiple drive types: only the OC_* parameters need adjusting per drive, the encoding logic stays the same.

Conclusion

`ENCODE_OPERATION_COMMAND` encapsulates the common Run/Direction/Stop-plus-Fault-Reset encoding for VFD control words in a single, vendor-neutral block - all concrete command codes come from outside, the block itself carries no drive-specific knowledge.

wifi

• – ◦ • – ◦ • – ◦ •

Introduction

The “wifi” function block is a Service Interface Function Block (SIFB) for controlling a WLAN connection. It provides the INIT, START, and STOP events for initializing, starting, and stopping the WLAN. The connection status is returned as a string via the STATUS output. The block is designed for use in automation systems that require a wireless network connection.

Interface Structure

Event Inputs

- **INIT** (EInit): Initializes the block and prepares the WLAN interface.
- **START** (EInit): Starts the WLAN connection.
- **STOP** (EInit): Stops the WLAN connection.

Event Outputs

- **INITO** (EInit): Confirms successful initialization. Triggered in conjunction with the STATUS data output.

Data Inputs

No data inputs available.

Data Outputs

- **STATUS** (WSTRING): Displays the current status of the WLAN service (e.g., “OK”, “Error”, “Connected”, “Disconnected”).

Adapters

No adapters available.

Functionality

The function block operates on the principle of a Service Interface Function Block. The internal logic is provided by the runtime environment. Typically, INIT is called first to configure the function block. The WLAN connection can then be activated with START. The connection is terminated with STOP. The STATUS output returns the current state after each operation.

Technical Features

- The function block is implemented as a SIFB (Service Interface Function Block) according to IEC 61499-2.
- The interface is open to both the RESOURCE and APPLICATION sides, enabling flexible integration.
- The exact implementation depends on the underlying hardware and operating system.

State Overview

The module goes through the following basic states:

- **Uninitialized**: After startup, before INIT is executed.
- **Initialized**: After successful INIT, ready for START.
- **Active (Connected)**: After successful START.
- **Inactive (Disconnected)**: After STOP or in case of an error.

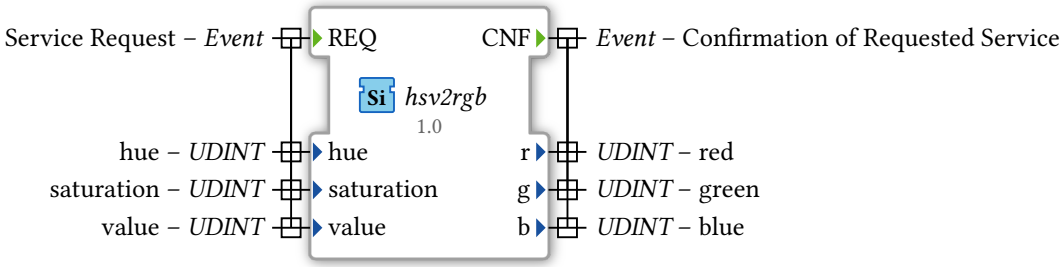
Application Scenarios

- Controlling a WLAN interface in agricultural machinery or other vehicles.
- Integrating devices into a wireless network for data transmission in automation technology.
- Remote maintenance and diagnostics via WLAN.

Comparison with Similar Modules

Similar modules include Ethernet or serial communication modules. Unlike these, the Wi-Fi module focuses specifically on wireless WLAN connections and offers a simplified, event-driven interface. Other modules often require more complex configurations or support multiple protocols.

Conclusion



The “wifi” function block offers a simple and standardized way to integrate a WLAN connection into IEC 61499 systems. With its three events INIT, START, and STOP, as well as its STATUS output, it is intuitive to use and particularly suitable for applications requiring fast and reliable wireless communication.

rgb

hsv2rgb

• − ◦ • − ◦ • − ◦ •

The function block `hsv2rgb` is a utility block for color space conversion. It converts a color defined in the HSV color model (Hue, Saturation, Value) into the corresponding values of the RGB color model (Red, Green, Blue). This is particularly useful for applications that need to control colors based on their perceptual properties (hue, saturation, brightness), while output devices (such as LEDs or displays) expect RGB values.

- **REQ (Service Request):** Triggers the conversion calculation. This event updates the current values at data inputs `hue`, `saturation`, and `value`.
- **CNF (Confirmation of Requested Service):** Triggered once the conversion is complete. This event outputs the calculated RGB values at data outputs `r`, `g`, and `b`.
- **hue (UDINT):** The hue in the HSV model. The value range is not predefined in the function block, but typically a range of 0-360° or 0-65535 is used.
- **value (UDINT):** The brightness value in the HSV model. Typical range: 0-100% or 0-255.
- **r (UDINT):** The calculated red component in the RGB model.
- **g (UDINT):** The calculated green component in the RGB model.
- **b (UDINT):** The calculated blue component in the RGB model.

Data Outputs

Data Inputs

Event Outputs

Event Inputs

Interface Structure

Introduction

Adapters

This function block does not use adapters.

The block operates in an event-driven manner. The internal algorithm starts when the `REQ` event occurs. It receives the HSV values at the data inputs and calculates the corresponding RGB values according to the standardized HSV-to-RGB conversion algorithm. After the calculation is complete, the results are output at the data outputs `r`, `g`, and `b`, and the `CNF` event signals that the new values are valid and ready for retrieval.

- **Data Type:** All input and output data are of type `UDINT` (unsigned double integer, 32-bit). This enables high resolution and accuracy in color representation.
- **Value Range:** The module itself does not define any scaling or limiting of the value ranges for HSV or RGB. The interpretation of the numerical values (e.g., 0-360 for Hue, 0-255 for RGB) is the responsibility of the connecting application. The conversion algorithm must be designed accordingly for the expected input range.
- **Deterministic Behavior:** The execution is deterministic and always produces the same RGB output values for identical input values.

The function block has a simple, stateless sequence:

1. **Wait State:** The block waits for the `REQ` event.
2. **Calculation State:** At `REQ`, the input data is read and the conversion is performed. This state is transient.
3. **Output State:** The results are written to the outputs and the `CNF` event is generated. The module immediately returns to standby mode.

- **Color Control of RGB LEDs:** User-friendly color selection via HSV parameters (e.g., rotary encoder or touch interface) with subsequent conversion for LED control.
- **Visualization Systems:** Conversion of alarm or status colors defined in HSV for display on RGB monitors or panels.

- **Industrial Lighting:** Dynamic lighting control in production or logistics environments, where color transitions are intuitively defined via brightness and saturation.
-

Unlike general-purpose computing blocks (such as `MUL`, `ADD`) or scalers, `hsv2rgb` is an application-specific block that encapsulates a complex, non-linear algorithm. It saves the user the time-consuming and error-prone implementation of the conversion to Structured Text or other languages. A direct counterpart, `rgb2hsv`, for the reverse conversion would be a similarly specialized block.

- Exercise_031

The `hsv2rgb` function block is a useful and specialized tool for all 4diac applications involving color manipulation. By encapsulating the conversion algorithm in a standardized IEC 61499 block, it significantly simplifies programming, promotes reusability, and increases software reliability. Its use is recommended where intuitive, human-perceived color control meets device-oriented RGB output.

strip_set_pixel

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `strip_set_pixel` is used to control an RGB LED strip. Its main function is to set the color of a single pixel (a single LED) on the strip or to turn off the entire strip. It is designed for use in control systems that require precise, pixel-by-pixel control of RGB LEDs.

Interface Structure

Event Inputs

- **INIT**: Initializes the function block. Must be triggered before first use.
- **set_pixel**: Triggers the command to set the color of a specific pixel. Linked to the data `index`, `red`, `green`, and `blue`.
- **clear**: Triggers the command to turn off (clear) all LEDs on the strip.

Event Outputs

- **INITO**: Confirms successful initialization of the function block.
- **set_pixel_CNF**: Confirms execution of the `set_pixel` command. Linked to the data output `set_pixel_return`.
- **clear_CNF**: Confirms execution of the `clear` command. Linked to the data output `clear_return`.

Data Inputs

- **index** (UDINT): The index (position) of the pixel on the LED strip to be set. The count typically starts at 0.
- **red** (UDINT): The red component of the color (value range depends on the hardware, e.g., 0-255).
- **green** (UDINT): The green component of the color (value range depends on the hardware, e.g., 0-255).
- **blue** (UDINT): The blue component of the color (value range depends on the hardware, e.g., 0-255).

Data Outputs

- **set_pixel_return** (DINT): Returns an error status after executing the `set_pixel` command. A value other than 0 indicates an error (e.g., invalid pixel index).
- **clear_return** (DINT): Returns an error status after executing the `clear` command. A value other than 0 indicates an error.

Adapter

This function block has no adapter interfaces.

Functionality

The function block operates in an event-driven manner. Upon receiving a `INIT` event, the underlying hardware (LED strip) is initialized, and the `INITO` event is generated.

The `set_pixel` event triggers the main command. The values present at the data inputs `index`, `red`, `green`, and `blue` at this time are read and sent to the LED strip to set the corresponding LED to the desired color. The `set_pixel_CNF` event is then output along with a status code (`set_pixel_return`).

The `clear` event sets all pixels of the strip to black (off), which is equivalent to clearing the current pattern. The `clear_CNF` event is then output with a status code (`clear_return`).

Technical Features

- The data inputs for the color values are of type `UDINT` (unsigned double integer), which allows for a large value range. The actual effective resolution (e.g., 8 bits = 0-255) depends on the connected hardware.
- The data outputs for feedback are of type signed `DINT` to represent positive and negative error codes.
- The function block follows the typical IEC 61499 Service Interface Pattern with separate acknowledgment events (`CNF`) for each command.

Status Overview

1. **Not Initialized**: After startup. Only the `INIT` event is valid.
2. **Initialized / Ready**: After successful execution of `INITO`, the commands `set_pixel` and `clear` can be received and processed. The function block returns to this state after each command.

Application Scenarios

- **Status Indicators**: Individual LEDs can be used as status or warning lights (e.g., machine in operation, fault at position X).
- **Simple Lighting Effects**: By sequentially setting individual pixels, chasing or flashing effects can be implemented.
- **Visualization of Process Data**: The color or brightness of a pixel can represent a process value (e.g., temperature, fill level).
-

⚖️ Comparison with Similar Components

Compared to components that transfer entire color patterns or images to an LED matrix (e.g., `strip_show` or `matrix_display`), `strip_set_pixel` operates at a very granular, pixel-by-pixel level. It offers maximum control over each individual LED but is less efficient for transferring complex images. Components like `strip_fill` typically set an entire area or all LEDs to a single color at once, while `strip_set_pixel` addresses each LED individually.

Compared to components that transfer entire color patterns or images to an LED matrix (e.g., `strip_show` or `matrix_display`), `strip_set_pixel` operates at a very granular, pixel-by-pixel level. It offers maximum control over each individual LED but is less efficient for transferring complex images. Components like `strip_fill` typically set an entire area or all LEDs to a single color at once, while `strip_set_pixel` addresses LEDs individually.

🛠️ Related Exercises

- Exercise_031

Conclusion

The `strip_set_pixel` function block is a fundamental and essential building block for controlling addressable RGB LED strips within 4diac. Its simple, event-based interface allows for precise and direct control of each individual pixel. Its strength lies in its simplicity for point-by-point control tasks, while for more complex animations, combining it with higher-level, sequencing blocks is recommended.

logiBUS_AI

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_AI GlobalConstants define a collection of constants for configuring analog inputs in the logiBUS system. These constants are used for simple and consistent referencing of the analog input channels.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

No adapters available

Functionality

The logiBUS_AI GlobalConstants provide predefined constants of type `logiBUS_AI_S`, each representing a specific analog input channel. Each constant contains a pin number that identifies the physical input channel.

Technical Specifications

- **Constant Type**: All constants are of the structured data type `logiBUS_AI_S`
- **Pin Assignment**: The constants `AnalogInput_I1` to `AnalogInput_I9` correspond to analog inputs 1 to 9
- **Invalid Reference**: The constant `Invalid` with pin value 255 serves as a marker for invalid or non-existent inputs
- **Initialization**: All constants are initialized with their corresponding pin values upon declaration

State Overview

Since these are constants, they do not undergo state changes. Their values remain unchanged throughout runtime.

Application Scenarios

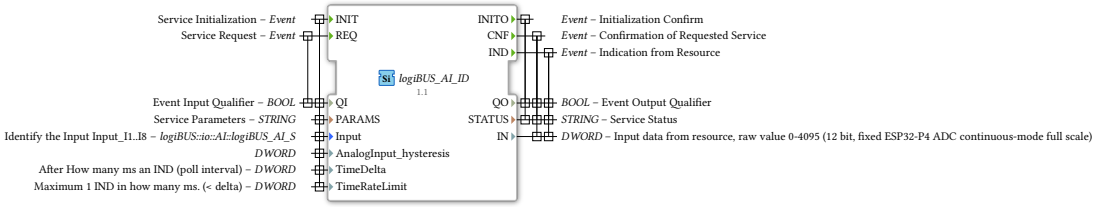
- Configuration of analog inputs in logiBUS systems
- Parameterization of function blocks that require analog inputs
- Type-safe referencing of analog channels in programming
- Error handling through the use of the Invalid constant

⚖️ Comparison with similar function blocks

Unlike function blocks with dynamic behavior, GlobalConstants offer:

- No runtime calculations
- No event handling
- Constants instead of variable values
- Direct initialization during declaration

Conclusion



The logiBUS_AI GlobalConstants provide an efficient and type-safe method for referencing analog inputs in the logiBUS system. The predefined constants simplify programming and reduce the potential for errors during channel configuration.

logiBUS_AI_ID

• – ○ • – ○ • – ○ •

Introduction

The logiBUS_AI_ID is a Service Interface Function Block for processing double-word input data. This block serves as an interface for analog inputs and provides functions for initializing, querying, and indicating input data.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation
- **IND**: Resource Indication

Data Inputs

- **QI** (BOOL): Event Input Qualifier - Enables/Disables the Service
- **PARAMS** (STRING): Service Parameter for Configuration
- **Input** (logiBUS_AI_S): Identifies the input (I1..I8) with the initial value “Invalid”
- **AnalogInput_hysteresis** (DWORD): Hysteresis Value for Analog Inputs. IND when the raw value changes by more than this value (0 = off, 1 = every change)
- **TimeDelta** (DWORD): Cyclic IND after at most this many ms (poll interval, 0 or 16#FFFFFFFF = off). Initial value 250
- **TimeRateLimit** (DWORD): Maximum of one IND per this many ms (less than TimeDelta). Initial value 100

Data Outputs

- **QO** (BOOL): Event Output Qualifier - Status of the Service Output
- **STATUS** (STRING): Service status information

- **IN** (DWORD): Input data from the resource — raw value 0-4095 (12 bit), fixed on the ESP32-P4 in continuous/DMA ADC mode, no other bit width selectable

Adapter

No adapter interfaces available.

Functionality

The Function Block enables communication with analog input devices via the logiBUS system. During INIT initialization, the service parameters are configured and the input is identified. Data can be queried via REQ, while IND processes asynchronous data announcements from the resource. The hysteresis function assists in filtering signal noise.

Technical Features

- **Raw full-scale value of `IN`**: 0-4095 (12 bit) — the ESP32-P4 ADC driver (continuous/DMA mode) has no selectable bit width on this chip, `SOC_ADC_DIGI_MIN_BITWIDTH` = `SOC_ADC_DIGI_MAX_BITWIDTH` = 12. Raw-to-volt conversion: `Vout = Dout × Vmax / 4096` (`Vmax` depends on the ADC attenuation `ADC_ATTEN_DB_12`).
- Uses special data types from the logiBUS::io::AI package
- Supports hysteresis functionality for analog signals
- Offers both synchronous (CNF) and asynchronous (IND) operating modes
- Initializes inputs with a defined “Invalid” state

State Overview

The function block has the following operating states:

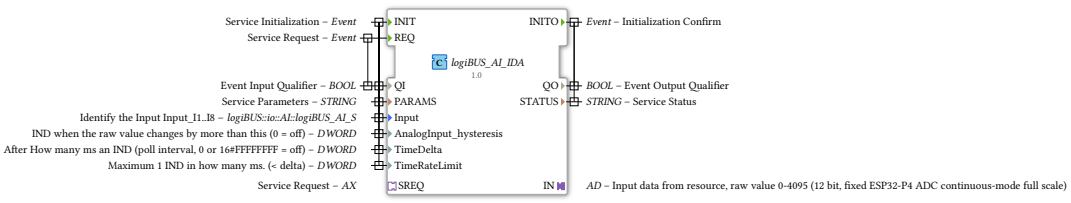
- Not initialized (before INIT)
- Initialized and ready (after INITO)
- Data query active (with REQ/CNF)
- Indication mode (with IND)

Application Scenarios

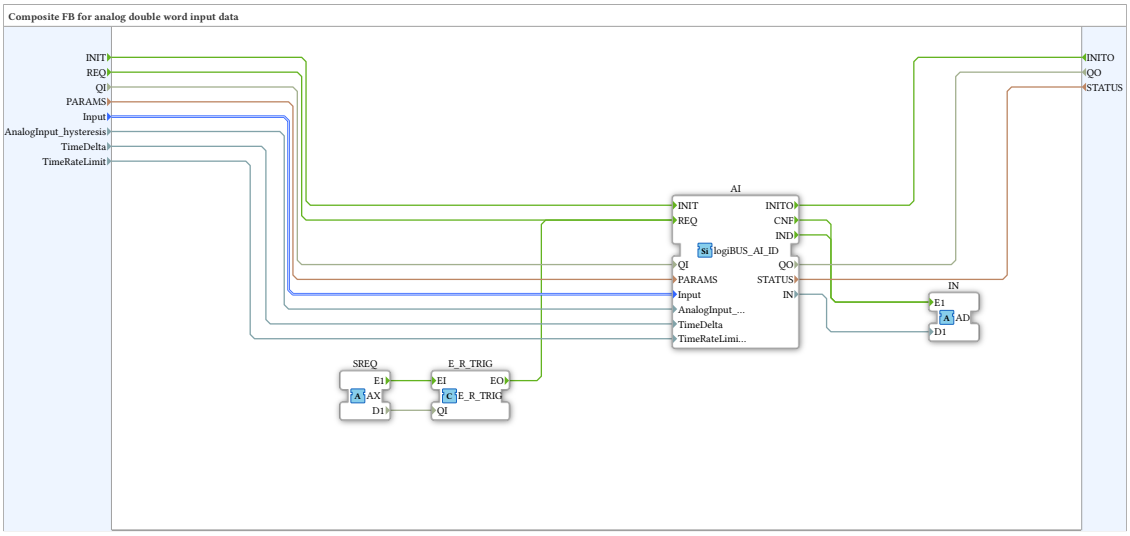
- Industrial automation systems with analog sensors
- Process control systems with hysteresis requirements
- Embedded systems with logiBUS communication
- Systems with multiple analog inputs (I1-I8)

⚖️ Comparison with Similar Function Blocks

Compared to simple analog input function blocks, logiBUS_AI_ID offers extended functions such as Hysteresis control, detailed status feedback, and a structured initialization procedure. Integration into the logiBUS system enables standardized communication.



🛠️ Related Exercises



- Exercise_028
- Exercise_034

Conclusion

The logiBUS_AI_ID Function Block provides a robust and flexible solution for connecting analog input devices in industrial control systems. Its extensive parameterization options and integrated hysteresis functionality make it particularly suitable for demanding automation applications.

logiBUS_AI_IDA

• – ○ • – ○ • – ○ •

Introduction

The function block `logiBUS_AI_IDA` is a composite function block (FB) for processing analog double-word input data. It serves as an interface between a logiBUS resource and the application by providing uniform analog input values via an adapter and returning status information (QO, STATUS) to the calling instance. The function block supports both initialization-driven and event-driven processing.

Interface Structure

Event Inputs

Event	Type	With	Description
INIT	EInit	QI, PARAMS, Input, AnalogInput_hysteresis, TimeDelta, TimeRateLimit	Service Initialization: Configuration of the analog input and start of data provisioning.
REQ	Event	QI	Service Request: Triggers immediate processing or a status update.

Event Outputs

Event	Type	With	Description
INITO	EInit	QO, STATUS	Confirmation of initialization with quality and status information.

Data Inputs

Name	Type	Initial Value	Description
QI	BOOL	–	Qualifier for events (e.g., enabling processing).
PARAMS	STRING	–	Service parameters (e.g., configuration strings).
Input	logiBUS::io::AI::logiBUS_AI_S	Invalid	Selection of the analog input (e.g., Input_I1...I8).
AnalogInput_hysteresis	DWORD	–	Hysteresis for change detection. A value of 0 requires TimeDelta to be non-zero.

TimeDelta	DWORD	250	Cycle time in ms for cyclic processing (16#FFFFFFFF = only on change).
TimeRateLimit	DWORD	100	Minimum interval in ms between two events (IND) (< TimeDelta).

Data Outputs

Name	Type	Description
QO	BOOL	Output qualifier (e.g., valid state after INIT).
STATUS	STRING	Status message (e.g., initialization error or OK).

Adapter

Direction	Name	Type	Description
Plug	IN	adapter::types::unidirectional::AD	Receives the analog input data from the resource — raw value 0-4095 (12 bit), fixed on the ESP32-P4 (no other bit width selectable in continuous/DMA ADC mode).
Socket	SREQ	adapter::types::unidirectional::AX	Allows an external service request.

Functionality

The block encapsulates the internal FB `logiBUS_AI_ID`, which contains the actual analog input processing logic. The internal network connects:

- **INIT → AI.INIT** starts the resource configuration.
- **AI.INITO → INITO** returns the initialization confirmation.
- **REQ → AI.REQ** triggers immediate processing.
- **SREQ.E1** (external service request event) is routed via **E_R_TRIG** (edge detection) to **AI.REQ** — this lets an external adapter trigger processing as well.
- **AI.IND** and **AI.CNF** — both connect to **IN.E1** (the plug output) and signal externally that new data is available on the `IN` adapter.
- The data inputs (QI, PARAMS, Input, hysteresis, TimeDelta, TimeRateLimit) are passed straight through to the internal block.
- The QO and STATUS outputs come from the internal block.

Cyclic processing follows `TimeDelta`. If `TimeDelta = 16#FFFFFFFF` is set, an event is only generated when the analog value changes (taking hysteresis into account).

Technical Details

- **Raw full-scale value of `IN`**: 0-4095 (12 bit) — the ESP32-P4 ADC driver (continuous/DMA mode) has no selectable bit width on this chip, `SOC_ADC_DIGI_MIN_BITWIDTH = SOC_ADC_DIGI_MAX_BITWIDTH = 12`. Raw-to-volt conversion: `Vout = Dout × Vmax / 4096` (`Vmax` depends on the ADC attenuation `ADC_ATTEN_DB_12`).
- **Hysteresis (`AnalogInput_hysteresis`)**: If the value is 0, the cycle time (`TimeDelta`) must be non-zero, otherwise no events can be triggered.
- **Timing**: `TimeDelta` and `TimeRateLimit` allow fine-tuning the behavior — e.g., cyclic polling (TimeDelta > 0) or pure change notification (TimeDelta = 0xFFFFFFFF).
- **External Service Request**: Another component (e.g., a higher-level control block) can request an update via socket `SREQ`.
- **Composite Architecture**: The block is implemented as a composite, which allows reuse of the proven `logiBUS_AI_ID` and simultaneously extends the interface.

State Overview

The block itself does not have an explicit state machine, as its behavior is determined by the internal FB `logiBUS_AI_ID`. The following basic processes can be identified:

1. **Initialization Phase**

- Event `INIT` → Internal function block is configured → Confirmation `INITO` with QO/STATUS.

1. **Data Provisioning (Cyclical / Change-Based)**

- After INIT, the internal function block regularly sends events via `IND` (or `CNF`) to the plug `IN`, or upon value change.

1. **Manual Request**

- The current processing is triggered by `REQ` or `SREQ`; results are also output via `IN`.

Application Scenarios

- **Analog Sensor Acquisition**: Logging in analog sensors (e.g., temperature, pressure, level) with configurable hysteresis and sampling rate.
- **Monitoring with Minimal Bus Load**: By setting `TimeDelta = 0xFFFFFFFF`, events are only sent when relevant changes occur.
- **Safety-Critical Applications**: Combination of cyclic polling (e.g., 250 ms) with a fast change alarm (`TimeRateLimit` limits the event frequency).
- **Control Bus Connection**: This function block is suitable as a generic interface for logiBUS-compatible analog input modules with a uniform adapter protocol.

Comparison with Similar Function Blocks

- **logiBUS_AI_ID** (internal FB): Provides the core logic but does not have an additional socket for external service requests. `logiBUS_AI_IDA` extends this functionality with `SREQ` and indirect triggering via `E_R_TRIG`.
- **logiBUS_AI_S** (data structure): Serves as a pure data type for identifying the analog channel; `logiBUS_AI_IDA` uses it as an input parameter.
- **Other composite function blocks for digital inputs**: Unlike digital function blocks, the focus is on analog conversion, hysteresis, and time-controlled change detection.

Conclusion

The `logiBUS_AI_IDA` offers a flexible and extended interface for processing analog inputs in logiBUS-based automation systems. Its configuration options (hysteresis, time parameters, external service requests) make it suitable for a wide range of applications – from simple cyclic acquisition to efficient change-based communication. The composite structure allows for a clear separation of core logic and event handling customizations.

logiBUS_AI_S

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `logiBUS_AI_S` is a structured data type (struct) used to configure an analog input (AI) channel within the logiBUS library. It defines the basic parameter structure required to address a physical pin of a logiBUS hardware module for acquiring analog signals.

Interface Structure

This is a structured data type (struct), therefore it does not have event or adapter interfaces in the conventional sense of an executable function block. Its structure consists of a single data element.

Data Inputs

The structure itself contains the following data element, which serves as an input parameter for a configuring function block (e.g., `logiBUS_AI`):

- **`Pin`** (`USINT`): This value specifies the physical hardware pin or channel of the logiBUS module from which the analog signal is to be read. The default value is `255`, which is typically interpreted as an invalid or unconfigured state.

Functionality

The data type `logiBUS_AI_S` is a pure data structure and has no active functionality. It serves as a container for configuration data. Its main purpose is the parametric description of an analog input. A higher-level I/O manager or device driver function block (such as `logiBUS_AI`) reads the values stored in an instance of this structure and uses them to correctly configure and control the corresponding hardware interface.

Technical Features

- **Initial Value:** The member `Pin` is predefined with the initial value `255`. This value is outside the typical range of valid pin numbers (often 0 to n) and can therefore be used to detect an uninitialized or faulty configuration.
- **Type Safety:** Using a structured data type instead of individual, unconnected parameters increases the type safety and maintainability of the code in the 4diac IDE.
- **Library Affiliation:** This type is part of the `logiBUS::io::AI` package, clearly indicating its membership in the logiBUS IO library for analog inputs.

Application Scenarios

This struct is used exclusively in scenarios where logiBUS hardware with analog input modules (e.g., for voltage or current measurement) is integrated into a 4diac FORTE application. Typical applications include:

- Process monitoring (temperature, pressure, level via sensors)
- Control voltage acquisition
- Configuration of multi-channel measurement systems where a separate instance of `logiBUS_AI_S` is created for each channel.

⚖️ Comparison with Similar Building Blocks

Within the logiBUS library, similar structured data types exist for other I/O functions, such as `logiBUS_DI_S` for digital inputs or `logiBUS_AO_S` for analog outputs. These differ primarily in their context-specific names and are designed for the respective type of signal processing. However, the basic structure (a `Pin` field) is often identical or very similar.

Conclusion

The `logiBUS_AI_S` data type is an essential configuration element for using analog inputs with logiBUS in 4diac. As a simple, well-defined structure, it enables clear and centralized management of hardware parameters and forms the basis for reliable connection of analog sensors to an IEC 61499 control system.

logiBUS_DI

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_DI GlobalConstants definition provides a collection of predefined constants for digital inputs of the logiBUS system. These constants define the pin assignments for various digital input channels and are used to configure logiBUS_DI function blocks.

Interface Structure

Event Inputs

No event inputs available - this is a constant definition

Event Outputs

No event outputs available - this is a constant definition

Data Inputs

No data inputs available - this is a constant definition

Data Outputs

No data outputs available - this is a constant definition

Adapters

No adapters available - this is a constant definition

Functionality

The GlobalConstants definition logiBUS_DI provides structured constants of type `logiBUS_DI_S`, each containing a specific pin value:

- **Input_I1** to **Input_I9**: Defines digital inputs 1 to 9 with corresponding pin numbers
- **Invalid**: Defines an invalid pin with the Value 255

These constants are used as initialization values for configuring digital inputs in the logiBUS system.

Technical Features

- **Structure Type**: All constants use the structured data type `logiBUS_DI_S`
- **Pin Range**: Valid pins range from 1 to 9; invalid configurations are indicated by pin 255
- **Package Membership**: The constants are organized in the package `logiBUS::io::DI`
- **Initialization**: All constants are initialized with their pin values upon declaration

State Overview

Since this is a pure constant definition, there are no state transitions or state machines.

Application Scenarios

- Configuration of digital input modules in logiBUS systems
- Parameterization of function blocks that process digital inputs
- Type-safe pin assignments in control programs
- Error handling through the use of the invalid constant

⚖️ Comparison with similar function blocks

Unlike function blocks with active logic, this is a pure constant definition that:

- Does not perform any active processing
- Does not process any events
- Provides only configuration data
- Is evaluated at compile time

Conclusion

The logiBUS_DI GlobalConstants offer a structured and type-safe method for configuring digital inputs in the logiBUS system. The predefined constants reduce the susceptibility to errors in pin assignment and improve the maintainability of control programs.

logiBUS_DI_Events

• – ◦ • – ◦ • – ◦ •

Introduction

The GlobalConstants definition `logiBUS_DI_Events` provides a comprehensive collection of event constants for digital inputs (DI) in the logiBUS system. These constants define various button press events and their unique identifiers, which are used in the control logic for processing user input via pushbuttons.

Functionality

The GlobalConstants definition `logiBUS_DI_Events` contains 14 different event constants of type `logiBUS_DI_Events_S`, each identified by a unique numeric value (`EType`). These constants are used to represent various states and events of pushbuttons in the control logic.

Technical Features

- **Structure Type**: All constants use the data type `logiBUS_DI_Events_S`
- **Value Range**: The EType values range from 0-12 for valid events, with 255 for invalid events
- **Package Membership**: `logiBUS::io::DI`
- **Constant Definition**: All values are declared as global constants (CONSTANT)

Documentation for the individual events: https://components.espressif.com/components/espressif/button

State Overview

The event constants cover the following states:

EType	Constant	Description
0	BUTTON_PRESS_DOWN	Button pressed
1	BUTTON_PRESS_UP	Button released
2	BUTTON_PRESS_REPEAT	Button pressed again
3	BUTTON_PRESS_REPEAT_DONE	Button repeat ended
4	BUTTON_SINGLE_CLICK	Single click
5	BUTTON_DOUBLE_CLICK	Double click
6	BUTTON_MULTIPLE_CLICK	Multi-click
7	BUTTON_LONG_PRESS_START	Long press begins
8	BUTTON_LONG_PRESS_HOLD	Long press is held
9	BUTTON_LONG_PRESS_UP	Long press ends
10	BUTTON_PRESS_END	Press ends
11	BUTTON_EVENT_MAX	Maximum event ID

12	BUTTON_NONE_PRESS	No key press
255	Invalid	Invalid event

Application Scenarios

- **User Interface Control**: Processing keystrokes on operator panels
- **Machine Control**: Capturing manual inputs on industrial controllers
- **Safety Systems**: Monitoring emergency stop buttons and safety switches
- **Menu Navigation**: Controlling display menus via keystrokes
- **State Monitoring**: Detecting various keystroke patterns

⚖️ Comparison with Similar Function Blocks

Unlike simple digital input blocks that only detect binary states (ON/OFF), `logiBUS_DI_Events` offers advanced event detection with:

- Time-resolved events (Press/Release)
- Complex interaction patterns (Clicks, Double-Clicks)
- Long-term detection (Long Press)
- Repeat functionality

Conclusion

The `logiBUS_DI_Events` The GlobalConstants definition provides a comprehensive and structured basis for processing push-button events in industrial control systems. Through standardized event codes, it enables a consistent and maintainable implementation of user interactions via digital inputs.

logiBUS_DI_Events_S

• – ◦ • – ◦ • – ◦ •

Introduction

The structured data type `logiBUS_DI_Events_S` is used to configure events for digital inputs (DI) within the logiBUS framework. It defines the event type that can be assigned to a specific digital input channel. This data type is an essential component for parameterizing logiBUS I/O function blocks.

Interface Structure

This block is a pure structured type and does not have any event or adapter interfaces in the conventional sense of a function block. Its structure is used as an input or output data parameter in other function blocks.

Data Inputs

Not applicable – This is a data type.

Data Outputs

Not applicable – This is a data type.

Adapters

Not applicable – This is a data type.

Functionality

The data type `logiBUS_DI_Events_S` encapsulates a single variable (`EType`) that represents an event type code. The default value is set to `255`, which typically corresponds to an inactive or unconfigured state. Specific values (e.g., 0, 1, 2, ...) are used to identify specific events (such as edge transitions) that can then be processed by higher-level control logic.

Technical Features

- **Data Type:** This is a structured data type (`STRUCT`) that is used as a complex data parameter in other function blocks.
- **Initial Value:** The contained variable `EType` is pre-initialized with the value `255`. This value likely serves as a placeholder or "invalid" indicator.

- **Base Type:** The variable `EType` is of type `USINT` (Unsigned Short Integer, 0-255), which provides a limited and efficient range of values for event codes.

State Overview

Since this is a passive data type, there is no state machine. The "state" is the stored value of the variable `EType`.

Application Scenarios

This structured data type is primarily used in conjunction with logiBUS I/O function blocks, for example:

- As an element in an array for configuring all digital inputs of a module.
- As a parameter to specify which physical event (e.g., rising edge) should trigger a logical event in the control program.

⚖️ Comparison with Similar Function Blocks

Unlike function blocks (FBs) such as `E_R_TRIG` or `F_TRIG`, which independently generate edge events, `logiBUS_DI_Events_S` is a pure configuration data type. It provides the information about *which* hardware event should be translated into such a logical edge event by a separate driver or hardware abstraction block.

Conclusion

The `logiBUS_DI_Events_S` is a fundamental configuration block within the logiBUS architecture. It enables flexible and parameterizable mapping of hardware events at digital inputs to software-based processing routines. Its simple structure, reduced to a `USINT`, ensures efficiency and ease of use in higher-level configuration structures.

logiBUS_DI_S

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `logiBUS_DI_S` is a structured data type (struct) used to configure a digital input (DI) within the logiBUS framework. It defines the basic parameters necessary to control a physical or logical input point on a logiBUS-compatible I/O system. This data type is typically used as input for specific I/O function blocks.

Interface Structure

As a structured data type, `logiBUS_DI_S` does not have event or adapter interfaces in the conventional sense. Its structure consists of a single data element.

Data Inputs

The structure itself represents the configurable data inputs. It is passed as a whole to a higher-level function block.

Name	Data Type	Initial Value	Comment
`Pin`	`USINT` (Unsigned Short Integer)	255	Defines the number of the input pin or channel to be addressed.

Data Outputs

This data type has no data outputs of its own.

Functionality

The data type `logiBUS_DI_S` is purely a data storage structure. Its function is limited to storing the value of the member `Pin`. The initial value `255` often serves as a default or invalid value (e.g., "not configured"). A specific I/O function block that expects this struct as an input reads the `Pin` value and uses it to perform hardware addressing for the digital input.

Technical Details

- **Data type `USINT`:** The use of a `USINT` (0…255) for the pin suggests that up to 256 different input channels per device or module can be addressed.

- **Initial value 255:** This value is outside the typical usable range (0...n, where n<255) and can be interpreted by the application logic or driver as an indicator of a missing configuration.
- **StructuredType:** As `StructuredType`, this block is not an executable function block, but a pure data type used in the declaration of variables and interfaces of other function blocks.

State Overview

Since it is a passive data type, `logiBUS_DI_S` does not have a state machine.

Application Scenarios

- **I/O Block Configuration:** This struct primarily serves as an input parameter for function blocks such as `logiBUS_DI` or similar, which perform the actual reading operation from a digital input.
- **Parameterization via Networks:** The structure can easily be instantiated and configured (`Pin` number set) in higher-level controllers (e.g., a PLC) and passed on to subordinate I/O nodes or driver blocks.
- **Structured Programming:** Enables clean encapsulation of configuration data for digital inputs, increasing code reusability and readability.

⚖️ Comparison with Similar Building Blocks

- **Simple `USINT` Variable:** Instead of a struct, a `USINT` variable could be used directly. However, the struct offers semantic clarity (the name `logiBUS_DI_S` describes its purpose) and is easier to extend if further configuration parameters (such as filter time or inversion) need to be added in the future.
- **Device-Specific Structs:** Within the logiBUS ecosystem, similar structs could exist for other functions (e.g., `logiBUS_DO_S` for digital outputs, `logiBUS_AI_S` for analog inputs). This would enable a uniform configuration philosophy across different I/O types.

🛠️ Related exercises

- Uebung_003a_sub
- IX_TO_Aux_QX
- IXA_TO_Aux_QXA
- IX_TO_logiBUS_LED_strip_QX

Conclusion

The `logiBUS_DI_S` is a basic and specific configuration block for the logiBUS I/O architecture. As a structured data type, it offers a standardized and clear method for defining the target address (pin) for a digital input. Its strength lies in its simplicity and its readiness for future extensions, making it a useful component for the structured configuration of fieldbus systems in 4diac FORTE.

logiBUS_IB

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_IB is a Service Interface Function Block for processing byte input data. This block serves as an input interface for logiBUS systems and enables communication with digital inputs. It supports special event handling such as key press repetitions and provides a standardized interface for initializing and operating input devices.

Interface Structure

Event Inputs
- **INIT**: Service Initialization Event
- Linked to: QI, PARAMS, Input, InputEvent
- **REQ**: Service Request Event
- Linked to: QI

Event Outputs
- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service Operation
- Linked to: QO, STATUS, IN
- **IND**: Indication from Resource Interface
- Linked to: QO, STATUS, IN

Data Inputs
- **QI** (BOOL): Event Input Qualifier - Controls the execution of service operations
- **PARAMS** (STRING): Service Parameters for Configuration
- **Input** (logiBUS_DI_S): Identifies the input (I1..I8), Initial value: Invalid
- **InputEvent** (logiBUS_DI_Events_S): Identifies the event (currently only REPEAT supported), Initial value: Invalid

Data Outputs
- **QO** (BOOL): Event Output Qualifier - Status of the service operation
- **STATUS** (STRING): Service status information
- **IN** (BYTE): Input data from the resource

Adapter
No adapter interfaces available.

Functionality
The logiBUS_IB Function Block operates as an input service interface for logiBUS systems. During initialization (INIT event), the service parameters are configured and the inputs are defined. The block can respond to both explicit requests (REQ event) and asynchronous events from the hardware. It offers special support for repeated button press events (BUTTON_PRESS_REPEAT).

Technical Features
- Supports special event types such as BUTTON_PRESS_REPEAT and BUTTON_PRESS_REPEAT_DONE
- Byte-based data input (8-bit)
- Flexible input configuration via PARAMS string
- Separate event outputs for acknowledgments (CNF) and hardware indications (IND)
- Initial value “Invalid” for unconfigured inputs

State Overview
The function block has the following operating states:

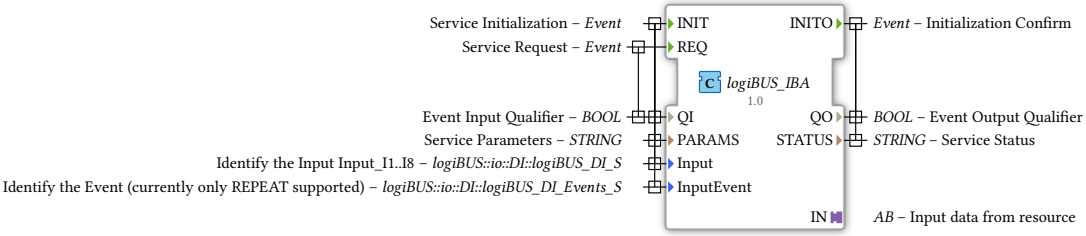
- **Not Initialized**: Before INIT event
- **Initialized**: After successful INIT operation
- **Ready**: For REQ requests and IND events
- **Error State**: In case of faulty operations (reportable via STATUS)

Application Scenarios
- Digital input modules with 8 inputs
- Keyboard interface with repeat function
- General digital input interfaces in logiBUS systems
- Hardware-related input operations with event handling

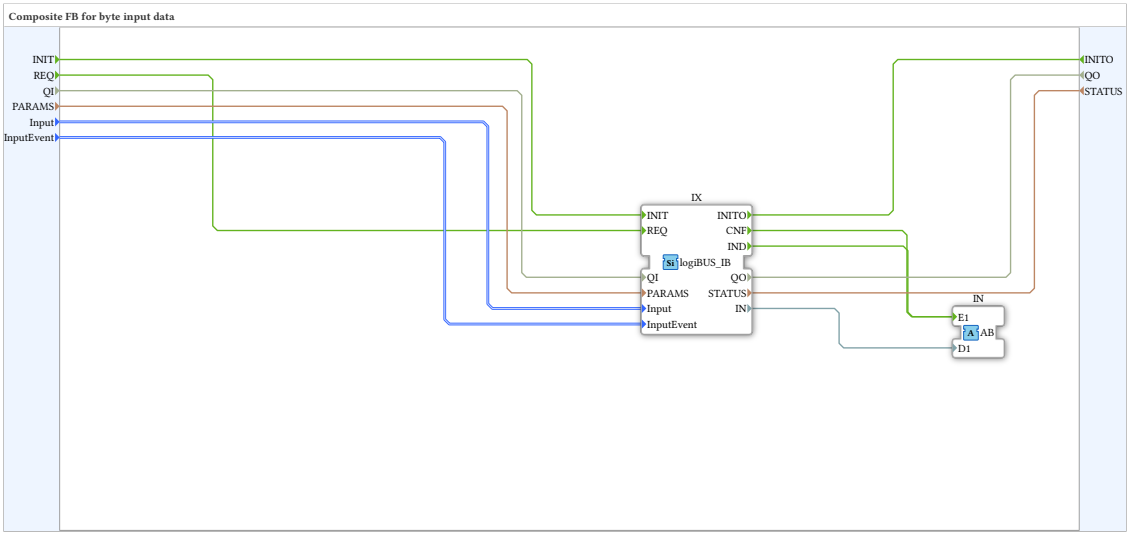
⚖️ Comparison with Similar Function Blocks

Compared to simple digital input blocks, logiBUS_IB offers enhanced service functionality with:

- Configurable configuration
- Event-based communication
- Status feedback
- Special support for key press repetitions



🛠️ Related Exercises



- Exercise_006c
- Exercise_011a

Conclusion

The logiBUS_IB Function Block represents a powerful and flexible solution for byte input data in logiBUS systems. Its service-oriented architecture and support for special event types make it particularly suitable for applications requiring advanced input functionalities such as key press repetitions.

logiBUS_IBA

• — ○ • — ○ • — ○ •

Introduction

The **logiBUS_IBA** function block is a composite block for processing byte input data via the logiBUS protocol. It encapsulates the initialization, configuration, and event control of a logiBUS input block and provides the data via an adapter. The block is designed for use in agricultural control systems.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Service initialization; takes over the configuration parameters (QI, PARAMS, Input, InputEvent)

REQ	Event	Service request to execute a function (dependent on QI)

Event Outputs

Event	Type	Description
INITO	EInit	Initialization confirmation; signals successful or failed initialization (QO, STATUS)

Data Inputs

Variable	Type	Description
QI	BOOL	Qualifier for event inputs; controls the activation of event processing
PARAMS	STRING	Service parameter (e.g., configuration data for the logiBUS driver)
Input	logiBUS::io::DI::logiBUS_DI_S	Selection of the physical input (e.g., Input_I1..I8); Default value: `logiBUS_DI::Invalid`
InputEvent	logiBUS::io::DI::logiBUS_DI_Events_S	Selection of the event type (currently only `REPEAT` is supported); Default value: `logiBUS_DI_Events::Invalid`

Data Outputs

Variable	Type	Description
QO	BOOL	Qualifier for event outputs; indicates the success of the operation
STATUS	STRING	Status message (e.g., error or success message)

Adapters

Adapter	Type	Description
IN	adapter::types::unidirectional::AB	Unidirectional adapter for providing input data to the higher-level resource

Functionality

The **logiBUS_IBA** function block works internally with an instance of the **logiBUS_IB** function block (from the `logiBUS::io::DI` library). The event and data paths are linked as follows:

- During the **INIT** event, the inputs `QI`, `PARAMS`, `Input`, and `InputEvent` are forwarded to the corresponding initialization of the internal function block. After initialization is complete, the output event **INITO** is set, and the outputs `QO` and `STATUS` are updated.
- The **REQ** event triggers the internal function block for processing a service request. The processing depends on the current state and the input parameters.
- Data read from the logiBUS input is transferred to the output adapter **IN** via the adapter connection (`IN.E1` and `IN.D1`). The adapter then provides the data to a higher-level function block or resource.
- Error and status signals are reported back via `QO` and `STATUS`.

Technical Features

- **Composite FB:** This function block encapsulates the complex initialization and data provision of a logiBUS input in a single interface.
- **Adapter-Based Data Output:** Input data is not output via separate data outputs, but rather via a **unidirectional adapter** (type `AB`). This allows for flexible coupling with other function blocks.
- **Configurable Inputs:** The physical input (I1..I8) and the event behavior (e.g., repetition) can be selected using the parameters `Input` and `InputEvent`.

- **License and Origin:** This function block is provided under the **Eclipse Public License 2.0** and is optimized for use in agricultural technology.

State Overview

This function block does not have an explicitly displayed state machine, as it is a composite function block. The internal behavior is determined by the included function block **logiBUS_IB**, which typically implements the following states:

- **IDLE** – Waiting for INIT or REQ
- **INIT** – Initialization with parameters
- **RUN** – Ready for operation, data processing active
- **ERROR** – Error state (status message via STATUS)

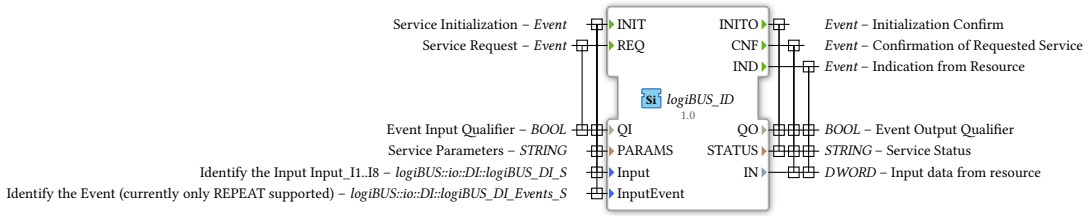
Application Scenarios

- **Agricultural Control Systems:** Acquisition of digital input signals (e.g., sensors, switches) via logiBUS and forwarding to a controller.
- **Input Modules in Fieldbus Systems:** The function block serves as a standardized interface for logiBUS inputs in IEC 61499-2 applications.
- **Prototypes and Test Setups:** Thanks to its configurability, the function block can be quickly adapted to various input configurations.

Comparison with Similar Function Blocks

- **logiBUS_IB:** The internal function block is a pure Basic Function Block; **logiBUS_IBA** adds an adapter output and simplified event control.
- **SYNC/D_SYNC:** These function blocks from the Sync library offer similar input configuration but without specific logiBUS protocol support.
- **Generic Input Adapter:** Compared to generic adapters, **logiBUS_IBA** offers a predefined logiBUS configuration, reducing development effort.

Conclusion



The **logiBUS_IBA** is a practical composite function block for integrating logiBUS inputs into IEC 61499-based automation systems. By combining initialization, parameter configuration, and adapter-based data output, it creates a clean and reusable interface. It is particularly suitable for agricultural applications that rely on the logiBUS protocol.

logiBUS_ID

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_ID function block is an input service interface module for double-word input data (DWORD). It serves as an interface for communication with logiBUS input devices and enables the processing of digital input signals in 4diac control systems.

Interface Structure

Event Inputs

- **INIT**: Service Initialization - Initializes the function block with parameters and configuration
- **REQ**: Service Request - Triggers a query of the current input data

Event Outputs

- **INITO**: Initialization Acknowledgement - Confirms successful initialization
- **CNF**: Confirmation of Requested Service - Acknowledges a REQ request

- **IND**: Indication from Resource - Signals asynchronous events from the input device

Data Inputs

- **QI**: Event Input Qualifier (BOOL) - Enables/Disables the service
- **PARAMS**: Service Parameters (STRING) - Configuration parameters for the service
- **Input**: Input Identifier (logiBUS_DI_S) - Identifies the input (I1..I8)
- **InputEvent**: Event Identifier (logiBUS_DI_Events_S) - Identifies the event (currently only REPEAT supported)

Data Outputs

- **QO**: Event Output Qualifier (BOOL) - Service output status
- **STATUS**: Service Status (STRING) - Service status information
- **IN**: Input Data from the Resource (DWORD) - Current input data from the device

Adapter

No adapter interfaces are available.

Functionality

The logiBUS_ID function block acts as a bridge between the 4diac system and logiBUS input devices. Device parameters are configured during initialization (INIT). The block can process both synchronous queries (REQ/CNF) and asynchronous events (IND). Input data is provided as a 32-bit double word (DWORD).

Technical Features

- Supports double-word input data (32-bit)
- Uses specific logiBUS data types for input and event configuration
- Offers both synchronous and asynchronous communication modes
- Initial values for input parameters are defined as “Invalid”

State Overview

The function block has the following operating states:

- Not initialized (before INIT)
- Initialized and ready (after successful INITO)
- Query mode (during REQ/CNF cycle)
- Event mode (during IND signaling)

Application Scenarios

- Connecting logiBUS input devices in automation systems
- Processing digital input signals in control applications
- Integration of button inputs (BUTTON_PRESS_UP, BUTTON_LONG_PRESS_HOLD, BUTTON_LONG_PRESS_UP)
- Monitoring of state changes at digital inputs

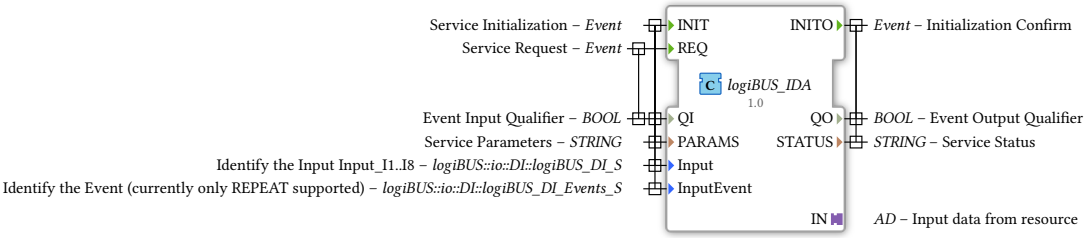
⚖️ Comparison with Similar Blocks

Compared to standard digital input blocks, logiBUS_ID:

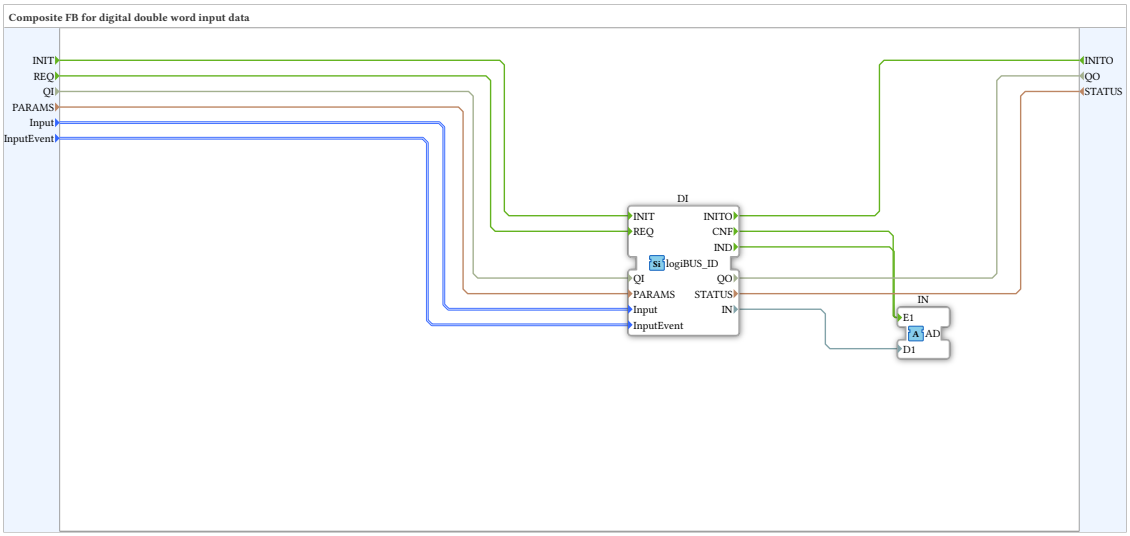
- Specific logiBUS integration
- Advanced event handling
- Configurable parameters via STRING parameters
- Asynchronous event indication

🛠️ Related exercises

- Exercise_011a2



Conclusion



The logiBUS_ID function block represents a specialized interface for logiBUS input devices in 4diac systems. Its flexible configuration and support for various operating modes make it ideal for applications requiring reliable processing of digital input signals with advanced event handling.

logiBUS_IDA

• – ○ • – ○ • – ○ •

Introduction

The **logiBUS_IDA** is a composite function block (CFB) for digital double-word input processing. It encapsulates an internal **logiBUS_ID** block and provides a uniform interface for initialization, parameterization, and event-driven data querying. The block is designed for use in logiBUS-based automation systems and supports the selection of an input channel as well as the configuration of the repeat event.

Interface Structure

Event Inputs

Event	Type	Description
INIT	EInit	Service initialization; expects valid parameters (QI, PARAMS, Input, InputEvent)
REQ	Event	Service request; triggers a new data query at the internal function block

Event Outputs

Event	Type	Description
INITO	EInit	Initialization confirmation; returns the status (QO, STATUS)

Data Inputs

Variable	Type	Description
QI	BOOL	Qualifier for the event input; controls the execution

PARAMS	STRING	Service parameter (e.g., configuration string)
Input	logiBUS_DI_S	Selection of the digital input channel (I1...I8); Default value: *Invalid*
InputEvent	logiBUS_DI_Events_S	Selection of the event type (currently only *REPEAT* supported); Default value: *Invalid*

Data Outputs

Variable	Type	Description
QO	BOOL	Qualifier of the output event
STATUS	STRING	Service status (e.g., error messages or operating state)

Adapters

Adapter	Type	Description
IN	adapter::types::unidirectional::AD	Unidirectional input adapter for receiving digital double-word data from the resource

Functionality

The **logiBUS_IDA** is implemented as a composite block that encapsulates a single **logiBUS_ID** function block.

Initialization occurs via the **INIT** event. The parameters *QI*, *PARAMS*, *Input*, and *InputEvent* are passed to the inner block. The inner block then configures the selected digital input channel and prepares for data acquisition. After successful initialization, **INITO** is output with the values *QO* and *STATUS*.

A cyclic or one-time read operation is triggered via the **REQ** event. The internal block reads the current value of the configured input (8-bit/double word) via the **IN** adapter and makes the result available internally for further processing. The actual data values are not directly used as output variables of the **logiBUS_IDA** They are available exclusively via the **IN** adapter at the output of the internal function block (see FBNetwork connections: DI.IN ⟶ IN.D1).

Technical Features

- **Composite Architecture**: Encapsulates complex logic in a reusable function block.
- **Event-driven Processing**: Separation of initialization (INIT) and operational request (REQ).
- **Adapter-Based Input/Output**: Digital double-word information is transmitted via a unidirectional adapter, which keeps the coupling to the resource flexible.
- **Configurable Parameters**: The input channel (I1...I8) and the event behavior (e.g., REPEAT) can be set at runtime.
- **Standard-Compliant IEC 61499-2**: The function block is modeled according to the standard and uses type safety through predefined structures (logiBUS_DI_S and logiBUS_DI_Events_S).

State Overview

The function block goes through the following main states:

1. **Initialization (INIT)**

- Entry: Event **INIT** is activated.
- Action: Internal function block is parameterized and started.
- Output: **INITO** with QO/STATUS.

1. **Operation (REQ)**

- Entry: Event **REQ** is activated.
- Action: Data query at the internal function block; value is provided via adapter **IN**.
- Cyclic repetition is possible if *InputEvent* is set to *REPEAT*.

Error states (e.g., invalid parameters or connection problems) are signaled via **STATUS**.

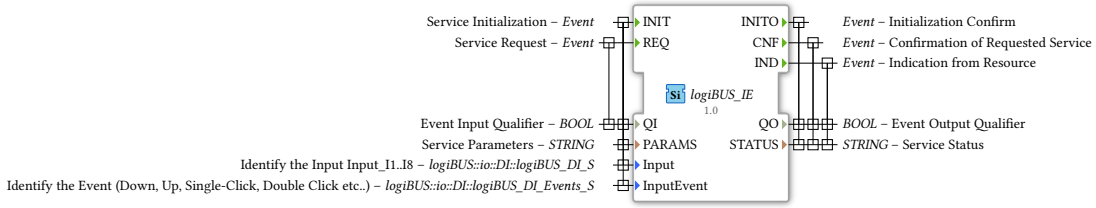
Application Scenarios

- **Digital Multiple Input in Agricultural Technology**: Acquisition of up to 8 digital sensors (e.g., limit switches, proximity switches) and summarization as a double word.
- **Fieldbus Connection**: Use in logiBUS networks for decentralized I/O acquisition.
- **Configurable Monitoring**: Configuration of the sampling behavior (event type) according to the controller's requirements.
- **Extended Diagnostics**: The STATUS output allows feedback of errors or operating states to the higher-level controller.

Comparison with Similar Function Blocks

Compared to a simple **logiBUS_DI**, the **logiBUS_IDA** offers an extended interface with explicit initialization (INIT) and event-driven requests (REQ). While a pure **logiBUS_ID** function block directly delivers the raw data via adapters, the **IDA** integrates the configuration of the channel and event behavior in a compact block. Similar composite function blocks from other fieldbus systems (e.g., CANopen, PROFIBUS) often implement comparable functionalities close to the processor, while the **logiBUS_IDA** is specifically tailored to the logiBUS protocol environment.

Conclusion



The **logiBUS_IDA** is a flexible composite function block for digital double-word input processing in IEC 61499 environments. It simplifies commissioning through its clear interface with initialization and request events and enables channel- and event-configured data acquisition. Thanks to adapter-based data transfer, it can be seamlessly integrated into existing logiBUS resources. The block is particularly suitable for applications requiring reliable initialization and repeated, parameterizable queries of digital inputs.

logiBUS_IE

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_IE function block is an input service interface module for event input data. It serves as an interface between the logiBUS system and the 4diac runtime environment for processing digital input signals with extended event detection functions.

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- Linked to: QI, PARAMS, Input, InputEvent
- **REQ**: Service Request
- Linked to: QI

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Services
- Linked to: QO, STATUS
- **IND**: Resource Indication
- Linked to: QO, STATUS

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameter
- **Input** (logiBUS_DI_S): Identifies the Input (I1..I8)

- Initial Value: Invalid
- **InputEvent** (logiBUS_DI_Events_S): Identifies the event (Down, Up, Single-Click, Double-Click, etc.)
- Initial value: Invalid

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (STRING): Service status

Adapter

No adapter interfaces available.

Functionality

This function block enables the processing of digital input signals with advanced event detection. Specific parameters can be configured via the INIT initialization. The block recognizes various input events such as key presses, releases, single clicks, and double clicks and signals these via the corresponding output events.

Technical Features

- Supports multiple event types (Down, Up, Single-Click, Double-Click)
- Flexible input configuration via PARAMS string
- Status feedback via STATUS output
- Initialization with invalid values for a safe start

State Overview

The function block has an initialized state and an operating state. After successful INIT initialization, it switches to the operating state, in which event processing and service requests can be handled.

Application Scenarios

- Operator Panel Controllers
- Keyboard Input Processing
- Mechanical Switch Monitoring
- User Interaction Systems
- Industrial Control Pushbuttons

⚖️ Comparison with Similar Function Blocks

Compared to simple digital input blocks, logiBUS_IE offers advanced event detection capabilities and can recognize complex input patterns such as double-clicks. The configurable design allows for flexible adaptation to various hardware interfaces.

logiBUS_IE2

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_IE2 is an input service interface function block for event input data. It serves as an interface for processing input events in logiBUS systems and enables the processing of various input event types such as key presses, clicks, and time-based events.

Interface Structure

Event Inputs

- **INIT** (Service Initialization) - Initializes the service with the following data:
- QI
- PARAMS
- Input
- InputEvent
- arg
- **REQ** (Service Request) - Requests a service with:
- QI

Event Outputs

- **INITO** (Initialization Confirm) - Confirms the initialization with:
- QO
- STATUS
- **CNF** (Confirmation of Requested Service) - Confirms the requested service with:
- QO
- STATUS
- **IND** (Indication from Resource) - Message from the resource with:
- QO
- STATUS

Data Inputs

- **QI** (BOOL) - Event Input Qualifier
- **PARAMS** (STRING) - Service Parameters
- **Input** (logiBUS_DI_S) - Identifies input Input_I1..I8 (Initial value: Invalid)
- **InputEvent** (logiBUS_DI_Events_S) - Identifies the event (Down, Up, Single-Click, Double-Click, etc.) (Initial value: Invalid)
- **arg** (UINT) - Long-press time event data OR multi-click event data (depending on the input event) (Initial value: 65535)

Data Outputs

- **QO** (BOOL) - Event Output Qualifier
- **STATUS** (STRING) - Service Status

Adapter

No adapter interfaces available.

Functionality

The logiBUS_IE2 function block processes input events from logiBUS inputs and converts them into standardized event messages. It supports various event types such as key presses (down/up), single clicks,

double clicks, and time-based events like long presses. The block can be configured via the INIT input and returns status information and acknowledgments via its outputs.

Technical Features

- Supports multiple inputs (I1 to I8)
- Processes various event types via the InputEvent variable
- Can process time-based events (long press) and count-based events (multiple clicks)
- Initialization with specific parameters via the PARAMS input
- Provides detailed status information via the STATUS output

State Overview

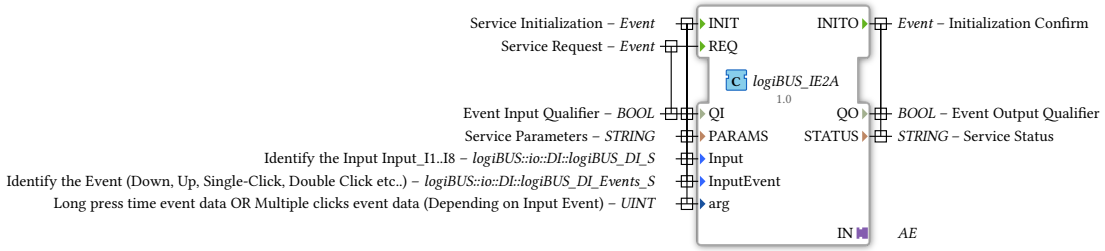
The function block has an initialization state (INIT/INITO) and operational states for service requests (REQ/CNF) as well as asynchronous event messages (IND). The exact state engine depends on the implementation.

Application Scenarios

- Operator panel controls with keypad input
- Machine control with event-based input
- Systems with complex keypad input sequences
- Applications with long-press and multi-click detection

⚖️ Comparison with similar modules

Compared to simple digital input modules, logiBUS_IE2 offers enhanced functionality for complex event detection and supports various input event types with configurable parameters.



🛠️ Related Exercises

Conclusion

The logiBUS_IE2 is a powerful function block for processing event input data in logiBUS systems. Its flexibility in event detection and extensive configuration options make it suitable for demanding control applications.

logiBUS_IE2A

• – ○ • – ○ • – ○ •

Introduction

The function block `logiBUS_IE2A` is a composite block (FB) for processing events at digital inputs of the logiBUS system. It extends the functionality of the underlying block `logiBUS_IE2` by adding a dedicated adapter output for event messages and allows the transfer of parameters such as long press times or multi-click counters. The block serves as a standardized interface between the logiBUS hardware and a higher-level control logic.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Service Initialization
REQ	Event	Service Request

Event Outputs

Name	Type	Comment
INITO	EInit	Initialization Acknowledgement

Data Inputs

Name	Type	Comment	Initial Value
QI	BOOL	Event Input Qualifier	–
PARAMS	STRING	Service Parameter	–
Input	`logiBUS::io::DI::logiBUS_DI_S`	Digital input identification (e.g., Input_I1..I8)	`logiBUS_DI::Invalid`
InputEvent	`logiBUS::io::DI::logiBUS_DI_Events`	Event identification (Down, Up, Single-Click, Double-Click, etc.)	`logiBUS_DI_Events::Invalid`
arg	UINT	Event data: Long press time or number of multiple clicks (depending on the event)	65535

Data Outputs

Name	Type	Comment
QO	BOOL	Event output qualifier
STATUS	STRING	Service status

Adapters

Name	Type	Description
IN	`adapter::types::unidirectional::AE`	Unidirectional adapter output for events (E1)

Functionality

The `logiBUS_IE2A` is a purely structural block that encapsulates the logic of the internal block `logiBUS_IE2`.

- Upon the arrival of an **INIT** event, the data inputs `QI`, `PARAMS`, `Input`, `InputEvent`, and `arg` are forwarded to the internal function block, where initialization is performed. After successful processing, an acknowledgment containing the output data `QO` and `STATUS` is returned via the **INITO** output.
- A **REQ** event triggers a new request (e.g., for another measurement) without resetting the parameters.
- The actual event messages of the digital input are routed by the internal function block (FB) to the adapter output **IN.E1** via its outputs `IND` and `CNF`. This allows the higher-level application to react to incoming events without needing to know the internal details of the function block.

The data flows are hard-coded in the internal network and conform to the protocol of `logiBUS_IE2`.

Technical Features

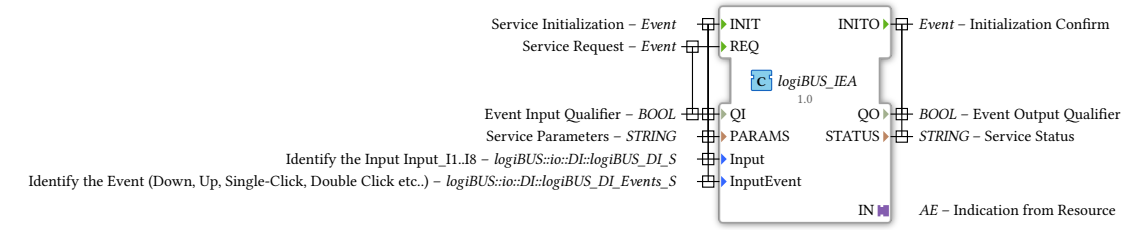
- **Composite Structure**: The function block does not contain its own state machine, but delegates all logic to the internal FB `logiBUS_IE2`.
- **Predefined Initial Values**: The inputs `Input` and `InputEvent` are pre-assigned to `Invalid`, and `arg` to `65535`. This prevents misconfigurations as long as the parameters are not explicitly set.
- **Adapter Output**: Event output is provided via a unidirectional adapter (`AE`), which enables loose coupling to the calling application.
- **Type Imports**: The function block uses specific type definitions from the packages `logiBUS::io::DI` and `logiBUS::io::DI::logiBUS_DI_Events`, ensuring consistent use within the logiBUS ecosystem.

State Overview

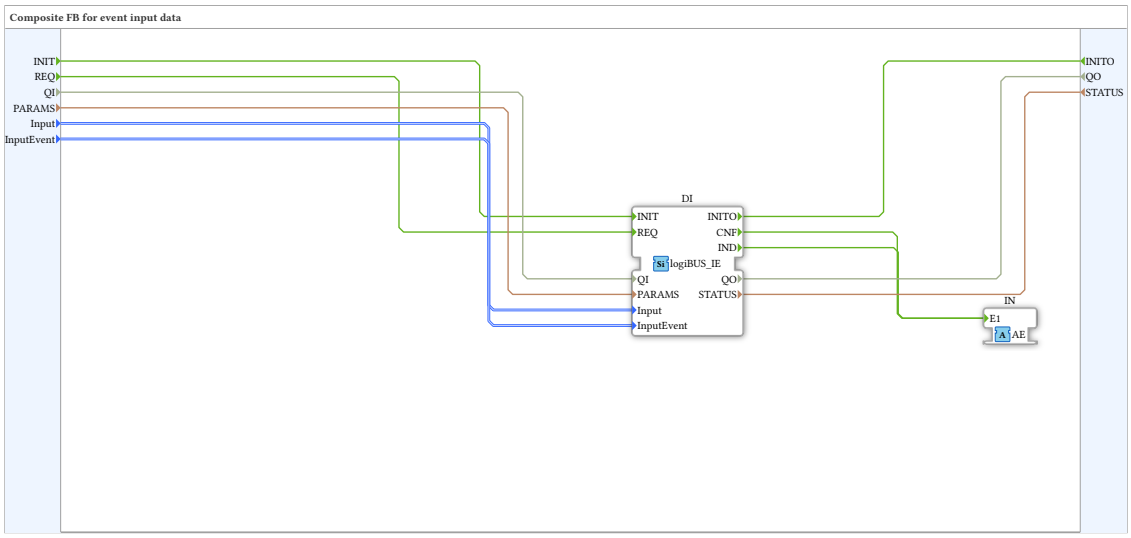
The `logiBUS_IE2A` does not have its own state machine (no ECC). The internal function block `logiBUS_IE2` implements the necessary states for event detection and output. From the perspective of the composite function block, only the cyclic processes INIT → INITO and REQ → (event output via adapter) are relevant.

Application Scenarios

- **Button and Switch Evaluation**: Detection of single and multiple clicks as well as long presses on the digital inputs of a logiBUS module.
- **Configurable Event Detection**: The `arg` input allows for dynamic definition of thresholds for long press times or the number of multiple clicks.
- **Integration into Higher-Level Controllers**: The adapter output enables seamless integration with automation systems that communicate via adapter interfaces.



Comparison with Similar Function Blocks



- **`logiBUS_IE2`**: This function block is used within `logiBUS_IE2A`. It offers the same functionality, but without the dedicated adapter output and without the aggregation of parameters in a composite structure.
- **`logiBUS_IE2S`** (if present): Another function block in the same family, which may differ in additional status outputs or other event selection.
- The **`logiBUS_IE2A`** is characterized by its simple configuration and standardized adapter interface, which facilitates reuse in different projects.

Conclusion

The `logiBUS_IE2A` is a pre-configured composite module for event-based processing of logiBUS digital inputs. It combines the proven logic of the `logiBUS_IE2` with an adapter output and configurable event data. Thanks to its clear interface and predefined initial values, it is particularly suitable for modular and standardized automation solutions where rapid integration and ease of use are paramount.

logiBUS_IEA

• — ○ • — ○ • — ○ •

Introduction

The composite function block `logiBUS_IEA` is used for event-driven processing of digital input data in a logiBUS fieldbus system. It encapsulates an internal `logiBUS_IE` block and makes its functionality available via a standardized interface. The function block enables the initialization and querying of events at a digital input and forwards the resulting indications to the resource via an adapter.

Interface Structure

Event Inputs

Name	Type	Comment	Data Carried
`INIT`	EInit	Service Initialization	`QI`, `PARAMS`, `Input`, `InputEvent`
`REQ`	Event	Service Request	`QI`

Event Outputs

Name	Type	Comment	Data Carried
`INITO`	EInit	Initialization Confirm	`QO`, `STATUS`

Data Inputs

Name	Type	Comment	Initial Value

QI	BOOL	Event Input Qualifier	–
PARAMS	STRING	Service Parameters	–
Input	logiBUS::io::DI::logiBUS_DI_S	Identifies the input (e.g., Input_I1..I8)	logiBUS_DI::Invalid
InputEvent	logiBUS::io::DI::logiBUS_DI_Events_S	Identifies the event (e.g., Down, Up, Single-Click, Double-Click)	logiBUS_DI_Events::Invalid

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier
STATUS	STRING	Service Status

Adapters

Name	Type	Comment
IN	adapter::types::unidirectional::AE	Indication from Resource

The adapter IN receives the events generated by the internal function block (DI.IND and DI.CNF) and forwards them as an "Indication" to the higher-level resource.

Functionality

The function block logiBUS_IEA operates as a pure composite function block, meaning it has no control over its own flow. Instead, it forwards all events and data to the embedded function block logiBUS::io::DI::logiBUS_IE.

- **INIT Event**:

The internal function block is initialized via the event input INIT. The parameters QI, PARAMS, Input, and InputEvent are passed. After successful initialization, the internal function block acknowledges with the event INITO, which is returned to the higher-level function block. The output data QO and STATUS are updated in the process.

- **REQ Event**:

With REQ (if QI is set), a request is sent to the internal function block. This block processes the configuration and triggers the corresponding actions when events are detected.

- **Indication via Adapter**:

The events IND (Indication) and CNF (Confirm) generated by the internal function block are routed to the adapter output IN.E1. This allows the surrounding resource to react to events such as button presses or double-clicks.

Technical Features

- **Composite Function Block**: The function block does not contain its own ECC (Execution Control Chart) but delegates all logic to the internal logiBUS_IE. This increases reusability and testability.
- **Generic Parameterization**: System-specific parameters can be passed as strings via the PARAMS input.
- **Adapter-Based Event Output**: The use of a unidirectional adapter (type AE) enables flexible coupling to the resource without hardwiring to event outputs.
- **Typed Input Selection**: The inputs Input and InputEvent utilize specific enumeration types (logiBUS_DI_S and logiBUS_DI_Events_S) that allow for secure and unambiguous configuration.

State Overview

Since logiBUS_IEA is a pure composite component, it does not have its own state machine. The state is determined by the internal component. Typical states of the internal logiBUS_IE include:

- **IDLE**: Waiting for INIT or configuration

- **WAIT**: Waiting for a detected event at the input
- **ACTIVE**: Event detected, indication sent
- **ERROR**: Initialization or communication error

The state transitions are indicated by the events `IND` and `CNF` and communicated externally via the adapter.

Application Scenarios

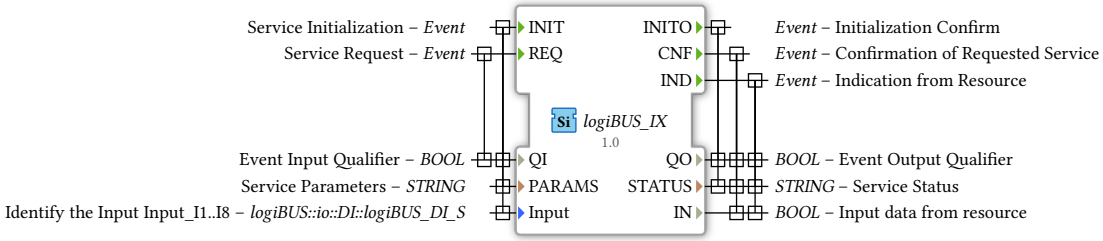
- **Event Detection at Digital Inputs**: Pushbuttons, switches, or sensors with multi-click functionality (single/double click) can be configured via `InputEvent`.
- **Machine Mode Control**: A digital input triggers a mode change when activated (e.g., a down event).
- **Configurable Initialization**: Bus parameters or filter times can be passed to the logiBUS controller via `PARAMS`.
- **Integration into Larger Composite Blocks**: The adapter `IN` allows connection to a higher-level control block (e.g., a resource manager).

Comparison with Similar Blocks

FB Type	Property
`logiBUS_DI`	Pure digital input without event detection; simple level retrieval
`logiBUS_IEA`	**This FB:** Event-based input with initialization and adapter for indication
`logiBUS_DI_Events`	Event Detection on a Single Input, but Without Initialization Logic

Compared to a simple digital input, the `logiBUS_IEA` offers a complete initialization interface and standardized event signaling via an adapter. Compared to a pure event block, it also includes the INIT functionality required for commissioning a logiBUS device.

Conclusion



The `logiBUS_IEA` composite block encapsulates the complex initialization and event processing of a logiBUS input module in a compact, reusable unit. Thanks to the clear separation of initialization and request processing, support for typed inputs, and adapter-based event output, it is particularly well-suited for use in modular automation solutions where reliable event-driven input acquisition is required.

logiBUS_IX

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_IX function block is an input service interface for Boolean input data, specifically designed for communication with logiBUS input modules. It serves as an interface between the control logic and physical input signals, enabling the querying of digital input values.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Request
- **IND**: Display from Resource Interface

Data Inputs

- **QI**: Event Input Qualifier (BOOL)
- **PARAMS**: Service Parameters (STRING)
- **Input**: Identifies Input I1..I8 (logiBUS_DI_S) - Initial Value: Invalid

Data Outputs

- **QO**: Event Output Qualifier (BOOL)
- **STATUS**: Service Status (STRING)
- **IN**: Input Data from Resource (BOOL)

Adapter

No adapter interfaces are available.

Functionality

The function block initializes itself via the INIT event and can then request input data via the REQ event. Upon successful initialization, it returns the INITO event. The actual input values are provided via the IN output, while the STATUS output provides information about the current operating state.

Technical Features

- Supports up to 8 digital inputs (I1..I8)
- Uses special logiBUS data types for input identification
- Provides comprehensive status feedback via the STATUS output
- Initializes with an invalid input value (Invalid)

State Overview

The function block typically goes through the following states:

1. **Not Initialized**: Before the INIT request
2. **Initialized**: After successful INIT processing
3. **Ready**: Can process REQ requests
4. **Active**: Currently processing a service request

Application Scenarios

- Querying digital input signals in automation systems
- Integrating logiBUS input modules into 4diac-based controllers
- Monitoring switch states and sensor signals
- Industrial I/O control with status monitoring

⚖️ Comparison with Similar Blocks

Compared to simple digital input blocks, this offers logiBUS_IX:

- Advanced status information
- Parameterizable service parameters
- Specific logiBUS hardware integration
- More comprehensive initialization and confirmation mechanisms

logiBUS_IXA

• – ○ • – ○ • – ○ •

Introduction

The logiBUS_IXA is a composite function block for processing Boolean input data. It serves as an interface for digital inputs and enables the initialization and querying of input signals via standardized service interfaces.

Interface Structure

Event Inputs

- **INIT**: Service initialization event with the associated data QI, PARAMS, and Input
- **REQ**: Service request event with the associated data value QI

Event Outputs

- **INITO**: Initialization confirmation with the associated data values QO and STATUS

Data Inputs

- **QI**: Boolean event input qualifier
- **PARAMS**: Service parameters as a string
- **Input**: Identifies inputs Q1 to Q8 with type logiBUS_DI_S and initial value “Invalid”

Data Outputs

- **QO**: Boolean event output qualifier
- **STATUS**: Service status as a string

Adapters

- **IN**: Unidirectional AX-type adapter for input data processing

Functionality

The logiBUS_IXA composite function block encapsulates the logiBUS_IX base function block and extends its functionality with additional adapter interfaces. Upon INIT events, parameters are forwarded to the internal IX block, which performs the initialization. IND events from the IX block are passed to the IN input adapter, while the data connections ensure the corresponding signal processing.

Technical Features

- Uses the specific data type logiBUS_DI_S for input identification
- Implements standardized service interfaces according to DIN 61499-2
- Supports parameter passing via the STRING data type
- Provides status feedback via the STATUS output

State Overview

The function block has two main states:

1. **Not initialized**: Before the INIT event
2. **Initialized and ready for operation**: After successful INIT confirmation

Application Scenarios

- Connecting digital inputs in automation systems
- Integration into logiBUS-based control architectures
- Use in PLC systems with Boolean signal processing requirements

⚖️ Comparison with Similar Blocks

Compared to simple digital input blocks, logiBUS_IXA offers extended service functionalities with parameterization options and status feedback. The composite structure enables better reusability and enhanced diagnostic capabilities.

DI_CAN

logiBUS_2_CAN_DI

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_2_CAN_DI GlobalConstants define constants for configuring digital inputs (DIs) in the logiBUS system via CAN bus. These constants are used for pin assignment for digital input channels and provide a standardized interface for hardware configuration.

Interface Structure

Constant Definitions

The GlobalConstants define three main constants for the digital input configuration:

- **Input_CI1**: Configuration for digital input channel 1
- **Input_CI2**: Configuration for digital input channel 2
- **Invalid**: Indicates an invalid or unconfigured input

Data Types

All constants use the structured data type `logiBUS_2_CAN_DI_S`, which contains the following component:

- **Pin**: Integer value for identifying the physical input pin

Functionality

The constants are not modified at runtime and are used exclusively for configuring the digital inputs. They define the hardware mapping between logical channels and physical pins in the CAN-based logiBUS system.

Technical Features

- **Pin Assignment**: Channel 1 is assigned to Pin 1, Channel 2 is assigned to Pin 2
- **Invalid Identifier**: The value 255 indicates an invalid or unavailable input

- **CAN Integration**: Specifically optimized for CAN-based logiBUS systems
- **Type Safety**: Use of structured data types for consistent configuration

Application Scenarios

- Configuration of digital inputs in logiBUS controllers
- Hardware abstraction in CAN-based automation systems
- Pin assignment in distributed I/O systems
- Error handling for unconfigured inputs

⚖️ Comparison with Similar Function Blocks

Compared to simple numeric constants, these structured constants offer:

- Higher type safety through structured data types
- Improved maintainability through centralized configuration
- Extensibility for additional parameters
- Compatibility with logiBUS system architecture

Conclusion

The logiBUS_2_CAN_DI GlobalConstants offer a robust and type-safe solution for configuring digital inputs in CAN-based logiBUS systems. Their structured approach enables clear hardware mapping and simplifies the maintenance and expansion of automation solutions.

logiBUS_2_CAN_DI_S

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `logiBUS_2_CAN_DI_S` is a structured data type (struct) used to configure a digital input (DI) for a logiBUS-CAN system. It defines the basic parameters required to address and use a physical input pin on a logiBUS-CAN module. This data type typically serves as input for higher-level function blocks that handle the actual communication via the CAN protocol.

Interface Structure

This is a structured data type (struct) and therefore has no event or adapter interfaces. Its structure consists of a single data element.

Data Inputs

Since it is a data type, these elements are used as input data within a higher-level function block.

Name	Data Type	Initial Value	Comment
`Pin`	`USINT` (Unsigned Short Integer)	255	Defines the number of the physical input pin on the logiBUS CAN module.

Data Outputs

(Not applicable for a structured data type)

Event Inputs

(Not applicable for a structured data type)

Event Outputs

(Not applicable for a structured data type)

Adapters

(Not applicable for a structured data type)

Functionality

The data type `logiBUS_2_CAN_DI_S` functions as a configuration container. The value `Pin` specifies which particular digital input of a logiBUS CAN I/O module is to be addressed. The initial value `255` represents a typical invalid or unconfigured state, requiring the user to explicitly assign a valid pin number. A higher-

level function block (e.g., a driver function block) reads this structure and uses the `Pin` information to generate or interpret the correct CAN telegrams that query the state (on/off) of the respective input.

Technical Features

- **Data type `USINT`:** The use of `USINT` (0 to 255) for the pin suggests that the logiBUS hardware can theoretically address up to 256 digital inputs per configuration structure. The value 255 is reserved as the default initial value.
- **Initial value 255:** This value serves as an indicator for an inactive or undefined configuration. It should be replaced with a valid pin number in the application.
- **Package name:** The data type is organized in the package `logiBUS::io::DI_CAN`, which clearly indicates its association with logiBUS CAN input communication.
-

State Overview

(Not applicable for a structured data type. The "state" is simply the stored value of the `Pin` variable.)

Application Scenarios

This structure type is used in scenarios where digital signals (e.g., switches, limit switches, sensor contacts) are to be read into a controller (e.g., an IEC 61499-based application in 4diac) via a CAN-based logiBUS network. Typical applications include:

- Machine controllers with decentralized, CAN-networked sensors.
- Mobile applications (vehicles, robots) with a robust bus system.
- Systems where digital input signals are distributed over long distances.
-

⚖️ Comparison with Similar Function Blocks

Unlike direct I/O function blocks (such as `E_SR` or `E_D_FF`), which process logical states, `logiBUS_2_CAN_DI_S` is a pure **configuration data type**. It is comparable to other structured hardware configuration types in 4diac (e.g., for serial interfaces or other fieldbuses) that encapsulate parameters for hardware connectivity. Its counterpart for digital outputs would be a corresponding struct type (e.g., `logiBUS_2_CAN_DO_S`).

Conclusion

The `logiBUS_2_CAN_DI_S` data type is an essential and streamlined configuration element for connecting digital inputs to a CAN-based logiBUS system within the 4diac IDE. By encapsulating the pin number in a structured variable, it enables clear, type-safe, and maintainable configuration of the hardware interface in higher-level control algorithms. Using a unique initial value helps to detect misconfigurations early.

logiBUS_2_CAN_IX

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `logiBUS_2_CAN_IX` is a service interface function block for Boolean input data, specifically designed for integrating logiBUS systems with CAN bus communication. It serves as an input interface for digital signals and enables communication between the control system and connected CAN-enabled devices.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- Linked to: QI, PARAMS, Input
- **REQ**: Service Request Event
- Linked to: QI

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service Request
- Linked to: QO, STATUS, IN
- **IND**: Indication from Resource
- Linked to: QO, STATUS, IN

Data Inputs

- **QI**: BOOL - Event Input Qualifier
- **PARAMS**: STRING - Service Parameter
- **Input**: logiBUS_2_CAN_DI_S - Identifies the Input Input_Q1..Q8
- Initial value: logiBUS_2_CAN_DI::Invalid

Data Outputs

- **QO**: BOOL - Event output qualifier
- **STATUS**: STRING - Service status
- **IN**: BOOL - Input data from the resource

Adapter

No adapter interfaces available.

Functionality

This function block operates as an input service interface for digital CAN signals. During initialization (INIT event), the service parameters are configured and the input channel is identified. Service requests can be made via the REQ event, while IND events signal incoming data from the resource. The block manages the communication status and outputs the received Boolean input data via the IN output.

Technical Features

- Special data types for logiBUS-CAN integration
- Initialization with invalid state as standard
- Separate acknowledgment and indication events for different operating states
- String-based status feedback for detailed fault diagnosis

State Overview

The function block goes through the following main states:

1. **Not Initialized**: Before INIT event
2. **Initialized**: After successful INIT acknowledgment
3. **Service Ready**: Can process REQ and IND events
4. **Fault State**: In case of communication problems (signaled via STATUS)

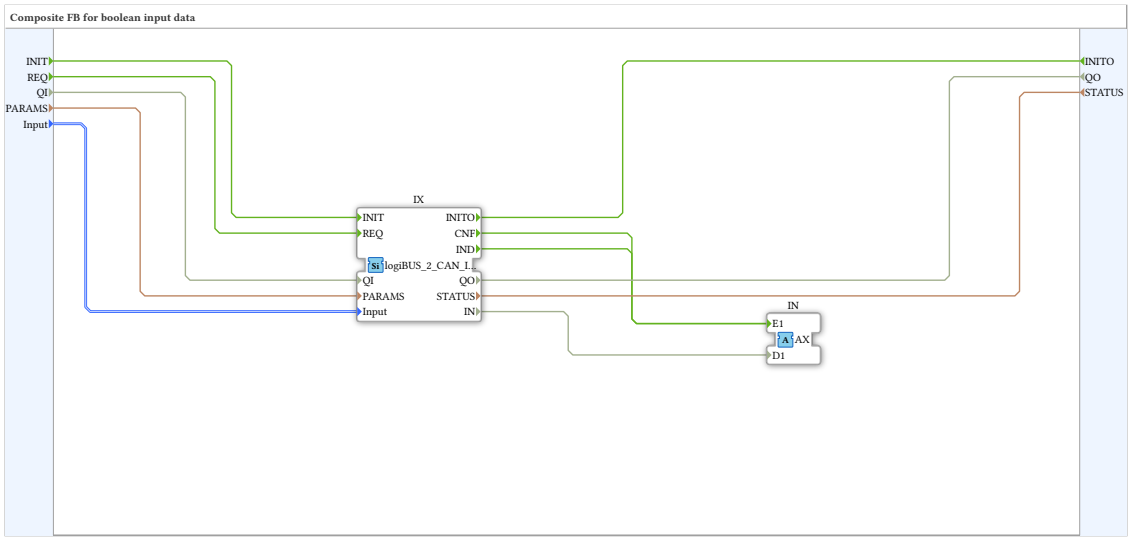
Application Scenarios

- Integration of logiBUS I/O modules into 4diac controllers
- CAN-based digital input signal processing
- Industrial automation systems with distributed I/Os
- Robot controllers with CAN peripherals

⚖️ Comparison with Similar Blocks

Compared to standard digital input blocks, this offers `logiBUS_2_CAN_IX` features dedicated CAN integration and enhanced status feedback. While simple DI blocks only offer direct signal processing, this block supports more complex protocol handling and error handling for industrial CAN networks.

Conclusion



The `logiBUS_2_CAN_IX` function block provides a robust and reliable interface for integrating CAN-based digital input signals into 4diac control systems. Its enhanced error handling and status feedback make it particularly suitable for demanding industrial applications where reliable communication with distributed I/O systems is required.

logiBUS_2_CAN_IXA

• – ○ • – ○ • – ○ •

Introduction

The logiBUS_2_CAN_IXA is a composite function block for processing Boolean input data via CAN bus interfaces. The block serves as an interface between logiBUS systems and CAN-based input devices and enables the initialization and querying of digital inputs.

Interface Structure

Event Inputs
- **INIT**: Service Initialization (with QI and PARAMS)
- **REQ**: Service Request (with QI)

Event Outputs
- **INITO**: Initialization Acknowledgement (with QO and STATUS)

Data Inputs
- **QI**: Event Input Qualifier (BOOL)
- **PARAMS**: Service Parameters (STRING)
- **Input**: Input Identification Input_Q1..Q8 (logiBUS_2_CAN_DI_S)

Data Outputs
- **QO**: Event Output Qualifier (BOOL)
- **STATUS**: Service Status (STRING)

Adapters
- **IN**: Unidirectional AX-type adapter for the Data Communication

Functionality
The composite function block internally uses the logiBUS_2_CAN_IX module to process CAN-based input data. During INIT initialization, the service parameters are passed and the module is configured. Input data can be queried via the REQ event. Processing is performed via the IN adapter, which enables communication with CAN input devices.

Technical Features
- Uses specific logiBUS data types for CAN communication
- Supports up to 8 digital inputs (Input_Q1 to Input_Q8)
- Initial value for input is “Invalid”
- Integrated error handling via STATUS output

State Overview
The function block goes through the following states:

1. **Not Initialized**: Before INIT call
2. **Initialization**: During INIT processing
3. **Ready**: After successful initialization (INITO confirmed)
4. **Query**: During REQ processing

Application Scenarios
- Connecting CAN-based sensors and switches to logiBUS systems
- Industrial automation with digital input signals
- Control systems in agricultural technology
- Distributed I/O systems via CAN bus

⚖️ Comparison with Similar Function Blocks
Compared to simple digital input function blocks, this offers logiBUS_2_CAN_IXA:

- CAN bus communication capability
- Extended parameterization options
- Integrated status feedback
- Specific logiBUS integration

Conclusion
The logiBUS_2_CAN_IXA is a specialized composite function block for the reliable integration of CAN-based digital inputs into logiBUS systems. Its structured initialization and query mechanisms make it particularly suitable for industrial applications requiring robust and configurable I/O interfaces.

logiBUS_DO

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_DO GlobalConstants define a collection of constants for configuring digital outputs (DOs) in the logiBUS system. These constants are used for pin assignment to digital output channels and provide a standardized interface for hardware configuration.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

No adapters available

Functionality

The logiBUS_DO GlobalConstants define structured constants of type `logiBUS_DO_S`, each containing a specific pin value for digital outputs. Constants `Output_Q1` to `Output_Q10` represent the available output channels with the corresponding pin numbers 1 to 10. The constant `Invalid` with the pin value 255 serves as an indicator for invalid or unconfigured outputs.

Technical Features

- **Constant Type**: All constants are of the structured data type `logiBUS_DO_S`
- **Pin Mapping**: Clear mapping of output names to physical pin numbers
- **Invalid Marking**: Special constant with pin value 255 for error handling
- **Package Structure**: Organized in the package `logiBUS::io::DQ`

State Overview

Since these are constants, there are no state transitions. The values are static and unchanging during runtime.

Application Scenarios

- Hardware configuration of logiBUS systems
- Pin assignment in function blocks for digital outputs
- Error handling for invalid output configurations
- Standardization of output designations in control applications

⚖️ Comparison with similar function blocks

Compared to other constant definitions, logiBUS_DO offers a specific structure for digital outputs with clear pin assignment and a defined invalid constant for robust error handling.

Conclusion

The logiBUS_DO GlobalConstants provide a standardized and maintainable solution for configuring digital outputs in logiBUS systems. The structured definition of the output channels and the provided invalid constant enable reliable and fault-tolerant hardware configuration.

logiBUS_DO_S

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `logiBUS_DO_S` is a structured data type (struct) used to configure a digital output (DO) within the logiBUS system. It defines the necessary parameters to uniquely address and control a physical output pin of a logiBUS I/O module. This data type is typically used as input for function blocks that provide the actual output functionality.

Interface Structure

As a structured data type, `logiBUS_DO_S` does not have event or adapter interfaces in the conventional sense of a function block. Instead, it defines a data structure that is passed as a whole to other blocks.

Data Inputs

The structure itself contains the following data field, which is populated when the type is instantiated:

Name	Data Type	Initial Value	Description
`Pin`	`USINT` (Unsigned Short Integer)	255	Defines the number of the physical output pin to be controlled. The value 255 represents an invalid/undefined state and serves as the default initialization.

Event Inputs

Not present. This type is a data structure only.

Event Outputs

Not present. This type is a data structure only.

Data Outputs

Not present. This type is a data structure only.

Adapters

Not present. This type is a data structure only.

Functionality

The `logiBUS_DO_S` struct acts as a configuration container. Its main task is to transport the information about the desired pin number (`Pin`) in a bundled and typed manner. A higher-level function block (e.g., a `logiBUS_DO` block) receives an instance of this struct, reads the `Pin` value, and uses this information to switch the corresponding physical output of the logiBUS hardware module.

The initial value of 255 for `Pin` indicates that the pin is not yet configured. Valid pin numbers are within the range supported by the respective logiBUS I/O module (e.g., 0-7 for an 8-channel module).

Technical Features

- **Typing:** Using a structured data type instead of a simple `USINT` increases type safety and application readability. It is clear that the value represents a logiBUS output pin.
- **Initial Value:** The initial value of 255 serves as a "Safe State" indicator. Before the structure is correctly configured, this value indicates an inactive or faulty state.
- **Package Assignment:** The struct is part of the `logiBUS::io::DQ` package, indicating its membership in the digital input/output (Digital I/O) of the logiBUS framework.

State Overview

Since it is a passive data type, `logiBUS_DO_S` does not have an internal state machine. The "state" is determined solely by the stored value of the `Pin` variable.

Application Scenarios

1. **Output Configuration:** This struct is primarily used to parameterize function blocks that control lamps, valves, relays, or other binary actuators via logiBUS modules.
2. **Structured Parameter Passing:** In more complex applications, multiple `logiBUS_DO_S` instances can be organized in arrays or other structures to centrally manage the configuration of all outputs in a station.
3. **Initialization:** The default initial value allows variables of this type to be declared without having to populate them immediately. The actual configuration (assigning a valid pin number) can be performed later in the program flow.

⚖️ Comparison with Similar Building Blocks

- **Simple `USINT`:** Directly using a `USINT` value for the pin number is possible, but offers less semantic clarity and type safety. The `logiBUS_DO_S` makes the purpose of the data element explicit.
- **`logiBUS_DI_S`:** This is the structural counterpart for digital inputs (DIs). It has an identical structure (a `USINT` field `Pin`), but conceptually belongs to the input side. Separating DO and DI structs improves code readability and maintainability.

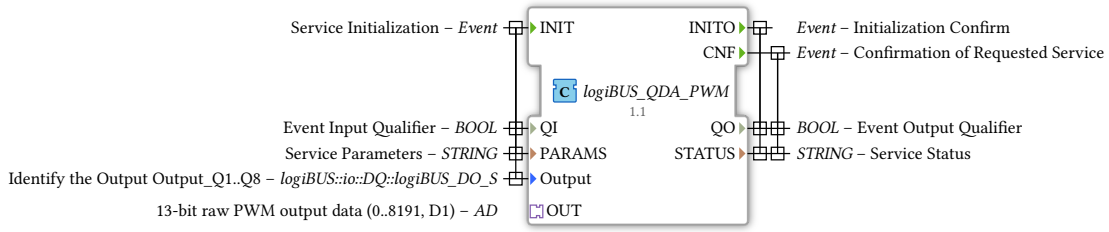
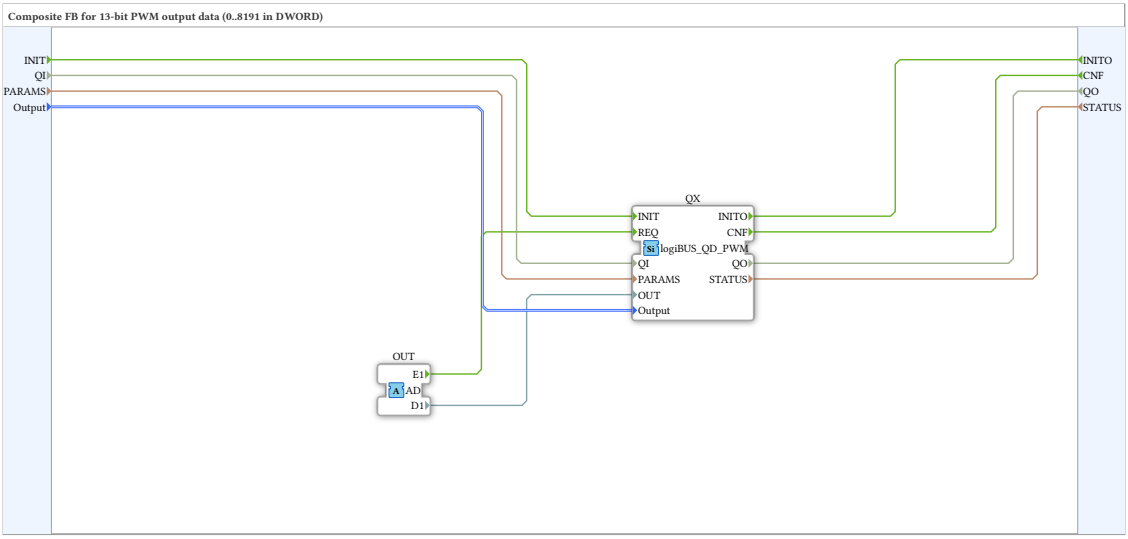
- Softkey_T_FF_ILOCK_TO_QX_BG



Conclusion



The The `logiBUS_DO_S` struct is a simple yet essential helper element in the logiBUS ecosystem of the 4diac IDE. It standardizes and formalizes the addressing of digital output pins, promotes type-safe programming, and, thanks to its defined initial value, serves as the basis for robust initialization logic. Its use is recommended when configuring logiBUS library function blocks for digital outputs.

logiBUS_QDA_PWM

• – ○ • – ○ • – ○ •

Introduction

The **logiBUS_QDA_PWM** function block is a composite block for controlling a PWM (Double Word) output via a logiBUS system. It encapsulates the initialization and triggering of an internal PWM output block and provides an adapter interface for receiving commands (events and data) from external sources. The block was developed for use in agricultural technology and is licensed under EPL 2.0.

Interface Structure

Event Inputs

Event	Type	Comment
INIT	EInit	Service Initialization
no further event input		*All triggers are handled via the adapter*

Event Outputs

Event	Type	Comment
INITO	EInit	Initialization Acknowledgement
CNF	Event	Acknowledgement of a requested service

Data Inputs

Variable	Type	Comment
QI	BOOL	Input Qualifier (Enable Initialization)
PARAMS	STRING	Service Parameter (e.g., Addressing, Configuration)

Output	logiBUS::io::DQ::logiBUS_DO_S	Output Identification (e.g., Output_Q1..Q8); Initial Value: *Invalid*

Data Outputs

Variable	Type	Comment
QO	BOOL	Output Qualifier (Initialization Status)
STATUS	STRING	Service Status (Failure/Success Message)

Adapters

Type	Name	Direction	Comment
adapter::types::unidirectional::AD	OUT	Socket	Receives trigger event (E1) and output data (D1) from the resource

Functionality

The function block is implemented as a composite and contains an internal instance of the function block `logiBUS::io::DQ::logiBUS_QD_PWM` (referred to here as *QX*). The logic can be described as follows:

1. **Initialization:**

An INIT event at the input triggers the initialization of the internal function block. The data inputs *QI*, *PARAMS*, and *Output* are then forwarded to the internal function block. After successful initialization, the event *INITO* is output, along with the output data *QO* and *STATUS*.

1. **Triggering via Adapter:**

The adapter *OUT* receives an external event *E1* and a data value *D1*. The event is forwarded to the internal function block as a *REQ* (Request), and the data *D1* as an *OUT* value. The internal function block processes this request and acknowledges it with the event *CNF*, which is then output to the external system via the *CNF* output. The associated output data *QO* and *STATUS* are updated.

This function block allows for a clean separation of initialization and cyclic output: Configuration is performed once via INIT, while the actual PWM output is triggered by the adapter.

Technical Features

- **Composite Function Block:** The function block encapsulates all the logic of a PWM output function block and provides a standardized adapter interface for data exchange with the resource.
- **13-Bit PWM Output (`0–8191`):** The adapter data element *D1* (`DWORD`) expects a 13-bit raw PWM value (`0` = 0% duty cycle, `8191` = 100% duty cycle, $2^{13} = 8192$ states).
- **Initialization Parameters:** Flexible configuration data, necessary for addressing or parameterizing the logiBUS module, can be passed via *PARAMS* (STRING).
- **Error Handling:** The *STATUS* output provides a textual description of the service status (e.g., error messages for invalid configurations).

State Overview

Since this is a composite function block without its own state machine, the state is defined by the internal function block *logiBUS_QD_PWM*. Typical states are:

- **IDLE:** Waiting for initialization or a trigger.
- **INITIALIZING:** During initialization (INIT received, INITO not yet sent).
- **OPERATIONAL:** Ready for cyclic triggers (via adapter).
- **ERROR:** Error state, indicated by *QO* = *FALSE* or *STATUS* with an error message.

The internal function block switches between these states depending on the events and data.

Application Scenarios

- **Agricultural Machinery:** Control of PWM-driven actuators (e.g., hydraulic valves, engine speed) via a logiBUS network.
- **Automation Systems:** Output of pulse-width modulated signals with 13-bit resolution (`0–8191`), controlled by a higher-level controller.

- **Remote Maintenance and Configuration:** The adapter allows new PWM values to be sent from a higher-level resource (e.g., HMI or PLC) without repeating the initialization process.

Comparison with Similar Function Blocks

Function Block	Type	Special Feature
logiBUS_QD_PWM	Composite/Basic	Directly controllable via INIT, REQ, CNF; without an adapter interface.
logiBUS_QDA_PWM	Composite	Like logiBUS_QD_PWM, but with an adapter for external triggering and data supply.
logiBUS_DO (simple)	Basic	Simple digital output, no PWM function.

The function block described here offers greater flexibility, as the actual output via the adapter can occur asynchronously from initialization. A disadvantage is the dependence on the correct provision of the adapter signals.

Conclusion

The **logiBUS_QDA_PWM** function block is a practical encapsulation of a PWM output for logiBUS. By combining INIT-based configuration and adapter-based triggering, it is particularly suitable for applications requiring one-time parameterization followed by cyclic or event-driven output. The use of standardized types and the clear separation of interfaces facilitate integration into IEC 61499-based control systems.

logiBUS_QD_PWM

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `logiBUS_QD_PWM` is an output service interface function block for double-word output data. It serves as an interface for controlling PWM (pulse-width modulation) outputs via the logiBUS system and enables the control of outputs Q1 to Q8.

Interface Structure

Event Inputs

- **INIT**: Service Initialization
- Linked to: QI, PARAMS, Output
- **REQ**: Service Request
- Linked to: QI, OUT

Event Outputs

- **INITO**: Initialization Acknowledgement
- Linked to: QO, STATUS
- **CNF**: Acknowledgement of Requested Service Operation
- Linked to: QO, STATUS

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **OUT** (DWORD): Output Data for the Resource (13-bit raw PWM value `0` to `8191`, corresponding to `0 %` to `100 %` duty cycle, $2^{13} = 8192$ states)
- **Output** (logiBUS_DO_S): Identifies the output Output_Q1..Q8
- Initial Value: `logiBUS_DO::Invalid`

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status

Adapters

No adapter interfaces available.

Functionality

This function block enables PWM control of outputs via the logiBUS system. During initialization (INIT), the service parameters are configured and the specific output is identified. PWM data (`OUT`, 13-bit value `0` to `8191` inside a DWORD variable) can be sent to the configured output via a REQ request. The block acknowledges both initialization and service requests via the corresponding output events.

Technical Features

- **13-Bit PWM Resolution**: Uses 13-bit normalization (`0` to `8191`) stored in a `DWORD` data type (`0` = 0% duty cycle, `8191` = 100% duty cycle, scaling factor for ISO-Designer: `0.0122085215480405` or `100 / 8191`).
- Supports up to 8 outputs (Q1-Q8) via output configuration
- String-based parameter configuration for flexible service settings
- Status feedback via STRING variable for detailed error information

State Overview

The function block has two main states:

1. **Not Initialized**: Block waits for an INIT event
2. **Initialized and Ready**: Block can process REQ requests and output PWM data

Application Scenarios

- Control of PWM-controlled actuators (motors, heating elements)
- Control of LED lighting with brightness control
- Control of valves with proportional control
- Industrial automation applications with logiBUS hardware

⚖️ Comparison with Similar Blocks

Compared to simple digital output blocks, `logiBUS_QD_PWM` offers precise PWM control with 13-bit resolution (`0–8191` inside a DWORD). Compared to analog output blocks, it enables direct PWM control without additional conversion.

logiBUS_QX

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_QX function block is an output service interface block for Boolean output data. It serves as an interface for controlling digital outputs via the logiBUS system and enables communication between the control application and the physical output channels.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters
- **OUT** (BOOL): Output Data for Resource
- **Output** (logiBUS_DO_S): Identifies the Output (Output_Q1..Q8), Initial Value: Invalid

Data Outputs

- **QO** (BOOL): Event Output Qualifier
- **STATUS** (STRING): Service Status Information

Adapters

No adapter interfaces available.

Functionality

The logiBUS_QX block manages communication with the digital output channels of the logiBUS system. During initialization (INIT event), the service parameters are configured and the specific output channel is identified. Boolean values (OUT) can be sent to the configured output channel via the REQ event. The block acknowledges each operation via the corresponding output events INITO and CNF.

Technical Features

- Uses specific logiBUS data types for output identification
- Supports up to 8 digital output channels (Q1-Q8)
- Provides detailed status feedback via the STATUS output
- Initializes outputs with an invalid state (Invalid)

State Overview

The block goes through the following main states:

1. **Not Initialized**: Before the first INIT operation
2. **Initialized**: After successful INIT operation, ready for REQ operations
3. **Active**: During the processing of REQ operations

Application Scenarios

- Control of digital actuators (relays, valves, lamps)
- Connection to logiBUS hardware outputs
- Automation systems with distributed I/O components
- Safety-relevant switching operations with status feedback

⚖️ Comparison with Similar Blocks

Compared to standard digital output blocks, logiBUS_QX offers:

- Specific Integration in logiBUS systems
- Advanced status feedback
- Parameterizable output configuration
- Higher level of abstraction for hardware access

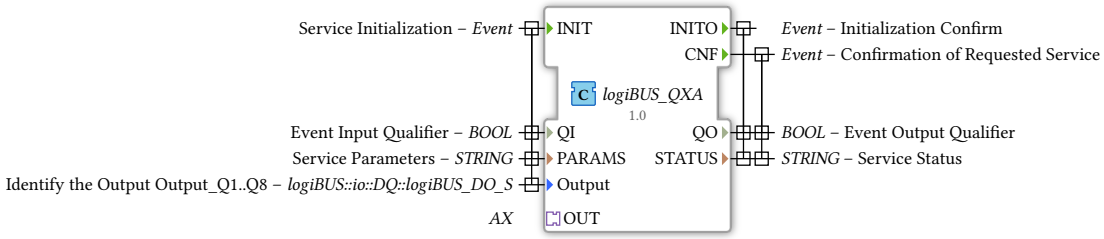
Conclusion

The logiBUS_QX function block represents a robust and reliable interface for controlling digital outputs in logiBUS-based automation systems. Its clear event structure and comprehensive status feedback make it suitable It is particularly suitable for applications that require high reliability and traceability of output operations.



logiBUS_QXA

• – ○ • – ○ • – ○ •

Introduction

The logiBUS_QXA is a composite function block for outputting Boolean data. It serves as an interface for digital output functions and enables the control of up to 8 digital outputs via a standardized protocol.

Interface Structure

Event Inputs

- **INIT**: Service initialization event with the associated data QI, PARAMS, and Output

Event Outputs

- **INITO**: Initialization acknowledgment with the data QO and STATUS
- **CNF**: Acknowledgement of the requested service with the data QO and STATUS

Data Inputs

- **QI**: Boolean event input qualifier
- **PARAMS**: Service parameters as a string
- **Output**: Identification of outputs Q1 to Q8 of type logiBUS_DO_S with initial value “Invalid”

Data Outputs

- **QO**: Boolean event output qualifier
- **STATUS**: Service status as a string

Adapters

- **OUT**: Unidirectional adapter of type AX For output communication

Functionality

The logiBUS_QXA acts as a wrapper for the logiBUS_QX function block and provides a unified interface for digital output functions. During initialization (INIT event), the configuration parameters are passed

and the outputs are configured accordingly. The block enables the control of up to 8 digital outputs via the output data structure.

Technical Features

- Uses the logiBUS_QX core function block for the actual output logic
- Supports up to 8 digital outputs (Q1 to Q8)
- Initialization with specific parameters via PARAMS input
- Feedback on the operating status via STATUS output

State Overview

The function block goes through the following states:

1. **Not Initialized**: Before the INIT event
2. **Initialization**: During processing of the INIT event
3. **Ready for Operation**: After successful initialization (INITO confirmation)
4. **Active Operation**: Processing of output requests via the OUT adapter

Application Scenarios

- Control of digital actuators in automation systems
- Connection of output modules in distributed control systems
- Integration into logiBUS-based control architectures
- Industrial automation with Boolean output signals

⚖️ Comparison with Similar Blocks

Compared to simple logiBUS_QXA offers the following features for digital output blocks:

- Extended parameterization options
- Status feedback for fault diagnosis
- Standardized interface via adapter
- Support for multiple outputs in a single structure

Conclusion

The logiBUS_QXA is a robust and flexible function block for digital output functions in industrial automation systems. Its standardized interface and comprehensive parameterization options make it ideally suited for use in complex control architectures with high demands on reliability and diagnostic capabilities.

DO-LED

LED_COLOURS

• – ◦ • – ◦ • – ◦ •

Introduction

LED_COLOURS is a global constant definition that provides standardized color values for LED displays. These constants are used in logiBUS systems for the uniform control of colored LED outputs.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

No adapters available

Functionality

LED_COLOURS defines a collection of global constants of type UINT (16-bit unsigned integer) that represent different LED colors. Each color is assigned a fixed numerical value:

- LED_RED: 1
- LED_YELLOW: 2
- LED_ORANGE: 3
- LED_GREEN: 4
- LED_BLUE: 5
- LED_WHITE: 6
- LED_MAGENTA: 7
- LED_CYAN: 8

Technical Specifications

- All constants are of type UINT (16-bit unsigned integer)
- Value range: 1-8 for the defined colors
- Constants are set at compile time and are immutable
- Part of the logiBUS::io::DO_LED package

State Overview

Since these are static constants, no state model exists

Application Scenarios

- Color coding in machine controllers
- Status indicators with colored LEDs
- Standardization of color control in distributed systems
- Visualization of operating states in industrial plants

⚖️ Comparison with similar Building Blocks

Unlike function blocks with dynamic behavior, these are purely static constant definitions. Similar constructs would be:

- ENUM data types for color definitions
- #define preprocessor instructions in C/C++
- Constant blocks in other IEC 61131 languages

Conclusion

LED_COLOURS offers a standardized and maintainable solution for controlling the color of LED displays in logiBUS systems. Centralized definition avoids inconsistencies and increases code reusability.

LED_FREQ

• – ○ • – ○ • – ○ •

Introduction

LED_FREQ is a collection of global constants for controlling LED blinking patterns with priority management. The constants define various blinking frequencies and operating modes for LEDs with assigned priority values that can be used in control applications.

Interface Structure

Event Inputs

No event inputs available

Event Outputs

No event outputs available

Data Inputs

No data inputs available

Data Outputs

No data outputs available

Adapters

No adapters available

Functionality

The global constants provide numerical values for different LED operating modes. Each mode has a specific priority value, with higher numbers representing a higher priority. The constants can be used in function blocks to control LED behavior and resolve priority conflicts.

Technical Features

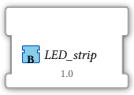
- **Data Type**: All constants are of type UINT (unsigned integer)
- **Priority Range**: Values from 0 to 6, where 6 represents the highest priority
- **Frequency Ranges**: 5 Hz, 2 Hz, 1 Hz, 0.5 Hz blinking and breathing effect
- **Package Membership**: logiBUS::io::DO_LED

State Overview

No state machine present - these are static constants

Application Scenarios

- Control of status LEDs in industrial control systems
- Prioritized display control in machine operator panels
- Visualization of operating states with varying urgency
- Multi-channel LED control with priority management



⚖️ Comparison with Similar Function Blocks

Unlike function blocks with dynamic behavior control, LED_FREQ offers static, predefined operating modes with fixed priorities. This allows for simpler implementation with known, standardized display requirements.

Conclusion

LED_FREQ offers an efficient method for defining standardized LED operating modes with integrated priority management. The constant collection is particularly suitable for applications requiring clear, predictable LED behavior patterns with defined priorities.

LED_strip

• – ○ • – ○ • – ○ •

Introduction

LED_strip is a GlobalConstants function block that provides global constants for controlling LED strips. The block defines an output variable for controlling LED strips and is part of the logiBUS system.

Interface Structure

Event Inputs

No event inputs available.

Event Outputs

No event outputs available.

Data Inputs

No data inputs available.

Data Outputs

No data outputs available.

Adapters

No adapters available.

Functionality

The LED_strip block defines a global constant `Output_strip` of type USINT (Unsigned Short Integer) with an initial value of 0. This constant serves as a reference for controlling the output of LED strips and can be used by other function blocks in the system.

Technical Details

- The constant `Output_strip` is of type USINT (8-bit unsigned integer)
- Initial value is 0
- Part of the logiBUS::io::DO_LED package
- Supports the Eclipse Public License 2.0

State Overview

Since this is a GlobalConstants block, there are no state transitions or management. The defined constant retains its fixed value throughout runtime.

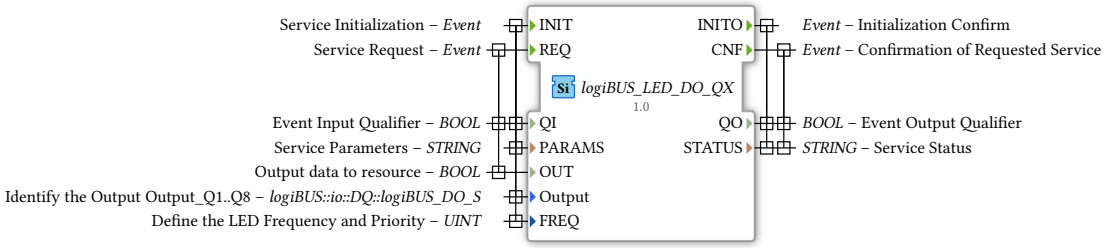
Application Scenarios

- Definition of output channels for LED strips
- Central management of hardware output references
- Use in combination with digital output blocks
- Integration into lighting control systems

⚖️ Comparison with similar blocks

Compared to other GlobalConstants blocks, LED_strip offers a specific constant for LED strip control. While general constant blocks define universal values, this block is designed for the specific requirements of LED control.

Conclusion



The LED_strip GlobalConstants block provides a simple and effective way to centrally manage output references for LED strips. By using it as a global constant, it enables consistent and maintainable integration into larger control systems.

logiBUS_LED_DO_QX

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_LED_DO_QX function block is an output service interface function block for Boolean output data. It is used to control LED outputs via the logiBUS system and offers special functions for frequency control of the LEDs.

Interface Structure

Event Inputs
- **INIT**: Service initialization with the associated variables QI, PARAMS, Output, and FREQ
- **REQ**: Service request with the associated variables QI and OUT

Event Outputs
- **INITO**: Initialization acknowledgment with the associated variables QO and STATUS
- **CNF**: Acknowledgement of requested service execution with the associated variables QO and STATUS

Data Inputs
- **QI**: Event input qualifier (BOOL)
- **PARAMS**: Service parameters (STRING)
- **OUT**: Output data to the resource (BOOL)
- **Output**: Identifies the output Output_Q1..Q8 (logiBUS::io::DQ::logiBUS_DO_S) - Initial value: Invalid
- **FREQ**: Defines the LED frequency and priority (UINT) - Initial value: LED_FREQ::LED_OFF

Data Outputs
- **QO**: Event output qualifier (BOOL)
- **STATUS**: Service status (STRING)

Adapter
No adapter interfaces available.

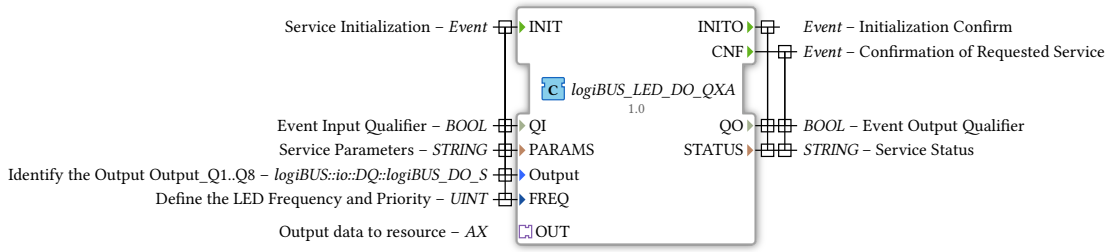
Functionality
This function block allows the control of LED outputs with configurable frequency settings. The INIT event input initializes the service, allowing configuration of the specific output (Output_Q1 to Q8) and the LED frequency. The REQ event input triggers the actual output operation, sending the Boolean value to the configured output.

Technical Features
- Supports frequency control for LED operation (blinking)
- Initialization with invalid value for the output
- Predefined frequency constants (LED_FREQ::LED_OFF as default)
- Specific output identification via the output parameter

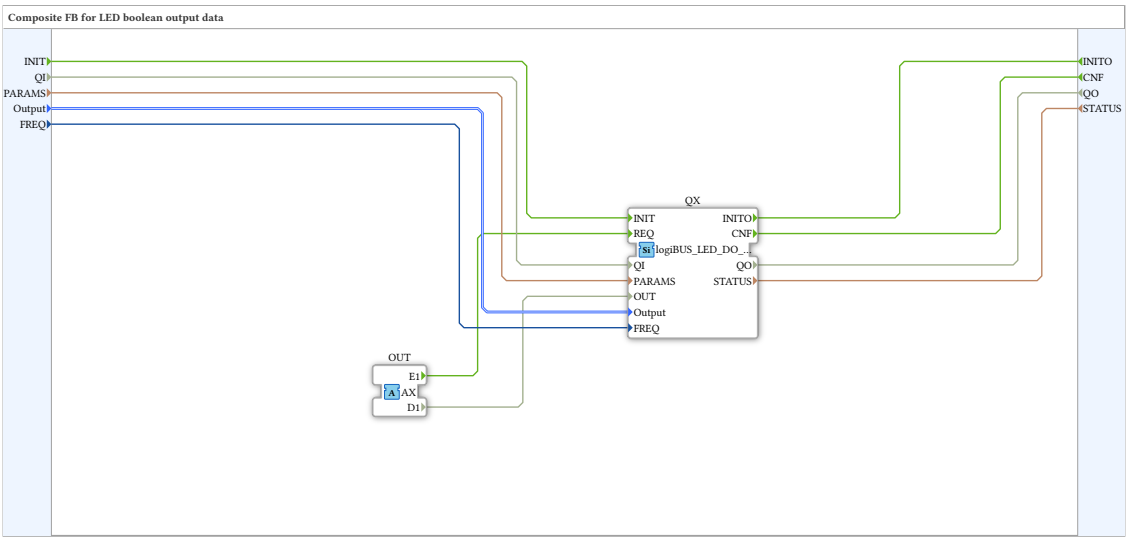
State Overview
The function block cycles through typical service interface states:

1. Uninitialized state
2. Initialization phase after an INIT event
3. Ready for operation after successful initialization
4. Active operating state during REQ processing

Application Scenarios
- Control of status LEDs in automation systems
- Visualization of process states with blinking signals
- Integration into logiBUS-based control systems
- Priority-controlled LED displays



⚖️ Comparison with similar function blocks
Compared to simple digital output blocks, logiBUS_LED_DO_QX offers advanced frequency control functions and specific LED optimizations. While standard DO blocks only offer simple on/off control, this block enables more complex blinking patterns and priority control.



🛠️ Related Exercises
- Exercise_029

Conclusion

The logiBUS_LED_DO_QX function block represents a specialized solution for LED output control in logiBUS systems. Thanks to its integrated frequency control and flexible output configuration, it is particularly suitable for applications requiring advanced visualization functions.

logiBUS_LED_DO_QXA

• – ○ • – ○ • – ○ •

Introduction

The **logiBUS_LED_DO_QXA** is a composite function block (FB) that simplifies the control of a single LED via the logiBUS system. It receives a Boolean value (e.g., from a control logic) and configures the desired LED output (Q1–Q8) with an adjustable frequency and priority. The FB encapsulates the communication with the underlying hardware driver and provides a standardized interface.

Interface Structure

Event Inputs

- **INIT** (EInit): Initializes the entire function logic.

Wired data: `QI`, `PARAMS`, `Output`, `FREQ`

Event Outputs

- **INITO** (EInit): Confirmation of successful initialization.

Wired data: `QO`, `STATUS`

- **CNF** (Event): Acknowledgement of a completed service order (e.g., after a value change).

Wired data: `QO`, `STATUS`

Data Inputs

- *QI* (BOOL): Event qualifier – enables processing of the input event.
- *PARAMS* (STRING): Service parameter, typically address or configuration data for the logiBUS node.

- *Output* (logiBUS::io::DQ::logiBUS_DO_S): Identification of the physical output (e.g., Q1...Q8). Initial value: `Invalid`.
- *FREQ* (UINT): Defines the desired LED frequency and priority. Initial value: `LED_FREQ::LED_OFF`.

Data Outputs

- *QO* (BOOL): Output qualifier – indicates the state of the last processing.
- *STATUS* (STRING): Message about the current service status (e.g., error code or "OK").

Adapter

- **OUT** (adapter::types::unidirectional::AX): Unidirectional adapter for passing the Boolean value to the resource.
- *E1* (Event): Signals a new data request.
- *D1* (BOOL): The value to be transmitted (LED on/off).

Functionality

1. **Initialization**

The FB is started by an INIT event. The supplied data (`QI`, `PARAMS`, `Output`, `FREQ`) are forwarded to the inner FB `logiBUS_LED_DO_QX`, which performs the actual logiBUS communication. If successful, `INITO` is sent with the output data `QO` and `STATUS`.

1. **Operation**

After initialization, the function block waits for the event `OUT.E1`. This event is triggered by the connected resource as soon as a new Boolean value (`OUT.D1`) is present. The event is passed on to the internal function block as `REQ`. This block then updates the LED output according to the configured `Output` identification and the specified `FREQ`.

1. **Confirmation**

After successful processing, the internal function block sends a `CNF` event, which is output externally as `CNF`. The outputs `QO` and `STATUS` indicate the current state.

Technical Features

- **Composite Function Block** – This function block simplifies the use of the complex driver function block `logiBUS_LED_DO_QX` by using a reduced interface.
- **Adapter Design** – The adapter `OUT` enables loose coupling between the control logic and the output channel. The Boolean value is passed in response to an event.
- **LED Frequency** – The parameter `FREQ` uses a predefined enumeration (`LED_FREQ`) to define blinking patterns or priorities (e.g., `LED_OFF`, `LED_ON`, `BLINK_1HZ`, ...).
- **Error Handling** – The output `STATUS` returns detailed messages (e.g., from `logiBUS::io::DQ::logiBUS_DO::Invalid`).

State Overview

The function block (FB) does not have explicit state machines in the XML network. The state logic is implemented through the interaction of INIT and the event/data connections:

- **Idle State** – After successful initialization, the FB waits for events from the adapter.
- **Processing** – A `OUT.E1` event triggers an update of the LED output.
- **Error State** – In case of failed initialization or communication errors, `STATUS` is set accordingly.

Application Scenarios

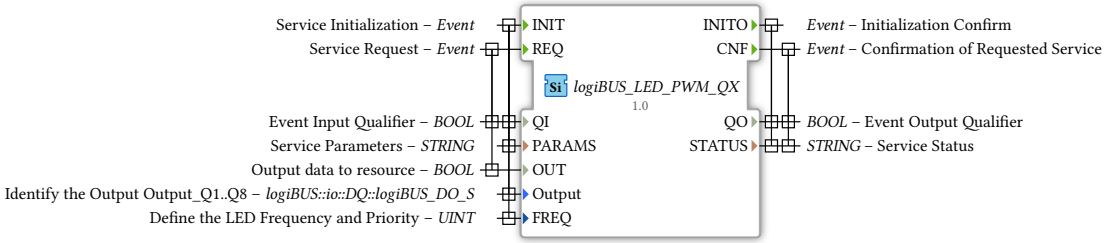
- **Agricultural and Agricultural Technology** – Control of indicator lights on machines, display of operating states via logiBUS.
- **Automation** – Simple on/off signals to distributed I/O modules, e.g., control cabinet LEDs.
- **Wireless Connection** – Use of the logiBUS protocol to bridge larger distances between the controller and the actuator.

Comparison with Similar Function Blocks

Compared to the direct driver function block `logiBUS_LED_DO_QX`, `logiBUS_LED_DO_QXA` offers a leaner interface and integrates initialization in a single step. Other composite function blocks in the `logiBUS_DO`

family focus on digital-binary outputs, while this function block is specifically designed for LED applications (with frequency support).

Conclusion



The `logiBUS_LED_DO_QXA` is a convenient composite function block for LED output via logiBUS. It reduces implementation complexity to just a few parameters and an event adapter. Its clear structure makes it particularly suitable for recurring switching tasks in distributed control systems.

logiBUS_LED_PWM_QX

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_LED_PWM_QX is an output service interface function block for Boolean output data with PWM functionality for LED control. This block enables the control of LED outputs with configurable frequencies and provides a standardized interface for communication with logiBUS I/O resources.

Interface Structure

Event Inputs

- **INIT**: Service initialization with parameters QI, PARAMS, Output, and FREQ
- **REQ**: Service request with parameters QI and OUT

Event Outputs

- **INITO**: Initialization acknowledgment with parameters QO and STATUS
- **CNF**: Acknowledgement of the requested service operation with parameters QO and STATUS

Data Inputs

- **QI**: BOOL - Event input qualifier
- **PARAMS**: STRING - Service parameter
- **OUT**: BOOL - Output data for the resource
- **Output**: logiBUS_DO_S - Identifies the output (Output_Q1..Q8), initial value: Invalid
- **FREQ**: UINT - Defines the LED frequency and priority Initial value: LED_FREQ::LED_OFF

Data Outputs

- **QO**: BOOL - Event output qualifier
- **STATUS**: STRING - Service status

Adapters

No adapter interfaces available.

Functionality

This function block manages the PWM control of LED outputs via the logiBUS system. During initialization (INIT event), the output configuration, frequency settings, and service parameters are passed. Output data (OUT) can be sent via the REQ event, which is then applied to the specified output at the configured PWM frequency.

Technical Features

- Supports various LED frequencies via the FREQ parameter
- Integrated error handling via STATUS output
- Typed output identification via logiBUS_DO_S data type

- Initialization with an invalid state for unconfigured outputs
- Frequency priority control for LED control

State Overview

The function block has the following operating states:

- **Not Initialized**: Before the INIT event, outputs are inactive
- **Initialized**: After successful INIT processing, ready for REQ operations
- **Active**: During PWM signal generation
- **Error**: In case of invalid parameters or configuration errors

Application Scenarios

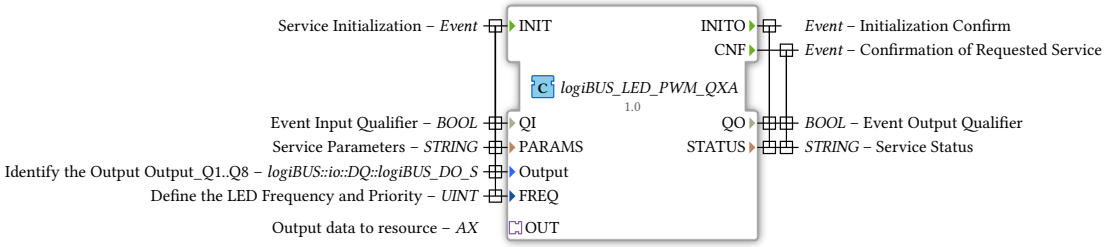
- Control of status LEDs in industrial control systems
- PWM-controlled lighting systems
- Visual signaling with variable brightness control
- Priority-controlled LED displays in logiBUS-based applications

⚖️ Comparison with similar devices Modules

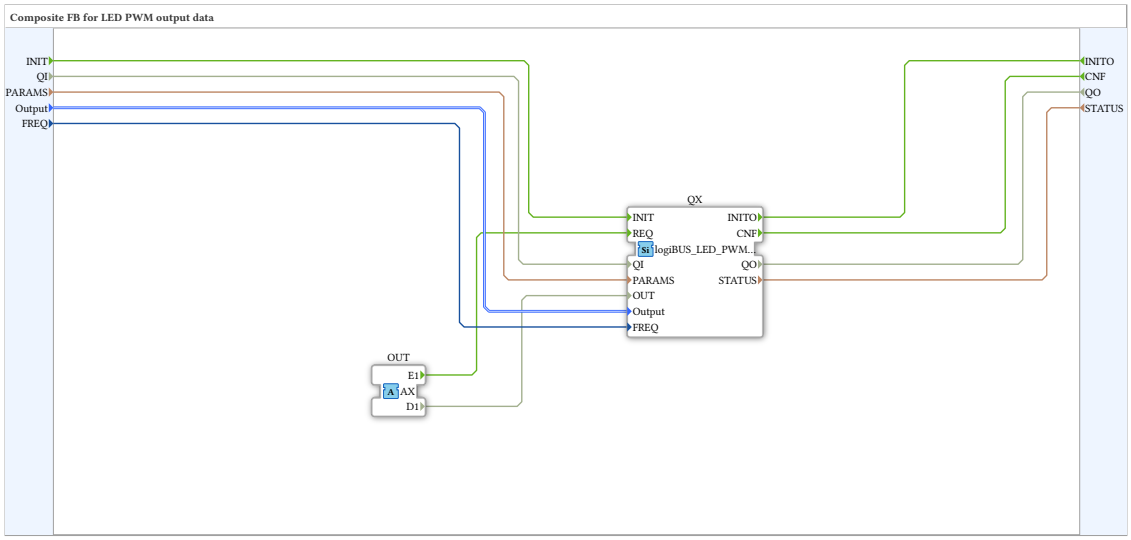
Compared to simple digital output modules, logiBUS_LED_PWM_QX offers advanced PWM functionality with frequency control and priority-based control. Integration into the logiBUS ecosystem enables standardized communication with I/O resources.

🛠️ Related Exercises

- Exercise_030



Conclusion



The logiBUS_LED_PWM_QX is a specialized function block for demanding LED control applications in industrial automation systems. With its PWM functionality, configurable frequencies, and integration into the logiBUS system, it provides a powerful solution for visual output scenarios with high demands on flexibility and reliability.

logiBUS_LED_PWM_QXA

• – ○ • – ○ • – ○ •

Introduction

The function block `logiBUS_LED_PWM_QXA` is a composite block for controlling a PWM-controlled LED via the logiBUS. It combines the configuration and output of an LED PWM signal and provides a uniform interface for initialization, parameterization, and operation.

Interface Structure

Event Inputs

Event	Type	With Variables	Description
`INIT`	EInit	`QI`, `PARAMS`, `Output`, `FREQ`	Service Initialization; starts the function block with the specified parameters

Event Outputs

Event	Type	With Variables	Description
`INITO`	Initialization	`QO`, `STATUS`	Confirmation of successful initialization
`CNF`	Event	`QO`, `STATUS`	Acknowledgement of a requested service (e.g., after a data request via the adapter)

Data Inputs

Variable	Type	Initial Value	Description
`QI`	BOOL	–	Qualifier for the event input (activation)
`PARAMS`	STRING	–	Service parameter for bus configuration
`Output`	`logiBUS::io::DQ::logiBUS_DO_S`	`Invalid`	Selection of physical output Q1..Q8
`FREQ`	UINT	`LED_OFF`	Frequency and priority of the LED PWM (e.g., from enumeration `LED_FREQ`)

Data Outputs

Variable	Type	Description
QO	BOOL	Qualifier for the event output (activation acknowledgement)
STATUS	STRING	Service status (error/success message)

Adapter

Adapter	Type	Description
OUT	adapter::types::unidirectional::AX	Output adapter for data transmission to the logiBUS resource (via event E1 and data D1)

Functionality

The function block is implemented as a composition and internally contains the sub-FB logiBUS_LED_PWM_QX, which implements the actual PWM control.

1. **Initialization (INIT):**

The FB is started by the event INIT. The parameters QI, PARAMS, Output, and FREQ are forwarded to the sub-function block. After successful initialization, the sub-function block returns INITO and the output data QO and STATUS.

1. **Operation:**

The adapter OUT receives an event from the resource at E1. This event is then passed through to the sub-function block as REQ. The sub-FB processes the request and sends the output data (the current PWM value and the status signal) to the resource via the adapter data channel OUT.D1. The sub-FB's acknowledgment CNF is output as CNF by the composite FB.

1. **Error Handling:**

If errors occur during initialization or operation, the status is reported via the variable STATUS. Output validation is performed via QO.

Technical Features

- **Composite Block**: The FB encapsulates the complexity of the PWM output and provides a simple interface for the user.
- **Typed Output Selection**: The input Output of type logiBUS_DO_S allows explicit assignment to a logiBUS digital output Q1..Q8. The initial value Invalid forces a valid selection before first use.
- **Frequency Setting**: The PWM frequency and priority can be defined via FREQ (type UINT). The initial value LED_OFF switches the LED off by default.
- **Adapter-Based Communication**: The unidirectional adapter AX transmits events and data between the FB and the higher-level logiBUS resource. The FB itself waits for external requests (E1) and returns data.

Adapter-Based Communication:** The unidirectional adapter AX transmits events and data between the FB and the higher-level logiBUS resource. The FB itself waits for external requests (E1) and returns data.
**

State Overview

Since this is a composite function block, it does not have explicit states of its own. However, the internal sub-FB logiBUS_LED_PWM_QX can pass through states such as "Initialization," "Ready," or "Error." These are reflected indirectly via the event outputs and the status variable:

- **After INIT**: The FB is in the initialized state (provided QO = TRUE and STATUS = „OK“ are present).
- **After CNF**: A requested action (e.g., a call via an adapter) has been confirmed. The FB remains operational.
- **Error State**: If STATUS contains an error message, the FB must be reinitialized. Repeating the INIT event resets all parameters.

Application Scenarios

- **PWM-Controlled Lighting**: Use in agricultural machinery or automation systems to adjust the brightness of LED work lights.
- **Light Signaling Systems**: Control of multiple LED outputs with different frequencies (e.g., flashing light, continuous light).
- **Dimming via logiBUS**: Integration into a logiBUS network where the PWM values are calculated centrally or decentrally.

Comparison with Similar Components

- **logiBUS_DO_S** (direct digital output): This component only switches binary outputs (on/off) without PWM. In contrast, `logiBUS_LED_PWM_QXA` offers a PWM function for dimmed LEDs.
- **logiBUS_LED_PWM_QX**: This is the internal sub-component that executes the pure PWM logic. The `QXA` composite function block extends it with an adapter connection and standard interface definition, simplifying integration into higher-end controllers.
- **Generic PWM Function Blocks**: Compared to platform-independent PWM blocks, this function block is specifically tailored to logiBUS hardware and offers the parameters and types commonly found there.

Conclusion

The `logiBUS_LED_PWM_QXA` function block encapsulates the PWM control of an LED via logiBUS in a compact composite block. Its clearly defined interface with initialization, adapter communication, and status feedback makes it easy to integrate into automation projects. The combination of output selection, frequency setting, and error handling makes it a robust component for dimmable lighting applications in industrial environments.

logiBUS_LED_strip_QX

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_LED_strip_QX function block is an output service interface function block for Boolean output data, specifically designed for controlling LED strips. It offers extensive configuration options for various LED parameters such as color, frequency, and output number.

Interface Structure

Event Inputs

- **INIT**: Service Initialization Event
- **REQ**: Service Request Event

Event Outputs

- **INITO**: Initialization Acknowledgement
- **CNF**: Acknowledgement of Requested Service Operation

Data Inputs

- **QI** (BOOL): Event Input Qualifier
- **PARAMS** (STRING): Service Parameters

- **OUT** (BOOL): Output Data to the Resource
- **Output** (USINT): Identifies the strip's output number (initial value: LED_strip::Output_strip)
- **Colour** (UINT): Identifies the color (initial value: LED_COLOURS::LED_GREEN)
- **FREQ** (UINT): Defines the LED frequency and priority (Initial value: LED_FREQ::LED_OFF)

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (STRING): Service status

Adapters

No adapter interfaces available.

Functionality

This function block enables the control of LED strips via a standardized interface. During initialization (INIT), configuration parameters such as output number, color, and frequency are set. Output data (OUT) can be sent to the LED strip via the REQ event. The block acknowledges each operation via the corresponding output events INITO and CNF.

Technical Features

- Support for various LED colors via the Colour parameter
- Configurable frequency settings for blinking functions
- Multiple outputs supported via the Output parameter
- Predefined initial values for quick commissioning
- Status feedback via the STRING parameter

State Overview

The function block has two main states:

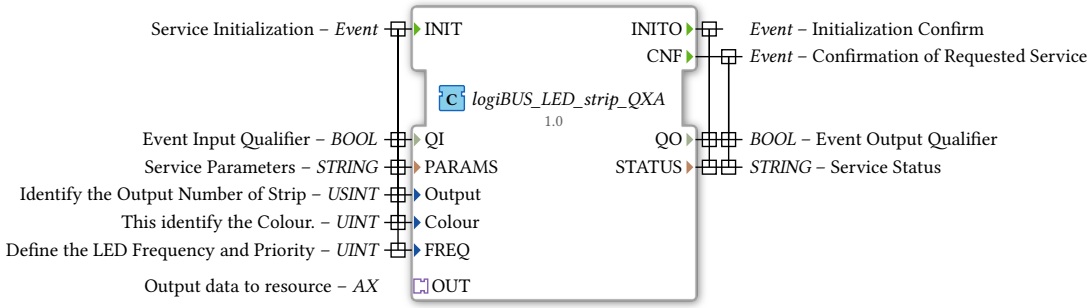
1. **Initialization State**: Activated by the INIT event
2. **Operating State**: Processes REQ requests after successful initialization

Application Scenarios

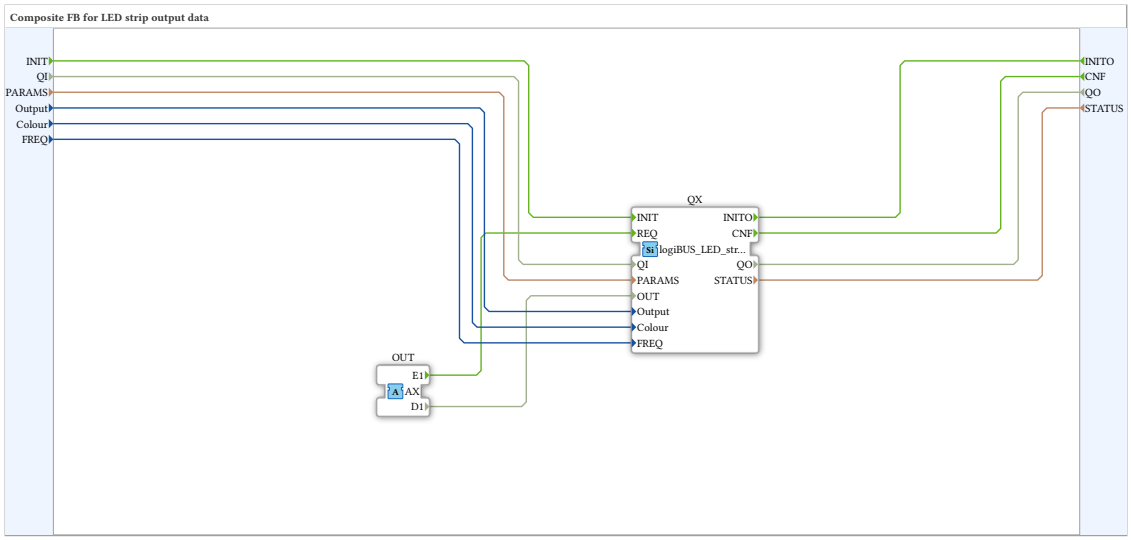
- Industrial lighting control
- Status indicators in automation systems
- Warning and signal light control
- Visualization of process states
- Building automation with LED lighting

⚖️ Comparison with Similar Function Blocks

Compared to simple digital output blocks, logiBUS_LED_strip_QX offers extended functionality for LED-specific applications, particularly through integrated color and frequency control and the ability to address multiple LED strips independently.



🛠️ Related Exercises



- Exercise_032
- Exercise_033_sub

Conclusion

The logiBUS_LED_strip_QX is a powerful function block for professional LED strip control in industrial automation solutions. Its flexible parameterization and reliable status feedback make it ideal for demanding lighting applications.

logiBUS_LED_strip_QXA

• – ○ • – ○ • – ○ •

Introduction

The function block **logiBUS_LED_strip_QXA** is a composite function block for controlling an LED strip via the logiBUS protocol. It encapsulates the communication with the hardware and enables color- and frequency-dependent control of individual outputs. This block is particularly suitable for use in agricultural technology, where flexible LED signaling is required.

Interface Structure

Event Inputs

Event	Description	With
INIT	Service Initialization	QI, PARAMS, Output, Color, FREQ

Event Outputs

Event	Description	With
INITO	Initialization Confirmation	QO, STATUS
CNF	Confirmation of Executed Request	QO, STATUS

Data Inputs

Name	Type	Description	Initial Value
QI	BOOL	Processing Enable (Event Qualifier)	-
PARAMS	STRING	Service Parameter (e.g., Bus Configuration)	-

Output	USINT	Output Identification (Strip Number)	`LED_strip::Output_strip`
Colour	UINT	LED Color Code	`LED_COLOURS::LED_GREEN`
FREQ	UINT	Frequency/Priority of the LED Display	`LED_FREQ::LED_OFF`

Data Outputs

Name	Type	Description
QO	BOOL	Output Qualifier (Processing Status)
STATUS	STRING	Status Message (e.g., Error Code)

Adapters

Adapter	Type	Description
OUT	`adapter::types::unidirectional::AX`	Unidirectional adapter interface for data transfer to the resource (output data to logiBUS)

Functionality

The function block operates as a composite FB, internally using the sub-block **logiBUS_LED_strip_QX**. After an **INIT** event, the parameters (QI, PARAMS, Output, Colour, FREQ) are passed to the internal FB. Initialization is acknowledged via **INITO**.

As soon as an event (E1) arrives via the **OUT* adapter, a **REQ** request is triggered in the internal FB. The current data (Colour, FREQ) is sent to the logiBUS LED strip. After successful execution, the internal FB acknowledges with **CNF**, which appears at the external output **CNF**.

Data flows:

- **Out.D1** → internal FB.QX.OUT (output data of the adapter)
- **Qi**, **PARAMS**, **Output**, **Colour**, **FREQ** → forwarded to QX accordingly.

The outputs **QO** and **STATUS** reflect the internal state of the sub-block.

Technical Features

- Composite FB: facilitates the reuse and encapsulation of the hardware control.
- Use of an adapter (OUT) for unidirectional data transfer to the logiBUS resource.
- Initial parameter values are predefined as constants (e.g., `LED_strip::Output_strip`, `LED_COLOURS::LED_GREEN`) but can be overwritten at runtime.
- The internal FB `logiBUS_LED_strip_QX` is responsible for the actual bus communication; this block only provides a simplified interface.
- Copyright and developer: HR Agrartechnik GmbH (Version 1.0, 2026-02-23).

State Overview

The function block has no explicitly modeled states; its behavior is determined by the sequence control of the composite network:

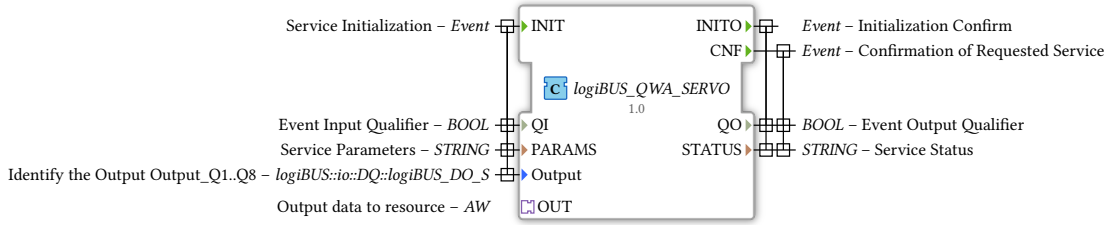
1. **Initialization State**: After **INIT**, the internal function block is configured and the bus connection is established.
2. **Ready State**: After successful initialization, the function block can be addressed via the adapter (OUT.E1).
3. **Execution State**: The request is sent to the LED strip until acknowledgment (**CNF**) is received.
4. **Error State**: If QO = FALSE or STATUS contains an error, communication is disrupted.

Application Scenarios

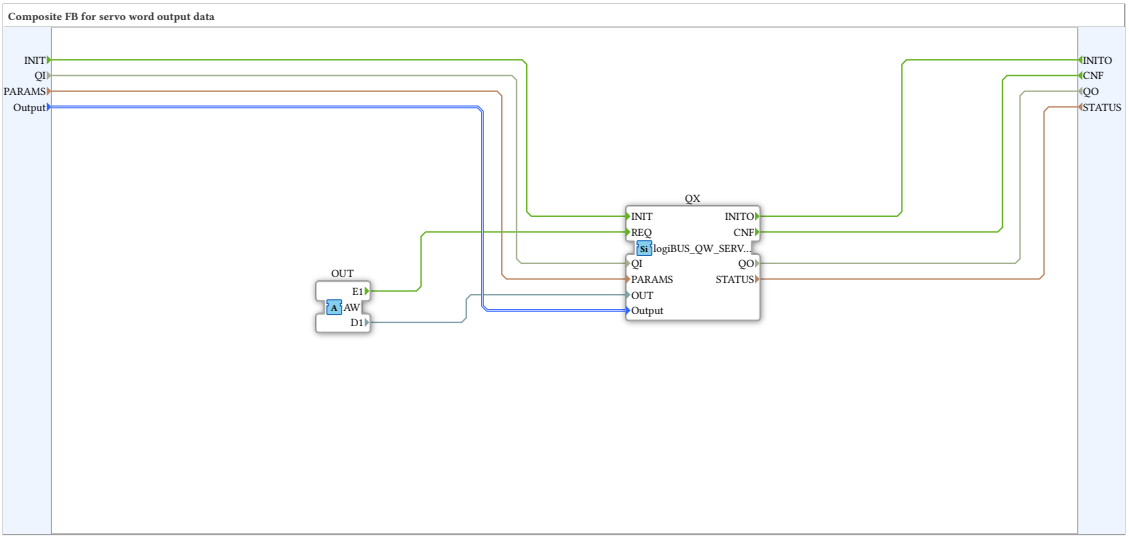
- **Agricultural Machinery**: Color-coded status indicators (e.g., green for ready, red for alarm) on LED strips.
- **Field Edge Lighting**: Control of multiple LED strip outputs with different colors and flashing frequencies.
- **Custom Signaling**: Integration into higher-level control systems for visualizing operating states.

- **Development and Testing**: Use as a simple building block for simulating and commissioning logiBUS components.

Comparison with Similar Building Blocks



- **logiBUS_LED_strip_QX** (direct FB): Offers a more detailed interface with multiple events (REQ) and data. The composite FB **QXA** described here simplifies its use through an adapter interface and a clear separation of initialization and execution.
- **logiBUS_DO_Bit**: Controls individual digital outputs; no color/frequency control.
- **Composite FBs in General**: The QXA is specifically designed for LED strip applications and reduces wiring effort in the higher-level network.



Conclusion

The **logiBUS_LED_strip_QXA** offers a convenient and standardized way to control LED strips via logiBUS in terms of color and flashing frequency. Thanks to its adapter-based interface, it can be easily integrated into larger systems without requiring knowledge of the bus communication details. The composite approach ensures clarity and reusability.

DO servo

logiBUS_QWA_SERVO

• – ○ • – ○ • – ○ •

Introduction

The **logiBUS_QWA_SERVO** is a composite function block (CFB) for outputting servo control words via a logiBUS. It encapsulates the initialization, parameterization, and output based on an internal function block (`logiBUS_QW_SERVO`) and provides a standardized interface. Developed under the Eclipse Public License 2.0 (Copyright 2026 HR Agrartechnik GmbH). *Comment from the XML: "Composite FB for servo word output data".*

Interface Structure

Event Inputs

Event	Type	With Variables	Description
INIT	EInit	QI, PARAMS, Output	Service Initialization

Event Outputs

Event	Type	With Variables	Description
INITO	EInit	QO, STATUS	Initialization Confirmation
CNF	Event	QO, STATUS	Confirmation of a Requested Action

Data Inputs

Name	Type	Initial Value	Description
QI	BOOL	–	Event Input Qualifier
PARAMS	STRING	–	Service Parameter (e.g., Bus Configuration)
Output	logiBUS::io::DQ::logiBUS_DO_S	Invalid	Identifies the output (Output_Q1 ... Output_Q8)

Data Outputs

Name	Type	Description
QO	BOOL	Event Output Qualifier
STATUS	STRING	Status Message (Error, OK, etc.)

Adapters

Adapter	Type	Direction	Description
OUT	adapter::types::unidirectional::AW	Socket	Output data for the resource (word output)

Functionality

The function block operates as a composite:

1. **Initialization** (INIT):

- Qualifier QI, parameter string PARAMS, and the desired output (Output) are passed.
- The internal function block logiBUS_QW_SERVO is initialized; after successful initialization, INITO is sent.

1. **Execution** (via adapter OUT):

- The event OUT.E1 is received by the adapter and forwarded to the internal function block (FB) as REQ.
- Simultaneously, the data is transferred to the internal FB (QX.OUT) via OUT.D1.

1. **Feedback**:

- The internal FB signals completion via CNF, which is forwarded to the external output CNF.
- Status and qualifier are output via QO and STATUS.

The actual control of the servo hardware is handled via the adapter OUT, which is connected to the resource.

Technical Features

- **Composite Design**: Encapsulates the complex initialization and execution control of the servo word output.
- **Adapter Interface**: The unidirectional adapter `AW` enables flexible connection to various physical output channels.
- **Output Selection**: The input `Output` allows selection between eight different outputs (`Q1`…`Q8`); the initial value `Invalid` prevents unintended actions before configuration.
- **Error Handling**: Status information is provided via `STATUS`; event sequences guarantee correct flow control.
- **License**: Eclipse Public License 2.0 (EPL-2.0) – free use and further development under the license terms.

State Overview

The function block (FB) does not have an explicitly modeled state machine; however, the following implicit state logic results from the event sequences:

State	Trigger	Response
Idle	–	Waiting for `INIT`
Initialize	Received `INIT`	Internal FB is started
Ready	`INITO` sent	Ready for requests via the adapter
Busy	`OUT.E1` received	Action is being executed (`REQ` is running)
Done	`CNF` sent	Action completed, returning to **Ready**
Error	Error during initialization or action	`STATUS` contains error description; reinitialization may be necessary

Application Scenarios

- **Agricultural Machinery**: Control of servo drives (e.g., for flaps, valves, actuators) via a logiBUS fieldbus.

Done | `CNF` | Action completed, returning to **Ready** | **Error** | Error during initialization or action | `STATUS` contains error description; reinitialization may be necessary |

- **Agricultural Machinery**: Control of servo drives (e.g., for flaps, valves, actuators) via a logiBUS fieldbus.

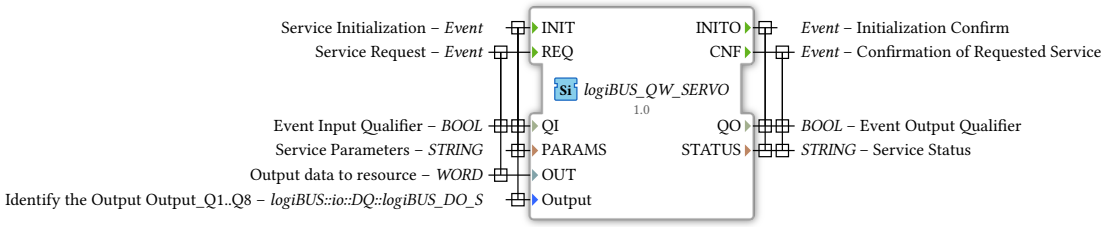
** - **Modular Output Block**: Used in distributed control systems where multiple servo outputs need to be parameterized depending on the machine configuration.

- **Parameterizable Configuration**: Bus address, protocol settings, and timing behavior can be defined via `PARAMS`.

Comparison with Similar Blocks

- **logiBUS_QW_SERVO** (internal FB): Implements direct word output and bus communication, while `logiBUS_QWA_SERVO` offers a higher level of abstraction with consolidated inputs/outputs.
- **logiBUS_DO_S Family**: Other blocks in this family address individual discrete outputs (e.g., logiBUS_DO) – the FB described here is specifically designed for servo word data and multiple simultaneous outputs.
- **Generic Word Output Function Blocks**: Compared to standardized `W`-type function blocks, this block offers an interface adapted to servo applications (e.g., `logiBUS_DO_S`-type).

Conclusion



The `logiBUS_QWA_SERVO` is a well-structured composite function block that simplifies the control of servo word outputs on a logiBUS. By separating initialization, execution, and error feedback, and using an adapter for the hardware interface, it is ideally suited for modular automation solutions in agricultural technology and similar industries. Licensing under EPL-2.0 allows for unrestricted use and customization.

logiBUS_QW_SERVO

• – ◦ • – ◦ • – ◦ •

Introduction

The logiBUS_QW_SERVO is an output service interface function block for word output data, specifically designed for controlling logiBUS servo outputs. This block enables the initialization and control of digital outputs via a standardized interface.

Interface Structure

Event Inputs

- **INIT**: Service initialization event with associated data QI, PARAMS, and Output
- **REQ**: Service request event with associated data QI and OUT

Event Outputs

- **INITO**: Initialization acknowledgment with associated data QO and STATUS
- **CNF**: Acknowledgement of the requested service operation with associated data QO and STATUS

Data Inputs

- **QI** (BOOL): Event input qualifier
- **PARAMS** (STRING): Service parameters for configuration
- **OUT** (WORD): Output data for the resource
- **Output** (logiBUS::io::DQ::logiBUS_DO_S): Identifies the output Output_Q1..Q8, initially with a value “Invalid”

Data Outputs

- **QO** (BOOL): Event output qualifier
- **STATUS** (STRING): Service status information

Adapters

No adapter interfaces available.

Functionality

This function block enables the initialization and control of logiBUS servo outputs. During INIT initialization, the service parameters are configured and the specific output is identified. Output data in WORD format can be sent to the resource via the REQ event. The block confirms both operations with corresponding output events (INITO and CNF) containing status information.

Technical Features

- Uses WORD data type for output data (16-bit)
- Supports specific logiBUS output identification via the output parameter
- Initialization with an “Invalid” value for the output parameter
- String-based parameter and status transmission

State Overview

The function block has two main operating states:

1. **Not Initialized**: Before INIT initialization
2. **Initialized and Ready**: After successful INIT initialization, ready for REQ requests

Application Scenarios

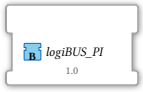
- Control of digital outputs in logiBUS systems
- Servo controllers with word data output
- Industrial automation applications with precise output control
- Embedded systems with a logiBUS interface

⚖️ Comparison with Similar Function Blocks

Compared to simple digital output blocks, logiBUS_QW_SERVO offers extended functionality through:

- Word-based data output (16-bit instead of individual bits)
- Specific servo control functions
- Detailed status feedback
- Configurable initialization

Conclusion



The logiBUS_QW_SERVO is a specialized function block for demanding output applications in logiBUS systems. Its word-based data processing and comprehensive status feedback make it particularly suitable for precise control tasks in industrial automation solutions.

logiBUS_PI

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `logiBUS_PI` is a collection of global constants for configuring pulse inputs in logiBUS systems. It defines preconfigured structures that represent the physical input pins of a logiBUS I/O module. These constants facilitate the simple and error-free assignment of hardware pins in higher-level function blocks or applications.

Interface Structure

logiBUS_PI` is a GlobalConstants block, not a traditional function block with event or data interfaces. Therefore, it has no event inputs, outputs, data inputs, outputs, or adapters.

The interface consists solely of the defined global constants. Each constant is of data type `logiBUS::io::PI::logiBUS_PI_S` and is instantiated with a specific initial value.

Defined Constants

The following constants are provided:

- `PulseInput_I1` to `PulseInput_I9`: Represent the physical pulse inputs 1 to 9. The initial value sets the structure field `Pin` to the corresponding value (1-9).
- `Invalid`: Represents an invalid or unused input. The initial value sets the structure field `Pin` to the value 255.

Functionality

The block `logiBUS_PI` itself does not perform any active functionality. It merely provides a library of predefined values. These values are of type `logiBUS_PI_S`, a structure that presumably contains at least the member `Pin`.

The constants are inserted into the application code at compile time. If another function block (e.g., a driver or measurement module) expects a parameter of type `logiBUS_PI_S`, one of these constants can be passed to uniquely select a specific hardware input.

Technical Features

- **Typing:** All constants are strictly of the structured data type `logiBUS_PI_S`. This enforces type-safe usage and prevents the unintentional assignment of simple integer values.
- **Initialization:** The initial values are specified using the ST syntax `(Pin := X)`, indicating structured initialization.
- **Invalid State:** The constant `Invalid` with pin value 255 provides a standardized way to indicate an unused or faulty channel.

State Overview

Since it is a constant block, `logiBUS_PI` has no internal state or state machine. The constant values are immutable (read-only) and remain constant throughout the application's runtime.

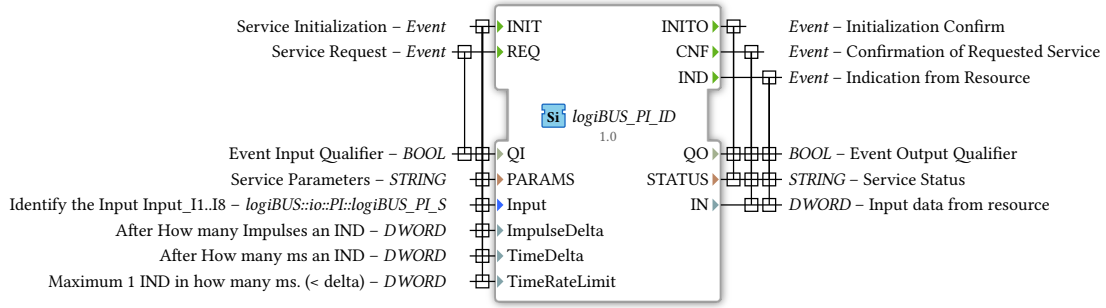
Application Scenarios

- **Hardware Configuration:** Primarily used to configure logiBUS I/O modules that provide pulse inputs (e.g., for encoders, frequency, or speed measurement).
- **Function Block Parameterization:** Simplified and readable parameterization of function blocks that require a specific pulse input. Instead of the magic number `3`, the self-explanatory constant `PulseInput_I3` is used.
- **Maintenance and Readability:** Increases the maintainability and readability of the application code, as the hardware assignment is directly apparent in the constant name.

⚖️ Comparison with Similar Blocks

Unlike function blocks such as `E_SR` (flip-flop) or `E_CYCLE` (cyclic event generator), `logiBUS_PI` does not implement any logic or algorithms. It is comparable to other constant blocks or ENUM definitions in IEC 61499 that encapsulate hardware-related parameters (e.g., `GPIO_PIN_XX` constants for Raspberry Pi). Its purpose is purely declarative and configurative.

Conclusion



The `logiBUS_PI` GlobalConstants block is an essential tool for low-level programming of logiBUS systems. By providing type-safe, predefined constants for pulse inputs, it enables clean, fault-resistant, and easily maintainable configuration of the input/output hardware. Its use promotes best practices in industrial automation programming.

logiBUS_PI_ID

• – ○ • – ○ • – ○ •

Introduction

The function block `logiBUS_PI_ID` is an input service interface module for 32-bit DWORD input data. It serves as an interface to a physical input module (presumably part of the logiBUS system) and enables the initialization, cyclic polling, and event-driven (interrupt) output of digital input values. The module can be configured to report status changes either after a specific number of pulses or after a defined time interval.

Interface Structure

Event Inputs

- **`INIT`**: Initializes the service. Accompanied by the data `QI`, `PARAMS`, `Input`, `ImpulseDelta`, `TimeDelta`, and `TimeRateLimit`.

- **REQ**: Triggers a cyclic poll of the input value. Accompanied by the data QI.

Event Outputs

- **INITO**: Confirms initialization. Returns the data QO and STATUS.
- **CNF**: Acknowledges a requested query (REQ). Returns the data QO, STATUS, and the current input value IN.
- **IND**: Indicates an event-driven status change (interrupt). Returns the data QO, STATUS, and the new input value IN.

Data Inputs

- **QI (BOOL)**: Qualifies the associated event input. The service is activated/executed at TRUE and deactivated at FALSE.
- **PARAMS (STRING)**: Contains service-specific parameters for initialization (e.g., hardware address, channel configuration).
- **Input (logiBUS_PI_S)**: Identifies the specific physical input (e.g., I1..I8). The initial value is logiBUS_PI::Invalid.
- **ImpulseDelta (DWORD)**: Defines after how many consecutive state changes (pulses) a IND event should be generated.
- **TimeDelta (DWORD)**: Defines the time interval in milliseconds after which a IND event should be generated if the value has changed.
- **TimeRateLimit (DWORD)**: At most one IND event per the given time in milliseconds (must be smaller than TimeDelta). The initial value is 100.

Data Outputs

- **QO (BOOL)**: Displays the service execution status. TRUE indicates success, FALSE signals an error.
- **STATUS (STRING)**: Provides a detailed status or error message from the service.
- **IN (DWORD)**: Contains the current 32-bit value read from the physical input.

Adapters

This function block has no adapter interfaces.

Functionality

The function block operates in two basic modes, controlled by the events REQ and IND:

1. **Polling Mode**: A REQ event queries the current input value, and the result is returned with a CNF event.
2. **Interrupt Mode**: After successful initialization (INIT/INITO), the function block continuously monitors the input. Upon a state change, the parameters ImpulseDelta and TimeDelta are evaluated. If one of the criteria is met (e.g., the defined number of pulses is reached or the time interval is exceeded *and* the value has changed), a IND event with the new value is automatically triggered.

Initialization (INIT) is a prerequisite for both operating modes. During initialization, the hardware resource is configured via PARAMS and the specific input via Input.

Technical Features

- **Data Type**: Processes 32-bit input data (DWORD).
- **Structured Input**: The input is not identified by a simple index, but by a structured data type (logiBUS_PI_S), which enables type-safe and unambiguous addressing.
- **Flexible Event Triggering**: The conditions for automatic event generation (IND) can be configured on both an impulse and time basis.
- **Service Interface**: Follows the typical pattern of a 4diac service interface function block (FB) with variables QI/QO and STATUS for consistent error handling.

Status Overview

1. **Inactive**: After startup or upon QI=FALSE.
2. **Initialization**: Upon receiving INIT with QI=TRUE. Configures the hardware interface. Ends with INITO (QO indicates success/failure).
3. **Ready (Polling)**: After successful initialization. The system responds to REQ events with CNF and the current value.
4. **Ready (Monitoring)**: After successful initialization. Continuously monitors the input and triggers IND events according to the configured ImpulseDelta and TimeDelta parameters.

Application Scenarios

- **Reading Counter Signals**: Acquiring pulses from a rotary encoder or rotary switch, using `ImpulseDelta` for preprocessing (e.g., reporting every 10th revolution).
- **Monitoring Status Groups**: Reading a 32-bit status word from a connected device, where changes only need to be reported at specific intervals (`TimeDelta`) to reduce CPU load.
- **Cyclic Polling of Switch Banks**: Polling multiple digital inputs grouped into a DWORD via regular `REQ` events.
-

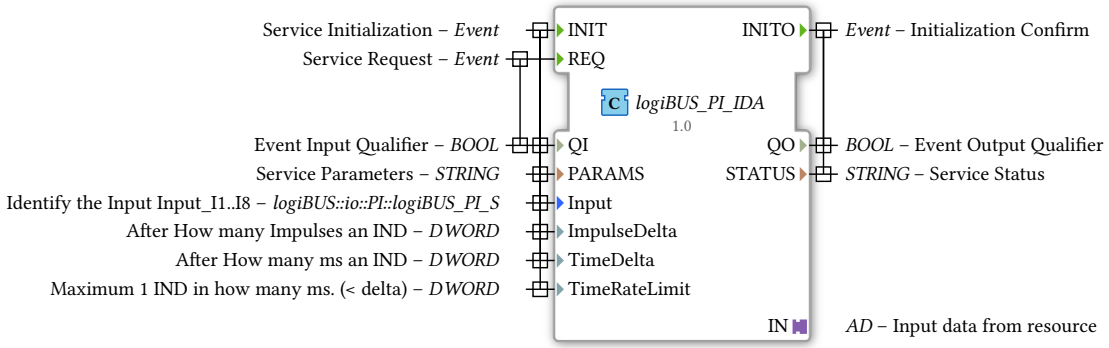
⚖️ Comparison with similar function blocks

- **Compared to `E_DEMUX` or `E_SELECT`**: These function blocks forward events or select data. `logiBUS_PI_ID` is specific to hardware communication and includes driver logic and initialization.
- **Compared to generic I/O function blocks (e.g., `WAGO_750_5xx_DI`)**: Similar function, but manufacturer-specific (here, logiBUS). Configuration is done via the structured parameters `Input` and `PARAMS` instead of fixed channel numbers.
- – **Compared to simpler input blocks**: Offers advanced features such as filtering event generation (`IND`) via `ImpulseDelta`/`TimeDelta`, which are typically not available in simple "Read" blocks.

🛠️ Related exercises

- Uebung_150
- Uebung_150_AX
- Uebung_151
- Uebung_151_AX
- Uebung_152
- Uebung_153

Conclusion



The `logiBUS_PI_ID` function block is a powerful and flexible interface for 32-bit digital inputs within the logiBUS ecosystem. By combining polling (`REQ`/`CNF`) and event-driven querying (`IND`)With configurable trigger criteria, it is suitable for a wide range of applications, from simple status queries to complex pulse evaluation. The strict separation of initialization and operating logic, along with comprehensive status reporting, makes it a robust component for industrial control applications.

logiBUS_PI_IDA

• – ○ • – ○ • – ○ •

Introduction

The **logiBUS_PI_IDA** is a composite function block (FB) for processing double-word input data (DWORD). It serves as an interface between a logiBUS fieldbus and the control logic. The FB enables parameterizable monitoring of pulse and time changes at a digital input. By configuring pulse delta, time delta, and a rate limit, the signaling behavior can be precisely tailored to the application. The block initializes the internal sub-block `logiBUS_PI_ID` and provides its results via a unidirectional adapter.

Interface Structure

Event Inputs

Name	Type	Comment
INIT	EInit	Service Initialization – Parameterization and Start
REQ	Event	Service Request – Triggers processing

Event Outputs

Name	Type	Comment
INIT	EInit	Initialization Confirm – Confirms successful initialization

Data Inputs

Name	Type	Initial Value	Comment
QI	BOOL	–	Event Input Qualifier (Enable/Disable)
PARAMS	STRING	–	Service Parameters (e.g., bus address, channel configuration)
Input	logiBUS::io::PI::logiBUS_PI_S	`Invalid`	Identifies the physical input (Input_I1..I8)
PulseDelta	DWORD	–	Number of pulses after which an indication (IND) is triggered
TimeDelta	DWORD	`250`	Time in ms after which a periodic indication (IND) is triggered

TimeRateLimit	DWORD	100	Minimum interval in ms between two indications (rate limiting)

Data Outputs

Name	Type	Comment
QO	BOOL	Event Output Qualifier – Status of the last processing
STATUS	STRING	Service Status – Error or Diagnostic Message

Adapter

Name	Type	Comment
IN	adapter::types::unidirectional::AD	Output data of the function block – delivers the processed events and values to the application

The adapter `IN` is connected to the events `IND` (indication) and `CNF` (confirmation), as well as the data value `D1` of the internal function block `logiBUS_PI_ID`.

Functionality

The function block (FB) operates as a composite, delegating all initialization and processing logic to the internal FB `logiBUS_PI_ID`.

1. **Initialization (INIT):**

Upon arrival of `INIT`, the parameters `QI`, `PARAMS`, `Input`, `ImpulseDelta`, `TimeDelta`, and `TimeRateLimit` are forwarded to the internal FB. This FB configures the hardware input and starts monitoring. After successful initialization, `INITO` is output.

1. **Processing (REQ):**

An event `REQ` triggers a query of the input value. The internal function block checks whether the configured thresholds (pulse counter, time limit) have been reached or exceeded. If so, the events `IND` and/or `CNF` are sent to the downstream logic via the adapter `IN`.

1. **Reporting Behavior:**

- **Pulse-Dependent:** If `ImpulseDelta > 0` occurs, an internal pulse counter is incremented after each change in the input signal. When the counter reaches the value of `ImpulseDelta`, an indication (`IND`) is triggered and the counter is reset.
- **Time-dependent:** Additionally or alternatively, a periodic indication is generated after `TimeDelta` milliseconds.
- **Lock logic:** If `ImpulseDelta = 0` is set, `TimeDelta` must not be 0 (error prevention). If `TimeDelta = 0xFFFFFFFF` is set, cyclic processing is deactivated – only pure value changes are reported.
- **Rate limit:** `TimeRateLimit` prevents excessively frequent indications; it ensures that at least the specified time in milliseconds elapses between two consecutive `IND` events.

Technical Features

- The function block (FB) internally uses the module `logiBUS_PI_ID`, which encapsulates the actual hardware connection and counting logic.
- If `ImpulseDelta = 0` is present, `TimeDelta > 0` must be set; otherwise, the behavior is undefined (see license information).
- A `TimeDelta` from `0xFFFFFFFF` disables the time-based indication – only pulse-driven or pure value changes are transmitted.
- The adapter `IN` provides the output data as a unidirectional data stream, which is further processed in the higher-level application.

If `ImpulseDelta = 0` is present, `TimeDelta > 0` must be set; otherwise, the behavior is undefined (see license information).

- A `TimeDelta` from `0xFFFFFFFF` disables the time-based indication – only pulse-driven or pure value changes are transmitted.
- The adapter `IN` provides the output data as a unidirectional data stream, which is further processed in the higher-level application. - The initial values (`Input`: `Invalid`, `TimeDelta`: `250`, `TimeRateLimit`: `100`) are sensibly preset to enable fast operation without additional configuration.

State Overview

Since the FB is a composite and the state logic is completely encapsulated in the internal FB `logiBUS_PI_ID`, a general state description is given here:

- **IDLE** – After a reset or failed initialization. No processing.
- **INIT** – Initialization is in progress (waiting for hardware feedback).
- **RUN** – Normal operation: Monitoring of pulses and time, triggering of indications.
- **ERROR** – Error state (e.g., invalid parameters, hardware error). Signaled via `STATUS`.

Transitions are triggered by `INIT`, `REQ`, and internal errors. The internal function block (FB) likely uses an Execution Control Chart (ECC) to implement these states.

Application Scenarios

- **Monitoring of Digital Inputs:** Connection of pushbuttons, switches, or limit switches, where both rapid pulse changes and regular status messages are required.
- **Pulse Counting:** E.g., detection of flow sensors or rotary encoders; the FB reports a measured value after each defined number of pulses.
- **Time-Controlled Queries:** In applications where the input value must be queried regularly (every ms), e.g., B. for long-term monitoring or safety testing.
- **Rate Limiting:** Prevents overloading of the bus communication during high-frequency signal changes.

Comparison with Similar Function Blocks

Function Block	Difference
`logiBUS_PI`	Simpler input function block without pulse and time-delta filters; only raw value changes.
`logiBUS_PI_ID`	Predecessor without composite structure and without adapter interface; direct event outputs.
`logiBUS_PI_IDA` (this function block)	Additionally offers an **adapter** for flexible further processing and combines pulse, time, and rate logic in a composite.

The `logiBUS_PI_IDA`This represents an extended and more modular variant, particularly suitable for complex automation projects with standardized interfaces.

Conclusion

The **logiBUS_PI_IDA** is a powerful composite function block for the configurable acquisition of digital input signals via the logiBUS. By combining pulse and time delta measurements with rate limiting, it can be flexibly adapted to a wide variety of requirements. The encapsulation of the logic within the internal block and the adapter interface facilitate reuse and integration into higher-level control programs. The function block is ideal for applications requiring precise and configurable signal evaluation with minimal resource consumption.

logiBUS_PI_S

• – ◦ • – ◦ • – ◦ •

Introduction

The function block `logiBUS_PI_S` is a structured data type used to configure a digital input (PI - likely "Peripheral Input") within the logiBUS framework. It defines the necessary parameters to address a specific physical pin of an I/O module or controller. This data type is typically used as an input parameter for corresponding I/O function blocks.

Interface Structure

As a data type (STRUCT), `logiBUS_PI_S` does not have event-driven interfaces, but defines only data fields.

Data Inputs

Not applicable – this is a data type, not an executable function block.

Internal Structure (Variables)

The structure consists of a single member:

- **`Pin`** (USINT, initial value: 255): This variable specifies the hardware pin number to be used as a digital input. The data type `USINT` (Unsigned Short Integer) allows values from 0 to 255. The default initial value of 255 is often used to represent an inactive or undefined state.

Adapter

Not present.

Functionality

The data type `logiBUS_PI_S` functions purely as a configuration container. It encapsulates the information about which physical pin should be addressed. The actual logic for querying the pin state lies within the function blocks that expect a variable of this type as an input (e.g., `logiBUS_PI` or similar). These blocks read the value from the `Pin` field and use it to control the corresponding hardware interface.

Technical Features

- **Initial Value:** The initial value of 255 for `Pin` is common practice to indicate an unconfigured or faulty state, as pin numbers in practice are usually significantly lower.
- **Package Assignment:** This data type is part of the `logiBUS::io::PI` package, which assigns it to the peripheral input category within the logiBUS library.
- **Type Hash:** The attribute `eclipse4diac::core::TypeHash` with an empty value indicates that an automatically generated hash is used for type compatibility within the system.

State Overview

Since this is a passive data type, there is no state machine or active states.

Application Scenarios

This structured data type is used to centralize and ensure type safety in the configuration of digital input channels in control applications with logiBUS-compatible hardware. Typical applications include:

- Configuration of push-button, switch, or sensor signals (e.g., limit switches, light barriers).
- Parameterization of function blocks that read digital inputs in a distributed I/O system (such as logiBUS).
- Simplification of code reuse and readability, as the pin configuration is bundled in a named structure.

⚖️ Comparison with Similar Components

- **Simple Data Types (e.g., USINT directly):** Using a structured `logiBUS_PI_S` variable is preferable to directly using a `USINT` variable for the pin number because it is semantically clearer and can be more easily extended when the configuration is expanded (e.g., to include filter time or inversion) without having to change all call points.
- **logiBUS_PO_S (Digital Output):** A complementary data type `logiBUS_PO_S` for configuring digital outputs (PO - Peripheral Output) with an identical or very similar structure likely exists.
- **logiBUS_PO_S (Digital Output):**

Conclusion

The `logiBUS_PI_S` data type is a fundamental, specific configuration block for connecting digital input signals in logiBUS-based IEC 61499 applications. Its simple, single-parameter structure enables clear and centralized hardware configuration and forms the basis for the corresponding functionality in the executing I/O function blocks.

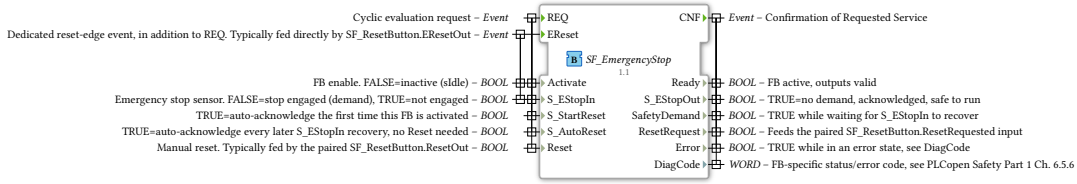
2.10.3.8 Safety

PLCopen



SF_EmergencyStop

• — ○ • — ○ • — ○ •

Introduction

`SF_EmergencyStop` is the PLCopen Safety function `SF_EmergencyStop` (Part 1 v2.10, Ch. 6.5) for **monitoring an emergency stop sensor** (`S_EStopIn`). The output `S_EStopOut` only becomes `TRUE` again after `S_EStopIn` is `TRUE` again **and** an acknowledgment has occurred (`S_StartReset`/`S_AutoReset`/`Reset`) - per EN ISO 13849-1:2015 5.2.2 and IEC 60204-1:2016 9.2.3.4.

Interface Structure

Event Inputs

- **REQ**: Cyclic evaluation request. Associated data: `Activate`, `S_EStopIn`, `S_StartReset`, `S_AutoReset`, `Reset`
- **EReset**: Dedicated reset-edge event in addition to `REQ`, typically fed directly by `SF_ResetButton.EResetOut`. Associated data: `Activate`, `S_EStopIn`

Event Outputs

- **CNF**: Confirmation of the requested service. Associated data: `Ready`, `S_EStopOut`, `SafetyDemand`, `ResetRequest`, `Error`, `DiagCode`

Data Inputs

- **Activate** (`BOOL`, default `FALSE`): Block enable; `FALSE` = inactive (`sIdle`)
- **S_EStopIn** (`BOOL`, default `FALSE`): Emergency stop sensor; `FALSE` = stop engaged (demand), `TRUE` = not engaged
- **S_StartReset** (`BOOL`, default `FALSE`): `TRUE` = auto-acknowledge the first time this block is activated

- **S_AutoReset** (BOOL, default FALSE): TRUE = auto-acknowledge every later recovery of S_EStopIn, no Reset needed
- **Reset** (BOOL, default FALSE): Manual reset, typically fed by the paired SF_ResetButton.ResetOut

Data Outputs

- **Ready** (BOOL): Block active, outputs valid
- **S_EStopOut** (BOOL): TRUE = no demand, acknowledged, safe to run
- **SafetyDemand** (BOOL): TRUE while waiting for S_EStopIn to recover
- **ResetRequest** (BOOL): Feeds the paired SF_ResetButton.ResetRequested input
- **Error** (BOOL): TRUE in an error state, see DiagCode
- **DiagCode** (WORD, default 16#0000): Block-specific status/error code (PLCopen Safety Part 1, Ch. 6.5.6)

Adapters

This function block uses no adapters.

How it works

The block is a basic FB with nine states. The outputs are set in each state by its own algorithm; afterwards CNF is fired.

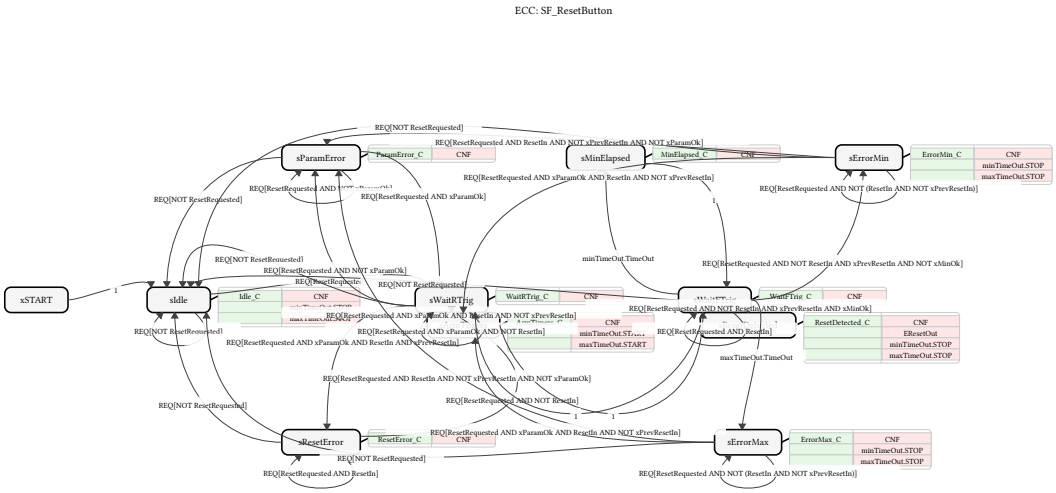
State	DiagCode	S_EStopOut	SafetyDemand	ResetRequest	Error	Meaning
sIdle	0000	FALSE	FALSE	FALSE	FALSE	Block not active
sInit	8001	FALSE	FALSE	FALSE	FALSE	Activated, S_StartReset is checked
sWaitEStopIn1	8802	FALSE	TRUE	FALSE	FALSE	First activation, waiting for S_EStopIn
sResetError1	C001	FALSE	FALSE	FALSE	TRUE	Reset stuck TRUE while waiting for S_EStopIn
sWaitReset1	8402	FALSE	FALSE	TRUE	FALSE	S_EStopIn is TRUE, waiting for a rising edge on Reset
sSafetyOutputEnabled	8000	TRUE	FALSE	FALSE	FALSE	Safety output enabled
sWaitEStopIn2	8804	FALSE	TRUE	NOT Reset	FALSE	Demand detected, waiting for S_EStopIn
sResetError2	C011	FALSE	FALSE	FALSE	TRUE	Reset stuck TRUE while waiting for S_EStopIn
sWaitReset2	8404	FALSE	FALSE	NOT Reset	FALSE	Waiting for S_AutoReset or a rising edge on Reset

Sequence:

1. `REQ` with `Activate = TRUE` in `sIdle` leads to `sInit`. If `S_EStopIn AND S_StartReset`, it goes directly to `sSafetyOutputEnabled`, otherwise to `sWaitEStopIn1`. `S_StartReset` only counts on this very first activation.
2. First activation: in `sWaitEStopIn1`, `Reset = TRUE` leads to the error `sResetError1`; once `S_EStopIn` is `TRUE` again, `sSafetyOutputEnabled` or `sWaitReset1` follows depending on `S_StartReset`. In `sWaitReset1`, the event `EReset` (with `S_EStopIn`) leads to `sSafetyOutputEnabled`; if `S_EStopIn` drops, it goes back to `sWaitEStopIn1`.
3. Operation: in `sSafetyOutputEnabled`, `S_EStopIn = FALSE` leads to `sWaitEStopIn2`.
4. Subsequent cycles: in `sWaitEStopIn2`, `Reset = TRUE` leads to the error `sResetError2`; once `S_EStopIn` is `TRUE` again, `sSafetyOutputEnabled` or `sWaitReset2` follows depending on `S_AutoReset`. In `sWaitReset2`, `S_AutoReset` or the event `EReset` leads to `sSafetyOutputEnabled`; if `S_EStopIn` drops, it goes back to `sWaitEStopIn2`.
5. From any state, `REQ` with `Activate = FALSE` leads back to `sIdle`.

Technical Details

- The error states `sResetError1`/`sResetError2` prevent a permanently present `Reset` from replacing the acknowledgment (`Reset` must be an edge).
- `ResetRequest` is combined with `NOT Reset` in the subsequent cycles (`sWaitEStopIn2`, `sWaitReset2`).
- The diagnostic codes come from `logiBUS::safety::PLCopen::const::DiagCodes` and `EmergencyStopDiagCodes`.

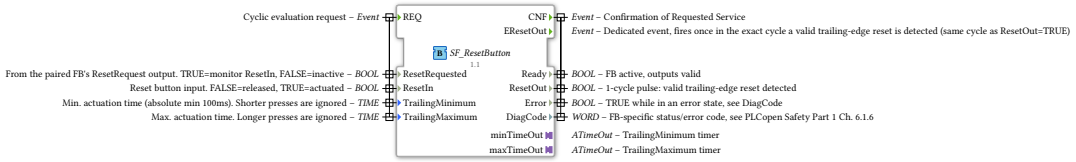


Application Scenarios

- Monitoring an emergency stop button with manual acknowledgment via `SF_ResetButton`
- Automatic restart on demand via `S_StartReset`/`S_AutoReset`

Summary

`SF_EmergencyStop` implements the PLCopen Safety state machine for emergency stop monitoring and enables the safety output only after the sensor has recovered and has been acknowledged.



SF_ResetButton

• – ○ • – ○ • – ○ •

Introduction

`SF_ResetButton` is the PLCopen safety block `SF_ResetButton` (PLCopen TC5 Safety Part 1 v2.10, chapter 6.1) with trailing-edge reset. It monitors a reset button: a valid reset exists when the button is pressed (rising edge) and released again (falling edge) after a time between `TrailingMinimum` and `TrailingMaximum`. `ResetOut` then outputs a single pulse.

Interface Structure

Event Inputs

- **REQ**: cyclic evaluation request
  - **Associated data**: `ResetRequested`, `ResetIn`, `TrailingMinimum`, `TrailingMaximum`

Event Outputs

- **CNF**: confirmation of the requested service
  - **Associated data**: `Ready`, `ResetOut`, `Error`, `DiagCode`
- **EResetOut**: dedicated event that fires once in exactly the cycle in which a valid trailing-edge reset is detected (same cycle as `ResetOut = TRUE`)

Data Inputs

- **ResetRequested** (BOOL): from the paired FB (`ResetRequest` output). TRUE = monitor `ResetIn`, FALSE = inactive (default TRUE)
- **ResetIn** (BOOL): reset button input. FALSE = released, TRUE = actuated (default FALSE)
- **TrailingMinimum** (TIME): minimum actuation time (absolute minimum 100 ms). Shorter actuations are not accepted as reset (default `T#350ms`)
- **TrailingMaximum** (TIME): maximum actuation time. Longer actuations are not accepted as reset (default `T#2s`)

Data Outputs

- **Ready** (BOOL): FB active, outputs valid
- **ResetOut** (BOOL): one-cycle pulse when a valid trailing-edge reset has been detected
- **Error** (BOOL): TRUE while an error state exists (see `DiagCode`)
- **DiagCode** (WORD): FB-specific status/error code (PLCopen Safety Part 1, chap. 6.1.6)

Adapters

- **minTimeOut** (plug, `iec61499::events::ATimeOut`): timer for `TrailingMinimum`
- **maxTimeOut** (plug, `iec61499::events::ATimeOut`): timer for `TrailingMaximum`

Functionality

The block is a basic FB with an ECC. Internal variables: `xPrevResetIn` (value of `ResetIn` in the previous cycle for edge detection), `xMinOk` (TRUE as soon as `TrailingMinimum` has elapsed since the rising edge) and `xParamOk` (`TrailingMinimum <= TrailingMaximum` and `TrailingMinimum >= T#100ms`).

- **Activation**: with `ResetRequested = FALSE` the block stays in state `sIdle`. With `ResetRequested = TRUE` it moves to `sWaitRTrig`.
- **`sWaitRTrig`**: if the parameters are invalid, `sParamError` follows. If `ResetIn` was already pressed before activation (`ResetIn AND xPrevResetIn`), `sResetError` follows. A fresh rising edge (`ResetIn AND NOT xPrevResetIn`) leads to `sArmTimers`.
- **`sArmTimers`**: sets `minTimeOut.DT := TrailingMinimum` and `maxTimeOut.DT := TrailingMaximum`, clears `xMinOk`, starts both timers (`minTimeOut.START`, `maxTimeOut.START`) and moves unconditionally to `sWaitFTrig`.
- **`sWaitFTrig`**: if `minTimeOut` expires, `xMinOk` is set via `sMinElapsed`. If `maxTimeOut` expires, `sErrorMax` follows. If the button is released (`NOT ResetIn AND xPrevResetIn`), the state `sResetDetected` follows when `xMinOk` is set, otherwise `sErrorMin`.
- **`sResetDetected`**: `ResetOut := TRUE`, `EResetOut` is output, both timers are stopped; then unconditionally back to `sWaitRTrig`.
- **Error states** (`sParamError`, `sResetError`, `sErrorMin`, `sErrorMax`): `Error := TRUE` with the respective `DiagCode`. From `sErrorMin`/`sErrorMax` a new rising edge leads back to `sArmTimers`, from `sResetError` releasing the button leads to `sWaitRTrig`. In every state, `ResetRequested = FALSE` leads back to `sIdle`.

Technical Details

- `EResetOut` is a non-literal IEC 61499 extension of the PLCopen interface: a dedicated event lets consumers wire the reset pulse directly instead of deriving it from `CNF` and `ResetOut` through an external gate (version 1.1)
- Structure following the pattern of `sequence_T_05` (ECC + `ATimeOut` plugs)
- `ResetOut` and `EResetOut` are active in exactly one cycle only
- The diagnostic codes come from the constants `DiagCodes` and `ResetButtonDiagCodes` (`logiBUS::safety::PLCopen::const`)

State Overview

State	DiagCode	Meaning
xSTART	-	initial state, moves unconditionally to `sIdle`
sIdle	0000	FB not active
sParamError	C000	parameter error: `TrailingMinimum > TrailingMaximum` or `TrailingMinimum < 100 ms`
sResetError	C001	reset error: `ResetIn` was already TRUE when `ResetRequested` became TRUE
sWaitRTrig	83E2	active, waits for the button to be actuated (rising edge)
sArmTimers	83F2	one-shot: (re)start both timers, then `sWaitFTrig`
sWaitFTrig	83F2	button pressed, waits for release (falling edge)
sMinElapsed	83F2	one-shot: set `xMinOk`, then back to `sWaitFTrig`
sErrorMin	C3F0	error: released before `TrailingMinimum` elapsed, waits for a new rising edge
sErrorMax	C3E0	error: `TrailingMaximum` elapsed before release, waits for a new rising edge
sResetDetected	8000	valid reset, 1-cycle pulse on `ResetOut` and `EResetOut`

Application Scenarios

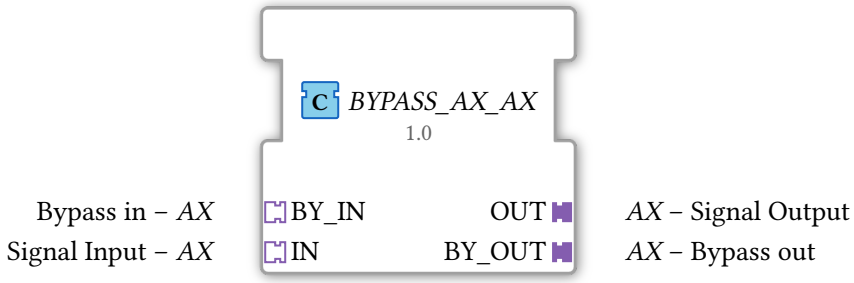
- Acknowledging a safety function (e.g. after an emergency stop) with a deliberate, time-limited button actuation
- Interplay with a block that requests the acknowledgement via `ResetRequest` and couples to `ResetRequested`

🛠️ Related Exercises

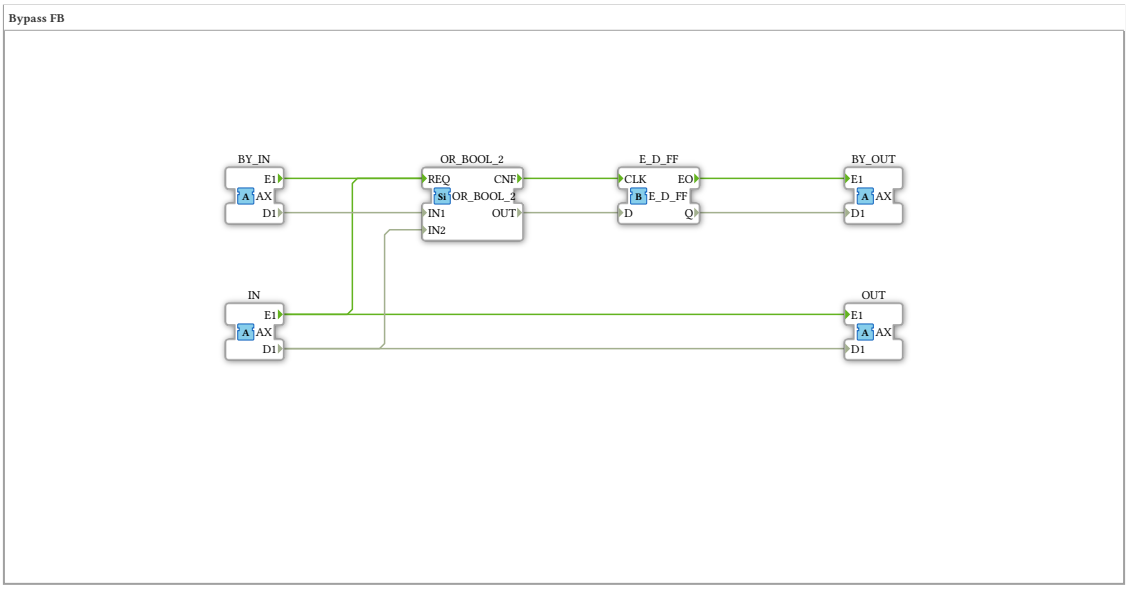
- Uebung_006_SAFE_AX

Conclusion

`SF_ResetButton` detects a valid trailing-edge reset according to PLCopen Safety, monitors the minimum and maximum actuation duration with two timers and reports errors via `Error` and `DiagCode`.



2.10.3.9 signal processing



...

Numeric Index (signal processing)

Here you will find all exercises from the `signalprocessing` workspace, listed in ascending order.

BYPASS_AX_AX

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **BYPASS_AX_AX** is used for forwarding and parallel bypass processing of AX signals. It combines a direct pass from input **IN** to output **OUT** with a Boolean OR operation on the incoming data, which is passed to the bypass output **BY_OUT** via an edge-triggered D flip-flop.

Interface Structure

Event Inputs

- **IN.E1** – Signal Input Event
- **BY_IN.E1** – Bypass Input Event

Event Outputs

- **OUT.E1** – Signal Output Event
- **BY_OUT.E1** – Bypass Output Event

Data Inputs

- **IN.D1** – Signal Input Data Value (Type depends on the AX adapter used)
- **BY_IN.D1** – Bypass Input Data Value (same type)

Data Outputs

- **OUT.D1** – Signal Output Data Value (identical to IN.D1)
- **BY_OUT.D1** – Bypass Output Data Value (Result of the OR operation, stored in the flip-flop)

Adapters

The function block uses four adapters of type `adapter::types::unidirectional::AX`:

- **IN** (Socket) – Signal input
- **BY_IN** (Socket) – Bypass input
- **OUT** (Plug) – Signal output
- **BY_OUT** (Plug) – Bypass output

Each AX adapter transmits one event/data pair (E1/D1) in one direction.

Functionality

The function block implements two parallel paths:

1. **Direct Path:**

An event on **IN.E1** is passed directly to **OUT.E1**, as is the corresponding data value **IN.D1** to **OUT.D1**. This represents a 1:1 pass-through of the signal.

1. **Bypass Path:**

An event on both **IN.E1** and **BY_IN.E1** triggers processing in the function block `OR_2_BOOL`. This block performs a Boolean operation on the data values **IN.D1** and **BY_IN.D1** – a logical OR operation on the two binary inputs.

The result of the operation is applied to the data input **D** of the D flip-flop (`E_D_FF`). The flip-flop's clock is triggered by the feedback signal `OR_2_BOOL.CNF`, i.e., after the OR operation is complete.

The flip-flop's output **Q** is set to **BY_OUT.D1**, and the corresponding event **BY_OUT.E1** is triggered by the flip-flop's output **EO**.

Technical Features

- **Boolean OR Operation:** The data is not added or mixed, but rather logically ORed. Therefore, the data values are considered Boolean (TRUE/FALSE).
- **Edge-Triggered Flip-Flops:** The bypass value is updated whenever at least one of the two inputs (IN or BY_IN) provides an event. The flip-flop stores the last calculated OR value.
- **Independent Event Propagation:** The direct path is asynchronous – every event on IN is immediately passed to OUT without waiting for the bypass path.

State Overview

The FB itself does not have its own state machine; however, a binary state is implemented using the internal D flip-flop:

- **State 0:** Flip-flop output Q = FALSE ⟶ BY_OUT.D1 = FALSE
- **State 1:** Flip-flop output Q = TRUE ⟶ BY_OUT.D1 = TRUE

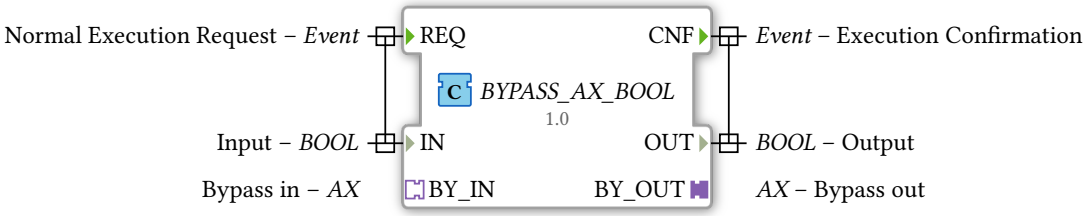
The state changes to the current D value on each rising edge of the clock (`OR_2_BOOL.CNF`). The initial state is undefined and may need to be initialized externally.

Application Scenarios

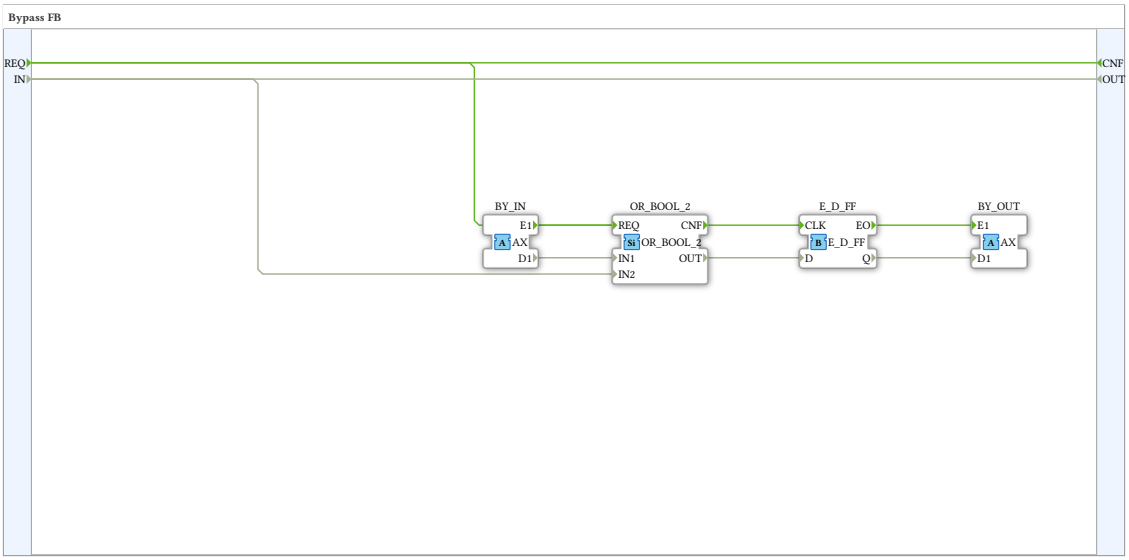
- **Bypass Circuit in Controllers:** A normal signal (IN ⟶ OUT) is to be passed through unchanged, while simultaneously creating an OR gate between the normal signal and an additional bypass signal for monitoring purposes.

State 0: - **Emergency Activation:** The bypass input can be used for manual override (e.g., "manual operation") while automatic operation continues at the main output.

- **Logical Signal Tracing:** The separate outputs allow both the original signal and the applied logic to be evaluated in parallel.



Comparison with Similar Function Blocks



- **Simple Pass-Through Function Block (e.g., MOVE_AX):** Passes the signal through 1:1 but does not generate a bypass output. BYPASS_AX_AX additionally offers the logic gate and a second output.
- **OR Function Block without Flip-Flop:** A simple OR gate would continuously update the bypass output without buffering. The integrated flip-flop provides edge-triggered updates, which is advantageous for cyclical control or time-decoupled events.
- **Adapter-based solution with two separate function blocks:** While it would be possible to wire an OR function block and a flip-flop function block separately, BYPASS_AX_AX encapsulates this functionality in a single compact block, reducing the number of connections and simplifying handling.

Conclusion

The **BYPASS_AX_AX** is a useful function block for applications requiring both direct signal forwarding and a logical OR operation with a stored output. Combining the pass-through and bypass paths in a single block keeps the network structure clear. The use of unidirectional AX adapters makes it compatible with typical industrial communication protocols based on the IEC 61499 standard.

BYPASS_AX_BOOL

• – ○ • – ○ • – ○ •

Introduction

The function block `BYPASS_AX_BOOL` implements a bypass function for a Boolean signal. It passes the value of the input `IN` directly to the output `OUT` and simultaneously creates a bypass path connected via an adapter. This path allows an external signal (`BY_IN.D1`) to be inserted into the internal logic and outputs the result via the output adapter `BY_OUT`.

Interface Structure

Event Inputs

Name	Type	Description
REQ	Event	Normal Execution Trigger

Event Outputs

Name	Type	Description
CNF	Event	Execution Acknowledgement

Data Inputs

Name	Type	Description

IN	BOOL	Input Signal

Data Outputs

Name	Type	Description
OUT	BOOL	Pass-Through Input Signal (Identical to IN)

Adapters

Role	Name	Type	Direction	Description
Plug	BY_OUT	adapter::types::unidirectional::AX	Output	Outputs the stored bypass state
Socket	BY_IN	adapter::types::unidirectional::AX	Input	Receives the bypass input signal (D1) and event (E1)

Functionality

Upon each event `REQ`, the output `CNF` is immediately set (event pass-through). Simultaneously, the data word `IN` is copied directly to `OUT`.

Internally, an OR operation is performed between `IN` and the adapter signal `BY_IN.D1`. This operation is triggered by `REQ` or by the event `BY_IN.E1`. The result of the OR operation is stored in an edge-triggered D flip-flop; the clock edge is generated by the completion of the OR calculation (event `CNF` of the internal OR block). The stored value of the flip-flop is output via the output adapter `BY_OUT.D1`, and the corresponding event output `BY_OUT.E1` is activated.

The module thus functions as a combination of a simple passthrough for `IN → OUT` and an edge-triggered bypass path that links and stores the incoming adapter signal with the current `IN`.

Technical Features

- The direct connection to `IN → OUT` is established without delay via internal logic – the value is available immediately.
- The bypass path uses a D flip-flop (`E_D_FF`) for state storage. The stored value is only updated on a rising edge of the internal clock, which is generated by the OR operation.
- The adapter `BY_IN` must be connected to use the bypass path; without it, the module behaves like a simple passthrough.
- The event `BY_IN.E1` can trigger the OR operation independently of `REQ`, allowing the bypass to be updated asynchronously.

State Overview

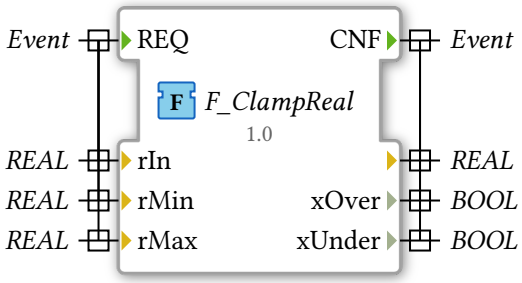
The component does not have an explicit state machine, but the internal D flip-flop stores a Boolean state (`Q = 0` or `Q = 1`). This state represents the last valid bypass value, which is output via the output adapter. The state only changes on a rising edge of the clock signal (completion of an OR operation).

Application Scenarios

- **Manual Override** of a digital signal in automation technology: The normal value (`IN`) is passed to the controller, while a manual intervention (e.g., via an operator interface) can be added and stored via the bypass.
- **Signal Monitoring and Correction**: An external monitoring system can display a correction value via the bypass adapter, which is then linked to the original signal.
- **Bypass for Testing Purposes**: During commissioning, the normal path (IN→OUT) can be maintained, while a test signal can be inserted via the bypass.

Comparison with Similar Function Blocks

- **Simple Passthrough** (e.g., `MOVE`): Would only transfer `IN` to `OUT`, without the possibility of external intervention.
- **Set/Reset Flip-Flop** (e.g., `SR`): Allows setting and resetting an output, but without directly passing through the input.
- **Selection Block** (e.g., `SEL`): Selects between two inputs – in this case, the input is always passed through, and the bypass is additively configured.



The BYPASS_AX_BOOL combines pass-through with integrated, edge-triggered logic for external signals.

Conclusion

The BYPASS_AX_BOOL function block is a specialized component for applications where a Boolean signal is passed through unchanged, but an external bypass signal is simultaneously mixed in and stored. The combination of direct passthrough and edge-triggered OR logic with memory enables flexible intervention in signal chains without interrupting normal operation. This component is particularly suitable for control systems that require both standard operation and temporary or permanent overrides.

Clamp

F_ClampReal

• – ◦ • – ◦ • – ◦ •

Introduction

The F_ClampReal function block (FB) restricts a REAL input value rIn to a defined range [rMin, rMax]. If rIn exceeds rMax, the output is set to rMax and the over-range flag is activated. If rIn is below rMin, the output is set to rMin and the under-range flag is set. Otherwise, the input passes through unchanged. This FB is useful for safe value limiting in control systems, signal conditioning, and boundary checking.

Interface Structure

The FB has one event input (REQ) and one event output (CNF). Data inputs (rIn, rMin, rMax) are read when REQ occurs, and the data outputs (rOut, xOver, xUnder) are provided with CNF.

Event Inputs

Event	Description
REQ	Trigger for performing the clamping operation.

Event Outputs

Event	Description
CNF	Confirmation that the operation has completed and outputs are valid.

Data Inputs

Name	Type	Description
rIn	REAL	Input value to be clamped.
rMin	REAL	Lower bound of the valid range.
rMax	REAL	Upper bound of the valid range.

Data Outputs

Name	Type	Description

rOut	REAL	Clamped result (equal to rIn if inside range). This corresponds to the unnamed output in the interface definition.
xOver	BOOL	TRUE if rIn > rMax, otherwise FALSE.
xUnder	BOOL	TRUE if rIn < rMin, otherwise FALSE.

Adapters

This FB does not use any adapters.

Functionality

Upon receiving the REQ event, the FB evaluates the following logic (written in Structured Text):

- If rIn > rMax, then rOut = rMax, xOver = TRUE, xUnder = FALSE.
- Else if rIn < rMin, then rOut = rMin, xOver = FALSE, xUnder = TRUE.
- Else, rOut = rIn, xOver = FALSE, xUnder = FALSE.

After the calculation, the CNF event is emitted, signalling that the output data are ready. The operation is purely combinatorial and does not rely on internal states.

Technical Features

- **Pure function**: No internal state, side effects, or memory usage.
- **Data types**: All inputs and the result are REAL (floating-point). Flags are BOOL.
- **Event-driven**: Uses the standard REQ/CNF handshake pattern for synchronous execution.
- **Range validation**: Assumes rMin ≤ rMax. If violated, behavior is undefined (but still follows the comparison logic).
- **Implementation**: Written in Structured Text, compatible with IEC 61499 and the 4diac IDE.

State Overview

The FB is stateless. It does not maintain any information between two invocations. Each execution is independent and based solely on the input values at the moment of REQ.

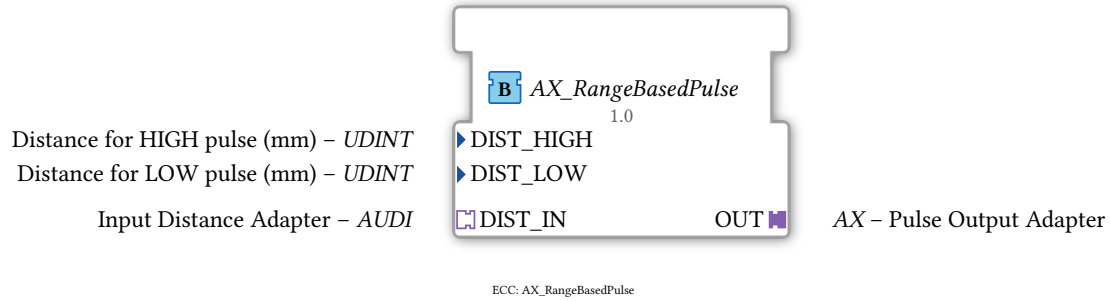
Application Scenarios

- **Safety interlocks**: Limit a setpoint or measured value to a safe operating range.
- **Signal conditioning**: For sensors that might produce out-of-range readings, e.g., clamping a temperature to a plausible band.
- **Control loops**: Prevent integral wind-up by limiting the controller output.
- **Validation**: Generate flags (xOver / xUnder) that can be used for alarming or diagnostics.

Comparison with Similar Blocks

Other clamping blocks may differ in:

- **Return type**: Some FBs only output the clamped value without flags; F_ClampReal additionally provides over- and under-range indicators.
- **Input type**: Analogous blocks exist for INT, LREAL, or other numeric types, but this FB is specifically for REAL.
- **Behavior on invalid range**: Some implementations swap rMin and rMax if rMax < rMin; this FB does not perform such a check.



Conclusion

F_ClampReal is a simple, reliable, and reusable function block for clamping REAL values to a specified interval. Its clean interface, stateless design, and integrated flag outputs make it suitable for a wide range of control and monitoring tasks in industrial automation environments.

Numeric Index (signal processing)

AX_RangeBasedPulse

• – ○ • – ○ • – ○ •

Introduction

This function block generates a pulse on an AX adapter based on a distance traveled (adapter version). It is licensed under the Eclipse Public License 2.0 and designed for use in signal processing of distance data.

Interface Structure

Event Inputs

- `DIST_IN.E1`: Event from the distance adapter that signals an update of the distance value.

Event Outputs

- `OUT.E1`: Event on the output adapter that is sent when the pulse output changes state.

Data Inputs

- `DIST_HIGH` (UDINT): Distance in mm that must be traveled to generate the HIGH pulse (initial value: 5000).
- `DIST_LOW` (UDINT): Distance in mm that must be traveled to generate the LOW pulse (initial value: 5000).
- `DIST_IN.D1` (UDINT): Current distance from the input adapter (updated via the event).

Data Outputs

- `OUT.D1` (BOOL): Pulse output – toggles between TRUE (HIGH) and FALSE (LOW) depending on the accumulated distance.

Adapters

- **DIST_IN (Socket):** Adapter of type `adapter::types::unidirectional::AUDI`. Provides a unidirectional distance value (`D1`) and a corresponding event (`E1`).
- **OUT (Plug):** Adapter of type `adapter::types::unidirectional::AX`. Provides a unidirectional Boolean value (`D1`) and an event (`E1`).

Functionality

The function block operates according to a hysteresis principle with two threshold values:

1. **Initialization:** During the first iteration (`FirstRun = TRUE`), the current distance is stored as the start value `LastDist`, the output `OUT.D1` is set to FALSE, and `FirstRun` is reset.
2. **State Check:** On each incoming event via `DIST_IN.E1`, the block executes the `CHECK` algorithm:

- If the current output is LOW (FALSE) and the new distance `DIST_IN.D1` reaches or exceeds the value `LastDist + DIST_LOW`, `OUT.D1` is set to TRUE and `LastDist` is updated to the current distance value.
- If the output is HIGH (TRUE) and the new distance reaches or exceeds the value `LastDist + DIST_HIGH`, `OUT.D1` is set to FALSE and `LastDist` is updated.

1. **Output:** When the state of `OUT.D1` changes, the event `OUT.E1` is sent, and the new state is stored in `LastState` for the next check.

Technical Features

- **Adapter-based Communication:** The use of plugs and sockets (`AX`, `AUDI`) enables modular and flexible interconnection in the 4diac IDE.
- **Asymmetric Pulse Widths:** The separate parameters `DIST_HIGH` and `DIST_LOW` allow for different distances for HIGH and LOW phases.
- **Asymmetric Pulse Widths:** - **Initialization Logic:** An internal `FirstRun` flag ensures that the first measurement is correctly set as the starting point.
- **Package Context:** The function block (FB) is intended for the `logiBUS::signalprocessing::distance` package.

State Overview

The Execution Control Chart (ECC) consists of four states:

- **START:** Waiting state after initialization or processing.
- **INIT:** Executes the `INIT` algorithm (setting the initial values). This state is only entered on the first iteration (`FirstRun = TRUE`).
- **CHECK:** Executes the `CHECK` algorithm for distance checking and modifies the output if necessary.
- **EMIT:** Executes the `SAVE` algorithm (stores the current output state) and sends the event `OUT.E1`.

Transitions:

- `START → INIT`: When `DIST_IN.E1` and `FirstRun = TRUE` arrive.
- `START → CHECK`: When `DIST_IN.E1` and `FirstRun = FALSE` arrive.
- `INIT → CHECK`: Immediately after `INIT` (condition 1).
- `CHECK → EMIT`: If `OUT.D1` has changed compared to `LastState`.
- `CHECK → START`: If no change occurs (`OUT.D1 = LastState`).
- `EMIT → START`: Immediately after `EMIT` (condition 1).

Application Scenarios

- **Distance Pulse Generators in Agricultural Technology:** Generating pulses after each defined distance traveled (e.g., a HIGH pulse every 5m, then a LOW pulse after another 5m) for control or counting tasks.
- **Distance-Based Switching Functions:** Triggering actions in conveyor systems, automated guided vehicles (AGVs), or automated machinery after specific distances have been traveled.
- **Pulse Width Modulation over Distance:** Variable pulse widths can be achieved by setting different values for `DIST_HIGH` and `DIST_LOW`, e.g., 10m HIGH and 2m LOW.

Comparison with Similar Function Blocks

- **Tone-Based Pulse Generators (e.g., `E_CYCLE`):** Generate pulses based on time, while `AX_RangeBasedPulse` operates based on distance – for applications without a fixed time base.

- **Simple Edge Detectors:** Detect signal changes, but without hysteresis and without accumulating distance.
- **Other Distance Adapter Function Blocks:** Function blocks exist that aggregate distance values, but this function block combines event processing with threshold logic and asymmetric configuration.

**

Conclusion

The `AX_RangeBasedPulse` function block offers a robust and flexible solution for distance-based pulse generation. Thanks to its adapter interface, separately configurable distance thresholds, and hysteresis logic, it is ideally suited for modular use in industrial control systems, particularly in agricultural technology and automation. Its implementation as a BasicFB ensures deterministic and predictable behavior.

AB_FIELDBUS_BYTE_TO_SIGNAL

• – ◦ • – ◦ • – ◦ •

Introduction

The function block **AB_FIELDBUS_BYTE_TO_SIGNAL** mirrors an incoming byte signal (via the adapter *IN*) to the output (*OUT*) if the signal is recognized as valid. Validity is indicated by a separate

output (*VALID*). The block encapsulates the processing of a fieldbus byte signal and ensures that only valid data is passed on to the subsequent logic. It is based on an internal `FIELDBUS_BYTE_TO_SIGNAL` block, supplemented by a D flip-flop for stable output of the validity signal.

Interface Structure

The function block has **no** direct event or data inputs/outputs at the top level. All communication takes place via three **adapter interfaces**:

Adapter	Direction	Type	Description
`IN`	Socket	`adapter::types::unidirectional::AB`	Input adapter for the byte signal and its associated event.
`OUT`	Plug	`adapter::types::unidirectional::AB`	Output adapter for the mirrored byte signal.
`VALID`	Plug	`adapter::types::unidirectional::AX`	Output adapter indicating the signal's validity status.

The adapters are of the **unidirectional** type, meaning they transmit data and events in one direction. The types `AB` and `AX` each contain one event input/output (E1) and one data input/output (D1, of type `ANY` and `BOOL`, respectively).

Event Inputs

None (events are received via the socket adapter `IN`).

Event Outputs

None (events are sent via the plug adapters `OUT` and `VALID`).

Data Inputs

None (data is received via the socket adapter `IN`).

Data Outputs

None (data is sent via the plug adapters `OUT` and `VALID`).

Adapters

IN (Socket)

- **E1**: Event input – triggers the processing of a new byte value.
- **D1**: Data input – the byte to be processed (e.g., a fieldbus datagram).

OUT (Plug)

- **E1**: Event output – activated after successful mirroring of a valid signal.
- **D1**: Data output – the mirrored byte signal (only if the value is valid).

VALID (Plug)

- **E1**: Event output – activated with every processing cycle, regardless of validity.
- **D1**: Data output (BOOL) – `TRUE` if the currently processed signal is valid; otherwise, `FALSE`.

Functionality

1. An incoming event at adapter `IN.E1` triggers the internal block `FIELDBUS_BYTE_TO_SIGNAL`, which processes the byte at `IN.D1`.
2. The internal block outputs `OUT` (the mirrored byte) and `VALID` (the validity information) at its outputs.
3. The output signal is immediately forwarded to adapter `OUT`, triggering an event (`OUT.E1`).
4. Simultaneously, the validity signal of the internal function block is applied to the D input of the D flip-flop (`E_D_FF`). The same event (`CNF` of the internal function block) clocks the flip-flop.
5. The flip-flop stores the validity value and outputs it stably to `VALID.D1`. An event is sent to `VALID.E1`.

Thus, the byte is always passed to `OUT` when it is valid. The validity state is retained until the next processing iteration.

Technical Features

- **Adapter-based communication**: The function block uses only adapter interfaces, which enables a modular and typed connection in the 4diac IDE.
- **D flip-flop for debouncing**: The validity signal is clocked by a flip-flop to ensure stability and prevent DIN rail effects.
- **License**: This component is released under the **Eclipse Public License 2.0** (Copyright HR Agrartechnik GmbH).
- **Compiler package**: `logiBUS::signalprocessing::fieldbus` – specifically for fieldbus applications.

State overview

The component does not have an explicit state machine at the top level; the states result from the interaction of the internal components:

State	Description
Idle	Waiting for an event at `IN.E1`.
